Note that convergence is rather slow, because the integrand is not bounded.

```
delete f:
```

### Example 3

We demonstrate multi-dimensional quadrature:

```
Q := numeric::quadrature:
Q(Q(exp(x*y), x = 0..y), y = 0..1)

0.6589510757
```

Also more complex types of nested calls are possible. We use numerically defined functions

```
b := y -> Q(exp(-t^2-t*y), t = y..infinity):
```

and

```
f := y -> cos(y^2) + Q(exp(x*y), x = 0..b(y)):
```

for the following quadrature:

```
Q(f(y), y = 0..1)

1.261578952
```

Multi dimensional quadrature is computationally expensive. Note that a call to `numeric::quadrature` evaluates the integrand at least  $3n$  times, where  $n$  is the number of nodes of the internal quadrature rule (by default,  $n = 20$  for  $DIGITS \leq 10$ ). The following triple quadrature would call the `exp` function no less than  $(320)^3 = 216000$  times!

```
Q(Q(Q(exp(x*y*z), x = 0..y+z), y = 0..z), z = 0..1)
```

For low precision goals, low order quadrature rules suffice. In the following, we reduce the computational costs by using Gauss-Legendre quadrature with 5 nodes. We use the shorthand notation `GL` to specify the `GaussLegendre` method:

```
DIGITS := 4:
Q(Q(Q(exp(x*y*z), x=0..y+z, GL=5), y=0..z, GL=5), z=0..1, GL=5)
```

```
0.665
```

```
delete Q, b, f, DIGITS:
```

## Example 4

We demonstrate how integrands given by user-defined procedures should be handled. The following integrand

```
f := proc(x) begin
 if x<1 then sin(x^2) else cos(x^5) end_if
end_proc:
```

cannot be called with a symbolic argument:

```
f(x)
```

```
Error: Cannot evaluate to Boolean. [_less]
Evaluating: f
```

# numeric::quadrature

---

Consequently, one must use `hold` to prevent premature evaluation of  $f(x)$ :

```
numeric::quadrature(hold(f)(x), x = -1..PI/2)
```

```
0.5354101317
```

Note that the above integrand is discontinuous at  $x = 1$ , causing slow convergence of the numerical quadrature. It is much more efficient to split the integral into two subquadratures with smooth integrands:

```
numeric::quadrature(sin(x^2), x = -1..1) +
numeric::quadrature(cos(x^5), x = 1..PI/2)
```

```
0.5354101318
```

See “Example 5” on page 18-302 for multi-dimensional quadrature of user-defined procedures.

```
delete f:
```

## Example 5

The following integrand

```
f := proc(x, y) begin
 if x<y then x-y else (x-y) + (x-y)^5 end_if
end_proc:
```

can only be called with numerical arguments and must be delayed twice for 2-dimensional quadrature:

```
Q := numeric::quadrature:
```

```
Q(Q(hold(hold(f)))(x, y), x = 0..1), y = 0..1)
```

0.02380952381

Note that delaying the integrand via `hold` will not work for triple or higher-dimensional quadrature! The user can handle this by making sure that the integrand can also be evaluated for symbolic arguments:

```
f := proc(x, y, z)
begin
 if not testtype([args()], Type::ListOf(Type::Numeric))
 then return(procname(args()))
 end_if;
 if x^2 + y^2 + z^2 <= 1
 then return(1)
 else return(0)
 end_if
end_proc:
```

Note that this function is not continuous, implying slow convergence of the numerical quadrature. For this reason, we use a low precision goal of only 2 digits and reduce the costs by using a low order quadrature rule:

```
DIGITS := 2:
Q(Q(Q(f(x, y, z), x=0..1, GL=5), y=0..1, GL=5), z=0..1, GL=5)
```

0.52

```
delete f, Q, DIGITS:
```

## Example 6

The following example uses non-adaptive Gauss-Tschebyscheff quadrature with an increasing number of nodes. The results converge quickly to the exact value:

# numeric::quadrature

---

```
a := exp(x)/sqrt(1 - x^2), x = -1..1:
numeric::quadrature(a, Adaptive = FALSE, GT = n) $ n = 3..7
```

```
3.97732196, 3.977462635, 3.977463259, 3.977463261, 3.977463261
```

```
delete a:
```

## Example 7

The improper integral  $\int_0^1 \frac{1}{x} dx = 10$  exists. Numerical convergence, however, is rather slow because of the singularity at  $x = 0$ :

```
numeric::quadrature(x^(-9/10), x = 0..1)
```

```
Warning: Precision goal is not achieved after 10000 function calls.
```

```
9.998221195
```

We remove the limit for the number of function calls and let `numeric::quadrature` grind along until a result is found. The time for the computation grows accordingly, the last digit is incorrect due to roundoff effects:

```
numeric::quadrature(x^(-9/10), x = 0..1, MaxCalls = infinity)
```

```
9.999999993
```

## Example 8

The following integral does not exist in the Riemann sense, because the integrand is not bounded:

```
numeric::quadrature(1/x, x = -1..2)
```

```
Warning: Precision goal is not achieved after 10000 function cal
```

```
116.9391252
```

We increase MaxCalls. There is no convergence of the numerical algorithm, because the integral does not exist. Consequently, some internal problem must arise: numeric::quadrature reaches its maximal recursive depth:

```
numeric::quadrature(1/x, x = -1..2, MaxCalls = infinity)
```

```
Warning: Precision goal is not achieved after 'MAXDEPTH=500' rec
```

```
3.262987586
```

## Parameters

**f(x)**

An arithmetical expression in  $x$

**x**

An identifier or an indexed identifier

**a, b**

Real or complex numerical values or  $\pm\infty$

## Options

**GaussLegendre, GaussTschebyscheff, NewtonCotes**

Options, specified as GaussLegendre = n, GaussTschebyscheff = n, NewtonCotes = n

## numeric::quadrature

---

The name of the underlying quadrature scheme. Each quadrature rule can be used with an arbitrary number of nodes specified by the positive integer  $n$ .

Usually there is no need to use this option to change the default method `GaussLegendre = n` with  $n = 20, 40, 80$  or  $160$ , depending on the precision goal determined by the environment variable `DIGITS`. Due to the corresponding high quadrature orders  $40, 80, 160$  or  $320$ , respectively, the default settings are suitable for high precision computations.

With `GaussLegendre = n`, an adaptive version of Gauss-Legendre quadrature with  $n$  nodes is used.

For  $DIGITS \leq 200$ , the weights and abscissae of Gaussian quadrature with  $n = 20, 40, 80$ , and  $160$  nodes are available and the integration starts immediately.

For  $DIGITS > 200$ , the routine `numeric::gldata` is called to compute the Gaussian data before the actual integration starts. This will be noted by some delay in the first call of `numeric::quadrature`.

For `DIGITS` much larger than  $200$ , it is recommended not to use the default setting but to use `GaussLegendre = n` with sufficiently high  $n$  instead. A reasonable choice is  $n \approx DIGITS$ .

With `GaussTschebyscheff = n`, non-adaptive Gauss-Tschebyscheff quadrature with  $n$  nodes is used. This method may only be used in conjunction with `Adaptive = FALSE`.

---

**Note** With `NewtonCotes = n`, an adaptive version of Newton-Cotes quadrature with  $n$  nodes is used. Note that these quadrature rules become numerically unstable for large  $n$  ( $n$  much larger than  $10$ ).

---

Following alternative names for the methods are accepted:

GaussLegendre, Gauss, GL,

GaussTschebyscheff, GT, GaussChebyshev, GC,

NewtonCotes, NC.

## Adaptive

Option, specified as `Adaptive = v`

`v` may be TRUE or FALSE. With `Adaptive = FALSE`, the internal error control is switched off.

The default setting is `Adaptive = TRUE`. An adaptive quadrature scheme with automatic control of the quadrature error is used.

The call `numeric::quadrature(f(x), x = a..b, method = n, Adaptive = FALSE)` returns the quadrature sum

$(b - a) \left( \sum_{i=1}^n B_i f(a + C_i (b - a)) \right)$  approximating  $\int_a^b f(x) dx$  without any control of the quadrature error. The weights  $B_i$  and abscissae  $C_i$  are determined by the quadrature rule given by `method = n`. For the methods `GaussLegendre`, `GaussTschebyscheff` and `NewtonCotes`, these data are available via `numeric::gldata`, `numeric::gtdata` and `numeric::ncdata`, respectively.

`Adaptive = FALSE` may only be used in conjunction with `method = n`.

Usually there is no need to switch off the internal adaptive quadrature via `Adaptive = FALSE`. This option is meant to give easy access to standard non-adaptive quadrature rules of Gauss-Legendre, Gauss-Tschebyscheff and Newton-Cotes type, respectively. The user may want to build his own adaptive quadrature based on these non-adaptive rules. Cf. “Example 6” on page 18-303.

## MaxCalls

Option, specified as `MaxCalls = m`

## numeric::quadrature

---

`m` must be a (large) positive integer or `infinity`. It is the maximal number of evaluations of the integrand, before `numeric::quadrature` gives up.

When called interactively, `numeric::quadrature` returns the approximation it has computed so far and issues a warning. See “Example 7” on page 18-304. When called from inside a procedure, `numeric::quadrature` returns `FAIL`.

The default value is  $m = \text{MAXDEPTH} * n$ . The environment variable `MAXDEPTH` (default value 500) represents the maximal recursive depth of a function.  $n$  is the number of nodes of the basic quadrature rule specified by the optional argument `method = n`. If no such method is specified by the user, then Gauss-Legendre quadrature is used with  $n = 20$  for  $DIGITS \leq 10$ ,  $n = 40$  for  $10 < DIGITS \leq 50$ ,  $n = 80$  for  $50 < DIGITS \leq 100$ ,  $n = 160$  for  $100 < DIGITS$ . Thus, for  $DIGITS = 10$ , the default setting is `MaxCalls = 10000`.

The default value of `m` ensures that the `MaxCalls` limit is reached before `numeric::quadrature` reaches its maximal internal recursive depth. Specifying `MaxCalls = infinity` removes this restriction and `numeric::quadrature` computes until it obtains an approximation with about `DIGITS` correct digits or until it runs into an internal error. The typical error that may occur is the evaluation of the integrand at a singularity. There also is the danger of `numeric::quadrature` reaching its maximal internal recursive depth. When called interactively, `numeric::quadrature` returns the approximation it has computed so far and issues a warning. See “Example 8” on page 18-304. When called from inside a procedure, `numeric::quadrature` returns `FAIL`.

### Return Values

Floating point number is returned, unless non-numerical symbolic objects in the integrand  $f(x)$  or in the boundaries  $a, b$  prevent numerical evaluation. In this case, `numeric::quadrature` returns itself symbolically. If numerical problems occur, then `FAIL` is returned.

### MuPAD Functions

int | numeric::gldata | numeric::gtdata | numeric::int |  
numeric::ncdata

# numeric::rank

---

**Purpose** Numerical estimate of the rank of a matrix

**Syntax** `numeric::rank(A, <eps>, options)`

**Description** `numeric::rank(A)` returns an integer indicating the rank of the matrix  $A$ .

All entries of the input matrix must be numerical, i.e., they must be floating-point numbers or expressions that can be converted to floating-point numbers.

The rank of a matrix coincides with the number of non-zero singular values.

A numerical estimate of the rank is computed by counting all singular values that are larger than  $epss_m ax$ , where  $s_m ax$  is the largest singular value. (All smaller singular values are regarded as round-off artifacts and treated as zero.)

**Environment Interactions** The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

**Examples** **Example 1**

We consider a quadratic matrix of rank 2:

```
A := matrix([[1, 1, I],
 [1, 2, 3],
 [2, 4, 6]]):
numeric::rank(A)
```

2

Hilbert matrices have full rank. However, they are extremely ill-conditioned and it is difficult to compute their rank numerically. The 10 10 Hilbert matrix has rank 10. Numerically, however, some of the singular values are so small that they may be regarded as zero resulting

in a smaller numerical rank. In particular, with the default value `eps =`

$\frac{1}{s_{max}}$ , two singular values are smaller than  $eps \cdot s_{max}$  where  $s_{max} = 1.7519\dots$  is the maximal singular value:

```
A := linalg::hilbert(10):
numeric::singularvalues(A)
```

```
[1.75191967, 0.3429295485, 0.03574181627, 0.002530890769, 0.0001287496143, 0.0000001228967739, 0.000000002147438818, 2.26674678 10-11, 1.093197787 10-13
```

```
numeric::rank(A)
```

```
8
```

We specify a second argument `eps = 10-14` to allow smaller singular values to be regarded as non-zero. Now, the numerical rank is 10:

```
numeric::rank(A, 10(-14))
```

```
10
```

```
delete A:
```

## Example 2

We consider a non-square matrix of rank 1:

```
A := matrix([[0, 0],
 [I, 1],
 [I, 1]]):
numeric::rank(A)
```

# numeric::rank

---

```
1
```

```
delete A:
```

## Example 3

We demonstrate the difference between hardware floats and software floats:

```
A := linalg::hilbert(15):
numeric::rank(A, 10^(-20), SoftwareFloats),
numeric::rank(A, 10^(-20), HardwareFloats)
```

```
14, 15
```

```
delete A:
```

## Parameters

**A**

An  $m \times n$  matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix

**eps**

Relative tolerance: regard all singular values  $s$  of  $A$  as zero if they satisfy  $s \leq \text{eps} s_{max}$ , where  $s_{max}$  is the largest singular value of  $A$ .

The default value of **eps** is  $\frac{1}{10^{\text{DIGITS}}}$ .

## Options

**Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

# numeric::rank

---

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

---

**Note** For ill-conditioned matrices, the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-312.

---

## Return Values

Positive integer.

## See Also

## MuPAD Functions

`linalg::rank`

**Purpose** Approximate a floating-point number by a rational number

**Syntax** `numeric::rationalize(object, <Exact | Minimize  
| Restore>, <digits>)`

**Description** `numeric::rationalize(object)` replaces all floating-point numbers in `object` by rational numbers.

An object of a library domain, characterized by `domtype(extop(object,0))=DOM_DOMAIN` is returned unchanged. For all other objects, `numeric::rationalize` is applied recursively to all operands. Objects of library domains can be rationalized if the domain has an appropriate `map` method. See “Example 5” on page 18-319.

A floating-point number  $f$  is approximated by a rational number  $r$  satisfying  $|f - r| < \varepsilon|f|$ .

**Note** With the options `Exact` and `Minimize`, the guaranteed precision

is  $\varepsilon = \frac{1}{10^{\text{digits}}}$ . With `Restore`, the guaranteed precision is only

$$\varepsilon = \frac{1}{10^{\frac{\text{digits}}{2}}}$$

The default precision is `digits = DIGITS`.

The user defined precision must not be larger than the internal floating-point precision set by `DIGITS`: an error occurs for `digits > DIGITS`.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS`.

**Examples** **Example 1**

`numeric::rationalize` is applied to each operand of a composite object:

## numeric::rationalize

---

```
numeric::rationalize(0.2*a+b^(0.7*I))
```

$$\frac{a}{5} + b^{\frac{7i}{10}}$$

```
numeric::rationalize([poly(0.2*x, [x]), sin(7.2*PI) + 1.0*I],
 exp(3 + ln(2.0*x))])
```

$$\left[ \left\{ \sin\left(\frac{36\pi}{5}\right) + i, \text{poly}\left(\frac{x}{5}, [x]\right) \right\}, e^{\ln(2x) + 3} \right]$$

### Example 2

We demonstrate the default strategy Exact:

```
numeric::rationalize(12.3 + 0.5*I),
numeric::rationalize(0.33333),
numeric::rationalize(1/3.0)
```

$$\frac{123}{10} + \frac{i}{2}, \frac{33333}{100000}, \frac{333333333333}{1000000000000}$$

```
numeric::rationalize(10^12/13.0),
numeric::rationalize(10^(-12)/13.0)
```

$$76923076923, \frac{76923076923}{100000000000000000000000000000000}$$

We reduce the precision of the approximation to 5 digits:

```
numeric::rationalize(10^12/13.0, 5),
numeric::rationalize(10^(-12)/13.0, 5)
```

$$76923100000, \frac{769231}{10000000000000000000}$$

### Example 3

We demonstrate the strategy `Minimize` for minimizing the complexity of the resulting rational number:

```
numeric::rationalize(1/13.0, 5),
numeric::rationalize(1/13.0, Minimize, 5),
numeric::rationalize(0.333331, 5),
numeric::rationalize(0.333331, Minimize, 5),
numeric::rationalize(14.285, 5),
numeric::rationalize(14.2857, Minimize, 5),
numeric::rationalize(1234.1/56789.2),
numeric::rationalize(1234.1/56789.2, Minimize)
```

$$\frac{769231}{10000000}, \frac{1}{13}, \frac{333331}{1000000}, \frac{1}{3}, \frac{2857}{200}, \frac{100}{7}, \frac{21731244673}{1000000000000}, \frac{12341}{567892}$$

We compute rational approximations of  $\pi$  with various precisions:

```
numeric::rationalize(float(PI), Minimize, i) $ i = 1..10
```

$$3, \frac{22}{7}, \frac{22}{7}, \frac{355}{113}, \frac{355}{113}, \frac{355}{113}, \frac{355}{113}, \frac{102573}{32650}, \frac{104348}{33215}, \frac{208341}{66317}$$

### Example 4

We demonstrate the strategy `Restore` for restoring rational numbers after elementary float operations. In many cases, also the `Minimize` strategy restores:

```
numeric::rationalize(1/7.3, Exact),
numeric::rationalize(1/7.3, Minimize),
numeric::rationalize(1/7.3, Restore)
```

## numeric::rationalize

---

$$\frac{13698630137}{100000000000}, \frac{10}{73}, \frac{10}{73}$$

However, using `Restore` improves the chances of recovering from roundoff effects:

```
numeric::rationalize(10^9/13.0, Minimize),
numeric::rationalize(10^9/13.0, Restore)
```

$$\frac{923076923}{12}, \frac{1000000000}{13}$$

```
DIGITS:= 11:
```

```
numeric::rationalize(1234.56/12345.67, Minimize),
numeric::rationalize(1234.56/12345.67, Restore)
```

$$\frac{88183}{881835}, \frac{123456}{1234567}$$

In some cases, `Restore` manages to recover from roundoff error propagation in composite arithmetical operations:

```
DIGITS:= 10:
```

```
x:= float(122393/75025):
y:= float(121393/75025):
z := (x^2 - y^2)/(x + y)
```

```
0.01332889037
```

```
numeric::rationalize(z, Restore)
```

$$\frac{40}{3001}$$

The result with Restore corresponds to exact arithmetic:

```
rx := numeric::rationalize(x, Restore):
ry := numeric::rationalize(y, Restore):
rx, ry, (rx^2 - ry^2)/(rx + ry)
```

$$\frac{122393}{75025}, \frac{121393}{75025}, \frac{40}{3001}$$

Note that an approximation with Restore may have a reduced precision of only digits/2:

```
x := 1.0 + 1/10^6:
numeric::rationalize(x, Exact),
numeric::rationalize(x, Restore)
```

$$\frac{1000001}{1000000}, 1$$

```
delete x, y, z, rx, ry:
```

## Example 5

The floats inside objects of library domains are not rationalized directly. However, for most domains the corresponding map method can forward numeric::rationalize to the operands:

```
Dom::Multiset(0.2, 0.2, 1/5, 0.3)
```

$$\{[0.2, 2], [\frac{1}{5}, 1], [0.3, 1]\}$$

```
numeric::rationalize(%), map(% , numeric::rationalize, Restore)
```

# numeric::rationalize

---

$$\{[0.2, 2], [\frac{1}{5}, 1], [0.3, 1]\}, \{[\frac{1}{5}, 3], [\frac{3}{10}, 1]\}$$

## Parameters

### object

An arbitrary MuPAD object

### digits

A positive integer (the number of decimal digits) not bigger than the environment variable DIGITS. It determines the precision of the rational approximation.

## Options

### Exact

Specifies the strategy for approximating floating-point numbers by rational numbers. This is the default strategy, so there is no real need to pass Exact as a parameter to numeric::rationalize.

Any real floating-point number  $f \neq 0.0$  has a unique representation

$$f = \text{sign}(f) \text{ mantissa } 10^{\text{exponent}}$$

With integer exponent and  $1.0 \leq \text{mantissa} < 10.0$ . With the option Exact, the float mantissa is replaced by the rational approximation

$$\frac{\text{round}(\text{mantissa } 10^{\text{digits}})}{10^{\text{digits}}}$$

This guarantees a relative precision of digits significant decimals of the rational approximation.

### Minimize

Specifies the strategy for approximating floating-point numbers by rational numbers. This strategy tries to minimize the complexity of the rational approximation, i.e., numerators and denominators are to be small.

The guaranteed precision of the rational approximation is `digits`.

See “Example 3” on page 18-317.

## Restore

Specifies the strategy for approximating floating-point numbers by rational numbers. This strategy tries to restore rational numbers obtained after *elementary* arithmetical operations applied to floating-point numbers. E.g., for rational `r`, the float division `f = 1/float(r)` introduces additional roundoff, which the Restore algorithm tries to eliminate: `numeric::rationalize(f, Restore) = 1/r`. This strategy, however, is purely heuristic and will not succeed when significant roundoff is caused by arithmetical float operations!

---

**Note** The guaranteed precision of the rational approximation is only `digits/2!`

---

See “Example 4” on page 18-317.

## Return Values

If the argument is an object of some kernel domain, then it is returned with all floating-point operands replaced by rational numbers. An object of some library domain is returned unchanged.

## Overloaded By

object

## Algorithms

Continued fraction (CF) expansion is used with the options `Minimize` and `Restore`.

## **numeric::rationalize**

---

With `Minimize`, the first CF approximation satisfying the precision criterion is returned.

The `Restore` algorithm stops, when large coefficients of the CF expansion are found.

## Purpose

Numerical search for a real root of a real univariate function

## Syntax

`numeric::realroot(f(x), x = a .. b, <SearchLevel = s>)`

## Description

`numeric::realroot(f(x), x = a..b)` computes a numerical real root of  $f(x)$  in the interval  $[a, b]$ .

The expression  $f(x)$  must not contain symbolic objects other than the indeterminate  $x$  that cannot be converted to numerical values via `float`. Symbolic objects such as  $\pi$  or  $\sqrt{2}$  etc. are accepted. The same holds true for the boundaries  $a, b$  of the search interval.

The function must produce real values. If `float(f(x))` does not yield real floating-point numbers for all real floating-point numbers  $x$  from the interval  $[a, b]$ , internal problems may occur. See “Example 5” on page 18-326.

`numeric::realroot` never tries to evaluate  $f(x)$  outside the search interval. Consequently, singularities outside the interval do not cause any problems. In many cases also singularities inside the interval do not affect the numerical search. However, `numeric::realroot` is not guaranteed to work in such a case. An error may occur, if the internal search accidentally hits a singularity. See “Example 5” on page 18-326.

Up to roundoff effects numerical roots  $r$  with  $|r| \geq \frac{1}{\text{DIGITS}}$  are computed to a relative precision of `DIGITS` significant decimal places. Roots of smaller absolute size are computed to an absolute precision

of  $\frac{1}{10^{\text{DIGITS}}}$ . These precision goals are not achieved, if significant roundoff occurs in the numerical evaluation of  $f(x)$ .

If  $f$  takes opposite signs at the endpoints  $a, b$  of the search interval and does not have zero-crossing singularities, then `numeric::realroot` is bound to find a root in the interval  $[a, b]$ .

User defined functions can be handled. See “Example 2” on page 18-324.

# numeric::realroot

---

---

**Note** `numeric::realroot` approximates a point where  $f(x)$  changes its sign. This is a root only if the function  $f$  is continuous. See “Example 3” on page 18-325.

---

Note that `numeric::realroots` may be used to isolate *all* real roots. However, this function is much slower than `numeric::realroot`, if  $f$  is not a polynomial.

For univariate polynomials we recommend to use `numeric::realroots` or `polylib::realroots` rather than `numeric::realroot`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

The following functions assume different signs at the boundaries, so the searches are bound to succeed:

```
numeric::realroot(x^3 - exp(3), x = -PI..10)
```

```
2.718281828
```

```
numeric::realroot(exp(-x[1]) = x[1], x[1] = 0..1)
```

```
0.5671432904
```

### Example 2

The following function cannot be evaluated for non-numerical  $x$ . So one has to delay evaluation via `hold`:

```
f := proc(x) begin
 if x<0 then 1 - x else exp(x) - 10*x end_if
```

```
end_proc:
numeric::realroot(hold(f)(x), x = -10..10)
```

```
0.1118325592
```

```
delete f:
```

### Example 3

numeric::realroot approximates a point, where  $f(x)$  changes its sign. For the following function this happens at the discontinuity  $x = 1$ :

```
f := proc(x) begin if x<1 then -1 else x end_if end_proc:
numeric::realroot(hold(f)(x), x = 0..3)
```

```
1.0
```

```
delete f:
```

### Example 4

The following function does not have a real root. Consequently, numeric::realroot fails:

```
numeric::realroot(x^2 + 1, x = -2..2)
```

```
FAIL
```

The following function does not have a real root in the search interval:

```
numeric::realroot(x^2 - 1, x = 2..3)
```

```
FAIL
```

# numeric::realroot

---

## Example 5

The following function is complex valued for  $x^2 < 3.5$ . An error occurs, when the internal search hits such a point:

```
numeric::realroot(ln(x^2 - 3.5), x = -2..3)
```

```
Error: Cannot evaluate to Boolean. [_less]
 Evaluating: numeric::BrentFindRoot
```

The singularity at  $x = 1$  does not cause any problem in the following call:

```
numeric::realroot((x-2)/(x-1), x = -10..10)
```

```
2.0
```

However, the singularity may be hit accidentally in the internal search:

```
numeric::realroot((x-2)/(x-1), x = 0..3)
```

```
Error: Division by zero. [_power]
 Evaluating: f
```

## Example 6

The following function has a root close to 1.0, which is difficult to detect. With the default search level  $s = 1$ , this root is not found:

```
f := 2 - exp(-100*(x - 2)^2) - 2*exp(-1000*(x - 1)^2):
numeric::realroot(f, x = 0..5)
```

```
FAIL
```

The root is detected with an increased search level:

```
numeric::realroot(f, x = 0..5, SearchLevel = 3)
```

```
1.0
```

```
delete f:
```

## Parameters

### **f(x)**

An arithmetical expression in one unknown  $x$  or a list, set, array, or matrix (`Cat::Matrix`) of expressions. Alternatively, equations in the form  $f_1(x) = f_2(x)$  equivalent to the expressions  $f_1(x) - f_2(x)$ .

### **x**

An identifier or an indexed identifier

### **a, b**

Finite real numerical values

## Options

### **SearchLevel**

Option, specified as `SearchLevel = s`

The nonnegative integer  $s$  controls the internal refinement of the search. The default value is  $s = 1$ . Increasing  $s$  increases the chance of finding roots that are difficult to detect numerically. See “Example 6” on page 18-326.

Note that increasing  $s$  by 1 may quadruple the time before FAIL is returned, if no real root is found. For this reason we recommend to restrict  $s$  to small values ( $s \leq 5$ , say).

## Return Values

Single numerical real root of domain type `DOM_FLOAT`. If no solution is found, then FAIL is returned.

# numeric::realroot

---

## Algorithms

A mixture of bisectioning, secant steps and quadratic interpolation is used by `numeric::realroot`.

| `polylib::realroots` | `solve`

## Concepts

- “Solve Equations Numerically”

## Purpose

Isolate intervals containing real roots of a univariate function

## Syntax

`numeric::realroots(f(x), <x = a .. b>, <eps>, <Merge = c>)`

## Description

`numeric::realroots(f(x), x = a..b)` searches for real roots of  $f(x)$  in the interval  $[a, b]$ . It returns a list of subintervals in which real roots of  $f(x)$  may exist. It is guaranteed that there are no real roots in the interval  $[a, b]$  lying outside the union of the returned subintervals.

With `Merge = FALSE`, all intervals returned by `numeric::realroots` have length  $b_i - a_i < eps$  with a default value  $eps = 0.01$ . The absolute precision of the root isolation may be redefined using the optional parameter `eps`.

**Note** The intervals returned by `numeric::realroots` define a subset of  $[a, b]$  that may contain real roots. For polynomial expressions  $f(x)$ , each of the subintervals of  $[a, b]$  returned by `numeric::realroots` is guaranteed to contain exactly one root. For non-polynomial expressions  $f(x)$ , however, some of the subintervals may contain no root! Cf. “Example 6” on page 18-333.

In any case, the complement  $[a, b] \setminus \left( \bigcup_{i \in \{1, \dots, n\}} [a_i, b_i] \right)$  of the subintervals  $[a_i, b_i]$  returned by `numeric::realroots` is guaranteed to contain no real roots. In particular, from the return value `[]`, one may positively conclude that no root exists in the search interval  $[a, b]$ . Cf. “Example 2” on page 18-331.

Symbolic parameters in  $f(x)$  are not allowed: `float(f(x))` must evaluate to a floating point number for all  $x$  from the interval  $[a, b]$ .

Infinite intervals of the form `x = -infinity..b` are not refined if  $b \leq -10^5$ .

Infinite intervals of the form `x = a..infinity` are not refined if  $a \geq 10^5$ .

# numeric::realroots

---

Such intervals are returned directly if `numeric::realroots` thinks that they may contain roots. Cf. “Example 5” on page 18-332.

$f(x)$  may contain complex expressions. Only the search parameter  $x$  is assumed to be real. For complex expressions  $f(x)$ , the intervals are returned where both the real and the imaginary part of the expression vanish simultaneously.

---

**Note** The expression  $f(x)$  must be suitable for interval arithmetic. In particular, MuPAD must be able to evaluate  $f(a..b)$ . Note that not all MuPAD functions support this kind of arithmetic.

---

Presently, the following special functions support interval arithmetic: `abs`, `arccos`, `arccosh`, `arccoth`, `arccot`, `arccsc`, `arccsch`, `arcsec`, `arcsech`, `arcsin`, `arcsinh`, `arctan`, `arctanh`, `arg`, `beta`, `ceil`, `cos`, `cosh`, `cot`, `coth`, `csc`, `csch`, `dirac`, `exp`, `floor`, `gamma`, `Im`, `ln`, `Re`, `round`, `sec`, `sech`, `sin`, `sinh`, `sqrt`, `tan`, `tanh`, `trunc`. Real roots can be searched for any expression that is built from these functions using the standard arithmetical operations `+`, `-`, `*`, `/`, `^`.

The default value is  $eps = 0.01$ . User defined precision goals must

satisfy  $eps \geq \frac{1}{10^{\text{DIGITS}}}$ .

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

The following expression has integer zeros. The solutions in the specified interval are approximated to the default precision 0.01:

```
numeric::realroots(sin(PI*x), x = -2..sqrt(2))
```

```
[[-2.0, -1.993331614], [-1.006410506, -0.9997421204], [-0.006152626661, 0.0005157
[0.9941052529, 1.000773639]]
```

The following equation is solved with an absolute precision of 7 digits:

```
numeric::realroots(x*sin(x) = exp(-x), x = -1..1, 10^(-7))
```

```
[[0.7271005511, 0.7271006107]]
```

## Example 2

The following expression does not have a real root:

```
numeric::realroots(exp(x) + x^2, x = -100..100)
```

```
[]
```

## Example 3

We demonstrate the option `Merge`. If interval arithmetic can not isolate roots to the desired precision *eps* (default 0.01), then adjacent intervals are produced, each of length smaller than *eps*. This happens in the following example:

```
numeric::realroots(ln(x^2 - 2*x + 2) = 0, x = -10..10,
Merge = FALSE)
```

```
[[0.869140625, 0.87890625], [0.87890625, 0.888671875], [0.888671875, 0.8984375], ...
[1.123046875, 1.1328125], [1.1328125, 1.142578125]]
```

With `Merge = TRUE`, these intervals are combined to a single larger interval. Since `Merge = TRUE` is the default setting for non-polynomial functions, it suffices to omit the option `Merge = FALSE`:

# numeric::realroots

---

```
numeric::realroots(ln(x^2 -2*x + 2) = 0, x = -10..10)
```

```
[[0.869140625, 1.142578125]]
```

## Example 4

The following expression has infinitely many solutions  $x = \frac{1}{n}$  with  $n = 1, 2, \dots$  in the search interval  $[0, 1]$ :

```
numeric::realroots(sin(PI/x), x = 0..1, 0.1, Merge = FALSE)
```

```
[[0.0, 0.0625], [0.0625, 0.125], [0.125, 0.1875], [0.1875, 0.25], [0.25, 0.3125], [0.3125, 0.375],
 [0.5, 0.5625], [0.9375, 1.0]]
```

Omitting `Merge = FALSE`, adjacent intervals are merged to larger intervals. The first of the following intervals contains infinitely many roots:

```
numeric::realroots(sin(PI/x), x = 0..1, 0.1)
```

```
[[0.0, 0.375], [0.4375, 0.5625], [0.9375, 1.0]]
```

## Example 5

If no search interval is specified, the entire real line is considered:

```
numeric::realroots(x^3 = exp(x))
```

```
[[1.841783524, 1.871585846], [4.523992538, 4.553794861], [100000.0, ∞]]
```

Apart from two finite intervals, `numeric::realroots` tells us that there may be a root close to infinity (but that there is positively no root close to -infinity). Analytically, it is clear that the subinterval  $[100000.0, \infty]$

cannot contain a root, since  $e^x$  grows much faster than  $x^3$  as  $x$  goes to infinity. If a finite upper limit for the search interval is specified, this fact is detected:

```
numeric::realroots(x^3 = exp(x), x = -infinity .. 10^100)

[[1.842076975, 1.877795331], [4.512024084, 4.556672029]]
```

We isolate the two finite roots more closely by specifying a precision

goal of  $\frac{1}{10^{\text{DIGITS}}}$ :

```
numeric::realroots(x^3 = exp(x), x = -infinity .. 10^100,
 10^(-DIGITS))

[[1.85718386, 1.85718386], [4.536403655, 4.536403655]]
```

## Example 6

The following equation has no root close to 0. However, interval arithmetic does not produce realistic values of  $\frac{\sin(\pi x)}{x}$  for small intervals containing  $x = 0$ , so an isolating interval around 0 is returned:

```
numeric::realroots(sin(PI*x)/x = 0, x = -1..1.2)

[[- 1.0, - 0.99140625], [- 0.003125, 0.00546875], [0.99375, 1.00234375]]
```

A similar phenomenon occurs with  $x^x = e^{x \ln(x)}$  in a neighbourhood of  $x = 0$ . An isolating interval around 0 is returned, although no solution exists there:

```
numeric::realroots(x^x*cos(PI*x) = tan(x), x = 0..1)
```

# numeric::realroots

---

```
[[0.0, 0.0078125], [0.328125, 0.3359375]]
```

This cannot be cured by increasing the precision goal:

```
numeric::realroots(x^x*cos(PI*x) = tan(x), x = 0..1,
10^(-DIGITS))
```

```
[[[0.0, 5.820766091 10-11], [0.3334737903, 0.3334737903]]]
```

## Parameters

### **f(x)**

An expression in one indeterminate  $x$  or a list, set, array, or matrix (Cat::Matrix) of expressions. Alternatively, equations in the form  $f_1(x) = f_2(x)$  equivalent to the expressions  $f_1(x) - f_2(x)$ .

### **x**

An identifier or an indexed identifier

### **a, b**

Real numbers or numerical expressions satisfying  $a < b$ . Also -infinity and infinity may be used.

### **eps**

A (small) positive real numerical value defining the precision goal. The default value is 0.01.

## Options

### **Merge**

Option, specified as Merge = b

b can be TRUE or FALSE. With Merge = FALSE, numeric::realroots returns subintervals of length not larger than eps. With Merge = TRUE, numeric::realroots

merges adjacent subintervals to larger intervals, i.e., subintervals of length larger than `eps` may be returned.

The default setting is `Merge = FALSE` for polynomial functions  $f(x)$ . Otherwise, it is `Merge = TRUE`.

`numeric::realroots` isolates intervals  $[a_i, b_i]$  that may contain roots. Internally, all these intervals satisfy  $b_i - a_i < eps$  where `eps` is the precision goal.

With `Merge = FALSE`, these intervals are returned.

With `Merge = TRUE`, adjacent intervals  $[a_i, b_i], [a_{i+1}, b_{i+1}]$  with  $b_i = a_{i+1}$  are combined to larger intervals  $[a_i, b_{i+1}]$ . See “Example 3” on page 18-331 and “Example 4” on page 18-332.

The default setting is `Merge = FALSE` for polynomial functions. Otherwise, it is `Merge = TRUE`.

## Return Values

List  $[[a_1, b_1], [a_2, b_2], \dots]$  of disjoint floating-point intervals  $[a_i, b_i] \subset [a, b]$  which may contain roots of  $f(x)$ . The empty list is returned if no root exists in the search interval  $[a, b]$ .

## Algorithms

Let  $X$  be a subset of the real numbers. Interval arithmetic produces a set  $F(X)$  such that the set of image values  $\{f(x) \mid x \in X\}$  is contained in  $F(X)$ . The MuPAD domain `DOM_INTERVAL` facilitates this kind of arithmetic. The routine `numeric::realroots` computes  $F := f(a_i \dots b_i)$  for various subintervals  $[a_i, b_i]$  of  $[a, b]$ . If  $F$  does not contain zero, then this subinterval is eliminated from the search interval. Otherwise, the subinterval is returned as a candidate for containing zeros of  $f(x)$ . However, one cannot conclude that  $F$  does indeed contain at least one zero, since  $F$  is usually larger than the true image set  $\{f(x) \mid x \in [a_i, b_i]\}$  (‘overestimation’).

For polynomials  $f(x)$ , the routine `polylib::realroots` is called. Its results are intersected with the search interval  $[a, b]$ . No interval arithmetic is used for polynomial expressions. For polynomial

# numeric::realroots

---

equations, each isolating interval returned by `numeric::realroots` is guaranteed to contain at least one root if `Merge = TRUE` is specified. With the default setting of `Merge = FALSE` for polynomials, each isolating interval is guaranteed to contain exactly one root.

### Concepts

- “Solve Equations Numerically”

## Purpose

Orthogonal matrix of the rotation about an axis

## Syntax

```
numeric::rotationMatrix(angle, axis, <Symbolic>,
<ReturnType = t>)
```

## Description

`numeric::rotationMatrix(angle, axis)` returns an orthogonal matrix corresponding to the rotation about the given axis by the given angle.

The rotation by the angle  $\alpha$  about the axis given by the vector  $[x, y, z]$  of Euclidean length 1 is given by the rotation matrix

$$e^{\alpha \begin{pmatrix} 0 & -z & y \\ z & 0 & -x \\ -y & x & 0 \end{pmatrix}} = \begin{pmatrix} tX^2 + c & tXy - sZ & tXz + sy \\ tXy + sZ & tY^2 + c & tYz - sX \\ tXz - sy & tYz + sX & tZ^2 + c \end{pmatrix}$$

with  $c = \cos(\alpha)$ ,  $s = \sin(\alpha)$ , and  $t = 1 - c = 2 \sin\left(\frac{\alpha}{2}\right)^2$ .

The rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation.

Use negative angles to rotate in the opposite direction.

The axis parameter of the routine does not need to be normalized to the Euclidean length 1. However, it must not be of zero length.

If no return type is specified via the option `ReturnType = t`, the domain type of the result depends on the type of the input matrix axis:

- If the axis is of domain type array, then the rotation matrix is returned as an array.
- If the axis is of domain type hfarray, then the result is returned as an hfarray.

# numeric::rotationMatrix

---

- If the axis is of domain type `Dom::DenseMatrix()`, then the rotation matrix is returned as a matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- If axis is of any different matrix type, the result is a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices axis of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.
- If axis is a list with 3 elements, the rotation matrix is also returned as an `Dom::Matrix()` over the ring of MuPAD expressions.

Without the option `Symbolic`, all arguments are automatically converted to floating-point arguments (if possible). Use the option `Symbolic` if no such conversion is desired.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

The rotation around the z axis by 45 degrees is given by the following matrix:

```
numeric::rotationMatrix(PI/4, [0, 0, 1])
```

$$\begin{pmatrix} 0.7071067812 & -0.7071067812 & 0 \\ 0.7071067812 & 0.7071067812 & 0 \\ 0 & 0 & 1.0 \end{pmatrix}$$

Symbolic arguments are accepted:

```
numeric::rotationMatrix(a, [1, 2, 3])
```

```
[[0.9285714286 cos(a) + 0.07142857143, 0.1428571429 - 0.8017837257 sin(a)
- 0.1428571429 cos(a), 0.5345224838 sin(a) - 0.2142857143 cos(a) + 0.2142857143],
[0.8017837257 sin(a) - 0.1428571429 cos(a) + 0.1428571429, 0.7142857143 cos(a)
+ 0.2857142857, 0.4285714286 - 0.2672612419 sin(a) - 0.4285714286 cos(a)],
[0.2142857143 - 0.5345224838 sin(a) - 0.2142857143 cos(a), 0.2672612419 sin(a) - 0.4
+ 0.4285714286, 0.3571428571 cos(a) + 0.6428571429]]
```

With the option `Symbolic`, no automatic conversion to floating-point numbers occurs:

```
numeric::rotationMatrix(a, [1, 2, 3], Symbolic)
```

$$\begin{pmatrix} \frac{13 \cos(a)}{14} + \frac{1}{14} & \frac{1}{7} - \frac{3\sqrt{14} \sin(a)}{14} - \frac{\cos(a)}{7} & \frac{\sqrt{14} \sin(a)}{7} - \frac{3 \cos(a)}{14} + \frac{3}{14} \\ \frac{3\sqrt{14} \sin(a)}{14} - \frac{\cos(a)}{7} + \frac{1}{7} & \frac{5 \cos(a)}{7} + \frac{2}{7} & \frac{3}{7} - \frac{\sqrt{14} \sin(a)}{14} - \frac{3 \cos(a)}{7} \\ \frac{3}{14} - \frac{\sqrt{14} \sin(a)}{7} - \frac{3 \cos(a)}{14} & \frac{\sqrt{14} \sin(a)}{14} - \frac{3 \cos(a)}{7} + \frac{3}{7} & \frac{5 \cos(a)}{14} + \frac{9}{14} \end{pmatrix}$$

## Example 2

The return type coincides with the type of the input parameter representing the axis:

```
numeric::rotationMatrix(0.3, matrix([1,2,3]))
```

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

```
domtype(%)
```

# numeric::rotationMatrix

---

```
Dom::Matrix()
```

```
numeric::rotationMatrix(0.3, hfarray(1..3, [1,2,3]))
```

```
(0.9585267399 -0.2305627908 0.1675329472)
(0.2433237939 0.9680974922 -0.05983959278)
(-0.1483914426 0.0981226021 0.9840487461)
```

```
domtype(%)
```

```
DOM_HFARRAY
```

The option `ReturnType` allows to specify the type of the result:

```
numeric::rotationMatrix(0.3, hfarray(1..3, [1,2,3]), ReturnType = m
```

```
(0.9585267399 -0.2305627908 0.1675329472)
(0.2433237939 0.9680974922 -0.05983959278)
(-0.1483914426 0.0981226021 0.9840487461)
```

```
domtype(%)
```

```
Dom::Matrix()
```

### Example 3

The direction of the rotation is given by the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation:

```
axis := matrix([0, 0, 1]):
vector := matrix([1, 0, 0]):
Q := numeric::rotationMatrix(PI/4, axis):
plot(plot::Arrow3d(axis, Color = RGB::Blue),
 plot::Arrow3d(vector, Color = RGB::Red),
 plot::Arrow3d(Q*vector, Color = RGB::Red),
 plot::Text3d("axis", [0.01, 0.01, 0.5]),
 plot::Text3d("vector", [1.05, 0, 0]),
 plot::Text3d("rotated vector", [0.75, 0.75, 0]),
 CameraDirection = [1, -2, 4],
 Scaling = Constrained, Axes = None):
```

Use negative angles to rotate in the opposite direction:

```
axis := matrix([0, 0, 1]):
vector := matrix([1, 0, 0]):
Q := numeric::rotationMatrix(-PI/4, axis):
plot(plot::Arrow3d(axis, Color = RGB::Blue),
```

# numeric::rotationMatrix

```
plot::Arrow3d(vector, Color = RGB::Red),
plot::Arrow3d(Q*vector, Color = RGB::Red),
plot::Text3d("axis", [0.01, 0.01, 0.5]),
plot::Text3d("vector", [1.05, 0, 0]),
plot::Text3d("rotated vector", [0.75, -0.75, 0]),
CameraDirection = [1, -2, 4],
Scaling = Constrained, Axes = None):
```

```
delete axis, vector, Q:
```

## Parameters

### angle

An arithmetical expression

### axis

A vector represented by a list with 3 entries or by a 3 1 matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix

## Options

### Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used.

### ReturnType

Option, specified as `ReturnType = t`

Return the result as a matrix of domain type `t`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `matrix`, or `densematrix`.

## Return Values

Depending on the type of the input matrix `axis`, the 3 3 rotation matrix is returned as a matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

# numeric::singularvalues

---

## Purpose

Numerical singular values of a matrix

## Syntax

```
numeric::singularvalues(A, <Hard | HardwareFloats
| Soft | SoftwareFloats>)
```

## Description

`numeric::singularvalues(A)` returns numerical singular values of the matrix  $A$ .

The singular values of an  $m \times n$  matrix  $A$  are the  $p = \min(m, n)$  real nonnegative square roots of the eigenvalues of  $A^H A$  (for  $p = n$ ) or of  $AA^H$  (for  $p = m$ ). The Hermitian transpose  $A^H$  is the complex conjugate of the transpose of  $A$ .

`numeric::singularvalues` returns a list of real singular values  $[d_1, \dots, d_p]$  sorted by `numeric::sort`, i.e.,  $d_1 \geq \dots \geq d_p \geq 0.0$ .

All entries of  $A$  must be numerical. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

`Cat::Matrix` objects, i.e., matrices  $A$  of a matrix domain such as `Dom::Matrix( )` or `Dom::SquareMatrix( )` are internally converted to arrays over expressions via `expr(A)`.

---

**Note** Singular values are approximated with an *absolute* precision

of  $\frac{1}{\text{DIGITS}} r$  where  $r$  is largest singular value of  $A$ . Consequently, large singular values should be computed correctly to `DIGITS` decimal places. The numerical approximations of small singular values are less accurate.

---

Singular values may also be computed via `map ( numeric::eigenvalues( A A^H ), sqrt )` or `map ( numeric::eigenvalues( A^H A ), sqrt )`, respectively.

The use of `numeric::singularvalues` avoids the costs of the matrix multiplication. Further, the eigenvalue routine requires about twice as

many DIGITS to compute small singular values with the same precision as `numeric::singularvalues`. Cf. “Example 2” on page 18-345.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

The singular values of  $A$  and  $A^H$  coincide:

```
A := array(1..3, 1..2, [[1, 2*I], [2, 3],[3, sqrt(2)]]):
```

```
numeric::singularvalues(A)
```

```
[4.994802008, 2.012946323]
```

The Hermitian transpose  $B = A^H$ :

```
B := array(1..2, 1..3, [[1, 2, 3], [-2*I, 3, sqrt(2)]]):
```

```
numeric::singularvalues(B)
```

```
[4.994802008, 2.012946323]
```

```
delete A, B:
```

### Example 2

We use `numeric::eigenvalues` to compute singular values:

```
A := matrix([[1/15, 2/15*I], [PI, 314159265358980/5000000000000])
```

The Hermitian transpose  $B = A^H$  can be computed by the methods `conjugate` and `transpose` of the matrix domain:

# numeric::singularvalues

---

```
B := A::dom::conjugate(A::dom::transpose(A)):
```

Note that  $A^H A$  is positive semi-definite and cannot have negative eigenvalues. However, computing small eigenvalues is numerically ill-conditioned, and a small negative value occurs due to roundoff:

```
numeric::eigenvalues(B*A)
```

```
[69.37024423, -2.310493271 10-15]
```

Consequently, an (incorrect) imaginary singular value is computed:

```
map(%, sqrt)
```

```
[8.32888013, 0.00000004806759065 i]
```

We have to increase DIGITS in order to compute this value more accurately:

```
DIGITS := 22:
map(numeric::eigenvalues(B*A), sqrt)
```

```
[8.328880130465871055353, 3.293453726225542754196 10-15]
```

With numeric::singularvalues, the standard precision suffices:

```
DIGITS := 10:
numeric::singularvalues(A, SoftwareFloats)
```

```
[8.32888013, 3.249076763 10-15]
```

```
numeric::singularvalues(A, HardwareFloats)
```

```
[8.32888013, 3.6920369 10-15]
```

```
delete A, B:
```

### Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of the small singular values is subject to severe roundoff effects. In the following results, both with HardwareFloats as well as with SoftwareFloats, the small singular values are dominated by numerical roundoff. Consequently, the results with HardwareFloats differ from those with SoftwareFloats:

```
numeric::singularvalues(linalg::hilbert(13))
```

```
[1.813830119, 0.396833076, ..., 8.878210699 10-16, 3.222901015 10-18]
```

```
A := linalg::hilbert(15):
numeric::singularvalues(A, HardwareFloats);
numeric::singularvalues(A, SoftwareFloats)
```

```
[1.845927746, 0.426627957, 0.05721209253, ..., 1.351581189 10-17, 5.696479572 10-18
```

```
[1.845927746, 0.426627957, 0.05721209253, ..., 9.682265893 10-19, 3.017915363 10-21
```

```
delete A:
```

# numeric::singularvalues

---

## Parameters    **A**

A numerical matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

## Options    **Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no **HardwareFloats** or **SoftwareFloats** are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix **A** is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`, or if one of the options **Soft**, **SoftwareFloats** or **Symbolic** is specified, MuPAD

computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 18-347.

---

## Return Values

Ordered list of real floating-point values.

## Algorithms

The code implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

### Related Examples

- “Compute Factorizations Numerically”

**Purpose** Numerical singular value decomposition of a matrix

**Syntax** `numeric::singularvectors(A, options)`

**Description** `numeric::singularvectors(A)` and the equivalent call `numeric::svd(A)` return numerical singular values and singular vectors of the matrix  $A$ .

All entries of  $A$  must be numerical. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

`Cat::Matrix` objects, i.e., matrices  $A$  of a matrix domain such as `Dom::Matrix( )` or `Dom::SquareMatrix( )` are internally converted to arrays over expressions via `expr(A)`.

The list  $[U, d, V, \text{res}_U, \text{res}_V]$  returned by `numeric::singularvectors` corresponds to the singular data of an  $m \times n$  matrix  $A$  as described below.

Let  $V^H$  denote the Hermitian transpose of the matrix  $V$ , i.e., the complex conjugate of the transpose. The singular value decomposition of an  $m \times n$  matrix  $A$  is a factorization  $A = UDV^H$ .  $D$  is an  $m \times n$  “diagonal” matrix with real nonnegative entries  $D_{ii} = d_i$ ,  $i = 1, \dots, p$  where  $p = \min(m, n)$ :

$$D = \begin{pmatrix} d_1 & & 0 \\ & \dots & \\ & & d_p \\ 0 & & & 0 \end{pmatrix}$$

or

$$D = \begin{pmatrix} d_1 & & & 0 \\ & \dots & & \\ & & d_p & \\ 0 & & & 0 \end{pmatrix},$$

# numeric::singularvectors

---

respectively. The list  $d = [d_1, \dots, d_p]$  returned by `numeric::singularvectors` are the “singular values” of  $A$ . They are sorted by `numeric::sort`, i.e.,  $d_1 \geq \dots \geq d_p \geq 0.0$ .

$U$  is a unitary  $m \times m$  matrix. Its  $i$ -th column is an eigenvector of  $AA^H$  associated with the eigenvalue  $d_i^2$  ( $d_i = 0$  for  $i > p$ ). These are the “left singular vectors” of  $A$ . They are returned by `numeric::singularvectors` as a matrix of floating-point numbers.

$V$  is a unitary  $n \times n$  matrix. Its  $i$ -th column is an eigenvector of  $A^HA$  associated with the eigenvalue  $d_i^2$  ( $d_i = 0$  for  $i > p$ ). These are the “right singular vectors” of  $A$ . They are returned by `numeric::singularvectors` as an array of floating-point numbers. The matrix  $V$  is normalized such that, in each column, the first entry of

absolute size larger than  $\frac{1}{10^{\text{DIGITS}}}$  is real and positive.

If no return type is specified via the option `ReturnType = t`, the domain type of the singular vectors  $U$  and  $V$  depends on the type of the input matrix  $A$ :

- The singular vectors of an array are returned as arrays.
- The singular vectors of an hfarray are returned as hfarrays.
- The singular vectors of a dense matrix of type `Dom::DenseMatrix()` are returned as dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the singular vectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices  $A$  of type `Dom::Matrix()`, `Dom::SquareMatrix()`, `Dom::MatrixGroup()` etc.

$res_U = [resU_1, \dots, resU_m]$  is a list of float residues associated with the left singular vectors:

$$resU_i = \langle A^H u_i, A^H u_i \rangle - d_i^2, \quad 1 \leq i \leq m$$

Here,  $u_i$  is the (normalized)  $i$ -th column of  $U$ ,  $\langle \dots, \dots \rangle$  is the usual complex Euclidean scalar product and  $d_i = 0$  for  $p < i \leq m$ .

$resV = [resV_1, \dots, resV_n]$  is a list of float residues associated with the right singular vectors:

$$resV_i = \langle A v_i, A v_i \rangle - d_i^2, \quad 1 \leq i \leq n$$

Here,  $v_i$  is the (normalized)  $i$ -th column of  $V$ ,  $d_i = 0$  for  $p < i \leq n$ .

The residues  $resU$ ,  $resV$  vanish for exact singular data  $U$ ,  $d$ ,  $V$ . Their sizes indicate the quality of the numerical data  $U$ ,  $d$ ,  $V$ .

---

**Note** Singular values are approximated with an *absolute* precision of

$\frac{1}{10^{\text{DIGITS}}}$   $r$ , where  $r$  is the largest singular value of  $A$ . Consequently, large singular values should be computed correctly to DIGITS decimal places. The numerical approximations of small singular values are less accurate.

---

The singular values computed by `numeric::singularvectors` are identical to those computed by `numeric::svd`.

Singular data may also be computed via `[d2, U, resU] := numeric::eigenvectors(A*A^H)` or `[d2, V, resV] := numeric::eigenvectors(A^H*A)`, respectively. The list `d2` is related to the singular values by

$$d2 = [d_1^2, d_2^2, \dots, d_p^2, 0, \dots, 0]$$

The use of `numeric::singularvectors` avoids the costs of the matrix multiplication. Further, the eigenvector routine requires about twice as many DIGITS to compute the data associated with small singular values

# numeric::singularvectors

---

with the same precision as `numeric::singularvectors`. Also note that the normalization of `U` and `V` may be different.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

Numerical expressions are converted to floats:

```
DIGITS := 5:
A := array(1..3, 1..2, [[1, PI], [2, 3], [3, exp(sqrt(2))]]):
[U, d, V, resU, resV] := numeric::singularvectors(A):
```

The singular data are:

```
U, d, V
```

$$\begin{pmatrix} 0.45729 & -0.88078 & 0.12293 \\ 0.51483 & 0.14947 & -0.84416 \\ 0.72515 & 0.44932 & 0.5218 \end{pmatrix}, [6.9986, 0.89905], \begin{pmatrix} 0.5233 & 0.85215 \\ 0.85215 & -0.5233 \end{pmatrix}$$

The small residues indicate that these results are not severely affected by roundoff:

```
resU, resV
```

$$[2.247 \cdot 10^{-14}, 2.247 \cdot 10^{-14}, 3.898 \cdot 10^{-32}], [5.6175 \cdot 10^{-15}, 5.6175 \cdot 10^{-15}]$$

```
delete DIGITS, A, U, d, V, resU, resV:
```

## Example 2

We demonstrate how to reconstruct a matrix from its singular data. With the specified `ReturnType`, the singular vectors are returned as matrices of type `Dom::Matrix()` and can be handled with the overloaded arithmetic:

```
DIGITS := 3:
A := array(1..2, 1..3, [[1.0, I, PI], [2, 3, I]]):
[U, d, V, resU, resV] := numeric::singularvectors(A, NoResidues,
 ReturnType = Dom::Matrix())
```

$$\left[ \begin{array}{c} \left( \begin{array}{cc} 0.514 - 0.028i & -0.788 + 0.336i \\ 0.857 + 0.014i & 0.487 - 0.168i \end{array} \right), [3.9, 3.27], \left( \begin{array}{ccc} 0.571 & 0.0568 & 0 \\ 0.652 - 0.121i & 0.55 + 0.0871i & -0.493 \\ 0.418 - 0.242i & -0.81 + 0.174i & -0.236 \end{array} \right) \\ \text{NIL} \end{array} \right]$$

A “diagonal” matrix is built from the singular values:

```
d := matrix(2, 3, d, Diagonal)
```

$$\begin{pmatrix} 3.9 & 0 & 0 \\ 0 & 3.27 & 0 \end{pmatrix}$$

We use the methods `conjugate` and `transpose` of the matrix domain to compute the Hermitian transpose of `V` and reconstruct `A`. Numerical roundoff is eliminated via `numeric::complexRound`:

```
VH := V::dom::conjugate(V::dom::transpose(V)):
map(U*d*VH, numeric::complexRound)
```

# numeric::singularvectors

---

$$\begin{pmatrix} 1.0 & 1.0i & 3.14 \\ 2.0 & 3.0 & 1.0i \end{pmatrix}$$

delete DIGITS, A, U, d, V, resU, resV, VH:

## Example 3

We demonstrate the use of hardware floats. The following matrix  $A$  is degenerate: it has rank 1. For the double eigenvalue 0 of the matrix  $A^H A$ , different base vectors of the corresponding eigenspace are returned with HardwareFloats and SoftwareFloats, respectively:

```
A := array(1..2, 1..3, [[1, 2, 3], [30, 60, 90]]):
[U1, d1, V1, resU1, resV1] := numeric::singularvectors(A, HardwareF
[U2, d2, V2, resU2, resV2] := numeric::singularvectors(A, SoftwareF
V1, V2
```

$$\begin{pmatrix} 0.2672612419 & 0.5345224838 & 0.8017837257 \\ 0.5345224838 & -0.7745419206 & 0.3381871191 \\ 0.8017837257 & 0.3381871191 & -0.4927193213 \end{pmatrix}, \begin{pmatrix} 0.2672612419 & 0.9561828875 & 0.1 \\ 0.5345224838 & -0.04390192219 & -0. \\ 0.8017837257 & -0.289459681 & 0.5 \end{pmatrix}$$

delete A, U1, d1, V1, resU1, resV1, U2, d2, V2, resU2, resV2:

## Parameters **A**

A numerical matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix.

## Options **Hard, HardwareFloats, Soft, SoftwareFloats**

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled

C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

# numeric::singularvectors

---

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 18-356.

---

## **NoLeftVectors**

Suppresses the computation of left singular vectors

If only right singular vectors are required, this option may be used to suppress the computation of  $U$  and the corresponding residues  $\text{res}_U$ . The return values for these data are `NIL`.

Depending on the size of  $U$ , this option may speed up the computation considerably.

## **NoRightVectors**

Suppresses the computation of right singular vectors

If only left singular vectors are required, this option may be used to suppress the computation of  $V$  and the corresponding residues  $\text{res}_V$ . The return values for these data are `NIL`.

Depending on the size of  $V$ , this option may speed up the computation considerably.

## NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues  $\text{res}_U$  and  $\text{res}_V$ . The return values for these data are NIL.

The alternative option name NoErrors used in previous MuPAD versions is still available.

## ReturnType

Option, specified as `ReturnType = t`

Return the left and right singular vectors as matrices of domain type  $t$ . The following return types  $t$  are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

This option determines the domain type of the matrices containing the singular vectors.

## NoWarning

Suppresses warnings

## Return Values

List  $[U, d, V, \text{res}_U, \text{res}_V]$ .  $U$  is a unitary square float matrix whose columns are left singular vectors. The list  $d$  contains the singular values.  $V$  is a unitary square float matrix whose columns are right singular vectors. The lists of float residues  $\text{res}_U$  and  $\text{res}_V$  provide error estimates for the numerical data.

# numeric::svd

---

**Purpose** Numerical singular value decomposition of a matrix

**Syntax** `numeric::svd(A, options)`

**Description** `numeric::svd(A)` and the equivalent call `numeric::singularvectors(A)` return numerical singular values and singular vectors of the matrix  $A$ .

All entries of  $A$  must be numerical. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

`Cat::Matrix` objects, i.e., matrices  $A$  of a matrix domain such as `Dom::Matrix( )` or `Dom::SquareMatrix( )` are internally converted to arrays over expressions via `expr(A)`.

The list  $[U, d, V, res_u, res_v]$  returned by `numeric::svd` corresponds to the singular data of an  $m \times n$  matrix  $A$  as described below.

Let  $V^H$  denote the Hermitian transpose of the matrix  $V$ , i.e., the complex conjugate of the transpose. The singular value decomposition of an  $m \times n$  matrix  $A$  is a factorization  $A = UDV^H$ .  $D$  is an  $m \times n$  “diagonal” matrix with real nonnegative entries  $D_{ii} = d_i$ ,  $i = 1, \dots, p$  where  $p = \min(m, n)$ :

$$D = \begin{pmatrix} d_1 & \dots & 0 \\ & & d_p \\ 0 & & 0 \end{pmatrix}$$

or

$$D = \begin{pmatrix} d_1 & \dots & 0 \\ 0 & & d_p & 0 \end{pmatrix},$$

respectively. The list  $d = [d_1, \dots, d_p]$  returned by `numeric::svd` are the “singular values” of  $A$ . They are sorted by `numeric::sort`, i.e.,  $d_1 \geq \dots \geq d_p \geq 0.0$ .

$U$  is a unitary  $m \times m$  matrix. Its  $i$ -th column is an eigenvector of  $AA^H$  associated with the eigenvalue  $d_i^2$  ( $d_i = 0$  for  $i > p$ ). These are the “left singular vectors” of  $A$ . They are returned by `numeric::svd` as a matrix of floating-point numbers.

$V$  is a unitary  $n \times n$  matrix. Its  $i$ -th column is an eigenvector of  $A^H A$  associated with the eigenvalue  $d_i^2$  ( $d_i = 0$  for  $i > p$ ). These are the “right singular vectors” of  $A$ . They are returned by `numeric::svd` as an array of floating-point numbers. The matrix  $V$  is normalized such that, in

each column, the first entry of absolute size larger than  $\frac{1}{10^{\text{DIGITS}}}$  is real and positive.

If no return type is specified via the option `ReturnType = t`, the domain type of the singular vectors  $U$  and  $V$  depends on the type of the input matrix  $A$ :

- The singular vectors of an array are returned as arrays.
- The singular vectors of an `hfarray` are returned as `hfarrays`.
- The singular vectors of a dense matrix of type `Dom::DenseMatrix()` are returned as dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the singular vectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices  $A$  of type `Dom::Matrix( )`, `Dom::SquareMatrix( )`, `Dom::MatrixGroup( )` etc.

$res_U = [resU_1, \dots, resU_m]$  is a list of float residues associated with the left singular vectors:

$$resU_i = \langle A^H u_i, A^H u_i \rangle - d_i^2, 1 \leq i \leq m$$

## numeric::svd

---

Here,  $u_i$  is the (normalized)  $i$ -th column of  $U$ ,  $\langle \dots, \dots \rangle$  is the usual complex Euclidean scalar product and  $d_i = 0$  for  $p < i \leq m$ .

$res_V = [resV_1, \dots, resV_n]$  is a list of float residues associated with the right singular vectors:

$$resV_i = \langle A v_i, A v_i \rangle - d_i^2, \quad 1 \leq i \leq n$$

Here,  $v_i$  is the (normalized)  $i$ -th column of  $V$ ,  $d_i = 0$  for  $p < i \leq n$ .

The residues  $res_U$ ,  $res_V$  vanish for exact singular data  $U$ ,  $d$ ,  $V$ . Their sizes indicate the quality of the numerical data  $U$ ,  $d$ ,  $V$ .

---

**Note** Singular values are approximated with an *absolute* precision of

$\frac{1}{\text{DIGITS}} r$ , where  $r$  is the largest singular value of  $A$ . Consequently, large singular values should be computed correctly to DIGITS decimal places. The numerical approximations of small singular values are less accurate.

---

The singular values computed by `numeric::svd` are identical to those computed by `numeric::singularvalues`.

Singular data may also be computed via `[d2, U, resU] := numeric::eigenvectors(A*A^H)` or `[d2, V, resV] := numeric::eigenvectors(A^H*A)`, respectively. The list `d2` is related to the singular values by

$$d2 = [d_1^2, d_2^2, \dots, d_p^2, 0, \dots, 0]$$

The use of `numeric::svd` avoids the costs of the matrix multiplication. Further, the eigenvector routine requires about twice as many DIGITS to compute the data associated with small singular values with the

same precision as `numeric::singularvectors`. Also note that the normalization of U and V may be different.

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

Numerical expressions are converted to floats:

```
DIGITS := 5:
A := array(1..3, 1..2, [[1, PI], [2, 3], [3, exp(sqrt(2))]]):
[U, d, V, resU, resV] := numeric::singularvectors(A):
```

The singular data are:

U, d, V

$$\begin{pmatrix} 0.45729 & -0.88078 & 0.12293 \\ 0.51483 & 0.14947 & -0.84416 \\ 0.72515 & 0.44932 & 0.5218 \end{pmatrix}, [6.9986, 0.89905], \begin{pmatrix} 0.5233 & 0.85215 \\ 0.85215 & -0.5233 \end{pmatrix}$$

The small residues indicate that these results are not severely affected by roundoff:

resU, resV

$$[2.247 \cdot 10^{-14}, 2.247 \cdot 10^{-14}, 3.898 \cdot 10^{-32}], [5.6175 \cdot 10^{-15}, 5.6175 \cdot 10^{-15}]$$

delete DIGITS, A, U, d, V, resU, resV:

## Example 2

We demonstrate how to reconstruct a matrix from its singular data. With the specified `ReturnType`, the singular vectors are returned as matrices of type `Dom::Matrix()` and can be handled with the overloaded arithmetic:

```
DIGITS := 3:
A := array(1..2, 1..3, [[1.0, I, PI], [2, 3, I]]):
[U, d, V, resU, resV] := numeric::singularvectors(A, NoResidues,
 ReturnType = Dom::Matrix())
```

$$\left[ \begin{pmatrix} 0.514 - 0.028i & -0.788 + 0.336i \\ 0.857 + 0.014i & 0.487 - 0.168i \end{pmatrix}, [3.9, 3.27], \begin{pmatrix} 0.571 & 0.0568 & 0.819 \\ 0.652 - 0.121i & 0.55 + 0.0871i & -0.493 + 0. \\ 0.418 - 0.242i & -0.81 + 0.174i & -0.236 + 0 \end{pmatrix} \right]$$

NIL

A “diagonal” matrix is built from the singular values:

```
d := matrix(2, 3, d, Diagonal)
```

$$\begin{pmatrix} 3.9 & 0 & 0 \\ 0 & 3.27 & 0 \end{pmatrix}$$

We use the methods `conjugate` and `transpose` of the matrix domain to compute the Hermitian transpose of `V` and reconstruct `A`. Numerical roundoff is eliminated via `numeric::complexRound`:

```
VH := V::dom::conjugate(V::dom::transpose(V)):
map(U*d*VH, numeric::complexRound)
```

$$\begin{pmatrix} 1.0 & 1.0i & 3.14 \\ 2.0 & 3.0 & 1.0i \end{pmatrix}$$

delete DIGITS, A, U, d, V, resU, resV, VH:

### Example 3

We demonstrate the use of hardware floats. The following matrix  $A$  is degenerate: it has rank 1. For the double eigenvalue 0 of the matrix  $A^H A$ , different base vectors of the corresponding eigenspace are returned with HardwareFloats and SoftwareFloats, respectively:

```
A := array(1..2, 1..3, [[1, 2, 3], [30, 60, 90]]):
[U1, d1, V1, resU1, resV1] := numeric::singularvectors(A, HardwareFloats):
[U2, d2, V2, resU2, resV2] := numeric::singularvectors(A, SoftwareFloats):
V1, V2
```

$$\begin{pmatrix} 0.2672612419 & 0.5345224838 & 0.8017837257 \\ 0.5345224838 & -0.7745419206 & 0.3381871191 \\ 0.8017837257 & 0.3381871191 & -0.4927193213 \end{pmatrix}, \begin{pmatrix} 0.2672612419 & 0.9561828875 \\ 0.5345224838 & -0.04390192219 \\ 0.8017837257 & -0.289459681 \end{pmatrix}$$

delete A, U1, d1, V1, resU1, resV1, U2, d2, V2, resU2, resV2:

### Parameters

**A**

A numerical matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix.

### Options

**Hard, HardwareFloats, Soft, SoftwareFloats**

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled

C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 18-365.

---

### **NoLeftVectors**

Suppresses the computation of left singular vectors

If only right singular vectors are required, this option may be used to suppress the computation of  $U$  and the corresponding residues  $\text{res}_U$ . The return values for these data are `NIL`.

Depending on the size of  $U$ , this option may speed up the computation considerably.

### **NoRightVectors**

Suppresses the computation of right singular vectors

If only left singular vectors are required, this option may be used to suppress the computation of  $V$  and the corresponding residues  $\text{res}_V$ . The return values for these data are `NIL`.

Depending on the size of  $V$ , this option may speed up the computation considerably.

## NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues  $\text{res}_U$  and  $\text{res}_V$ . The return values for these data are NIL.

The alternative option name NoErrors used in previous MuPAD versions is still available.

## ReturnType

Option, specified as `ReturnType = t`

Return the left and right singular vectors as matrices of domain type  $t$ . The following return types  $t$  are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

This option determines the domain type of the matrices containing the singular vectors.

## NoWarning

Suppresses warnings

## Return Values

List  $[U, d, V, \text{res}_U, \text{res}_V]$ .  $U$  is a unitary square float matrix whose columns are left singular vectors. The list  $d$  contains the singular values.  $V$  is a unitary square float matrix whose columns are right singular vectors. The lists of float residues  $\text{res}_U$  and  $\text{res}_V$  provide error estimates for the numerical data.

## Related Examples

- “Compute Factorizations Numerically”

**Purpose** Numerical solution of equations (the float attribute of solve)

**Syntax** `numeric::solve(eqs, <vars>, options)`  
`float(holdsolve(eqs, <vars>, options))`  
`float(freesolve(eqs, <vars>, options))`

**Description** `numeric::solve` computes numerical solutions of equations. For polynomial equations, *all* solutions are returned. For non-polynomial equations, only *one* solution, if any, is returned unless the option `AllRealRoots` is used.

---

**Note** Note that only for polynomial/rational equations *all* solutions are searched for. For non-polynomial/non-rational equations, only one solution, if any, is returned unless the option `AllRealRoots` is used.

---

If the equations contain non-polynomial expressions, it is in general not possible to isolate *all* roots numerically. Think of equations such as  $\sin(\frac{1}{x}) = 0$  that have infinitely many real solutions around the origin! If a complete set of *all* real solutions of a single non-polynomial/non-rational equation in one unknown is desired, you may try the option `AllRealRoots`. With this option, a heuristics tries to isolate all real solutions of the equation. This, however, is purely heuristical: there is no rigor in the algorithm and it is not guaranteed that all solutions are found. Alternatively, you may also use the routine `numeric::realroots` to isolate the intervals in which solutions may exist.

`numeric::solve` is a simple interface function unifying the functionality of the numerical solvers `numeric::fsolve`, `numeric::linsolve`, `numeric::polyroots`, and `numeric::polysysroots`. The return format of these routines is changed to make it consistent with the return values of the symbolic solver `solve`.

You may call the specialized numerical solvers directly. However, note the return types specific to each of these solvers.

## numeric::solve

---

`numeric::solve` classifies the equations as follows:

- If `eqs` is a single univariate polynomial equation, then it is directly passed to `numeric::polyroots`. Cf. “Example 2” on page 18-372. The roots are returned as a set or as a `Dom::Multiset` if `Multiple` is used.
- If `eqs` is a multivariate polynomial equation or a list or set of such equations, then the equations and the appropriate optional arguments are passed to either `numeric::linsolve` or `numeric::polysysroots`. Cf. “Example 3” on page 18-373. The roots are returned as a set or as a `Dom::Multiset` if `Multiple` is used.
- A rational equation or a set or list of rational equations is replaced by its/their numerator(s). Such equations are processed like polynomial equations.
- If `eqs` is a non-polynomial/non-rational equation or a set or list containing such an equation, then the equations and the appropriate optional arguments are passed to the numerical solver `numeric::fsolve`.

---

**Note** For non-polynomial equations, only a single numerical root is returned, unless `AllRealRoots` is specified! Cf. “Example 4” on page 18-373.

---

---

**Note** For non-polynomial equations, there must not be more equations than unknowns!

---

Using `Multiple` for non-polynomial equations leads to an error, unless the option `AllRealRoots` is specified, too!

---

**Note** For systems of multivariate non-polynomial equations, MuPAD uses a Newton search. It must be able to evaluate the partial derivatives of the equations with respect to the variables to be solved for.

---

For a single univariate equation, first a bisectioning scheme with quadratic interpolation is used that does not require any differentiation of the equation. If this is not successful, a Newton search is started that requires the derivative of the functions involved.

For convenience, also polynomials of domain type DOM\_POLY are accepted, wherever an equation is expected.

---

**Note** In contrast to the symbolic solver `solve`, the numerical solver does not react to properties of identifiers set via `assume`. To use these properties, call `float ( hold( solve )(arguments))` instead.

---

If the user does not specify indeterminates to be solved for, then the indeterminates are internally chosen by `numeric::indets(eqs)`.

Starting points such as `x = a` or search ranges such as `x = a..b` specified in `vars` are ignored if `eqs` is a polynomial equation or a system of polynomial equations.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

The following three solver calls are equivalent:

```
eqs := {x^2 = sin(y), y^2 = cos(x)}:
```

# numeric::solve

---

```
numeric::solve(eqs, {x, y}),
float(hold(solve)(eqs, {x, y})),
float(freeze(solve)(eqs, {x,y}))
```

```
{[x = -0.8517004887, y = 0.8116062151]}, {[x = -0.8517004887, y = 0.8116062151]},
{[x = -0.8517004887, y = 0.8116062151]}
```

```
delete eqs:
```

## Example 2

We demonstrate the root search for univariate polynomials:

```
numeric::solve(x^6 - PI*x^2 = sin(3), x)
```

```
{- 1.339589766, 1.339589766, 1.322706295 i, 0.2120113223 i, -0.2120113223 i, -1.322706
```

Polynomials of type DOM\_POLY can be used as input:

```
numeric::solve(poly((x - 1/3)^3, [x]), x)
```

```
{0.3333333333}
```

With `Multiple`, a `Dom::Multiset` is returned, indicating the multiplicity of the root:

```
numeric::solve(x^3 - x^2 + x/3 - 1/27, x, Multiple)
```

```
{[0.3333333333, 3]}
```

### Example 3

We demonstrate the root search for polynomial systems. Note that the symbolic solver `solve` is involved if the system is nonlinear. Symbolic parameters are accepted:

```
numeric::solve({x^2 + y^2 = 1, x^2 - y^2 = exp(z)}, {x, y})
```

$$\left\{ \left[ x = -0.7071067812 \sqrt{e^z + 1.0}, y = -0.7071067812 \sqrt{1.0 - 1.0 e^z} \right], \dots, \right. \\ \left. \left[ x = 0.7071067812 \sqrt{e^z + 1.0}, y = 0.7071067812 \sqrt{1.0 - 1.0 e^z} \right] \right\}$$

### Example 4

We demonstrate the root search for non-polynomial equations. Without the option `AllRealRoots`, only one solution is searched for:

```
eq := exp(-x) - 10*x^2:
numeric::solve(eq, x)
```

```
{0.2755302947}
```

Since `numeric::solve` just calls the root finder `numeric::fsolve`, one may also use this routine directly. Note the different output format:

```
numeric::fsolve(eq, x)
```

```
[x = 0.2755302947]
```

The input syntax of `numeric::solve` and `numeric::fsolve` are identical, i.e., starting points, search ranges and options may be used. E.g., another solution of the previous equation is found by a restricted search over the interval  $[-1, 0]$ :

# numeric::solve

---

```
numeric::solve(eq, x = -1..0, RestrictedSearch)
```

```
{- 0.3829657727}
```

We use the option `AllRealRoots` to isolate all real solutions of the equation:

```
numeric::solve(eq, x, AllRealRoots)
```

```
{- 5.827897796, - 0.3829657727, 0.2755302947}
```

With the following call we restrict the search to the negative semi-axis:

```
numeric::solve(eq, x = -infinity..0, AllRealRoots)
```

```
{- 5.827897796, - 0.3829657727}
```

## Example 5

For the following system, `numeric::solve` finds the solution with positive  $y$ :

```
eqs := [exp(x) = 2*y^2, sin(y) = y*x^3]:
numeric::solve(eqs, [x, y])
```

```
{[x = 0.9290711314, y = 1.125201325]}
```

Another solution with negative  $y$  is found with an appropriate search range:

```
numeric::solve(eqs, [x = 1, y = -infinity..0])
```

```
{[x = 0.9290711314, y = - 1.125201325]}
```

```
delete eq, eqs:
```

## Parameters

### eqs

An equation, a list, set, array, or matrix (`Cat::Matrix`) of equations. Also arithmetical expressions are accepted and interpreted as homogeneous equations.

### vars

An unknown, a list of unknowns or a set of unknowns. Unknowns may be identifiers or indexed identifiers. Also equations of the form  $x=a$  or  $x=a..b$  are accepted wherever an unknown  $x$  is expected. This way, starting points and search ranges are specified for the numerical search. They must be numerical; infinite search ranges are accepted.

## Options

### AllRealRoots

Only to be used if `eqs` is a single equation in one unknown. With this option, a *heuristics* is used to find *all* real solutions of the equation.

---

**Note** Note that there is no guarantee that all real solutions will be found.

---

---

**Note** Interval arithmetic is used to isolate search intervals for the solutions. The expressions in `eqs` must be suitable for such arithmetic. Internally, the procedure `numeric::realroots` is called. See the help page of `numeric::realroots` for restrictions on the expressions in `eqs`.

---

# numeric::solve

---

---

**Note** There is no rigor in the heuristics behind this option. There is no guarantee that all real solutions will be found!

---

---

**Note** The equation must be suitable for evaluation with interval arithmetic. See `numeric::realroots` for restrictions on the expressions in the equation.

---

With `AllRealRoots`, only the additional options `Multiple` and `NoWarning` have an effect. All other options such as `UnrestrictedSearch` etc. are ignored.

It is highly recommend to specify a search interval by a call such as `numeric::solve(f(x), x = a..b, AllRealRoots)`. In this case, only the real solutions between `a` and `b` are searched for.

The search for all real solutions may be very time consuming!

## **Multiple**

Only to be used if `eqs` is a polynomial equation or a system of polynomial equations or in conjunction with the option `AllRealRoots`. With this option, information on the multiplicity of degenerate polynomial roots is returned.

It changes the return type from `DOM_SET` to `Dom::Multiset`.

## **FixedPrecision**

Only to be used if `eqs` is a single univariate polynomial. It launches a quick numerical search with fixed internal precision.

It is passed to `numeric::polyroots`, which uses a numerical search with fixed internal precision. This is fast, but degenerate roots may be returned with a restricted precision. See the help page of `numeric::polyroots` for details.

## **SquareFree**

Only to be used if `eqs` is a single univariate polynomial. Symbolic square free factorization is applied, before the numerical search starts.

It is passed to `numeric::polyroots`, which preprocesses the polynomial by a symbolic square free factorization. See the help page of `numeric::polyroots` for details.

## **Factor**

Only to be used if `eqs` is a single univariate polynomial. Symbolic factorization is applied, before the numerical search starts.

It is passed to `numeric::polyroots`, which preprocesses the polynomial by a symbolic factorization. See the help page of `numeric::polyroots` for details.

## **RestrictedSearch**

The numerical search is restricted to the search ranges specified in `vars`.

This option is passed to `numeric::fsolve`, which uses a corresponding search strategy when looking for roots in the search range specified in `vars`. It must be used only in conjunction with search range and only for non-polynomial equations.

See `numeric::fsolve` for details.

## **UnrestrictedSearch**

The numerical search may return results outside the search ranges specified in `vars`.

This option is passed to `numeric::fsolve`, which uses a corresponding search strategy when looking for roots in the search range specified in `vars`. It must be use only in conjunction with search ranges and only for non-polynomial equations.

See `numeric::fsolve` for details.

## **MultiSolutions**

# numeric::solve

---

Only to be used for non-polynomial equations in conjunction with `RestrictedSearch`. Several roots may be returned.

It is passed to `numeric::fsolve`, which returns a sequence of all roots found in the internal search. See the help page of `numeric::fsolve` for details.

## Random

Only to be used for non-polynomial equations. With this option, several calls to `numeric::solve` may lead to different solutions of the equation(s).

It is passed to `numeric::fsolve` which switches to a random search strategy. See the help page of `numeric::fsolve` for details.

## NoWarning

This option only has an effect when it is used for polynomial equations in conjunction with `AllRealRoots`. When you use `AllRealRoots`, warnings are issued if interval arithmetic indicates technical difficulties such as serious overestimation (for example, when encountering multiple roots). With this option, the warnings are suppressed.

---

**Note** This option has an effect if `eqs` is a multivariate polynomial system or a univariate polynomial with a symbolic parameter.

---

In such a case, this option is passed to `numeric::polysysroots`.

## Return Values

Set of numerical solutions. With the option `Multiple`, a set of domain type `Dom::Multiset` is returned.

## Concepts

- “Solve Equations Numerically”

# numeric::sort

---

**Purpose** Sort a numerical list

**Syntax** `numeric::sort(list)`

**Description** `numeric::sort(list)` sorts the elements in `list`.

The elements of the list are sorted such that their real parts are descending. Elements with the same real part are sorted from large absolute value to small absolute value. In case of a tie (i.e., two elements form a complex conjugate pair), the element with positive imaginary part comes first.

The elements of the list are converted to floating-point numbers via `float`. Elements that cannot be converted lead to an error.

This function is used to sort the return values of `numeric::eigenvalues`, `numeric::eigenvectors`, `numeric::polyroots`, `numeric::singularvalues`, and `numeric::singularvectors`.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS`.

**Examples** **Example 1**

The elements in the sorted list have descending real parts:

```
numeric::sort([1, 2.0, I, -3, -I, PI, sqrt(2)])

[3.141592654, 2.0, 1.414213562, 1.0, 1.0 i, -1.0 i, -3.0]
```

In the following example, the sorting criterion does not seem to be satisfied. Elements with the same real part are supposed to be ordered from large absolute values to small absolute values:

```
x := sin(PI/3):
L := numeric::sort([x, sin(float(PI/3)) - I, x + I])
```

```
[0.8660254038 + 1.0 i, 0.8660254038 - 1.0 i, 0.8660254038]
```

This is explained by the fact that the floating-point numbers internally have a more accurate representation than shown on the screen. The real part of the last element is indeed a little bit smaller than the other real parts:

```
DIGITS := 20:
L
```

```
[0.8660254037844386469 + 1.0 i, 0.8660254037844386469 - 1.0 i, 0.8660254037844386
```

```
delete x, L, DIGITS:
```

**Parameters**

# numeric::spectralradius

---

## Purpose

Spectral radius of a matrix

## Syntax

```
numeric::spectralradius(A, <x0>, <n>, <mode>,
<ReturnType = t>, <NoWarning>)
```

## Description

`numeric::spectralradius(A)` returns data corresponding to the eigenvalue of the matrix `A` that has the largest absolute value.

`numeric::spectralradius` and `numeric::spectralRadius` are equivalent.

The spectral radius of a matrix with eigenvalues  $\lambda_i$  is  $\max(|\lambda_i|)$ .

The return value `lambda` is an approximation of the corresponding eigenvalue: `abs(lambda)` is the spectral radius.

The return value `x` is the corresponding normalized eigenvector:

$$\|x\|_2 = 1.$$

The return value `residue` =  $\|A x - \text{lambda } x\|_2$  provides an error estimate for the eigenvalue. For Hermitian matrices this is a rigorous upper bound for the error  $|\text{lambda} - \lambda_{\text{exact}}|$ , where  $\lambda_{\text{exact}}$  is the exact eigenvalue.

`numeric::spectralradius` implements the power method to compute the eigenvalue and the associated eigenvector defining the spectral

radius: the vector iteration  $x_i = \frac{A^i x_0}{\|A^i x_0\|_2}$  “converges” towards the eigenspace associated with the spectral radius. The starting vector  $x_0$  is provided by the second argument of `numeric::spectralradius`. If no starting vector is provided by the user, a randomly chosen vector is used.

---

**Note** The iteration does not converge (converges slowly), if the spectral radius is generated by several distinct eigenvalues with the same (similar) absolute value.

---

Internally, the iteration stops, when the approximation of the eigenvalue becomes stationary within the relative precision given by DIGITS. If this does not happen within  $n$  iterations, then a warning is issued and the present values are returned. Cf. “Example 4” on page 18-386.

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

We let the routine choose a random starting vector:

```
A := matrix(2, 2, [[10, 1], [1, 20]]):
numeric::spectralradius(A)
```

```
[20.09901951, (0.0985376181
 0.9951333267), 0.000000001332123191]
```

We define a starting vector as a 1-dimensional array and allow a maximum of 1000 internal iterations:

```
A := array(1..2, 1..2, [[1, 2], [5, -10]]):
x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0, 1000)
```

```
[-10.84428877, (0.1665007247 - 0.9860413321i), 7.808576008 10-11]
```

Next, we use a list to specify a starting vector:

```
A := array(1..2, 1..2, [[I, 3], [3, I]]):
numeric::spectralradius(A, [1, 1], 1000)
```

# numeric::spectralradius

---

```
[3.0 + 1.0 i, [0.7071067812, 0.7071067812], 0.0]
```

```
delete A, x0:
```

## Example 2

With the default setting of DIGITS = 10, the following result is computed using HardwareFloats.

```
A := hfarray(1..2, 1..2, [[10^4, 10^4], [50, 60]]):
x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0)
```

```
[10050.0498, (0.9999874753 0.00500491737), 0.000000004820940092]
```

We request SoftwareFloats in the next call. Note the difference in the trailing digits:

```
numeric::spectralradius(A, x0, Soft)
```

```
[10050.0498, (0.9999874753 0.00500491737), 0.000000004820942201]
```

```
delete DIGITS, A, x0:
```

## Example 3

The eigenvector that is returned can have various types. If no starting vector is provided, the type of the matrix determines the type of the eigenvector:

```
A:= array(1..2, 1..2, [[1, 2], [3, 4]]):
[1, x, residue]:= numeric::spectralradius(A);
```

```
[5.372281324, (0.4159735579 0.9093767091), 0.0000000002881934691]
```

```
domtype(x)
```

```
DOM_ARRAY
```

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):
[1, x, residue]:= numeric::spectralradius(A):
domtype(x)
```

```
DOM_HFARRAY
```

```
A:= matrix(2, 2, [[1, 2], [3, 4]]):
[1, x, residue]:= numeric::spectralradius(A):
domtype(x)
```

```
Dom::Matrix()
```

If a starting vector is provided, its type determines the type of the return vector:

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):
x0:= [1, 1]:
[1, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_LIST
```

```
x0:= array(1..2, [1, 1]):
[1, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_ARRAY
```

# numeric::spectralradius

---

```
x0:= hfarray(1..2, [1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

DOM\_HFARRAY

```
x0:= matrix([1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

Dom::Matrix()

The return type can be requested explicitly:

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DOM_L
domtype(x)
```

DOM\_LIST

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DOM_H
domtype(x)
```

DOM\_HFARRAY

```
delete A, x0, l, x, residue:
```

## Example 4

The following matrix has two distinct eigenvalues 1 and -1 of the same absolute value. The power method must fail.

```
A := array(1..2, 1..2, [[1, 0], [0, -1]]):
```

We allow a maximum of 1000 internal steps. The call results in a warning. The large residue also indicates that the power method did not converge:

```
numeric::spectralradius(A, [1, 1], 1000)
```

```
Warning: There is no convergence of vector iteration. [numeric::
```

```
[1.0, [0.7071067812, -0.7071067812], 1.414213562]
```

```
delete A:
```

## Parameters

### **A**

An  $m \times m$  array of domain type DOM\_ARRAY or DOM\_HFARRAY or a matrix of category Cat::Matrix

### **$x_0$**

A starting vector: a 1-dimensional array, or an hfarray, or a list of length  $m$ . Also 2-dimensional arrays (array(1..m, 1..1, ...), hfarray(1..m, 1..1, ...)) and matrices representing vectors are accepted.

### **n**

The maximal number of iterations: a positive integer. The default value is 1000.

### **mode**

One of the flags Hard, HardwareFloats, Soft, or SoftwareFloats

## Options

### **Hard, HardwareFloats, Soft, SoftwareFloats**

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard

and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

## ReturnType

Option, specified as `ReturnType = t`

Return the eigenvector associated with the spectral radius as a vector of domain type `t`. The following return types are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `DOM_LIST`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## NoWarning

Suppresses warnings

## Return Values

A list `[lambda, x, residue]` is returned. The floating-point number `lambda` is an approximation of the eigenvalue of largest absolute value. The vector `x` is a numerical eigenvector corresponding to `lambda`. `residue` is a floating-point number indicating the numerical quality of `lambda` and `x`.

If no return type is requested via the `ReturnType` option, the type of the returned vector `x` coincides with the type of the input vector  $x_0$  (i.e., it is a 1-dimensional array of type `DOM_ARRAY` or `DOM_HFARRAY`, respectively, or a list, or a column vector of type `matrix` or `densematrix`). If no starting vector is specified, the type of `x` is determined by the type of `A`.

[linalg::eigenvectors](#) | [numeric::eigenvalues](#) |  
[numeric::eigenvectors](#) | [numeric::singularvalues](#) |  
[numeric::singularvectors](#) | [numeric::svd](#)

**Purpose**

Spectral radius of a matrix

**Syntax**

```
numeric::spectralRadius(A, <x0>, <n>, <mode>,
<ReturnType = t>, <NoWarning>)
```

**Description**

`numeric::spectralRadius(A)` returns data corresponding to the eigenvalue of the matrix A that has the largest absolute value.

`numeric::spectralRadius` and `numeric::spectralradius` are equivalent.

The spectral radius of a matrix with eigenvalues  $\lambda_i$  is  $\max(|\lambda_i|)$ .

The return value `lambda` is an approximation of the corresponding eigenvalue: `abs(lambda)` is the spectral radius.

The return value `x` is the corresponding normalized eigenvector:

$$\|x\|_2 = 1.$$

The return value `residue` =  $\|Ax - \lambda x\|_2$  provides an error estimate for the eigenvalue. For Hermitian matrices this is a rigorous upper bound for the error  $|\lambda - \lambda_{exact}|$ , where  $\lambda_{exact}$  is the exact eigenvalue.

`numeric::spectralRadius` implements the power method to compute the eigenvalue and the associated eigenvector defining the spectral

radius: the vector iteration  $x_i = \frac{A^i x_0}{\|A^i x_0\|_2}$  “converges” towards the eigenspace associated with the spectral radius. The starting vector  $x_0$  is provided by the second argument of `numeric::spectralradius`. If no starting vector is provided by the user, a randomly chosen vector is used.

---

**Note** The iteration does not converge (converges slowly), if the spectral radius is generated by several distinct eigenvalues with the same (similar) absolute value.

---

# numeric::spectralRadius

---

Internally, the iteration stops, when the approximation of the eigenvalue becomes stationary within the relative precision given by DIGITS. If this does not happen within  $n$  iterations, then a warning is issued and the present values are returned. Cf. “Example 4” on page 18-395.

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

We let the routine choose a random starting vector:

```
A := matrix(2, 2, [[10, 1], [1, 20]]):
numeric::spectralradius(A)
```

```
[20.09901951, (0.0985376181
 0.9951333267), 0.000000001332123191]
```

We define a starting vector as a 1-dimensional array and allow a maximum of 1000 internal iterations:

```
A := array(1..2, 1..2, [[1, 2], [5, -10]]):
x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0, 1000)
```

```
[-10.84428877, (0.1665007247 - 0.9860413321 i), 7.808576008 10-11]
```

Next, we use a list to specify a starting vector:

```
A := array(1..2, 1..2, [[I, 3], [3, I]]):
numeric::spectralradius(A, [1, 1], 1000)
```

```
[3.0 + 1.0 i, [0.7071067812, 0.7071067812], 0.0]
```

```
delete A, x0:
```

## Example 2

With the default setting of DIGITS = 10, the following result is computed using HardwareFloats.

```
A := hfarray(1..2, 1..2, [[10^4, 10^4], [50, 60]]):
x0 := array(1..2, [1, 1]):
numeric::spectralradius(A, x0)
```

```
[10050.0498, (0.9999874753 0.00500491737), 0.000000004820940092]
```

We request SoftwareFloats in the next call. Note the difference in the trailing digits:

```
numeric::spectralradius(A, x0, Soft)
```

```
[10050.0498, (0.9999874753 0.00500491737), 0.000000004820942201]
```

```
delete DIGITS, A, x0:
```

## Example 3

The eigenvector that is returned can have various types. If no starting vector is provided, the type of the matrix determines the type of the eigenvector:

```
A:= array(1..2, 1..2, [[1, 2], [3, 4]]):
[1, x, residue]:= numeric::spectralradius(A);
```

```
[5.372281324, (0.4159735579 0.9093767091), 0.0000000002881934691]
```

# numeric::spectralRadius

---

```
domtype(x)
```

```
DOM_ARRAY
```

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):
[1, x, residue]:= numeric::spectralradius(A):
domtype(x)
```

```
DOM_HFARRAY
```

```
A:= matrix(2, 2, [[1, 2], [3, 4]]):
[1, x, residue]:= numeric::spectralradius(A):
domtype(x)
```

```
Dom::Matrix()
```

If a starting vector is provided, its type determines the type of the return vector:

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):
x0:= [1, 1]:
[1, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_LIST
```

```
x0:= array(1..2, [1, 1]):
[1, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

```
DOM_ARRAY
```

```
x0:= hfarray(1..2, [1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

DOM\_HFARRAY

```
x0:= matrix([1, 1]):
[l, x, residue]:= numeric::spectralradius(A, x0):
domtype(x)
```

Dom::Matrix()

The return type can be requested explicitly:

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DO
domtype(x)
```

DOM\_LIST

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DO
domtype(x)
```

DOM\_HFARRAY

```
delete A, x0, l, x, residue:
```

## Example 4

The following matrix has two distinct eigenvalues 1 and -1 of the same absolute value. The power method must fail.

```
A := array(1..2, 1..2, [[1, 0], [0, -1]]):
```

# numeric::spectralRadius

---

We allow a maximum of 1000 internal steps. The call results in a warning. The large residue also indicates that the power method did not converge:

```
numeric::spectralradius(A, [1, 1], 1000)
```

```
Warning: There is no convergence of vector iteration. [numeric::spe
```

```
[1.0, [0.7071067812, -0.7071067812], 1.414213562]
```

```
delete A:
```

## Parameters

### **A**

An  $m \times m$  array of domain type DOM\_ARRAY or DOM\_HFARRAY or a matrix of category Cat::Matrix

### **$x_0$**

A starting vector: a 1-dimensional array, or an hfarray, or a list of length  $m$ . Also 2-dimensional arrays (array(1..m, 1..1, ...), hfarray(1..m, 1..1, ...)) and matrices representing vectors are accepted.

### **n**

The maximal number of iterations: a positive integer. The default value is 1000.

### **mode**

One of the flags Hard, HardwareFloats, Soft, or SoftwareFloats

## Options

### **Hard, HardwareFloats, Soft, SoftwareFloats**

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard

and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

# numeric::spectralRadius

---

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

## **ReturnType**

Option, specified as `ReturnType = t`

Return the eigenvector associated with the spectral radius as a vector of domain type `t`. The following return types are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `DOM_LIST`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## **NoWarning**

Suppresses warnings

## **Return Values**

A list `[lambda, x, residue]` is returned. The floating-point number `lambda` is an approximation of the eigenvalue of largest absolute value. The vector `x` is a numerical eigenvector corresponding to `lambda`. `residue` is a floating-point number indicating the numerical quality of `lambda` and `x`.

If no return type is requested via the `ReturnType` option, the type of the returned vector `x` coincides with the type of the input vector  $x_0$  (i.e., it is a 1-dimensional array of type `DOM_ARRAY` or `DOM_HFARRAY`, respectively, or a list, or a column vector of type `matrix` or `densematrix`. If no starting vector is specified, the type of `x` is determined by the type of `A`.

[numeric::singularvectors](#) | [numeric::svd](#)

# numeric::sum

---

**Purpose** Numerical approximation of sums (the Float attribute of Sum )

**Syntax**

```
numeric::sum(f(x), x = a .. b)
numeric::sum(f(x), x in {x1, x2, ...})
numeric::sum(f(x), x = {x1, x2, ...})
numeric::sum(f(x), x in RootOf(p(X), X))
numeric::sum(f(x), x = RootOf(p(X), X))
float(holdsum(f(x), x = a .. b))
float(holdsum(f(x), x in {x1, x2, ...}))
float(holdsum(f(x), x = {x1, x2, ...}))
float(holdsum(f(x), x in RootOf(p(X), X)))
float(holdsum(f(x), x = RootOf(p(X), X)))
float(freesum(f(x), x = a .. b))
float(freesum(f(x), x in {x1, x2, ...}))
float(freesum(f(x), x = {x1, x2, ...}))
float(freesum(f(x), x in RootOf(p(X), X)))
float(freesum(f(x), x = RootOf(p(X), X)))
```

**Description** numeric::sum(f(i), i=a..b) computes a numerical approximation of  $\sum_{i=a}^b f(i)$ .

numeric::sum(f(x), x = {x<sub>1</sub>, x<sub>2</sub>, ...}) computes a numerical approximation of  $\sum_{x \in \{x_1, x_2, \dots\}} f(x)$ .

numeric::sum(f(x), x in RootOf(p(X), X)) computes a numerical approximation of  $\sum_{x \in \text{RootOf}(p(X), X)} f(x)$ .

The call numeric::sum( ) is equivalent to calling the float attribute of sum via float ( hold( sum ) ( ) ) or float ( freeze( sum ) ( ) ).

If there are other symbolic parameters in  $f(x)$ , apart from the summation variable  $x$ , a symbolic sum is returned. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floating-point numbers.

**Note** For infinite sums, the expression  $f(i)$  with integer  $i$  must have an extension  $f(x)$  to all real  $x$  in the interval  $[a, b]$ . Internally, the integral  $\int_a^b f(x) dx$  is computed numerically and used in the approximation process.

**Note** For finite sums, `numeric::sum` just returns `_plus (float(f(i)$i=a..b))`. Note that numerical cancellation may occur! If  $f(i)$  does not contain floating-point numbers, cancellation can be avoided summing the symbolic terms by `_plus(f(i)$i=a..b)` instead. Cf. “Example 3” on page 18-403.

Convergence is fast, if  $f(x)$  decays rapidly for  $x \rightarrow \text{infinity}$  or  $|x| \rightarrow \text{infinity}$ , respectively

**Note** Convergence may be slow for alternating sums containing expressions such as  $(-1)^i$ . Such sums are also often subject to cancellation problems!

The call `numeric::sum(f(x), x = {x1, x2, ...})` computes numerical approximations of  $x_1, x_2$  etc., substitutes these values into  $f(x)$  and adds up the results. This process may be subject to cancellation problems!

The calls `numeric::sum(f(x), x = {x1, x2, ...})` and `numeric::sum(f(x), x = {x1, x2, ...})` are equivalent.

The call `numeric::sum(f(x), x in RootOf(p(X), X))` computes numerical approximations of all roots of  $p$ , substitutes these values into  $f(x)$  and adds up the results. Cf. “Example 4” on page 18-404. This process may be subject to cancellation problems!

The calls `numeric::sum(f(x), x in RootOf(p(X), X))` and `numeric::sum(f(x), x = RootOf(p(X), X))` are equivalent.

# numeric::sum

---

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

We demonstrate some equivalent calls for numerical summation:

```
numeric::sum(1/i!, i = 0..infinity),
float(hold(sum)(1/i!, i = 0..infinity)),
float(freeze(sum)(1/i!, i = 0..infinity))
```

2.718281828, 2.718281828, 2.718281828

The MuPAD symbolic summation `sum` does not find a simple representation of the following sum:

```
sum(1/i!/(i^2+1)!, i = 0..infinity)
```

$$\sum_{i=0}^{\infty} \frac{1}{(i^2 + 1)! i!}$$

The following float evaluation calls `numeric::sum`:

```
float(%)
```

1.504166713

The exact value of the following sum is  $\pi \coth(\pi)$ :

```
numeric::sum(1/(1+i^2), i = -infinity..infinity) =
float(PI*coth(PI))
```

3.153348095 = 3.153348095

### Example 2

The following sum cannot be evaluated numerically because of the symbolic parameter x:

```
numeric::sum(1/(x+i^2), i = -infinity..infinity)
```

$$\text{numeric::sum}\left(\frac{1}{i^2 + x}, i = -\infty.. \infty\right)$$

### Example 3

We demonstrate numerical cancellation when summing the Taylor series for  $e^{-20}$ :

```
exp(-20.0) <> numeric::sum((-20)^i/i!, i = 0..100)
```

0.000000002061153622 ≠ 0.000000002148938644

Also the infinite sum suffers from cancellation:

```
exp(-20.0) <> numeric::sum((-20)^i/i!, i = 0..infinity)
```

0.000000002061153622 ≠ 0.000000002205327316

Cancellation can be avoided using a finite sum with exact terms:

```
exp(-20.0) = float(_plus((-20)^i/i! $ i = 0..100))
```

0.000000002061153622 = 0.000000002061153622

# numeric::sum

---

## Example 4

The following call computes the numerical roots of the polynomial in the `RootOf` expression and sums over all the roots:

```
numeric::sum(exp(x)/x, x in RootOf(X^10 - X - PI, X))
```

```
9.681693381
```

## Parameters

**f(x)**

An arithmetical expression in  $x$

**i, x**

Summation variables: identifiers or indexed identifiers

**a, b**

Integers or  $\pm\text{infinity}$  satisfying  $a \leq b$

**x<sub>1</sub>, x<sub>2</sub>, ...**

Numerical expressions

**p(X)**

A univariate polynomial expression in  $X$

**X**

The indeterminate of  $p$ : an identifier or an indexed identifier

## Return Values

Floating point number or a symbolic expression of type `numeric::sum`.

## Algorithms

Depending on whether the series is alternating or monotone, `numeric::sum` tries a number of strategies to calculate its limit: Levin's  $u$  transformation, the Euler-MacLaurin formula or van Wijngaarden's trick.

The Euler-MacLaurin formula is

$$\sum_{i=a}^b f(i) = \frac{f(a) + f(b)}{2} + \int_a^b f(x) dx + \left( \sum_{m=1}^M \frac{B_{2m}}{(2m)!} \left( f(b)^{(2m-1)} - f(a)^{(2m-1)} \right) \right) + \dots$$

involving the Bernoulli numbers  $B_{2m}$ .

# numlib::checkPrimalityCertificate

**Purpose** Test the primality certificate

**Syntax** numlib::checkPrimalityCertificate(certificate)

**Description** numlib::checkPrimalityCertificate tests the certificate of primality returned by numlib::proveprime. For large prime numbers, the numlib::proveprime function generates certificates that provide all data you need for proving primality of a number by the Atkin-Goldwasser-Kilian-Morain algorithm. See “Example 1” on page 19-3.

For small prime numbers, numlib::proveprime does not return a certificate of primality. Instead, it returns TRUE. For nonprime numbers numlib::proveprime returns FALSE. In both cases, you do not need to use numlib::checkPrimalityCertificate.

## Examples **Example 1**

Use the numlib::proveprime function to check the primality of the number 1299709. The function returns the following sequence of lists. This sequence is the certificate of primality:

```
certificate := numlib::proveprime(1299709)
```

```
[1299709, 15, [2, 2, 2, 2, 2, 107, 379], 700619, 67686, 0, 796444, [107, 379]]
```

The certificate provides all data that you need for proving primality of 1299709 by the Atkin-Goldwasser-Kilian-Morain algorithm. You can substitute the numbers into the algorithm and verify the primality of the number. Alternatively, you can verify the certificate by using the numlib::checkPrimalityCertificate function:

```
numlib::checkPrimalityCertificate(certificate)
```

```
TRUE
```

# numlib::checkPrimalityCertificate

---

## Parameters

**certificate**

A list or a sequence of lists returned by `numlib::proveprime`

## Return Values

TRUE or FALSE

## See Also

## MuPAD Functions

`ifactor` | `numlib::proveprime`

## Concepts

- “Primes and Factorizations”

**Purpose** Domain of continued fractions

**Syntax** numlib::contfrac(x, <n>)

**Description** numlib::contfrac(x) creates a continued fraction approximation for the real number x.

If x is an integer or a rational number and n is not specified, a continued fraction is returned that represents x exactly. Cf. “Example 1” on page 19-5.

Irrational numerical values x such as  $1 + \sqrt{2}$  or  $\text{PI}/3$  are first converted to floating-point numbers. The first n significant decimals of floating-point numbers are taken into account. If n is not specified,  $n = \text{DIGITS}$  is used. The value of the continued fraction (given by numlib::contfrac ::rational) satisfies

$$|x - \text{numlib::contfrac::rational}(x)| \leq |x| \frac{1}{10^n}$$

Integers or rational numbers are also converted to floating point numbers, if a precision n is specified.

Objects of type numlib::contfrac can be handled by the usual arithmetical operations. They are sensitive to the environment variable DIGITS if floating-point numbers or irrational numerical values are involved.

Use contfrac to compute continued fraction approximations of expressions involving symbolic parameters.

## Examples **Example 1**

For rational numbers, exact representations are returned:

```
numlib::contfrac(123/1234)
```

# numlib::contfrac

---

$$\frac{1}{10 + \frac{1}{30 + \frac{1}{1 + \frac{1}{3 + \dots}}}}$$

The rational representation (the second operand of the continued fraction) coincides with the original rational:

```
numlib::contfrac::rational(%), expr(%), op(%, 2)
```

$$\frac{123}{1234}, \frac{123}{1234}, \frac{123}{1234}$$

Restricted continued fraction approximations can be computed by passing a precision as second argument:

```
numlib::contfrac(123/1234, 2),
numlib::contfrac(123/1234, 3),
numlib::contfrac(123/1234, 5)
```

$$\frac{1}{10 + \dots}, \frac{1}{10 + \frac{1}{30 + \dots}}, \frac{1}{10 + \frac{1}{30 + \frac{1}{1 + \frac{1}{3 + \dots}}}}$$

$$\frac{1}{10 + \dots}, \frac{1}{10 + \frac{1}{30 + \dots}}, \frac{1}{10 + \frac{1}{30 + \frac{1}{1 + \frac{1}{3 + \dots}}}}$$

## Example 2

The coefficients are extracted by the method nthcoeff:

```
cf := numlib::contfrac(12/123)
```

$$\frac{1}{10 + \frac{1}{4 + \dots}}$$

```
nthcoeff(cf, 1), nthcoeff(cf, 2), nthcoeff(cf, 3), nthcoeff(cf,
0, 10, 4, FAIL
```

The internal list of coefficients can also be queried via op:

```
op(cf, 1)
```

```
[0, 10, 4]
```

```
delete cf:
```

### Example 3

numlib::contfrac can also compute continued fraction approximations of irrational numbers:

```
numlib::contfrac(PI, 2),
numlib::contfrac(PI, 4),
numlib::contfrac(PI, 5)
```

$$3 + \frac{1}{7 + \dots}, 3 + \frac{1}{7 + \frac{1}{15 + \dots}}, 3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \dots}}}$$

# numlib::contfrac

---

$$3 + \frac{1}{7 + \dots}, 3 + \frac{1}{7 + \frac{1}{15 + \dots}}, 3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \dots}}}$$

A finite continued fraction approximation may be regarded as an interval of numbers (the symbol ... represents a number between 0 and 1):

```
numlib::contfrac::rationalInterval(numlib::contfrac(PI, 2));
```

$$\left[ \frac{25}{8}, \frac{22}{7} \right]$$

```
float(%)
```

$$[3.125, 3.142857143]$$

## Example 4

All basic arithmetical operations are available for continued fractions:

```
x := numlib::contfrac(PI, 3):
y := numlib::contfrac(1/12):
DIGITS:= 3: 3/x + sqrt(2)*y^(1/3)
```

$$1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{2 + \frac{1}{1 + \frac{1}{26 + \dots}}}}}}$$

$$1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{2 + \frac{1}{1 + \frac{1}{26 + \dots}}}}}}$$

delete x, y, DIGITS:

**Example 5**

We search for a simple continued fraction in an interval:

numlib::contfrac::convert(1/2 - 1/10^8, 1/2 + 1/10^8)

$$\frac{1}{2 + \dots}$$

$$\frac{1}{2 + \dots}$$

numlib::contfrac::convert(PI, PI + 1/10^10)

$$3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \frac{1}{292 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \dots}}}}}}}}$$

# numlib::contfrac

---

$$3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \frac{1}{292 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \dots}}}}}}}}$$

## Parameters

**x**

A real numerical expression

**n**

The number of significant digits: a positive integer greater one

## Methods

Mathematical Methods

**\_plus - Sum of two continued fractions**

`_plus(x, y)`

**\_mult - Product of two continued fractions**

`_mult(x, y)`

**\_invert - Reciprocal of a continued fraction**

`_invert(x)`

Inverting a continued fraction means a shift of the coefficients by one to the left or to the right.

If  $x$  is an exact representation of a rational number, the continued fraction expansion of the reciprocal is also an exact representation.

**\_power - Power of a continued fraction**

`_power(x, m)`

Access Methods

**print - Print a continued fraction**

```
print(cf)
```

**See Also**

**MuPAD  
Functions**

contfrac | numeric::rationalize

# numlib::contfracPeriodic

---

**Purpose** Periodic continued fraction expansions

**Syntax** `numlib::contfracPeriodic(p, q, n)`

**Description** `numlib::contfracPeriodic(p, q, n)` returns the continued fraction expansion of  $p + q\sqrt{n}$  as a sequence of two lists: the first one contains the non-periodic part, the second one contains the periodic part of the expansion.

The non-periodic part may be an empty list. No periodic part is returned for rational input, i.e.,  $q = 0$  or  $n$  square.

## Examples

### Example 1

The non-periodic part may start with zero. All other coefficients of a continued fraction expansion are positive:

```
numlib::contfracPeriodic(2/7, 1/7, 2)
```

```
[0, 2, 19], [1, 8, 1, 18]
```

The result agrees with that one of `contfrac`:

```
op(contfrac(2/7 + 1/7 *sqrt(2)), 1)
```

```
[0, 2, 19, 1, 8, 1, 18, 1, 8, 1]
```

### Example 2

The golden mean is famous for its simple continued fraction expansion:

```
numlib::contfracPeriodic(1/2, 1/2, 5)
```

```
[], [1]
```

## Example 3

Since 81 is a perfect square, there is no periodic part in the continued fraction expansion of its square root:

```
numlib::contfracPeriodic(0, 1, 81)
```

```
[9]
```

## Parameters

**p**

A rational number

**q**

A rational number

**n**

A positive integer

## Return Values

If  $p + q\sqrt{n}$  is a rational number, then `numlib::contfracPeriodic` returns one list, otherwise two lists of integers.

## Algorithms

A real number has a periodic continued fraction expansion if and only if it is of the form  $p + q\sqrt{n}$ .

## See Also

## MuPAD Functions

`numlib::contfrac` | `numlib::sqrt2cfrac`

# numlib::cornacchia

---

**Purpose** Cornacchia's algorithm

**Syntax** `numlib::cornacchia(a, b, m)`

**Description** `numlib::cornacchia(a, b, m)` returns all pairs of positive and relatively prime integers  $x, y$  that solve the equation  $ax^2 + by^2 = m$ .  
The arguments  $a, b, m$  must be pairwise relatively prime.

**Examples** **Example 1**

We compute the solutions to  $3x^2 + 5y^2 = 74533332452454382449233$ :

```
numlib::cornacchia(3, 5, 74533332452454382449233)
{[22457088474, 120847316879]}
```

**Example 2**

For non-prime  $m$ , there may be many solutions:

```
numlib::cornacchia(1, 4, 5*13*17*29*73)
{[103, 763], [151, 761], [217, 757], [521, 719], [553, 713], [583, 707], [809, 649], [887, 623],
 [1127, 517], [1159, 499], [1367, 343], [1369, 341], [1463, 223], [1481, 191], [1529, 19]}
```

**Parameters**

- a**  
A positive integer
- b**  
A positive integer
- m**  
A positive integer

**Return  
Values**

numlib::cornacchia returns a set each element of which is a list of two positive integers.

**See Also****MuPAD  
Functions**

numlib::msqrts

# numlib::decimal

---

**Purpose** Infinite representation of rational numbers

**Syntax** `numlib::decimal(q)`

**Description** `numlib::decimal(q)` computes the decimal expansion of a rational number  $q$ .

If  $q$  is a nonnegative rational number whose decimal expansion is finite, then `numlib::decimal(q)` returns the expression sequence starting with the integral part of  $q$  and followed by the digits after the decimal point.

If  $q$  is a nonnegative rational number whose decimal expansion is infinite, then `numlib::decimal(q)` returns the expression sequence starting with the integral part of  $q$ , followed by the digits of the pre-period and terminated with a list, containing the digits of a minimal period.

## Examples

### Example 1

Computing the decimal expansion of 1999:

```
numlib::decimal(1999)
```

```
1999
```

### Example 2

Computing the (finite) decimal expansion of  $\frac{52187}{78125}$ :

```
numlib::decimal(52187/78125)
```

```
0, 6, 6, 7, 9, 9, 3, 6
```

### Example 3

Computing the (infinite) decimal expansion of  $\frac{111}{7}$ :

```
numlib::decimal(111/7)
```

```
15, [8, 5, 7, 1, 4, 2]
```

## Example 4

Computing the (infinite) decimal expansion of  $\frac{37}{28}$ :

```
numlib::decimal(37/28)
```

```
1, 3, 2, [1, 4, 2, 8, 5, 7]
```

## Parameters

**q**

Nonnegative rational number

## Return Values

`numlib::decimal(q)` returns an expression sequence consisting of nonnegative integers or an expression sequence consisting of nonnegative integers and terminated by a list of nonnegative integers.

# numlib::divisors

---

**Purpose** Divisors of an integer

**Syntax** `numlib::divisors(n)`

**Description** `numlib::divisors(n)` returns the list of positive divisors of `n`.  
If `a` is a non-zero integer then `numlib::divisors(a)` returns the sorted list of all positive divisors of `a`.  
`numlib::divisors(0)` returns `[0]`.  
`numlib::divisors` returns an error if the argument evaluates to a number of wrong type.

## Examples

### Example 1

We compute the list of all positive divisors of 72:

```
numlib::divisors(72)
```

```
[1, 2, 3, 4, 6, 8, 9, 12, 18, 24, 36, 72]
```

### Example 2

`numlib::divisors` returns the positive divisors of negative numbers, too:

```
numlib::divisors(-63)
```

```
[1, 3, 7, 9, 21, 63]
```

**Parameters** `n`

Integer

**Return Values** `numlib::divisors` returns a list of nonnegative integers.

## Algorithms

Internally, ifactor is used for factoring n.

## See Also

## MuPAD Functions

[ifactor](#) | [numlib::numdivisors](#) | [numlib::tau](#) |

[polylib::divisors](#)

# numlib::ecm

---

## Purpose

Factor an integer using the elliptic curve method

---

**Note** numlib::ecm has been removed. Use ifactor instead.

---

## Syntax

```
numlib::ecm(n)
numlib::ecm(n, BaseBound)
numlib::ecm(n, Base)
numlib::ecm(n, BaseBound, s)
numlib::ecm(n, Base, s)
numlib::ecm(n, BaseBound, s, Step2Bound)
numlib::ecm(n, Base, s, Step2Bound)
```

## Description

numlib::ecm(n) tries to factor the positive integer n using the elliptic curve method. Basically, it takes an elliptic curve modulo n and a point on that curve and computes some multiple of that point. This multiplication may fail; in this case, a proper factor of n can be found. Otherwise, the point computed is likely to have small order; it is used in a post-processing step.

numlib::ecm(n, BaseBound, s, Step2Bound) and numlib::ecm(n, Base, s, Step2Bound) do the same, but lets you specify internal parameters of the algorithm. The last, or the last two, parameters can be omitted.

The starting point is computed from the parameter s. It is chosen at random if s is not given.

The starting point chosen is multiplied either by all primes in Base, or all primes below BaseBound, or — if neither of both is given — by all primes below 1000.

The post-processing step consists of a certain number of iterations, determined by the parameter Step2Bound. By default, 100 times BaseBound (or the maximum of Base, respectively) is chosen.

**Parameters****n**

Positive integer

**BaseBound**

Positive integer

**Base**

List of primes

**s**

Integer

**Step2Bound**

Positive integer

**Return Values**

numlib::ecm returns an integer that divides n; the return value may equal 1 or n.

**References**

A description of the algorithm can be found in “Speeding the Pollard and Elliptic Curve Methods of Factorization”, by Peter Montgomery, Math. of Comp. 48 (177), pages 243-264, January 1987.

**See Also****MuPAD Functions**

ifactor

# numlib::factorGaussInt

---

**Purpose** Factorization of Gaussian integers

**Syntax** `numlib::factorGaussInt(n)`

**Description** `numlib::factorGaussInt(n)` returns the factorization of the Gaussian integer  $n$  into Gaussian primes. Among associate primes, that one with smallest polar angle is chosen.

**Examples** **Example 1**

In the Gaussian integers, 3 remains prime while 5 does not:

```
numlib::factorGaussInt(3), numlib::factorGaussInt(5)
```

```
[1, 3, 1], [-i, 1 + 2i, 1, 2 + i, 1]
```

**Example 2**

The argument to `numlib::factorGaussInt` may be any Gaussian integer, that is, every complex number of the form  $a + bi$  where  $a$  and  $b$  are integers:

```
numlib::factorGaussInt(2+2*I)
```

```
[-i, 1 + i, 3]
```

**Parameters** **n**

An integer, or a complex number whose real and imaginary part are integers

**Return Values** `numlib::factorGaussInt` returns a list  $[u, p_1, a_1, \dots, p_k, a_k]$  where  $u$  is a unit in the Gaussian integers, the  $p_i$  are Gaussian primes and the  $a_i$  are positive integers, such that  $n = u \left( \prod_{i=1}^k p_i^{a_i} \right)$ .

## Algorithms

The function `ifactor` is used to factor the norm; this step takes most of the running time. Hence, the running time of the algorithm mainly depends on the size of the prime factors of the norm of  $n$ .

## See Also

## MuPAD Functions

`factor`

# numlib::fibonacci

---

**Purpose** Fibonacci numbers

**Syntax** `numlib::fibonacci(n)`

**Description** `numlib::fibonacci(n)` returns the  $n$ -th Fibonacci number.  
If  $n$  is a nonnegative integer then `numlib::fibonacci(n)` returns the  $n$ -th Fibonacci number.  
`numlib::fibonacci` returns an error if the argument evaluates to a number of wrong type. `numlib::fibonacci` returns the unevaluated function call if  $n$  does not evaluate to a number.

**Examples** **Example 1**

We compute the 201st Fibonacci number:

```
numlib::fibonacci(201)
```

```
453973694165307953197296969697410619233826
```

**Parameters** **n**  
A nonnegative integer

**Return Values** Nonnegative integer, or the function call with its arguments evaluated.

**Algorithms** The  $n$ -th Fibonacci number  $F_n$  is defined by the recursion formula  $F_0 = 0$ ,  $F_1 = 1$ , and  $F_{n+2} = F_n + F_{n+1}$ .  
`numlib::fibonacci` uses quadratic recursion formulas.

**Purpose** Decoding of ASCII codes

**Syntax** `numlib::fromAscii(listOfCodes)`

**Description** If `L` is a list of ASCII codes then `numlib::fromAscii(L)` returns the string coded by `L`.

ASCII codes of non-printable characters, i. e., codes between 0 and 8 and between 11 and 31, are ignored.

`numlib::fromAscii` returns an error if its argument is not a list of integers between 0 and 127, i. e., not a list of legal ASCII codes.

## Examples **Example 1**

Non-printable characters are ignored, but tabulator and newline characters are decoded.

```
L := [0,1,2,3,9,10,31,10,9,32,45,32,101,105,110,32,
 84,101,115,116,32,61,32,97,32,116,101,115,116]:
```

```
numlib::fromAscii(L)
```

```
" [] - ein Test = a test"
```

**Parameters** **listOfCodes**  
A list of ASCII codes

**Return Values** String

## See Also

**MuPAD Functions** `numlib::toAscii`

# numlib::g\_adic

---

**Purpose** G-adic representation of a nonnegative integer

**Syntax** numlib::g\_adic(number, base)

**Description** numlib::g\_adic(0, g) returns [0].

numlib::g\_adic returns an error if the arguments evaluate to numbers which are not both of the correct type.

If  $a$  is a natural number and  $g$  is an integer such that  $|g| > 1$ , numlib::g\_adic( $a$ ,  $g$ ) returns the  $g$ -adic representation of  $a$  as a list  $[a_0, \dots, a_r]$  such that

$$a = a_0 + a_1 g + a_2 g^2 + \dots + a_r g^r$$

and  $0 \leq a_i < |g|$  für  $i = 0, \dots, r - 1$  and  $0 < a_r < |g|$ .

## Examples

### Example 1

Computing the dyadic representation of 1994:

```
numlib::g_adic(1994, 2)
```

```
[0, 1, 0, 1, 0, 0, 1, 1, 1, 1, 1]
```

### Example 2

Computing the hexadecimal representation of 2001:

```
numlib::g_adic(2001, 16)
```

```
[1, 13, 7]
```

**Parameters****number**

An nonnegative integer

**base**

An integer with absolute value is greater than 1

**Return Values**

List of nonnegative integers, or the function call with evaluated arguments if one of the arguments is not a number.

**See Also****MuPAD Functions**

`genpoly` | `int2text` | `text2int`

# numlib::ichrem

---

**Purpose** Chinese remainder theorem for integers

**Syntax** numlib::ichrem(a, m)

**Description** numlib::ichrem(a,m) returns the least nonnegative integer  $x$  such that  $x \equiv a_i \pmod{m_i}$  for  $i = 1, \dots, \text{nops}(m)$  if such a number exists; otherwise numlib::ichrem(a,m) returns FAIL.

The entries in  $m$  need not be pairwise coprime.

numlib::ichrem(a,m) returns an error if  $a$  is not a list of integers or  $m$  is not a list of natural numbers or  $a$  and  $m$  are not lists of the same length.

## Examples

### Example 1

Here the moduli are pairwise coprime. In this case, a solution always exists:

```
numlib::ichrem([2,3,2],[3,5,7])
```

```
23
```

### Example 2

Here the moduli are not pairwise coprime, and a solution does not exist:

```
numlib::ichrem([5,6,8],[20,21,22])
```

```
FAIL
```

### Example 3

Also here the moduli are not pairwise coprime, but a solution nevertheless exists:

```
numlib::ichrem([5,6,7],[20,21,22])
```

4605

## Parameters

**a**

A list of integers

**m**

A list of natural numbers of the same length as a

## Return Values

Either a nonnegative integer or FAIL.

## See Also

## MuPAD Functions

numlib::lincongruence

# numlib::igcdmult

---

**Purpose** Extended Euclidean algorithm for integers

**Syntax** `numlib::igcdmult(par1, par2, )`

**Description** `numlib::igcdmult` is an extension of the kernel function `igcdex`.

`numlib::igcdmult` returns an error if the arguments evaluate to numbers which are not all of the correct type.

For integers  $a_1, a_2, \dots, a_n$ , `numlib::igcdmult(a_1, a_2, \dots, a_n)` returns a list  $[d, v_1, \dots, v_n]$  of integers such that  $d$  is the nonnegative greatest common divisor of  $a_1, a_2, \dots, a_n$  and  $d = a_1*v_1 + a_2*v_2 + \dots + a_n*v_n$ .

For integers  $a_1, a_2, \dots, a_n$ , `numlib::igcdmult(a_1, a_2, \dots, a_n)` returns a list  $[d, v_1, \dots, v_n]$  of integers such that  $d$  is the nonnegative greatest common divisor of  $a_1, a_2, \dots, a_n$  and  $d = a_1*v_1 + a_2*v_2 + \dots + a_n*v_n$ .

## Examples

### Example 1

Computing the greatest non-negative common divisor  $d$  of 455, 385, 165, 273 and integers  $v_1, v_2, v_3, v_4$  such that  $d = 455v_1 + 385v_2 + 165v_3 + 273v_4$ :

```
numlib::igcdmult(455,385,165,273)
```

```
[1, -7630, 9156, -327, 2]
```

## Parameters

**par1**

Integer

**par2, ...**

Integers

## Return Values

List of integers, or the function call with evaluated arguments if some argument is not a number.

**See Also**

**MuPAD  
Functions**

[igcd](#) | [igcdex](#)

# numlib::invphi

---

**Purpose** Inverse of the Euler phi function

**Syntax** numlib::invphi(n)

**Description** numlib::invphi(n) computes all positive integers  $i$  with  $\varphi(i) = n$ .

**Examples** **Example 1**

We compute all numbers  $i$  with  $\varphi(i) = 500$ :

```
s := numlib::invphi(500)
```

```
[625, 753, 1004, 1250, 1506]
```

Test for correctness:

```
map(s, numlib::phi)
```

```
[500, 500, 500, 500, 500]
```

**Parameters** **n**

A positive integer

**Return Values** List of positive integer numbers.

**See Also**

**MuPAD Functions** numlib::phi

<b>Purpose</b>	Test for perfect powers
<b>Syntax</b>	<code>numlib::ispower(n)</code>
<b>Description</b>	<p><code>numlib::ispower(n)</code> tests whether <math>n</math> is of the form <math>a^k</math> for some integers <math>a, k</math> with <math>a, k \geq 2</math>.</p> <p><code>numlib::ispower</code> returns <code>FALSE</code> if <math>n</math> is not a perfect power.</p> <p>Among several pairs <math>(a, k)</math> for which <math>n = a^k</math>, that one with minimal <math>a</math> is returned.</p>
<b>Examples</b>	<p><b>Example 1</b></p> <p>This number is a perfect power:</p> <pre>numlib::ispower(1977326743)</pre> <pre>7, 11</pre> <p>This number is not a perfect power:</p> <pre>numlib::ispower(1977326744)</pre> <pre>FALSE</pre>
<b>Parameters</b>	<p><b>n</b></p> <p>An integer</p>
<b>Return Values</b>	<code>numlib::ispower</code> returns a sequence of two positive integers greater than 1, or <code>FALSE</code> if $n$ is not a perfect power.

# numlib::ispower

---

## MuPAD Functions

`_power` | `ifactor` | `isqrt`

**Purpose** Test for quadratic residues

**Syntax** `numlib::isquadres(a, m)`

**Description** If the integer number `a` is a quadratic residue modulo the natural number `m` `numlib::isquadres(a,m)` returns `TRUE`, and if `a` is a quadratic non-residue modulo `m` `numlib::isquadres(a,m)` returns `FALSE`.

If `a` and `m` are not coprime `numlib::isquadres(a,m)` returns an error.

`numlib::isquadres` returns an error if the arguments evaluate to numbers which are not both of the correct type.

`numlib::isquadres` returns the function call with its arguments evaluated if the arguments do not evaluate to numbers.

## Examples

### Example 1

132132 is a quadratic residue modulo 3231227:

```
numlib::isquadres(132132, 3231227)
```

```
TRUE
```

### Example 2

222222 is a quadratic non-residue modulo 324899:

```
numlib::isquadres(222222,324899)
```

```
FALSE
```

### Example 3

37 is a quadratic residue modulo 48884:

```
numlib::isquadres(37,48884)
```

# numlib::isquadres

---

TRUE

## Parameters

**a**

An integer

**m**

A natural number coprime to a

## Return Values

numlib::isquadres returns TRUE, FALSE, or the function call with its arguments evaluated.

## See Also

## MuPAD Functions

numlib::legendre | numlib::jacobi | numlib::msqrts

**Purpose** Test for perfect squares

**Syntax** numlib::issqr(a)

**Description** numlib::issqr(a) returns TRUE if a is the square of an integer, and FALSE otherwise.

## Examples

### Example 1

361 is the square of 19:

```
numlib::issqr(361)
```

```
TRUE
```

### Example 2

362 is not a square:

```
numlib::issqr(362)
```

```
FALSE
```

### Example 3

Negative integers are not squares:

```
numlib::issqr(-361)
```

```
FALSE
```

## Parameters

**a**

An integer

# numlib::issqr

---

## **Return Values**

numlib::issqr returns TRUE, FALSE, or the unevaluated call.

## **See Also**

## **MuPAD Functions**

isqrt | numlib::ispower | sqrt

**Purpose** Jacobi symbol

**Syntax** numlib::jacobi(a, m)

**Description** numlib::jacobi(a,m) returns the Jacobi symbol  $(a | m)$ .  
numlib::jacobi returns an error if one of its arguments evaluates to a number of wrong type.

## Examples

### Example 1

Computing the Jacobi symbol  $(222222 | 304679)$ :

```
numlib::jacobi(222222, 304679)
```

```
- 1
```

### Example 2

Computing the Jacobi-Symbol  $(222222 | 324889)$ :

```
numlib::jacobi(222222, 324899)
```

```
1
```

### Example 3

Computing the Jacobi symbol  $(222222 | 333333)$ :

```
numlib::jacobi(222222, 333333)
```

```
0
```

## Parameters

**a**

An integer

# numlib::jacobi

---

**m**

An odd positive integer

## Return Values

numlib::jacobi( $a, m$ ) returns 0, 1, or -1, or the function call with evaluated arguments if one of the arguments is not a number.

## Algorithms

numlib::jacobi doesn't use ifactor.

If  $a$  is an integer and  $m$  is an odd integer not coprime to  $a$  then by definition the Jacobi Symbol  $(a | m)$  is zero.

## See Also

## MuPAD Functions

numlib::legendre | numlib::isquadres

**Purpose** Von Mangoldt's function

**Syntax** `numlib::Lambda(m)`

**Description** `numlib::Lambda(m)` returns the value of von Mangoldt's function at  $m$ . It is an error if  $m$  is a number but not a natural number. If  $m$  is not a number, `numlib::Lambda` returns the unevaluated function call.

**Examples** **Example 1**

`numlib::Lambda` takes on non-zero values only for prime powers:

```
numlib::Lambda(49)
```

```
ln(7)
```

```
numlib::Lambda(48)
```

```
0
```

**Example 2**

`numlib::Lambda` returns the function call if its argument is not a number:

```
numlib::Lambda(3+n^4)
```

```
numlib::Lambda($n^4 + 3$)
```

**Parameters** **m**  
Arithmetical expression

# numlib::Lambda

---

## Return Values

numlib::Lambda returns an arithmetical expression

## Algorithms

The function value of Lambda at  $m$  is defined to be  $\log p$  if  $m = p^n$  for some prime number  $p$  and some positive integer  $n$ , and to be zero for positive integers that are not prime powers.

## See Also

## MuPAD Functions

numlib::ispower

**Purpose** Carmichael function

**Syntax** `numlib::lambda(n)`

**Description** `numlib::lambda(n)` returns the value of the Carmichael function at  $n$ .  
If  $m$  is a natural number then `numlib::lambda(m)` returns the value of the Carmichael function in  $m$ , i. e., the maximal order of an element in the group of units modulo  $m$ .  
`numlib::lambda` returns an error if the argument evaluates to a number of wrong type. `numlib::lambda` returns the function call with its argument evaluated if  $m$  is not a number.

**Examples** **Example 1**

We compute the value of the Carmichael function  $\lambda$  in 97:

```
numlib::lambda(97)
```

```
96
```

**Example 2**

We compute the value of the Carmichael function  $\lambda$  in 96:

```
numlib::lambda(96)
```

```
8
```

**Parameters** **n**  
A natural number

**Return Values** `numlib::lambda(n)` returns a natural number, or the function call with its argument evaluated.

# numlib::lambda

---

**Algorithms** Internally, `ifactor` is used for factoring `n`.

**See Also**

**MuPAD  
Functions** `numlib::order` | `numlib::phi`

**Purpose** Legendre symbol

**Syntax** `numlib::legendre(a, p)`

**Description** `numlib::legendre(a, p)` returns the Legendre symbol  $(a \mid p)$ .  
`numlib::legendre` returns an error if one of its arguments evaluates to a number of wrong type.  
`numlib::legendre` returns the function call with evaluated arguments if at least one of its arguments does not evaluate to a number.

## Examples

### Example 1

Computing the Legendre symbol  $(132132 \mid 3231277)$ :

```
numlib::legendre(132132,3231277)
```

```
1
```

### Example 2

Computing the Legendre symbol  $(132131 \mid 3231277)$ :

```
numlib::legendre(132131,3231277)
```

```
-1
```

### Example 3

Computing the Legendre symbol  $(-303 \mid 101)$ :

```
numlib::legendre(-303,101)
```

```
0
```

# numlib::legendre

---

## Parameters

**a**

An integer

**p**

An odd prime

## Return Values

`numlib::legendre(a,p)` returns -1, 0, 1, or the function call with evaluated arguments.

## Algorithms

If  $p$  is an odd prime and if  $a$  is an integer divisible by  $p$  then by definition the Legendre symbol  $(a \mid p)$  is zero.

## See Also

## MuPAD Functions

`numlib::jacobi` | `numlib::isquadres`

**Purpose** Linear congruence

**Syntax** numlib::lincongruence(a, b, m)

**Description** numlib::lincongruence(a,b,m) returns an error if one of the arguments evaluates to a number of wrong type.

For integers a and b and a non-zero integer m numlib::lincongruence(a,b,m) returns the sorted list of all solutions  $x \in \{0, 1, \dots, m - 1\}$  of the linear congruence  $a x \equiv b \pmod{m}$  if this congruence is solvable. Otherwise FAIL is returned.

For integers a and b and a non-zero integer m numlib::lincongruence(a,b,m) returns the sorted list of all solutions  $x \in \{0, 1, \dots, m - 1\}$  of the linear congruence  $a x \equiv b \pmod{m}$  if this congruence is solvable. Otherwise FAIL is returned.

## Examples

### Example 1

A linear congruence possessing one solution:

```
numlib::lincongruence(7,19,23)
```

```
[6]
```

### Example 2

A linear congruence possessing several solutions:

```
numlib::lincongruence(77,209,253)
```

```
[6, 29, 52, 75, 98, 121, 144, 167, 190, 213, 236]
```

### Example 3

A linear congruence possessing no solutions:

# numlib::lincongruence

---

```
numlib::lincongruence(77,208,253)
```

```
FAIL
```

## Parameters

**a**

An integer

**b**

An integer

**m**

A non-zero integer

## Return Values

numlib::lincongruence(a,b,m) returns a list of nonnegative integers if the linear congruence is solvable.

numlib::lincongruence(a,b,m) returns FAIL if the linear congruence is not solvable.

numlib::lincongruence(a,b,m) returns the function call with its arguments evaluated if one of the arguments is a symbolic expression.

## See Also

## MuPAD Functions

numlib::ichrem | numlib::mroots | numlib::msqrts

**Purpose** Mersenne primes

**Syntax** numlib::mersenne(n)  
numlib::mersenne()

**Description** numlib::mersenne() returns the list of known Mersenne primes  $p$ . For these numbers, the Mersenne number  $2^p - 1$  is prime.

numlib::mersenne(n) returns the  $n$ th currently known Mersenne prime. The numbers of the Mersenne primes after the 40th prime can change in the future. More Mersenne primes might be found.

## Examples **Example 1**

The following primes  $p$  are known to have the property that the Mersenne number  $2^p - 1$  is prime:

```
numlib::mersenne()
```

```
[2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127, 521, 607, 1279, 2203, 2281, 3217, 4253, 4421, 11213, 19937, 21701, 23209, 44497, 86243, 110503, 132049, 216091, 756839, 859433, 1398269, 2976221, 3021377, 6972593, 13466917, 20996011, 24036583, 25964951, 3021377, 32582657, 37156667, 42643801, 43112609, 57885161]
```

## **Example 2**

Display the 10th Mersenne prime:

```
numlib::mersenne(10)
```

```
89
```

**Return Values** Natural number or a list of natural numbers.

# numlib::mersenne

---

## References

See <http://www.mersenne.org/>

**Purpose** Möbius function

**Syntax** `numlib::moebius(n)`

**Description** `numlib::moebius(n)` returns the value of the Möbius function at  $n$ .  
`numlib::moebius` returns an error if the argument evaluates to a number of wrong type.  
If  $n$  is a natural number `numlib::moebius(n)` returns the value of the Möbius function in  $n$ .  
If  $n$  is not a number, `numlib::moebius(n)` returns the function call with its argument evaluated.

**Examples** **Example 1**

Computing the value of the Möbius function  $\mu$  at 99937:

```
numlib::moebius(99937)
```

```
0
```

**Example 2**

`numlib::moebius` works for arbitrarily large integers:

```
numlib::moebius(453973694165307953197296969697410619233826)
```

```
-1
```

**Parameters** **n**  
A natural number

**Return Values** `numlib::moebius(n)` returns a nonnegative integer.

# numlib::moebius

---

## Algorithms

Internally, `ifactor` is used for factoring  $n$ .

## See Also

## MuPAD Functions

`numlib::lambda` | `numlib::phi`

**Purpose** Multi-polynomial Quadratic Sieve

---

**Note** numlib::mpqs has been removed. Use ifactor instead.

---

**Syntax** numlib::mpqs(n, options)

**Description** numlib::mpqs(n) returns a proper factor of n, using some version of the quadratic sieve. n is returned if it is prime.

The multi-polynomial quadratic sieve is an algorithm to factor large integers without small prime factors. For small integers that can be factored within a reasonable amount of time by ifactor, using this algorithm does not pay off.

**Parameters** n  
Integer

## Options

### InteractiveInput

Prompt the user for all parameters given below

### SieveArrayLimit

Option, specified as SieveArrayLimit = M

For any polynomial  $f$ ,  $f(x)$  is tested for  $-M \leq x \leq M$ . M must be a positive integer.

### Tolerance

Option, specified as Tolerance = t

Sets an exponent  $t$  that is used to define “smoothness” of values investigated by the sieve: if the maximum of the factorbase is  $b$ , let a value pass the first part of the sieve step if it has presumably no prime divisor greater than  $b^t$ .  $t$  must be a positive real number.

### Factorbase

Option, specified as `Factorbase = l`

Define `l` to be the factor base. `l` must be a list of primes; they are investigated whether they divide a certain set of values of each polynomial.

## **MaxInFactorbase**

Option, specified as `MaxInFactorbase = b`

The factorbase consists of all suitable primes that are smaller than `b`. `b` must be a positive integer. This option cannot be used together with `Factorbase`.

## **NumberOfPolynomials**

Option, specified as `NumberOfPolynomials = N`

The number of polynomials the values of which are tested for smoothness. `N` must be a positive integer.

## **LargeFactorBound**

Option, specified as `LargeFactorBound = K`

Define `K` to be the bound below which every factor of a given value must be to make that value pass the trial-division part of the sieve step and become a sieve report. All prime numbers outside the factor base, but below that bound, are added to the factor base if they divide at least two sieve reports. `K` must be a positive integer.

## **CollectInformation**

Do not return a divisor of `n`, but some information on the course of the algorithm.

## **Return Values**

`numlib::mpqs` returns a positive integer dividing `n`, or `FAIL` if `n` is not prime, but a proper factor could not be found. If the option `CollectInformation` has been given, a list of equations is returned; each of the equations contains some piece of information on an intermediate result in some step of the algorithm.

Functions**

ifactor

# numlib::mroots

---

**Purpose** Modular roots of polynomials

**Syntax** numlib::mroots(P, m)

**Description** numlib::mroots(P,m) returns an error if P is not a polynomial over the integers or m is not a natural number.

For a univariate polynomial P over the integers and for a natural number m the function call numlib::mroots(P,m) returns the sorted list of all integers  $x \in \{0, 1, \dots, m - 1\}$  such that  $P(x) \equiv 0 \pmod{m}$ .

For a multivariate polynomial P, numlib::mroots(P, m) returns a lexicographically sorted list of all lists  $[x_1, \dots, x_n]$  of integers between 0 and  $m - 1$  such that  $P(x_1, \dots, x_n) \equiv 0 \pmod{m}$ .

For a univariate polynomial P over the integers and for a natural number m the function call numlib::mroots(P,m) returns the sorted list of all integers  $x \in \{0, 1, \dots, m - 1\}$  such that  $P(x) \equiv 0 \pmod{m}$ .

For a multivariate polynomial P, numlib::mroots(P, m) returns a lexicographically sorted list of all lists  $[x_1, \dots, x_n]$  of integers between 0 and  $m - 1$  such that  $P(x_1, \dots, x_n) \equiv 0 \pmod{m}$ .

## Examples

### Example 1

Defining a polynomial

```
P := poly(3*T^7 + 2*T^2 + T - 17, [T])
```

```
poly(3 T7 + 2 T2 + T - 17, [T])
```

and computing its roots modulo 1751:

```
numlib::mroots(P, 1751)
```

```
[221, 260, 612, 736, 1127, 1496]
```

The polynomial  $P$  doesn't have roots modulo 1994:

```
numlib::mroots(P, 1994)
```

```
[]
```

### Example 2

We use `numlib::mroots` to find all points on a particular elliptic curve modulo 13:

```
numlib::mroots(poly(y^2 - x^3 - x - 2, [x, y]), 13)
```

```
[[1, 2], [1, 11], [2, 5], [2, 8], [6, 4], [6, 9], [7, 1], [7, 12], [9, 5], [9, 8], [12, 0]]
```

### Parameters

**P**

A polynomial over the integers

**m**

A natural number

### Return Values

If  $P$  is univariate, `numlib::mroots` returns a list of nonnegative integers. If  $P$  has more than one variable, `numlib::mroots` returns a list of lists of nonnegative integers.

### Algorithms

`numlib::mroots` uses `factor`.

# numlib::mroots

---

## See Also

## MuPAD Functions

`numlib::lincongruence` | `numlib::msqrts`

**Purpose** Modular square roots

**Syntax** `numlib::msqrts(a, m)`

**Description** `numlib::msqrts(a,m)` returns the list of all integers  $x \in \{0, 1, \dots, m - 1\}$  such that  $x^2 \equiv a \pmod{m}$ .

## Examples

### Example 1

Computing the square roots of 132132 modulo 3231227:

```
numlib::msqrts(132132,3231227)
```

```
[219207, 3012020]
```

### Example 2

There are no square roots of 222222 modulo 324899:

```
numlib::msqrts(222222,324899)
```

```
[]
```

### Example 3

48884 is a composite number, so a number can have more than two square roots modulo 48884:

```
numlib::msqrts(37,48884)
```

```
[383, 585, 23857, 24059, 24825, 25027, 48299, 48501]
```

## Parameters

**a**

An integer

# numlib::msqrts

---

**m**

A natural number relatively prime to a

## **Return Values**

`numlib::msqrts(a,m)` returns a list of nonnegative integers

## **Algorithms**

`numlib::msqrts` uses D. Shanks' algorithm RESSOL.

## **See Also**

## MuPAD Functions

numlib::divisors | numlib::numprimedivisors |  
numlib::primedivisors

**Purpose** Number of prime factors of an integer

**Syntax** `numlib::numprimedivisors(n)`

**Description** `numlib::numprimedivisors(n)` returns the number of prime factors of the integer `n`, counted without multiplicity.

`numlib::numprimedivisors` and `numlib::omega` are synonyms.

`numlib::numprimedivisors(0)` returns 0.

`numlib::numprimedivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::numprimedivisors` returns an error if the argument evaluates to a number of wrong type.

## Examples **Example 1**

We compute the number of primes dividing 6746328388800:

```
numlib::numprimedivisors(6746328388800)
```

```
9
```

**Parameters** `n`  
An integer

**Return Values** `numlib::numprimedivisors(n)` returns a nonnegative integer.

**Algorithms** Internally, `ifactor` is used for factoring `n`.

# numlib::numprimedivisors

---

### **MuPAD Functions**

numlib::numprimedivisors | numlib::primedivisors |  
numlib::numdivisors

<b>Purpose</b>	Number of prime divisors (with multiplicity)
<b>Syntax</b>	<code>numlib::Omega(a)</code>
<b>Description</b>	<code>numlib::Omega(a)</code> returns, for a given positive integer $a$ , the finite sum $\sum_p \alpha(p, a)$ , where $p$ runs through all primes, and $\alpha(p, a)$ denotes the highest exponent for which $p^a$ divides $a$ .
<b>Examples</b>	<b>Example 1</b> In contrast to <code>numlib::numprimedivisors</code> , the prime factor 2 of 120 is counted thrice: <pre>numlib::Omega(120)</pre> 5 The same happens here: <pre>numlib::Omega(8)</pre> 3
<b>Parameters</b>	<b>a</b> Positive integer
<b>Return Values</b>	<code>numlib::Omega</code> returns a positive integer.
<b>See Also</b>	
<b>MuPAD Functions</b>	<code>numlib::numprimedivisors</code>

# numlib::order

---

**Purpose** Order of a residue class

**Syntax** `numlib::order(a, m)`

**Description** `numlib::order(a,m)` returns the order of the residue class modulo `m` of `a` in the group of units modulo `m` if `a` and `m` are coprime.

`numlib::order(a,m)` returns the function call with its arguments evaluated if `a` or `m` is not a number.

`numlib::order` returns an error if one of the arguments evaluates to a number of wrong type.

## Examples

### Example 1

We compute the order of the residue class of 23 in the unit group modulo 2161:

```
numlib::order(23, 2161)
```

```
2160
```

### Example 2

We compute the order of all elements in the unit group modulo 13:

```
map([$ 1..12], numlib::order, 13)
```

```
[1, 12, 3, 6, 4, 12, 12, 4, 3, 6, 12, 2]
```

### Example 3

The residue class of 7 is not a unit in the ring modulo 21:

```
numlib::order(7,21)
```

FAIL

## Parameters

**a**

An integer

**m**

A natural number

## Return Values

numlib::order(a,m) returns a natural number if a is coprime to m, and FAIL if a is not coprime to m.

## Algorithms

numlib::order uses ifactor and numlib::phi.

## See Also

## MuPAD Functions

numlib::lambda | numlib::phi

# numlib::phi

---

**Purpose** Euler phi function

**Syntax** numlib::phi(*n*)

**Description** numlib::phi(*n*) calculates the Euler  $\phi$  function of the argument *n*, i.e. the number of numbers smaller than  $|n|$  which are relatively prime to *n*. Cf. “Example 1” on page 19-70.

numlib::phi returns an error if the argument is a number but not an integer unequal to zero.

numlib::phi returns the function call with evaluated arguments if the argument is not a number. Cf. “Example 2” on page 19-70.

## Examples **Example 1**

numlib::phi works on integers unequal zero:

```
numlib::phi(-7), numlib::phi(10)
```

```
6, 4
```

## **Example 2**

numlib::phi is returned as a function call with evaluated argument:

```
x := a: numlib::phi(x)
```

```
numlib::phi(a)
```

**Parameters** **n**

Integer not equal to zero

**Return Values**

numlib::phi returns a positive integer, if the argument evaluates to an integer unequal zero. If the argument cannot be evaluate to a number, the function call with evaluated arguments is returned .

**Overloaded By**

n

**See Also****MuPAD Functions**

numlib::invphi

# numlib::pi

---

**Purpose** Number of primes up to a given bound

**Syntax** `numlib::pi(x)`

**Description** `numlib::pi(x)` returns the number of primes not exceeding  $x$ .

If the argument  $x$  is a real number (an integer, rational, or floating-point number), then the number of primes below  $x$  is returned. If  $x$  is a complex number, `numlib::pi` stops with an error. For every other kind of arithmetical expression  $x$ , an unevaluated call is returned.

`numlib::pi` becomes slightly faster if the internal prime number table is large. `ifactor(PrimeLimit)` displays the limit of the internal prime number table; it can be set by the user via the command line flag `-L`.

Internally, a fast kernel function with constant memory consumption is used for the computation.

## Examples

### Example 1

There are two primes less or equal 3:

```
numlib::pi(3)
```

```
2
```

### Example 2

Also larger inputs can be handled fast:

```
numlib::pi(150000000)
```

```
8444396
```

### Example 3

Floating point arguments are allowed, too.

```
numlib::pi(28.72)
```

```
9
```

**Parameters****x**

An arithmetical expression

**Return Values**

Non-negative integer or an unevaluated call to numlib::pi

**Algorithms**

A Lehmer-type algorithm is used, with no precomputed sieve array and no remember tables. In contrast to the algorithm in “Computing  $\pi$ : The Meissel-Lehmer method”, this means constant memory consumption, at the price of slowness.

**References**

[1] Lagarias, J.C., V.S. Miller, and A.M. Odlyzko. “Computing  $\pi$ : The Meissel-Lehmer method”, Math. Comp., Vol. 44, No. 170 (1985), pp. 537-560

isprime | ithprime | nextprime | prevprime

# numlib::pollard

---

**Purpose** Pollard's rho factorization algorithm

---

**Note** numlib::pollard has been removed. Use ifactor instead.

---

**Syntax** numlib::pollard(*n*, <*m*>)

**Description** numlib::pollard returns either *n* if *n* is said to be prime by isprime, or *g*, *n/g* if a factor *g* was found. If after *m* iterations still no factor has been found, FAIL is returned.

Please note that the algorithm is not deterministic, thus two calls with the same arguments may give different results.

**Parameters** ***n*, *m***  
Positive integers

**Return Values** numlib::pollard returns *n*, a sequence of two factors, or FAIL.

**See Also**

**MuPAD Functions** ifactor

## Purpose

Primality proving using elliptic curves

## Syntax

```
numlib::proveprime(n)
```

## Description

`numlib::proveprime(n)` tests whether  $n$  is a prime. Unlike `isprime`, `numlib::proveprime` always returns a correct answer.

`numlib::proveprime` returns the following values:

- TRUE when it can prove that the number is a prime.
- FALSE when it can prove that the number is not a prime.
- FAIL when it cannot prove that the number is a prime and cannot prove otherwise. In such cases, the input most likely is a prime.
- A primality certificate, which is a list or a sequence of lists containing proof for the primality of the number. Typically, `numlib::proveprime` returns primality certificates for very large numbers.

A primality certificate is a sequence of lists of the form  $[N, D, l_m, a, b, x, y, l_s]$ , where

- $N$  is a pseudoprime
- $D$  is an integer (fundamental discriminant)
- $l_m$  is a list of prime factors
- $a, b, x, y$  are integers modulo  $N$
- $l_s$  is another list of prime factors (subset of the factors in  $l_m$ )

`numlib::checkPrimalityCertificate` checks primality certificates produced by `numlib::proveprime`.

## Examples

### Example 1

Proving that 1159523 is prime can be reduced to proving that 10343 is prime:

# numlib::proveprime

---

```
certificate := numlib::proveprime(1159523)
```

```
[1159523, 7, [2, 2, 2, 2, 7, 10343], 1012280, 1061361, 0, 726669, [10343]]
```

## Example 2

Typically, the primality of the input is reduced to the primality of a smaller integer, the primality of that integer is reduced to the primality of an even smaller integer, and so on.

```
numlib::proveprime(179424673)
```

```
[179424673, 7, [2, 2, 2, 2, 11213771], 116768436, 77845624, 1, 110562161, [11213771]],
[11213771, 7, [2, 2, 2, 2, 487, 1439], 9255809, 9908463, 2, 1041453, [487, 1439]]
```

Use `numlib::checkPrimalityCertificate` to check the result:

```
numlib::checkPrimalityCertificate(%)
```

```
TRUE
```

## Parameters

**n**

Positive integer.

## Return Values

TRUE, FALSE, FAIL, or a list or sequence of lists.

## References

`numlib::proveprime` implements the Atkin-Goldwasser-Kilian-Morain algorithm for proving primality. For information about primality proving and this particular algorithm, see:

`ifactor` | `isprime` | `ithprime` | `nextprime` | `prevprime`

# numlib::primedivisors

---

**Purpose** Prime factors of an integer

**Syntax** `numlib::primedivisors(n)`

**Description** `numlib::primedivisors(n)` returns a list containing the different prime divisors of the integer `n`.

If `a` is a non-zero integer then, `numlib::primedivisors(a)` returns the sorted list of the different prime divisors of `a`.

`numlib::primedivisors(0)` returns `[0]`.

`numlib::primedivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::primedivisors` returns an error if the argument evaluates to a number of wrong type.

## Examples **Example 1**

We compute the list of prime divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):

```
numlib::primedivisors(6746328388800)
```

```
[2, 3, 5, 7, 11, 13, 17, 19, 23]
```

**Parameters** `n`

An integer

**Return Values** `numlib::primedivisors(n)` returns a list of nonnegative integers.

**Algorithms** Internally, `ifactor` is used for factoring `n`.

## See Also

`ifactor` | `isprime` | `numlib::divisors` | `numlib::numdivisors`  
| `numlib::numprimedivisors` | `numlib::proveprime`

# numlib::primroot

---

**Purpose** Primitive roots

**Syntax** numlib::primroot(m)  
numlib::primroot(a, m)

**Description** numlib::primroot(m) returns the least positive primitive root modulo m if there exist primitive roots modulo m.  
numlib::primroot(a, m) returns the least primitive root modulo m not smaller than a if there exist primitive roots modulo m.

**Examples** **Example 1**

We compute the least positive primitive root modulo the prime number 40487:

```
numlib::primroot(40487)
```

```
5
```

**Example 2**

We compute the least primitive root modulo  $40487^2 = 1639197169$ :

```
numlib::primroot(1639197169)
```

```
10
```

**Example 3**

Now we compute least primitive root modulo 40487 which is  $\geq 111111111$ :

```
numlib::primroot(111111111,40487)
```

```
111111116
```

## Example 4

There are no primitive roots modulo 324013370:

```
numlib::primroot(324013370)
```

```
FAIL
```

## Parameters

**a**

An integer

**m**

A natural number

## Return Values

numlib::primroot returns an integer or FAIL.

## Algorithms

numlib::primroot uses ifactor.

## See Also

## MuPAD Functions

numlib::order

# numlib::reconstructRational

---

**Purpose** Reconstruct a rational number from its image modulo N

**Syntax** `numlib::reconstructRational(a, n)`

**Description** `numlib::reconstructRational(a, n)` returns two integers  $p, q$  of absolute value smaller than  $\sqrt{n/2}$  with  $p$  congruent to  $a \cdot q$  modulo  $n$ , or FAIL if such  $p, q$  do not exist.

`numlib::reconstructRational(a, n)` returns  $p, q$  solving  $p \equiv a q \pmod{n}$ . However,  $p/q \pmod{n}$  equals  $a$  only if  $p$  and  $q$  are relatively prime.

The solution  $p, q$  satisfies the following conditions:  $p$  is strictly between  $-\sqrt{n/2}$  and  $\sqrt{n/2}$ ,  $q$  is strictly between  $0$  and  $\sqrt{n/2}$ .

Several pairs  $p, q$  satisfying these conditions may exist, in which case their ratios  $p/q$  are all the same; then the smallest of them is returned.

## Examples

### Example 1

We want to solve  $p \equiv 7 q \pmod{12}$ :

```
numlib::reconstructRational(7, 12)
```

2, 2

Modulo 98, the same congruence has no small solution. The solution  $p=7, q=1$  is not small enough as 7 is not smaller than  $\sqrt{98/2}$  but just equal.

```
numlib::reconstructRational(7, 98)
```

FAIL

## Example 2

Rational number reconstruction is mostly used as the last step of a modular algorithm. Let us compute the gcd of the following polynomials:

```
f:= poly(x^5 + 22/35*x^3 + 3/8*x^2 + 3/35*x + 9/56, [x]):
g:= poly(x^5 + 2/5*x^4 + 22/35*x^3 + 153/280*x^2 + 3/35*x + 9/56
[x]):
```

Of course, the function gcd is able to do this. However, suppose we know that for some reason that the gcd has small coefficients with numerator and denominator both smaller than 10. Then we can use a modular algorithm with a smaller modulus than gcd would do: to be able to reconstruct these from their residue class modulo n, it is

sufficient that  $\sqrt{\frac{n}{2}} > 10$ , e.g.,  $n=211$ .

```
gcd(poly(f, IntMod(211)), poly(g, IntMod(211)))
```

```
poly(x^2 - 90, [x], IntMod(211))
```

Rational number reconstruction shows that the constant coefficient must be  $3/7$ :

```
numlib::reconstructRational(-90, 211)
```

```
3, 7
```

This is true indeed:

```
gcd(f,g)
```

```
poly(x^2 + 3/7, [x])
```

# numlib::reconstructRational

---

## Parameters

**a**

Integer

**n**

A positive integer

## Return Values

Sequence consisting of an integer and a positive integer; or FAIL

## References

## MuPAD Functions

numlib::lincongruence

**Purpose** Sum of divisors of an integer

**Syntax** `numlib::sigma(n)`  
`numlib::sigma(n, k)`

**Description** `numlib::sigma(n)` returns the sum of the positive divisors of `n`.  
`numlib::sigma(n, k)` returns the sum of the `k`-th powers of the positive divisors of `n`.  
`numlib::sigma(0)` returns 0.  
`numlib::sigma` returns the function call with evaluated argument if at least one argument is not a number.  
`numlib::sigma` returns an error if one of its arguments evaluates to a number of wrong type.  
`numlib::sigma(n,0)` is the same as `numlib::numdivisors(n)` and `numlib::tau(n)`.  
`numlib::sigma(n,1)` is the same function as `numlib::sumdivisors(n)` and `numlib::sigma(n)`.

**Examples** **Example 1**

The sum of the positive divisors of 120 is 360:

```
numlib::sigma(120)
```

```
360
```

**Example 2**

The sum of the fifth powers of the positive divisors of 120 is 25799815800:

```
numlib::sigma(120,5)
```

# numlib::sigma

---

25799815800

## Parameters

**n**

An integer

**k**

A nonnegative integer

## Return Values

numlib::sigma returns an integer.

## Algorithms

Internally, ifactor is used for factoring n.

## See Also

## MuPAD Functions

numlib::divisors | numlib::numdivisors

**Purpose** Continued fraction expansion of square roots

**Syntax** `numlib::sqrt2cfrac(a)`

**Description** `numlib::sqrt2cfrac(a)` returns the continued fraction expansion of the square root of `a` as a sequence of two lists: the first one contains the non-periodic (integer) part, the second one contains the periodic part of the expansion.

**Examples** **Example 1**

The square root of 87 can be written as  $9 + q$ , where  $q$  is a number

satisfying  $q = \frac{1}{3 + \frac{1}{q}}$ :

```
numlib::sqrt2cfrac(87)
```

```
[9], [3, 18]
```

**Example 2**

Since 81 is a perfect square, there is no periodic part in the continued fraction expansion of its square root:

```
numlib::sqrt2cfrac(81)
```

```
[9]
```

**Parameters** **a**

A positive integer

# numlib::sqrt2cfrac

---

## Return Values

If  $a$  is a perfect square, `numlib::sqrt2cfrac` returns a list with one entry; otherwise `numlib::sqrt2cfrac` returns a sequence of two lists, the first consisting of one integer, the second consisting of one or more integers.

## See Also

## MuPAD Functions

`numlib::contfrac`

**Purpose** Square root of a quadratic residue modulo a prime

**Syntax** numlib::sqrtmodp(a, p)

**Description** numlib::sqrtmodp(a, p) computes a solution  $x$  to the congruence  $x^2 \equiv a \pmod{p}$ .

numlib::sqrtmodp(a, p) computes an integer  $x$  that satisfies  $x^2 \equiv a \pmod{p}$ .

$a$  must be a quadratic residue modulo  $p$ , and  $p$  must be a prime. This is not checked! Unless this is known to be the case, numlib::msqrts must be used. On the other hand, numlib::sqrtmodp is faster than numlib::msqrts.

**Examples** **Example 1**

One square root of 132132 modulo 3231227 is 3012020:

```
numlib::sqrtmodp(132132, 3231227)
```

```
3012020
```

**Parameters** **a**  
An integer

**p**  
A prime unequal to 2

**Return Values** numlib::sqrtmodp returns an integer.

**Algorithms** numlib::sqrtmodp uses D. Shanks' algorithm RESSOL.

# numlib::sqrtmodp

---

## See Also

## MuPAD Functions

numlib::msqrts

**Purpose** Sum of divisors of an integer

**Syntax** `numlib::sumdivisors(n)`

**Description** `numlib::sumdivisors(n)` returns the sum of the positive divisors of the integer `n`.

`numlib::sumdivisors(0)` returns 0.

`numlib::sumdivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::sumdivisors` returns an error if the argument evaluates to a number of wrong type.

`numlib::sumdivisors(n)` is the same as `numlib::sigma(n, 1)`.

## Examples

### Example 1

The sum of the positive divisors of 120 is 360:

```
numlib::sumdivisors(120)
```

```
360
```

### Example 2

The sum of the positive divisors of - 63 is 104:

```
numlib::sumdivisors(-63)
```

```
104
```

**Parameters** `n`

An integer

# numlib::sumdivisors

---

## **Return Values**

numlib::sumdivisors(n) returns a nonnegative integer.

## **Algorithms**

Internally, ifactor is used for factoring n.

## **See Also**

## **MuPAD Functions**

numlib::sigma | numlib::divisors | numlib::numdivisors

**Purpose** Sum of digits of an integer

**Syntax** numlib::sumOfDigits(n, <base>)

**Description** numlib::sumOfDigits(n, base) computes the sum of digits of n in the given base base); if the base is not given, it defaults to 10.

The sum of digits may be larger than the base. For certain purposes (testing divisibility by  $b - 1$ , where  $b$  is the base), it may be useful to apply numlib::sumOfDigits over and over to the result. This is not done automatically. See “Example 2” on page 19-93.

## Examples **Example 1**

We compute the decimal and the binary sum of digits of 11:

```
numlib::sumOfDigits(11), numlib::sumOfDigits(11, 2)
```

2, 3

## **Example 2**

We want to test whether 9 divides a given number, using the school method:

```
n:= 24373463462374324:
repeat n:= numlib::sumOfDigits(n); print(n) until n < 10 end:
delete n:
```

67

13

4

# numlib::sumOfDigits

---

This only makes sense for demonstration purposes, as the following command achieves the same but much faster:

```
24373463462374324 mod 9
```

```
4
```

## Parameters

**n**

Non-negative integer

**base**

Integer greater than one

## Return Values

Non-negative integer

## See Also

## MuPAD Functions

numlib::g\_adic

**Purpose** Number of divisors of an integer

**Syntax** `numlib::tau(n)`

**Description** `numlib::tau(n)` returns the number of positive divisors of  $n$ .  
`numlib::tau(0)` returns 0.

`numlib::tau` returns the function call with evaluated argument if the argument is not a number.

`numlib::tau` returns an error if the argument evaluates to a number of wrong type.

`numlib::tau` is the same function as `numlib::numdivisors`.

**Examples** **Example 1**

We compute the number of positive divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):

```
numlib::tau(6746328388800)
```

```
10080
```

**Parameters** **n**  
An integer

**Return Values** `numlib::tau` returns a nonnegative integer.

**Algorithms** Internally, `ifactor` is used for factoring  $n$ .

# numlib::tau

---

## See Also

### **MuPAD Functions**

numlib::divisors | numlib::numprimedivisors |  
numlib::primedivisors

**Purpose** ASCII encoding of a string

**Syntax** numlib::toAscii(s)

**Description** numlib::toAscii(s) returns the list of ASCII codes of the characters in the string s.

numlib::toAscii returns an error if its argument is not a string.

**Examples**      **Example 1**

The ASCII coding of a well-known name:

```
numlib::toAscii("MuPAD - Multi Processing Algebra Data Tool")
```

```
[77, 117, 80, 65, 68, 32, 45, 32, 77, 117, 108, 116, 105, 32, 80, 114, 111, 99, 101, 115, 108, 32, 65, 108, 103, 101, 98, 114, 97, 32, 68, 97, 116, 97, 111, 108]
```

and the ASCII coding of an empty string:

```
numlib::toAscii("")
```

```
[]
```

**Parameters**      **s**

A string

**Return Values** numlib::toAscii(s) returns a list of nonnegative integers.

# numlib::toAscii

ode::wronskian

# ode::companionSystem

---

**Purpose** Companion matrix of a linear homogeneous ordinary differential equation

**Syntax** `ode::companionSystem(Ly, y(x), <R>)`

**Description** `ode::companionSystem(Ly, y(x))` returns the companion matrix associated to Ly. If the optional argument R is given, the elements of the matrix are in R.

## Examples **Example 1**

We compute the companion matrix of the following differential equation:

`Ly := 4*x^2*diff(y(x),x$3)+diff(y(x),x$2)+4*x*diff(y(x),x)-y(x)`

$$4x \frac{\partial}{\partial x} y(x) - y(x) + 4x^2 \frac{\partial^3}{\partial x^3} y(x) + \frac{\partial^2}{\partial x^2} y(x)$$

`ode::companionSystem(Ly, y(x))`

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{4x^2} & -\frac{1}{x} & -\frac{1}{4x^2} \end{pmatrix}$$

## Parameters

**Ly**

A linear homogeneous ordinary differential equation.

**y(x)**

The dependent function of Ly.

**R**

A field of functions or numbers of characteristic zero, default is  
`Dom::ExpressionField(normal)`.

## **Return Values**

Object of type `Dom::Matrix`.

# ode::cyclicVector

---

**Purpose** Transforms a linear differential system to an equivalent linear differential system with a companion matrix.

**Syntax** `ode::cyclicVector(A, x, <v>)`

**Description** `ode::cyclicVector(A, x, v)` converts a first order homogeneous differential system  $Y' = AY$  into a corresponding first order homogeneous differential system  $Z' = BZ$ , where B is a companion matrix, by substituting  $Z = PY$  using the potential cyclic vector v. If v is not cyclic then an empty list is returned otherwise a list is returned whose first element is a list corresponding to the last row of B and second element is the invertible matrix P.

When the optional argument v is not given then the vector  $[1, 0, \dots, 0]$  is tested. If it is not cyclic then a suitable one is determined randomly by the procedure.

## Examples **Example 1**

We compute a differential system equivalent to the following differential system:

```
A := matrix([[x^2-1,1,0], [0,x^2+5*x+1/3,1], [0,0,2]])
```

$$\begin{pmatrix} x^2 - 1 & 1 & 0 \\ 0 & x^2 + 5x + \frac{1}{3} & 1 \\ 0 & 0 & 2 \end{pmatrix}$$

```
ode::cyclicVector(A, x)
```

$$\left[ \left[ 2x^4 + 6x^3 - \frac{49x^2}{3} - \frac{38x}{3} + \frac{19}{3}, -x^4 - 5x^3 - \frac{10x^2}{3} + x + \frac{20}{3}, 2x^2 + 5x + \frac{4}{3} \right], \right. \\ \left. \begin{pmatrix} 1 & 0 & 0 \\ x^2 - 1 & 1 & 0 \\ 2x - 2x^2 + x^4 + 1 & 5x + 2x^2 - \frac{2}{3} & 1 \end{pmatrix} \right]$$

So [1,0,0] is a cyclic vector; [x,0,0] is also a cyclic vector:

```
l := ode::cyclicVector(A, x, [x,0,0])
```

$$\left[ \left[ \frac{6x^7 + 21x^6 - 34x^5 - 28x^4 + 28x^3 + 10x^2 + 8x + 18}{3x^3}, -\frac{3x^6 + 15x^5 + 10x^4 + 9x^3 + 10x^2 + 6x + 9}{3x^2} \right], \right. \\ \left. \frac{6x^3 + 15x^2 + 4x + 9}{3x} \right], \begin{pmatrix} x & 0 & 0 \\ -x + x^3 + 1 & x & 0 \\ x + 4x^2 - 2x^3 + x^5 - 2 - \frac{2x}{3} + 5x^2 + 2x^3 + 2x \end{pmatrix} \right]$$

And we can build easily a linear homogeneous differential equation associated to it (c.f. ode::mkODE):

```
-ode::mkODE(l[1].[-1], y, x)
```

# ode::cyclicVector

---

$$\frac{(3x^6 + 15x^5 + 10x^4 + 9x^3 + 10x^2 + 8x + 18) \frac{\partial}{\partial x} y(x)}{3x^2} - \frac{(6x^3 + 15x^2 + 4x + 9) \frac{\partial^2}{\partial x^2} y(x)}{3x} - \frac{y(x)(6x^7 + 21x^6 - 34x^5 - 28x^4 + 28x^3 + 10x^2 + 8x + 18)}{3x^3} + \frac{\partial^3}{\partial x^3} y(x)$$

## Parameters

**A**

A square matrix of type Dom::Matrix.

**x**

The independent variable.

**v**

A list of size the dimension of A, default is [1, 0, ..., 0].

## Return Values

List, possibly empty, of two lists.

## See Also

## MuPAD Functions

ode::scalarEquation

**Purpose** D'Alembert reduction of a linear homogeneous ordinary differential equation

**Syntax** `ode::dAlembert(Ly, y(x), v)`

**Description** `ode::dAlembert(Ly, y(x), v)` returns the reduced differential equation of Ly using the method of reduction of d'Alembert and the function v. If v is a solution of Ly and u is a solution of the reduced differential equation then  $v + tu$  is another solution of Ly.

### Examples **Example 1**

Consider the following differential equation:

`Ly := 2/x^3*y(x) - 2/x^2*diff(y(x),x) + 1/x*diff(y(x),x$2) + diff(y(x),x$3)`

$$\frac{2 y(x)}{x^3} - \frac{2 \frac{\partial}{\partial x} y(x)}{x^2} + \frac{\frac{\partial^2}{\partial x^2} y(x)}{x} + \frac{\partial^3}{\partial x^3} y(x)$$

We easily check that x is a particular solution of Ly:

`ode::evalOde(Ly, y(x)=x)`

0

Then we reduce the equation Ly using this special solution:

`R := ode::dAlembert(Ly, y(x), x)`

# ode::dAlembert

---

$$4 \frac{\partial}{\partial x} y(x) + \frac{\partial^2}{\partial x^2} y(x)$$

The solutions of the equation R are not too hard to find:

```
ode::evalOde(R, y(x)=1), ode::evalOde(R, y(x)=1/x^3)
```

```
0, 0
```

So a basis of solutions of Ly is therefore

$\left\{ x, x \operatorname{hold}(\operatorname{int})(1, x) = x^2, x \operatorname{hold}(\operatorname{int})\left(\frac{1}{x^3}, x\right) = -\frac{1}{2x} \right\}$  which can be checked directly:

```
ode::solve(Ly, y(x))
```

$$\left\{ \frac{C4}{x} - \frac{x(C3 + 2C2x)}{6} \right\}$$

## Parameters

**Ly**

A homogeneous linear differential equation.

**y(x)**

The dependent function of Ly.

**v**

An expression.

## Return Values

Expression.

**Purpose** Applies an expression at a linear ordinary differential equation

**Syntax** `ode::evalOde(Ly, y(x))`

**Description** `ode::evalOde(Ly, y(x) = v)` evaluates `Ly` replacing `y(x)` by `v` and simplifying the result. This can be useful to check a solution candidate, for example.

**Examples** **Example 1**

We evaluate the following differential equation for various expressions:

`Ly := (x^2+1)*diff(y(x),x$2)+x*diff(y(x),x)-4*y(x)`

$$(x^2 + 1) \frac{\partial^2}{\partial x^2} y(x) + x \frac{\partial}{\partial x} y(x) - 4 y(x)$$

`ode::evalOde(Ly, y(x) = 2*x^2+1),`

`ode::evalOde(Ly, y(x) = exp(x)),`

`ode::evalOde(Ly, y(x) = RootOf(Z^3+x*Z+1, Z))`

$$0, x^2 e^x - 3 e^x + x e^x, -18 Z^2 x^4 - 54 Z^2 x^2 + 243 Z^2 x - 60 Z x^6 - 4 Z x^4 - 756 Z x^3 + 54 Z x^2 - 36 x^3 + 162 x^2$$

**Parameters** **Ly**

A linear ordinary differential equation.

**y(x)**

The dependent function of `Ly`.

**v**

An expression.

# ode::evalOde

---

## **Return Values**

Expression.

**Purpose** Exponential solutions of a homogeneous linear ordinary differential equation

**Syntax** `ode::exponentialSolutions(Ly, y(x), <Generic>)`

**Description** `ode::exponentialSolutions(Ly, y(x))` returns a fundamental set of the exponential solutions of `Ly`, i.e. solutions  $z$  such that  $\frac{z'}{z}$  is a rational function of  $x$ . When the option `Generic` is given, a generic form of them is returned.

---

**Note** `ode::exponentialSolutions` does not return any eventual solution that is exponential over the algebraic closure of  $(x)$  but not over  $(x)$ .

---

## Examples

### Example 1

We compute the exponential solutions of the following differential equation :

```
Ly:=diff(y(x),x$4)-2*x*diff(y(x),x$3)+(-x+x^2-5)*diff(y(x),x$2)+
(4*x+2*x^2)*diff(y(x),x)+(2+x-x^3)*y(x)
```

$$\frac{\partial^4}{\partial x^4} y(x) - 2x \frac{\partial^3}{\partial x^3} y(x) - (-x^2 + x + 5) \frac{\partial^2}{\partial x^2} y(x) + (2x^2 + 4x) \frac{\partial}{\partial x} y(x) + y(x) (-x^3 + x + 2)$$

```
ode::exponentialSolutions(Ly, y(x)),
ode::exponentialSolutions(Ly, y(x), Generic)
```

$$\left\{ e^{\frac{x^2}{2}}, x e^{\frac{x^2}{2}} \right\}, C_2 e^{\frac{x^2}{2}} + C_1 x e^{\frac{x^2}{2}}$$

# ode::exponentialSolutions

---

## Example 2

No exponential solution over the algebraic closure of  $(x)$  is returned:

```
ode::exponentialSolutions(diff(y(x),x$2)+y(x), y(x))
```

$\emptyset$

whereas  $\left\{ e^{ix}, \frac{1}{e^{ix}} \right\}$  is a basis of solutions of the above differential equation.

## Parameters

### $Ly$

A homogeneous linear ordinary differential equation with coefficients in the field  $(x)$  of rational functions over the rationals.

### $y(x)$

The dependent function of  $Ly$ .

## Return Values

set, possibly empty, of functions or an expression.

**Purpose**

Exponents of a linear ordinary differential equation

**Syntax**

`ode::exponents(Ly, y(x), p)`

**Description**

`ode::exponents` returns the set of exponents of a homogeneous linear differential equation at a given point.

`ode::exponents(Ly, y(x), p)` returns the set of (local) exponents of  $Ly$  at the place  $p$ . If the place is infinity then one uses  $\frac{1}{x}$  instead. They are defined as roots (in an algebraic closure of  $(x)$ ) of the indicial equation (c.f. `ode::indicialEquation`) of  $Ly$  so the set of exponents may be empty, see “Example 2” on page 20-14.

**Examples****Example 1**

We compute the exponents of the following differential equation at the regular point 0 and at the singular points -1 and *infinity*:

`Ly := diff(y(x),x$2)+4/(x+1)*diff(y(x),x)+2/(x+1)^2*y(x)`

$$\frac{4}{x+1} \frac{\partial}{\partial x} y(x) + \frac{2}{(x+1)^2} y(x) + \frac{\partial^2}{\partial x^2} y(x)$$

`ode::exponents(Ly, y(x), x)`

`{0, 1}`

`ode::exponents(Ly, y(x), x+1)`

`{-2, -1}`

`ode::exponents(Ly, y(x), 1/x)`

# ode::exponents

{1, 2}

## Example 2

It may happen that at a place the set of exponents is empty; this corresponds to an irregular singular point:

```
Ly := (2*x+4)*diff(y(x),x)/(2*x+x^2-2)-2*y(x)/(2*x+x^2-2)-
 (4*x+x^2)/(2*x+x^2-2)*diff(y(x),x$2)+diff(y(x),x$3)
```

$$\frac{(2x+4) \frac{\partial}{\partial x} y(x)}{x^2+2x-2} - \frac{(x^2+4x) \frac{\partial^2}{\partial x^2} y(x)}{x^2+2x-2} - \frac{2y(x)}{x^2+2x-2} + \frac{\partial^3}{\partial x^3} y(x)$$

```
ode::exponents(Ly, y(x), 1/x)
```

$\emptyset$

```
ode::exponents(Ly, y(x), x^2+2*x-2)
```

{0, 1, 3}

## Parameters

**Ly**

A homogeneous linear differential equation over  $(x)$ .

**y(x)**

The dependent function of Ly.

**P**

An irreducible polynomial in  $x$  or  $1/x$ .

**Return Values**

set, possibly empty.

**See Also****MuPAD Functions**

`ode::indicialEquation` | `ode::isFuchsian`

# ode::getOrder

---

**Purpose** Order of an ordinary differential equation

**Syntax** `ode::getOrder(Ly, y(x))`

**Description** `ode::getOrder(Ly, y(x))` returns the order of Ly for the dependent function  $y(x)$ , i.e. the highest degree of derivative of Ly.

**Examples** **Example 1**

We can compute orders for linear and nonlinear ordinary differential equations:

```
ode::getOrder(diff(y(x),x$2)-x*y(x)-airyAi(x), y(x))
```

2

```
ode::getOrder(y(x)*diff(y(x),x$3)^2-exp(y(x)), y(x))
```

3

```
ode::getOrder(y(x)*diff(y(x),x$3)^2-exp(y(x)), z(x))
```

-∞

**Parameters** **Ly**  
An ordinary differential equation.

**y(x)**  
The dependent function of Ly.

**Return Values**  
Either -infinity or a positive integer.

**Purpose** Indicial equation of a linear ordinary differential equation

**Syntax** `ode::indicialEquation(Ly, y(x), p, u)`

**Description** `ode::indicialEquation(Ly, y(x), p, u)` returns the indicial equation in the variable  $u$  of  $Ly$  at the place  $p$ . If the place is infinity then one uses  $\frac{1}{x}$  instead. The result is FAIL if the place corresponds to an irregular singular point of  $Ly$ .

**Examples** **Example 1**

We compute the indicial equations of the following differential equation at the regular point 1 and at the singular points 0 and *infinity*:

$$Ly := 1/x^3*y(x)*(4*x-10) - 1/x^2*(4*x^3-10)*diff(y(x),x) - 9/2/x*diff(y(x),x^2)+diff(y(x),x^3)$$

$$\frac{y(x)(4x-10)}{x^3} - \frac{9 \frac{\partial^2}{\partial x^2} y(x)}{2x} - \frac{(4x^3-10) \frac{\partial}{\partial x} y(x)}{x^2} + \frac{\partial^3}{\partial x^3} y(x)$$

`ode::indicialEquation(Ly, y(x), x-1, U)`

$$U^3 - 3U^2 + 2U$$

`ode::indicialEquation(Ly, y(x), 1/x, U)`

FAIL

`ode::indicialEquation(Ly, y(x), x, U)`

# ode::indicialEquation

---

$$2 U^3 - 15 U^2 + 33 U - 20$$

The roots of the indicial equation correspond to the (local) exponents:

```
solve(%, U), ode::exponents(Ly, y(x), x)
```

$$\left\{1, \frac{5}{2}, 4\right\}, \left\{1, \frac{5}{2}, 4\right\}$$

## Parameters

**Ly**

A homogeneous linear differential equation over  $(x)$ .

**y(x)**

The dependent function of Ly.

**P**

An irreducible polynomial in  $x$  or  $1/x$ .

**u**

An element of type DOM\_IDENT.

## Return Values

FAIL or a polynomial expression in  $u$ .

## See Also

## MuPAD Functions

ode::indicialEquation | ode::isFuchsian

**Purpose**

Tests if a homogeneous linear ordinary differential equation is of Fuchsian type

**Syntax**

`ode::isFuchsian(Ly, y(x), <AllExponents>)`

**Description**

`ode::isFuchsian` returns TRUE if `Ly` is of Fuchsian type, i.e., all the singular points (including the point at infinity) of `Ly` are regular. It returns FALSE if at least one singular point is irregular. When the option `AllExponents` is given, either FALSE is returned or a list where each element is a table containing, at each regular singular point of `Ly` the place, the indicial equation and the exponents.

**Examples****Example 1**

We test if the following differential equation is Fuchsian:

`Ly:=x*(1-x)*diff(y(x),x$2)+(1-x)*diff(y(x),x)+10*y(x)`

$$-x(x-1)\frac{\partial^2}{\partial x^2}y(x)-(x-1)\frac{\partial}{\partial x}y(x)+10y(x)$$

`ode::isFuchsian(Ly, y(x))`

TRUE

We can have a look of the indicial equations, exponents at each regular singular point of `Ly`:

`ode::isFuchsian(Ly, y(x), AllExponents)`

# ode::isFuchsian

exponents	{0}	exponents	{0, 1}	exponents	$\{\sqrt{10}, -\sqrt{10}\}$
indicialEq	$X^2 2^2$	indicialEq	$X^2 2 - X^2 2^2$	indicialEq	$-X^2 2^2 + 10$
place	$x$	place	$x - 1$	place	$\frac{1}{x}$

## Example 2

In this example, the Airy equation, the only singular point is at infinity and is irregular:

```
ode::isFuchsian(diff(y(x),x$2)-x*y(x), y(x))
```

```
FALSE
```

## Parameters

**Ly**

A homogeneous linear ordinary differential equation with coefficients in the field  $(x)$  of rational functions over the rationals.

**y(x)**

The dependent function of Ly.

## Options

**AllExponents**

Return a list of tables of indicial equations and exponents for regular singular points.

## Return Values

TRUE, FALSE or a list.

**Purpose**

Test for a linear ordinary differential equation

**Syntax**

```
ode::isLODE(Ly, y(x), <Homogeneous | HlodeOverRF |
Hlode | LodeOverRF | Lode>)
```

**Description**

`ode::isLODE(Ly, y(x))` returns TRUE if `Ly` is a linear ordinary differential equation in `y(x)`, FALSE otherwise. If an optional argument is given then the result is discussed as follows:

- **Homogeneous:** returns TRUE if `Ly` is homogeneous, FALSE otherwise.
- **HlodeOverRF:** returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is homogeneous with rational functions coefficients, FALSE otherwise.
- **Hlode:** returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is homogeneous, FALSE otherwise.
- **LodeOverRF:** returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` has rational functions coefficients, FALSE otherwise.
- **Lode:** returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is a linear ordinary differential equation, FALSE otherwise.

**Examples****Example 1**

We test the following differential equations:

```
ode::isLODE(y(x)^2+x^2*diff(y(x),x)+x, y(x))
```

FALSE

```
ode::isLODE(y(x)+x^2*diff(y(x),x)+x, y(x))
```

TRUE

# ode::isLODE

---

```
ode::isLODE(y(x)+x^2*diff(y(x),x)+x, y(x), Hlode)
```

FALSE

```
ode::isLODE(
 y(x)+x^2*diff(y(x),x)+x*diff(y(x),x$2), y(x), HlodeOverRF)
```

$$y(x) + x^2 \frac{\partial}{\partial x} y(x) + x \frac{\partial^2}{\partial x^2} y(x), y, x, 2$$

```
ode::isLODE(
 x+x^2*diff(y(x),x)+exp(x)*diff(y(x),x$2), y(x), LodeOverRF)
```

FALSE

## Parameters

**Ly**

An expression.

**y(x)**

The dependent function of Ly.

## Return Values

Either TRUE, FALSE or a sequence of type `_exprseq`.

**Purpose** Builds a linear homogeneous ordinary differential equation from a list of coefficient functions

**Syntax** `ode::mkODE(l, y, x)`

**Description** `ode::mkODE(l, y, x)` returns a linear homogeneous ordinary differential equation  $Ly$  in  $y(x)$  where the coefficients are the entries of the list  $l$ . The last element of the list  $l$  corresponds to the leading coefficients of  $Ly$ .

### Examples **Example 1**

We generate the linear ODE for  $y(x)$  with the coefficients  $-1$ ,  $4x$  and  $4x^2$  of  $y(x)$ ,  $y'(x)$  and  $y''(x)$ , respectively:

```
ode::mkODE([-1, 4*x, 4*x^2], y, x)
```

$$4x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x) + 4x \frac{\partial}{\partial x} y(x)$$

### Parameters

**l**

A list of coefficient functions.

**y**

The dependent variable of the resulting differential equation.

**x**

The independent variable of the resulting differential equation.

### Return Values

Expression.

# ode::normalize

---

**Purpose** Normalized form of a linear ordinary differential equation

**Syntax** `ode::normalize(Ly, y, x, n)`

**Description** `ode::normalize(Ly, y, x, n)` computes the normalized form of the n-th order linear ordinary differential equation Ly, i.e. whose leading coefficient (the coefficient of the highest derivative of y(x) in Ly) is 1.

## Examples **Example 1**

We normalize the following differential equation:

```
Ly:=-diff(y(x),x,x)/x+y(x)/4/x^3-diff(y(x),x)/x^2
```

$$\frac{y(x)}{4x^3} - \frac{\frac{\partial}{\partial x} y(x)}{x^2} - \frac{\frac{\partial^2}{\partial x^2} y(x)}{x}$$

```
ode::normalize(Ly, y, x, 2)
```

$$\frac{\frac{\partial}{\partial x} y(x)}{x} - \frac{y(x)}{4x^2} + \frac{\partial^2}{\partial x^2} y(x)$$

**Parameters** **Ly**

A homogeneous linear ordinary differential equation.

**y**

The dependent variable of Ly.

**x**

The independent variable of Ly.

**n**

The order of  $Ly$ .

## **Return Values**

Expression representing a linear differential equation.

# ode::polynomialSolutions

---

**Purpose** Polynomial solutions of a homogeneous linear ordinary differential equation

**Syntax** `ode::polynomialSolutions(Ly, y(x), <Generic>)`

**Description** `ode::polynomialSolutions` computes a fundamental set of polynomial solutions of a homogeneous linear ordinary differential equation.

`ode::polynomialSolutions` returns a fundamental set of the polynomial solutions of `Ly`, i.e., solutions in the ring  $\mathbb{Q}[x]$ . When the option `Generic` is given, a generic form of them is returned.

## Examples **Example 1**

We compute the polynomial solutions of the following differential equation:

```
Ly:=3*x*diff(y(x),x,x)-x*diff(y(x),x)+9*y(x)
```

$$3x \frac{\partial^2}{\partial x^2} y(x) - x \frac{\partial}{\partial x} y(x) + 9 y(x)$$

```
ode::polynomialSolutions(Ly, y(x))
```

```
{x9 - 216 x8 + 18144 x7 - 762048 x6 + 17146080 x5 - 205752960 x4 + 1234517760 x3 - 31744
+ 2380855680 x}
```

```
ode::polynomialSolutions(Ly, y(x), Generic)
```

$$C1 (x^9 - 216 x^8 + 18144 x^7 - 762048 x^6 + 17146080 x^5 - 205752960 x^4 + 1234517760 x^3 - 2380855680 x)$$

**Parameters****Ly**

A homogeneous linear ordinary differential equation with coefficients in the field  $(x)$  of rational functions over the rationals.

**y(x)**

The dependent function of Ly.

**Return Values**

set, possibly empty, of functions or an expression

**See Also****MuPAD Functions**

ode::rationalSolutions

# ode::rationalSolutions

---

**Purpose** Rational solutions of a homogeneous linear ordinary differential equation

**Syntax** `ode::rationalSolutions(Ly, y(x), <Generic>)`

**Description** `ode::rationalSolutions` returns a fundamental set of the rational solutions of `Ly`, i.e., solutions in the field  $(x)$ . When the option `Generic` is given, a generic form of them is returned.

## Examples **Example 1**

We compute the rational solutions of the following differential equation:

$$Ly := (4x^5 + 8x^3 + 4x) \operatorname{diff}(y(x), x, x) + (36x^4 + 32x^2 - 4) \operatorname{diff}(y(x), x) + 48x^3 y(x)$$

$$48x^3 y(x) + (4x^5 + 8x^3 + 4x) \frac{\partial^2}{\partial x^2} y(x) + (36x^4 + 32x^2 - 4) \frac{\partial}{\partial x} y(x)$$

`ode::rationalSolutions(Ly, y(x))`

$$\left\{ \frac{1}{x^6 + 3x^4 + 3x^2 + 1}, \frac{x^4 + 2x^2}{x^6 + 3x^4 + 3x^2 + 1} \right\}$$

`ode::rationalSolutions(Ly, y(x), Generic)`

$$\frac{C1}{x^6 + 3x^4 + 3x^2 + 1} + \frac{C2(x^4 + 2x^2)}{x^6 + 3x^4 + 3x^2 + 1}$$

**Parameters** `Ly`

A homogeneous linear ordinary differential equation with coefficients in the field  $(x)$  of rational functions over the rationals.

**$y(x)$**

The dependent function of  $Ly$ .

## **Return Values**

set, possibly empty, of functions or an expression

## **See Also**

## **MuPAD Functions**

`ode::polynomialSolutions`

# ode::ratSys

---

**Purpose** Rational solutions of a first order homogeneous linear differential system

**Syntax** `ode::ratSys(M, x)`

**Description** `ode::ratSys(M, x)` computes a fundamental set of rational solutions of the first order homogeneous linear differential system  $Y' = MY$ . This method uses a cyclic vector and therefore is not optimal.

## Examples **Example 1**

We compute the rational solutions of the following differential system:

```
A := matrix([[2*(x+x^2-9)/x/(x-2), 2*(x^2-6)/x/(x-2)],
 [-3*(2*x+x^2-12)/x/(x-2), -(2*x+3*x^2-24)/x/(x-2)]])
```

$$\begin{pmatrix} \frac{2x^2+2x-18}{x(x-2)} & \frac{2x^2-12}{x(x-2)} \\ -\frac{3x^2+6x-36}{x(x-2)} & -\frac{3x^2+2x-24}{x(x-2)} \end{pmatrix}$$

```
v := ode::ratSys(A, x)
```

$$\left\{ \left( \begin{array}{c} \frac{x+2}{x^3} \\ -\frac{x+4}{x^3} \end{array} \right) \right\}$$

And we can check the result:

```
diff(v[1], x) = normal(A*v[1])
```

$$\begin{pmatrix} -\frac{2(x+3)}{x^4} \\ \frac{2(x+6)}{x^4} \end{pmatrix} = \begin{pmatrix} -\frac{2(x+3)}{x^4} \\ \frac{2(x+6)}{x^4} \end{pmatrix}$$

**Parameters****M**

A square matrix of type `Dom::Matrix` with coefficients in the field  $(x)$  of rational functions over the rationals.

**x**

The independent function.

**Return Values**

set, possibly empty, of objects of type `Dom::Matrix`.

**See Also****MuPAD Functions**

`ode::rationalSolutions` | `ode::cyclicVector` |  
`ode::scalarEquation`

# ode::scalarEquation

---

**Purpose** Transforms a linear differential system to an equivalent scalar linear differential equation

**Syntax** `ode::scalarEquation(A, x, y, <Transform>)`

**Description** `ode::scalarEquation` converts a first order homogeneous linear differential system to an equivalent homogeneous scalar linear differential equation using the method of cyclic vector.

`ode::scalarEquation(A, x, y)` returns a scalar homogeneous linear differential equation in  $y(x)$  equivalent to the first order homogeneous differential system  $Y' = AY$  using the method of the cyclic vector. If the option `Transform` is given then a list is returned whose first element is the corresponding differential equation  $Ly$  and second element is an invertible matrix  $P$  such that  $C = P' P^{-1} + P A P^{-1}$  is the companion matrix associated to  $Ly$ ; hence if  $Z$  is a solution of the differential system  $Y' = AY$  then  $PZ$  is a solution of the system  $Y' = CY$ .

## Examples **Example 1**

We compute a linear differential equation equivalent to the following differential system:

```
A := matrix([[x^2-1,1,0], [0,x^2+5*x+1/3,1], [0,0,2]])
```

$$\begin{pmatrix} x^2 - 1 & 1 & 0 \\ 0 & x^2 + 5x + \frac{1}{3} & 1 \\ 0 & 0 & 2 \end{pmatrix}$$

```
l := ode::scalarEquation(A, x, y, Transform)
```

$$\left[ \frac{\partial^3}{\partial x^3} y(x) - \left( 2x^2 + 5x + \frac{4}{3} \right) \frac{\partial^2}{\partial x^2} y(x) + \left( x^4 + 5x^3 + \frac{10x^2}{3} - x - \frac{20}{3} \right) \frac{\partial}{\partial x} y(x) - y(x) \left( 2x^4 + 6x^3 - \frac{49x^2}{3} - \frac{38x}{3} + \frac{19}{3} \right), \begin{pmatrix} 1 & 0 & 0 \\ x^2 - 1 & 1 & 0 \\ 2x - 2x^2 + x^4 + 1 & 5x + 2x^2 - \frac{2}{3} & 1 \end{pmatrix} \right]$$

And we can check that, for  $P=1[2]$ ,  $P' P^{-1} + P A P^{-1}$  is the companion matrix associated to  $1[1]$ :

```
P := 1[2]:
bool(diff(P,x)*P^(-1)+P*A*P^(-1) =
ode::companionSystem(1[1], y(x)))
```

TRUE

## Parameters

**A**

A square matrix of type `Dom::Matrix`.

**x**

The independent variable of the resulting scalar differential equation.

**y**

The dependent variable of the resulting scalar differential equation.

## ode::scalarEquation

---

### **Return Values**

Expression or a list.

### **See Also**

### **MuPAD Functions**

`ode::cyclicVector`

**Purpose**

Series solutions of an ordinary differential equation

**Syntax**

```
ode::series(Ly, y(x), x | x = x0, <order>)
ode::series({Ly, <inits>}, y(x), x | x = x0, <order>)
```

**Description**

`ode::series(Ly, y(x), x = x0)` computes the first terms of the series expansions of the solutions of `Ly` with respect to the variable `x` around the point `x0`.

`ode::series` tries to compute either the Taylor series, the Laurent series or the Puiseux series of the solutions of the differential equation `Ly` around the point `x=x0`.

Suppose that `Ly` is a nonlinear differential equation. If `x0` is an ordinary point of `Ly` then a Taylor series is computed otherwise an expression of type "series" is returned. If initial conditions are given at the point `x0` then the answer is expressed in terms of the function `y(x)` and its derivatives evaluated at the point `x0`. See "Example 1" on page 20-35.

Suppose that `Ly` is a linear differential equation. If `x0` is an ordinary point of `Ly` then a Taylor series is computed, if `Ly` is furthermore homogeneous and `x0` is a regular point then a Puiseux series is computed (containing possible logarithmic terms), otherwise an expression of type "series" is returned. If initial conditions are given at the point `x0` then the answer is either expressed in terms of the function `y(x)` and its derivatives evaluated at the point `x0` or it may be expressed in terms of arbitrary constants.

**Examples****Example 1**

Consider the following nonlinear differential equation:

$$Ly := x^2 \operatorname{diff}(y(x), x) + y(x) - x$$

$$y(x) - x + x^2 \frac{\partial}{\partial x} y(x)$$

# ode::series

---

We compute the series solutions at the point 0 which is a singular point:

```
ode::series(Ly, y(x), x=0)
```

$$\text{series}\left(y(x) - x + x^2 \frac{\partial}{\partial x} y(x), y(x), x = 0\right)$$

Then we compute the series solutions at the regular point 1:

```
ode::series(Ly, y(x), x=1)
```

$$\left\{ y(1) - (x-1)(y(1)-1) + \left(\frac{3y(1)}{2} - 1\right)(x-1)^2 - \left(\frac{13y(1)}{6} - \frac{4}{3}\right)(x-1)^3 + \left(\frac{73y(1)}{24} - \frac{11}{6}\right)(x-1)^4 - \left(\frac{167y(1)}{40} - \frac{5}{2}\right)(x-1)^5 + O((x-1)^6) \right\}$$

And we can also put some initial conditions at the point 1:

```
ode::series({y(1)=1}, Ly, y(x), x=1)
```

$$\left\{ 1 + \frac{(x-1)^2}{2} - \frac{5(x-1)^3}{6} + \frac{29(x-1)^4}{24} - \frac{67(x-1)^5}{40} + O((x-1)^6) \right\}$$

## Example 2

Consider the following linear differential equation:

```
Ly := (2*x+x^3)*diff(y(x),x$2) - diff(y(x),x) - 6*x*y(x)
```

$$(x^3 + 2x) \frac{\partial^2}{\partial x^2} y(x) - \frac{\partial}{\partial x} y(x) - 6x y(x)$$

We compute the series solutions at the regular point 1:

```
ode::series(Ly, y(x), x=1)
```

$$\left\{ y(1) + y'(1)(x-1) + (x-1)^2 \left( \frac{y'(1)}{6} + y(1) \right) - \left( \frac{y(1)}{9} - \frac{7y'(1)}{27} \right) (x-1)^3 + \left( \frac{y(1)}{12} - \frac{y'(1)}{36} \right) (x-1)^4 + \left( \frac{y(1)}{90} - \frac{2y'(1)}{135} \right) (x-1)^5 + \mathcal{O}((x-1)^6) \right\}$$

The series solutions at the regular singular point 0:

```
ode::series(Ly, y(x), x=0)
```

$$\left\{ 1 + 3x^2 + \frac{3x^4}{5} + \mathcal{O}(x^6), x^{3/2} + \frac{3x^{7/2}}{8} - \frac{3x^{11/2}}{128} + \mathcal{O}(x^{15/2}) \right\}$$

Also the series solutions at the regular singular point *infinity*:

```
ode::series(Ly, y(x), x=infinity)
```

$$\left\{ \frac{1}{x^2} - \frac{1}{x^4} + \frac{11}{9x^6} + \mathcal{O}\left(\frac{1}{x^8}\right), 2880x^3 + 4320x - \frac{1080}{x} + \mathcal{O}\left(\frac{1}{x^3}\right) \right\}$$

### Example 3

Consider the following linear differential equation:

```
Ly := x^2*diff(y(x),x$2) - x*diff(y(x),x) + (1-x)*y(x)
```

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x)(x-1) - x \frac{\partial}{\partial x} y(x)$$

# ode::series

---

We compute the series solutions at the regular singular point 0:

```
ode::series(Ly, y(x), x)
```

$$\left\{ x \ln(x) + x^2 (\ln(x) - 2) + x^3 \left( \frac{\ln(x)}{4} - \frac{3}{4} \right) + x^4 \left( \frac{\ln(x)}{36} - \frac{11}{108} \right) + x^5 \left( \frac{\ln(x)}{576} - \frac{25}{3456} \right) + x^6 \left( \frac{\ln(x)}{14400} \right) + \mathcal{O}(x^7), x + x^2 + \frac{x^3}{4} + \frac{x^4}{36} + \frac{x^5}{576} + \frac{x^6}{14400} + \mathcal{O}(x^7) \right\}$$

And at the same point we look for solutions satisfying the initial condition  $y(0) = 1$  and  $y'(0) = 0$ :

```
ode::series({y(0)=1, Ly}, y(x), x)
```

$\emptyset$

```
ode::series({y(0)=0, Ly}, y(x), x)
```

$$\left\{ C_4 x \ln(x) + C_4 x^2 (\ln(x) - 2) + C_4 x^3 \left( \frac{\ln(x)}{4} - \frac{3}{4} \right) + C_4 x^4 \left( \frac{\ln(x)}{36} - \frac{11}{108} \right) + C_4 x^5 \left( \frac{\ln(x)}{576} - \frac{25}{3456} \right) + C_4 x^6 \left( \frac{\ln(x)}{14400} - \frac{137}{432000} \right) + \mathcal{O}(x^7), C_3 x + C_3 x^2 + \frac{C_3 x^3}{4} + \frac{C_3 x^4}{36} + \frac{C_3 x^5}{576} + \frac{C_3 x^6}{14400} + \mathcal{O}(x^7) \right\}$$

## Parameters

**Ly**

An ordinary differential equation.

**y(x)**

The dependent function of Ly.

**x**

The independent variable of  $Ly$ .

**x0**

The expansion point: an arithmetical expression. If not specified, the default expansion point 0 is used .

**inits**

The initial or boundary conditions: a sequence of equations.

**order**

The number of terms to be computed: a nonnegative integer.  
The default order is given by the environment variable ORDER (default value 6).

**Return Values**

Either a list, maybe empty, of objects of type `Series::Puisseux` or an expression of type "series".

# ode::solve

---

**Purpose** Solving ordinary differential equations

**Syntax** `ode::solve(o, options)`  
`solve(o, options)`

**Description** `ode::solve` computes solutions for ordinary differential equations.

`ode::solve(o)` returns the set of solutions of the ordinary differential equation `o`. You can also call the generic function `solve(o)`.

The solver detects the type of the differential equation and chooses an algorithm according to the detected equation type. If you know the type of the equation, you can use the option `Type = OdeType` to pass the equation type to the solver. Passing the equation type to the solver increases performance.

The solver recognizes the following values of `OdeType`:

- `Abel` - Abel differential equation
- `Bernoulli` - Bernoulli differential equation
- `Chini` - Chini differential equation
- `Clairaut` - Clairaut differential equation
- `ExactFirstOrder` - exact first order ordinary differential equation
- `ExactSecondOrder` - exact second order ordinary differential equation
- `Homogeneous` - homogeneous first order ordinary differential equation
- `Lagrange` - Lagrange differential equation
- `Riccati` - Riccati differential equation

See the Background section for more details on the classes of ordinary differential equations.

If the solver cannot identify the equation with the type you indicated, it issues a warning and returns the special value `FAIL`.

To solve an ordinary differential equation disregarding possible conditions on the parameters of the equation, use `IgnoreSpecialCases` option. This option eliminates receiving a set of special cases as an answer.

To solve an ordinary differential equation in a simplified manner, use the `IgnoreAnalyticConstraints` option. This option can provide simple solutions for the equations for which the direct use of the solver gives complicated results. If you use the `IgnoreAnalyticConstraints` option, always check the answer. This option can lead to wrong or incomplete results. See “Example 3” on page 20-43.

The solutions of ordinary differential equations can contain arbitrary constants of integration. The solver generates the constants of integration using the format of an uppercase letter `C` followed by an automatically generated number, for example `C13`.

The solver does not always verify the uniqueness and completeness of the returned solution. For example:

- The solver does not validate the Lipschitz-conditions on the ordinary differential equation for the Picard-Lindelöf Theorem.
- For some complex nonlinear systems of differential equations the solver returns constant solutions and does not warn you that other solutions exist.

The solver might ignore assumptions that you set on symbolic parameters and variables or use them only partially. More precisely, `ode::solve` passes assumptions to the functions that it calls internally. While these functions can use the specified assumptions, `ode::solve` itself does not use them in most of its internal algorithms. The same happens if you define an ordinary differential equation using `ode` and solve it using `solve`.

## Examples

### Example 1

To define an ordinary differential equation, use the `ode` command:

# ode::solve

---

```
o:= ode(y'(x) = y(x)^2, y(x))
```

```
ode(y'(x) - y(x)^2, y(x))
```

To solve the equation, enter:

```
ode::solve(o)
```

```
{0, - 1 / (C3 + x)}
```

or more efficiently:

```
solve(o)
```

```
{0, - 1 / (C7 + x)}
```

Internally, the function `ode::solve` calls the function `solve`.

## Example 2

You can solve an ordinary differential equation with a symbolic parameter and an initial condition:

```
o:= ode({y'(x) = a*y(x)^2, y(a) = ln(a)}, y(x)):
solve(o)
```

```
{ {0} if a = 1
 { 1 / (-a x + a^2) if a ≠ 1
 ln(a) }
```

To reduce the number of returned solutions, use the option `IgnoreSpecialCases`. For example, you can drop the solution for the parameter  $a = 1$ :

```
solve(o, IgnoreSpecialCases)
```

$$\left\{ \frac{1}{\frac{1}{\ln(a)} - a X + a^2} \right\}$$

With the `IgnoreSpecialCases` option, a returned set of solutions can be incomplete.

### Example 3

The solver can return `piecewise` solutions:

```
o:= ode(y'(x) = a/y(x)^2 + b*y(x), y(x)):
solve(o)
```

# ode::solve

$$\left\{ \begin{array}{ll}
 \{C18\} & \text{if } a = 0 \wedge b = 0 \\
 \left\{ \frac{(-a)^{1/3}}{b^{1/3}}, \left(-\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \left(-\frac{a - e^{3b(C19 \cdot x)}}{b}\right)^{1/3}, \left(-\frac{a - e^{3b(C19 \cdot x)}}{b}\right)^{1/3}, \right. & \text{if } a \neq 0 \wedge b \neq 0 \\
 \left. \frac{(-a)^{1/3} \left(-\frac{1}{2} + \frac{\sqrt{3}i}{2}\right)}{b^{1/3}}, -\left(\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \left(-\frac{a - e^{3b(C19 \cdot x)}}{b}\right)^{1/3}, -\frac{(-a)^{1/3} \left(\frac{1}{2} + \frac{\sqrt{3}i}{2}\right)}{b^{1/3}} \right\} & \\
 \emptyset & \text{if } (a = 0 \vee b = 0) \wedge (a \neq 0 \vee b = 0) \wedge (a \neq 0 \wedge b \neq 0) \\
 \left\{ \left(-\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \left(-\frac{a - e^{3b(C19 \cdot x)}}{b}\right)^{1/3}, \right. & \text{if } ((a = 0 \wedge b \neq 0) \vee (a \neq 0 \wedge b = 0)) \wedge (a = 0 \vee b = 0) \wedge (a \neq 0 \wedge b \neq 0) \\
 \left. \left(-\frac{a - e^{3b(C19 \cdot x)}}{b}\right)^{1/3}, -\left(\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \left(-\frac{a - e^{3b(C19 \cdot x)}}{b}\right)^{1/3} \right\} &
 \end{array} \right.$$

This solution is complete and mathematically correct for all possible values of the parameter  $a$  and variable  $x$ . Also you can try the option `IgnoreAnalyticConstraints` to obtain a particular solution that is correct under a set of common assumptions:

`solve(o, IgnoreAnalyticConstraints)`

$$\left\{ \frac{(-a)^{1/3}}{b^{1/3}}, \left(-\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \left(-\frac{a - e^{3b(C24 \cdot x)}}{b}\right)^{1/3}, \left(-\frac{a - e^{3b(C24 \cdot x)}}{b}\right)^{1/3}, \right. \\
 \left. \frac{(-a)^{1/3} \left(-\frac{1}{2} + \frac{\sqrt{3}i}{2}\right)}{b^{1/3}}, -\left(\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \left(-\frac{a - e^{3b(C24 \cdot x)}}{b}\right)^{1/3}, -\frac{(-a)^{1/3} \left(\frac{1}{2} + \frac{\sqrt{3}i}{2}\right)}{b^{1/3}} \right\}$$

The solver accepts several options:

```
solve(o, Type = Bernoulli, IgnoreAnalyticConstraints)
```

$$\left\{ \left( -\frac{1}{2} + \frac{\sqrt{3}i}{2} \right) \left( -\frac{a - C26 b e^{3bx}}{b} \right)^{1/3}, \left( -\frac{a - C26 b e^{3bx}}{b} \right)^{1/3}, -\left( \frac{1}{2} + \frac{\sqrt{3}i}{2} \right) \left( -\frac{a - C26 b e^{3bx}}{b} \right)^{1/3} \right\}$$

#### Example 4

Suppose, you want to solve an ordinary differential equation from the class of Bernoulli equations:

```
o:= ode(y'(x) = (- 1/x + 2*I)*y(x) + 1/x*y(x)^2, y(x)):
solve(o)
```

$$\left\{ 0, \frac{e^{-\ln(x) \cdot 2xi}}{C28 + 2 Ei(1, -2xi) i + \frac{e^{2xi}}{x}} \right\}$$

The solver recognizes the type of the equation and uses the algorithm for solving Bernoulli equations. To improve performance, you can explicitly pass the type of the equation to the solver:

```
solve(o, Type = Bernoulli)
```

$$\left\{ 0, \frac{x e^{-\ln(x) \cdot 2xi}}{e^{2xi} + C29 x + 2xi Ei(1, -2xi) i} \right\}$$

To solve the Clairaut equation with the initial conditions, enter:

```
o:= ode({(x*y'(x)-y(x))^2 - y'(x)^2 - 1 = 0, y(1) = 1}, y(x)):
solve(o, Type = Clairaut)
```

```
{1}
```

If the solver cannot identify the equation with the type you indicated, it issues a warning and returns the special value FAIL:

```
o:= ode({(x*y'(x)-y(x))^2 - y'(x)^2 - 1 = 0, y(1) = 1}, y(x)):
solve(o, Type = Lagrange)
```

```
Warning: Cannot detect the Lagrange ODE. [ode::lagrange]
```

```
FAIL
```

## Example 5

Some ordinary differential equations belong to several classes. For example, some Chini equations are also homogeneous and some Lagrange equations are also Clairaut equations. If an equation belongs to several classes simultaneously, the solver can present its solution in different forms. The form of a solution depends on the class with which an equation is identified. For example, suppose you want to solve the Chini differential equation. You can explicitly pass the type of the equation to the solver:

```
o:= ode(y'(x) = 1/x*y(x)^2 + 1/x*y(x) + x, y(x)):
L:= solve(o, Type = Chini)
```

```
{x tan(C31 + x), -x i, x i}
```

You also can let the solver recognize the type of the equation:

```
solve(o)
```

$$\left\{ -x i, -x i + \frac{2 e^{2 x i} e^{\ln(x)-2 x i}}{2 C33 e^{2 x i} - i} \right\}$$

The solver does not return the type with which an ordinary differential equation is internally identified. If you want to verify that both solution sets are equivalent, use the rewrite function with target exp on the first set of solutions:

```
rewrite(L, exp)
```

$$\left\{ -x i, x i, -\frac{x \left( e^{2 C31 i + 2 x i} i - i \right)}{e^{2 C31 i + 2 x i} + 1} \right\}$$

### Example 6

MuPAD solves some classes of Riccati ordinary differential equations that involve arbitrary functions. For example, the following equation contains the arbitrary function  $f(x)$ :

```
eq := diff(y(x), x) - f(x)*y(x)^2 + a^2*x^(2*n)*f(x) - a*n*x^(n
```

$$\frac{\partial}{\partial x} y(x) - f(x) y(x)^2 + a^2 x^{2n} f(x) - a n x^{n-1}$$

For this equation the solver returns:

```
solve(ode(eq, y(x)))
```

# ode::solve

$$\left\{ a x^n, a x^n + \frac{e^{\int 2 a x^n f(x) dx}}{C35 - \int e^{\int 2 a x^n f(x) dx} f(x) dx} \right\}$$

You also can solve an equation with more than one arbitrary function.  
For example, the following equations contain  $f(x)$  and  $g(x)$ :

$$\text{eq} := \text{diff}(y(x), x) - g(x)*f(x)*y(x) - g(x) - \text{diff}(f(x), x)*y(x)^2 - y(x)^2 \frac{\partial}{\partial x} f(x) + \frac{\partial}{\partial x} y(x) - f(x) g(x) y(x) - g(x)$$

The returned solution is:

$$\text{solve}(\text{ode}(\text{eq}, y(x)))$$

$$\left\{ \frac{e^{\int f(x) g(x) dx - 2 \ln(f(x))}}{C37 - \int e^{\int f(x) g(x) dx - 2 \ln(f(x))} \frac{\partial}{\partial x} f(x) dx} - \frac{1}{f(x)}, -\frac{1}{f(x)} \right\}$$

## Example 7

Suppose, you want to solve the following second-order ordinary differential equation:

$$\text{eq} := x^2*(x^2+1)*\text{diff}(y(x), x, x) + x*(2*x^2+1)*\text{diff}(y(x), x) - (nu*(nu+1))$$

$$x (2 x^2 + 1) \frac{\partial}{\partial x} y(x) - y(x) (n^2 + nu (nu + 1) x^2) + x^2 (x^2 + 1) \frac{\partial^2}{\partial x^2} y(x)$$

The solver returns the result in terms of the hypergeometric function  ${}_1F_2$  (see hypergeom):

```
solve(ode(eq, y(x)))
```

$$\left\{ \frac{C39 {}_2F_1\left(\frac{nu}{2} - \frac{n}{2} + \frac{1}{2}, \frac{n}{2} + \frac{nu}{2} + \frac{1}{2}; nu + \frac{3}{2}; -\frac{1}{x^2}\right)}{X^{nu+1}} + C40 X^{nu} {}_2F_1\left(-\frac{n}{2} - \frac{nu}{2}, \frac{n}{2} - \frac{nu}{2}; \frac{1}{2} - nu; -\frac{1}{x^2}\right) \right.$$

### Example 8

The solver can handle some third- and higher-order ordinary differential equations. For example, solve the following third-order linear differential equations:

```
eq := ode(sin(x)*y'''(x) + cos(x)*y(x), y(x)):
solve(eq)
```

$$\{C42 \sin(x)\}$$

```
eq := ode(6*y(x) + x^3*y'''(x), y(x)):
solve(eq)
```

$$\left\{ C47 X^{2+\sqrt{2}i} - \frac{X^{2+\sqrt{2}i} \left( \frac{C46}{22} + \frac{3\sqrt{2}C46i}{44} \right)}{X^{3+\sqrt{2}i}} + \frac{\sqrt{2} C48 \frac{1}{x^{2\sqrt{2}i}} X^{2+\sqrt{2}i} i}{4} + \frac{\sqrt{2} \frac{1}{x^{2\sqrt{2}i}} X^{2+\sqrt{2}i} \left( \frac{3C46}{11} + \right)}{4 X^{3-\sqrt{2}i}} \right.$$

### Example 9

The solver also can handle some nonlinear first-order ordinary differential equations. For example, solve the following first-order linear differential equations:

```
eq := ode(y(x)*diff(y(x), x) - y(x) - x^3 - 4*x^4 - 4*x^7, y(x)):
solve(eq)
```

# ode::solve

---

$$\left\{x^4 + x + \frac{1}{4}\right\}$$

```
eq := ode(exp(x/2)/4 - 2*exp(x) - y(x) + x*exp(x/2) + y(x)*y'(x), y)
solve(eq)
```

$$\left\{x - 2 e^{\frac{x}{2}} + \frac{1}{4}\right\}$$

## Parameters

o

An ordinary differential equation, an object of the type ode.

## Options

### Type

Option, specified as `Type = OdeType`

Indicates the type of the ordinary differential equation and accepts the following arguments: Abel, Bernoulli, Chini, Clairaut, ExactFirstOrder, ExactSecondOrder, Homogeneous, Lagrange, Riccati.

### MaxDegree

Option, specified as `MaxDegree = n`

Pass the option to the generic solver, which is called internally for all intermediate equations. See the list of options for the solve function for further information.

### IgnoreSpecialCases

Pass the option to the generic solver, which is called internally for all intermediate equations, and to the integrator `int`, which is called for computing all intermediate integrals. See the list of options for the solve function for further information.

### IgnoreAnalyticConstraints

Pass the option to the generic solver, which is called internally for all intermediate equations, and to the integrator `int`, which is called for computing all intermediate integrals. See the list of options for the `solve` function for further information.

## Return Values

Set of solutions of the ordinary differential equation or the special value `FAIL`. For additional information on the return values, see the `solve` help page.

## Concepts

- “Solve Ordinary Differential Equations and Systems”

# ode::symmetricPower

---

**Purpose** Symmetric power of a homogeneous linear ordinary differential equation

**Syntax** `ode::symmetricPower(Ly, y(x), m)`

**Description** `ode::symmetricPower(Ly, y(x), m)` computes the  $m$ -th symmetric power of  $Ly$ . This is the lowest order linear ordinary differential equation whose solution space consists exactly of all possible  $m$ -th powerproducts of solutions of  $Ly$ .

## Examples **Example 1**

We compute the second symmetric power of the following differential equation:

```
Ly:=x^2*diff(y(x),x$2) - (36*x^6*exp(4*x^3)+9*x^6+2)*y(x)
```

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x) \left( 36 x^6 e^{4x^3} + 9 x^6 + 2 \right)$$

```
ode::symmetricPower(Ly, y(x), 2)
```

$$\frac{\partial^3}{\partial x^3} y(x) - \left( 144 x^4 e^{4x^3} + \frac{8}{x^2} + 36 x^4 \right) \frac{\partial}{\partial x} y(x) - y(x) \left( 288 x^3 e^{4x^3} + 864 x^6 e^{4x^3} - \frac{8}{x^3} + 72 x \right)$$

**Parameters** **Ly**

A homogeneous linear ordinary differential equation.

**y(x)**

The dependent function of  $Ly$ .

**m**

A positive integer.

## Return Values

Linear differential equation

# ode::unimodular

---

**Purpose** Unimodular transformation of a linear ordinary differential equation

**Syntax** `ode::unimodular(Ly, y(x), <Transform>)`

**Description** `ode::unimodular(Ly, y(x))` tests if the linear homogeneous differential equation `Ly` has a unimodular Galois group (i.e. the wronskian lies in the base field  $(x)$ ), if not transforms `Ly` into a unimodular one (by changing the second highest coefficient to zero) and returns a table with index equation and `factorOfTransformation` containing respectively the transformed differential equation and the factor of transformation `Wn` such that a solution of the transformed equation multiplied by `Wn` is a solution of `Ly`.

If the option `Transform` is given then `Ly` is transformed unconditionally even if `Ly` has yet a unimodular Galois group.

## Examples

### Example 1

We test if the following differential equation has a unimodular Galois group:

```
Ly := y(x)*6+x*diff(y(x),x)*(-2)+diff(y(x),x$2)*(-x^2+1)
```

$$-(x^2 - 1) \frac{\partial^2}{\partial x^2} y(x) - 2x \frac{\partial}{\partial x} y(x) + 6 y(x)$$

```
ode::unimodular(Ly, y(x))
```

---

equation	$6 y(x) - 2x \frac{\partial}{\partial x} y(x) - (x^2 - 1) \frac{\partial^2}{\partial x^2} y(x)$
factorOfTransformation	1

It is unimodular since the factor of transformation is 1. We can also check this by computing the wronskian of Ly which is a rational function:

```
ode::wronskian(Ly,y(x))
```

$$\frac{1}{x^2 - 1}$$

Now we transform Ly into a differential equation whose wronskian is 1:

```
ode::unimodular(Ly, y(x), Transform)
```

equation	$\frac{\partial^2}{\partial x^2} y(x) - \frac{y(x)(6x^2-7)}{-2x^2 \cdot x^4 + 1}$
factorOfTransformation	$\sqrt{\frac{1}{x^2-1}}$

```
ode::wronskian(%[equation], y(x))
```

$$1$$

## Parameters

**Ly**

A homogeneous linear differential equation over (x).

**y(x)**

The dependent function of Ly.

## Return Values

table.

# ode::unimodular

---

## See Also

### MuPAD Functions

ode::wronskian

**Purpose** Coefficients of a homogeneous linear ODE

**Syntax** `ode::vectorize(Ly, y, x, n)`

**Description** `ode::vectorize(Ly, y, x, n)` returns the list of coefficients of the  $n$ -th order homogeneous linear ordinary differential equation `Ly`.

### Examples **Example 1**

We compute the list of coefficients of the following differential equation:

```
Ly := 4*x^2*diff(y(x), x$3)+exp(x^2)*diff(y(x),x$2)+
 4*x*diff(y(x),x)-y(x)
```

$$4x \frac{\partial}{\partial x} y(x) - y(x) + e^{x^2} \frac{\partial^2}{\partial x^2} y(x) + 4x^2 \frac{\partial^3}{\partial x^3} y(x)$$

```
ode::vectorize(Ly, y, x, 3)
```

$$[-1, 4x, e^{x^2}, 4x^2]$$

### Parameters

**Ly**

A homogeneous linear ordinary differential equation.

**y**

The dependent variable of `Ly`.

**x**

The independent variable of `Ly`.

**n**

The order of `Ly`, a positive integer.

## ode::vectorize

---

### **Return Values**

list

**Purpose** Wronskian of functions or of a linear homogeneous ordinary differential equation

**Syntax** `ode::wronskian(l, x, <R>)`  
`ode::wronskian(Ly, y(x), <R>)`

**Description** `ode::wronskian` computes the wronskian (determinant) of functions or of a linear homogeneous ordinary differential equation.

`ode::wronskian(l, x)` returns the wronskian, i.e. the determinant of the wronskian matrix, of the elements of `l` with respect to `x`.

`ode::wronskian(Ly, y(x))` returns the wronskian of `Ly` defined as the element `w` such that  $W' = -a_{n-1} W$ , where  $a_{n-1}$  is the coefficient of `Ly` of degree  $n - 1$  and  $n$  the order of `Ly`.

If the optional argument `R` is given, then the specified differential ring will be chosen for representing the entries of the wronskian matrix.

## Examples **Example 1**

We compute the wronskian of  $[2x^2+1, x\sqrt{1+x^2}, y(x)]$  which is a linear differential equation in `y(x)`:

`Ly:=ode::wronskian([2*x^2+1, x*sqrt(1+x^2), y(x)], x)`

$$\begin{aligned}
 & 4x\sqrt{x^2+1}\frac{\partial}{\partial x}y(x) - 4x^2\sqrt{x^2+1}\frac{\partial^2}{\partial x^2}y(x) - 4y(x)\left(\sqrt{x^2+1} + \frac{x^2}{\sqrt{x^2+1}}\right) \\
 & - (2x^2+1)\left(\frac{3x}{\sqrt{x^2+1}} - \frac{x^3}{(x^2+1)^{3/2}}\right)\frac{\partial}{\partial x}y(x) + 4xy(x)\left(\frac{3x}{\sqrt{x^2+1}} - \frac{x^3}{(x^2+1)^{3/2}}\right) \\
 & + (2x^2+1)\left(\sqrt{x^2+1} + \frac{x^2}{\sqrt{x^2+1}}\right)\frac{\partial^2}{\partial x^2}y(x)
 \end{aligned}$$

# ode::wronskian

---

```
Ly := numer(normal(Ly))
```

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - 4 y(x) + x \frac{\partial}{\partial x} y(x) + \frac{\partial^2}{\partial x^2} y(x)$$

And we can check that a basis of solutions of Ly is as expected:

```
ode::solve(Ly, y(x))
```

$$\left\{ C2 \left( x + \sqrt{x^2 + 1} \right)^2 + \frac{C3}{\left( x + \sqrt{x^2 + 1} \right)^2} \right\}$$

We can also compute the wronskian of Ly, which is, up to a constant, the wronskian of  $x^2+1$  and  $x*\text{sqrt}(x^2+1)$ :

```
ode::wronskian(Ly, y(x)),
simplify(ode::wronskian([x^2+1/2,x*sqrt(1+x^2)], x))
```

$$\frac{1}{\sqrt{x^2 + 1}}, \frac{1}{2\sqrt{x^2 + 1}}$$

## Parameters

**I**

A list of functions of the variable  $x$ .

**Ly**

A homogeneous linear ordinary differential equation.

**y(x)**

The dependent function of Ly.

**R**

A differential ring, default is `Dom::ExpressionField(id, iszero@normal)`.

## **Return Values**

Expression in  $x$ .

# ode::wronskian

---

# orthpoly – Orthogonal Polynomials

---

orthpoly::chebyshev1  
orthpoly::chebyshev2  
orthpoly::curtz  
orthpoly::gegenbauer  
orthpoly::hermite  
orthpoly::jacobi  
orthpoly::laguerre  
orthpoly::legendre

# orthpoly::chebyshev1

---

**Purpose** The Chebyshev polynomials of the first kind

**Syntax** `orthpoly::chebyshev1(n, x)`

**Description** `orthpoly::chebyshev1(n, x)` computes the value of the  $n$ -th degree Chebyshev polynomial of the first kind at the point  $x$ .

These polynomials have integer coefficients.

Evaluation is fast and numerically stable for real floating point values  $x$  from the interval  $[-1.0, 1.0]$ . Cf. “Example 2” on page 21-3.

`orthpoly::chebyshev2` implements the Chebyshev polynomials of the second kind.

## Examples **Example 1**

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::chebyshev1(2, x)
```

```
poly(2 x2 - 1, [x])
```

```
orthpoly::chebyshev1(3, x[1])
```

```
poly(4 x13 - 3 x1, [x1])
```

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::chebyshev1(2, 6*x)
```

```
72 x2 - 1
```

```
orthpoly::chebyshev1(3, x[1] + 2)
```

```
4 x13 + 24 x12 + 45 x1 + 26
```

“Arithmetical expressions” include numbers:

```
orthpoly::chebyshev1(2, sqrt(2)),
orthpoly::chebyshev1(3, 8 + I),
orthpoly::chebyshev1(1000, 0.3)
```

```
3, 1928 + 761 i, -0.9991251116
```

If no integer degree is specified, `orthpoly::chebyshev1` returns itself symbolically:

```
orthpoly::chebyshev1(n, x), orthpoly::chebyshev1(1/2, x)
```

```
orthpoly::chebyshev1(n, x), orthpoly::chebyshev1($\frac{1}{2}$, x)
```

## Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::chebyshev1(200, 0.3)
```

```
- 0.3169632681
```

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
T200 := orthpoly::chebyshev1(200, x):
```

# orthpoly::chebyshev1

---

```
DIGITS := 10: evalp(T200, x = 0.3)
```

```
- 3912167.235
```

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 20: evalp(T200, x = 0.3)
```

```
- 0.31710101442512309682
```

```
delete DIGITS, T200:
```

## Parameters

**n**

A nonnegative integer: the degree of the polynomial.

**x**

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM\_IDENT) or an indexed identifier (of type "\_index").

## Return Values

If  $x$  is an indeterminate, then a polynomial of domain type DOM\_POLY is returned. If  $x$  is an arithmetical expression, then the value of the Chebyshev polynomial at this point is returned as an arithmetical expression. If  $n$  is not a nonnegative integer, then orthpoly::chebyshev1 returns itself symbolically.

## Algorithms

The Chebyshev polynomials are given by  $T(n, x) = \cos(n \arccos(x))$  for real  $x \in [-1, 1]$ . This representation is used by orthpoly::chebyshev1 for floating-point values in this range.

These polynomials satisfy the recursion formula

$$T(n, x) = 2 x T(n - 1, x) - T(n - 2, x)$$

with  $T(0, x) = 1$  and  $T(1, x) = x$ .

They are orthogonal on the interval  $[-1, 1]$  with respect to the weight

function  $w(x) = \frac{1}{\sqrt{1-x^2}}$ .

$T(n, x)$  is a special [Jacobi](#) polynomial:

$$T(n, x) = \frac{2^{2n} n!^2}{(2n)!} P\left(n, -\frac{1}{2}, -\frac{1}{2}, x\right)$$

# orthpoly::chebyshev2

---

**Purpose** The Chebyshev polynomials of the second kind

**Syntax** `orthpoly::chebyshev2(n, x)`

**Description** `orthpoly::chebyshev2(n, x)` computes the value of the  $n$ -th degree Chebyshev polynomial of the second kind at the point  $x$ .

These polynomials have integer coefficients.

Evaluation is fast and numerically stable for real floating point values  $x$  from the interval  $[-1.0, 1.0]$ . Cf. “Example 2” on page 21-7.

`orthpoly::chebyshev1` implements the Chebyshev polynomials of the first kind.

## Examples

### Example 1

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::chebyshev2(2, x)
```

```
poly(4 x2 - 1, [x])
```

```
orthpoly::chebyshev2(3, x[1])
```

```
poly(8 x13 - 4 x1, [x1])
```

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::chebyshev2(2, 6*x)
```

```
144 x2 - 1
```

```
orthpoly::chebyshev2(3, x[1] + 2)
```

```
8 x13 + 48 x12 + 92 x1 + 56
```

“Arithmetical expressions” include numbers:

```
orthpoly::chebyshev2(2, sqrt(2)),
orthpoly::chebyshev2(3, 8 + I),
orthpoly::chebyshev2(1000, 0.3)
```

```
7, 3872 + 1524 i, -1.012277265
```

If no integer degree is specified, then `orthpoly::chebyshev2` returns itself symbolically:

```
orthpoly::chebyshev2(n, x), orthpoly::chebyshev2(1/2, x)
```

```
orthpoly::chebyshev2(n, x), orthpoly::chebyshev2($\frac{1}{2}$, x)
```

## Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::chebyshev2(200, 0.3)
```

```
-0.01869337443
```

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
U200 := orthpoly::chebyshev2(200, x):
```

# orthpoly::chebyshev2

---

```
DIGITS := 10: evalp(U200, x = 0.3)
```

```
- 3872355.739
```

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 20: evalp(U200, x = 0.3)
```

```
- 0.018233184138451814741
```

```
delete DIGITS, U200:
```

## Parameters

**n**

A nonnegative integer: the degree of the polynomial.

**x**

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM\_IDENT) or an indexed identifier (of type "\_index").

## Return Values

If  $x$  is an indeterminate, then a polynomial of domain type DOM\_POLY is returned. If  $x$  is an arithmetical expression, then the value of the Chebyshev polynomial at this point is returned as an arithmetical expression. If  $n$  is not a nonnegative integer, then orthpoly::chebyshev2 returns itself symbolically.

## Algorithms

The Chebyshev polynomials of the second kind are given by

$$U(n, x) = \frac{\sin((n + 1) \arccos(x))}{\sin(\arccos(x))}$$

for real  $x$   $[-1, 1]$ . This representation is used by `orthpoly::chebyshev2` for floating-point values in this range.

These polynomials satisfy the recursion formula

$$U(n, x) = 2x U(n-1, x) - U(n-2, x)$$

with  $U(0, x) = 1$  and  $U(1, x) = 2x$ .

They are orthogonal on the interval  $[-1, 1]$  with respect to the weight function  $w(x) = \sqrt{1-x^2}$ .

$U(n, x)$  coincides with the Gegenbauer polynomial  $G(n, 1, x)$ .

$U(n, x)$  is a special Jacobi polynomial:

$$U(n, x) = \frac{2^{2n} n! (n+1)!}{(2n+1)!} P\left(n, \frac{1}{2}, \frac{1}{2}, x\right)$$

### MuPAD Functions

`orthpoly::chebyshev1` | `orthpoly::gegenbauer` |  
`orthpoly::jacobi`

# orthpoly::curtz

---

**Purpose** The Curtz polynomials

**Syntax** `orthpoly::curtz(n, x)`

**Description** `orthpoly::curtz(n,x)` computes the value of the  $n$ -th degree Curtz polynomial at the point  $x$ .

These polynomials have rational coefficients.

Evaluation for real floating-point values  $x$  is numerically stable. Cf. “Example 2” on page 21-11.

## Examples

### Example 1

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::curtz(2, x)
```

$$\text{poly}\left(x^2 - x + \frac{1}{3}, [x]\right)$$

```
orthpoly::curtz(3, x[1])
```

$$\text{poly}\left(x_1^3 - \frac{3x_1^2}{2} + \frac{11x_1}{12} - \frac{1}{4}, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::curtz(2, 6*x)
```

$$36x^2 - 6x + \frac{1}{3}$$

```
orthpoly::curtz(3, x[1] + 2)
```

$$x_1^3 + \frac{9x_1^2}{2} + \frac{83x_1}{12} + \frac{43}{12}$$

“Arithmetical expressions” include numbers:

```
orthpoly::curtz(2, sqrt(2)), orthpoly::curtz(3, 8 + I),
orthpoly::curtz(100, 0.3)
```

$$\frac{7}{3} - \sqrt{2}, \frac{4807}{12} + \frac{2015i}{12}, 0.001395122936$$

If no integer degree is specified, then `orthpoly::curtz` returns itself symbolically:

```
orthpoly::curtz(n, x), orthpoly::curtz(1/2, x)
```

$$\text{orthpoly::curtz}(n, x), \text{orthpoly::curtz}\left(\frac{1}{2}, x\right)$$

## Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::curtz(50, 1.2)
```

```
0.0003843630923
```

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

# orthpoly::curtz

---

```
orthpoly::curtz(50, x): evalp(%, x = 1.2)
```

```
0.0003849036173
```

Note that only 3 digits are correct due to numerical round-off.

## Parameters

**n**

A nonnegative integer: the degree of the polynomial.

**x**

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM\_IDENT) or an indexed identifier (of type "\_index").

## Return Values

If  $x$  is an indeterminate, then a polynomial of domain type DOM\_POLY is returned. If  $x$  is an arithmetical expression, then the value of the Curtz polynomial at this point is returned as an arithmetical expression. If  $n$  is not a nonnegative integer, then `orthpoly::curtz` returns itself symbolically.

## Algorithms

The Curtz polynomials are given by the recursion formula

$$C(n, x) = x^n + x \left( \sum_{i=1}^{n-1} \frac{(-1)^i}{i+1} C(n-i-1, x) \right) + \frac{(-1)^n}{n+1}$$

with  $C(0, x) = 1$ .

**Purpose** The Gegenbauer (ultraspherical) polynomials

**Syntax** `orthpoly::gegenbauer(n, a, x)`

**Description** `orthpoly::gegenbauer(n, a, x)` computes the value of the  $n$ -th degree Gegenbauer polynomial with parameter  $a$  at the point  $x$ .

Evaluation for real floating-point values  $x$  from the interval  $[-1.0, 1.0]$  is numerically stable. See “Example 2” on page 21-14.

## Examples

### Example 1

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::gegenbauer(2, a, x)
```

```
poly((2 a + 2 a2) x2 - a, [x])
```

```
orthpoly::gegenbauer(3, 2, x[1])
```

```
poly(32 x13 - 12 x1, [x1])
```

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::gegenbauer(2, a, 6*x)
```

```
72 a2 x2 + 72 a x2 - a
```

```
orthpoly::gegenbauer(3, 2, x[1] + 2)
```

# orthpoly::gegenbauer

---

$$32 x_1^3 + 192 x_1^2 + 372 x_1 + 232$$

“Arithmetical expressions” include numbers:

```
orthpoly::gegenbauer(2, a, sqrt(2)),
orthpoly::gegenbauer(3, 0.4, 8 + I),
orthpoly::gegenbauer(1000, -1/3, 0.3)
```

$$4 a^2 + 3 a, 865.536 + 341.152 i, 0.00006046127974$$

If no integer degree is specified, then `orthpoly::gegenbauer` returns itself symbolically:

```
orthpoly::gegenbauer(n, a, x), orthpoly::gegenbauer(1/2, 2, x)
```

$$\text{orthpoly::gegenbauer}(n, a, x), \text{orthpoly::gegenbauer}\left(\frac{1}{2}, 2, x\right)$$

## Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::gegenbauer(200, 4, 0.3)
```

$$165549.7263$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
G200 := orthpoly::gegenbauer(200, 4, x):
```

```
DIGITS := 10: evalp(G200, x = 0.3)
```

- 6.270612376 10<sup>11</sup>

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

DIGITS := 20: evalp(G200, x = 0.3)

165454.59819021060509

delete DIGITS, G200:

## Parameters

**n**

A nonnegative integer: the degree of the polynomial.

**a**

An arithmetical expression.

**x**

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM\_IDENT) or an indexed identifier (of type "\_index").

## Return Values

If x is an indeterminate, then a polynomial of domain type DOM\_POLY is returned. If x is an arithmetical expression, then the value of the Gegenbauer polynomial at this point is returned as an arithmetical expression. If n is not a nonnegative integer, then orthpoly::gegenbauer returns itself symbolically.

## Algorithms

The Gegenbauer polynomials are given by the recursion formula

$$G(n, a, x) = \frac{2(n-1+a)}{n} x G(n-1, a, x) - \frac{n-2+2a}{n} G(n-2, a, x)$$

with  $G(0, a, x) = 1$ ,  $G(1, a, x) = 2ax$ .

For fixed real  $a > -\frac{1}{2}$  these polynomials are orthogonal on the interval  $[-1, 1]$  with respect to the weight function  $W(x) = (1 - x^2)^{a - \frac{1}{2}}$ .

$G(n, \frac{1}{2}, x)$  coincides with the Legendre polynomial  $P(n, x)$ .

$G(n, 1, x)$  coincides with the Chebyshev polynomial  $U(n, x)$  of the second kind.

The polynomials  $G(n, 0, x)$  are trivial.

<b>Purpose</b>	The Hermite polynomials
<b>Syntax</b>	<code>orthpoly::hermite(n, x)</code>
<b>Description</b>	<code>orthpoly::hermite(n,x)</code> computes the value of the $n$ -th degree Hermite polynomial at the point $x$ . These polynomials have integer coefficients.
<b>Examples</b>	<b>Example 1</b> Polynomials of domain type <code>DOM_POLY</code> are returned, if identifiers or indexed identifiers are specified:  <code>orthpoly::hermite(2, x)</code>  <code>poly(4 x<sup>2</sup> - 2, [x])</code>  <code>orthpoly::hermite(3, x[1])</code>  <code>poly(8 x<sub>1</sub><sup>3</sup> - 12 x<sub>1</sub>, [x<sub>1</sub>])</code>  However, using arithmetical expressions as input the “values” of these polynomials are returned:  <code>orthpoly::hermite(2, 6*x)</code>  <code>144 x<sup>2</sup> - 2</code>  <code>orthpoly::hermite(3, x[1] + 2)</code>  <code>8 x<sub>1</sub><sup>3</sup> + 48 x<sub>1</sub><sup>2</sup> + 84 x<sub>1</sub> + 40</code>

# orthpoly::hermite

---

“Arithmetical expressions” include numbers:

```
orthpoly::hermite(2, sqrt(2)), orthpoly::hermite(3, 8 + I),
orthpoly::hermite(1000, 0.3);
```

```
6, 3808 + 1516 i, 2.26821486 101433
```

If no integer degree is specified, then `orthpoly::hermite` returns itself symbolically:

```
orthpoly::hermite(n, x), orthpoly::hermite(1/2, x)
```

```
orthpoly::hermite(n, x), orthpoly::hermite($\frac{1}{2}$, x)
```

## Parameters

**n**

A nonnegative integer: the degree of the polynomial.

**x**

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

## Return Values

If `x` is an indeterminate, then a polynomial of domain type `DOM_POLY` is returned. If `x` is an arithmetical expression, then the value of the Hermite polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::hermite` returns itself symbolically.

## Algorithms

The Hermite polynomials are given by the recursion formula

$$H(n, x) = 2x H(n - 1, x) - 2(n - 1) H(n - 2, x)$$

with  $H(0, x) = 1$  and  $H(1, x) = 2x$ .

These polynomials are orthogonal on the real line with respect to the

weight function  $w(x) = \frac{1}{\sqrt{2}} e^{-x^2}$ .

# orthpoly::jacobi

---

**Purpose** The Jacobi polynomials

**Syntax** `orthpoly::jacobi(n, a, b, x)`

**Description** `orthpoly::jacobi(n, a, b, x)` computes the value of the  $n$ -th degree Jacobi polynomial with parameters  $a$  and  $b$  at the point  $x$ .  
Evaluation for real floating-point values  $x$  from the interval  $[-1.0, 1.0]$  is numerically stable. Cf. “Example 2” on page 21-21.

## Examples **Example 1**

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::jacobi(2, a, b, x)
```

$$\text{poly}\left(\left(\frac{7a}{8} + \frac{7b}{8} + \frac{ab}{4} + \frac{a^2}{8} + \frac{b^2}{8} + \frac{3}{2}\right)x^2 + \left(\frac{3a}{4} - \frac{3b}{4} + \frac{a^2}{4} - \frac{b^2}{4}\right)x - \frac{a}{8} - \frac{b}{8} - \frac{ab}{4} + \frac{a^2}{8} + \frac{b^2}{8}\right)$$

```
orthpoly::jacobi(3, 4, 5, x[1])
```

$$\text{poly}\left(\frac{455x_1^3}{8} - \frac{91x_1^2}{8} - \frac{91x_1}{8} + \frac{7}{8}, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::jacobi(2, 4, b, 6*x)
```

$$\frac{9b^2x^2}{2} - \frac{3b^2x}{2} + \frac{b^2}{8} + \frac{135bx^2}{2} - \frac{9bx}{2} - \frac{9b}{8} + 252x^2 + 42x + 1$$

```
orthpoly::jacobi(2, 0, I, x[1] + 2)
```

$$x_1^2 \left( \frac{11}{8} + \frac{7i}{8} \right) + x_1 \left( \frac{23}{4} + \frac{11i}{4} \right) + \frac{43}{8} + \frac{15i}{8}$$

“Arithmetical expressions” include numbers:

```
orthpoly::jacobi(2, 1/2, -1/2, sqrt(2)),
orthpoly::jacobi(3, 2, 5, 8 + I),
orthpoly::jacobi(1000, 1, 2, 0.3);
```

$$\frac{3\sqrt{2}}{4} + \frac{21}{8}, \frac{31733}{2} + \frac{12859i}{2}, -0.06546648097$$

If no integer degree is specified, then `orthpoly::jacobi` returns itself symbolically:

```
orthpoly::jacobi(n, a, b, x), orthpoly::jacobi(1/2, 0, 1, 1)
```

$$\text{orthpoly::jacobi}(n, a, b, x), \text{orthpoly::jacobi}\left(\frac{1}{2}, 0, 1, 1\right)$$

## Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::jacobi(100, 1/2, 3/2, 0.9)
```

0.2560339406

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
P100 := orthpoly::jacobi(100, 1/2, 3/2, x):
```

# orthpoly::jacobi

---

```
evalp(P100, x = 0.9)
```

```
- 8.6781052 1015
```

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 30: evalp(P100, x = 0.9)
```

```
0.256030968488207303016930946513
```

```
delete P100, DIGITS:
```

## Parameters

**n**

A nonnegative integer: the degree of the polynomial.

**a, b**

Arithmetical expressions.

**x**

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM\_IDENT) or an indexed identifier (of type "\_index").

## Return Values

If  $x$  is an indeterminate, then a polynomial of domain type DOM\_POLY is returned. If  $x$  is an arithmetical expression, then the value of the Jacobi polynomial at this point is returned as an arithmetical expression. If  $n$  is not a nonnegative integer, then `orthpoly::jacobi` returns itself symbolically.

## Algorithms

The Jacobi polynomials are given by the recursion formula

$$2n c_n c_{2n-2} P(n, a, b, x) = c_{2n-1} \left( c_{2n-2} c_{2n} x + a^2 - b^2 \right) P(n-1, a, b, x) - 2(n-1+a)(n-1+b) c_{2n} P(n-2, a, b, x)$$

with  $c_i = i + a + b$  and

$$P(0, a, b, x) = 1, P(1, a, b, x) = \frac{a-b}{2} + \left( 1 + \frac{a+b}{2} \right) x$$

For fixed real  $a > -1$ ,  $b > -1$  the Jacobi polynomials are orthogonal on the interval  $[-1, 1]$  with respect to the weight function  $w(x) = (1-x)^a(1+x)^b$ .

For special values of the parameters  $a, b$  the Jacobi polynomials are related to the Legendre polynomials

$$P(n, x) = P(n, 0, 0, x)$$

to the Chebyshev polynomials of the first kind

$$T(n, x) = \frac{2^{2n} n!^2}{(2n)!} P\left(n, -\frac{1}{2}, -\frac{1}{2}, x\right)$$

to the Chebyshev polynomials of the second kind

$$U(n, x) = \frac{2^{2n} n! (n+1)!}{(2n+1)!} P\left(n, \frac{1}{2}, \frac{1}{2}, x\right)$$

and to the Gegenbauer polynomials, respectively:

## orthpoly::jacobi

---

$$G(n, a, x) = \frac{\Gamma(a + \frac{1}{2}) \Gamma(n + 2a)}{\Gamma(2a) \Gamma(n + a + \frac{1}{2})} P\left(n, a - \frac{1}{2}, a - \frac{1}{2}, x\right)$$

### See Also

### MuPAD Functions

orthpoly::chebyshev1 | orthpoly::chebyshev2 |  
orthpoly::gegenbauer | orthpoly::legendre

**Purpose** The (generalized) Laguerre polynomials

**Syntax** `orthpoly::laguerre(n, a, x)`

**Description** `orthpoly::laguerre(n, a, x)` computes the value of the generalized  $n$ -th degree Laguerre polynomial with parameter  $a$  at the point  $x$ .

The standard Laguerre polynomials correspond to  $a = 0$ . They have rational coefficients.

**Examples** **Example 1**

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

`orthpoly::laguerre(2, a, x)`

$$\text{poly}\left(\frac{x^2}{2} + (-a - 2)x + \frac{3a}{2} + \frac{a^2}{2} + 1, [x]\right)$$

`orthpoly::laguerre(3, a, x[1])`

$$\text{poly}\left(-\frac{x_1^3}{6} + \left(\frac{a}{2} + \frac{3}{2}\right)x_1^2 + \left(-\frac{5a}{2} - \frac{a^2}{2} - 3\right)x_1 + \frac{11a}{6} + a^2 + \frac{a^3}{6} + 1, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

`orthpoly::laguerre(2, 4, 6*x)`

$$18x^2 - 36x + 15$$

`orthpoly::laguerre(2, 2/3*I, x[1] + 2)`

# orthpoly::laguerre

---

$$\frac{x_1^2}{2} - \frac{2x_1 i}{3} - \frac{11}{9} - \frac{i}{3}$$

“Arithmetical expressions” include numbers:

```
orthpoly::laguerre(2, a, sqrt(2)),
orthpoly::laguerre(3, 0.4, 8 + I),
orthpoly::laguerre(1000, 3, 0.3);
```

$$\frac{3a}{2} - \sqrt{2}a - 2\sqrt{2} + \frac{a^2}{2} + 2, -4.969333333 - 8.713333333i, -15691.69498$$

If no integer degree is specified, then `orthpoly::laguerre` returns itself symbolically:

```
orthpoly::laguerre(n, a, x), orthpoly::laguerre(1/2, a, x)
```

$$\text{orthpoly::laguerre}(n, a, x), \text{orthpoly::laguerre}\left(\frac{1}{2}, a, x\right)$$

## Parameters

**n**

A nonnegative integer: the degree of the polynomial.

**a**

An arithmetical expression.

**x**

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

## Return Values

If  $x$  is an indeterminate, then a polynomial of domain type `DOM_POLY` is returned. If  $x$  is an arithmetical expression, then the value of the Laguerre polynomial at this point is returned as an arithmetical expression. If  $n$  is not a nonnegative integer, then `orthpoly::laguerre` returns itself symbolically.

## Algorithms

The Laguerre polynomials are given by the recursion formula

$$L(n, a, x) = \frac{2n + a - 1 - x}{n} L(n - 1, a, x) - \frac{n + a - 1}{n} L(n - 2, a, x)$$

with  $L(0, a, x) = 1$  and  $L(1, a, x) = 1 + a - x$ .

For fixed real  $a > -1$  these polynomials are orthogonal on the interval

$[0, \infty)$  with respect to the weight function  $w(x) = \frac{1}{(x^a e)^x}$ .

# orthpoly::legendre

---

**Purpose** The Legendre polynomials

**Syntax** `orthpoly::legendre(n, x)`

**Description** `orthpoly::legendre(n, x)` computes the value of the  $n$ -th degree Legendre polynomial at the point  $x$ .

These polynomials have rational coefficients.

Evaluation for real floating-point values  $x$  from the interval  $[-1.0, 1.0]$  is numerically stable. Cf. “Example 2” on page 21-29.

Use `numeric::gldata` to compute the roots of the Legendre polynomials. Cf. “Example 3” on page 21-30.

## Examples

### Example 1

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::legendre(2, x)
```

$$\text{poly}\left(\frac{3x^2}{2} - \frac{1}{2}, [x]\right)$$

```
orthpoly::legendre(3, x[1])
```

$$\text{poly}\left(\frac{5x_1^3}{2} - \frac{3x_1}{2}, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::legendre(2, 6*x)
```

$$54 x^2 - \frac{1}{2}$$

```
orthpoly::legendre(3, x[1] + 2)
```

$$\frac{5 x_1^3}{2} + 15 x_1^2 + \frac{57 x_1}{2} + 17$$

“Arithmetical expressions” include numbers:

```
orthpoly::legendre(2, sqrt(2)), orthpoly::legendre(3, 8 + I),
orthpoly::legendre(1000, 0.3)
```

$$\frac{5}{2}, 1208 + 476 i, -0.02566916751$$

If no integer degree is specified, then `orthpoly::legendre` returns itself symbolically:

```
orthpoly::legendre(n, x), orthpoly::legendre(1/2, x)
```

$$\text{orthpoly::legendre}(n, x), \text{orthpoly::legendre}\left(\frac{1}{2}, x\right)$$

## Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::legendre(100, 0.9)
```

$$0.1022658206$$

## orthpoly::legendre

---

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
P100 := orthpoly::legendre(100, x):
evalp(P100, x = 0.9)
```

```
8.284745953 1014
```

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 30: evalp(P100, x = 0.9)
```

```
0.102276303910546875548266967112
```

```
delete P100, DIGITS:
```

### Example 3

We recommend to use `numeric::gldata` for computing roots of the Legendre polynomial  $P(n, x)$ . This routine provides all roots of the function  $Q(n, y) = P(n, 2y - 1)$ :

```
QRoots := numeric::gldata(5, DIGITS)[2]
```

```
[0.04691007703, 0.2307653449, $\frac{1}{2}$, 0.7692346551, 0.953089923]
```

These values are easily transformed to roots of  $P(n, x)$ :

```
PRoots := map(QRoots, y -> 2*y - 1)
```

```
[- 0.9061798459, - 0.5384693101, 0, 0.5384693101, 0.9061798459]
```

```
orthpoly::legendre(5, r) $ r in PRoots
```

```
- 1.080385781 10-14, - 1.387778781 10-18, 0, 1.387778781 10-18, 1.081218448 10-14
```

```
delete QRoots, PRoots:
```

## Parameters

**n**

A nonnegative integer: the degree of the polynomial.

**x**

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

## Return Values

If `x` is an indeterminate, then a polynomial of domain type `DOM_POLY` is returned. If `x` is an arithmetical expression, then the value of the Legendre polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::legendre` returns itself symbolically.

## Algorithms

The Legendre polynomials are given by  $P(n, x) = \frac{1}{2^n n!} \frac{d^n}{dx^n} (x^2 - 1)^n$ . They satisfy the recursion formula

$$P(n, x) = \frac{2n-1}{n} x P(n-1, x) - \frac{n-1}{n} P(n-2, x)$$

with  $P(0, x) = 1$  and  $P(1, x) = x$ .

## orthpoly::legendre

---

They are orthogonal on the interval  $[-1, 1]$  with respect to the weight function  $w(x) = 1$ .

$P(n, x)$  coincides with the Gegenbauer polynomial  $G(n, \frac{1}{2}, x)$ .

$P(n, x)$  coincides with the Jacobi polynomial  $P(n, 0, 0, x)$ .

output::ordinal  
output::roman  
output::subexpr  
output::tableForm  
output::tree

# output::asciiAbbreviate

**Purpose** Generates a procedure for creating an ASCII formatted output

**Syntax** `output::asciiAbbreviate(<varname>)`

**Description** `output::asciiAbbreviate` generates a procedure for creating ASCII formatted outputs of expressions

By default, MuPAD generates ASCII abbreviations using the # symbol followed by numbers. Using the argument `varname` you can customize the names of abbreviated subexpressions. See “Example 2” on page 22-3.

If you want to use abbreviations in all ASCII PrettyPrint output expressions, pass the procedure generated by `output::asciiAbbreviate` to `Pref::output`. See “Example 3” on page 22-3.

## Examples Example 1

The generated procedure `ascii` produces ASCII code for MuPAD expressions:

```
ascii:=output::asciiAbbreviate():
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
ascii(y)
```

$$\left\{ \begin{array}{l} \left\{ \frac{1}{3} \sqrt[3]{\frac{1}{2} \sqrt{\frac{1}{3}} + \frac{1}{3}} + \sqrt[3]{\frac{1}{2} \sqrt{\frac{1}{3}} - \frac{1}{3}} \right\} \\ \left\{ \frac{1}{3} \sqrt[3]{\frac{1}{2} \sqrt{\frac{1}{3}} + \frac{1}{3}} - \sqrt[3]{\frac{1}{2} \sqrt{\frac{1}{3}} - \frac{1}{3}} \right\} \\ \left\{ \frac{1}{3} \sqrt[3]{\frac{1}{2} \sqrt{\frac{1}{3}} + \frac{1}{3}} - \sqrt[3]{\frac{1}{2} \sqrt{\frac{1}{3}} + \frac{1}{3}} \right\} \end{array} \right.$$

where

$$\#1 = \begin{array}{l} / \quad 1/2 \quad 1/2 \quad \backslash 1/3 \\ | \quad 31 \quad 108 \quad 1 \quad | \\ \backslash \quad 108 \quad 2 \quad / \end{array}$$

## Example 2

You can customize the names of abbreviated subexpressions:

```
ascii:=output::asciiAbbreviate(t):
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
ascii(y)
```

$$\left\{ \left\{ \frac{1}{3} \sqrt[3]{\frac{1}{3} \sqrt{\frac{1}{3} + t_1}} + t_1 \sqrt[3]{\frac{1}{3} \sqrt{\frac{1}{3} + t_1}} \right\}, \frac{1}{6} \sqrt[3]{\frac{1}{3} + t_1} \sqrt[3]{\frac{1}{3} + t_1} + \frac{1}{6} \sqrt[3]{\frac{1}{3} + t_1} \sqrt[3]{\frac{1}{3} + t_1} \right\}$$

where

$$t_1 = \frac{\sqrt[3]{31} \sqrt[3]{108} \sqrt[3]{108} \sqrt[3]{2}}{\sqrt[3]{108} \sqrt[3]{2}}$$

## Example 3

The generated procedure can serve as an input for Pref::output:

```
Pref::output(output::asciiAbbreviate(u)):
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3)
```

$$\left\{ \left\{ \frac{1}{3} \sqrt[3]{\frac{1}{3} \sqrt{\frac{1}{3} + u_1}} + u_1 \sqrt[3]{\frac{1}{3} \sqrt{\frac{1}{3} + u_1}} \right\}, \frac{1}{6} \sqrt[3]{\frac{1}{3} + u_1} \sqrt[3]{\frac{1}{3} + u_1} + \frac{1}{6} \sqrt[3]{\frac{1}{3} + u_1} \sqrt[3]{\frac{1}{3} + u_1} \right\}$$

# output::asciiAbbreviate

---

where

$$u1 = \begin{array}{|c|} \hline / \quad 1/2 \quad 1/2 \quad \backslash 1/3 \\ | \quad 31 \quad 108 \quad 1 \quad | \\ | \quad \text{-----} \quad - \quad - \quad | \\ \backslash \quad 108 \quad 2 \quad / \\ \hline \end{array}$$

## Parameters

**varname**

A base name for the abbreviation variables

## Return Values

Procedure for creating an ASCII formatted output

## See Also

## MuPAD Functions

output::subexpr | Pref::abbreviateOutput | Pref::output

<b>Purpose</b>	Put delimiters around multi-line strings
<b>Syntax</b>	<code>output::fence(left, right, string, &lt;width, &lt;base&gt;&gt;)</code>
<b>Description</b>	<code>output::fence(l, r, str)</code> encloses the multi-line string in the delimiters indicated by <code>l</code> and <code>r</code>  <code>output::fence</code> , in combination with <code>strprint</code> , can be used for overloading <code>print</code> (and thereby, standard screen output) for “pretty-printing”. (Note: This will not affect “Typesetting” output.)

## Examples **Example 1**

For all examples on this page we assume the `TEXTWIDTH 75`:

```
TEXTWIDTH := 75:
```

Since useful examples are more complicated, we present the effect of `output::fence` with some more-or-less random garbage. First, we define a domain that uses `output::fence` for output:

```
domain Fence
 print := x -> output::fence("(", ")", extop(x, 1));
 new := x -> new(dom, x);
end_domain:
```

`Fence` expects a string in its constructor and we defined the output to use `output::fence` to put parentheses around the input:

```
print(Plain, Fence("abc"))
```

```
(abc)
```

Strings of height two are only partly placed inside parentheses, for consistency with the pretty-printer:

## output::fence

---

```
print(Plain, Fence("abc\ndef"), sin(x^2))
```

```
abc 2
(def), sin(x)
```

Strings of height more than two are fully bracketed:

```
print(Plain, Fence("abc\ndef\nghi"))
```

```
/ abc \
| def |
\ ghi /
```

### Example 2

The next step in using `output::fence` is to enclose expressions in parentheses. For this, the information from `strprint` is useful:

```
domain FenceExpr
 print := proc(x)
 local str, h1, w1, h, w, b;
 begin
 [str, h1, w1, h, w, b] := strprint(All, extop(x));
 output::fence("{", "}", str, w, b);
 end_proc;
 new := x -> new(dom, x);
end_domain:

print(Plain, FenceExpr(x), FenceExpr(x^2), FenceExpr(x^2/2*y))
```

```
 { 2 --
 2 { x y |
{x], {x], { ---- |
```

```
{ 2 --
```

As you can see, the sixth operand of the return value of `strprint(All, )` should be given to `output::fence` to get nicely aligned baselines.

### Example 3

The non-typeset screen output of `abs` is as follows:

```
print(Plain, abs(x), abs(x^y), abs((x/y)^z))
```

```
|x|, |y|, |x|, |y|, |x|, |y|, |x|, |y|
|x|, |x|, |x|, |x|, |x|, |x|, |x|, |x|
|\y/ |y/ |y/ |y/ |y/ |y/ |y/ |y/
```

The code responsible for this output is the second operand of the `absfunction` environment:

```
expose(op(abs, 2))

proc(ex)
 local str;
begin
 if PRETTYPRINT then
 str := strprint(All, op(ex));
 if str[1] <> "" and str[2] = str[4] then
 if str[1][1] = "\n" then
 str[1] := str[1][2..-1];
 str[6] := str[6] - 1
 else
 if str[1][1..2] = "\r\n" then
 str[1] := str[1][3..-1];
 str[6] := str[6] - 1
 end_if
 end_if
 end_if
 end_if
end
```

## output::fence

---

```
 end_if;
 output::fence("|", "|", str[1], str[3], str[6])
 else
 FAIL
 end_if
else
 FAIL
end_if
end_proc
```

There are two differences to what we have done in the example above: First, the code reacts to PRETTYPRINT. This is because with PRETTYPRINT = FALSE, the abs function shall be printed in functional notation:

```
PRETTYPRINT := FALSE:
print(Plain, abs(x));
delete PRETTYPRINT:
```

```
abs(x)
```

The second difference is more subtle: strprint reacts to TEXTWIDTH and may return a string consisting of more than one logical line. In this case, fencing the returned string leads to strange results:

```
print(Plain, FenceExpr(_plus(x.i $ i = 0..30)))
```

```
{ x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9 + x10 + x11 + x12
+ --
{
 |
{ x14 + x15 + x16 + x17 + x18 + x19 + x20 + x21 + x22 + x23 + x2
+ |
{
```

```
{ |
 x26 + x27 + x28 + x29 + x30
 --
```

Apart from the fact that the string with added delimiter symbols is too wide for TEXTWIDTH, drawing large delimiters to the left and the right of the long string is hardly the right thing to do. `output::fence` does not offer a way to handle line breaks gracefully (which should not be done on formatted strings in any case and is outside the regime of `output::fence`), and for `abs` it would be a highly questionable thing to do. Therefore, `abs` will print in functional notation for long arguments:

```
print(Plain, abs(_plus(x.i $ i = 0..30)))
```

```
abs(x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9 + x10 + x11
 x13 + x14 + x15 + x16 + x17 + x18 + x19 + x20 + x21 + x22 + x
 x25 + x26 + x27 + x28 + x29 + x30)
```

## Parameters

### left, right

Strings indicating the type of delimiter: "(", ")", "[", "]", "[+", "+]", "{", "}", "|", "| ", or " |".

### string

The string to enclose

### width

The width of the string to enclose. Defaults to the width of the widest line in `string`.

### base

## output::fence

---

The baseline of the string, counted from the first line. Defaults to the bottom line of the string. If set to -1, the baseline is vertically centered.

### **Return Values**

String

### **See Also**

### **MuPAD Functions**

strprint

**Purpose** Pretty output of text combined with formulas

**Syntax** `output::mathText(str1, expr1, <str2, <expr2>, >)`

**Description** `output::mathText( str1, expr1, str2, )` creates an object of combined strings and expressions. This object prints itself nicely in various output formats.

## Examples **Example 1**

`output::mathText` creates an object representing combined text and formulas:

```
messageWithMath := output::mathText("The integral ",
 hold(int(sin(x)*cos(x), x)),
 " is equal to ", int(sin(x)*cos(x)),
```

The integral  $\int \cos(x) \sin(x) dx$  is equal to  $\frac{\sin(x)^2}{2}$

They can be printed with the ASCII pretty-printer as well:

```
print(Plain, messageWithMath)
```

The integral  $\int \sin(x) \cos(x) dx$  is equal to  $\frac{\sin(x)^2}{2}$

Same for the ASCII lineprint output:

```
PRETTYPRINT := FALSE:
print(Plain, messageWithMath):
delete PRETTYPRINT:
```

## output::mathText

---

The integral `int(sin(x)*cos(x), x)` is equal to `(1/2)*sin(x)^2`

### Parameters

`str1`, `str2`

Strings

`expr1`, `expr2`

Expressions

### Return Values

Object of type `output::mathText`

### See Also

### MuPAD Functions

`strprint`

**Purpose** Ordinal numbers

**Syntax** `output::ordinal(i)`

**Description** `output::ordinal` converts an integer to the corresponding english ordinal number. The return value is a string and can be used in messages.

**Examples** **Example 1**

Convert some numbers to the corresponding english ordinal string:

```
map([0, 1, 2, 3, 4, 22, 134, 2001], output::ordinal)
```

```
["0th", "1st", "2nd", "3rd", "4th", "22nd", "134th", "2001st"]
```

**Parameters** **i**  
An integer number

**Return Values** String with the English ordinal number

**See Also**

**MuPAD Functions** `info` | `print`

## output::roman

---

**Purpose** Roman numerals

**Syntax** `output::roman(n)`

**Description** `output::roman` converts an integer to the corresponding roman numeral. The return value is a string and can be used in messages.

### **Examples** **Example 1**

Convert some numbers to the corresponding roman numerals:

```
map([1, 2, 3, 4, 22, 134, 2001], output::roman)
```

```
["I", "II", "III", "IV", "XXII", "CXXXIV", "MMI"]
```

Now, thanks to alias backsubstitution, we can trick MuPAD into computing with roman numerals:

```
alias(`I`=1): // I is a reserved word in MuPAD, so we use `I` instead
for i from 2 to 1000 do
 eval(text2expr("alias(".output::roman(i)."]=" .expr2text(i).)");")
end_for:
II+II;
XIII*XXIV
```

```
IV
```

```
CCCXII
```

```
unalias(`I`):
for i from 2 to 1000 do
 eval(text2expr("unalias(".output::roman(i).)");");
end_for:
```

**Parameters**    **n**  
Positive integer

**Return Values**    String containing the roman numeral

**See Also**

**MuPAD Functions**    `info` | `print`

# output::subexpr

**Purpose** Abbreviates a expression

**Syntax** `output::subexpr(e, <varname>)`

**Description** `output::subexpr` rewrites symbolic expression in terms of common subexpressions.

If an expression `e` contains common subexpressions, `output::subexpr(e)` returns a list that contains the abbreviated expression and the abbreviations in a form of equations. With `output::subexpr` you get the same abbreviations as you see in the outputs. See “Example 1” on page 22-16.

An output of this command does not depend on the current setting of `Pref::abbreviateOutput`.

By default, MuPAD generates abbreviations using the # symbol followed by numbers. Using the argument `varname`, you can customize the names of abbreviated subexpressions. See “Example 2” on page 22-16.

## Examples

### Example 1

You can abbreviate an expression:

```
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
output::subexpr(y)
```

$$\left[ \left\{ \#_1 - \frac{1}{3 \#_1}, \frac{1}{6 \#_1} - \frac{\#_1}{2} + \frac{\sqrt{3} \left( \frac{1}{3 \#_1} + \#_1 \right) i}{2}, \frac{1}{6 \#_1} - \frac{\#_1}{2} - \frac{\sqrt{3} \left( \frac{1}{3 \#_1} + \#_1 \right) i}{2} \right\}, \#_1 = \left( \frac{\sqrt{31} \sqrt{108}}{108} \right) \right]$$

### Example 2

You can customize the names of abbreviated subexpressions:

```
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
output::subexpr(y, t)
```

$$\left[ \left\{ t1 - \frac{1}{3 t1}, \frac{1}{6 t1} - \frac{t1}{2} - \frac{\sqrt{3} \left( \frac{1}{3 t1} + t1 \right) i}{2}, \frac{1}{6 t1} - \frac{t1}{2} + \frac{\sqrt{3} \left( \frac{1}{3 t1} + t1 \right) i}{2} \right\}, t1 = \left( \frac{\sqrt{31} \sqrt{108}}{108} - \frac{1}{2} \right) \right]$$

**Parameters****e**

A MuPAD expression

**varname**

A base name for the abbreviation variables

**Return  
Values**

List that contains the abbreviated expression and the abbreviations as equations

**See Also****MuPAD  
Functions**

Pref::abbreviateOutput | output::asciiAbbreviate

# output::tableForm

---

**Purpose** Printing objects in table form

**Syntax** `output::tableForm(obj, <separator>, options)`

**Description** `output::tableForm(obj)` prints the elements of the given object `obj` in table form.

The width of the table and the number of columns depends on the size of `TEXTWIDTH` (see options `Width` and `Columns`). The width of a column depends on the widest entry in this column.

`output::tableForm` determines the number of columns, that the total width of the table fits into `TEXTWIDTH`.

The columns are separated by one space by default.

If `separator` is given, then it is printed between each column (instead of one space). Appending spaces to the separator results additionally space between columns. By default the separator is one space.

If the first argument `obj` is a table or a domain, `output::tableForm` uses the option `Columns = 2` (two columns) and the separator `"= "` as default.

Without the option `Sort` the objects are converted to strings and then sorted alphabetically. To avoid any sorting the option `Sort = FALSE` must be given.

## Examples

### Example 1

For all examples on this page we assume the `TEXTWIDTH 75`:

```
TEXTWIDTH := 75:
```

Print some random numbers in table form:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30])
```

```
11647 12826 26280 26292 28315 30908 36523 42073 4682 47334 52640 5
```

```
5829 615 62580 65904 66223 6719 69451 69903 77904 78221 80528
86068 89016 90516 91008 92791 9532
```

Some random strings are created. The columns should have all the same width (Unique) and be printed centered. The strings should not be sorted:

```
output::tableForm([_concat("*" $ random(10)()) $ k = 1..20],
 Unique, Center, Sort = FALSE)
```

```
"*****" "*****" "*****" "*****" " " "*****"
"*****" "*****" "*****" "*****" "*****" "*****"
"*****" "*****" "*****" "*****" "*****" "*****"
```

The option Unquoted prevents printing of quotes (see fprint):

```
output::tableForm([_concat("*" $ random(10)()) $ k = 1..20],
 Unique, Center, Sort = FALSE, Unquoted)
```

```
***** * ***** ***** ***** ***** ** *
***** * ***** ***** ** ***** ***** *
* *****
```

## Example 2

The next object is a MuPAD table and should be printed as a table with two columns. The table contains some random numbers and their sum of the digits:

```
SEED := -1:
T := table(op(map([random(10000000)() $ k = 1..10],
 proc(X)
 local Xs, k;
```

## output::tableForm

---

```
begin
 Xs := expr2text(X);
 X = _plus(text2expr(substring(Xs, k))
 $ k = 1..length(Xs))
end_proc)):
output::tableForm(T)
```

19962580 = 40

25878221 = 35

37777904 = 44

41281013 = 20

43856426 = 38

46169451 = 36

66926292 = 42

80330908 = 31

89306719 = 43

94386068 = 44

Domains are also printed in this form by default:

```
output::tableForm(newDomain("Test",
 table("type" = "Test",
 "info" = "only a testdomain")))
```

"info" = "only a testdomain"

"key" = "Test"

```
"type" = "Test"
```

### Example 3

The next table should consist of four columns:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], Columns = 4)
```

```
11647 12826 26280 26292
```

```
28315 30908 36523 42073
```

```
4682 47334 52640 56426
```

```
5829 615 62580 65904
```

```
66223 6719 69451 69903
```

```
77904 78221 80528 81013
```

```
86068 89016 90516 91008
```

```
92791 9532
```

The next table should have a maximal width of 50 characters:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], Width = 50)
```

```
11647 12826 26280 26292 28315 30908 36523 42073
```

```
4682 47334 52640 56426 5829 615 62580 65904
```

```
66223 6719 69451 69903 77904 78221 80528 81013
```

```
86068 89016 90516 91008 92791 9532
```

# output::tableForm

---

delete T:

## Example 4

The next examples show different usage of separators. First one single separator:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], "|")

11647|12826|26280|26292|28315|30908|36523|42073|4682 |47334|52640|5
5829|615 |62580|65904|66223|6719 |69451|69903|77904|78221|80528|81
86068|89016|90516|91008|92791|9532
```

Now a list with a separator character between each column. If the list is too short, the characters are used from beginning of the list again etc.:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], ["|", " ", " "])

11647|12826 26280 26292|28315 30908 36523|42073 4682 47334|52640 5
5829|615 62580 65904|66223 6719 69451|69903 77904 78221|80528 81
86068|89016 90516 91008|92791 9532
```

Only the first both columns should be separated by a vertical line:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], ["|", " " $ 10])

11647|12826 26280 26292 28315 30908 36523 42073 4682 47334 52640 5
5829|615 62580 65904 66223 6719 69451 69903 77904 78221 80528 81
86068|89016 90516 91008 92791 9532
```

Additionally a character can be appended to each entry:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
 ["|", " " $ 10], Append = ",")

11647,|12826, 26280, 26292, 28315, 30908, 36523, 42073, 4682, 4
56426,|5829, 615, 62580, 65904, 66223, 6719, 69451, 69903, 7
80528,|81013, 86068, 89016, 90516, 91008, 92791, 9532,
```

## Example 5

The next examples show different usage of sorting. Without the option Sort the numbers are sorted as strings in lexicographical order:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30])

11647 12826 26280 26292 28315 30908 36523 42073 4682 47334 5264
5829 615 62580 65904 66223 6719 69451 69903 77904 78221 80528
86068 89016 90516 91008 92791 9532
```

Sort = FALSE avoids any sorting:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], Sort = FALSE)

30908 6719 26292 56426 81013 69451 77904 78221 86068 62580 4733
9532 5829 28315 65904 42073 80528 4682 52640 69903 92791 36523
89016 91008 615 66223 90516 11647
```

## output::tableForm

---

Any sorting can be done with a special defined procedure, e.g., sort the numbers in reverse order:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
 Sort = ((X,Y) -> Y < X))
```

```
92791 91008 90516 89016 86068 81013 80528 78221 77904 69903 69451 6
65904 62580 56426 52640 47334 42073 36523 30908 28315 26292 26280 1
11647 9532 6719 5829 4682 615
```

At last a user defined procedure is given that sorts the numbers by the sum of their digits ascending:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
 Sort = proc(X,Y)
 local crossfoot;
 begin
 crossfoot :=
 proc(X)
 local Xs, k;
 begin
 Xs := expr2text(X);
 _plus(text2expr(substring(Xs, k))
 $ k = 1..length(Xs))
 end_proc;
 crossfoot(X) < crossfoot(Y)
 end_proc)
```

```
615 81013 42073 52640 91008 26280 36523 11647 12826 66223 9532 283
30908 4682 78221 26292 90516 47334 62580 56426 80528 6719 5829 65
89016 69451 77904 69903 92791 86068
```

## Parameters

### **obj**

A list, set or table of any MuPAD objects or a domain

### **separator**

A string between columns

## Options

### **Unquoted**

Strings are printed without quotes

The output function `fprint` is called with the option `Unquoted`.

### **Unique**

All columns are of the same width

All columns are printed with the same width, the widest column determines the width of each column.

### **Width**

Option, specified as `Width = w`

The maximal width of the table is set to `w` (instead of `TEXTWIDTH`).  
`w` must be a positive integer.

### **Columns**

Option, specified as `Columns = c`

The number of columns is set to `c`. The width of the table depends on the width of any column.

---

**Note** `output::tableForm` called with this option takes not care about the value of `TEXTWIDTH`.

---

`c` must be a positive integer.

### **Center, Left, Right**

# output::tableForm

---

The entries of each column are aligned left-justified, centered or justified.

## Sort

Option, specified as `Sort = procedure`

The entries are sorted with the given procedure. Entries can be printed unsorted, when procedure is the object `FALSE`.

## Output

Option, specified as `Output = file`

Output into a file. If `file` is a string, a file named `file` is opened and overwritten and closed after writing. If `file` is a file descriptor (the return value of `fopen`), the table is appended to `file` without closing `file`.

## String

Return as a string that can be printed

The string contains line breaks, and can be printed with `print` or `fprint` and option `Unquoted`.

## Append

Option, specified as `Append = string`

Character string is appended to each entry of the list

## Return Values

Void object `null()`

## See Also

## MuPAD Functions

`output::tree` | `print` | `fopen` | `fprint` | `fclose` | `sort`

**Purpose**

Display of trees

**Syntax**

`output::tree(Tree, <indentdepth, <charlist>, <Small>>)`

**Description**

`output::tree` displays trees given as specially MuPAD lists.

The first object of the list is the root of the tree. All further objects are nodes or subtrees of the tree. A subtree is again a special list (as described), and any other MuPAD object will be interpreted as node of the tree.

The elements of the tree will be printed by MuPAD, when the tree will be displayed, so it's recommended to use strings as objects or objects with a well defined display.

The return value is a string that contains all chars to display the tree. With functions `print` and `fprint` and the option `Unquoted` the tree can be displayed.

The parameter `charlist` is a list with five characters. The default value is `["|", "+", "-", " ", " "]`. The characters have the following meaning (described in the order of the list).

The vertical lines of the tree, the connection between vertical and horizontal line (i.e., an arm, but not the last arm), an arm (vertical line), the last connection to an arm in a subtree, a char between an arm and the description of the arm.

**Examples**

**Example 1**

`output::tree` displays special nested lists as trees:

```
TREE := ["a1", "a2", ["b1", "b2", ["c1", "c2"], "b3"],
 ["d1", "d2", "d3"]]:
print(Unquoted, output::tree(TREE))
```

```
a1
|
+-- a2
```

## output::tree

---

```
|
+-- b1
| |
| +-- b2
| |
| +-- c1
| | |
| | \-- c2
| |
| \-- b3
|-- d1
| |
| +-- d2
| |
| \-- d3
```

```
print(Unquoted, output::tree(TREE, 3, Small)):
```

```
a1
+- a2
+- b1
| +- b2
| +- c1
| | \-- c2
| \-- b3
\-- d1
 +- d2
 \-- d3
```

The chars can be defined by the user:

```
print(Unquoted, output::tree(TREE, 6, ["|", "|", ".", "\\", " "])):
```

```

a1
|
|..... a2
|
|..... b1
| |
| |..... b2
| |
| |..... c1
| |
| |..... c2
| \
| \..... b3
|
\..... d1
|
|..... d2
|
\..... d3

```

**Parameters****Tree**

The tree, given as a special list

**indentdepth**

Indent depth for each subtree

**charlist**

The chars that illustrate the tree structure

**Options****Small**

Suppresses the display of a space line between every tree entry to reduce the height of the tree

## output::tree

---

### **Return Values**

String object to display

### **See Also**

### **MuPAD Functions**

`adt::Tree` | `prog::exprlist` | `prog::exptree`

# RGB::ColorNames

---

**Purpose** Find predefined colors by name

**Syntax** `RGB::ColorNames()`  
`RGB::ColorNames(subname)`

**Description** `RGB::ColorNames(str)` returns a list of names of colors in the RGB name space whose names contain `str`.  
`RGB::ColorNames` goes through the list of predefined color names and returns those whose names contain the string or identifier given as input, if any.

**Environment Interactions** `RGB::plotColorPalette` plots a list of color samples with names.

## **Examples** **Example 1**

The following call returns all predefined color names containing “Olive”:

```
RGB::ColorNames("Olive")
```

```
[Olive, OliveDrab, OliveGreen, OliveGreenDark]
```

The RGB values of these colors are:

```
RGB::Olive, RGB::OliveDrab, RGB::OliveGreen,
RGB::OliveGreenDark
```

```
[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0],
[0.333293, 0.419599, 0.184301]
```

## **Example 2**

The following call plots all predefined colors containing “Olive”:

```
RGB::plotColorPalette("Olive")
```

When the list of colors found gets larger, they are distributed over more lines:

```
RGB::plotColorPalette("Blue")
```

# RGB::ColorNames

---

## Colors containing 'Blue'

## Parameters

**subname**

A part of a color name: a string or an identifier

## Return Values

RGB::ColorNames returns a list of predefined color names.

RGB::plotColorPalette returns the empty object, null().

## See Also

## MuPAD Functions

RGB::plotColorPalette

# RGB::plotColorPalette

---

**Purpose** Display predefined colors

**Syntax** `RGB::plotColorPalette(subname)`

**Description** `RGB::plotColorPalette(str)` displays the colors in the RGB name space whose names contain `str`.  
`RGB::plotColorPalette` uses `RGB::ColorNames` and plots samples of the colors found by this routine, in tabular fashion.

**Environment Interactions** `RGB::plotColorPalette` plots a list of color samples with names.

## Examples **Example 1**

The following call returns all predefined color names containing “Olive”:

```
RGB::ColorNames("Olive")
```

```
[Olive, OliveDrab, OliveGreen, OliveGreenDark]
```

The RGB values of these colors are:

```
RGB::Olive, RGB::OliveDrab, RGB::OliveGreen,
RGB::OliveGreenDark
```

```
[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0],
[0.333293, 0.419599, 0.184301]
```

## **Example 2**

The following call plots all predefined colors containing “Olive”:

```
RGB::plotColorPalette("Olive")
```

When the list of colors found gets larger, they are distributed over more lines:

```
RGB::plotColorPalette("Blue")
```

# RGB::plotColorPalette

Colors containing 'Blue'

## Parameters

**subname**

A part of a color name: a string or an identifier

## Return Values

RGB::ColorNames returns a list of predefined color names.  
RGB::plotColorPalette returns the empty object, null().

## See Also

## MuPAD Functions

RGB::ColorNames

# RGB::colorName

---

**Purpose** Find names of predefined colors

**Syntax** `RGB::colorName(rgb, <Exact>)`

**Description** `RGB::colorName([r, g, b])` looks for the predefined color with values closest to [r, g, b] and returns its name.

`RGB::colorName([r, g, b], Exact)` looks for a predefined color with values exactly [r, g, b] and returns its name.

The RGB namespace contains predefined color names, accessible as `RGB::Blue` etc. `RGB::colorName` performs a reverse lookup, finding the name of a color given as RGB values.

Since rather often, colors will stem from calculations with floating-point numbers, no exact matches can be expected in this reverse lookup. Therefore, by default, `RGB::colorName` will perform a “fuzzy” search, returning the predefined color which is closest (in Euclidean distance in RGB space) to the input. Cf. “Example 2” on page 23-18.

## Examples

### Example 1

`RGB::colorName` returns the symbolic name of predefined colors:

```
RGB::colorName([0, 1, 0])
```

```
RGB::Green
```

```
RGB::colorName([0, 1, 0, 0.5])
```

```
RGB::Green.[0.5]
```

### Example 2

When performing calculations on color values, the results will rarely be exact, even if the unavoidable round-off errors are too small to be displayed on the screen:

```
a := RGB::Olive;
b := RGB::fromHSV(RGB::toHSV(RGB::Olive))
```

```
[0.230003, 0.370006, 0.170003]
```

```
[0.230003, 0.370006, 0.170003]
```

```
bool(a = b)
```

```
FALSE
```

Therefore, `RGB::colorName` by default searches in a “fuzzy” fashion:

```
RGB::colorName(a);
RGB::colorName(b)
```

```
RGB::Olive
```

```
RGB::Olive
```

In cases where this is undesirable, the option `Exact` can be used to switch to exact searching:

```
RGB::colorName(a, Exact);
RGB::colorName(b, Exact)
```

```
RGB::Olive
```

```
FAIL
```

# RGB::colorName

---

The predefined color names do not fill RGB space uniformly, therefore, the color found by `RGB::colorName` may be quite different from the one entered. The following plot shows the predefined colors in RGB space:

```
plot(plot::Scene3d(
 plot::PointList3d([c.[c] $ c in RGB::ColorList]),
 ZXRatio = 1, BackgroundStyle = TopBottom,
 BackgroundColor = RGB::Grey,
 BackgroundColor2 = RGB::White,
 Margin=0))
```

## Parameters `rgb`

An RGB or RGBA color specification: A list of three or four real numbers in the interval  $[0, 1]$ .

## Options

### Exact

Only return an exact match, FAIL if none exists.

## Return Values

If a color was found, RGB::colorName returns an expression of the form RGB::Name or RGB::Name.[a]. If given Exact and no match was found, FAIL is returned. If given symbolic input parameters, an unevaluated call is returned.

## See Also

## MuPAD Functions

RGB

# RGB::fromWaveLength

---

**Purpose** Get the RGB color of monochromatic light

**Syntax** `RGB::fromWaveLength(o, <a>)`

**Description** `RGB::fromWaveLength( o )` returns an approximative RGB specification for light of wavelength  $\lambda nm$ .

Light consists of photons, each of which has a distinct wavelength. These different wavelengths cause color perception. `RGB::fromWaveLength` calculates an RGB triple corresponding to a given wave length.

Different displays show the same RGB color in slightly different ways. For this reason, the so-called “gamma correction” has been invented. `RGB::fromWaveLength` accepts a second argument, for fine-tuning the assumed gamma correction that enters the calculation.

Color perception depends on a number of factors, including individual differences. Therefore, such a calculation can only return an approximation. `RGB::fromWaveLength` uses the model published by Dan Bruton for the conversion.

For wavelengths outside the visible spectrum (which ranges from  $380nm$  to  $780nm$ ), `RGB::fromWaveLength` returns black.

## Examples

### Example 1

White light, when sent through a prism, is split into the commonly known spectrum, because the prism refracts different wavelengths differently. This spectrum can easily be reproduced by `RGB::fromWaveLength`:

```
plot(plot::Raster([[RGB::fromWaveLength(i) $ i=380..780]]),
 Scaling = Unconstrained, Height = 20)
```

## Example 2

Bruton's conversion model looks like this:

```
plotfunc2d(
 plot::Raster([[RGB::fromWaveLength(i) $ i = 380..780]],
 x = 380..780, y = -0.2..0),
 (x -> RGB::fromWaveLength(x)[i]) $ i = 1..3,
 x = 380..780,
 Colors = [RGB::Red, RGB::Green, RGB::Blue],
 LegendVisible = FALSE,
 XTicksNumber = Low,
 Scaling = Unconstrained,
 Axes = Automatic)
```

# RGB::fromWaveLength

---

## Parameters

The wavelength: a real-valued constant (interpreted as nanometers) or a length expression

The “gamma correcture” for the display, defaults to 0.8

## Return Values

RGB color: a list of three floating-point values

## See Also

## MuPAD Functions

RGB | RGB::fromHSV

**Purpose** Pick a color uniformly at random in RGB color space

**Syntax** `RGB::random()`

**Description** `RGB::random()` returns a random color. The colors returned are distributed independently and uniformly in the RGB color space.

**Examples** **Example 1**

`RGB::random` can be used to produce high-frequency noise:

```
plot(plot::Raster([[RGB::random() $ x = 0..42] $ y = 0..42]))
```

**Example 2**

It is possible to use `RGB::random` directly as a color function, but the result may be unexpected:

```
plot(plot::Waterman(5, FillColorFunction = RGB::random))
```

## RGB::random

---

The reason is that the color function will be called repeatedly if the same point is met again. It is a better idea to create a bunch of random colors and then use the parameters passed into the color functions to get some consistency into the choice of colors:

```
colors := [RGB::random() $ i = 1..42]:
plot(plot::Waterman(5, FillColorFunction=((x,y,z,i) -> colors[i])))
```

## Return Values

RGB color: A list of three floating-point values.

## See Also

## MuPAD Functions

RGB | frandom

# RGB::toHSV

---

**Purpose** Convert RGB colors to HSV

**Syntax** RGB::toHSV([r, g, b, <a>])

**Description** RGB::toHSV( RGBcolor ) returns RGBcolor expressed in HSV values, with hue in the range 0..360 (i.e., in degrees) and saturation and value in the range 0..1.

## Examples **Example 1**

With the RGB::fromHSV utility, all colors in a MuPAD graphics can be specified easily as HSV colors. For example, the color “violet” is given by the HSV values [290, 0.4, 0.6], whereas “dark green” is given by the HSV specification [120, 1, 0.4]. Hence, a semi-transparent violet sphere intersected by an opaque dark green plain may be specified as follows:

```
plot(plot::Sphere(1, [0, 0, 0],
 Color = RGB::fromHSV([290, 0.4, 0.6]).[0.5]),
 plot::Surface([x, y, 0.5], x = -1 .. 1, y = -1 .. 1,
 Mesh = [2, 2],
 Color = RGB::fromHSV([120, 1, 0.4]))
):
```

## Example 2

There are numerous ways of displaying complex-valued functions of a complex argument, see for example `plot::Conformal`. One of these is to use a color scheme that interprets the complex plane as a section through HSV color space at a fixed value, say, 1. To plot this scheme in MuPAD, we use `plot::Density`, providing the following color function:

```
f_color := (x, y, fz, a) ->
 RGB::fromHSV([180/float(PI)*arg(fz), abs(fz), 1]):
```

The identity function is thus shown as follows:

```
plot(plot::Density((x, y) -> x + I*y, x = -1..1, y = -1..1,
 XMesh = 50, YMesh = 50,
 FillColorFunction = f_color))
```

# RGB::toHSV

---

$z \rightarrow z^2$  doubles the argument of a complex function, resulting in the following picture:

```
plot(plot::Density((x, y) -> (x + I*y)^2, x = -1..1, y = -1..1,
 XMesh = 50, YMesh = 50,
 FillColorFunction = f_color))
```

To plot the complex sine function, we choose a larger rectangle, since the sine is too similar to the identity in small neighborhoods of the origin to be of interest:

```
plot(plot::Density((x, y) -> sin(x + I*y), x = -2..2, y = -2..2,
 XMesh = 50, YMesh = 50,
 FillColorFunction = f_color))
```

# RGB::toHSV

---

$z \rightarrow z^{4/3}$  is clearly discontinuous along the negative real axis:

```
plot(plot::Density((x, y) -> (x + I*y)^(4/3),
 x = -1..1, y = -1..1,
 XMesh = 50, YMesh = 50,
 FillColorFunction = f_color))
```

## Parameters

**r, g, b**

The red, green, and blue contributions of an RGB color: numerical values between 0 and 1.

**a**

The translucency (alpha) value: a numerical value between 0 and 1.

## Return Values

a list with three or four floating-point values, depending on whether a was given in the input.

## See Also

## MuPAD Functions

RGB::fromHSV

# RGB::fromHSV

---

**Purpose** Convert HSV colors to RGB

**Syntax** RGB::fromHSV([h, s, v, <a>])

**Description** RGB::fromHSV(HSVcolor) is the inverse of RGB::toHSV: Given color coordinates in HSV, this function returns the corresponding RGB color. Cf. “Example 2” on page 23-35.

**Examples**      **Example 1**

With the RGB::fromHSV utility, all colors in a MuPAD graphics can be specified easily as HSV colors. For example, the color “violet” is given by the HSV values [290, 0.4, 0.6], whereas “dark green” is given by the HSV specification [120, 1, 0.4]. Hence, a semi-transparent violet sphere intersected by an opaque dark green plain may be specified as follows:

```
plot(plot::Sphere(1, [0, 0, 0],
 Color = RGB::fromHSV([290, 0.4, 0.6]).[0.5]),
 plot::Surface([x, y, 0.5], x = -1 .. 1, y = -1 .. 1,
 Mesh = [2, 2],
 Color = RGB::fromHSV([120, 1, 0.4]))
):
```

## Example 2

There are numerous ways of displaying complex-valued functions of a complex argument, see for example `plot::Conformal`. One of these is to use a color scheme that interprets the complex plane as a section through HSV color space at a fixed value, say, 1. To plot this scheme in MuPAD, we use `plot::Density`, providing the following color function:

```
f_color := (x, y, fz, a) ->
 RGB::fromHSV([180/float(PI)*arg(fz), abs(fz), 1]):
```

The identity function is thus shown as follows:

```
plot(plot::Density((x, y) -> x + I*y, x = -1..1, y = -1..1,
 XMesh = 50, YMesh = 50,
 FillColorFunction = f_color))
```

## RGB::fromHSV

---

$z \rightarrow z^2$  doubles the argument of a complex function, resulting in the following picture:

```
plot(plot::Density((x, y) -> (x + I*y)^2, x = -1..1, y = -1..1,
 XMesh = 50, YMesh = 50,
 FillColorFunction = f_color))
```

To plot the complex sine function, we choose a larger rectangle, since the sine is too similar to the identity in small neighborhoods of the origin to be of interest:

```
plot(plot::Density((x, y) -> sin(x + I*y), x = -2..2, y = -2..2,
 XMesh = 50, YMesh = 50,
 FillColorFunction = f_color))
```

## RGB::fromHSV

---

$z \rightarrow z^{4/3}$  is clearly discontinuous along the negative real axis:

```
plot(plot::Density((x, y) -> (x + I*y)^(4/3),
 x = -1..1, y = -1..1,
 XMesh = 50, YMesh = 50,
 FillColorFunction = f_color))
```

## Parameters

**a**

The translucency (alpha) value: a numerical value between 0 and 1.

**h**

The “hue” in an HSV specification: a numerical value between 0 and 360

**s**

The “saturation” in an HSV specification: a numerical value between 0 and 1

**v**

The “value” in an HSV specification: a numerical value between 0 and 1

# RGB::fromHSV

---

## **Return Values**

a list with three or four floating-point values, depending on whether a was given in the input.

RGB::toHSV

<b>Purpose</b>	Easy plotting
<b>Syntax</b>	<code>plot::easy(&lt;arg, &gt;, options)</code>
<b>Description</b>	<p><code>plot::easy( arg , &lt;options&gt;, )</code> transforms data and expressions into graphical objects.</p> <p><code>plot::easy</code> accepts graphical objects and graphical attributes as input and returns them unchanged.</p> <p><code>plot::easy</code> supports the options listed above. Additionally, it accepts arbitrary data and expressions and tries to transform them into valid graphical objects.</p> <p><code>plot::easy</code> supports the option <code>Colors=[c<sub>1</sub>,...c<sub>2</sub>]</code> for automatically coloring newly generated graphical objects. The given list is used instead of the internally defined default color list.</p> <p><code>plot::easy</code> accepts the options <code>Mesh</code> and <code>Submesh</code> and uses them for each newly generated graphical object.</p> <p>The function <code>plot</code> calls <code>plot::easy</code> for preprocessing its input before plotting.</p> <p><code>plot::easy</code> tries to handle standard situations intuitively in order to make plotting as easy as possible. However, it supports only a small subset of the graphical objects, attributes and expressions available in MuPAD and thus does not claim to be complete.</p> <p>Users that want to plot other objects or control specific details of their graphics explicitly, still have to create their graphical objects manually, e.g. using <code>plot::Function2d</code> and <code>plot::Point2d</code>, and to use graphical attributes like <code>LineStyle =Dashed</code> directly.</p> <p><code>plot::easy</code> sets a new color for each object that it creates, if no color is predefined in the given context.</p> <p><code>plot::easy</code> accepts sets <code>{...}</code> as group definition and transforms them into graphical objects of type <code>plot::Group2d(...)</code> or <code>plot::Group3d(...)</code>, respectively. All elements of a group share the</p>

same color, if colors were not specified explicitly for single objects. Note that, regular graphical objects usually have a predefined color.

`plot::easy` accepts a nested set `{{...}}` as scene definition and transforms it into the graphical object `plot::Scene2d(...)` or `plot::Scene3d(...)`, respectively.

Creating a graphical object may require the specification of value ranges for variables. If they are not specified explicitly then `plot::easy` tries use ranges specified for other variables and/or uses the default value range `-5..5`.

## Examples

### Example 1

`plot::easy` tries to transform all given data and expressions into valid graphical objects and attributes:

```
plot::easy(sin(x), [PI/2,1])
```

```
plot::Function2d(sin(x), x = -5..5), plot::Point2d($\frac{\pi}{2}$, 1, PointColor = RGB::Red, LegendText =
```

Since the function `plot` calls the function `plot::easy` for preprocessing its input data, scenes like above can directly be plotted using `plot`:

```
plot(sin(x), [PI/2,1], #x=PI/2, #y=1)
```

Now, it is only a small step to animate this scene:

```
plot(sin(x), {[x,sin(x)], #Points}, #x=x, #y=sin(x))
```

Note: Graphical objects and attributes, as well as data that `plot::easy` cannot transform, are returned unchanged:

```
plot::easy(x, plot::Point2d(1,1), LineStyle=Dashed, "UnknownObject")
```

```
plot::Function2d(x, x = -5..5), plot::Point2d(1, 1), LineStyle = Dashed, "UnknownObject"
```

This is why `plot` returns the following error message when it is executed with the above arguments:

```
plot(x, plot::Point2d(1,1), LineStyle=Dashed, "UnknownObject");
```

```
Error: The arguments 'UnknownObject' are unexpected. [plot::Canvas:
```

## Example 2

Points can be entered as lists with two or three values. Alternatively, a corresponding column vector in combination with the option `#Points` (alias `#P`, see “Example 18” on page 23-74) can be used.

Note that for plotting animated points the option `#Points` is required. Otherwise a curve (when entered a list) or an arrow (when entered a vector) is plotted:

```
plot([0,1], [s,s^2], {[s,s^2], #Points}, s=-2..2,
 matrix([t,t^2]), {matrix([t,t^2]), #Points}, t= 2..-2
)
```

See also: `plot::Point2d`, `plot::Point3d`.

## Example 3

Arrows can be specified as column vectors with two or three elements. Alternatively, a list in combination with the option #Arrows (alias #A, see “Example 13” on page 23-69) can be used:

```
plot(matrix([0,1]), matrix([s,s^2]), s=2..-2,
 [t,t^2], {[t,t^2], #Arrows}, t=-2..2
)
```

If an arrow should start at coordinates other than (0,0) or (0,0,0), respectively, then a list of two column vectors or a corresponding list of lists in combination with the option #Arrows (alias #A, see “Example 13” on page 23-69) can be used:

```
u:= matrix([3,2]):
v:= matrix([1,4]):
w:= (1-a)*u + a*v:
u, v, w;
```

$$\begin{pmatrix} 3 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 4 \end{pmatrix}, \begin{pmatrix} 3-2a \\ 2a+2 \end{pmatrix}$$

```
plot(u, v, [u,w], a=0.1..1, #Arrows)
```

```
delete u, v, w:
```

See also: `plot::Arrow2d`, `plot::Arrow3d`.

#### Example 4

Polygons can be specified as lists, tables or matrices. In the following example, polygons are plotted using different input styles. The option `#Origin` (alias `#0`, see “Example 17” on page 23-73) ensures that the origin of the coordinate system is visible in the scene as well:

```
plot([[1,3],[2,5],[3,3],[4,8]],
```

```
table(1=4,2=6,3=4,4=9),
[matrix([1,5]),matrix([2,7]),matrix([3,5]),matrix([4,10])],
matrix([[1,6],[2,8],[3,6],[4,11]]),
#Origin)
```

Note that polygons are displayed as points when option #Points (alias #P, see “Example 18” on page 23-74) is used:

```
plot([[1,3],[2,5],[3,3],[4,8]],
table(1=4,2=6,3=4,4=9),
[matrix([1,5]),matrix([2,7]),matrix([3,5]),matrix([4,10])],
matrix([[1,6],[2,8],[3,6],[4,11]]),
#Points, #Origin)
```

Note that the following polygons with two elements are displayed as arrows when option `#Arrows` (alias `#A`, see “Example 13” on page 23-69) is used:

```
plot([[1,4],[2,6]],
 [matrix([1,5]),matrix([2,7])],
 matrix([[1,6],[2,8]]),
 #Arrows, #Origin)
```

See also: `plot::Polygon2d`, `plot::Polygon3d`.

## Example 5

Point lists can be specified as lists, tables or matrices. For each point an RGBa color has to be specified. In the following example, point lists are plotted using different input styles. The option `#Origin` (alias `#0`, see “Example 17” on page 23-73) ensures that the origin of the coordinate system is visible in the scene as well:

```
plot([[1,2,RGB::Red], [2,4,[0,1,0]], [3,3,[0,0,1,0.5]]],
 [matrix([1,3,RGB::Red]),matrix([2,5,[0,1,0]]),matrix([3,4,[0,0,1,0.5]]),
 matrix([1,4,RGB::Red], [2,6,[0,1,0]], [3,5,[0,0,1,0.5]])],
 table(1=[5,RGB::Red], 2=[7,[0,1,0]], 3=[6,[0,0,1,0.5]]),
 #Origin)
```

Note that the following point lists are displayed as arrows when option `#Arrows` (alias `#A`, see “Example 13” on page 23-69) is used:

```
plot([[1,2,RGB::Red], [2,4,[0,1,0]] ,[3,3,[0,0,1,0.5]]],
 [matrix([1,3,RGB::Red]),matrix([2,5,[0,1,0]]),matrix([3,4,[
matrix([[1,4,RGB::Red], [2,6,[0,1,0]], [3,5,[0,0,1,0.5]])],
 table(1=[5,RGB::Red], 2=[7,[0,1,0]] ,3=[6,[0,0,1,0.5]]),
 #Arrows, #Origin)
```

See also: `plot::PointList2d`, `plot::PointList2d`.

### Example 6

For drawing horizontal and vertical infinite lines, the short syntax `#x = e` and `#y = e` with `e` is a real expression, can be used:

```
plot(sin(x), [PI/2,1], #x=PI/2, #y=1, #Legend)
```

For drawing horizontal and vertical infinite planes, the short syntax  $\#x = e$ ,  $\#y = e$  and  $\#z = e$ , with  $e$  is a real expression, can be used.

Both, lines and planes can also be animated:

```
plot([t,0,t^2], {[t,0,t^2], #Points}, #x=t, #z=t^2, #Legend)
```

See also: `plot::Line2d`, `plot::Plane`.

### Example 7

A curve can be specified as list with two or three elements, where at least one element depends on a free variable. If option `#Points` (alias `#P`, see “Example 18” on page 23-74) is set, then instead of a curve, an animated point is plotted that moves along the curve.

```
plot([t,sin(t)], {[t,sin(t)], #Points}, t=0..2*PI)
```

See also: `plot::Curve2d`, `plot::Curve3d`.

### Example 8

`plot::easy` tries to transform expressions that are no lists, sets, matrices, equations or inequalities into graphs of 2D or 3D functions. We plot some graphs of 2D functions:

```
plot(sin(x), tan(x), x)
```

We plot a simple 3D function. Note that the option #3D (alias #3, see “Example 12” on page 23-66) is required in the following example for plotting a 3D function. Otherwise, an animated 2D function is created.

```
plot(m*x, #3D)
```

We plot a simple 2D animation: a point and the corresponding tangent of the sine function move along the sine function graph:

```
f:= x -> sin(x):
plot(f(x), x = -PI..PI,
 {[a, f(a)], #Points}, f'(a)*(x-a) + f(a), a = -PI/2..PI/2)
```

We plot a piecewise defined function:

```
plot(piecewise([x < 1, -x^2 + 1], [x >= 1, x + 5]), #x=1, #Legend)
```

The same piecewise defined function is now written in a shorter syntax. Note the difference between defining one function with two branches (left) and defining two functions (right):

```
plot({{[[x < 1, -x^2 + 1], [x >= 1, x + 5]], #x=1}},
 {{ [x < 1, -x^2 + 1], [x >= 1, x + 5] , #x=1}},
 #Legend)
```

See also: `plot::Function2d`, `plot::Function3d`.

## Example 9

An implicit function can be specified as an equation:

```
plot(u^5 + x^2 = 1 - u^3)
```

Note that the option #3D (alias #3, see “Example 12” on page 23-66) may be required to plot planes given as cartesian equations. Otherwise, an animated 2D graph might be created. This depends on the number of variable of the equation.

```
E1:= 2*x + 30*y - 2*z = 5:
E2:= -x + 7*y - z = 12:
E3:= -4*x + 2*y + z = 0:
plot(E1, E2, E3, #3D, #Legend)
```

delete E1, E2, E3:

See also: `plot::Implicit2d`, `plot::Implicit3d`.

### Example 10

An inequality can be displayed directly:

```
plot(u^5+x^2 < 1-u^3)
```

The same is true for a list of inequalities and equations:

```
plot([x < 3, x > 1, y < 4, y > -4])
```

See also: `plot::Inequality`.

### Example 11

To display a 2D text at a certain position, an equation of a coordinate tuple and a character string or a procedure can be entered:

```
plot([t, t^2],
 {[t, t^2], #Points},
 [t, t^2] = "moving text")
```

We display a 3D text. As in any other context of `plot::easy`, we can use regular graphical attributes like `TextFont =Center` as well:

```
DIGITS := 2:
plot([t, t^2, 1],
 {[t, t^2, 1], #Points},
 [t, t^2, 1] = (t->" x = ".[t, t^2, 1.0]),
 TextFont=[Bold]):
delete DIGITS:
```

See also: `plot::Text2d`, `plot::Text3d`.

## Example 12

Usually `plot::easy` creates a 2D scene, unless one of the arguments is a 3D object or can only be transformed to a 3D object or the option `#3D` is used.

```
plot(sin(x), #3)
```

However, the option `#3D` is only a hint. It is ignored if the current scene can only be a 2D scene. In the following example, the 2D point determines the dimension of the scene:

```
plot([PI/2,1], sin(x), #3)
```

In the following example, the 3D point determines the dimension of the scene. There is no need to use option #3D in order to create a 3d scene:

```
plot([PI/2,1,0], sin(x))
```

### Example 13

With option `#Arrows`, arrows instead of points or curves are created. When used within a `{...}`-group, it affects the elements of this group or scene only.

```
plot({{ [-5,25], [5,25], [x,x^2] }},
 {{ [-5,25], [5,25], [x,x^2], #A }})
```

## Example 14

Option `#Constrained` creates a coordinate system with constrained scaled axes. This is a shortcut for `Scaling = Constrained`.

```
plot({{ x^2 }}, {{ x^2, #C }})
```

### Example 15

Option `#Grid` creates a coordinate system with grid lines. This is a shortcut for `GridVisible = TRUE`.

```
plot({{ x^2 }}, {{ x^2, #G }})
```

## Example 16

Option `#Legend` creates a legend. This is a shortcut for `LegendVisible = TRUE` in combination with `LegendEntry = TRUE`. Note that `plot::easy` explicitly sets a legend text for each graphical object it creates.

```
plot([0,-6], x^2-5, [t,t^2], #L)
```

### Example 17

Option #Origin includes the coordinates (0,0) or (0,0,0), respectively, into the viewing box of the current scene.

```
plot({{[2,2], [3,3]}}, {{[2,2], [3,3], #0}})
```

### Example 18

Using option `#Points`, points instead of arrows or curves are created. Furthermore, this option sets the attributes `PointsVisible =TRUE` and `LinesVisible =FALSE`. When used within a `{...}`-group, it affects the elements of this group or scene only.

```
plot({[-5,25], [x,x^2], #Gray}, {matrix([5,25]), [x,x^2], #P})
```

### Example 19

$\#X / \#Y / \#Z = a..b$  sets the x- / y- / z-range of the viewing box of the scene to  $a..b$ . This is a shortcut for `ViewingBoxXRange / ViewingBoxYRange / ViewingBoxZRange = a..b`.

```
plot({{x^2, sin(x)}}, {{x^2, sin(x), #Y=0..4}})
```

We draw a 3D scene with a restricted viewing box. Therefore, only a quarter of the sphere is visible:

```
plot({{plot::Sphere(1)}},
 {{plot::Sphere(1), #X=0..1, #Y=0..1, #Z=0..1}})
```

**Parameters**

**arg**

Any object

**Options**

**#3D**

Alias #3. Creates a 3D instead of a 2D scene, if possible. Usually, a 2D scene is created unless one of the arguments is a 3D object or can only be transformed into one.

**#Arrows**

Alias #A. Creates arrows instead of points. When used within a {...}-group, it affects the elements of this group or scene only.

**#Constrained**

Alias #C. Creates a coordinate system with axes having the same scaling. This is a shortcut for `Scaling =Constrained`.

**#Grid**

Alias #G. Creates a coordinate system with grid lines. This is a shortcut for `GridVisible =TRUE`.

## #Legend

Alias #L. Creates a legend. This is a shortcut for `LegendEntry =TRUE` and `LegendVisible =TRUE`. When used within a {...}-group, it affects the elements of this group or scene only. Note that `plot::easy` explicitly sets a legend text for each graphical object it creates.

## #Origin

Alias #O. Includes the coordinates (0,0) or (0,0,0), respectively, into the viewing box of the current scene.

## #Points

Alias #P. Creates points instead arrows or curves. Furthermore, it sets the attributes `PointsVisible =TRUE` and `LinesVisible =FALSE`. When used within a {...}-group, it affects the elements of this group or scene only.

## #XRange

Option, specified as `#XRange = a .. b`

Alias `#X = a .. b`. Sets the x-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxXRange =a..b`.

## #YRange

Option, specified as `#YRange = a .. b`

Alias `#Y = a .. b`. Sets the y-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxYRange =a..b`.

## #ZRange

Option, specified as `#ZRange = a .. b`

Alias `#Z = a .. b`. Sets the z-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxZRange =a..b`.

## #<Colorname>

If `RGB ::<Colorname>` is a valid color name in MuPAD, `#<Colorname>` is transformed to `Color = RGB ::<Colorname>`, `LineColorType =Flat` and for 3D objects additionally `FillColorType =Flat`. Transparent RGB colors can be specified as `#<Colorname>.[t]`, with `t` is in `0..1`. If `#<Colorname>` is a valid color following the html conventions then instead of `RGB ::<Colorname>`, the corresponding RGB or RGBA color value is inserted. When used within a `{...}`-group, it affects the elements of this group or scene only.

**#<Colorname1> .. #<Colorname2>**

If `RGB ::<Colorname1>` and `RGB ::<Colorname2>` are valid color names in MuPAD, this option is transformed to:

`Color = RGB ::<Colorname1>`, `LineColorType =Dichromatic`, `LineColor2 = RGB ::<Colorname2>` in 2D scenes and to:

`Color = RGB ::<Colorname1>`, `FillColorType =Dichromatic`, `FillColor2 = RGB ::<Colorname2>` in 3D scenes.

Transparent RGB colors can be specified as `#<Colorname>.[t]`, with `t` is in `0..1`. If `#<Colorname1>` and/or `#<Colorname2>` are valid colors following the html conventions then instead of `RGB ::<Colorname1>` and/or, `RGB ::<Colorname2>` the corresponding RGB or RGBA color values are inserted. When used within a `{...}`-group, it affects the elements of this group or scene only.

**Return Values**

A sequence of graphical objects and graphical attributes as well as objects that could not be transformed by `plot::easy`.

**Overloaded By**

`arg`

**Algorithms**

Let  $c_i$  be real constants and  $f$  and  $f_i$  be real functions. `plot::easy` automatically carries out the following transformations:

Graphical object	Data or mathematical expression
plot::Point2d:	$[c_1, c_2], \{[f_1(x), f_2(x)], \#Points\}, \{matrix([f_1(x), f_2(x)]), \#Points\}.$
plot::Point3d:	$[c_1, c_2, c_3], \{[f_1(x), f_2(x), f_3(x)], \#Points\}, \{matrix([f_1(x), f_2(x), f_3(x)]), \#Points\}.$
plot::Arrow2d:	$matrix([c_1, c_2]), \{[c_1, c_2], \#Arrows\}, \{matrix([f_1(x), f_2(x)]), matrix([f_3(x), f_4(x)]), \#Arrows\}, \{matrix([f_1(x), f_2(x), [f_3(x), f_4(x)]), \#Arrows\}, \{[f_1(x), f_2(x)], [f_3(x), f_4(x)]\}, \#Arrows\}.$
plot::Arrow3d:	$matrix([c_1, c_2, c_3]), \{[c_1, c_2, c_3], \#Arrows\}, \{matrix([f_1(x), f_2(x), f_3(x)]), matrix([f_4(x), f_5(x), f_6(x)]), \#Arrows\}, \{matrix([f_1(x), f_2(x), f_3(x), [f_4(x), f_5(x), f_6(x)]), \#Arrows\}, \{[f_1(x), f_2(x), f_3(x)], [f_4(x), f_5(x), f_6(x)]\}, \#Arrows\}.$
plot::Polygon2d:	$[[f_1(x), f_2(x)], \dots], [matrix([f_1(x), f_2(x)]), \dots], matrix([f_1(x), f_2(x)], \dots), table(f_1(x)=f_2(x), \dots).$
plot::Polygon3d:	$[[f_1(x), f_2(x), f_3(x)], \dots], [matrix([f_1(x), f_2(x), f_3(x)]), \dots], matrix([f_1(x), f_2(x), f_3(x)], \dots), table(f_1(x)=[f_2(x), f_3(x)], \dots).$

Graphical object	Data or mathematical expression
plot::PointList2d:	[[f <sub>1</sub> (x), f <sub>2</sub> (x), RGBa],...], [matrix([f <sub>1</sub> (x), f <sub>2</sub> (x), RGBa]),...], matrix([f <sub>1</sub> (x), f <sub>2</sub> (x), RGBa],...), table(f <sub>1</sub> (x)=f <sub>2</sub> (x), RGBa),...).
plot::PointList3d:	[[f <sub>1</sub> (x), f <sub>2</sub> (x), f <sub>3</sub> (x), RGBa],...], [matrix([f <sub>1</sub> (x), f <sub>2</sub> (x), f <sub>3</sub> (x), RGBa]),...], matrix([f <sub>1</sub> (x), f <sub>2</sub> (x), f <sub>3</sub> (x), RGBa],...)]. table(f <sub>1</sub> (x)=f <sub>2</sub> (x), f <sub>3</sub> (x), RGBa),...).
plot::Line2d:	#x= f(x), #y= f(x).
plot::Plane:	#z= f(x), {#x= f(x) , #3D}, {#y= f(x) , #3D}, {#z= f(x) , #3D}.
plot::Curve2d:	[f <sub>1</sub> (x), f <sub>2</sub> (x)].
plot::Curve3d:	[f <sub>1</sub> (x), f <sub>2</sub> (x), f <sub>3</sub> (x)].
plot::Function2d:	f(x), f(x, a), [cond <sub>1</sub> , f(x)], [[cond <sub>1</sub> , f(x)],...].
plot::Function3d:	f(x, y, a), [cond <sub>1</sub> , f(x, y, a)], [[cond <sub>1</sub> , f(x, y, a)],...], {f(x), #3D}, {f(x, a), #3D}.
plot::Implicit2d:	f <sub>1</sub> (x, y, a)=f <sub>2</sub> (x, y, a).
plot::Implicit3d:	f <sub>1</sub> (x, y, z, a)=f <sub>2</sub> (x, y, z, a), {f <sub>1</sub> (x, y, a)=f <sub>2</sub> (x, y, a), #3D}.
plot::Inequality:	f <sub>1</sub> (x, a) < f <sub>2</sub> (x, a), f <sub>1</sub> (x, a) f <sub>2</sub> (x, a), f <sub>1</sub> (x, a) > f <sub>2</sub> (x, a), f <sub>1</sub> (x, a) f <sub>2</sub> (x, a), [f <sub>1</sub> (x, a)<f <sub>2</sub> (x, a), f <sub>3</sub> (x, a)>f <sub>4</sub> (x, a), f <sub>5</sub> (x, a)=f <sub>6</sub> (x, a),...].

Graphical object	Data or mathematical expression
plot::Text2d:	$[f_1(x), f_2(x)] = \text{text}$ , $\text{matrix}([f_1(x), f_2(x)]) = \text{text}$ , $[f_1(x), f_2(x)] = \text{procedure}$ , $\text{matrix}([f_1(x), f_2(x)]) = \text{procedure}$ .
plot::Text3d:	$[f_1(x), f_2(x), f_3(x)] = \text{text}$ , $\text{matrix}([f_1(x), f_2(x), f_3(x)]) = \text{text}$ , $[f_1(x), f_2(x), f_3(x)] = \text{procedure}$ , $\text{matrix}([f_1(x), f_2(x), f_3(x)]) = \text{procedure}$ .

### MuPAD Functions

plot

**Purpose** Get current default setting of attributes

**Syntax** `plot::getDefault(type::attr)`

**Description** `plot::getDefault(plot::Object::Attribute)` enquires the current default.

**Examples** **Example 1**

By default, function plots use relatively thin lines:

```
plotfunc2d(sin(x))
```

For some applications, this is undesirable, for example when projecting graphics for a larger audience. It is always possible to set thicker lines in the call:

```
plotfunc2d(sin(x), LineWidth = 1*unit::mm)
```

## plot::getDefault

---

However, this is distracting and cumbersome. Using `plot::setDefault`, we change the default setting once and for the whole session:

```
plot::setDefault(plot::Function2d::LineWidth = 1*unit::mm):
plotfunc2d(sin(x))
```

One thing you should know in this context: `plotfunc2d` and `plotfunc3d` use `plot::Function2d` and `plot::Function3d` for the actual plotting. Changing color and legend settings of the latter two does not influence the former, however, since `plotfunc2d` and `plotfunc3d` set color and legend settings explicitly.

## Parameters

### **type**

A domain of the plot library, i.e., an object type such as `plot::Function2d`

### **attr**

Attributes admissible for the object type `type`

## Return Values

`plot::setDefault` returns the previous default value(s).  
`plot::getDefault` returns the current default value.

# plot::getDefault

---

## Algorithms

“Admissible attributes” includes all the attributes the object itself reacts to. Hints cannot be set or changed with `plot::setDefault`.

For attributes marked as “mandatory,” default values are read and used the moment an object is created. Default values of attributes marked as “optional” or “inherited” are read when the object is plotted and can therefore be changed after creating an object.

## See Also

### MuPAD Functions

`plot::setDefault`

## Purpose

Set default setting of attributes

## Syntax

```
plot::setDefault(type::attr = value,)
```

## Description

`plot::setDefault(plot::Object::Attribute = Value)` sets the default of the attribute `Attribute` for objects of type `plot::Object` to `Value`.

While not all attributes have defaults, it is in general possible to set defaults for them, although some examples like setting a default function to plot for `plot::Function2d` are probably more exotic than others, to say the least.

Defaults are set and retrieved per object; with the exception of `OutputFile` and `OutputOptions`, the attribute must be prefixed with the name of the object type the setting shall be valid for. There is, e.g., no function to turn of all lines on all 3D objects. `OutputFile` and `OutputOptions` are not associated with an object and must be set directly.

To delete a default (which is not recommended for attributes having a default in the standard installation), set value to `FAIL`.

## Examples

### Example 1

By default, function plots use relatively thin lines:

```
plotfunc2d(sin(x))
```

## plot::setDefault

---

For some applications, this is undesirable, for example when projecting graphics for a larger audience. It is always possible to set thicker lines in the call:

```
plotfunc2d(sin(x), LineWidth = 1*unit::mm)
```

However, this is distracting and cumbersome. Using `plot::setDefault`, we change the default setting once and for the whole session:

```
plot::setDefault(plot::Function2d::LineWidth = 1*unit::mm):
plotfunc2d(sin(x))
```

# plot::setDefault

---

One thing you should know in this context: `plotfunc2d` and `plotfunc3d` use `plot::Function2d` and `plot::Function3d` for the actual plotting. Changing color and legend settings of the latter two does not influence the former, however, since `plotfunc2d` and `plotfunc3d` set color and legend settings explicitly.

## Parameters

### **type**

A domain of the plot library, i.e., an object type such as `plot::Function2d`

### **attr**

Attributes admissible for the object type `type`

### **value**

The new default value: a value admissible for `attr` in objects of type `type`

## Return Values

`plot::setDefault` returns the previous default value(s).  
`plot::getDefault` returns the current default value.

## Algorithms

“Admissible attributes” includes all the attributes the object itself reacts to. Hints cannot be set or changed with `plot::setDefault`.

For attributes marked as “mandatory,” default values are read and used the moment an object is created. Default values of attributes marked as “optional” or “inherited” are read when the object is plotted and can therefore be changed after creating an object.

## See Also

## MuPAD Functions

`plot::getDefault`

# plot::copy

---

**Purpose** Make a physical copy of a plot object

**Syntax** `plot::copy(obj)`

**Description** Plot objects usually have a reference effect. `plot::copy` creates copies which are independent of the original.

Objects created from inside the `plot` library have a *reference effect*: If you make another reference to some object, say by calling `o2 := o1`; and then change an attribute of `o2`, e.g., setting `o2::Visible := FALSE`, this change will also effect the object referred to by `o1`, since they actually refer to the same object. To create an actual copy of an object instead, use `o2 := plot::copy(o1)`;

The function `plot::modify` is a variant of `plot::copy`. It allows setting new values of attributes in the same call, as in `o2 := plot::modify(o1, Visible = FALSE)`;

## Examples

### Example 1

The following call does *not* create two points, but rather one which we can access by two names:

```
A := plot::Point2d(0, 0):
B := A:
```

This surfaces as soon as we try to modify ‘one of the points’:

```
B::Position := [1, 1]:
A
```

```
plot::Point2d(1, 1)
```

Instead, we can use `plot::modify` to achieve the desired effect:

```
B := plot::modify(A, Position = [2, 2]):
A, B
```

`plot::Point2d(1, 1), plot::Point2d(2, 2)`

---

**Note** Note that `plot::modify` does not modify its argument, but returns a modified copy instead, whatever the name may suggest.

---

**Parameters****obj**

Plot objects

**Return Values**

Object of the same type as `obj`

**See Also****MuPAD Functions**

`plot::modify`

# plot::modify

---

**Purpose** Make a physical copy of a plot object setting new values of attributes in the same call

**Syntax** `plot::modify(obj, <attr, >)`

**Description** Plot objects usually have a reference effect. `plot::modify` creates copies which are independent of the original.

Objects created from inside the `plot` library have a *reference effect*: If you make another reference to some object, say by calling `o2 := o1`; and then change an attribute of `o2`, e.g., setting `o2::Visible := FALSE`, this change will also effect the object referred to by `o1`, since they actually refer to the same object. To create an actual copy of an object instead, use `o2 := plot::copy(o1)`;

The function `plot::modify` is a variant of `plot::copy`. It allows setting new values of attributes in the same call, as in `o2 := plot::modify(o1, Visible = FALSE)`;

## Examples

### Example 1

The following call does *not* create two points, but rather one which we can access by two names:

```
A := plot::Point2d(0, 0):
B := A:
```

This surfaces as soon as we try to modify ‘one of the points’:

```
B::Position := [1, 1]:
A
```

```
plot::Point2d(1, 1)
```

Instead, we can use `plot::modify` to achieve the desired effect:

```
B := plot::modify(A, Position = [2, 2]):
```

A, B

plot::Point2d(1, 1), plot::Point2d(2, 2)

---

**Note** Note that `plot::modify` does not modify its argument, but returns a modified copy instead, whatever the name may suggest.

---

## Parameters

**obj**

Plot objects

**attr**

Attributes admissible for the object `obj`, in the form `Attribute = Value`

## Return Values

Object of the same type as `obj`

## See Also

## MuPAD Functions

`plot::copy`

# plot::delaunay

---

**Purpose** Compute the Delaunay triangulation of a set of points

**Syntax** `plot::delaunay(L)`

**Description** `plot::delaunay` computes the Delaunay triangulation of a list of points in arbitrary dimension.

The Delaunay triangulation of a list of points is a triangulation of their convex hull such that for each edge of the triangulation, there is a circle containing the two endpoints of this edge but no other point of the list.

**Environment Interactions** Although `plot::delaunay` accepts and returns floating-point values, the actual computations take place in hardware floating-points and are therefore *not* affected by the value of DIGITS.

**Examples** **Example 1**

Delaunay triangulation does not introduce new points:

```
n0 := 10:
l := [[Re, Im](exp(float(2*I*PI*n)/n0)) $ n = 1.. n0]:
d := plot::delaunay(l):
plot(plot::PointList2d(l, PointSize=3),
 plot::Polygon2d(t, Closed) $ t in d)
```

**Parameters**

**L**

A list of points, which are given as lists of real values

**Return Values**

List of simplices in the dimension of the points in L, given as lists of floating-point values.

**Algorithms**

plot::delaunay uses qhull from the Geometry Center of the University of Minnesota, see [www.qhull.org](http://www.qhull.org).

# plot::hull

---

**Purpose** Compute the convex hull of a set of points

**Syntax** `plot::hull(L)`

**Description** `plot::hull` computes the convex hull of a list of points in any dimension, i.e., the smallest convex region containing all the points. Such a region is bounded by simplices (straight lines in the plane, triangles in 3D) and it is these simplices which `plot::hull` returns.

**Environment Interactions** Although `plot::hull` accepts and returns floating point values, the actual computations take place in hardware floating points and are therefore *not* affected by the value of DIGITS.

## Examples **Example 1**

We generate a list of random points and compute their convex hull:

```
X := stats::uniformRandom(0, 20):
l := [[X(), X()] $ i = 1..10]:
h := plot::hull(l):
```

The convex hull is returned as lists of lists, as accepted by `plot::Polygon2d`:

```
h[1]
```

```
[[17.58320254, 18.38769696], [3.063130321, 19.89625562]]
```

```
plot(plot::PointList2d(l),
 plot::Polygon2d(t) $ t in h,
 Closed, PointSize=2)
```

## Example 2

The convex hull of a list of points in 3D is also easy to visualize:

```
l := [[x, y, z] $ y = z..x $ z = -x..x $ x = 0..10]:
h := plot::hull(l):
plot(plot::PointList3d(l, PointSize=1),
 plot::Polygon3d(t) $ t in h,
 Closed, Filled, FillColor=RGB::LightOrange.[0.6])
```

# plot:hull

---

## Parameters **L**

A list of points, which are given as lists of real values

## Return Values

List of simplices of dimension one less than that of the points in **L**, given as lists of lists of floating-point values.

## Algorithms

`plot::hull` uses `qhull` from the Geometry Center of the University of Minnesota, see [www.qhull.org](http://www.qhull.org).

**Purpose** Circular and elliptical arcs in 2D

**Syntax**

```
plot::Arc2d(r, <[cx, cy]>, <Æ .. >, <a =
amin .. amax>, options)
plot::Arc2d([r1, r2], <[cx, cy]>, <Æ .. >, <a =
amin .. amax>, options)
```

**Description** `plot::Arc2d(r, [x, y], Æ .. )` creates a circular arc with radius  $r$  and center  $(x, y)$  with a polar angle between  $a$  and  $\beta$ .

`plot::Arc2d([ r1, r2], [x, y], Æ .. )` creates a corresponding elliptical arc with semi-axes  $r_1, r_2$ .

The angle of a point on the arc is the usual polar angle to the positive  $x$ -axis known from polar coordinates. It is measured in radians.

If no range for the polar angle is specified, a full circle/ellipse is created.

If no center point is specified, an arc with center  $[0, 0]$  is created.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Angle	rotation angle	0
AngleEnd	end of angle range	PI/2
AngleBegin	begin of angle range	0
AngleRange	angle range	0 .. PI/2
AntiAliased	antialiased lines and points?	TRUE
Center	center of objects, rotation center	[0, 0]

## plot::Arc2d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
Closed	open or closed polygons	FALSE
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
SemiAxes	semi axes of ellipses and ellipsoids	[1, 1]
SemiAxisX	first semi axis of ellipses and ellipsoids	1
SemiAxisY	second semi axis of ellipses and ellipsoids	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

# plot::Arc2d

---

Attribute	Purpose	Default Value
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

An arc is a segment of a circle:

```
circle := plot::Circle2d(3, [0, 0]):
arc := plot::Arc2d(3, [0, 0], 0 .. PI/4, LineColor = RGB::Red,
 LineWidth = 1.5*unit::mm):
plot(circle, arc)
```

```
delete circle, arc:
```

### Example 2

The center of an arc may be given as the second argument to `plot::Arc2d`:

```
arc1 := plot::Arc2d(3, [1, 3], 0..PI/2, Closed = TRUE):
arc2 := plot::Arc2d(3, [3, 1], -PI ..0, Closed = TRUE):
plot(arc1, arc2)
```

## plot::Arc2d

---

The center is accessible as the attribute `Center` of the arc object. We change the center of the second arc:

```
arc2::Center := [1, 3]:
plot(arc1, arc2)
```

```
delete arc1, arc2:
```

### Example 3

A filled arc is a segment of a circle, like a piece of pie:

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE))
```

## plot::Arc2d

---

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, Closed = TRUE))
```

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE,
 FillPattern = Solid, LinesVisible = FALSE),
 AxesInFront = TRUE)
```

## plot::Arc2d

---

### Example 4

When giving a list of two radii, `plot::Arc2d` draws a segment of an ellipse with the corresponding semi-axes:

```
arc1 := plot::Arc2d([2, 1], 0 .. PI, Color = RGB::Blue):
arc2 := plot::Arc2d([2, 1], -PI .. 0, Color = RGB::Red):
plot(arc1, arc2)
```

```
delete arc1, arc2:
```

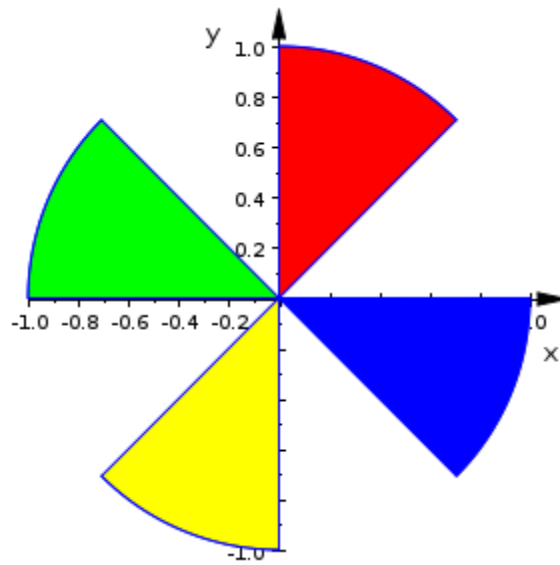

### Example 5

To plot or animate segments of a tilted ellipse, use the attribute Angle:

```
arc:= [1, 1], [0, 0], PI/4..PI/2, Filled, Closed, FillPattern=So
plot(plot::Arc2d(arc, Angle=a+0, a=0..2*PI, FillColor=RGB::
 plot::Arc2d(arc, Angle=a+1/2*PI, a=0..2*PI, FillColor=RGB::
 plot::Arc2d(arc, Angle=a+PI, a=0..2*PI, FillColor=RGB::
 plot::Arc2d(arc, Angle=a+3/2*PI, a=0..2*PI, FillColor=RGB::
```

# plot::Arc2d

---

`delete arc:`

## **Example 6**

Further examples of animated 2D arcs:

```
plot(plot::Arc2d(1, a .. PI, a = 0..PI))
```

```
plot(plot::Arc2d([1 + a^2/2, 1 + a], -PI/2 .. PI/2, a = 0..4))
```

## Example 7

We plot an animated 3D arc:

```
plot(plot::Arc3d(1, [0,0,0], [0,a,1-a], 0..3/2*PI, a = 0..1))
```

### Example 8

We plot a colored 3D arcs:

```
plot(plot::Arc3d(1, [0,0,0], 0.1..2*PI-0.1, Filled,
 LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType =
 FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType =
))
```

## Parameters $r$

The radius of the circle. This must be a real numerical value or an arithmetical expression of the animation parameter  $a$ .

$r$  is equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

## $r_1$ , $r_2$

The semi-axes of an elliptical arc. They must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$r_1$ ,  $r_2$  are equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

## $c_x$ , $c_y$

The center point. The coordinates  $c_x$ ,  $c_y$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ . If no center is specified, an arc centered at the origin is created.

$c_x$ ,  $c_y$  are equivalent to the attribute `Center`.

..

The angle range in radians:  $\Delta$  and  $\text{start}$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ . The default range is  $0 \dots 2 \cdot \text{PI}$ .

$\Delta \dots$  is equivalent to the attribute `AngleRange`.

**a**

Animation parameter, specified as  $a = a_{\min} \dots a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Examples

### Example 1

An arc is a segment of a circle:

```
circle := plot::Circle2d(3, [0, 0]):
arc := plot::Arc2d(3, [0, 0], 0 .. PI/4, LineColor = RGB::Red,
 LineWidth = 1.5*unit::mm):
plot(circle, arc)
```

# plot::Arc3d

---

```
delete circle, arc:
```

## Example 2

The center of an arc may be given as the second argument to `plot::Arc2d`:

```
arc1 := plot::Arc2d(3, [1, 3], 0..PI/2, Closed = TRUE):
arc2 := plot::Arc2d(3, [3, 1], -PI ..0, Closed = TRUE):
plot(arc1, arc2)
```

The center is accessible as the attribute `Center` of the arc object. We change the center of the second arc:

```
arc2::Center := [1, 3]:
plot(arc1, arc2)
```

```
delete arc1, arc2:
```

### Example 3

A filled arc is a segment of a circle, like a piece of pie:

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE))
```

## plot::Arc3d

---

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, Closed = TRUE))
```

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE,
 FillPattern = Solid, LinesVisible = FALSE),
 AxesInFront = TRUE)
```

## Example 4

When giving a list of two radii, `plot::Arc2d` draws a segment of an ellipse with the corresponding semi-axes:

```
arc1 := plot::Arc2d([2, 1], 0 .. PI, Color = RGB::Blue):
arc2 := plot::Arc2d([2, 1], -PI .. 0, Color = RGB::Red):
plot(arc1, arc2)
```

```
delete arc1, arc2:
```

### Example 5

To plot or animate segments of a tilted ellipse, use the attribute `Angle`:

```
arc:= [1, 1], [0, 0], PI/4..PI/2, Filled, Closed, FillPattern=So
plot(plot::Arc2d(arc, Angle=a+0, a=0..2*PI, FillColor=RGB::
 plot::Arc2d(arc, Angle=a+1/2*PI, a=0..2*PI, FillColor=RGB::
 plot::Arc2d(arc, Angle=a+PI, a=0..2*PI, FillColor=RGB::
 plot::Arc2d(arc, Angle=a+3/2*PI, a=0..2*PI, FillColor=RGB::
```

## plot::Arc3d

---

`delete arc:`

### **Example 6**

Further examples of animated 2D arcs:

```
plot(plot::Arc2d(1, a .. PI, a = 0..PI))
```

```
plot(plot::Arc2d([1 + a^2/2, 1 + a], -PI/2 .. PI/2, a = 0..4))
```

## Example 7

We plot an animated 3D arc:

```
plot(plot::Arc3d(1, [0,0,0], [0,a,1-a], 0..3/2*PI, a = 0..1))
```

### Example 8

We plot a colored 3D arcs:

```
plot(plot::Arc3d(1, [0,0,0], 0.1..2*PI-0.1, Filled,
 LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType =
 FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType =
))
```

## Parameters $r$

The radius of the circle. This must be a real numerical value or an arithmetical expression of the animation parameter  $a$ .

$r$  is equivalent to the attributes SemiAxisX, SemiAxisY.

## $r_1, r_2$

The semi-axes of an elliptical arc. They must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$r_1, r_2$  are equivalent to the attributes SemiAxisX, SemiAxisY.

## $c_x, c_y, c_z$

The center point. The coordinates  $c_x, c_y, c_z$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ . If no center is specified, an arc centered at the origin is created.

$c_x, c_y, c_z$  are equivalent to the attribute Center.

**$n_x, n_y, n_z$** 

The normal vector. The coordinates  $n_x, n_y, n_z$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ . If no normal vector is specified, the arc is created in the xy-plane.

$n_x, n_y, n_z$  are equivalent to the attribute Normal.

..

The angle range in radians:  $\Delta$  and  $\text{end}$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ . The default range is  $0 \dots 2*PI$ .

$\Delta \dots \text{end}$  is equivalent to the attribute AngleRange.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

plot | plot::copy

**MuPAD  
Graphical  
Primitives**

plot::Arc2d | plot::Circle2d | plot::Ellipse2d |  
plot::Ellipse3d

# plot::Arrow2d

---

**Purpose** 2D arrows

**Syntax** `plot::Arrow2d(<[x1, y1]>, [x2, y2], <a = amin .. amax>, options)`

**Description** `plot::Arrow2d([ x1, y1], [ x2, y2])` creates a 2D arrow from the point (x<sub>1</sub>, y<sub>1</sub>) to the point (x<sub>2</sub>, y<sub>2</sub>).

`plot::Arrow2d([ x2, y2])` creates a 2D arrow from the point (0, 0) to the point (x<sub>2</sub>, y<sub>2</sub>).

The points defining an arrow can also be passed as vectors.

The appearance of arrows can be controlled by various attributes:

- `Color` sets the color.
- `LineWidth` and `LineStyle` set the width and the style (solid, dashed, dotted).
- `TipLength`, `TipAngle`, and `TipStyle` control the arrow tip.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Color</code>	the main color	<code>RGB::Blue</code>
<code>Frames</code>	the number of frames in an animation	50
<code>From</code>	starting point of arrows and lines	[0, 0]

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
FromX	starting point of arrows and lines, x-coordinate	0
FromY	starting point of arrows and lines, y-coordinate	0
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

## plot::Arrow2d

---

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
TipAngle	opening angle of arrow heads	$(2*PI) / 15$
TipStyle	presentation style of arrow heads	Filled
TipLength	length of arrow heads	4
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
To	end point of arrows and lines	[1, 0]
ToX	end point of arrows and lines, x-coordinate	1
ToY	end point of arrows and lines, y-coordinate	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We create and plot some arrows:

```
plot(plot::Arrow2d([1, 1]), plot::Arrow2d([1, 3]),
 plot::Arrow2d([1, 1], [1, 3]))
```

# plot::Arrow2d

---

Various attributes are available to control the presentation style of an arrow:

```
plot(plot::Arrow2d([1, 1], Color = RGB::Red,
 TipStyle = Open, TipLength = 10*unit::mm),
 plot::Arrow2d([-1, 1], Color = RGB::Green,
 LineWidth = 0.8*unit::mm,
 TipStyle = Closed, TipAngle = PI/2),
 plot::Arrow2d([0, -sqrt(2)], Color = RGB::Blue,
 LineStyle = Dashed),
 Axes = None)
```

Here are corresponding arrows in 3D:

```
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red,
 TipStyle = Open, TipLength = 10*unit::mm),
 plot::Arrow3d([-1, 1, 0], Color = RGB::Green,
 LineWidth = 0.8*unit::mm,
 TipStyle = Closed, TipAngle = PI/2),
 plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue,
 LineStyle = Dashed),
 CameraDirection = [0, -1, 1000])
```

## plot::Arrow2d

---

We use `Tubular = TRUE`:

```
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red,
 TipLength = 10*unit::mm),
 plot::Arrow3d([-1, 1, 0], Color = RGB::Green,
 TubeDiameter = 1.5*unit::mm,
 TipAngle = PI/2),
 plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue),
 Tubular = TRUE, CameraDirection = [0, -1, 1000])
```

### Example 2

We plot an arrow with fixed starting point and animated end point:

```
plot(plot::Circle2d(2, [1, 2]),
 plot::Arrow2d([1, 2], [1 + 2*cos(a), 2 + 2*sin(a)],
 a = 0..2*PI))
```

# plot::Arrow2d

---

## Parameters

**$x_1, y_1$**

The coordinates of the starting point: real numerical values or arithmetical expressions of the animation parameter  $a$ . If no starting point is specified, an arrow starting at the origin is created.

$x_1, y_1$  are equivalent to the attributes FromX, FromY.

**$x_2, y_2$**

The coordinates of the end point: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x_2, y_2$  are equivalent to the attributes ToX, ToY.

**$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

`plot::Arrow3d` | `plot::Line2d` | `plot::Line3d` |  
`plot::VectorField2d`

# plot::Arrow3d

---

**Purpose** 3D arrows

**Syntax** `plot::Arrow3d(<[x1, y1, z1]>, [x2, y2, z2], <a = amin .. amax>, options)`

**Description** `plot::Arrow3d([ x1, y1, z1], [ x2, y2, z2])` creates a 3D arrow from the point (x<sub>1</sub>, y<sub>1</sub>, z<sub>1</sub>) to the point (x<sub>2</sub>, y<sub>2</sub>, z<sub>2</sub>).  
`plot::Arrow3d([ x2, y2, z2])` creates a 3D arrow from the point (0, 0, 0) to the point (x<sub>2</sub>, y<sub>2</sub>, z<sub>2</sub>).

The points defining an arrow can also be passed as vectors.

The appearance of arrows can be controlled by various attributes:

- Color sets the color.
- LineWidth and LineStyle set the width and the style (solid, dashed, dotted).
- TipLength, TipAngle, and TipStyle control the arrow tip.
- With Tubular = TRUE, 3D arrows are rendered as 3D tubes with a diameter set by TubeDiameter. The arrow head is rendered as a cone.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::Blue
Frames	the number of frames in an animation	50
From	starting point of arrows and lines	[0, 0, 0]

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
FromX	starting point of arrows and lines, x-coordinate	0
FromY	starting point of arrows and lines, y-coordinate	0
FromZ	starting point of arrows and lines, z-coordinate	0
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
Name	the name of a plot object (for browser and legend)	

## plot::Arrow3d

---

Attribute	Purpose	Default Value
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
TipAngle	opening angle of arrow heads	$(2 * \text{PI}) / 15$
TipStyle	presentation style of arrow heads	Filled
TipLength	length of arrow heads	4
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
To	end point of arrows and lines	[1, 0, 0]
ToX	end point of arrows and lines, x-coordinate	1
ToY	end point of arrows and lines, y-coordinate	0
ToZ	end point of arrows and lines, z-coordinate	0
Tubular	display 3D arrows and lines as tubes?	FALSE
TubeDiameter	diameter of tubular arrows and lines.	1.0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

# plot::Arrow3d

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We create and plot some arrows:

```
plot(plot::Arrow2d([1, 1]), plot::Arrow2d([1, 3]),
 plot::Arrow2d([1, 1], [1, 3]))
```

Various attributes are available to control the presentation style of an arrow:

```
plot(plot::Arrow2d([1, 1], Color = RGB::Red,
 TipStyle = Open, TipLength = 10*unit::mm),
 plot::Arrow2d([-1, 1], Color = RGB::Green,
 LineWidth = 0.8*unit::mm,
 TipStyle = Closed, TipAngle = PI/2),
 plot::Arrow2d([0, -sqrt(2)], Color = RGB::Blue,
 LineStyle = Dashed),
 Axes = None)
```

Here are corresponding arrows in 3D:

```
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red,
 TipStyle = Open, TipLength = 10*unit::mm),
 plot::Arrow3d([-1, 1, 0], Color = RGB::Green,
 LineWidth = 0.8*unit::mm,
 TipStyle = Closed, TipAngle = PI/2),
 plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue,
 LineStyle = Dashed),
 Axes = None)
```

# plot::Arrow3d

```
CameraDirection = [0, -1, 1000])
```

We use Tubular = TRUE:

```
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red,
 TipLength = 10*unit::mm),
 plot::Arrow3d([-1, 1, 0], Color = RGB::Green,
 TubeDiameter = 1.5*unit::mm,
 TipAngle = PI/2),
 plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue),
 Tubular = TRUE, CameraDirection = [0, -1, 1000])
```

### Example 2

We plot an arrow with fixed starting point and animated end point:

```
plot(plot::Circle2d(2, [1, 2]),
 plot::Arrow2d([1, 2], [1 + 2*cos(a), 2 + 2*sin(a)],
 a = 0..2*PI))
```

# plot::Arrow3d

---

## Parameters

**$x_1, y_1, z_1$**

The coordinates of the starting point: real numerical values or arithmetical expressions of the animation parameter  $a$ . If no starting point is specified, an arrow starting at the origin is created.

$x_1, y_1, z_1$  are equivalent to the attributes FromX, FromY, FromZ.

**$x_2, y_2, z_2$**

The coordinates of the end point: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x_2, y_2, z_2$  are equivalent to the attributes ToX, ToY, ToZ.

**$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Bars2d

---

**Purpose** 2D bar chart

**Syntax**  
`plot::Bars2d([[a1, a2, ], [b1, b2, ], ], <a = amin .. amax>, options)`  
`plot::Bars2d([a1, a2, ], <a = amin .. amax>, options)`

**Description** `plot::Bars2d([[ a1, a2, ...], [ b1, b2, ...], ...])` generates a bar chart with bar heights a<sub>1</sub>, b<sub>1</sub>, ..., a<sub>2</sub>, b<sub>2</sub>, ...

`plot::Bars2d([ a1, a2, ...])` creates a bar chart with bars of height a<sub>1</sub>, a<sub>2</sub>, ...

With `plot::Bars2d([[ a1, a2, ...], [ b1, b2, ...], ...])`, bars are plotted in the order a<sub>1</sub>, b<sub>1</sub>, ..., a gap, a<sub>2</sub>, b<sub>2</sub>, ... Cf. “Example 2” on page 23-160.

The horizontal positions and the widths of the bars may be controlled by the attributes `BarCenters` and `BarWidths`, respectively.

The attribute `GroupStyle` provides grouping options.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	FALSE
<code>BarStyle</code>	display style of bar plots	Boxes
<code>BarWidths</code>	widths of bars	[[1.0]]
<code>BarCenters</code>	position of bars	
<code>Color</code>	the main color	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
Data	the (statistical) data to plot	
DrawMode	orientation of boxes and bars	Vertical
Filled	filled or transparent areas and surfaces	TRUE
FillPatterns	list of area fill types	[Solid]
Frames	the number of frames in an animation	50
GroupStyle	grouping options in 2D bar plots	MultipleBars
Legend	makes a legend entry

VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

# plot::Bars2d

---

## Examples

### Example 1

Given a single list of values, `plot::Bars2d` plots bars of the corresponding height, filled solidly in one color:

```
plot(plot::Bars2d([1, 2, 3, 4, 5]))
```

### Example 2

When asked to plot a list of lists of values, `plot::Bars2d` will group the first entries of all lists, the second entries and so on, with a small gap between the groups:

```
plot(plot::Bars2d([[5, 10, 24, -3],
 [6, 5, 2, 18],
 [19, 45, 12, -10]]))
```

### Example 3

The appearance of the plots can be controlled with a number of attributes. For example, `Colors` accepts a list of colors for the bars and `Shadows` switches on “shadows,” giving a slight impression of depth:

```
plot(plot::Bars2d([[5, 10, 24, -3],
 [6, 5, 2, 18],
 [19, 45, 12, -10]],
 Colors = [RGB::Red, RGB::Green, RGB::Blue],
 Shadows = TRUE))
```

# plot::Bars2d

---

Using DrawMode, plot::Bars2d can be made to draw horizontal bars instead of vertical ones:

```
plot(plot::Bars2d([[.5, 1.0, 2.4, -.3],
 [.6, .5, .2, 1.8],
 [1.9, 4.5, 1.2, -1.0]],
 Colors = [RGB::Red,RGB::Green,RGB::Blue],
 Shadows = TRUE, DrawMode = Horizontal))
```

BarStyle is used to plot points or lines instead of rectangles:

```
plot(plot::Bars2d([[5, 10, 24, -3],
 [6, 5, 2, 18],
 [19, 45, 12, -10]], BarStyle = Lines))
```

# plot::Bars2d

---

## Example 4

We demonstrate alternative grouping styles:

```
plot(plot::Bars2d([[5, 10, 15, 20],
 [6, 5, 4, 3],
 [10, 5, 3, 1]], GroupStyle = MultipleBars))
```

```
plot(plot::Bars2d([[5, 10, 15, 20],
 [6, 5, 4, 3],
 [10, 5, 3, 1]], GroupStyle = SingleBars))
```

# plot::Bars2d

---

## Example 5

To plot a single group of data with different colors, they must be placed in individual lists:

```
plot(plot::Bars2d([[binomial(15,i)] $ i = 0..15],
 Colors = [[1-j/15, j/15, 0.9] $ j = 0..15]),
 XAxisVisible)
```

### Example 6

plot::Bars2d accepts input in form of lists (as above), as a matrix, or as a one- or two-dimensional array:

```
L := [[2, 1, 2, 4, 5],
 [1, 2, 3, 2, 1],
 [2, -1, -3, 1, 2],
 [5, 4, 3, 2, 1],
 [2, 1, 2, 1, 2]]:
M := matrix(L):
A := array(1..5, 1..5,
 (1,1) = 2, (1,2) = 1, (1,3) = 2, (1,4) = 4, (1,5) = 5,
 (2,1) = 1, (2,2) = 2, (2,3) = 3, (2,4) = 2, (2,5) = 1,
 (3,1) = 2, (3,2) = 1, (3,3) = -3, (3,4) = 1, (3,5) = 2,
 (4,1) = 5, (4,2) = 4, (4,3) = 3, (4,4) = 2, (4,5) = 1,
 (5,1) = 2, (5,2) = 1, (5,3) = 2, (5,4) = 1, (5,5) = 2)
plot(plot::Bars2d(L))
```

# plot::Bars2d

---

```
plot(plot::Bars2d(M))
```

```
plot(plot::Bars2d(A))
```

## Example 7

Here is a real life example of a bar plot taken from a German magazine. It visualizes data related to waste management. We reproduce the plot via MuPAD. The main ingredient is a bar plot generated via `plot::Bars2d` with the option `GroupStyle = SingleBars`. Generating the annotations is somewhat tricky:

```
data := [[25 , 24.6, 30.8],
 [2 , 2.8, 11],
 [7.1, 3.3, 4.05]]:

sw := 1.5:
bw := 2.0:
n := nops(data):
w := sw + bw:
myticks := [(i-1)* w + sw + bw/2 $ i = 1..n]:

m := nops(data[1]):
```

```

datalabels := ["Prognos", "LAGA", "BDE"]:

// cumulative data for the groups
datasums := _concat(datalabels[i].": ".
 expr2text(_plus(data[j][i]$j=1..m)).
 " megatons " $i=1..n):

// generate a list of text objects containing the data values
// and place them in the centers of the bars:
datatext := []:
for i from 1 to n do
 h := 0;
 for j from 1 to m do
 d := data[j][i];
 datatext := datatext, plot::Text2d(expr2text(d),
 [myticks[i], h + d/2],
 TextFont = [8, RGB::White],
 VerticalAlignment = Center,
 HorizontalAlignment = Center),
 h := h + d
 end
end:
end:

```

Here is the bar plot with the annotations. Many scene options are used to fine tune the graphics:

```

S1:=plot::Scene2d(
 plot::Bars2d(data,
 Colors=[RGB::LimeGreen, RGB::Blue, RGB::Red],
 GroupStyle = SingleBars,
 BarCenters = [myticks[i] $ i=1..n],
 BarWidths = [[bw]],
 DrawMode = Vertical),

 // scene options:

```

```
ViewingBox = [0 .. w*n + sw, 0 .. 50],

// options for the grid
XGridVisible = FALSE,
YGridVisible = TRUE,
XSubgridVisible = FALSE,
YSubgridVisible = TRUE,
GridLineColor = RGB::DarkGrey,
SubgridLineColor = RGB::DarkGrey,

// options for the axes
Axes = Boxed,
AxesTips = FALSE,
AxesInFront = TRUE,
AxesTitleFont = ["Arial", 12, Bold],
XAxisVisible = TRUE,
YAxisTitleOrientation = Vertical,
YAxisTitleAlignment = Center,
YAxisTitle = "megatons",
XAxisTitle = "",

// options for the ticks along the axes
TicksLabelFont = ["Arial", 10],
XTicksVisible = FALSE,
XTicksNumber = None,
XTicksAt = [myticks[i] = datalabels[i] $ i=1..n],

// layout
RightMargin = 50,

// annotation
datatext,

// header and footer
Header = "Capacities in megatons",
HeaderFont = ["Arial", 12, Bold],
Footer = "\n\nAmount of waste taken into account:\n".datasums,
```

```

FooterFont = ["Arial", 8],
FooterAlignment = Left,

// use a yellowish background
BackgroundColor = [0.886275, 0.870588, 0.294118]
):

plot(S1)

```

Next, we build a legend made of colored rectangles and text objects:

```

S2 := plot::Scene2d(
 ViewingBox = [0..20, 0..50],
 Axes = None,
 plot::Rectangle(13..13.5, 35..36,
 Filled = TRUE,
 FillPattern = Solid,
 FillColor = RGB::Red,

```

## plot::Bars2d

---

```
 LineColor = RGB::Black),
plot::Text2d("missing capacities", [14, 35],
 HorizontalAlignment = Left,
 TextFont = ["Arial", 8]),
plot::Rectangle(13..13.5, 29..30,
 Filled = TRUE,
 FillPattern = Solid,
 FillColor = RGB::Blue,
 LineColor = RGB::Black),
plot::Text2d("planned and potential capacities", [14, 29],
 HorizontalAlignment = Left, TextFont = ["Arial", 8])
plot::Rectangle(13..13.5, 23..24,
 Filled = TRUE,
 FillPattern = Solid,
 FillColor = RGB::Green,
 LineColor = RGB::Black),
plot::Text2d("known capacities", [14, 23],
 HorizontalAlignment = Left,
 TextFont = ["Arial", 8])
):
plot(S2, BorderWidth = 0.2)
```

The final picture consists of the bar plot S1 and the legend S2. We just put S2 on top of S1, making the background of S2 transparent:

```
S1::Width := 1: S1::Height := 1:
S2::Width := 1: S2::Height := 1:
S1::Bottom := 0: S1::Left := 0:
S2::Bottom := 0: S2::Left := 0:
S1::BackgroundTransparent := FALSE:
S2::BackgroundTransparent := TRUE:
```

```
plot(S1, S2, Layout = Relative)
```

# plot::Bars2d

`delete data, datalabels, datasums, datatext, myticks, sw, bw, n, m, w, i, h, j, d, S1, S2:`

## Parameters

$a_1, a_2, \dots, b_1, b_2, \dots, \dots$

Real-valued expressions, possibly in the animation parameter.

$a_1, a_2, \dots, b_1, b_2, \dots, \dots$  is equivalent to the attribute `Data`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

**MuPAD  
Graphical  
Primitives**

`plot::Bars3d` | `plot::Histogram2d` | `plot::Scatterplot`

# plot::Bars3d

---

**Purpose** 3D bar chart of matrix data

**Syntax**  
`plot::Bars3d(A, <x = xmin .. xmax, y = ymin .. ymax>, <a = amin .. amax>, options)`  
`plot::Bars3d(L, <x = xmin .. xmax, y = ymin .. ymax>, <a = amin .. amax>, options)`

**Description** `plot::Bars3d(A)` generates a 3D bar chart with bar heights given by the entries of the matrix `A`.

The rows of the matrix are plotted along the  $x$  coordinate, the columns along the  $y$  coordinate.

Different rows may be regarded as different classes of data. Each row has a different color determined by the attribute `Colors = [ c1, c2, ... ]` with RGB or RGBa colors  $c_1, c_2$  etc.

The simplest way to obtain a uniform coloring of all rows with the color `c` is to specify the attribute `Color = c`.

Arrays/matrices do not need to be indexed from 1. E.g.,

```
A = array(`i_{min}` .. `i_{max}`, `j_{min}` .. `j_{max}`, [..data..])
```

yields a bar chart with  $i_{\max} - i_{\min} + 1$  rows and  $j_{\max} - j_{\min} + 1$  columns, stretching from  $x_{\min}$  to  $x_{\max}$  in  $x$  direction and from  $y_{\min}$  to  $y_{\max}$  in  $y$  direction.

If no plot range ``x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`` is specified,  $x_{\min} = j_{\min} - 1$ ,  $x_{\max} = j_{\max}$ ,  $y_{\min} = i_{\min} - 1$ ,  $y_{\max} = i_{\max}$  is used.

When the values are specified by a list of lists `L` and no plot range ``x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`` is specified,  $x_{\min} = 0$ ,  $x_{\max} = m$ ,  $y_{\min} = 0$ ,  $y_{\max} = n$  is used, where  $n$  is the length of `L` and  $m$  is the (common) length of the sublists in `L`. All sublists (“rows”) must have the same length.

The attribute `BarStyle` allows to switch the style of the bars between `Boxes` (bars), `Lines` (vertical lines), `LinesPoints` (vertical lines and points), and `Points`(points only). See “Example 1” on page 23-183.

The attribute `Gap = [gx, gy]` or, equivalently, `XGap = gx`, `YGap = gy` allows to introduce gaps between adjacent bars. The values `gx`, `gy` may be real numerical values between 0 and 1 or expressions of the animation parameter `a`. These values set the fraction of the space reserved for a bar that is not filled by the bar.

With `gx = 0`, `gy = 0`, there are no gaps. With `gx = 0.5`, `gy = 0.5`, the gaps between adjacent bars are of the same size as the bars. With `gx = 1`, `gy = 1`, there bars become lines.

Values of `gx`, `gy` larger than 1 are treated like 1, negative values like 0.

The `Gap` attribute has an effect only for `BarStyle = Boxes`.

The attribute `Ground = z0` determines the `z` value of the lower or upper face of the bars. Matrix values `m > z0` are displayed as bars stretching in `z` direction from the lower face `z0` to the upper face `m`. Matrix values `m < z0` are displayed as bars stretching in `z` direction from the upper face `z0` down to the lower face `m`.

The parameter `z0` has to be a numerical real value or an expression of the animation parameter `a`.

If the attribute `Ground = z0` is not specified, the default value `z0 = 0` is used.

## Attributes

PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	

## plot::Bars3d

---

Attribute	Purpose	Default Value
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XGap	gaps in x direction between the bars of a bar chart	0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YGap	gaps in y direction between the bars of a bar chart	0
YMax	final value of parameter “y”	
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

## Examples

### Example 1

We create some random matrix data and plot them as a bar chart:

```
A := matrix::random(5, 10, frandom) :
plot(plot::Bars3d(A, Gap = [0.4, 0.7]))
```

# plot::Bars3d

---

We create bar charts of the data with different `BarStyle` options:

```
plot(plot::Scene3d(plot::Bars3d(A, BarStyle = Boxes)),
 plot::Scene3d(plot::Bars3d(A, BarStyle = Lines)),
 plot::Scene3d(plot::Bars3d(A, BarStyle = Points)),
 plot::Scene3d(plot::Bars3d(A, BarStyle = LinesPoints)),
 PointSize = 2.0*unit::mm, LineWidth = 0.5*unit::mm
):
```

delete A:

## Example 2

We demonstrate the positioning of bar charts by specifying ranges for the  $x$  and the  $y$  coordinate. The following two bar charts are plotted in one scene. They are placed side by side via suitable  $x$  ranges:

```
A := matrix::random(5, 5, frandom):
plot(plot::Bars3d(A, x = 0 .. 0.9, y = 0 .. 1,
 BarStyle = LinesPoints),
 plot::Bars3d(A, x = 1.1 .. 2, y = 0 .. 1,
 Gap = [0.3, 0.7])):
```

```
delete A:
```

### Example 3

We demonstrate the attributes Ground and Color:

```
A := matrix::random(5, 10, frandom):
plot(plot::Scene3d(plot::Bars3d(A, Ground = 0,
 Color = RGB::Grey)),
 plot::Scene3d(plot::Bars3d(A, Ground = 0.5,
 Color = RGB::Grey)),
 Layout = Horizontal):
```

In the next call, the ground level is animated. Note that in animations one must specify ranges for the  $x$  and  $y$  coordinates. We include a transparent plane visualizing the ground level:

```
plot(plot::Bars3d(A, x = 0 .. 1, y = 0 .. 1, a = 0 .. PI,
 Color = RGB::Grey, Gap = [0.5, 0.5],
 Ground = sin(a)),
 plot::Surface([x, y, sin(a) + 0.001],
 x = 0 .. 1, y = 0 .. 1, a = 0 .. PI,
 Mesh = [2, 2], Color = RGB::Blue.[0.5])):
```

delete A:

## Parameters

### A

An array of domain type `DOM_ARRAY` or a matrix of category `Cat::Matrix` (e.g., of type `matrix` or `densematrix`) containing real numerical values or expressions of the animation parameter  $a$ . Rows/columns of the array, respectively matrix, correspond to rows/columns of the bar chart.

A is equivalent to the attribute `Data`.

### L

A list of lists of real numerical values or expressions of the animation parameter  $a$ . Each sublist of  $L$  represents a row of the bar chart.

L is equivalent to the attribute `Data`.

**x**

Name of the horizontal variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $x$  direction.

$x$  is equivalent to the attribute XName.

 **$x_{\min}$  ..  $x_{\max}$** 

The range of the horizontal variable:  $x_{\min}$ ,  $x_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$x_{\min}$  ..  $x_{\max}$  is equivalent to the attribute XRange.

**y**

Name of the vertical variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $y$  direction.

$y$  is equivalent to the attribute YName.

 **$y_{\min}$  ..  $y_{\max}$** 

The range of the vertical variable:  $y_{\min}$ ,  $y_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$y_{\min}$  ..  $y_{\max}$  is equivalent to the attribute YRange.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Bars3d

---

**MuPAD**  
**Graphical**  
**Primitives**

`plot::Bars2d` | `plot::Histogram2d` | `plot::Matrixplot`

**Purpose** Boxes in 3D

**Syntax**  
`plot::Box(xmin .. xmax, ymin .. ymax, zmin .. zmax, <a = amin .. amax>, options)`  
`plot::Box([xmin, ymin, zmin], [xmax, ymax, zmax], <a = amin .. amax>, options)`

**Description** `plot::Box(`x_{min}`..`x_{max}``, `y_{min}`..`y_{max}``, `z_{min}`..`z_{max}``)` creates the 3D box

$$\{(x \ y \ z) \mid x_{min} \leq x \leq x_{max}, y_{min} \leq y \leq y_{max}, z_{min} \leq z \leq z_{max}\}$$

`plot::Box([xmin, ymin, zmin], [xmax, ymax, zmax])` produces the same box.

`plot::Box` creates 3D boxes with edges parallel to the coordinate axes. Using `plot::Rotate3d` or `plot::Transform3d` one can create boxes and parallelepipeds with arbitrary orientation. Cf. examples “Example 3” on page 23-196 and “Example 4” on page 23-199.

**Attributes**

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::LightBlue
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

YMax	final value of parameter "y"	1
YMin	initial value of parameter "y"	-1
YRange	range of parameter "y"	-1 .. 1
ZMax	final value of parameter "z"	1
ZMin	initial value of parameter "z"	-1
ZRange	range of parameter "z"	-1 .. 1

## Examples

### Example 1

We draw a box consisting of its edges and a filled box:

```
plot(plot::Box(-3..-1, 0..2, 0..1, Filled = FALSE,
 LineColor = RGB::Black),
```

```
plot::Box(1..3, 0..2, 0..1, Filled = TRUE,
 FillColor = RGB::Red),
Axes = None, Scaling = Constrained)
```

## Example 2

The borders of a box can be animated:

```
plot(plot::Box([1, 1, 1], [2, 2, 2 + sin(r)], r = 0..2*PI)):
```

### Example 3

We want to display a cube “standing” on one of its corners. First, we define the cube:

```
b0 := plot::Box(0..1, 0..1, 0..1)
```

```
plot::Box(0..1, 0..1, 0..1)
```

Now, rotating the cube to stand on a corner is equivalent to first rotating around the  $x$ -axis by 45 degrees, then rotating around the  $y$ -axis:

```
b1 := plot::Rotate3d(b0, Axis = [1, 0, 0], Angle = -PI/4):
plot(b1, Scaling = Constrained)
```

```
b2 := plot::Rotate3d(b1, Axis = [0, 1, 0], Angle = 7*PI/36):
plot(b2, Scaling = Constrained)
```

# plot::Box

---

Finally, we let it rotate around the  $z$ -axis:

```
plot(plot::Rotate3d(b2, Axis = [0, 0, 1], Angle = a,
 a = 0..2*PI/3),
 Scaling = Constrained)
```

`delete b0, b1, b2:`

#### Example 4

A parallelepiped can be obtained from a `plot::Box` by a linear transformation:

```
plot(plot::Transform3d([0, 0, 0], [1, 1, 0,
 1, 1, 3,
 0, 3, 1],
 plot::Box(0..1, 0..1, 0..1)),
 Scaling = Constrained,
 CameraDirection = [-27, -12, 22])
```

## Parameters

**$x_{\min}$ ,  $y_{\min}$ ,  $z_{\min}$**

The lower borders: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$x_{\min}$ ,  $y_{\min}$ ,  $z_{\min}$  are equivalent to the attributes XMin, YMin, ZMin.

**$x_{\max}$ ,  $y_{\max}$ ,  $z_{\max}$**

The upper borders: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$x_{\max}$ ,  $y_{\max}$ ,  $z_{\max}$  are equivalent to the attributes XMax, YMax, ZMax.

**$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Boxplot

---

**Purpose** Statistical box plots

**Syntax**

```
plot::Boxplot(L1, , <a = amin .. amax>, options)
plot::Boxplot([L1,], <a = amin .. amax>, options)
plot::Boxplot(A, <a = amin .. amax>, options)
plot::Boxplot(s, <c1, >, <a = amin .. amax>, options)
plot::Boxplot(s, <[c1,]>, <a = amin .. amax>, options)
```

**Description** plot::Boxplot(data) creates a box plot of the given data.

plot::Boxplot creates a box plot of discrete data samples. Box plots reduce data samples to a number of descriptive parameters and are a useful means of comparing statistical data.

In particular, each data sample is represented as one box. A typical box consists of the following subparts:

- A “central box” representing the central 50% of the data. Its lower and upper boundary lines are at the 25%/75% quantile of the data. A central line indicates the median of the data.
- Two vertical lines extending from the central box indicating the remaining data outside the central box that are not regarded as outliers. These lines extend maximally to  $\frac{3}{2}$  times the height of the central box but not past the range of the data.
- Outliers: these are points indicating the remaining data.

# plot::Boxplot

---

With the special attribute `Notched = TRUE`, the sides of the boxes can be notched, thus providing additional information on the data sample. The horizontal width of the notches may be set by the attribute `NotchWidth`.

The special attributes `BoxCenters` and `BoxWidths` allow to center the boxes at arbitrary positions along the horizontal axis and to set the horizontal width of the boxes, respectively.

The special attribute `Averaged` determines whether the quantile values are computed with or without the option `Averaged` (cf. `stats::empiricalQuantile`).

Specifying `DrawMode = Horizontal`, the boxes are rotated by 90 degrees.

The attribute `Colors` allows to specify the color of each box in a box plot. A common color for all boxes may be specified via `Color`.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	FALSE
<code>Averaged</code>	mode for computing quantile lines in box plots	TRUE
<code>BoxWidths</code>	widths of boxes in a box plot	[0.8]
<code>BoxCenters</code>	position of boxes in a box plot	[1]
<code>Color</code>	the main color	

Attribute	Purpose	Default Value
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson]
Data	the (statistical) data to plot	
DrawMode	orientation of boxes and bars	Vertical
Filled	filled or transparent areas and surfaces	TRUE
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE

## plot::Boxplot

---

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
Notched	notched boxes in box plots	FALSE
NotchWidth	width of notches in box plots	0.2
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

Attribute	Purpose	Default Value
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

Just to show basic usage of `plot::Boxplot`, we plot some data samples chosen arbitrarily:

```
data1 := [5, 10, 24, -4, 13]:
data2 := [7, 9, -1, 4, 10, 8, 12, 10, 15]:
b := plot::Boxplot(data1, data2):
plot(b)
```

# plot::Boxplot

We can modify the appearance of the box plot in various ways:

```
b::Notched := TRUE:
b::Colors := [RGB::Green, RGB::Black]:
b::BoxCenters := [2, 3]:
b::FillPattern := XCrossedLines:

plot(b)
```

delete b:

## Example 2

It is possible to shift the whole plot in  $x$ -direction by providing a center for the first box via `BoxCenters`:

```
A := matrix([[5, 6, 19],
 [10, 5, 45],
 [24, 2, 12],
 [-3, 18, -10],
 [-4, 0, - 4]]):
```

```
plot(plot::Boxplot(A, BoxCenters = [2], Notched = TRUE,
 FillPattern = Solid))
```

# plot::Boxplot

delete A:

### Example 3

The primary use of `plot::Boxplot` is comparing data sets. We shall do this for data produced by the following random number generators:

```
f := stats::normalRandom(1, 0.2):
g := stats::uniformRandom(0, 2):
```

Now, we create small samples and compare their boxes:

```
data1 := [f() $ k = 1..100]: // Red
data2 := [f() $ k = 1..100]: // Green
data3 := [g() $ k = 1..100]: // Blue
plot(plot::Boxplot(data1, data2, data1, data3, data2, data3,
 Colors = [RGB::Red, RGB::Green, RGB::Red, RGB::Blue,
 RGB::Green, RGB::Blue],
 BoxCenters = [1, 2, 4, 5, 7, 8], Notched = TRUE))
```

Comparing the central boxes, the blue data differ significantly from the red and the green data. The red and green boxes, however, are quite similar – as they should, given that the red and green data were produced by the same random generator `f`.

```
delete f, g, data1, data2, data3:
```

#### Example 4

For symmetric input data, the images generated by `plot::Boxplot` are symmetric, too:

```
plot(plot::Boxplot([$0..10], [5+5*sin(PI*n/20) $ n=-10..10], Not
```

# plot::Boxplot

## Example 5

By default, the quantile lines of the boxes are computed with the option `Averaged` (see `stats::empiricalQuantile` for details). When using `Averaged = FALSE`, the quantiles are computed without this option:

```
r := random(0..10):
SEED := 123:
data := [r() $ k = 1..250]:
plot(plot::Boxplot(data, Averaged = TRUE, BoxCenters = 0.5, Color =
 plot::Boxplot(data, Averaged = FALSE, BoxCenters = 1.5, Color =
)):
```

```
delete r, SEED, data:
```

### Example 6

Box plots can be animated. We create two data samples and fuse them to a symbolic superposition:

```
f1 := stats::normalRandom(0, 1):
f2 := stats::normalRandom(4, 8):
data0 := sort([f1() $ k = 1..100]):
data1 := sort([f2() $ k = 1..100]):
data01 := [(1 - a)*data0[i] + a*data1[i] $ i = 1..100]:
```

The box associated with the data sample data01 changes from the box associated with data0 to the box associated with data1 as the animation parameter increases from  $a = 0$  to  $a = 1$ :

```
plot(plot::Boxplot(data0, data01, data1, a = 0..1))
```

# plot::Boxplot

```
delete f1, f2, data0, data1, data01:
```

## Parameters

**L<sub>1</sub>, ...**

Data samples: lists of numerical real values or arithmetical expressions of the animation parameter *a*.

L<sub>1</sub>, ... is equivalent to the attribute Data.

**A**

An array of domain type DOM\_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) providing numerical real values or arithmetical expressions of the animation parameter *a*. The columns are regarded as separate data samples. Also a 1-dimensional array, regarded as a single data sample, is accepted.

A is equivalent to the attribute Data.

**s**

A data collection of domain type `stats::sample`. The columns in `s` are regarded as separate data samples.

`s` is equivalent to the attribute `Data`.

**c<sub>1</sub>, ...**

Column indices into `s`: positive integers. These indices, if given, indicate that only the specified columns in `s` should be used as data samples. If no column indices are specified, *all* columns in `s` are used as data samples.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Bars2d` | `plot::Bars3d` | `plot::Histogram2d` |  
`plot::Scatterplot`

# plot::Circle2d

---

**Purpose** 2D circles

**Syntax** `plot::Circle2d(r, <[x, y]>, <a = amin .. amax>, options)`

**Description** `plot::Circle2d(r, [x, y])` creates a 2D circle with radius  $r$  and center  $(x, y)$ .

Per default circles are drawn as lines both in 2D and 3D. The attribute `LineColor` or, equivalently, `Color` serves for setting the line color.

Use the attribute `Filled = TRUE` to create filled circles in 2D.

In 2D, one can choose between hatched and solidly filled circles via the attribute `FillPattern`. The fill color is determined by `FillColor`. The circumferential line can be “switched off” via `LinesVisible = FALSE`.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Center</code>	center of objects, rotation center	[0, 0]
<code>CenterX</code>	center of objects, rotation center, x-component	0
<code>CenterY</code>	center of objects, rotation center, y-component	0
<code>Color</code>	the main color	<code>RGB::Blue</code>
<code>Filled</code>	filled or transparent areas and surfaces	FALSE

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	DiagonalLines

Attribute	Purpose	Default Value
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

Circles centered at the origin are created if only a radius is specified:

```
plot(plot::Circle2d(3)):
```

# plot::Circle2d

---

A center may be given as a list of coordinates:

```
plot(plot::Circle2d(1, [1, 1]),
 plot::Circle2d(2, [1, 2]),
 plot::Circle2d(3, [1, 3])):
```

### Example 2

Radius and center of a circle can be animated. We plot an animated circle with a changing radius and a center moving on a spiral:

```
plot(plot::Curve2d([a*cos(2*a), a*sin(2*a)], a = 0..PI),
 plot::Point2d([a*cos(2*a), a*sin(2*a)], a = 0..PI,
 PointSize = 2*unit:mm),
 plot::Circle2d(0.2 + sin(a), [a*cos(2*a), a*sin(2*a)],
 a = 0..PI))
```

### Example 3

In three dimensions, a circle requires a normal vector. We animate this vector:

```
normal_ := plot::Arrow3d(
 [0, 0, 0],
 [sin(2*a), sin(a)*cos(2*a), cos(a)*cos(2*a)],
 a = 0..2*PI):
circle := plot::Circle3d(1, [0, 0, 0], normal_::To,
 a = 0..2*PI, Filled):
plot(normal_, circle)
```

**Parameters** **r**

The radius: a real numerical value or an arithmetical expression in the animation parameter  $a$ .

$r$  is equivalent to the attribute Radius.

 **$x, y$** 

The center. The coordinates  $x, y$  must be real numerical values or arithmetical expressions in the animation parameter  $a$ . If no center is specified, a circle centered at the origin is created.

$x, y$  are equivalent to the attributes CenterX, CenterY.

 **$a$** 

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Circle2d

---

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Circle3d` | `plot::Cone` | `plot::Sphere`

**Purpose** 3D circles

**Syntax** `plot::Circle3d(r, <[x, y, z]>, <a = amin .. amax>, options)`  
`plot::Circle3d(r, [x, y, z], [nx, ny, nz], <a = amin .. amax>, options)`

**Description** `plot::Circle3d(r, [x, y, z], [ nx, ny, nz])` creates a 3D circle with radius  $r$ , center  $(x, y, z)$ , and normal vector  $(n_x, n_y, n_z)$ .

Per default circles are drawn as lines both in 2D and 3D. The attribute `LineColor` or, equivalently, `Color` serves for setting the line color.

Use the attribute `Filled = TRUE` to create circular discs in 3D.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	<code>TRUE</code>
<code>Center</code>	center of objects, rotation center	<code>[0, 0, 0]</code>
<code>CenterX</code>	center of objects, rotation center, x-component	<code>0</code>
<code>CenterY</code>	center of objects, rotation center, y-component	<code>0</code>
<code>CenterZ</code>	center of objects, rotation center, z-component	<code>0</code>
<code>Color</code>	the main color	<code>RGB::Blue</code>
<code>Filled</code>	filled or transparent areas and surfaces	<code>FALSE</code>

## plot::Circle3d

---

Attribute	Purpose	Default Value
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Normal	normal vector of circles and discs, etc. in 3D	[0, 0, 1]
NormalX	normal vector of circles and discs, etc. in 3D, x-component	0
NormalY	normal vector of circles and discs, etc. in 3D, y-component	0
NormalZ	normal vector of circles and discs, etc. in 3D, z-component	1
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Radius	radius of circles, spheres etc.	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	

# plot::Circle3d

Attribute	Purpose	Default Value
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

Circles centered at the origin are created if only a radius is specified:

```
plot(plot::Circle2d(3)):
```

A center may be given as a list of coordinates:

```
plot(plot::Circle2d(1, [1, 1]),
 plot::Circle2d(2, [1, 2]),
 plot::Circle2d(3, [1, 3])):
```

## Example 2

Radius and center of a circle can be animated. We plot an animated circle with a changing radius and a center moving on a spiral:

```
plot(plot::Curve2d([a*cos(2*a), a*sin(2*a)], a = 0..PI),
 plot::Point2d([a*cos(2*a), a*sin(2*a)], a = 0..PI,
 PointSize = 2*unit::mm),
 plot::Circle2d(0.2 + sin(a), [a*cos(2*a), a*sin(2*a)],
 a = 0..PI))
```

### Example 3

In three dimensions, a circle requires a normal vector. We animate this vector:

```
normal_ := plot::Arrow3d(
 [0, 0, 0],
 [sin(2*a), sin(a)*cos(2*a), cos(a)*cos(2*a)],
 a = 0..2*PI):
circle := plot::Circle3d(1, [0, 0, 0], normal_::To,
 a = 0..2*PI, Filled):
plot(normal_, circle)
```

# plot::Circle3d

---

## Parameters $r$

The radius: a real numerical value or an arithmetical expression in the animation parameter  $a$ .

$r$  is equivalent to the attribute `Radius`.

## $x, y, z$

The center. The coordinates  $x, y, z$  must be real numerical values or arithmetical expressions in the animation parameter  $a$ . If no center is specified, a circle centered at the origin is created.

$x, y, z$  are equivalent to the attributes `CenterX`, `CenterY`, `CenterZ`.

## $n_x, n_y, n_z$

The normal vector. The components  $n_x, n_y, n_z$  must be real numerical values or arithmetical expressions in the animation parameter  $a$ . If no normal is specified, the normal  $(0, 0, 1)$  is used.

$n_x$ ,  $n_y$ ,  $n_z$  are equivalent to the attributes NormalX, NormalY, NormalZ.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

plot::Circle2d | plot::Cone | plot::Sphere

# plot::Cone

---

**Purpose** Cones and frustums

**Syntax** `plot::Cone(br, [bx, by, bz], <tr>, [tx, ty, tz], <a = amin .. amax>, options)`

**Description** `plot::Cone(br, [ bx, by, bz], [ tx, ty, tz])` creates a cone stretching from the base with radius `br` and center `[bx, by, bz]` to the top `[tx, ty, tz]`.

`plot::Cone(br, [ bx, by, bz], tr, [ tx, ty, tz])` creates a conical frustum from the base center `[bx, by, bz]` to the top center `[tx, ty, tz]`. The base radius is `br`, the top radius is `tr`.

The lower center and upper center of the cone can also be passed as vectors.

The optional “top radius” `tr` for creating a frustum may also be specified as the attribute `TopRadius = tr`.

The upper and lower faces of a cone/frustum are not filled. They can be added as filled `plot::Circle3ds`.

Note that only circular cones can be created with `plot::Cone`. For elliptical bases, use a `plot::Surface` primitive or apply a `plot::Scale3d` transformation.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Base</code>	base center of cones, cylinders, pyramids and prisms	[0, 0, 0]

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
BaseX	x-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseY	y-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseZ	z-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseRadius	base radius of cones/conical frustums and pyramids/frustums of pyramids	1
Color	the main color	RGB::LightBlue
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]

## plot:Cone

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0

TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Top	top center of cones, cylinders, pyramids and prisms	[0, 0, 1]
TopX	base and top center of cones, cylinders, pyramids and prisms	0
TopY	base and top center of cones, cylinders, pyramids and prisms	0
TopZ	base and top center of cones, cylinders, pyramids and prisms	1

# plot::Cone

---

Attribute	Purpose	Default Value
TopRadius	top radius of cones/conical frustums and pyramids/frustums of pyramids	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We draw a cone with base radius 6:

```
plot(plot::Cone(6, [0, 0, 0], [0, 0, 10])):
```

### Example 2

We create a conical frustum by specifying a non-zero top radius. Note that no discs are attached to the base and the top. You can look through the frustum:

```
br := 16: base := [3, 4, 5]:
tr:= 7: top := [11, 12, 13]:
plot(plot::Cone(br, base, tr, top, FillColor = RGB::Red)):
```

## plot::Cone

---

We add the discs at the base and the top. Their normals  $n$  are given as the vector from the base to the top:

```
n := zip(top, base, _subtract):
plot(plot::Circle3d(br, base, n, Filled = TRUE),
 plot::Circle3d(tr, top, n, Filled = TRUE),
 plot::Cone(br, base, tr, top),
 LinesVisible = FALSE, FillColor = RGB::Red):
```

```
delete br, base, tr, top, n:
```

### Example 3

A tube or cylinder (in the mathematical sense, i.e., the lateral sides of a physical cylinder) is a special case of a conical frustum with the same top and bottom radius:

```
plot(plot::Cone(6, [0, 0, 0], 6, [11, 12, 13],
 FillColor = RGB::Yellow,
 LinesVisible = TRUE)):
```

# plot::Cone

---

## Example 4

Bottom and top radii and centers can be animated:

```
plot(plot::Cone(sin(a)^2, [sin(2*a), cos(2*a), 0],
 cos(a)^2, [cos(2*a), sin(2*a), 1],
 a = 0..PI, FillColor = RGB::Green)):
```

## Parameters

### **br**

The base radius of the cone. This must be a real numerical value or an arithmetical expression of the animation parameter  $a$ .

$br$  is equivalent to the attribute BaseRadius.

### **$b_x$ , $b_y$ , $b_z$**

The lower center point. The coordinates  $b_x$ ,  $b_y$ ,  $b_z$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$b_x$ ,  $b_y$ ,  $b_z$  are equivalent to the attributes BaseX, BaseY, BaseZ.

### **tr**

The top radius of the cone/conical frustum. This must be a real numerical value or an arithmetical expression of the animation parameter  $a$ . If no top radius is specified, a cone with top radius  $tr = 0$  is created.

# plot::Cone

---

`tr` is equivalent to the attribute `TopRadius`.

**`tx`, `ty`, `tz`**

The upper center point. The coordinates `tx`, `ty`, `tz` must be real numerical values or arithmetical expressions of the animation parameter `a`.

`tx`, `ty`, `tz` are equivalent to the attributes `TopX`, `TopY`, `TopZ`.

**`a`**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where `amin` is the initial parameter value, and `amax` is the final parameter value.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Cylinder` | `plot::Pyramid` | `plot::Prism`

**Purpose** (complex-valued) conformal function plot

**Syntax** `plot::Conformal(f, z = z1 .. z2, <a = amin .. amax>, options)`

**Description** `plot::Conformal(f(z), z = z1..z2 )` is a plot of the conformal function  $f$  over the complex interval  $z_1..z_2$ .

`plot::Conformal` creates plots of (conformal) complex-valued functions of one complex variable. They are displayed by showing the image of a rectangular grid over an interval.

By default, the attribute `LineColorType = Flat` is set. All curves are displayed with the color given by the attribute `LineColor` (or `Color` for short).

When specifying the attribute `LineColorType = Dichromatic`, a color blend from `LineColor` to `LineColor2` is used (“height coloring”).

When specifying the attribute `LineColorType = Functional` without specifying a `LineColorFunction`, all curves parametrized by the real part of the pre-image points are displayed with the flat color `LineColor`, whereas all curves parametrized by the imaginary part of the pre-image points are displayed with the flat color `LineColor2`.

A user defined `LineColorFunction` is a procedure `(z, x, y, flag) -> RGB-color` that will be called with complex floating-point arguments  $z$  from the range of pre-images of the conformal function  $f$ , the real floating point values  $x = \text{Re}(f(z))$ ,  $y = \text{Im}(f(z))$ , and the integer value `flag` which has the values 1 or 2. The flag value 1 determines the color of the curves parametrized by the real part of  $z$ , the flag value 2 determines the color of the curves parametrized by the imaginary part of  $z$ . The color function must return an RGB color, i.e., a list of 3 real floating point values between 0.0 and 1.0. For example,

```
LineColorFunction = proc(z, x, y, flag)
begin
 if flag = 1 then
 return(RGB::Blue)
 else
```

```
 return(RGB::Red)
 end_if;
end_proc
```

displays all curves parametrized by  $\operatorname{Re}(z)$  in blue, while the orthogonal curves, parametrized by  $\operatorname{Im}(z)$ , are displayed in red.

See the examples in the documentation of `RGB` for another way of displaying complex functions.

## Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	0
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE
Color	the main color	RGB::Blue
Frames	the number of frames in an animation	50
Function	function expression or procedure	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink

Attribute	Purpose	Default Value
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Mesh	number of sample points	[11, 11]
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5

# plot::Conformal

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
PointsVisible	visibility of mesh points	FALSE
Submesh	density of submesh (additional sample points)	[0, 0]
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMesh	number of sample points for parameter "x"	11
XSubmesh	density of additional sample points for parameter "x"	0
YMesh	number of sample points for parameter "y"	11
YSubmesh	density of additional sample points for parameter "y"	0
ZMax	final value of parameter "z"	
ZMin	initial value of parameter "z"	
ZName	name of parameter "z"	
ZRange	range of parameter "z"	

# plot::Conformal

---

## Examples

### Example 1

By plotting the identity function, we are presented the pre-image used by `plot::Conformal`:

```
plot(plot::Conformal(z, z = 0..1+I))
```

The important property of conformal functions, as far as plots are concerned, is that orthogonal lines are mapped onto curves meeting orthogonally:

```
plot(plot::Conformal(z^2, z = 0..1+I))
```

This property allows to visually detect overlapping regions (in some cases); in the following example this is the case in the left semi-plane:

```
plot(plot::Conformal(z^(3/2), z = -1-I..1+I))
```

# plot::Conformal

---

## Example 2

The default mesh may in some cases be too coarse:

```
plot(plot::Conformal(sin(z^2), z = 0..1+I))
```

There are at least three ways of improving this plot. Firstly, we can set Mesh to a higher value:

```
plot(plot::Conformal(sin(z^2), z = 0..1+I, Mesh = [50, 50]))
```

# plot::Conformal

---

Another option would be to increase Submesh to get smoother, not more, lines:

```
plot(plot::Conformal(sin(z^2), z = 0..1+I, Submesh = [2, 2]))
```

Finally, we can also ask for an adaptive refinement of the submesh by setting `AdaptiveMesh` to some positive value:

```
plot(plot::Conformal(sin(z^2), z = 0..1+I, AdaptiveMesh = 2))
```

### Example 3

Here is the image of the complex rectangle  $0 \leq \operatorname{Re}(z) \leq x$ ,  $0 \leq \operatorname{Im}(z) \leq 1$  under the map  $z \rightarrow \operatorname{besselJ}(0, z)$ . We choose  $x$  as the second positive root of  $\operatorname{Im}(\operatorname{besselJ}(0, x + I))$ :

```
numeric::solve(Im(besselJ(0, x + I)), x = i .. i+1) $ i = 0..7
```

```
{0.0}, 0, 0, {3.791394324}, 0, 0, {6.993364687}, 0
```

```
plot(plot::Conformal(besselJ(0, z), z = 0 .. 6.9934 + I,
Mesh = [31, 10]))
```

**Parameters**

**f**

An expression in  $z$  and the animation parameter, if present. Expected to be conformal in  $z$ .

$f$  is equivalent to the attribute Function.

**z**

The independent variable: An identifier or indexed identifier.

$z$  is equivalent to the attribute ZName.

**$z_1 .. z_2$**

The (complex) range over which  $f$  should be plotted:  $z_1$  and  $z_2$  should be complex-valued expressions, possibly in the animation parameter.

$z_1 .. z_2$  is equivalent to the attribute ZRange.

**a**

# plot::Conformal

---

Animation parameter, specified as  $\mathbf{a} = \mathbf{a}_{\min} . \mathbf{a}_{\max}$ , where  $\mathbf{a}_{\min}$  is the initial parameter value, and  $\mathbf{a}_{\max}$  is the final parameter value.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Curve2d` | `plot::Function2d`

**Purpose** Parameterized 2D curves

**Syntax**

```
plot::Curve2d([x, y], t = t_min .. t_max, <a =
a_min .. a_max>, options)
plot::Curve2d(A_2d, t = t_min .. t_max, <a = a_min ..
a_max>, options)
plot::Curve2d(piecewiseF(t), t = t_min .. t_max, <a
= a_min .. a_max>, options)
```

**Description** `plot::Curve2d([x(t), y(t)], t = t_min .. t_max)` creates the planar curve

$$\{(x(t), y(t)) \mid t_{\min} \leq t \leq t_{\max}\}$$

`plot::Curve2d` and `plot::Curve3d` construct curves in one parameter (see “Example 1” on page 23-263), possibly animated (see “Example 2” on page 23-264). The curves may contain poles, in which case automatic clipping is used by default (see “Example 4” on page 23-268).

By default, curves are sampled at equidistant values of the parameter `t`. The attribute `AdaptiveMesh` can be used to change this behavior, such that a denser sampling rate is used in areas of higher curvature. Cf. “Example 5” on page 23-270.

Curves are graphical objects that can be manipulated, see the examples and the documentation of the parameters listed below for details.

## Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	0
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE

## plot::Curve2d

---

Attribute	Purpose	Default Value
AntiAliased	antialiased lines and points?	TRUE

VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
YFunction	function for y values	

## Examples

### Example 1

Archimedes' Spiral is defined by  $f(r) = (r \sin(r), r \cos(r))$ . The corresponding call to `plot::Curve2d` reads:

```
curve := plot::Curve2d([r*sin(r), r*cos(r)], r = 0..35)
```

```
plot::Curve2d([r sin(r), r cos(r)], r = 0..35)
```

```
plot(curve)
```

# plot::Curve2d

---

Note that this particular example is even more straightforward to plot using `plot::Polar`.

## Example 2

Continuing the example from above, we define an easy animation by making the angular part time-dependent:

```
curve := plot::Curve2d([r*sin(r-t), r*cos(r-t)],
 r = 0..35, t = 0..2*PI,
 TimeEnd = 5,
 ViewingBox = [-25..25, -25..25]):
plot(curve)
```

Note that to start the animation, you have to double-click the image in the notebook and choose “Start” from the “Animation” menu.

### Example 3

Another useful and easy type of animation is achieved by animating the parameter range. This creates the illusion of the curve being drawn in real time:

```
curve := plot::Curve2d([sin(thet), cos(thet)],
 thet = 0..a,
 a = 0..2*PI):
plot(curve)
```

## plot::Curve2d

---

```
curve := plot::Curve3d([sin(thet)*cos(20*thet),
 sin(thet)*sin(20*thet),
 cos(thet)],
 thet = 0..a,
 a = 0..PI):

plot(curve)
```

Combining this with an animated LineColorFunction, you can even simulate motion:

```
colorfunc := (thet, x, y, a) -> [a-thet, a-thet, 1.0]:
curve := plot::Curve2d([sin(3*thet), sin(4*thet)],
 thet = a-1..a,
 LineColorFunction = colorfunc,
 LineWidth = 1,
 a = 0..2*PI):

plot(curve)
```

## plot::Curve2d

---

### Example 4

Curves with poles are automatically clipped:

```
curve := plot::Curve2d([(1+tan(3*t)^2)*sin(t),
 (1+tan(3*t)^2)*cos(t)],
 t = 0..2*PI):
plot(curve);
```

If the automatically chosen viewing box is not to your liking, you can explicitly set other values:

```
curve::ViewingBox := [-2..2, -2..2]:
plot(curve)
```

# plot::Curve2d

---

## Example 5

By default, curves are drawn by evaluating at equidistant values of the curve parameter. For curves that have few regions of high curvature, this may be inappropriate:

```
plot(plot::Curve2d([arctan(t), t^2-10*exp(-50*t^2)],
t = -PI..PI))
```

Note the hard “kink” at the bottom of the picture. On the other hand, the remainder of the curve is sufficiently smooth, so globally increasing the number of evaluation points is not desirable. `AdaptiveMesh` makes `plot::Curve2d` look for these kinks and adaptively increase the mesh density in problematic areas:

```
plot(plot::Curve2d([arctan(t), t^2-10*exp(-50*t^2)],
 t = -PI..PI, AdaptiveMesh = 2))
```

## plot::Curve2d

---

### Example 6

To display a curve in the complex plane, map the list-valued function  $[\text{Re}, \text{Im}]$  to the curve:

```
plot(plot::Curve2d([Re, Im](zeta(I*y+1/2)), y=0..42,
 AdaptiveMesh=3),
 XAxisTitle = "Re(z)", YAxisTitle = "Im(z)")
```

### Example 7

Create the following piecewise function:

```
f := piecewise([t < 0, [t, sin(10*t)^2, t^3]], [t >= 0, [t, 5*t/
```

$$\begin{cases} [t, \sin(10 t)^2, t^3] & \text{if } t < 0 \\ [t, 5 t e^{-t}, -t^2] & \text{if } 0 \leq t \end{cases}$$

Now, plot this function:

```
plot(plot::Curve3d(f, t = -10..10))
```

# plot::Curve2d

---

## Parameters

**x, y**

Real-valued expressions in  $t$  (and possibly the animation parameter)

**A<sub>2d</sub>**

A matrix of category `Cat::Matrix` with two entries that provide the parametrization  $x, y$  of a 2D curve

**piecewiseF(t)**

A `piecewise` object

**t**

An identifier or an indexed identifier

**t<sub>min</sub>, t<sub>max</sub>**

Real-valued expressions (possibly in the animation parameter)

**a**

Animation parameter, specified as  $a = a_{\min} . . a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Curve3d

---

**Purpose** Parameterized 3D curves

**Syntax**  
`plot::Curve3d([x, y, z], t = tmin .. tmax, <a = amin .. amax>, options)`  
`plot::Curve3d(A3d, t = tmin .. tmax, <a = amin .. amax>, options)`  
`plot::Curve3d(piecewiseF(t), t = tmin .. tmax, <a = amin .. amax>, options)`

**Description** `plot::Curve3d([x(t), y(t), z(t)], t = tmin.. tmax)` creates the space curve

$$\{(x(t), y(t), z(t)) \mid t_{\min} \leq t \leq t_{\max}\}$$

`plot::Curve2d` and `plot::Curve3d` construct curves in one parameter (see “Example 1” on page 23-280), possibly animated (see “Example 2” on page 23-281). The curves may contain poles, in which case automatic clipping is used by default (see “Example 4” on page 23-285).

By default, curves are sampled at equidistant values of the parameter  $t$ . The attribute `AdaptiveMesh` can be used to change this behavior, such that a denser sampling rate is used in areas of higher curvature. Cf. “Example 5” on page 23-287.

Curves are graphical objects that can be manipulated, see the examples and the documentation of the parameters listed below for details.

## Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	0
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Color</code>	the main color	RGB::Blue

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
DiscontinuitySearch	semi-symbolic search for discontinuities	TRUE
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0

# plot::Curve3d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	121
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Submesh	density of submesh (additional sample points)	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
UMax	final value of parameter "u"	5
UMesh	number of sample points for parameter "u"	121
UMin	initial value of parameter "u"	-5
UName	name of parameter "u"	
URange	range of parameter "u"	-5 .. 5
USubmesh	density of additional sample points for parameter "u"	0

# plot::Curve3d

---

Attribute	Purpose	Default Value
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
YFunction	function for y values	
ZFunction	function for z values	

## Examples

### Example 1

Archimedes' Spiral is defined by  $f(r) = (r\sin(r), r\cos(r))$ . The corresponding call to `plot::Curve2d` reads:

```
curve := plot::Curve2d([r*sin(r), r*cos(r)], r = 0..35)
```

```
plot::Curve2d([r sin(r), r cos(r)], r = 0..35)
```

```
plot(curve)
```

Note that this particular example is even more straightforward to plot using `plot::Polar`.

### Example 2

Continuing the example from above, we define an easy animation by making the angular part time-dependent:

```
curve := plot::Curve2d([r*sin(r-t), r*cos(r-t)],
 r = 0..35, t = 0..2*PI,
 TimeEnd = 5,
 ViewingBox = [-25..25, -25..25]):
plot(curve)
```

# plot::Curve3d

---

Note that to start the animation, you have to double-click the image in the notebook and choose “Start” from the “Animation” menu.

### Example 3

Another useful and easy type of animation is achieved by animating the parameter range. This creates the illusion of the curve being drawn in real time:

```
curve := plot::Curve2d([sin(thet), cos(thet)],
 thet = 0..a,
 a = 0..2*PI):
plot(curve)
```

```
curve := plot::Curve3d([sin(thet)*cos(20*thet),
 sin(thet)*sin(20*thet),
 cos(thet)],
 thet = 0..a,
 a = 0..PI):

plot(curve)
```

## plot::Curve3d

---

Combining this with an animated LineColorFunction, you can even simulate motion:

```
colorfunc := (thet, x, y, a) -> [a-thet, a-thet, 1.0]:
curve := plot::Curve2d([sin(3*thet), sin(4*thet)],
 thet = a-1..a,
 LineColorFunction = colorfunc,
 LineWidth = 1,
 a = 0..2*PI):

plot(curve)
```

#### Example 4

Curves with poles are automatically clipped:

```
curve := plot::Curve2d([(1+tan(3*t)^2)*sin(t),
 (1+tan(3*t)^2)*cos(t)],
 t = 0..2*PI):
plot(curve);
```

## plot::Curve3d

---

If the automatically chosen viewing box is not to your liking, you can explicitly set other values:

```
curve::ViewingBox := [-2..2, -2..2]:
plot(curve)
```

### Example 5

By default, curves are drawn by evaluating at equidistant values of the curve parameter. For curves that have few regions of high curvature, this may be inappropriate:

```
plot(plot::Curve2d([arctan(t), t^2-10*exp(-50*t^2)],
 t = -PI..PI))
```

## plot::Curve3d

---

Note the hard “kink” at the bottom of the picture. On the other hand, the remainder of the curve is sufficiently smooth, so globally increasing the number of evaluation points is not desirable. `AdaptiveMesh` makes `plot::Curve2d` look for these kinks and adaptively increase the mesh density in problematic areas:

```
plot(plot::Curve2d([arctan(t), t^2-10*exp(-50*t^2)],
 t = -PI..PI, AdaptiveMesh = 2))
```

### Example 6

To display a curve in the complex plane, map the list-valued function  $[\text{Re}, \text{Im}]$  to the curve:

```
plot(plot::Curve2d([Re, Im](zeta(I*y+1/2)), y=0..42,
 AdaptiveMesh=3),
 XAxisTitle = "Re(z)", YAxisTitle = "Im(z)")
```

# plot::Curve3d

## Example 7

Create the following piecewise function:

```
f := piecewise([t < 0, [t, sin(10*t)^2, t^3]], [t >= 0, [t, 5*t/exp
```

$$\begin{cases} [t, \sin(10 t)^2, t^3] & \text{if } t < 0 \\ [t, 5 t e^{-t}, -t^2] & \text{if } 0 \leq t \end{cases}$$

Now, plot this function:

```
plot(plot::Curve3d(f, t = -10..10))
```

## Parameters

**$x, y, z$**

Real-valued expressions in  $t$  (and possibly the animation parameter)

**$A_{3d}$**

A matrix of category `Cat::Matrix` with three entries that provide the parametrization  $x, y, z$  of a 3D curve

**piecewiseF(t)**

A `piecewise` object

**t**

An identifier or an indexed identifier

**$t_{\min}, t_{\max}$**

Real-valued expressions (possibly in the animation parameter)

# plot::Curve3d

---

**a**

Animation parameter, specified as  $a = a_{\min}..a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

**Purpose**           Cylinders

**Syntax**           `plot::Cylinder(r, [x1, y1, z1], [x2, y2, z2], <a = amin .. amax>, options)`

**Description**     `plot::Cylinder(r, [x1, y1, z1] , [x2, y2, z2] )` creates a cylinder of radius  $r$  with an axis from the point  $[x_1, y_1, z_1]$  to the point  $[x_2, y_2, z_2]$ .

The base center and top center of the cylinder can also be passed as vectors.

A cylinder created by `plot::Cylinder` consists of the lateral surface and the “lids” (discs with centers  $[x_1, y_1, z_1]$  and  $[x_2, y_2, z_2]$ , respectively.)

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Base	base center of cones, cylinders, pyramids and prisms	[0, 0, 0]
BaseX	x-coordinate of top center of cones, cylinders, pyramids and prisms	0

VisibleBeforeBegin	object visible before its animation time starts?	TRUE

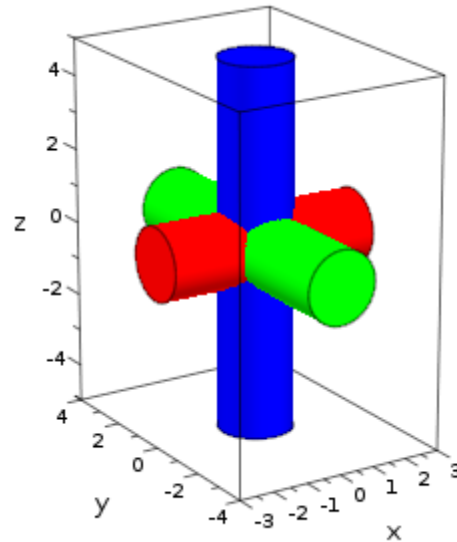

## Examples

### Example 1

We plot three cylinders with symmetry axes given by the coordinate axes:

```
plot(plot::Cylinder(1, [-3, 0, 0], [3, 0, 0],
 Color = RGB::Red),
 plot::Cylinder(1, [0, -4, 0], [0, 4, 0],
 Color = RGB::Green),
```

```
plot::Cylinder(1, [0, 0, -5], [0, 0, 5],
 Color = RGB::Blue):
```

## Example 2

All parameters of a cylinder can be animated:

```
plot(plot::Cylinder(a, [0, 0, a], [0, 0, 3 - a],
 a = 1 .. 2))
```

# plot::Cylinder

---

## Parameters **r**

The radius of the cylinder: a real numerical value or an arithmetical expression of the animation parameter **a**.

**r** is equivalent to the attribute **Radius**.

## **x<sub>1</sub>, y<sub>1</sub>, z<sub>1</sub>**

Components of the base center: real numerical values or expressions of the animation parameter **a**.

**x<sub>1</sub>, y<sub>1</sub>, z<sub>1</sub>** are equivalent to the attributes **BaseX, BaseY, BaseZ**.

## **x<sub>2</sub>, y<sub>2</sub>, z<sub>2</sub>**

Components of the top center: real numerical values or expressions of the animation parameter **a**.

**x<sub>2</sub>, y<sub>2</sub>, z<sub>2</sub>** are equivalent to the attributes **TopX, TopY, TopZ**.

## **a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Cylindrical

---

## Purpose

Surfaces in 3D parameterized in cylindrical coordinates

## Syntax

```
plot::Cylindrical([r, , z], u = u_min .. u_max, v = v_min ..
v_max, <a = a_min .. a_max>, options)
```

## Description

`plot::Cylindrical` creates surfaces parametrized in cylindrical coordinates.

The surface given by a mapping (“parametrization”)

$(u, v) \rightarrow (r(u, v), \phi(u, v), z(u, v))$  is the set of all image points

$$\left\{ \begin{pmatrix} r(u, v) \\ \phi(u, v) \\ z(u, v) \end{pmatrix} \middle| u \in [u_{\min}, u_{\max}], v \in [v_{\min}, v_{\max}] \right\}$$

in cylindrical coordinates, which translate to the usual “Cartesian” coordinates as

$$\begin{aligned} x &= r \cos(\phi) \\ y &= r \sin(\phi) \\ z &= z \end{aligned}$$

$r$  is referred to as “radius,”  $\phi$  as “polar angle,” and  $z$  as the “height” of a point.

The functions  $r$ ,  $\phi$ ,  $z$  are evaluated on a regular equidistant mesh of sample points in the  $u$ - $v$  plane. This mesh is determined by the attributes `UMesh`, `VMesh`. By default, the attribute `AdaptiveMesh = 0` is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of `UMesh`, `VMesh` or `USubmesh`, `VSubmesh`, or set `AdaptiveMesh = n` with some (small) positive integer  $n$ . If necessary, up to  $2^n - 1$  additional points are placed in each direction

of the  $u$ - $v$  plane between adjacent points of the initial equidistant mesh. Cf. “Example 2” on page 23-310.

“Coordinate lines” (“parameter lines”) are curves on the surface.

The phrase “ULines” refers to the curves  $(r(u, v_0), \phi(u, v_0), z(u, v_0))$  with the parameter  $u$  running from  $u_{\min}$  to  $u_{\max}$ , while  $v_0$  is some fixed value from the interval  $[v_{\min}, v_{\max}]$ .

The phrase “VLines” refers to the curves  $(r(u_0, v), \phi(u_0, v), z(u_0, v))$  with the parameter  $v$  running from  $v_{\min}$  to  $v_{\max}$ , while  $u_0$  is some fixed value from the interval  $[u_{\min}, u_{\max}]$ .

By default, the parameter curves are visible. They may be switched off by specifying `ULinesVisible = FALSE` and `VLinesVisible = FALSE`, respectively.

The coordinate lines controlled by `ULinesVisible = TRUE/FALSE` and `VLinesVisible = TRUE/FALSE` indicate the equidistant mesh in the  $u$ - $v$  plane set via the `UMesh`, `VMesh` attributes. If the mesh is refined by the `USubmesh`, `VSubmesh` attributes, or by the adaptive mechanism controlled by `AdaptiveMesh = n`, no additional parameter lines are drawn.

As far as the numerical approximation of the surface is concerned, the settings

$$\text{UMesh} = n_u, \text{VMesh} = n_v, \text{USubmesh} = m_u, \text{VSubmesh} = m_v$$

and

$$\begin{aligned} \text{UMesh} &= (n_u - 1) (m_u + 1) + 1, \text{VMesh} = (n_v - 1) (m_v + 1) + 1, \\ \text{USubmesh} &= 0, \text{VSubmesh} = 0 \end{aligned}$$

are equivalent. However, in the first setting,  $n_u$  parameter lines are visible in the  $u$  direction, while in the latter setting  $(n_u - 1) (m_u + 1) + 1$  parameter lines are visible. Cf. “Example 2” on page 23-310.

Use `Filled = FALSE` to obtain a wireframe representation of the surface.

If the expressions/functions  $r$  and/or  $z$  contain singularities, it is recommended (but not strictly necessary) to use the attribute

ViewingBox to set a suitable viewing box. No such precautions are necessary for  $\varphi$ , although singularities in this function may result in poorly rendered surfaces – in many cases setting the attributes Mesh and/or AdaptiveMesh to higher values will help. Cf. “Example 3” on page 23-314.

## Attributes

Attribute	Purpose	Default Value
AdaptiveMesh	adaptive sampling	0
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0

Attribute	Purpose	Default Value
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0

## plot::Cylindrical

---

Attribute	Purpose	Default Value
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[25, 25]
MeshVisible	visibility of irregular mesh lines in 3D	FALSE

YFunction	function for y values	
ZContours	contour lines at constant z values	[]
ZFunction	function for z values	

## Examples

### Example 1

Using a constant radius for `plot::Cylindrical`, with the other two functions straight from the surface parameters, results in a right cylinder. This explains the name “cylindrical coordinates”:

```
plot(plot::Cylindrical([1, phi, z], phi = 0..2*PI, z = -1..1))
```

## plot::Cylindrical

---

Other straightforward examples include cones and paraboloids of revolution:

```
plot(plot::Cylindrical([r, phi, 2*r], r = 0..1, phi = 0..2*PI))
```

```
plot(plot::Cylindrical([r, phi, r^2], r = 0..1, phi = 0..2*PI))
```

# plot::Cylindrical

---

## Example 2

Cylindrical surfaces are drawn from evaluations on an equidistant mesh of points. In some cases, the default mesh density is insufficient or otherwise inappropriate:

```
plot(plot::Cylindrical([cos(phi^2), phi, z],
 phi=-2.8..2.8, z=0..1/2))
```

One possible change to this plot command is to explicitly set the mesh with the attribute `Mesh`. Note that this setting influences the density of parameter lines:

```
plot(plot::Cylindrical([cos(phi^2), phi, z],
 phi=-2.8..2.8, z=0..1/2,
 Mesh = [100, 5]))
```

# plot::Cylindrical

---

To increase the mesh density without introducing additional parameter lines, you can use submesh settings:

```
plot(plot::Cylindrical([cos(phi^2), phi, z],
 phi=-2.8..2.8, z=0..1/2,
 VMesh = 5, USubmesh = 3))
```

Finally, we can also ask `plot::Cylindrical` to refine the mesh only in areas of higher curvature. In the following example, we allow for  $2^3 = 8$  additional points between each two neighboring points of the initial mesh:

```
plot(plot::Cylindrical([cos(phi^2), phi, z],
 phi=-2.8..2.8, z=0..1/2,
 VMesh = 5, AdaptiveMesh = 3))
```

# plot::Cylindrical

---

### Example 3

If the radius- or the  $z$ -function/expression contains singularities, `plot::Cylindrical` employs heuristic clipping to select a range to display:

```
plot(plot::Cylindrical([1/sqrt((phi - PI)^2 + z^2), phi, z],
phi = 0..2*PI, z = -1..1))
```

While these heuristics work well in many cases, there are also examples where they do not select a useful box:

```
plot(plot::Cylindrical([1/((phi - PI)^2 + z^2), phi, z],
phi = 0.. 2*PI, z = -1..1))
```

## plot::Cylindrical

---

In these cases, the user should set the range to display explicitly:

```
plot(plot::Cylindrical([1/((phi - PI)^2+z^2), phi, z],
 phi = 0..2*PI, z = -1..1),
 ViewingBox = [-2..0.3, -1.5..1.5, -1..1])
```

#### Example 4

Since the transformation from cylindrical to orthogonal coordinates is reversible (up to reducing the angle to the range  $[0, 2\pi]$ ), it is possible to plot any surface with `plot::Cylindrical` (although this is probably more a curiosity than really useful):

```
trans := linalg::ogCoordTab[Cylindrical, InverseTransformation]:
cyl := trans(x, y, sin(x^2+y^2))
```

$$\left[ \sqrt{x^2 + y^2}, \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right) + \text{sign}(y) (\text{sign}(y) - 1) \left(\pi - \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right)\right), \sin(x^2 + y^2) \right]$$

```
plot(plot::Cylindrical(cyl, x = -2..2, y = -2..2))
```

# plot::Cylindrical

---

## Parameters $r, \phi, z$

The coordinate functions: arithmetical expressions or piecewise objects depending on the surface parameters  $u, v$  and the animation parameter  $a$ . Alternatively, procedures that accept 2 input parameters  $u, v$  or 3 input parameters  $u, v, a$  and return a real numerical value when the input parameters are numerical.

$r, \phi, z$  are equivalent to the attributes XFunction, YFunction, ZFunction.

## $u$

The first surface parameter: an identifier or an indexed identifier.

$u$  is equivalent to the attributes UName, UMin, UMax.

## $u_{\min} \dots u_{\max}$

The plot range for the parameter  $u$ :  $u_{\min}, u_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ .

$u_{\min} .. u_{\max}$  is equivalent to the attributes URange, UMin, UMax.

## **v**

The second surface parameter: an identifier or an indexed identifier.

v is equivalent to the attribute VName.

## **v<sub>min</sub> .. v<sub>max</sub>**

The plot range for the parameter v:  $v_{\min}$ ,  $v_{\max}$  must be numerical real values or expressions of the animation parameter a.

$v_{\min} .. v_{\max}$  is equivalent to the attributes VRange, VMin, VMax.

## **a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Density

---

**Purpose** Density plot

**Syntax**

```
plot::Density(f, x = xmin .. xmax, y = ymin .. ymax,
<a = amin .. amax>, options)
plot::Density(A, <x = xmin .. xmax, y = ymin .. ymax>,
<a = amin .. amax>, options)
plot::Density(L, <x = xmin .. xmax, y = ymin .. ymax>,
<a = amin .. amax>, options)
```

**Description** `plot::Density(f(x, y), x = `x_{min}` .. `x_{max}` , y = `y_{min}` .. `y_{max}` )` generates a regular 2D mesh of rectangles extending from the lower left corner ( $x_{\min}, y_{\min}$ ) to the upper right corner ( $x_{\max}, y_{\max}$ ). The rectangle with midpoint  $(x, y)$  is colored according to a color scheme based on the “density” value  $f(x, y)$ .

`plot::Density` serves for the visualization of 3D data  $(x, y, f(x, y))$  by a 2D plot. Roughly speaking, it corresponds to a colored 3D function graph of the density function  $f(x, y)$  viewed from above. However, in contrast to the 3D function graph, `plot::Density` does not use smooth interpolation (“shading”) of the color between adjacent rectangles.

If the density data are provided by an array or matrix  $A$  or by a list  $L$ , the number of rectangles in the density plot is given automatically by the format of  $A$  or  $L$ , respectively.

If the density data are given by an expression or function  $f$ , the attribute `Mesh = [m, n]` serves for advising `plot::Density` to create a grid of  $m n$  rectangles. Alternatively, one may set `XMesh = m, YMesh = n`.

With the default `FillColorType = Dichromatic`, the rectangle with density value  $f(x, y)$  at the midpoint  $(x, y)$  is colored with the color

$$\frac{f(x, y) - f_{\min}}{f_{\max} - f_{\min}} \times \text{fillcolor} + \frac{f_{\max} - f(x, y)}{f_{\max} - f_{\min}} \times \text{fillcolor2}$$

where  $f_{\min}$  and  $f_{\max}$  are the minimal/maximal density values in the graphics and `fillcolor`, `fillcolor2` are the RGB values of the attributes `FillColor` and `FillColor2`, respectively. Thus, `fillcolor` indicates high density values whereas `fillcolor2` indicates low density values.

If  $f_{\min} = f_{\max}$ , a flat coloring with `fillcolor` is used.

With `FillColorType = Monochrome`, the rectangle with density value  $f(x, y)$  at the midpoint  $(x, y)$  is colored with the color

$$\frac{f(x, y) - f_{\min}}{f_{\max} - f_{\min}} \times \text{fillcolor}$$

The user may specify a fill color function via `FillColorFunction = mycolorfunction` to override the density coloring described above. The procedure `mycolorfunction` will be called with the arguments

`mycolorfunction(x, y, f(x, y, a) a)`,

where  $(x, y)$  are the midpoints of the rectangles and  $a$  is the animation parameter. The color function must return an RGB or RGBA color value.

When density values are specified by an array or a matrix  $A$ , the low indices correspond to the lower left corner of the graphics. The high indices correspond to the upper right corner.

Arrays/matrices do not need to be indexed from 1. E.g.,

```
A = array(`i_{min}` .. `i_{max}`, `j_{min}` ..
`j_{max}`, [..density values..])
```

yields a graphical array with

```
XMesh = j_max - j_min + 1, YMesh = i_max - i_min + 1.
```

If no plot range ``x_{min}` .. `x_{max}``, ``y_{min}` .. `y_{max}`` is specified,

```
x_min = j_min - 1, x_max = j_max, y_min = i_min - 1, y_max = i_max
```

# plot::Density

is used.

When density values are specified by a list of lists  $L$ , the first entries in the list correspond to the lower left corner of the graphics. The last entries correspond to the upper right corner.

If no plot range ``x_{min}` .. `x_{max}``, ``y_{min}` .. `y_{max}`` is specified,

$$x_{\min} = 0, x_{\max} = m, y_{\min} = 0, y_{\max} = n$$

is used, where  $n$  is the length of  $L$  and  $m$  is the (common) length of the sublists in  $L$ . All sublists (“rows”) must have the same length.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter  $a$  that is different from the variables  $x, y$ . Thus, in animations, both the ranges `x = `x_{min}` .. `x_{max}``, `y = `y_{min}` .. `y_{max}`` as well as the animation range `a = `a_{min}` .. `a_{max}`` must be specified.

The related plot routine `plot::Raster` provides a similar functionality. However, `plot::Raster` does not use an automatic color scheme based on density values. The user must provide RGB or RGBA values instead.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	FALSE
Color	the main color	RGB::Red
DensityData	density values for a density plot	
DensityFunction	density function for a density plot	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	FALSE
Mesh	number of sample points	[25, 25]
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

## plot::Density

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles

TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter "x"	
XMesh	number of sample points for parameter "x"	25
XMin	initial value of parameter "x"	
XName	name of parameter "x"	
XRange	range of parameter "x"	
YMax	final value of parameter "y"	
YMesh	number of sample points for parameter "y"	25
YMin	initial value of parameter "y"	
YName	name of parameter "y"	
YRange	range of parameter "y"	

# plot::Density

---

## Examples

### Example 1

We generate a density plot:

```
p := plot::Density(cos(x^2 + y^2), x = -3..3, y = -2..2,
Mesh = [60, 40]):
```

The plot object is rendered:

```
plot(p, Axes = Frame):
```

This turns into a black and white graphics when suitable colors are specified:

```
plot(plot::Scene2d(p, FillColor = RGB::White,
FillColor2 = RGB::Black),
plot::Scene2d(p, FillColor = RGB::Black,
FillColor2 = RGB::White),
Width = 120*unit::mm, Height = 45*unit::mm,
```

Layout = Horizontal, Axes = Frame):

delete p:

## Example 2

We demonstrate the use of a user-defined color function:

```
mycolor := proc(x, y, f)
begin
 if f >= 2/3 then RGB::Red
 elif f >= 1/3 then RGB::Orange;
 elif f >= 0 then RGB::Yellow;
 elif f >= -1/3 then RGB::BlueLight;
 elif f >= -2/3 then RGB::Blue;
 else RGB::SlateBlueDark;
 end_if;
end_proc;
plot(plot::Density(cos(x^2 + y^2), x = -3..3, y = -2..2,
 Mesh = [60, 40],
 FillColorFunction = mycolor),
 Axes = Frame):
```

# plot::Density

---

`delete mycolor:`

### Example 3

In this example, we demonstrate how `plot::Density` can be used to plot gray data from an external source. Assume, there is an external PortableGrayMap text file `Norton.pgm` containing data such as

```
P2
240 180
255
249 237 228 231 245 218 229 195 ...
```

The first line contains the “magic value” P2 indicating that this is a PGM text file. The second line contains the pixel width and pixel height of the picture. The number 255 in the third line is the scale of the following gray values.

The remaining data consist of integers between 0 (black) and 255 (white), each representing the gray value of a pixel (row by row).

We import the text data via `import::readdata`:

```
graydata := import::readdata("Norton.pgm", NonNested):
```

This is a long list of all data items in the file. We extract the 4 items in the first three lines:

```
[magicvalue, xmesh, ymesh, maxgray] := graydata[1..4]
```

```
[P2, 240, 180, 255]
```

We delete the header from the pixel data. (If there are comments in the PGM file, they must be deleted, too).

```
for i from 1 to 4 do
 delete graydata[1];
end_for:
```

We transform the plain data list to a nested list containing the gray data of the rows as sublists. (The call to `level` is not really necessary, but it speeds up the conversion considerably on the interactive level.)

```
L := level([graydata[(i - 1)*xmesh + 1 .. i*xmesh] $ i=1..ymesh])
```

This list can be passed to `plot::Density`:

```
plot(plot::Density(L, FillColor = RGB::White,
 FillColor2 = RGB::Black),
 Width = 80*unit::mm, Height = 60*unit::mm):
```

## plot::Density

---

The image is upside down, because the PGM files stores the pixel data row by row in the usual reading order starting with the upper left corner of the image. The MuPAD routine `plot::Density`, however, follows the mathematical orientation of the coordinate axes, i.e., the first pixel value is interpreted as the lower left corner of the image. We have to re-order the rows in the `graydata` list via `revert`:

```
plot(plot::Density(revert(L), FillColor = RGB::White,
 FillColor2= RGB::Black),
 Width = 80*unit::mm, Height = 60*unit::mm):
```

The routines `import::readbitmap` and `plot::Raster` provide an alternative way to import and display the bitmap image. See the help page of `plot::Raster` for examples. This, however, takes more memory, because the bitmap data are imported as RGB color values, whereas only density values (gray data) are needed for `plot::Density`.

`delete graydata, magicvalue, xmesh, ymesh, maxgray, i, L:`

#### Example 4

The Mandelbrot set is one of the best-known fractals. It arises when considering the iteration  $z_{n+1} = z_n^2 + c$ ,  $z_0 = 0$  in the complex plane. For sufficiently large values  $|c|$  of the complex parameter  $c$ , the sequence  $z_n$  diverges to infinity; it converges for sufficiently small values of  $|c|$ . The boundary of the region of those  $c$  values that lead to divergence of  $z_n$  is of particular interest: this border is highly complicated and of a fractal nature.

In particular, it is known that the series  $z_n$  diverges to infinity, whenever one of the iterates satisfies  $|z_n| > 2$ . This fact is used by the following procedure `f` as stopping criterion. The return value provides information, how many iterates  $z_0, \dots, z_n$  it takes to escape from the region  $|z| \leq 2$  of (potential) convergence. These data are to be used to color the complex  $c$  plane (i.e., the  $(x,y)$  plane) by a density plot:

## plot::Density

---

```
f := proc(x, y)
local c, z, n;
begin
 c := x + I*y;
 z := 0.0;
 for n from 0 to 100 do
 z := z^2 + c;
 if abs(z) > 2 then
 break;
 end_if;
 end_for;
 if n < 70 then
 n mod 5;
 else n - 70;
 end_if;
end_proc;
```

Depending on your computer, the following computations may take some time. On a very fast machine, you can increase the following values of *xmesh*, *ymesh*. This will use up more computing time but will lead to better graphical results:

```
xmesh := 100: ymesh := 100:
```

The following region in the *x-y* plane is to be considered:

```
xmin[1] := -2.0: xmax[1] := 0.5:
ymin[1] := -1.2: ymax[1] := 1.2:
```

The region  $xmin_1 \leq x \leq xmax_1$ ,  $ymin_1 \leq y \leq ymax_1$  is divided into *xmesh* *ymesh* rectangles. Each rectangle is colored by a density plot according to the “escape times” computed by the procedure *f*. This procedure can be passed directly to `plot::Density`:

```
p1 := plot::Density(f, x = xmin[1].. xmax[1],
 y = ymin[1] .. ymax[1],
 Mesh = [xmesh, ymesh],
```

```
FillColor = RGB::Black,
FillColor2 = RGB::Red):
```

In addition, a rectangle is produced that indicates a region that is to be magnified in the following:

```
xmin[2] := -0.24: xmax[2] := -0.01:
ymin[2] := 0.63: ymax[2] := 0.92:
r1 := plot::Rectangle(xmin[2] .. xmax[2], ymin[2] .. ymax[2],
 LineColor = RGB::White):
```

```
plot(p1, r1):
```

The density values of the blow-up are not computed directly by `plot::Density`. They are computed separately and stored in an array `A`:

```
dx := (xmax[2] - xmin[2])/xmesh:
```

## plot::Density

---

```
dy := (ymax[2] - ymin[2])/ymesh:
A := array(1..ymesh, 1..xmesh,
 [[f(xmin[2]+ (j - 1/2)*dx, ymin[2] + (i - 1/2)*dy)
 $ j = 1..xmesh] $ i = 1..ymesh]):
p2 := plot::Density(A, x = xmin[2] .. xmax[2], y = ymin[2] .. ymax[2],
 FillColor = RGB::Black, FillColor2 = RGB::Red):
```

In addition, a further rectangle is produced to indicate a region of interest to be blown up later on:

```
xmin[3] := -0.045: xmax[3] := -0.015:
ymin[3] := 0.773: ymax[3] := 0.815:
r2 := plot::Rectangle(xmin[3] .. xmax[3], ymin[3] .. ymax[3],
 LineColor = RGB::White):
```

```
plot(p2, r2):
```

The density values of the next blow-up are again computed separately and stored in a nested list  $L$ :

```
dx := (xmax[3] - xmin[3])/xmesh:
dy := (ymax[3] - ymin[3])/ymesh:
L := [[f(xmin[3] + (j - 1/2)*dx, ymin[3] + (i - 1/2)*dy)
 $ j= 1..xmesh] $ i = 1..ymesh]:
p3 := plot::Density(L, x = xmin[3] .. xmax[3], y = ymin[3] .. ymax[3],
 FillColor = RGB::Black, FillColor2 = RGB::Red)

plot(p3):
```

The density objects are to be placed in a single graphics. It consists of the Mandelbrot set  $p1$  as computed above and of modifications of the density plots  $p2$  and  $p3$ . Redefining the attributes  $XRange$ ,  $YRange$ , we move  $p2$ ,  $p3$  to places in the  $x$ - $y$  plane where they are not overlapped by  $p1$ . Note that this does not change the graphical content of  $p2$ ,  $p3$ , because it is given by the data  $A$  and  $L$ , respectively, which remain

## plot::Density

---

unchanged. (If the ranges were changed in p1, another plot call of p1 would call the procedure f at different points of the plane resulting in a different graphics.)

```
p2::XRange := 0.60 .. 1.60: p2::YRange := 0.05 .. 1.15:
p3::XRange := 0.60 .. 1.60: p3::YRange := -1.15 .. -0.05:
```

The Mandelbrot set and the two blow-ups are placed in one scene. In addition, some arrows are added to indicate the origin of the blow-ups. Note that it is quite important here that the arrows are passed to the plot command after the density plots. Otherwise, they would be hidden by the density plots: graphical objects are painted in the ordering in which they are passed to plot:

```
plot(p1, p2, p3,
 plot::Arrow2d([(xmin[2] + xmax[2])/2,
 (ymin[2] + ymax[2])/2,
 [(p2::XMin + p2::XMax)/2,
 (p2::YMin + p2::YMax)/2],
 LineColor = RGB::Blue),
 plot::Arrow2d([1.50, 0.65],
 [(p3::XMin + p3::XMax)/2,
 (p3::YMin + p3::YMax)/2],
 LineColor = RGB::Blue)
):
```

delete f, xmesh, ymesh, xmin, xmax, ymin, ymax,  
dx, dy, p1, p2, p3, r1, r2, A, L:

## Parameters

**f**

The density values: an arithmetical expression in 2 variables  $x, y$  and the animation parameter  $a$ . Alternatively, a procedure that accepts 2 input parameters  $x, y$  or 3 input parameters  $x, y, a$  and returns a real density value.

$f$  is equivalent to the attribute DensityFunction.

**x**

Name of the horizontal variable: an identifier or an indexed identifier.

$x$  is equivalent to the attribute XName.

**$x_{\min}$  ..  $x_{\max}$**

## plot::Density

---

The range of the horizontal variable:  $x_{\min}$ ,  $x_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$x_{\min} .. x_{\max}$  is equivalent to the attributes XRange, XMin, XMax.

### **y**

Name of the vertical variable: an identifier or an indexed identifier.

$y$  is equivalent to the attribute YName.

### **y<sub>min</sub> .. y<sub>max</sub>**

The range of the vertical variable:  $y_{\min}$ ,  $y_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$y_{\min} .. y_{\max}$  is equivalent to the attributes YRange, YMin, YMax.

### **A**

An array of domain type DOM\_ARRAY or a matrix of category `Cat::Matrix` (e.g., of type `matrix` or `densematrix`) providing numerical density values or expressions of the animation parameter  $a$ . Rows/columns of the array, respectively matrix, correspond to rows/columns of the graphical array.

$A$  is equivalent to the attribute DensityData.

### **L**

A list of lists of numerical density values or expressions of the animation parameter  $a$ . Each sublist of  $L$  represents a row of the graphical array. The number of sublists in  $L$  yields the value of the attribute XMesh. The (common) length of the sublists yields the value of the attribute YMesh.

$L$  is equivalent to the attribute DensityData.

### **a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Examples

### Example 1

We create a plot of an ellipse with center point (1, 1) and semi-axes of lengths 3 and 1:

```
ellipse := plot::Ellipse2d(3, 1, [1, 1]):
plot(ellipse)
```

## plot::Ellipse2d

---

We apply a rotation:

```
plot(ellipse, plot::Rotate2d(PI/4, [1, 1], ellipse))
```

`delete ellipse:`

### **Example 2**

We plot an animated 3D ellipse:

```
plot(plot::Ellipse3d(1, 1, [0,0,0], [0,a,1-a], a = 0..1))
```

# plot::Ellipse2d

---

## Example 3

We plot a colored 3D ellipse:

```
plot(plot::Ellipse3d(2, 1, [0,0,0], Filled,
 LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType = Di
 FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType = Di
))
```

## Parameters

$r_1, r_2$

The semi-axes of an ellipse. They must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$r_1, r_2$  are equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

$c_x, c_y$

The center. The coordinates  $c_x, c_y$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ . If no center is specified, the ellipse is centered at the origin.

$c_x, c_y$  are equivalent to the attribute `Center`.

$a$

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink

Attribute	Purpose	Default Value
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
Normal	normal vector of circles and discs, etc. in 3D	[0, 0, 1]
NormalX	normal vector of circles and discs, etc. in 3D, x-component	0
NormalY	normal vector of circles and discs, etc. in 3D, y-component	0
NormalZ	normal vector of circles and discs, etc. in 3D, z-component	1

# plot::Ellipse3d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
SemiAxes	semi axes of ellipses and ellipsoids	
SemiAxisX	first semi axis of ellipses and ellipsoids	2
SemiAxisY	second semi axis of ellipses and ellipsoids	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

Attribute	Purpose	Default Value

TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We create a plot of an ellipse with center point (1, 1) and semi-axes of lengths 3 and 1:

```
ellipse := plot::Ellipse2d(3, 1, [1, 1]):
plot(ellipse)
```

## plot::Ellipse3d

---

We apply a rotation:

```
plot(ellipse, plot::Rotate2d(PI/4, [1, 1], ellipse))
```

`delete ellipse:`

## Example 2

We plot an animated 3D ellipse:

```
plot(plot::Ellipse3d(1, 1, [0,0,0], [0,a,1-a], a = 0..1))
```

# plot::Ellipse3d

---

## Example 3

We plot a colored 3D ellipse:

```
plot(plot::Ellipse3d(2, 1, [0,0,0], Filled,
 LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType = Di
 FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType = Di
))
```

## Parameters

### $r_1, r_2$

The semi-axes of an ellipse. They must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$r_1, r_2$  are equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

### $c_x, c_y, c_z$

The center. The coordinates  $c_x, c_y, c_z$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ . If no center is specified, the ellipse is centered at the origin.

$c_x, c_y, c_z$  are equivalent to the attribute `Center`.

### $n_x, n_y, n_z$

The normal vector. The coordinates  $n_x, n_y, n_z$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ . If no normal vector is specified, the ellipse is created in the  $xy$ -plane.

# plot::Ellipse3d

---

$n_x$ ,  $n_y$ ,  $n_z$  are equivalent to the attribute Normal.

## **a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Purpose

2D function graphs

## Syntax

```
plot::Function2d(f, options)
plot::Function2d(f, x = xmin .. xmax, <a =
amin .. amax>, options)
```

## Description

`plot::Function2d` creates the 2D graph of a univariate function.

The graphics ignores all points, where the expression/function `f` does not produce a numerical real value. See “Example 2” on page 23-367.

The expression/function `f` may have singularities in the plot range. Although a heuristics is used to find a reasonable `y` range when singularities are present, it is highly recommended to specify a `y` range via `ViewingBoxYRange = `y_{min}` .. `y_{max}`` with suitable numerical real values `ymin`, `ymax`. See “Example 3” on page 23-368.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter `a` that is different from the independent variable `x`. Thus, in animations, both the `x`-range `x = `x_{min}` .. `x_{max}`` as well as the animation range `a = `a_{min}` .. `a_{max}`` must be specified. See “Example 4” on page 23-370.

The function `f` is evaluated on an equidistant mesh of sample points determined by the attribute `XMesh` (or the shorthand notation `Mesh`). By default, the attribute `AdaptiveMesh = 0` is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of `XMesh` or set `AdaptiveMesh = n` with some (small) positive integer `n`. If necessary, up to  $2^n$  additional points are placed between adjacent points of the initial equidistant mesh. See “Example 5” on page 23-371.

By default, the attribute `DiscontinuitySearch = TRUE` is set. This triggers a semi-symbolic preprocessing of the expression `f` to search for discontinuities and singularities. At each singular point, the function graph is split into disjoint branches to the left and to the right of the singularity. This avoids graphical artifacts such as lines connecting points to the left and to the right of a singularity.

## plot::Function2d

---

If the function is known to be regular in the plot range, the semi-symbolic search may be disabled by specifying `DiscontinuitySearch = FALSE`. This will improve the efficiency of the plot commands.

Singular points are highlighted by a vertical line unless `VerticalAsymptotesVisible = FALSE` is specified. Its style may be set by the attributes `VerticalAsymptotesStyle`, `VerticalAsymptotesWidth`, and `VerticalAsymptotesColor`.

---

**Note** This functionality is only available if the function is specified by an arithmetical expression or a procedure that accepts symbolic arguments. It is not available if the function is specified by a `piecewise` object or by a procedure that accepts only numerical arguments.

---

See “Example 6” on page 23-375.

`plot::Hatch` allows to hatch areas between function graphs. See “Example 7” on page 23-377.

### Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	2
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Color</code>	the main color	<code>RGB::Blue</code>
<code>DiscontinuitySearch</code>	semi-symbolic search for discontinuities	TRUE
<code>Frames</code>	the number of frames in an animation	50

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Function	function expression or procedure

LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Mesh	number of sample points	121

## plot::Function2d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Submesh	density of submesh (additional sample points)	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
VerticalAsymptotesColor	color of vertical asymptotes indicating poles	RGB::Grey50
VerticalAsymptotesWidth	the width of vertical asymptotes indicating poles	0.2
VerticalAsymptotesStyle	the style of vertical asymptotes indicating poles	Dashed
VerticalAsymptotesVisible	vertical asymptotes indicating poles	TRUE
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

# plot::Function2d

---

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter "x"	5
XMesh	number of sample points for parameter "x"	121
XMin	initial value of parameter "x"	-5
XName	name of parameter "x"	
XRange	range of parameter "x"	-5 .. 5
XSubmesh	density of additional sample points for parameter "x"	0

## Examples

### Example 1

The following call returns an object representing the graph of the sine function over the interval  $[0, 2\pi]$ :

```
f := plot::Function2d(sin(x), x = 0 .. 2*PI)
```

```
plot::Function2d(sin(x), x = 0..2 π)
```

Call `plot` to plot the graph:

```
plot(f):
```

Functions can also be specified by `piecewise` objects or procedures:

```
f := piecewise([x < 1, 1 - x], [x >= 1, x^2]):
plot(plot::Function2d(f, x = -2 .. 4)):
```

## plot::Function2d

---

```
f := proc(x)
begin
 if x^2 - 2*x < 0 then
 0
 else
 x^2 - 2*x
 end_if:
end_proc:
plot(plot::Function2d(f, x = -2 .. 4)):
```

```
delete f:
```

## Example 2

Non-real values are ignored in a plot:

```
plot(plot::Function2d(sqrt(1 - x^2), x = -2 .. 2),
 Scaling = Constrained):
```

# plot::Function2d

---

## Example 3

We plot a function with singularities:

```
f := plot::Function2d(sin(x)/(1 - x) - 1/cos(x), x = 0 .. PI):
plot(f):
```

We specify an explicit viewing range for the  $y$  direction:

```
plot(f, ViewingBoxYRange = -20 .. 10):
```

# plot::Function2d

---

`delete f:`

## Example 4

We generate an animation of a parametrized function:

```
plot(plot::Function2d(a*sin(x) + (1 - a)*cos(x),
 x = -PI .. PI, a = 0 .. 1)):
```

**Example 5**

The standard mesh for the numerical evaluation of a function graph does not suffice to generate a satisfying graphics in the following case:

```
plot(plot::Function2d(sin(PI/x), x = -1 .. 1)):
```

## plot::Function2d

---

We increase the number of mesh points:

```
plot(plot::Function2d(sin(PI/x), x = -1 .. 1, XMesh = 1000)):
```

Alternatively, we enable adaptive sampling by setting `AdaptiveMesh` to some positive value:

```
plot(plot::Function2d(sin(PI/x), x = -1 .. 1, AdaptiveMesh = 3))
```

## plot::Function2d

---

Finally, we increase the XMesh value and use adaptive sampling:

```
plot(plot::Function2d(sin(PI/x), x = -1 .. 1, XMesh = 1000,
 AdaptiveMesh = 3)):
```

### Example 6

With `VerticalAsymptotesVisible = TRUE/FALSE`, singular points are highlighted by a vertical asymptote, or this highlighting is switched off, respectively:

```
plot(plot::Function2d(ln(x + PI) + 1/(x - 1) - 1/(x + 1)^2,
 x = -4 .. 4,
 VerticalAsymptotesVisible = TRUE,
 ViewingBoxYRange = -10 .. 10)):
```

## plot::Function2d

---

```
plot(plot::Function2d(ln(x + PI) + 1/(x - 1) - 1/(x + 1)^2,
 x = -4 .. 4,
 VerticalAsymptotesVisible = FALSE,
 ViewingBoxYRange = -10 .. 10)):
```

### Example 7

The `plot::Hatch` object allows to hatch regions between functions. It expects graphical objects of type `plot::Function2d` or `plot::Curve2d` as boundaries:

```
f1:= plot::Function2d(sin(x), x = -PI .. 2*PI):
f2:= plot::Function2d(cos(x), x = -PI .. 2*PI):
plot(f1, f2, plot::Hatch(f1, f2, -1 .. 5)):
```

# plot::Function2d

---

delete f1, f2:

## Parameters **f**

The function: an arithmetical expression or a `piecewise` object in the independent variable  $x$  and the animation parameter  $a$ . Alternatively, a procedure that accepts 1 input parameter  $x$  or 2 input parameters  $x, a$  and returns a real numerical value when the input parameters are numerical.

`f` is equivalent to the attribute `Function`.

## **x**

The independent variable: an identifier or an indexed identifier.

`x` is equivalent to the attribute `XName`.

**`xmin`** .. **`xmax`**

The plot range:  $x_{\min}$ ,  $x_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ . If not specified, the default range  $x = -5 \dots 5$  is used.

$x_{\min} \dots x_{\max}$  is equivalent to the attributes XRange, XMin, XMax.

**a**

Animation parameter, specified as  $a = a_{\min} \dots a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

[plot::Function3d](#)

# plot::Function3d

---

**Purpose** 3D function graphs

**Syntax**  
`plot::Function3d(f, options)`  
`plot::Function3d(f, x = xmin .. xmax, y = ymin .. ymax,  
<a = amin .. amax>, options)`

**Description** `plot::Function3d` creates the 3D graph of a function in 2 variables.

The expression  $f(x, y)$  is evaluated at finitely many points  $x, y$  in the plot range. There may be singularities. Although a heuristics is used to find a reasonable  $z$  range when singularities are present, it is highly recommended to specify a  $z$  range via `ViewingBoxZRange = `z_{min}` .. `z_{max}`` with suitable numerical real values  $z_{\min}, z_{\max}$ . See “Example 2” on page 23-390.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter  $a$  that is different from the independent variables  $x, y$ . Thus, in animations, the  $x$ -range `x = `x_{min}` .. `x_{max}``, the  $y$ -range `y = `y_{min}` .. `y_{max}`` as well as the animation range `a = `a_{min}` .. `a_{max}`` must be specified. See “Example 3” on page 23-392.

The function  $f$  is evaluated on a regular equidistant mesh of sample points determined by the attributes `XMesh` and `YMesh` (or the shorthand-notation for both, `Mesh`). By default, the attribute `AdaptiveMesh = 0` is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of `XMesh` and `YMesh` or set `AdaptiveMesh = n` with some (small) positive integer  $n$ . This may result in up to  $4^n$  times as many triangles as used with `AdaptiveMesh = 0`, potentially more when  $f$  has non-isolated singularities. See “Example 4” on page 23-393.

The “coordinate lines” (“parameter lines”) are curves on the function graph.

The phrase “XLines” refers to the curves  $(x, y_0, f(x, y_0))$  with the parameter  $x$  running from  $x_{\min}$  to  $x_{\max}$ , while  $y_0$  is some fixed value from the interval  $[y_{\min}, y_{\max}]$ .

The phrase “YLines” refers to the curves  $(x_0, y, f(x_0, y))$  with the parameter  $y$  running from  $y_{\min}$  to  $y_{\max}$ , while  $x_0$  is some fixed value from the interval  $[x_{\min}, x_{\max}]$ .

By default, the parameter lines are visible. They may be “switched off” by specifying `XLinesVisible = FALSE` and `YLinesVisible = FALSE`, respectively.

The coordinate lines controlled by `XLinesVisible = TRUE/FALSE` and `YLinesVisible = TRUE/FALSE` indicate the equidistant regular mesh set via the `Mesh` attributes. If the mesh is refined by the `Submesh` attributes or by the adaptive mechanism controlled by `AdaptiveMesh = n`, no additional parameter lines are drawn.

As far as the numerical approximation of the function graph is concerned, the settings

`Mesh = [nx, ny], Submesh = [mx, my]`

and

`Mesh = [(nx - 1) (mx + 1) + 1, (ny - 1) (my + 1) + 1], Submesh = [0, 0]`

are equivalent. However, in the first setting,  $n_x$  parameter lines are visible in the  $x$  direction, while in the latter setting  $(n_x - 1) (m_x + 1) + 1$  parameter lines are visible. See “Example 5” on page 23-396.

## Attributes

ZContours	contour lines at constant z values	[]

## Examples

### Example 1

The following call returns an object representing the graph of the function  $\sin(x^2 + y^2)$  over the region  $-2 \leq x \leq 2$ ,  $-2 \leq y \leq 2$ :

```
g := plot::Function3d(sin(x^2 + y^2), x = -2..2, y = -2..2)
```

```
plot::Function3d(sin(x^2 + y^2), x = -2..2, y = -2..2)
```

Call `plot` to plot the graph:

```
plot(g)
```

## plot::Function3d

---

Functions can also be specified by piecewise objects or procedures:

```
f := piecewise([x < y, 0], [x >= y, (x - y)^2]):
plot(plot::Function3d(f, x = -2 .. 4, y = -1 .. 3))
```

```
f := proc(x, y)
begin
 if x + y^2 + 2*y < 0 then
 0
 else
 x + y^2 + 2*y
 end_if:
end_proc:
plot(plot::Function3d(f, x = -3 .. 2, y = -2 .. 2))
```

## plot::Function3d

---

```
delete g, f
```

### Example 2

We plot a function with singularities:

```
f := plot::Function3d(x/y + y/x, x = -1 .. 1, y = - 1 .. 1):
plot(f)
```

We specify an explicit viewing range for the  $z$  direction:

```
plot(f, ViewingBoxZRange = -20 .. 20)
```

## plot::Function3d

---

```
delete f
```

### Example 3

We generate an animation of a parametrized function:

```
plot(plot::Function3d(sin((x - a)^2 + y^2),
 x = -2 .. 2, y = -2 .. 2, a = 0 .. 5))
```

#### Example 4

The standard mesh for the numerical evaluation of a function graph does not suffice to generate a satisfying graphics in the following case:

```
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)),
x = -20 .. 20, y = -20 .. 20))
```

## plot::Function3d

---

We increase the number of mesh points. Here, we use `XSubmesh` and `YSubmesh` to place 2 additional points in each direction between each pair of neighboring points of the default mesh. This increases the runtime by a factor of 9:

```
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)),
 x = -20 .. 20, y = -20 .. 20,
 Submesh = [2, 2]))
```

Alternatively, we enable adaptive sampling by setting the value of `AdaptiveMesh` to some positive value:

```
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)),
 x = -20 .. 20, y = -20 .. 20,
 AdaptiveMesh = 2))
```

## plot::Function3d

---

### Example 5

By default, the parameter lines of a function graph are “switched on”:

```
plot(plot::Function3d(x^2 + y^2, x = 0 .. 1, y = 0 .. 1))
```

The parameter lines are “switched off” by setting `XLinesVisible`, `YLinesVisible`:

```
plot(plot::Function3d(x^2 + y^2, x = 0 .. 1, y = 0 .. 1,
 XLinesVisible = FALSE,
 YLinesVisible = FALSE))
```

## plot::Function3d

---

The number of parameter lines are determined by the Mesh attributes:

```
plot(plot::Function3d(x^2 + y^2, x = 0 .. 1, y = 0 .. 1,
 Mesh = [5, 12]))
```

When the mesh is refined via the `Submesh` attributes, the numerical approximation of the surface becomes smoother. However, the number of parameter lines is not increased:

```
plot(plot::Function3d(x^2 + y^2, x = 0 .. 1, y = 0 .. 1,
 Mesh = [5, 12],
 XSubmesh = 1, YSubmesh = 2))
```

## plot::Function3d

---

### Example 6

Functions need not be defined over the whole parameter range:

```
plot(plot::Function3d(sqrt(1-x^2-y^2), x=-1..1, y=-1..1))
```

```
plot(plot::Function3d(sqrt(sin(x)+cos(y))))
```

## plot::Function3d

---

This makes for an easy way of plotting a function over a non-rectangular area:

```
chi := piecewise([x^2 < abs(y), 1])
```

```
{ 1 if $x^2 < |y|$
```

```
plot(plot::Function3d(chi*sin(x+cos(y))),
 CameraDirection=[-1,0,0.5])
```

## Parameters **f**

The function: an arithmetical expression or a `piecewise` object in the independent variables  $x, y$  and the animation parameter  $a$ . Alternatively, a procedure that accepts 2 input parameter  $x, y$  or 3 input parameters  $x, y, a$  and returns a numerical value when the input parameters are numerical.

`f` is equivalent to the attribute `Function`.

## **x**

The first independent variable: an identifier or an indexed identifier.

`x` is equivalent to the attribute `XName`.

**`xmin .. xmax`**

# plot::Function3d

---

The plot range in  $x$  direction:  $x_{\min}$ ,  $x_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ . If not specified, the default range  $x = -5 \dots 5$  is used.

$x_{\min} \dots x_{\max}$  is equivalent to the attributes XRange, XMin, XMax.

## **y**

The second independent variable: an identifier or an indexed identifier.

$y$  is equivalent to the attribute YName.

## **y<sub>min</sub> .. y<sub>max</sub>**

The plot range in  $y$  direction:  $y_{\min}$ ,  $y_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ . If not specified, the default range  $y = -5 \dots 5$  is used.

$y_{\min} \dots y_{\max}$  is equivalent to the attributes YRange, YMin, YMax.

## **a**

Animation parameter, specified as  $a = a_{\min} \dots a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

[plot::Function2d](#) | [plot::Surface](#)

## Purpose

Hatched area

## Syntax

```
plot::Hatch(f1, f2, <x1 .. x2>, <a = amin .. amax>, options)
plot::Hatch(f1, <base>, <x1 .. x2>, <a = amin ..
amax>, options)
plot::Hatch(c, <a = amin .. amax>, options)
```

## Description

`plot::Hatch(f)` hatches the area between the function `f` and the x-axis.

`plot::Hatch(f, base)` hatches the area between the function `f` and the horizontal line  $y = base$ .

`plot::Hatch(f, g)` hatches the area between the two functions `f` and `g`.

`plot::Hatch(c)` hatches the area enclosed by the curve `c`.

`plot::Hatch(f, base)` is the hatched area between a function `f` of type `plot::Function2d` and a line parallel to the x-axis with  $y = base$ . If `base` is omitted, the area between the function and the x-axis will be hatched (the baseline is assumed to be the x-axis). See “Example 1” on page 23-408.

`plot::Hatch(f1, f2)` is the hatched area between two functions `f1` and `f2`. See “Example 2” on page 23-411.

`plot::Hatch(c)` is the hatched area enclosed by a `plot::Curve2d`. A curve is closed automatically by connecting the starting point and the end point. See “Example 3” on page 23-412.

The hatch may be restricted to the left and to the right by a range `x_..x_`. See “Example 4” on page 23-414.

The attributes `FillColor` and `FillPattern` can be used to change the color and pattern of the hatched area. See “Example 5” on page 23-419.

---

**Note** A `plot::Hatch` is only the hatched area *without* outlining functions or curves! To see the border lines, you need to plot them separately as demonstrated in the examples.

---

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE
Baseline	constant second function delimiting hatch	
Color	the main color	RGB::Red
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Function1	first function/curve delimiting hatch	
Function2	second function delimiting hatch	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter "x"	infinity
XMin	initial value of parameter "x"	-infinity
XRange	range of parameter "x"	-infinity .. infinity

## Examples

### Example 1

If given a single `plot::Function2d` object, `plot::Hatch` hatches the area between the curve and the x-axis:

```
f := plot::Function2d(sin(x), x = -PI..PI):
plot(plot::Hatch(f), f)
```

Note that `plot::Hatch` requires an *object* of type `plot::Function2d`, not just a function expression:

```
plot::Hatch(sin(x))
```

Error: No 'plot::Function2d' or 'plot::Curve2d' is given. [plot:

`plot::Hatch` can be asked to hatch the area between a function graph and some constant value (i.e., some line parallel to the x-axis):

```
plot(plot::Hatch(f, 1), f)
```

# plot::Hatch

---

For functions with poles, keeping `VerticalAsymptotesVisible` set to `TRUE` is highly recommended:

```
f := plot::Function2d(1/(x - 1)):
h := plot::Hatch(f):
plot(f, h)
```

```
delete f, h:
```

## Example 2

By passing two functions to `plot::Hatch`, we ask for a hatch of the area between the two:

```
f := plot::Function2d(sin(x), x = -4 .. 4, Color = RGB::Blue):
g := plot::Function2d(cos(2*x), x = -4 .. 4, Color=RGB::Black):
h := plot::Hatch(f, g):
plot(f, g, h)
```

# plot::Hatch

---

```
delete f, g, h:
```

### Example 3

plot::Hatch can also hatch the inner part of a plot::Curve2d object:

```
circle := plot::Curve2d([sin(t), cos(t)], t=0..2*PI):
plot(circle, plot::Hatch(circle))
```

If the curve is not closed, `plot::Hatch` regards the first and last point to be connected:

```
circle::UMax := 3*PI/2:
plot(circle, plot::Hatch(circle))
```

# plot::Hatch

---

```
delete circle:
```

## Example 4

By default, `plot::Hatch` extends as far to the left and right as possible without leaving the common definition area of all given functions:

```
f := plot::Function2d(sin(x), x = 0 .. 5):
g := plot::Function2d(-cos(x), x = -1 .. 4):
h := plot::Hatch(f, g):
plot(f, g, h)
```

You can restrict this range by giving an explicit range of x values:

```
h := plot::Hatch(f, g, 1 .. 3):
plot(f, g, h)
```

# plot::Hatch

---

However, it is *not* possible to extend the range beyond the common definition range of both functions:

```
h := plot::Hatch(f, g, -1 .. 3):
plot(f, g, h)
```

The restriction of the  $x$  range also works for hatching curve objects:

```
c := plot::Curve2d([sin(5*x), cos(7*x)], x = 0 .. 2*PI):
h := plot::Hatch(c, 0 .. 1):
plot(c, h)
```

# plot::Hatch

---

Note that `plot::Hatch` reacts to the smoothness of the curve. This is one of the reasons why you have to provide a *objects* instead of expressions for the functions or curves:

```
c::AdaptiveMesh := 2:
plot(c, h)
```

```
delete f, g, h, c:
```

### Example 5

One of the most useful attributes of `plot::Hatch` is `FillPattern`, which can take one of the values `DiagonalLines` (the default), `FDiagonalLines`, `HorizontalLines`, `VerticalLines`, `CrossedLines`, `XCrossedLines`, or `Solid`:

```
f := plot::Function2d(sin(x)):
h := plot::Hatch(f, FillPattern = VerticalLines):
plot(f, h)
```

## plot::Hatch

---

Another attribute that will often be useful is `FillColor`, to change the color of the hatch. We set the value right in our existing hatch object:

```
h::FillPattern := CrossedLines:
h::FillColor := RGB::Blue:
plot(f, h)
```

delete f, h:

### Example 6

The function(s) or curve, the baseline, and the restriction of the  $x$  range can be animated:

```
f := plot::Function2d(sin(x + a), x = -PI..PI, a = 0..2*PI):
g := plot::Function2d(cos(x - a), x = -PI..PI, a = 0..4*PI):
plot(f, g, plot::Hatch(f, g, x0 .. x0+1, x0 = -PI..3))
```

# plot::Hatch

---

```
f := plot::Function2d(sin(a*x), x=-PI..PI, a=0.2..3):
plot(f, plot::Hatch(f))
```

```
delete f, g:
```

### Example 7

A “hatch” may also be a solid area fill:

```
plot(plot::Hatch(
 plot::Curve2d([abs(r)*sin(r), abs(r)*cos(r)], r = -PI..PI),
 FillPattern = Solid, FillColor = RGB::Red, Axes = None))
```

## Parameters

**$f_1, f_2$**

The outlining function(s) of the hatch: objects of type `plot::Function2d`.

$f_1, f_2$  are equivalent to the attributes `Function1, Function2`.

**$c$**

The outlining curve of the hatch: a parametrized curve of type `plot::Curve2d`.

$c$  is equivalent to the attribute `Function1`.

**base**

The base line of the hatch: a numerical real value or an arithmetical expression of the animation parameter `a`.

`base` is equivalent to the attribute `Baseline`.

**$x_1 \dots x_2$**

A range on the x-axis limiting the hatch to the left and the right hand side: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$x_1 .. x_2$  is equivalent to the attributes XMin, XMax, XRange.

**a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

`plot::Curve2d` | `plot::Function2d` | `plot::Sweep`

# plot::Histogram2d

---

**Purpose** Histogram plots of data

**Syntax** `plot::Histogram2d(data, <a = amin .. amax>, options)`

**Description** `plot::Histogram2d` creates a histogram plot of the given data, showing the frequency distribution in a user-definable cell array.

By default, data is grouped into 7 classes of equal width. To increase the number of cells, but still have them be of equal width, set `Cells = [n]`, as in “Example 1” on page 23-429. For full control over the classes, set `Cells` to a list specifying the cells, as in “Example 2” on page 23-432.

As long as the attribute `Area` is not changed from its default value of 0, `plot::Histogram2d` displays the absolute number of data in a class as the height of the corresponding bar. With `Area = a`,  $a > 0$ , the whole plot will take area  $a$ , with each rectangle area proportional to the number of data points in its cell. “Example 3” on page 23-434 shows the difference in detail.

By default, cells (“classes”) given by the attribute `Cells = [a1 .. b1, a2 .. b2, dots]` are interpreted as a collection of semi-open intervals  $(a_i, b_i]$  that are closed at the right boundary. A data item  $x$  is tallied into the  $i$ -th cell if it satisfies  $a_i < x \leq b_i$ . Use the option `CellsClosed = Left` or the equivalent `ClassesClosed = Left` to interpret the classes as the semi-open intervals  $[a_i, b_i)$  that are closed at the left boundary.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Area</code>	the area of a histogram plot	0

Attribute	Purpose	Default Value
Cells	classes of histogram plots	[7]
CellsClosed	interpretation of the classes in histogram plots	Right
ClassesClosed	interpretation of the classes in histogram plots	[Right]
Color	the main color	RGB::GeraniumLake
Data	the (statistical) data to plot	
DrawMode	orientation of boxes and bars	Vertical
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::GeraniumLake
FillPattern	type of area filling	Solid
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black
LineWidth	width of lines	0.35

## plot::Histogram2d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles

VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

To plot a histogram of a normally distributed process, we first create a generator of random numbers with this distribution:

```
X := stats::normalRandom(0, 1)
```

```
proc X() ... end
```

# plot::Histogram2d

---

Next, we create a small number of “measurements”:

```
data := [X() $ i = 1..20]
```

```
[- 0.5297400457, - 0.5694234147, - 0.5161446272, - 1.090814471, 1.782520584, 0.637033
0.6902341601, 0.3399758858, 1.177699186, - 0.5970692982, - 1.386247581, - 0.978322
- 0.7891413081, 0.2090732178, 0.2186783746, - 0.7392138209, 0.6496128588, 0.62586
3.606896706, - 0.3319378999]
```

This data is ready to be put into plot::Histogram2d:

```
plot(plot::Histogram2d(data))
```

This plot, if nothing else, shows that 20 samples are very few. Let us repeat the process with more data:

```
data := [X() $ i = 1..300]:
```

```
plot(plot::Histogram2d(data))
```

On the other hand, this amount of data certainly justifies a finer classification:

```
plot(plot::Histogram2d(data, Cells = [15]))
```

# plot::Histogram2d

---

## Example 2

It is also possible to give the cells (classes) directly. To do so, you should give them as ranges or lists with two elements, as in the following example:

```
X := stats::normalRandom(0, 1):
data := [X() $ i = 1 .. 100]:
min(data), max(data)
```

```
- 3.266420216, 2.409775834
```

```
h := plot::Histogram2d(data,
 Cells = [-2.5..-1.5, -1.5..-1, -1..0,
 0..1, 1..1.5, 1.5..2.5])
```

```
plot::Histogram2d(...)
```

```
plot(h)
```

It is even possible to use `-infinity` and `infinity` as border values in the cells:

```
h::Cells := [-infinity..-2, -2..-1, -1..0,
 0..1, 1..2, 2..infinity]:
plot(h)
```

# plot::Histogram2d

---

### Example 3

One potential problem with classes of non-equal width is that still the *height* of the bars corresponds to the *number* of data points in a class. To see why this may be a problem, consider data perfectly uniformly distributed:

```
data := [i/1000 $ i = 1..1000]:
```

Plotting a histogram of this data, we see only very small deviations from a rectangle, caused by the fact that 1000 and 7 are coprime:

```
plot(plot::Histogram2d(data))
```

However, plotting a histogram with uneven classes, the image looks very much different:

```
plot(plot::Histogram2d(data,
 Cells = [0..1/2, 1/2..2/3, 2/3..3/4, 3/4..4/5, 4/5..1]))
```

## plot::Histogram2d

---

To make not the *height*, but rather the *area* of a bar depend on the number of samples in a class, set `Area` to a positive value:

```
plot(plot::Histogram2d(data,
 Cells = [0..1/2, 1/2..2/3, 2/3..3/4, 3/4..4/5, 4/5..1],
 Area = 1))
```

Note that with `Area = 1`, a histogram plot is scaled accordingly to the probability density function of the variable displayed:

```
X := stats::normalRandom(0, 1):
data := [X() $ i = 1..1000]:
h := plot::Histogram2d(data, Cells = [15],
 Area = 1, Color = RGB::Blue):
f := plot::Function2d(stats::normalPDF(0, 1),
 x = -3..3, LineWidth = 1*unit::mm,
 Color = RGB::Black):
plot(h, f)
```

# plot::Histogram2d

---

`delete X, data, h, f:`

## Parameters

### **data**

The data to plot: A list of real values or expressions in the animation parameter  $a$ .

`data` is equivalent to the attribute `Data`.

### **a**

Animation parameter, specified as  $a = a_{\min}..a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## See Also

### **MuPAD Functions**

`plot` | `plot::copy` | `stats::frequency`

## **MuPAD Graphical Primitives**

`plot::Bars2d` | `plot::Boxplot` | `plot::Scatterplot`

# plot::Implicit2d

---

**Purpose** Contour lines of a function from  $R^2$  to  $R$

**Syntax** `plot::Implicit2d(f, x = x_min .. x_max, y = y_min .. y_max,  
<a = a_min .. a_max>, options)`

**Description** `plot::Implicit2d(f(x, y), x = `x_{min}` .. `x_{max}` , y =  
`y_{min}` .. `y_{max}` )` plots the curves where the smooth function  $f$  is zero.

`plot::Implicit2d(f, x = `x_{min}` .. `x_{max}` , y =  
`y_{min}` .. `y_{max}` )` plots the zeroes of  $f$  in the given range, i.e.,  
the set  $\{(x, y) \mid x_{\min} \leq x \leq x_{\max}, y_{\min} \leq y \leq y_{\max}, f(x, y) = 0\}$ .

`plot::Implicit2d` assumes that  $f$  is *regular almost everywhere* on this curve, which means that  $f$  must be differentiable and at least one of its partial derivatives must be nonzero.

To plot other contours than zeroes, use the option `Contours`.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE

YRange	range of parameter "y"	

# plot::Implicit2d

---

## Examples

### Example 1

It is well-known that a circle can be described as

$$\{(x, y) \mid x^2 + y^2 = r^2\}:$$

```
plot(plot::Implicit2d(x^2+y^2-1, x = -1..1, y = -1..1))
```

Note that `plot::Implicit2d` uses the given range completely, even if there is nothing to plot at a border:

```
plot(plot::Implicit2d(x^2+y^2-1, x = -2..2, y = -2..2))
```

### Example 2

plot::Implicit2d handles functions which are not regular at isolated points on the contours:

```
plot(plot::Implicit2d((x-y)*(x+y), x = -1..1, y = -1..1))
```

## plot::Implicit2d

---

However, it fails if the function is singular on more than isolated points:

```
plot(plot::Implicit2d(0, x = -1..1, y = -1..1))
```

### Example 3

We plot some of the elliptic curves  $y^2 = x^3 + 4x + c$ :

```
plot(plot::Implicit2d(y^2 - x^3 + 4*x, x = -3..3, y = -4..4,
 Contours = [c $ c = -3..6]))
```

## plot::Implicit2d

---

### Example 4

Like most graphical objects, `plot::Implicit2d` can be animated easily:

```
plot(plot::Implicit2d(x^2 - y^2 = (x - a*y)*(x^2 + y^2),
 x = -2..2, y = -2..2, a = -2..2))
```

**Parameters** **f**

A real-valued expression or an equation in  $x$ ,  $y$ , and possibly the animation parameter.

$f$  is equivalent to the attribute Function.

**$x$ ,  $y$**

identifiers.

$x$ ,  $y$  are equivalent to the attributes XName, YName.

**$x_{min} .. x_{max}$ ,  $y_{min} .. y_{max}$**

Real-valued expressions, possibly in the animation parameter.

The image is plotted with  $x$  in the range  $x_{min} \leq x \leq x_{max}$  and  $y_{min} \leq y \leq y_{max}$ .

$x_{min} .. x_{max}$ ,  $y_{min} .. y_{max}$  are equivalent to the attributes XRange, XMin, XMax, YRange, YMin, YMax.

# plot::Implicit2d

---

**a**

Animation parameter, specified as  $\mathbf{a} = \mathbf{a}_{\min} . . \mathbf{a}_{\max}$ , where  $\mathbf{a}_{\min}$  is the initial parameter value, and  $\mathbf{a}_{\max}$  is the final parameter value.

## Algorithms

plot::Implicit2d uses a curve tracking method: It first generates starting points on the curve and then uses a predictor-corrector method to follow the curve thus found in both directions, using the implicit function theorem.

## See Also

### MuPAD Functions

plot | plot::copy

### MuPAD Graphical Primitives

plot::Curve2d | plot::Implicit3d

## Purpose

Contour surfaces of a function from  $\mathbb{R}^3$  to  $\mathbb{R}$

## Syntax

```
plot::Implicit3d(f, x = x_min .. x_max, y = y_min .. y_max, z
= z_min .. z_max, <a = a_min .. a_max>, options)
```

## Description

`plot::Implicit3d(f(x, y, z), x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` , z = `z_{min}`..`z_{max}` )` plots the surfaces where the smooth function  $f$  is zero.

`plot::Implicit3d(f, x = `x_{min}`..`x_{max}` , y = `y_{min}`..`y_{max}` , z = `z_{min}`..`z_{max}` )` plots the (two-dimensional part of the) zeroes of  $f$  in the given range, i.e., the set  $\{(x, y, z) \mid x_{\min} \leq x \leq x_{\max}, y_{\min} \leq y \leq y_{\max}, z_{\min} \leq z \leq z_{\max}, f(x, y, z) = 0\}$ .

`plot::Implicit3d` assumes that  $f$  is *regular almost everywhere* on this surface, which means that  $f$  must be differentiable and at least two of its partial derivatives must be nonzero.

`plot::Implicit3d` evaluates the given function on an equidistant, three-dimensional mesh, the coarsity of which can be set with the attributes `XMesh`, `YMesh`, and `ZMesh` for each of the three directions, or with the combining attribute `Mesh` that sets all three of these simultaneously.

After finding an initial triangulation of the surface from the numerical data on the initial grid, `plot::Implicit3d` optionally performs adaptive subdivision of the triangles. To make a long story short: If the initial calculation misses details altogether, adaptive refinement will not find them either. On the other hand, if the initial calculation shows spurious spikes, adaptive refinement will result in a much more realistic image, at the expense of time; the higher the value of `AdaptiveMesh`, the more. Increasing `AdaptiveMesh` by one may in extreme cases increase calculation time by a factor of eight or more!

The details of the algorithm are as follows: On top level, the “effective adaptive level” is set to the value of the attribute `AdaptiveMesh`. If, for a given edge, the effective adaptive level is positive and the edge is not very short already, compared with the size of the complete image, and inserting a new point on the implicit surface near the middle of

# plot:Implicit3d

---

this edge would cause the two new edges to have an angle of less than 170 degrees, then the edge is split, the adjoining triangles are split accordingly (taking into account all their edges) and all the new edges caused by this operation are examined with an effective adaptive level reduced by one.

To plot other contours than zeroes, use the option `Contours`.

## Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	0
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Color</code>	the main color	RGB::Red
<code>Contours</code>	the contours of an implicit function	[0]
<code>Filled</code>	filled or transparent areas and surfaces	TRUE
<code>FillColor</code>	color of areas and surfaces	RGB::Red
<code>FillColor2</code>	second color of areas and surfaces for color blends	RGB::CornflowerBlue
<code>FillColorType</code>	surface filling types	Dichromatic
<code>FillColorFunction</code>	functional area/surface coloring	
<code>FillColorDirection</code>	the direction of color transitions on surfaces	[0, 0, 1]

Attribute	Purpose	Default Value
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Function	function expression or procedure	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Black.[0.15]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	

## plot:Implicit3d

---

Attribute	Purpose	Default Value
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[11, 11, 11]
MeshVisible	visibility of irregular mesh lines in 3D	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointStyle	the presentation style of points	FilledCircles

Attribute	Purpose	Default Value
PointsVisible	visibility of mesh points	FALSE
Shading	smooth color blend of surfaces	Smooth
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

XName	name of parameter "x"	
XRange	range of parameter "x"	
YContours	contour lines at constant y values	[Automatic, 15]
YMax	final value of parameter "y"	
YMesh	number of sample points for parameter "y"	11

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	
ZContours	contour lines at constant z values	[Automatic, 15]
ZMax	final value of parameter “z”	
ZMesh	number of sample points for parameter “z”	11
ZMin	initial value of parameter “z”	
ZName	name of parameter “z”	
ZRange	range of parameter “z”	

## Examples

### Example 1

The set of  $x, y, z$  where  $x^2 + y^2 + z^2 = 1$  form a sphere:

```
plot(plot::Implicit3d(x^2 + y^2 + z^2 - 1,
 x = -1.5..1.5,
 y = -1.5..1.5,
 z = -1.5..1.5),
 Scaling = Constrained)
```

## plot::Implicit3d

---

### Example 2

The set of zeroes of a product is the union of the zeroes of the individual functions:

```
plot(plot::Implicit3d((x^2 + y^2 + z^2 - 1) * x,
 x = -1.5..1.5,
 y = -1.5..1.5,
 z = -1.5..1.5),
 Scaling = Constrained)
```

Note that this image is largely dominated by artifacts caused by the coarse evaluation mesh. Increasing this mesh improves the graphics, but increases computation time:

```
plot(plot::Implicit3d((x^2 + y^2 + z^2 - 1) * x,
 x = -1.5..1.5,
 y = -1.5..1.5,
 z = -1.5..1.5,
 Mesh = [21, 9, 9], AdaptiveMesh = 2),
 Scaling = Constrained)
```

## plot::Implicit3d

---

### Example 3

With `MeshVisible = TRUE`, the internal triangulation becomes visible:

```
plot(plot::Implicit3d(z^2 - sin(z - x^2*y^2) = 0,
 x = -1 .. 1, y = -1 .. 1, z = 0 .. 1,
 AdaptiveMesh = 2, MeshVisible = TRUE,
 LineColor = RGB::Black.[0.25])):
```

#### Example 4

Using functions that are not continuously differentiable, it is possible to generate sharp edges in the images:

```
plot(plot::Implicit3d(min(x^2 + y^2 + z^2 - 2, -z),
 x = -2..2, y = -2..2, z = -1.5..0.5),
 Axes = None, Scaling = Constrained)
```

## plot::Implicit3d

---

Just like in the preceding example, these sharp corners are prime sources of artifacts, which may require a finer initial mesh and/or adaptive mesh refinement:

```
im := plot::Implicit3d(min(x^2 + y, y^2 - z),
 x = -2..2, y = -2..2, z = 0..1):
plot(im)
```

```
plot(im, AdaptiveMesh = 3)
```

# plot::Implicit3d

---

## Example 5

Animating `plot::Implicit3d` objects takes a lot of time. It is easy and fast, though, to add an animated camera object:

```
plot(plot::Implicit3d(sin(x)+sin(y)+sin(z), x=-5..5, y=-5..5, z=-5..5),
 plot::Camera([42*sin(t),42*cos(t),42*cos(t-sin(t))], [0,0,0],
 PI/12, t=0..2*PI),
 AnimationStyle=Loop)
```

**Parameters**    **f**

A real-valued expression or an equation in  $x$ ,  $y$ ,  $z$ , and possibly the animation parameter.

$f$  is equivalent to the attribute Function.

**$x$ ,  $y$ ,  $z$**

identifiers.

$x$ ,  $y$ ,  $z$  are equivalent to the attributes XName, YName, ZName.

**$x_{min} .. x_{max}$ ,  $y_{min} .. y_{max}$ ,  $z_{min} .. z_{max}$**

Real-valued expressions, possibly in the animation parameter.

The image is plotted with  $x$  in the range  $x_{min} \leq x \leq x_{max}$ ,  $y_{min} \leq y \leq y_{max}$  and  $z_{min} \leq z \leq z_{max}$ .

$x_{min} .. x_{max}$ ,  $y_{min} .. y_{max}$ ,  $z_{min} .. z_{max}$  are equivalent to the attributes XRange, XMin, XMax, YRange, YMin, YMax, ZRange, ZMin, ZMax.

# plot::Implicit3d

---

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## See Also

### MuPAD Functions

[plot](#) | [plot::copy](#)

### MuPAD Graphical Primitives

[plot::Implicit2d](#) | [plot::Surface](#)

## Purpose

Display areas where inequalities are fulfilled

## Syntax

```
plot::Inequality(ineq, x = x_min .. x_max, y = y_min ..
y_max, <a = a_min .. a_max>, options)
plot::Inequality([ineq1,], x = x_min .. x_max, y = y_min ..
y_max, <a = a_min .. a_max>, options)
```

## Description

`plot::Inequality(f(x, y) < g(x, y), x = `x_{min}` .. `x_{max}`, y = `y_{min}` .. `y_{max}` )` fills the rectangle  $x_{\min}$   $x_{\max}$ ,  $y_{\min}$   $y_{\max}$  with several colors, indicating which points satisfy the inequality.

`plot::Inequality` computes a (more or less coarse) rasterization of the area specified by ``x_{min}` .. `x_{max}`` and ``y_{min}` .. `y_{max}`` and colors subareas according to whether all of the given inequalities are fulfilled (these are colored in `FillColorTrue`), at least one inequality is nowhere fulfilled in the subarea (`FillColorFalse`) or the granularity is insufficient to decide for either of these cases (`FillColorUnknown`).

You can control the density of the rasterization with the attribute `Mesh`. Cf. “Example 2” on page 23-472.

`plot::Inequality` uses interval numerics for evaluation, so the results are reliable, but certain special functions (such as `hypergeom`) cannot be used because they are not supported for intervals.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	<code>TRUE</code>

YMax	final value of parameter “y”	
YMesh	number of sample points for parameter “y”	256
YMin	initial value of parameter “y”	

Attribute	Purpose	Default Value
YName	name of parameter "y"	
YRange	range of parameter "y"	

## Examples

### Example 1

With a single inequality, `plot::Inequality` colors the area where it is fulfilled or violated, with areas at the border line, where the inequality is fulfilled in some parts of the rectangle and violated in other parts:

```
plot(plot::Inequality(x^2 + y^2 < 1,
 x = -1.5..1.5, y = -1.5..1.5))
```

When giving more than one inequality, only those areas where *all* inequalities are fulfilled are painted in blue (or whatever you set

# plot::Inequality

FillColorTrue to), while all rectangles where *any* inequality is violated (over the whole rectangle) are colored red:

```
plot(plot::Inequality([x^2 + y^2 < 1, abs(x) > 1/3],
 x = -1.5..1.5, y = -1.5..1.5))
```

## Example 2

To get a more detailed image from plot::Inequality, increase the mesh density:

```
plot(plot::Inequality([x^2 + y^2 < 1, abs(x) > 1/3],
 x = -1.5..1.5, y = -1.5..1.5,
 Mesh = [120, 80]))
```

### Example 3

Almost all parameters of `plot::Inequality` can be animated (the `mesh` is one exception though):

```
plot(plot::Inequality([abs(x)^a + abs(y)^a < 1],
 x = -1.5+sin(a)..1.5+sin(a),
 y = -1.5+cos(a)..1.5+cos(a),
 Mesh = [64, 64],
 a = 1..2*PI+1))
```

# plot::Inequality

## Parameters `ineq, ineq1, ...`

Inequalities to plot: Expressions of the form  $f(x, y) < g(x, y)$ ,  $f(x, y) \leq g(x, y)$ ,  $f(x, y) = g(x, y)$ ,  $f(x, y) \geq g(x, y)$ , or  $f(x, y) > g(x, y)$ .

`ineq, ineq1, ...` is equivalent to the attribute `Inequalities`.

## `x, y`

Identifiers or indexed identifiers. These denote the free variables spanning the plane.

`x, y` are equivalent to the attributes `XName`, `YName`.

## `xmin .. xmax, ymin .. ymax`

The ranges for `x` and `y`. `xmin`, `xmax`, `ymin`, and `ymax` must be real numerical values, or expressions of the animation parameter `a`.

$x_{\min} .. x_{\max}, y_{\min} .. y_{\max}$  are equivalent to the attributes XRange, YRange.

**a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

`plot::Density` | `plot::Implicit2d` | `plot::Raster`

# plot::Integral

---

## Purpose

Numerical approximation of an integral

## Syntax

```
plot::Integral(f, <n>, <IntMethod = m>, <a =
amin .. amax>, options)
```

## Description

`plot::Integral(f, IntMethod = m)` visualizes the approximation of the integral of the function `f` using the numerical quadrature method `m`. Riemann sums, the trapezoidal rule, and the Simpson rule are available.

`plot::Integral(f, n, IntMethod = m)` uses `n` subintervals to approximate the integral.

The attribute `IntMethod` determines the numerical method. Riemann sums, the trapezoidal rule, or the Simpson rule are available. See the help page of `IntMethod` for further details. Cf. “Example 1” on page 23-480.

`plot::Integral` does not plot the function graph of the integrand. If the integrand is to be plotted, too, `f` has to be passed to the `plot` command together with the approximation object of type `plot::Integral`.

If no quadrature method is specified by `IntMethod = m`, `plot::Integral` just hatches the area between the function `f` and the x-axis.

Several `plot::Integral` objects can be plotted together to illustrate the difference between various quadrature methods. The order of the objects in the `plot` command determines the object in front.

The plot contains a text object providing information about the quadrature method, the value of the approximation, the exact value of the integral, the quadrature error, and the number of nodes. See the help page of the attribute `ShowInfo` for further details.

**Attributes**

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>

VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

If a single `plot::Function2d` object is given without specifying an approximation method, `plot::Integral` just hatches the area between the function graph and the x-axis:

```
f := plot::Function2d(cos(x), x = -PI..PI):
plot(plot::Integral(f), f)
```

Exact: 0.00  
Integral: 0.00

Note that `plot::Integral` requires an *object* of type `plot::Function2d`, not just a function expression:

```
plot::Integral(sin(x))
```

Error: The first argument must be a 'plot::Function2d' object. [

If an approximation method is specified, the numerical quadrature value computed by this method is displayed:

```
plot(plot::Integral(f, IntMethod = RiemannLower))
```

# plot::Integral

---

RiemannLower: -1.26  
Integral: 0.00

The number of quadrature intervals can be set by passing a second argument  $n$  or by specifying `Nodes = n`:

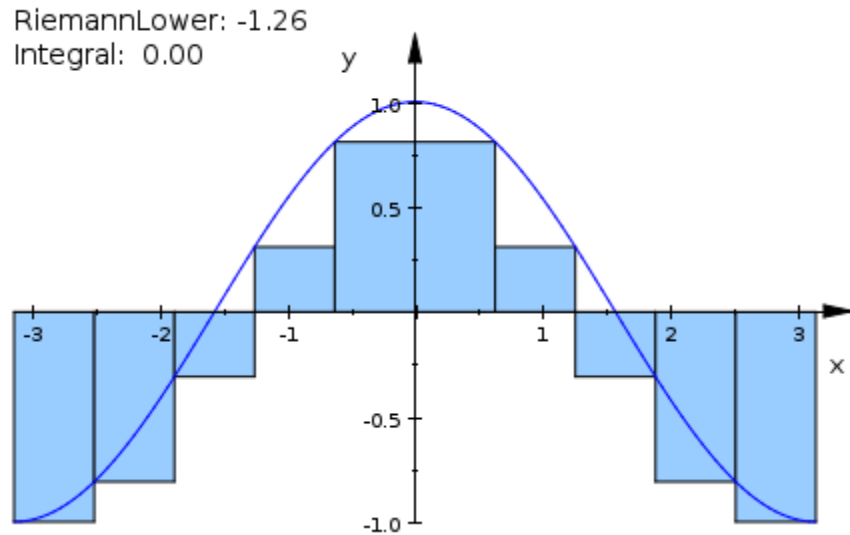

```
plot(plot::Integral(f, 20, IntMethod = RiemannLower))
```

To see the integrand in the plot, the function object must be passed together with the approximation object. The order determines which object is in front:

```
plot(plot::Integral(f, IntMethod = RiemannLower), f)
```

# plot::Integral

```
delete f:
```

## Example 2

The displayed information can be configured by the user:

```
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannLower,
 ShowInfo = [1, IntMethod = "Riemann lower sum",
 Integral = "Exact value",
 2, Error = "Difference"]), f)
```

Riemann lower sum: 60.0  
 Exact value: 83.3  
 Difference: 23.33

`delete f:`

### Example 3

One may combine several approximation objects, e.g., lower and upper sum:

```
f := plot::Function2d(x^2, x = -5..5):
plot(plot::Integral(f, IntMethod = RiemannUpper,
 Color = RGB::Blue),
 plot::Integral(f, IntMethod = RiemannLower,
 Color = RGB::LightYellow),
 f)
```

# plot::Integral

The automatically placed information texts overlap. To correct this, the option `ShowInfo` must be used. In the text of the upper sum, one additional empty line is inserted. Apart from this, both objects use the default value, therefore there is not need to specify `ShowInfo` in the second object:

```
plot(plot::Integral(f, IntMethod = RiemannUpper,
 ShowInfo = [IntMethod, "", Integral]),
 plot::Integral(f, IntMethod = RiemannLower,
 Color = RGB::LightYellow),
 f)
```

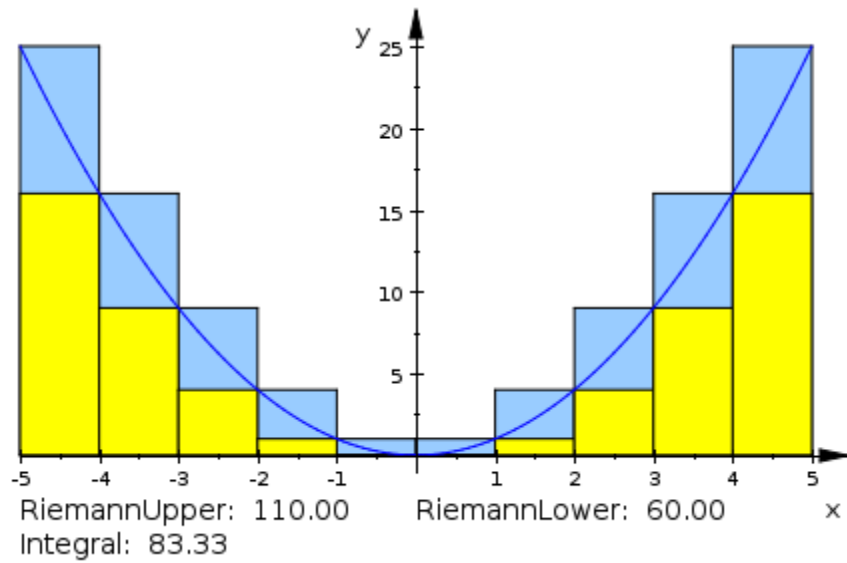

The info text can be positioned explicitly:

```
plot(plot::Integral(f, IntMethod = RiemannUpper,
 ShowInfo = [IntMethod, Integral,
 Position = [-5, -1]],
 VerticalAlignment = Top),
 plot::Integral(f, IntMethod = RiemannLower, Color = RGB::Ye,
 ShowInfo = [IntMethod,
 Position = [0, -1]],
 VerticalAlignment = Top),
 f)
```

# plot::Integral

`delete f:`

## Example 4

`plot::Integral` can be animated:

```
f := plot::Function2d(sin(a*x), x = 0..PI, a = 1.5):
plot(plot::Integral(f, 50, IntMethod = RiemannMiddle), f)
```

Increasing the number of nodes decreases the quadrature error:

```
f := plot::Function2d(sin(x), x = 0..PI):
plot(plot::Integral(f, N, N = 10..50, IntMethod = RiemannLower),
```

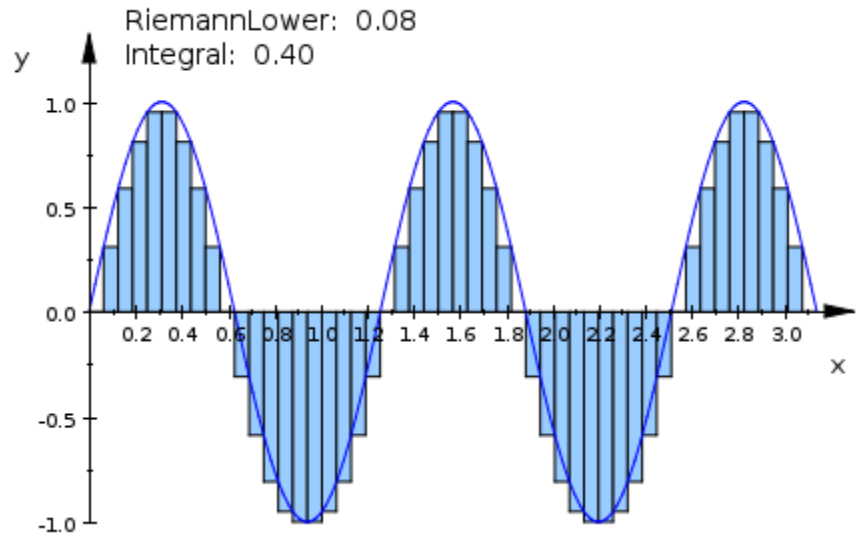

# plot::Integral

---

The function and the number of nodes can be animated simultaneously:

```
f := plot::Function2d(sin(a*x), x = 0..PI, a = 1..5):
plot(plot::Integral(f, N, N = 10..50, IntMethod = RiemannLower), f)
```

delete f:

## Parameters

**f**

The integrand: an object of type `plot::Function2d`.

f is equivalent to the attribute `Function1`.

**n**

The number of subintervals (a positive integer) or a list of real numbers representing nodes of the integration variable.

n is equivalent to the attribute `Nodes`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Integral

---

## Options

### IntMethod

Option, specified as `IntMethod = m`

The quadrature method; see `IntMethod`

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Function2d` | `plot::Hatch` | `plot::Text2d`

## Purpose

Plotting iterated functions

## Syntax

```
plot::Iteration(f, x0, <n>, x = xmin .. xmax, <a =
amin .. amax>, options)
```

## Description

`plot::Iteration(f, x0, n, x = `x_{min}` .. `x_{max}`)` is a graphical object visualizing the iteration  $x_i = f(x_{i-1})$  ( $i = 1, \dots, n$ ) of the given starting point  $x_0$ .

The iteration is visualized by connecting the points  $(x_0, 0)$  and  $(x_0, x_1)$  by a vertical line. For any step of the iteration, a horizontal line is drawn from the point  $(x_{i-1}, x_i)$  (on the graph of  $f$ ) to the point  $(x_i, x_i)$  on the main diagonal. From there, a vertical line is drawn to the next pair  $(x_i, x_{i+1})$  of the iteration.

The iteration object neither includes the graph of the function  $y = f(x)$  nor the main diagonal  $y = x$ . You need to plot them separately if you wish the function and/or the diagonal to be in your picture! See the examples.

The iteration is stopped prematurely when the iterated point leaves the plot range ``x_{min}` .. `x_{max}``. Cf. “Example 3” on page 23-501.

Despite the fact that the number of iterations  $n$  represents an integer, it can be animated! Cf. “Example 4” on page 23-503

The default color used for the iteration plot is `RGB::Grey50`. It can be modified by setting the attribute `Color` or `LineColor`. Cf. “Example 1” on page 23-496.

The default line style is solid. It can be modified by setting the attribute `LineStyle`.

# plot::Iteration

Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
StartingPoint	starting point of the iteration	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

# plot::Iteration

Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter "x"	
XMin	initial value of parameter "x"	
XName	name of parameter "x"	
XRange	range of parameter "x"	

## Examples

### Example 1

We consider the logistic map for the parameter value 3, i.e., the parabola  $f(x) = 3x(1 - x)$  for  $x \in [0, 1]$ . We iterate the starting point  $x_0 = 0.5$ :

```
f := plot::Function2d(3*x*(1 - x), x = 0..1,
 Color = RGB::Blue):
x0 := 0.5:
```

We plot the iteration (without specifying the number of iterations), the parabola  $f$  and the diagonal line  $g(x) = x$ :

```
g := plot::Function2d(x, x = 0..1, Color = RGB::Red):
it := plot::Iteration(3*x*(1 - x), x0, x = 0..1):
plot(f, g, it)
```

We increase the number of iterations to 50 and change the color of the lines to RGB::Black:

```
it::Iterations := 50:
it::Color := RGB::Black:
plot(f, g, it)
```

# plot::Iteration

---

Finally, we animate the number of steps, allowing to follow the course of the iteration:

```
it := plot::Iteration(3*x*(1 - x), x0, n, x = 0..1,
 n = 1..50, Color = RGB::Black):
plot(f, g, it)
```

```
delete f, g, it:
```

### Example 2

We consider the logistic map  $f(x) = ax(1 - x)$  for  $x \in [0, 1]$  and the animation parameter  $a$  running from  $a = 2$  to  $a = 4$ :

```
f := plot::Function2d(a*x*(1 - x), x = 0..1, a = 2..4,
 Color = RGB::Black):
```

We define the iteration of the starting point  $x_0 = 0.2$  by  $f$  and plot it together with the function graph of  $f(x)$  and the diagonal line  $g(x) = x$ :

```
g := plot::Function2d(x, x = 0..1, Color = RGB::Black):
it1 := plot::Iteration(a*x*(1 - x), 0.2, 30, x = 0..1,
 a = 2..4, Color = RGB::Red):
plot(f, g, it1)
```

# plot::Iteration

---

We define an additional iteration starting at  $x_0 = 0.21$  and add it to the plot:

```
it2 := plot::Iteration(a*x*(1 - x), 0.21, 30, x = 0..1,
 a = 2..4, Color = RGB::Blue):
plot(f, g, it1, it2)
```

For small values of  $a$ , the two iterations converge to the same fixed point. When  $a$  approaches the value 4, the iterations drift into chaos.

```
delete f, g, it1, it2:
```

### Example 3

Consider the iteration of the starting point  $x_0 = 0.2$  by the logistic map  $f(x) = x(x - 1)$  with the plot range  $x \in [0, 1]$ :

```
f := plot::Function2d(x*(x - 1), x = 0..1):
it := plot::Iteration(x*(x - 1), 0.2, x = 0..1):
plot(f, it)
```

# plot::Iteration

---

We see that only one step of the iteration is plotted. The reason is that the point  $x_1 = f(x_0)$  is negative and, hence, not contained in the requested plot range  $x = 0..1$ . We modify the plot range:

```
f::XRange:= -0.5..1:
it::XRange:= -0.5..1:
plot(f, it)
```

```
delete f, it:
```

## Example 4

We animate the parameter  $n$  that sets the number of iterations. We set the time range for the animation to 40 (seconds). Using `Frames`, the total number of frames is chosen such that approximately 10 frames are used to visualize the step from  $n$  to  $n + 1$ :

```
f := plot::Function2d(4*x*(1 - x), x = 0..1):
g := plot::Function2d(x, x = 0..1):
it := plot::Iteration(4*x*(1 - x), 0.4, n, x = 0..1,
 LineStyle = Dashed,
 n = 0..40, Frames = 411,
 TimeRange = 0..40):

plot(f, g, it)
```

# plot::Iteration

---

delete f, g, it:

## Parameters **f**

The iteration function: an arithmetical expression in the independent variable  $x$  and the animation parameter  $a$ . Alternatively, a procedure that accepts 1 input parameter  $x$  or 2 input parameters  $x$ ,  $a$  and returns a real numerical value when the input parameters are numerical.

$f$  is equivalent to the attribute Function.

## **$x_0$**

The starting point for the iteration:  $x_0$  must be a numerical real value or an expression in the animation parameter  $a$ .

$x_0$  is equivalent to the attribute StartingPoint.

## **n**

The number of iterations:  $n$  must be a positive integer or an expression in the animation parameter  $a$ .

$n$  is equivalent to the attribute `Iterations`.

**x**

The independent variable: an identifier or an indexed identifier.

$x$  is equivalent to the attribute `XName`.

**$x_{\min} .. x_{\max}$**

The plot range:  $x_{\min}$ ,  $x_{\max}$  must be numerical real values or expressions in the animation parameter  $a$ .

$x_{\min} .. x_{\max}$  is equivalent to the attributes `XRange`, `XMin`, `XMax`.

**a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

`plot::Lsys`

# plot::Line2d

---

**Purpose** 2D line segments

**Syntax** `plot::Line2d([x1, y1], [x2, y2], <a = amin .. amax>, options)`

**Description** `plot::Line2d([x1, y1], [x2, y2])` creates a 2D line segment between the points  $(x_1, y_1)$  and  $(x_2, y_2)$ .

The end points may be passed as lists or vectors.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE
Color	the main color	RGB::Blue
Extension	line extensions	Finite
Frames	the number of frames in an animation	50
From	starting point of arrows and lines	[0, 0]
FromX	starting point of arrows and lines, x-coordinate	0
FromY	starting point of arrows and lines, y-coordinate	0
Legend	makes a legend entry	
LegendText	short explanatory text for legend	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	

## plot::Line2d

---

Attribute	Purpose	Default Value
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
To	end point of arrows and lines	[1, 0]
ToX	end point of arrows and lines, x-coordinate	1
ToY	end point of arrows and lines, y-coordinate	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We create a 2D line segment:

```
plot(plot::Line2d([1, 2], [3, -1]))
```

The `LineStyle` can be changed from `Solid`, as is the default, to `Dashed` or `Dotted`. Likewise `LineColor` and `LineWidth` can be set explicitly:

```
plot(plot::Line2d([1, 2], [3, -1],
 LineStyle = Dashed,
 LineWidth = 2.5*unit::mm,
 LineColor = RGB::Green))
```

# plot::Line2d

---

## Example 2

We plot two animated 3D line segments starting off parallel, ending up skew:

```
plot(plot::Line3d([0, 0, 0], [a, a, 1], a = 0..1),
 plot::Line3d([1, 0, 0], [a, 0, 1], a = 1..0))
```

In addition to `LineStyle`, `LineColor` and `LineWidth`, 3D line segments support the style option `Tubular`. If this is set to `TRUE`, the `TubeDiameter` can be set explicitly:

```
plot(plot::Line3d([0.1, 0, 0], [1, 0, 0]),
 plot::Line3d([0, 0.1, 0], [0, 1, 0]),
 plot::Line3d([0, 0, -0.1], [0, 0, -1]),
 ViewingBox = [-0.2..1.2, -0.2..1.2, -1..0.2],
 Tubular = TRUE, TubeDiameter = 5.0*unit::mm)
```

## Parameters

**$x_1, y_1$**

The coordinates of one end point: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x_1, y_1$  are equivalent to the attributes FromX, FromY.

**$x_2, y_2$**

The coordinates of the other end point: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x_2, y_2, z_2$  are equivalent to the attributes ToX, ToY, ToZ.

**$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

 plot::Line3d([0, 0.1, 0], [0, 1, 0]),
 plot::Line3d([0, 0, -0.1], [0, 0, -1]),
 ViewingBox = [-0.2..1.2, -0.2..1.2, -1..0.2],
 Tubular = TRUE, TubeDiameter = 5.0*unit::mm)
```

## Parameters

### $x_1, y_1, z_1$

The coordinates of one end point: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x_1, y_1, z_1$  are equivalent to the attributes FromX, FromY, FromZ.

### $x_2, y_2, z_2$

The coordinates of the other end point: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x_2, y_2, z_2$  are equivalent to the attributes ToX, ToY, ToZ.

### $a$

Animation parameter, specified as  $a = a_{\min} + a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Line3d

---

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Line2d` | `plot::Polygon2d` | `plot::Polygon3d` |  
`plot::Rectangle`

**Purpose**

Finite lists of 2D points

**Syntax**

```
plot::Listplot([y1, y2,], <x = xmin .. xmax>, <a =
amin .. amax>, options)
plot::Listplot(A1, <x = xmin .. xmax>, <a =
amin .. amax>, options)
plot::Listplot([[x1, y1], [x2, y2],], <a =
amin .. amax>, options)
plot::Listplot(A2, <a = amin .. amax>, options)
```

**Description**

plot::Listplot serves for visualizing discrete data values [y<sub>1</sub>, y<sub>2</sub>, ]. If no range x = `x\_{min}` .. `x\_{max}` is specified, the data are plotted as the points [x<sub>1</sub>, y<sub>1</sub>], [x<sub>2</sub>, y<sub>2</sub>] etc. with equidistant x-values x<sub>1</sub> = 1, x<sub>2</sub> = 2 etc. If a range x = `x\_{min}` .. `x\_{max}` is specified, equidistant x-values between x<sub>min</sub> and x<sub>max</sub> are used.

If the data are specified as a list of coordinate pairs [[x<sub>1</sub>, y<sub>1</sub>], [x<sub>2</sub>, y<sub>2</sub>], ], plot::Listplot generates plot points with these coordinates.

With the attribute LinesVisible = TRUE, each pair of consecutive data points is connected by a curve.

With InterpolationStyle = Linear (default), the points are connected by straight line segments.

With InterpolationStyle = Cubic, a cubic spline curve is used to connect the points. The spline curve between two data points is rendered as a collection of m + 1 straight line segments, where m is specified by the attribute Submesh = m.

Use LinesVisible = FALSE, if only the data points without connecting lines are to be rendered.

# plot::Listplot

---

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE
Data	the (statistical) data to plot	
FillColorDirection	the direction of color transitions on surfaces	[0, 0]
Frames	the number of frames in an animation	50
InterpolationStyle	interpolation via linear or cubic splines	Linear
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointColor	the color of points	RGB::Black
PointStyle	the presentation style of points	FilledCircles

# plot::Listplot

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
PointsVisible	visibility of mesh points	TRUE
Submesh	density of submesh (additional sample points)	6
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter "x"	
XMin	initial value of parameter "x"	
XName	name of parameter "x"	
XRange	range of parameter "x"	
XSubmesh	density of additional sample points for parameter "x"	6

## Examples

### Example 1

We plot 5 discrete data values as points with equidistant  $x$ -values 1, 2, 3, 4, 5:

```
plot(plot::Listplot([1, 0, 1, 0, 1]))
```

# plot::Listplot

---

We plot two data samples and place them side by side by specifying suitable ranges for the horizontal variable:

```
plot(plot::Listplot([1, 0, 2, 1], x = 0..1, Color = RGB::Red),
 plot::Listplot([0, 1, 0, 2], x = 1..2, Color = RGB::Blue))
```

We specify  $x$ -coordinates for the data points:

```
plot(plot::Listplot([[0.1, 1], [0.15, 0], [0.2, 1],
 [0.3, 0], [0.5, 1]]))
```

# plot::Listplot

---

## Example 2

We demonstrate the difference between linear and cubic spline interpolation:

```
plot(plot::Listplot([10, 0, 20, 0, 30], Color = RGB::Red,
 InterpolationStyle = Linear),
 plot::Listplot([10, 0, 20, 0, 30], Color = RGB::Blue,
 InterpolationStyle = Cubic))
```

We smoothen the cubic spline curve by increasing the Submesh value:

```
plot(plot::Listplot([10, 0, 20, 0, 30], Color = RGB::Red,
 InterpolationStyle = Linear),
 plot::Listplot([10, 0, 20, 0, 30], Color = RGB::Blue,
 InterpolationStyle = Cubic, Submesh = 12))
```

### Example 3

A random variable describing the number of successes in  $n$  Bernoulli trials with success probability  $p$  is binomially distributed with expectation value  $np$  and variance  $np(1 - p)$ . For large values of  $n$ , the binomial distribution is approximated by a corresponding normal distribution.

We use `plot::Listplot` to visualize the discrete probability values of the binomial distribution. The normal distribution is visualized via `plot::Function2d`:

```
n := 10: p:= 0.4:
plot(plot::Listplot([stats::binomialPF(n, p)(i) $ i = 0..n],
 x = 0..n, Color = RGB::Red),
 plot::Function2d(stats::normalPDF(n*p, n*p*(1 - p))(x),
 x = 0..n, Color = RGB::Blue)):
```

delete n, p:

## Parameters

$y_1, y_2, \dots$

Vertical coordinates: numerical values or expressions of the animation parameter  $a$ .

$y_1, y_2, \dots$  is equivalent to the attribute Data.

$x$

Name of the horizontal coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $x$  direction.

$x$  is equivalent to the attribute XName.

$x_{\min} \dots x_{\max}$

The range of the horizontal coordinate:  $x_{\min}$ ,  $x_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

# plot::Listplot

---

$x_{\min} .. x_{\max}$  is equivalent to the attributes XRange, XMin, XMax.

## **A<sub>1</sub>**

A 1-dimensional array of domain type DOM\_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) with 1 row or 1 column. The entries must be numerical real values or arithmetical expressions of the animation parameter  $a$ . The entries in  $A_1$  are regarded as data values  $[y_1, y_2]$  etc..

$A_1$  is equivalent to the attribute Data.

## **x<sub>1</sub>, x<sub>2</sub>, ...**

Horizontal coordinates: numerical values or expressions of the animation parameter  $a$ .

## **A<sub>2</sub>**

A 2-dimensional array of domain type DOM\_ARRAY or a matrix of category Cat::Matrix (e.g., of type matrix or densematrix) with at least two rows and two columns. The entries must be numerical real values or arithmetical expressions of the animation parameter  $a$ . The  $i$ -th row is regarded as the data point  $(x_i, y_i)$ . If more than 2 columns are provided, only the data in the first two columns are considered; all additional columns are ignored.

$A_2$  is equivalent to the attribute Data.

## **a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## MuPAD Functions

plot | plot::copy

**MuPAD  
Graphical  
Primitives**

`plot::PointList2d` | `plot::Polygon2d` | `plot::Scatterplot`

# plot::Lsys

---

## Purpose

Lindenmayer systems

## Syntax

```
plot::Lsys(alpha, start, trans, , <a = amin ..
amax>, options)
```

## Description

`plot::Lsys` creates Lindenmayer systems, i.e., string rewriting systems controlling turtle graphics.

Lindenmayer systems, or L-systems for short, are based on the concept of iteratively transforming a string of symbols into another string. After a finite number of iterations, the resulting string is translated into a sequence of movement commands to a “turtle” (see `plot::Turtle`), which can be drawn on the screen.

In `plot::Lsys`, the string of symbols is represented by a string of characters, i.e., a `DOM_STRING`. *Transformation rules* are given as equations mapping strings of length 1 to strings of arbitrary length. *Turtle rules* are given as equations mapping strings of length 1 to simple movement commands: `Line`, `Move`, `Left`, `Right`, `Push`, `Pop`, `Noop`, or a color specification.

The commands are mostly self-explanatory. `Left` and `Right` turn by the amount set in the slot `RotationAngle`; the initial direction is “up”. `Line` and `Move` move by the amount set in `StepLength`, where `Move` does not draw a line. `Push` stores the current state (position, direction, color) on a stack from where it can later be reactivated using `Pop`. `Noop` means “ignore this, no operation”. A color specification changes the line color.

The following turtle rules are used by default (but can be disabled by giving other rules for the left-hand sides):

```
"F" = Line, "f" = Move, "[" = Push, "]" = Pop, "+" = Left, "-" =
Right.
```

**Attributes**

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
RotationAngle	angle of rotation commands in L-systems	
StartRule	start rule of an L-system	
StepLength	length of movement commands in L-systems	1.0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	

Attribute	Purpose	Default Value
TitlePositionY	position of object titles, y component	
TurtleRules	rules translating L-system symbols to turtle movements	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

As a very simple system, we consider the following iteration rule: “replace each line forward by the sequence “line forward, move forward without painting, line forward.””:

```
l := plot::Lsys(0, "F", "F" = "FfF");
```

Note that we do not provide an iteration rule for "f". This means “leave f alone, do not change it.”

The start state is displayed by plotting the system after zero generations:

```
l::Generations := 0:
plot(l)
```

Increasing the number of generations, we see the effect of our transformation rule:

```
l::Generations := 1:
plot(l)
```

```
l::Generations := 2:
plot(l)
```

# plot::Lsys

---

```
l::Generations := 3:
plot(l)
```

The following variant of this simple example produces approximations to the Cantor set:

```
l := plot::Lsys(0, "F", "F" = "FfF", "f" = "fff");
plot(l)
```

## Example 2

To get more interesting examples, we include rotations into our rules:

```
l := plot::Lsys(PI/2, "F-F-F-F", "F" = "F-F+F+FF-F-F+F",
 Generations = 3)
```

```
plot::Lsys($\frac{\pi}{2}$, "F-F-F-F", IterationRules = ["F" = "F-F+F+FF-F-F+F"], TurtleRules = [], Generations = 3)
```

As you can see, `plot::Lsys` has detected that our rule is an iteration rule. We could have used this syntax directly when creating the object. We have not given turtle rules, so the defaults are used:

```
plot(l)
```

### Example 3

The Peano curve is a famous example of a space filling curve. In the limit process, increasing the number of iterations while decreasing the length of the forward steps, it actually fills the plane. There are different constructions known, the one shown here fills a square tilted by  $45^\circ$ :

```
peano := plot::Lsys(PI/2, "F", "F" = "F+F-F-F-F+F+F-F"):
```

The transformation rule says to replace each straight line with the following construction:

```
peano::Generations := 1:
plot(peano)
```

After a few iterations, the lines already get very close to one another:

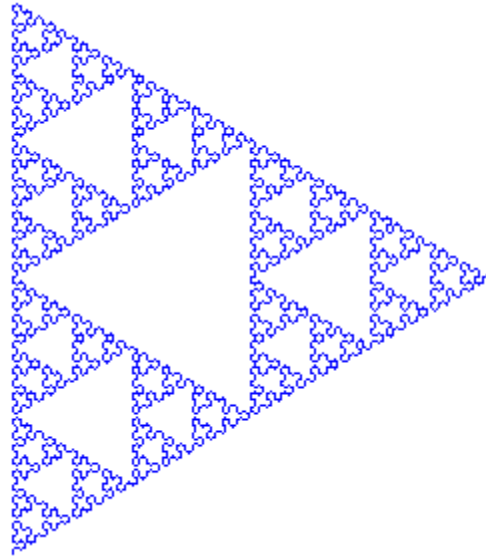

```
peano::Generations := 5:
plot(peano)
```

#### Example 4

Many L-systems contain different types of lines: While they are drawn exactly the same, their transformation rules are different from one another. The following example shows an image similar to the Sierpinski triangle:

```
l := plot::Lsys(PI/3, "R", "L" = "R+L+R", "R" = "L-R-L",
 "L" = Line, "R" = Line,
 Generations = 7):
plot(l)
```

## Example 5

The Push and Pop operations can be used to draw “arms” in an L-system:

```
plot(plot::Lsys(23*PI/180, "F", "F" = "FF-[-F+F+F]+[+F-F-F]",
Generations = 4))
```

### Example 6

L-systems have been used to simulate plant growth. We show an example here that uses the symbols B, H, and G to change the color of lines:

```
l := plot::Lsys(PI/9, "BL", "L" = "BR[+HL]BR[-GL]+HL",
 "R" = "RR", "L" = Line, "R" = Line,
 "B" = RGB::Brown, "H" = RGB::ForestGreen,
 "G" = RGB::SpringGreen, Generations = 6):
plot(l)
```

## plot::Lsys

---

The attribute `Generations` can be animated. This way, we can actually make the “plant” “grow:”

```
plot(plot::Lsys(a*PI/45, "BL", "L" = "BR[+HL]BR[-GL]+HL", "R" = "RR",
"L" = Line, "R" = Line, "B" = RGB::Brown,
"H" = RGB::ForestGreen, "G" = RGB::SpringGreen,
Generations = a, a = 1 .. 6)):
```

### Example 7

L-systems can display a couple of popular fractals. One example is the Koch snowflake, generated by replacing each straight line with a straight line, followed by a left turn of  $60^\circ$ , another straight line, a right turn of  $120^\circ$ , another straight line, another left turn of  $60^\circ$  and a final straight line:

```
koch := plot::Lsys(PI/3, "F--F--F", "F" = "F+F--F+F"):
```

The starting rule has been chosen to be an equilateral triangle:

```
koch::Generations := 0:
plot(koch)
```

The first generation looks like this:

```
koch::Generations := 1:
plot(koch)
```

The limit is pretty well approximated after five generations:

```
koch::Generations := 5:
plot(koch)
```

Finally, we use `plot::modify` and the "StepLength" slot to show the first couple of iterations superimposed on one another:

```
colors := [RGB::Red, RGB::Green, RGB::Blue, RGB::Yellow, RGB::DimGr
plot(plot::modify(koch, Generations = i,
 StepLength = 3^(-i),
 LineColor = colors[i+1]) $ i = 0..4)
```

### Example 8

Another well-known example of a fractal generated by an L-system is Heighway's Dragon curve. Informally, it is generated by "drawing a right angle and then replacing each right angle by a smaller right angle" (Gardner). It has been used in the book "Jurassic Park" by Michael Crichton and thereby got another nickname, the "Jurassic Park fractal."

```
plot(plot::Lsys(PI/2, "L", "L" = "L+R+", "R" = "-L-R",
 "L" = Line, "R" = Line, Generations = 9))
```

It is interesting to note that the iteration rules of this curve are equivalent to appending a mirrored copy of the curve to its end:

```
plot(plot::Lsys(PI/2, "L", "L" = "L+R+", "R" = "-L-R",
"L" = Line, "R" = Line, Generations = a,
a = 1..9))
```

### Example 9

While the L-system of the previous example corresponds to the definition found in the literature, the images in at least one popular source show another system (while the definition given is the one from above), namely:

```
plot(plot::Lsys(PI/4, "X-F-Y", "X" = "X+F+Y", "Y" = "X-F-Y",
 "X" = Line, "Y" = Line, Generations = 9)):
```

## Example 10

An L-system may contain letters that are not meant to show in the final graphic, so they form some sort of “markers” for subsequent iterations. For this purpose, you may use the turtle rule Noop:

```
plot(plot::Lsys(PI/12,
 "X+X",
 "X" = "[F+F+F+F[---X-Y]++++F+++++F-F-F-F]",
 "Y" = "[F+F+F+F[---Y]++++F+++++F-F-F-F]",
 "X" = Noop, "Y" = Noop,
 Generations = 3))
```

```
plot(plot::Lsys(PI/2, "FB",
 "A" = "FBFA+HFA+FB-FA", "B" = "FB+FA-FB-JFBFA",
 "F" = "", "H" = "-", "J" = "+",
 "A" = Noop, "B" = Noop, "H" = Noop, "J" = Noop))
```

## Example 11

Using this rule, we can use the following formulation of the popular Hilbert curve due to Ken Philip:

```
plot(plot::Lsys(PI/2, "x", "x" = "-yF+xFx+Fy-", "y" = "+xF-yFy-Fx+"
"x" = Noop, "y" = Noop))
```

To animate the creation process of the Hilbert curve, we adjust the length of the lines to the current number of iteration steps:

```
plot(plot::Lsys(PI/2, "x", "x" = "-yF+xFx+Fy-", "y" = "+xF-yFy-F",
 "x" = Noop, "y" = Noop,
 Generations = i, StepLength = 1/(2^i-1),
 i = 1..6, Frames = 6))
```

## Example 12

In some cases, systems will need small angles and long strings in order to specify the desired directions. Take for example the following system:

```
plot(plot::Lsys(7*PI/15, "F", "F"="F+F--F+F",
 Generations=4))
```

The rotations to the right use an angle of  $\frac{7\pi}{15}$ , while that to the left (the sharp spike) is a turn of  $\frac{14\pi}{15}$ . It would look more natural, however, to have the turtle start to the right, i.e., at an angle of  $-\frac{\pi}{2}$ . Since no multiple of  $\frac{7\pi}{15}$  is equal to  $\frac{\pi}{2}$  modulo  $2\pi$ , this requires that we use a smaller angle, adjusting our iteration rule:

```
plot(plot::Lsys(7*PI/30, "+++++F",
"F"="F++F---F++F", Generations=4))
```

## Parameters

### **alpha**

Angle (in radians) for turning commands. Animatable.

alpha is equivalent to the attribute `RotationAngle`.

### **start**

String used as the starting rule.

start is equivalent to the attribute `StartRule`.

### **trans, ...**

Iteration and Turtle command rules (see below).

trans, ... is equivalent to the attributes `IterationRules`, `TurtleRules`.

### **a**

Animation parameter, specified as  $\mathbf{a} = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Algorithms

Lindenmayer systems are “string rewriting systems.” MuPAD implements only context-free L-systems, which are analyzed in a similar context as context-free grammars.

Many examples of L-systems can be found, among other places, in “The Fractal Geometry of Nature” by Benoît Mandelbrot.

`plot::Turtle`

# plot::Matrixplot

---

**Purpose** Surface plot of matrix data

**Syntax**

```
plot::Matrixplot(A, options)
plot::Matrixplot(A, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
plot::Matrixplot(row_1, row_2, , options)
plot::Matrixplot(row_1, row_2, , x = x_min .. x_max, y =
y_min .. y_max, <a = a_min .. a_max>, options)
plot::Matrixplot([row_1, row_2,], options)
plot::Matrixplot([row_1, row_2,], x = x_min .. x_max, y =
y_min .. y_max, <a = a_min .. a_max>, options)
plot::Matrixplot(s, <c_1, c_2, >, options)
plot::Matrixplot(s, <c_1, c_2, >, x = x_min .. x_max, y =
y_min .. y_max, <a = a_min .. a_max>, options)
plot::Matrixplot(s, <[c_1, c_2,]>, options)
plot::Matrixplot(s, <[c_1, c_2,]>, x = x_min .. x_max, y =
y_min .. y_max, <a = a_min .. a_max>, options)
```

**Description** `plot::Matrixplot(A)` visualizes the matrix  $A$  as a 3D function graph by interpolating the matrix values as a function of the matrix indices.

`Matrixplot` interprets the indices of a matrix as  $x$  and  $y$  coordinates and the corresponding matrix entry as the corresponding  $z$  coordinate. Thus, the matrix is regarded as a discretized function in 2 variables. The function graph is displayed as a 3D surface using interpolation between the data points.

If no ranges  $x = \text{'x\_min'} .. \text{'x\_max'}$ ,  $y = \text{'y\_min'} .. \text{'y\_max'}$  are specified, the matrix entry  $A[i, j]$  is displayed as the 3D point  $x = j, y = i, z = A[i, j]$  with integer positions  $i, j$ . If plot ranges are specified, the matrix indices  $i, j$  are used to define an equidistant mesh in the plot range.

The attribute `InterpolationStyle` allows to define the surface via linear or cubic spline interpolation of the data points: Choose between `InterpolationStyle = Linear` or `InterpolationStyle = Cubic`. The default is linear interpolation. With cubic interpolation, the data surface may be smoothed by setting the numbers  $m_x, m_y$  of plot points

between the data points via the attribute `Submesh = [mx, my]`. The numbers `mx`, `my` must be (small) non-negative integers.

With `InterpolationStyle = Linear`, symbolic values and complex numbers are accepted and ignored, leading to gaps in the surface. With `InterpolationStyle = Cubic`, symbolic values or complex numbers lead to an error. Cf. “Example 4” on page 23-577.

Per default, the data points are rendered on the surface. Use `PointsVisible = FALSE` to make them disappear.

Animations are triggered by specifying a range `a = `a_{min}` .. `a_{max}`` for a parameter `a` that is different from the variables `x`, `y`. Thus, in animations, both the ranges `x = `x_{min}` .. `x_{max}``, `y = `y_{min}` .. `y_{max}`` as well as the animation range `a = `a_{min}` .. `a_{max}`` must be specified.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Color</code>	the main color	<code>RGB::Red</code>
<code>Data</code>	the (statistical) data to plot	
<code>Filled</code>	filled or transparent areas and surfaces	TRUE
<code>FillColor</code>	color of areas and surfaces	<code>RGB::Red</code>
<code>FillColor2</code>	second color of areas and surfaces for color blends	<code>RGB::CornflowerBlue</code>
<code>FillColorType</code>	surface filling types	Dichromatic

## plot::Matrixplot

---

Attribute	Purpose	Default Value
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
InterpolationStyle	interpolation via linear or cubic splines	Linear
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointColor	the color of points	RGB:MidnightBlue

# plot::Matrixplot

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	TRUE
Shading	smooth color blend of surfaces	Smooth
Submesh	density of submesh (additional sample points)	[2, 2]
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XLinesVisible	visibility of parameter lines (x lines)	TRUE
XMax	final value of parameter "x"	
XMin	initial value of parameter "x"	
XName	name of parameter "x"	
XRange	range of parameter "x"	
XSubmesh	density of additional sample points for parameter "x"	2

# plot::Matrixplot

---

Attribute	Purpose	Default Value
YLinesVisible	visibility of parameter lines (y lines)	TRUE
YMax	final value of parameter “y”	
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	
YSubmesh	density of additional sample points for parameter “y”	2

## Examples

### Example 1

This example demonstrates the general calling syntax. The data are passed in different ways using a list of rows, an array, and a matrix, respectively:

```
A := [[2, 1, 1],
 [3, 4, 3],
 [3, 5, 4],
 [2, 6, 5]]:
plot(plot::Matrixplot(A))
```

With `InterpolationStyle = Cubic`, the matrix data are plotted as a cubic spline surface:

```
A := array(1..4, 1..3, A):
plot(plot::Matrixplot(A, InterpolationStyle = Cubic)):
```

# plot::Matrixplot

---

The spline surface can be smoothed by using the Submesh attribute to add further evaluation points:

```
A := matrix(A):
plot(plot::Matrixplot(A, Submesh = [6, 6],
 InterpolationStyle = Cubic)):
```

delete A:

## Example 2

Various plot attributes can be specified:

```
plot(plot::Matrixplot(
 [[-0.5, 0.5, 0.7, 0.5, -1],
 [1.2, 1.3, 1.4, 1.4, 1],
 [1.4, 1.5, 1.6, 1.5, 1.2],
 [0.6, 0.8, 1, 1, 1],
 [-0.7, 0.5, 0.5, 0, -1]],
 PointsVisible = FALSE,
 FillColor = RGB::Green,
 LineColor = RGB::Red))
```

### Example 3

Choosing appropriate coordinate ranges, we place two matrix plots side by side:

```
plot(plot::Matrixplot(matrix::random(5, 5, frandom),
 x = 0..1, y = 0..1,
 Color = RGB::Red),
plot::Matrixplot(matrix::random(6, 6, frandom),
 x = 2..3, y = 0..1,
 Color = RGB::Green),
Scaling = Constrained)
```

#### Example 4

We plot a Hilbert matrix:

```
A := linalg::hilbert(10):
plot(plot::Matrixplot(A), CameraDirection = [3, 2, 1])
```

# plot::Matrixplot

---

Some of the entries are replaced by values that cannot be plotted.  
Consequently, the plot contains holes:

```
A[2, 2] := NIL:
A[4, 5] := infinity:
A[5, 5] := x:
plot(plot::Matrixplot(A), CameraDirection = [3, 2, 1])
```

With `InterpolationStyle = Cubic`, an error is raised:

```
plot(plot::Matrixplot(A, InterpolationStyle = Cubic))
```

Error: Data contains nonreal numeric values. Use 'Style = Linear

delete A:

## Parameters

### A

A matrix of category `Cat::Matrix` or an array containing real numerical values or expressions of the animation parameter `a`.

A is equivalent to the attribute `Data`.

**row<sub>1</sub>, row<sub>2</sub>, ...**

# plot::Matrixplot

---

The matrix rows: each row must be a list of real numerical values or expressions of the animation parameter  $a$ . All rows must have the same length.

$\text{row}_1, \text{row}_2, \dots$  is equivalent to the attribute `Data`.

**s**

A data sample of domain type `stats::sample`.

`s` is equivalent to the attribute `Data`.

**c<sub>1</sub>, c<sub>2</sub>, ...**

Column indices of `s`: positive integers. These indices, if given, indicate that only the specified columns should be used. The indexed columns must contain real numerical values or expressions of the animation parameter  $a$ . If no columns are specified, all columns of `s` are used.

**x**

Name of the first coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $x$  direction.

`x` is equivalent to the attribute `XName`.

**x<sub>min</sub> .. x<sub>max</sub>**

The range of the first coordinate:  $x_{\min}, x_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$x_{\min} .. x_{\max}$  is equivalent to the attributes `XRange`, `XMin`, `XMax`.

**y**

Name of the second coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $y$  direction.

`y` is equivalent to the attribute `YName`.

**y<sub>min</sub> .. y<sub>max</sub>**

The range of the second coordinate:  $y_{\min}$ ,  $y_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$y_{\min} .. y_{\max}$  is equivalent to the attributes YRange, YMin, YMax.

**a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

plot::Function3d | plot::Surface

# plot::MuPADCube

---

**Purpose** “the cube” (the logo)

**Syntax** `plot::MuPADCube(<r>, <[cx, cy, cz]>, <a = amin .. amax>, options)`

**Description** `plot::MuPADCube()` creates the “MuPAD cube” as a graphical 3D primitive.

This object only exists for demonstration purposes.

`plot::MuPADCube` accepts the attribute `Colors` which defines the colors of the spheres and the cylinders between the spheres. Its value is a list of RGB or RGBA colors:

- The color list may contain one to four values determining the colors of the spheres.
- If a 5th color is given, it determines the color of the cylinders.
- If the list contains nine colors (not less), the first and last four determine the colors of the 8 spheres. The fifth color determines the color of the cylinders.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Center</code>	center of objects, rotation center	[0, 0, 0]
<code>CenterX</code>	center of objects, rotation center, x-component	0
<code>CenterY</code>	center of objects, rotation center, y-component	0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
CenterZ	center of objects, rotation center, z-component	0
Colors	list of colors to use	[RGB::Green, RGB::Blue, RGB::Red, RGB::Yellow, RGB::Antique]
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Radius	radius of circles, spheres etc.	1

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

The MuPAD logo:

```
plot(plot::MuPADCube())
```

The MuPAD logo with strange colors:

```
plot(plot::MuPADCube(Colors = [RGB::Titanium $ 4, RGB::Gold],
```

# plot::MuPADCube

---

```
BackgroundColor = RGB::Cobalt))
```

A collection of “MuPAD cubes”:

```
plot(plot::MuPADCube(Center = [2*k, 2*l, 2*m])
 $ k = 0..1 $ l = 0..1 $ m = 0..1)
```

The MuPAD logo with animated size:

```
plot(plot::MuPADCube(1 - abs(a), [0, 0, 0], a = -1..1))
```

## Parameters

**r**

The size of the object (the radius of the surrounding sphere): a real numerical value or an arithmetical expression of the animation parameter  $a$ . The default value of the radius is 1.

$r$  is equivalent to the attribute `Radius`.

**$c_x$ ,  $c_y$ ,  $c_z$**

The coordinates of the center: real numerical values or arithmetical expressions of the animation parameter  $a$ . By default, a cube centered at the origin is created.

$c_x$ ,  $c_y$ ,  $c_z$  are equivalent to the attributes `CenterX`, `CenterY`, `CenterZ`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

plot::Ode2d([Automatic, tstart, tend, tstep], f, Y0, <[G1, <Style = style1>, <Color = c1>], [G2, <Style = style2>, <Color = c2>], >, <method>, <RelativeError = rtol>, <AbsoluteError = atol>, <Stepsize = h>, <a = amin .. amax>, options)
```

**Description** plot::Ode2d(f, [t<sub>0</sub>, t<sub>1</sub>, ], Y<sub>0</sub>) renders two-dimensional projections of the solutions of the initial value problem given by f, t<sub>0</sub> and Y<sub>0</sub>.

plot::Ode2d(f, [t<sub>0</sub>, t<sub>1</sub>, ], Y<sub>0</sub>, [G]) computes a mesh of numerical sample points Y(t<sub>0</sub>), Y(t<sub>1</sub>), ... representing the solution Y(t) of the first order differential equation (dynamical system)

$$\frac{\partial}{\partial t} Y = f(t, Y), Y(t_0) = Y_0, t_0, t \in \mathbb{R}, Y_0, Y(t) \in \mathbb{C}^n$$

The procedure

$$G: (t, Y) \rightarrow [x(t, Y), y(t, Y)] \quad \text{or} \quad G: (t, Y) \rightarrow [x(t, Y), y(t, Y), z(t, Y)]$$

maps these solution points  $(t_i, Y(t_i))$  in  $n$  to a mesh of 2D plot points  $[x_i, y_i]$ . These points can be connected by straight lines or interpolating splines.

The calling syntax of `plot::Ode2d` and `plot::Ode3d` as well as the functionality of these two procedures is identical. The only difference is that `plot::Ode2d` expects graphical generators  $G_1, G_2$  etc. that produce graphical 2D points, whereas `plot::Ode3d` expects graphical generators producing 3D points.

Internally, a sequence of numerical sample points

```
Y_1 := numeric::odesolve(f, t_0..t_1, Y_0, Options),
```

```
Y_2 := numeric::odesolve(f, t_1..t_2, Y_1, Options) etc.
```

is computed, where `Options` is some combination of `method`, `RelativeError = rtol`, `AbsoluteError = atol`, and `Stepsize = h`. See `numeric::odesolve` for details on the vector field procedure `f`, the initial condition  $Y_0$ , and the options.

The utility function `numeric::ode2vectorfield` may be used to produce the input parameters `f`, `t_0`,  $Y_0$  from a set of differential expressions representing the ODE. Cf. “Example 1” on page 23-597.

Each of the “generators of plot data”  $G_1, G_2$  etc. creates a graphical solution curve from the numerical sample points  $Y_0, Y_1$  etc. Each generator  $G$ , say, is internally called in the form  $G(t_0, Y_0), G(t_1, Y_1), \dots$  to produce a sequence of plot points in 2D.

The solver `numeric::odesolve` returns the solution points  $Y_0, Y_1$  etc. as lists or 1-dimensional arrays (the actual type is determined by the initial value  $Y_0$ ). Consequently, each generator  $G$  must accept two arguments  $(t, Y)$ :  $t$  is a real parameter,  $Y$  is a “vector” (either a list or a 1-dimensional array).

Each generator must return a list with 2 elements representing the  $(x, y)$  coordinates of the graphical point associated with a solution point  $(t, Y)$  of the ODE.

All generators must produce graphical data of the same dimension, i.e., 2D data as lists with 2 elements for `plot::Ode2d`.

Some examples:

`G := (t, Y) -> [t, Y_1]` creates a 2D plot of the first component of the solution vector along the  $y$ -axis, plotted against the time variable  $t$  along the  $x$ -axis

`G := (t, Y) -> [Y_1, Y_2]` creates a 2D phase plot, plotting the first component of the solution along the  $x$ -axis and the second component along the  $y$ -axis. The result is a solution curve in phase space (parametrized by the time  $t$ ).

If no generators are given, `plot::Ode2d` by default plots all components of the solution as functions of time, using `[Splines, Points]` as the style.

Note that arbitrary values associated with the solution curve may be displayed graphically by an appropriate generator  $G$ . See “Example 2” on page 23-598 and “Example 5” on page 23-604.

Several generators  $G_1, G_2$  etc. can be specified to generate several curves associated with the same numerical mesh  $Y_0, Y_1, \dots$ . See “Example 1” on page 23-597, “Example 2” on page 23-598, and “Example 3” on page 23-601.

The graphical data produced by each of the generators  $G_1, G_2$  etc. consists of a sequence of mesh points in 2D or 3D, respectively.

With `Style = Points`, the graphical data are displayed as a discrete set of points.

With `Style = Lines`, the graphical data points are displayed as a curve consisting of straight line segments between the sample points. The points themselves are not displayed.

With `Style = Splines`, the graphical data points are displayed as a smooth spline curve connecting the sample points. The points themselves are not displayed.

With `Style = [Splines, Points]` and `Style = [Lines, Points]`, the effects of the styles used are combined, i.e., both the evaluation points and the straight lines or splines, respectively, are displayed.

The plot attributes accepted by `plot::Ode2d, Ode3d` include `Submesh = n`, where  $n$  is some positive integer. This attribute only has an effect on the curves which are returned for the graphical generators with `Style = Splines` and `Style = [Splines, Points]`, respectively. It serves for smoothening the graphical spline curve using a sufficiently high number of plot points.

$n$  is the number of plot points between two consecutive numerical points corresponding to the time mesh. The default value is  $n = 4$ , i.e., the splines are plotted as 5 straight line segments connecting the numerical sample points.

## Attributes

Attribute	Purpose	Default Value
<code>AbsoluteError</code>	maximal absolute discretization error	
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Colors</code>	list of colors to use	[ <code>RGB::Blue</code> , <code>RGB::Red</code> , <code>RGB::Green</code> , <code>RGB::MuPADGold</code> , <code>RGB::Orange</code> , <code>RGB::Cyan</code> , <code>RGB::Magenta</code> , <code>RGB::LimeGreen</code> , <code>RGB::CadmiumYellowLight</code> , <code>RGB::AlizarinCrimson</code> , <code>RGB::Aqua</code> , <code>RGB::Lavender</code> , <code>RGB::SeaGreen</code> , <code>RGB::AureolineYellow</code> ,

# plot::Ode2d

Attribute	Purpose	Default Value
		RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
Frames	the number of frames in an animation	50
Function	function expression or procedure	
InitialConditions	initial conditions of the ODE	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ODEMethod	the numerical scheme used for solving the ODE	DOPRI78
ParameterEnd	end value of the animation parameter	

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	TRUE
Projectors	project an ODE solution to graphical points	
RelativeError	maximal relative discretization error	
Stepsize	set a constant step size	
Submesh	density of submesh (additional sample points)	4
TimeEnd	end time of the animation	10.0
TimeMesh	the numerical time mesh	
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
USubmesh	density of additional sample points for parameter "u"	4
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

## Example 1

The following procedure `f` together with the initial value `Y0` represent

the initial value problem  $\frac{d}{dt} Y = f(t, Y) = t Y - Y^2$ ,  $Y(0) = 2$ . In MuPAD, the 1-dimensional vector  $Y$  is represented by a list with one element. The body of the function `f` below addresses the first (and only) entry of this list as  $Y_1$  and returns the 1-dimensional vector  $tY - Y^2$  as a list with one element. Also the initial condition  $Y_0$  is a 1-dimensional vector represented by a list:

```
f := (t, Y) -> [t*Y[1] - Y[1]^2]:
Y0 := [2]:
```

Alternatively, the utility function `numeric::ode2vectorfield` can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] := [numeric::ode2vectorfield(
 {y'(t) = t*y(t) - y(t)^2, y(0) = 2}, [y(t)])]
```

```
[proc f(t, Y) ... end, 0, [2]]
```

The numerical solution is to consist of sample points over the time mesh  $t_i = i$ ,  $i = 0, 1, \dots, 10$ . We use the default generator of `plot::Ode2d`. This generates the sample points together with a smooth spline curve connecting these points:

```
p := plot::Ode2d(f, [$ 0..10], Y0,
 PointSize = 2*unit::mm,
 PointStyle = Stars):
```

Finally, the ode solution is rendered by a call to `plot`:

```
plot(p, TicksDistance = 2.0, GridVisible = TRUE,
 SubgridVisible = TRUE):
```

## Example 2

We consider the nonlinear oscillator  $y'' + y^7 = 0$ ,  
 $y(0) = 1$ ,  $y'(0) = 0$ . As a dynamical system for  $Y = [y, y']$ , we have  
to solve the following initial value problem  $\frac{\partial}{\partial t} Y = f(t, Y)$ ,  $Y(0) = Y_0$ :

```
f := (t, Y) -> [Y[2], - Y[1]^7]:
Y0 := [1, 0]:
```

The following generator produces a plot of the solution  $Y(t)$  against  
the time parameter  $t$ :

```
G1 := (t, Y) -> [t, Y[1]]:
```

Further, we are interested in the values of the function  $F = \frac{y^2}{2} + \frac{y'^2}{2}$ . The generator G2 produces the values  $F(y(t), y'(t))$  along the solution and plots these values against  $t$ :

```
G2 := (t, Y) -> [t, Y[1]^2/2 + Y[2]^2/2]:
```

The energy function (the “Hamiltonian”)  $H = \frac{y'^2}{2} + \frac{y^8}{8}$  should be conserved along the solution curve. We define a corresponding generator G3 to plot  $H(y(t), y'(t))$  as a function of  $t$ :

```
G3 := (t, Y) -> [t, Y[1]^8/8 + Y[2]^2/2]:
```

The solution curve is combined with the graph of the function  $F(t) = F(y(t), y'(t))$  and the conserved energy  $H(t) = H(y(t), y'(t))$ :

```
p := plot::Ode2d(f, [i/2 $ i = 0..40], Y0,
 [G1, Style = Lines, Color = RGB::Red],
 [G1, Style = Points, Color = RGB::Black],
 [G2, Style = Lines, Color = RGB::Blue],
 [G2, Style = Points, Color = RGB::Black],
 [G3, Style = Lines, Color = RGB::Green],
 [G3, Style = Points, Color = RGB::Black],
 PointSize = 1.5*unit::mm,
 LineWidth = 0.2*unit::mm
):
```

Note that by using each generator twice, we are able to set different colors for the lines and points. The renderer is called:

```
plot(p):
```

# plot::Ode2d

To visualize the dependency of the trajectory on the initial conditions, we animate `plot::Ode2d` over different values of  $y'(0)$ :

```
plot(plot::Ode2d(f, [i/6 $ i = 0..120], [1, a], a = -1/2..1/2,
 [G1, Style = Lines, Color = RGB::Red],
 [G2, Style = Lines, Color = RGB::Blue],
 [G3, Style = Lines, Color = RGB::Green],
 LineWidth = 0.2*unit::mm, Frames=25))
```

### Example 3

We consider the initial value problem  $y' = f(t, y) = t \sin(t + y^2)$ ,  
 $y(0) = 0$ :

```
f := (t, y) -> t*sin(t + y^2): Y0:= [0]:
```

The following vector field is tangent to the solution curves:

```
p1 := plot::VectorField2d([1, f(t, y)], t = 0..4, y = -1.2..1.2,
 Mesh = [21, 25], Color = RGB::Black):
```

The following object represents the plot of the solution as a function of t:

```
p2 := plot::Ode2d(
 (t,Y) -> [f(t, Y[1])], [i/3 $ i=0..12], Y0,
 [(t, Y) -> [t, Y[1]], Style = Points, Color = RGB::Red],
 [(t, Y) -> [t, Y[1]], Style = Splines, Color = RGB::Blue]):
```

We define the point size explicitly:

```
p2::PointSize := 2*unit::mm:
```

Finally, we combine the vector field and the ODE plot to a scene and call the renderer:

```
plot(p1, p2, XTicksDistance = 0.5, YTicksDistance = 0.2,
 Axes = Frame, AxesTitles = ["t", "y"],
 GridVisible = TRUE):
```

## Example 4

By default, `numeric::odesolve` (which is used by `plot::Ode2d` and `plot::Ode3d` internally) uses adaptive step sizes and a method of order 8. Usually, there is no reason to change these settings, except for demonstrative purposes. In the following animation, we use a straightforward explicit Euler method (of first order) and show how decreasing the step size improves the quality of the calculated solution.

Our differential equation is  $y' = y$ , obviously fulfilled by the exponential function:

```
[f, t0, Y0] := [numeric::ode2vectorfield(
 {y'(t)=y(t), y(0)=1}, [y(t)])]:
```

To judge the quality of the numerical solution, we plot the symbolic solution alongside the approximation:

```
plot(plot::Function2d(exp(x), x=0..3,
 Color = RGB::Black, LineStyle = Dashed),
 plot::Ode2d(f, [Automatic, 0, 3, 1/n], Y0, n = 1..50,
 EULER1, StepSize = 1/n,
 [(t, Y) -> [t, Y[1]], Style=[Lines, Points]]))
```

## Example 5

We consider the nonlinear oscillator  $y'' + y^3 = \sin(t)$ ,  
 $y(0) = 0$ ,  $y'(0) = 0.5$ . As a dynamical system for  $Y = [y, y']$ , we  
have to solve the following initial value problem  $\frac{\partial}{\partial t} Y = f(t, Y)$ ,  $Y(0)$   
 $= Y_0$ :

```
f := (t, Y) -> [Y[2], sin(t) - Y[1]^3]:
Y0 := [0, 0.5]:
```

The following generator produces a phase plot in the  $(x, y)$  plane,  
embedded in a 3D plot:

```
G1 := (t, Y) -> [Y[1], Y[2], 0]:
```

Further, we use the  $z$  coordinate of the 3D plot to display the value of  
the “energy” function  $E = \frac{y^2}{2} + \frac{y'^2}{2}$  over the phase curve:

```
G2 := (t, Y) -> [Y[1], Y[2], (Y[1]^2 + Y[2]^2)/2]:
```

The phase curve in the  $(x, y)$  plane is combined with the graph of the  
energy function:

```
p := plot::Ode3d(f, [i/5 $ i = 0..100], Y0,
 [G1, Style = Splines, Color = RGB::Red],
 [G2, Style = Points, Color = RGB::Black],
 [G2, Style = Lines, Color = RGB::Blue]):
```

We set an explicit size of the points used in the representation of the  
energy:

```
p::PointSize := 2*unit::mm:
```

The renderer is called:

```
plot(p, AxesTitles = ["y", "y'", "E"],
 CameraDirection = [10, -15, 5]):
```

### Example 6

The Lorenz ODE is the system

$$\frac{\partial}{\partial t} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} p(y-x) \\ -x z + r x - y \\ x y - b z \end{pmatrix}$$

with fixed parameters  $p, r, b$ . As a dynamical system for  $Y = [x, y, z]$ , we have to solve the ODE  $\frac{\partial}{\partial t} Y = f(t, Y)$  with the following vector field:

```
f := proc(t, Y)
 local x, y, z;
```

```
begin
 [x, y, z] := Y:
 [p*(y - x), -x*z + r*x - y, x*y - b*z]
end_proc:
```

We consider the following parameters and the following initial condition  $Y_0$ :

```
p := 10: r := 28: b := 1:
Y0 := [1, 1, 1]:
```

The following generator `Gxyz` produces a 3D phase plot of the solution. The generator `Gyz` projects the solution curve to the  $(y, z)$  plane with  $x = 20$ ; the generator `Gxz` projects the solution curve to the  $(x, z)$  plane with  $y = -15$ ; the generator `Gxy` projects the solution curve to the  $(x, y)$  plane with  $z = 0$ :

```
Gxyz := (t, Y) -> Y:
Gyz := (t, Y) -> [20, Y[2], Y[3]]:
Gxz := (t, Y) -> [Y[1], -15, Y[3]]:
Gxy := (t, Y) -> [Y[1], Y[2], 0]:
```

With these generators, we create a 3D plot object consisting of the phase curve and its projections.

```
object := plot::Ode3d(f, [i/10 $ i=1..100], Y0,
 [Gxyz, Style = Splines, Color = RGB::Red],
 [Gyz, Style = Splines, Color = RGB::Grey50],
 [Gxz, Style = Splines, Color = RGB::Grey50],
 [Gxy, Style = Splines, Color = RGB::Grey50],
 Submesh = 7):
```

Finally, the plot is rendered. This call is somewhat time consuming because it calls the numerical solver `numeric::odesolve` to produce the graphical data:

```
plot(object, CameraDirection = [-220, 110, 150])
```

## Parameters **f**

The vector field of the ODE: a procedure. See `numeric::odesolve` for details.

`f` is equivalent to the attribute `Function`.

### **t<sub>0</sub>, t<sub>1</sub>, ...**

The time mesh: real numerical values. If data are displayed with `Style = Splines`, these values must be in ascending order.

`t0, t1, ...` is equivalent to the attribute `TimeMesh`.

### **t<sub>start</sub>, t<sub>end</sub>, t<sub>step</sub>**

The time mesh: real numerical values. `tend` must be larger than `tstart` and `tstep` must be positive and should be smaller than  $t_{end} - t_{start}$ .

`tstart, tend, tstep` are equivalent to the attribute `TimeMesh`.

## **$Y_0$**

The initial condition of the ODE: a list or a 1-dimensional array.  
See `numeric::odesolve`.

$Y_0$  is equivalent to the attribute `InitialConditions`.

## **$G_1, G_2, \dots$**

“generators of plot data”: procedures mapping a solution point  $(t, Y(t))$  to a list  $[x, y]$  or  $[x, y, z]$  representing a plot point in 2D or 3D, respectively.

$G_1, G_2, \dots$  is equivalent to the attribute `Projectors`.

## **method**

Use a specific numerical scheme (see `numeric::odesolve`)

## **a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## **Options**

### **Style**

Option, specified as `Style = style`

Sets the style in which the plot data are displayed. The following styles are available: `Points`, `Lines`, `Splines`, `[Lines, Points]`, and `[Splines, Points]`. The default style is `[Splines, Points]`.

### **Color**

Option, specified as `Color = c`

Sets the RGB color `c` in which the plot data are displayed. The default color of the  $i$ th generator is the  $i$ th entry of the attribute `Colors`.

### **RelErr**

Option, specified as `RelErr = rtol`

Sets a numerical discretization tolerance (see `numeric::odesolve`)

## **AbsErr**

Option, specified as `AbsErr = atol`

Sets a numerical discretization tolerance (see `numeric::odesolve`)

## **Stepsize**

Option, specified as `Stepsize = h`

Sets a constant stepsize (see `numeric::odesolve`)

plot::Ode3d([t0, t1,], f, Y0, <[G1, <Style = style1>, <Color = c1>], [G2, <Style = style2>, <Color = c2>], >, <method>, <RelativeError = rtol>, <AbsoluteError = atol>, <Stepsize = h>, <a = amin .. amax>, options)
plot::Ode3d([Automatic, tstart, tend, tstep], f, Y0, <[G1, <Style = style1>, <Color = c1>], [G2, <Style = style2>, <Color = c2>], >, <method>, <RelativeError = rtol>, <AbsoluteError = atol>, <Stepsize = h>, <a = amin .. amax>, options)
```

**Description** `plot::Ode3d(f, [t0, t1, ], Y0)` renders three-dimensional projections of the solutions of the initial value problem given by  $f$ ,  $t_0$  and  $Y_0$ .

`plot::Ode3d(f, [t0, t1, ], Y0, [G])` computes a mesh of numerical sample points  $Y(t_0), Y(t_1), \dots$  representing the solution  $Y(t)$  of the first order differential equation (dynamical system)

$$\frac{\partial}{\partial t} Y = f(t, Y), Y(t_0) = Y_0, t_0, t \in \mathbb{R}, Y_0, Y(t) \in \mathbb{C}^n$$

The procedure

$$G: (t, Y) \rightarrow [x(t, Y), y(t, Y)] \quad \text{or} \quad G: (t, Y) \rightarrow [x(t, Y), y(t, Y), z(t, Y)]$$

maps these solution points  $(t_i, Y(t_i))$  in  $n$  to a mesh of 3D plot points  $[x_i, y_i, z_i]$ . These points can be connected by straight lines or interpolating splines.

The calling syntax of `plot::Ode2d` and `plot::Ode3d` as well as the functionality of these two procedures is identical. The only difference is that `plot::Ode2d` expects graphical generators  $G_1, G_2$  etc. that produce graphical 2D points, whereas `plot::Ode3d` expects graphical generators producing 3D points.

Internally, a sequence of numerical sample points

```
Y_1 := numeric::odesolve(f, t_0..t_1, Y_0, Options),
```

```
Y_2 := numeric::odesolve(f, t_1..t_2, Y_1, Options) etc.
```

is computed, where `Options` is some combination of `method`, `RelativeError = rtol`, `AbsoluteError = atol`, and `Stepsize = h`. See `numeric::odesolve` for details on the vector field procedure `f`, the initial condition  $Y_0$ , and the options.

The utility function `numeric::ode2vectorfield` may be used to produce the input parameters `f`, `t_0`,  $Y_0$  from a set of differential expressions representing the ODE. Cf. “Example 1” on page 23-616.

Each of the “generators of plot data”  $G_1, G_2$  etc. creates a graphical solution curve from the numerical sample points  $Y_0, Y_1$  etc. Each generator  $G$ , say, is internally called in the form  $G(t_0, Y_0), G(t_1, Y_1), \dots$  to produce a sequence of plot points in 3D.

The solver `numeric::odesolve` returns the solution points  $Y_0, Y_1$  etc. as lists or 1-dimensional arrays (the actual type is determined by the initial value  $Y_0$ ). Consequently, each generator  $G$  must accept two arguments  $(t, Y)$ :  $t$  is a real parameter,  $Y$  is a “vector” (either a list or a 1-dimensional array).

Each generator must return a list with 3 elements representing the  $(x, y, z)$  coordinates of the graphical point associated with a solution point  $(t, Y)$  of the ODE.

All generators must produce graphical data of the same dimension, i.e., for `plot::Ode3d`, 3D data as lists with 3 elements.

Some examples:

`G := (t, Y) -> [Y_1, Y_2, Y_3]` creates a 3D phase plot of the first three components of the solution curve.

If no generators are given, `plot::Ode3d` by default plots each group of two components as functions of time with the same style.

Note that arbitrary values associated with the solution curve may be displayed graphically by an appropriate generator `G`. See “Example 2” on page 23-618 and “Example 5” on page 23-624.

Several generators  $G_1, G_2$  etc. can be specified to generate several curves associated with the same numerical mesh  $Y_0, Y_1, \dots$ . See “Example 1” on page 23-616, “Example 2” on page 23-618, and “Example 3” on page 23-621.

The graphical data produced by each of the generators  $G_1, G_2$  etc. consists of a sequence of mesh points in 2D or 3D, respectively.

With `Style = Points`, the graphical data are displayed as a discrete set of points.

With `Style = Lines`, the graphical data points are displayed as a curve consisting of straight line segments between the sample points. The points themselves are not displayed.

With `Style = Splines`, the graphical data points are displayed as a smooth spline curve connecting the sample points. The points themselves are not displayed.

With `Style = [Splines, Points]` and `Style = [Lines, Points]`, the effects of the styles used are combined, i.e., both the evaluation points and the straight lines or splines, respectively, are displayed.

The plot attributes accepted by `plot::Ode2d, Ode3d` include `Submesh = n`, where  $n$  is some positive integer. This attribute only has an effect on the curves which are returned for the graphical generators with `Style = Splines` and `Style = [Splines, Points]`, respectively. It serves for smoothening the graphical spline curve using a sufficiently high number of plot points.

$n$  is the number of plot points between two consecutive numerical points corresponding to the time mesh. The default value is  $n = 4$ , i.e., the splines are plotted as 5 straight line segments connecting the numerical sample points.

## Attributes

Attribute	Purpose	Default Value
AbsoluteError	maximal absolute discretization error	
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
Frames	the number of frames in an animation	50

# plot::Ode3d

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Function	function expression or procedure	
InitialConditions	initial conditions of the ODE	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ODEMethod	the numerical scheme used for solving the ODE	DOPRI78
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5

Attribute	Purpose	Default Value
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	TRUE
Projectors	project an ODE solution to graphical points	
RelativeError	maximal relative discretization error	
Stepsize	set a constant step size	
Submesh	density of submesh (additional sample points)	4
TimeEnd	end time of the animation	10.0
TimeMesh	the numerical time mesh	
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

Attribute	Purpose	Default Value
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
USubmesh	density of additional sample points for parameter “u”	4
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

The following procedure `f` together with the initial value `Y0` represent

the initial value problem  $\frac{d}{dt} Y = f(t, Y) = t Y - Y^2$ ,  $Y(0) = 2$ . In MuPAD, the 1-dimensional vector  $Y$  is represented by a list with one element. The body of the function `f` below addresses the first (and only) entry of this list as  $Y_1$ , and returns the 1-dimensional vector  $tY - Y^2$  as a

list with one element. Also the initial condition  $Y_0$  is a 1-dimensional vector represented by a list:

```
f := (t, Y) -> [t*Y[1] - Y[1]^2]:
Y0 := [2]:
```

Alternatively, the utility function `numeric::ode2vectorfield` can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] := [numeric::ode2vectorfield(
 {y'(t) = t*y(t) - y(t)^2, y(0) = 2}, [y(t)])]
```

```
[proc f(t, Y) ... end, 0, [2]]
```

The numerical solution is to consist of sample points over the time mesh  $t_i = i, i = 0, 1, \dots, 10$ . We use the default generator of `plot::Ode2d`. This generates the sample points together with a smooth spline curve connecting these points:

```
p := plot::Ode2d(f, [$ 0..10], Y0,
 PointSize = 2*unit::mm,
 PointStyle = Stars):
```

Finally, the ode solution is rendered by a call to `plot`:

```
plot(p, TicksDistance = 2.0, GridVisible = TRUE,
 SubgridVisible = TRUE):
```

## Example 2

We consider the nonlinear oscillator  $y'' + y^7 = 0$ ,  
 $y(0) = 1$ ,  $y'(0) = 0$ . As a dynamical system for  $Y = [y, y']$ , we have  
to solve the following initial value problem  $\frac{\partial}{\partial t} Y = f(t, Y)$ ,  $Y(0) = Y_0$ :

```
f := (t, Y) -> [Y[2], - Y[1]^7]:
Y0 := [1, 0]:
```

The following generator produces a plot of the solution  $Y(t)$  against  
the time parameter  $t$ :

```
G1 := (t, Y) -> [t, Y[1]]:
```

Further, we are interested in the values of the function  $F = \frac{y^2}{2} + \frac{y'^2}{2}$ . The generator G2 produces the values  $F(y(t), y'(t))$  along the solution and plots these values against  $t$ :

```
G2 := (t, Y) -> [t, Y[1]^2/2 + Y[2]^2/2]:
```

The energy function (the “Hamiltonian”)  $H = \frac{y'^2}{2} + \frac{y^8}{8}$  should be conserved along the solution curve. We define a corresponding generator G3 to plot  $H(y(t), y'(t))$  as a function of  $t$ :

```
G3 := (t, Y) -> [t, Y[1]^8/8 + Y[2]^2/2]:
```

The solution curve is combined with the graph of the function  $F(t) = F(y(t), y'(t))$  and the conserved energy  $H(t) = H(y(t), y'(t))$ :

```
p := plot::Ode2d(f, [i/2 $ i = 0..40], Y0,
 [G1, Style = Lines, Color = RGB::Red],
 [G1, Style = Points, Color = RGB::Black],
 [G2, Style = Lines, Color = RGB::Blue],
 [G2, Style = Points, Color = RGB::Black],
 [G3, Style = Lines, Color = RGB::Green],
 [G3, Style = Points, Color = RGB::Black],
 PointSize = 1.5*unit::mm,
 LineWidth = 0.2*unit::mm
):
```

Note that by using each generator twice, we are able to set different colors for the lines and points. The renderer is called:

```
plot(p):
```

# plot::Ode3d

To visualize the dependency of the trajectory on the initial conditions, we animate `plot::Ode2d` over different values of  $y'(0)$ :

```
plot(plot::Ode2d(f, [i/6 $ i = 0..120], [1, a], a = -1/2..1/2,
 [G1, Style = Lines, Color = RGB::Red],
 [G2, Style = Lines, Color = RGB::Blue],
 [G3, Style = Lines, Color = RGB::Green],
 LineWidth = 0.2*unit::mm, Frames=25))
```

### Example 3

We consider the initial value problem  $y' = f(t, y) = t \sin(t + y^2)$ ,  
 $y(0) = 0$ :

```
f := (t, y) -> t*sin(t + y^2): Y0:= [0]:
```

The following vector field is tangent to the solution curves:

```
p1 := plot::VectorField2d([1, f(t, y)], t = 0..4, y = -1.2..1.2,
 Mesh = [21, 25], Color = RGB::Black):
```

The following object represents the plot of the solution as a function of t:

```
p2 := plot::Ode2d(
 (t,Y) -> [f(t, Y[1])], [i/3 $ i=0..12], Y0,
 [(t, Y) -> [t, Y[1]], Style = Points, Color = RGB::Red],
 [(t, Y) -> [t, Y[1]], Style = Splines, Color = RGB::Blue]):
```

We define the point size explicitly:

```
p2::PointSize := 2*unit::mm:
```

Finally, we combine the vector field and the ODE plot to a scene and call the renderer:

```
plot(p1, p2, XTicksDistance = 0.5, YTicksDistance = 0.2,
 Axes = Frame, AxesTitles = ["t", "y"],
 GridVisible = TRUE):
```

## Example 4

By default, `numeric::odesolve` (which is used by `plot::Ode2d` and `plot::Ode3d` internally) uses adaptive step sizes and a method of order 8. Usually, there is no reason to change these settings, except for demonstrative purposes. In the following animation, we use a straightforward explicit Euler method (of first order) and show how decreasing the step size improves the quality of the calculated solution.

Our differential equation is  $y' = y$ , obviously fulfilled by the exponential function:

```
[f, t0, Y0] := [numeric::ode2vectorfield(
 {y'(t)=y(t), y(0)=1}, [y(t)])]:
```

To judge the quality of the numerical solution, we plot the symbolic solution alongside the approximation:

```
plot(plot::Function2d(exp(x), x=0..3,
 Color = RGB::Black, LineStyle = Dashed),
 plot::Ode2d(f, [Automatic, 0, 3, 1/n], Y0, n = 1..50,
 EULER1, StepSize = 1/n,
 [(t, Y) -> [t, Y[1]], Style=[Lines, Points]]))
```

## Example 5

We consider the nonlinear oscillator  $y'' + y^3 = \sin(t)$ ,  
 $y(0) = 0$ ,  $y'(0) = 0.5$ . As a dynamical system for  $Y = [y, y']$ , we  
have to solve the following initial value problem  $\frac{\partial}{\partial t} Y = f(t, Y)$ ,  $Y(0)$   
 $= Y_0$ :

```
f := (t, Y) -> [Y[2], sin(t) - Y[1]^3]:
Y0 := [0, 0.5]:
```

The following generator produces a phase plot in the  $(x, y)$  plane,  
embedded in a 3D plot:

```
G1 := (t, Y) -> [Y[1], Y[2], 0]:
```

Further, we use the  $z$  coordinate of the 3D plot to display the value of  
the “energy” function  $E = \frac{y^2}{2} + \frac{y'^2}{2}$  over the phase curve:

```
G2 := (t, Y) -> [Y[1], Y[2], (Y[1]^2 + Y[2]^2)/2]:
```

The phase curve in the  $(x, y)$  plane is combined with the graph of the  
energy function:

```
p := plot::Ode3d(f, [i/5 $ i = 0..100], Y0,
 [G1, Style = Splines, Color = RGB::Red],
 [G2, Style = Points, Color = RGB::Black],
 [G2, Style = Lines, Color = RGB::Blue]):
```

We set an explicit size of the points used in the representation of the  
energy:

```
p::PointSize := 2*unit::mm:
```

The renderer is called:

```
plot(p, AxesTitles = ["y", "y'", "E"],
 CameraDirection = [10, -15, 5]):
```

### Example 6

The Lorenz ODE is the system

$$\frac{\partial}{\partial t} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} p(y-x) \\ -xz + r x - y \\ xy - bz \end{pmatrix}$$

with fixed parameters  $p, r, b$ . As a dynamical system for  $Y = [x, y, z]$ , we have to solve the ODE  $\frac{\partial}{\partial t} Y = f(t, Y)$  with the following vector field:

```
f := proc(t, Y)
 local x, y, z;
```

## plot::Ode3d

---

```
begin
 [x, y, z] := Y:
 [p*(y - x), -x*z + r*x - y, x*y - b*z]
end_proc:
```

We consider the following parameters and the following initial condition  $Y_0$ :

```
p := 10: r := 28: b := 1:
Y0 := [1, 1, 1]:
```

The following generator  $G_{xyz}$  produces a 3D phase plot of the solution. The generator  $G_{yz}$  projects the solution curve to the  $(y, z)$  plane with  $x = 20$ ; the generator  $G_{xz}$  projects the solution curve to the  $(x, z)$  plane with  $y = -15$ ; the generator  $G_{xy}$  projects the solution curve to the  $(x, y)$  plane with  $z = 0$ :

```
Gxyz := (t, Y) -> Y:
Gyz := (t, Y) -> [20, Y[2], Y[3]]:
Gxz := (t, Y) -> [Y[1], -15, Y[3]]:
Gxy := (t, Y) -> [Y[1], Y[2], 0]:
```

With these generators, we create a 3D plot object consisting of the phase curve and its projections.

```
object := plot::Ode3d(f, [i/10 $ i=1..100], Y0,
 [Gxyz, Style = Splines, Color = RGB::Red],
 [Gyz, Style = Splines, Color = RGB::Grey50],
 [Gxz, Style = Splines, Color = RGB::Grey50],
 [Gxy, Style = Splines, Color = RGB::Grey50],
 Submesh = 7):
```

Finally, the plot is rendered. This call is somewhat time consuming because it calls the numerical solver `numeric::odesolve` to produce the graphical data:

```
plot(object, CameraDirection = [-220, 110, 150])
```

## Parameters **f**

The vector field of the ODE: a procedure. See `numeric::odesolve` for details.

`f` is equivalent to the attribute `Function`.

### **t<sub>0</sub>, t<sub>1</sub>, ...**

The time mesh: real numerical values. If data are displayed with `Style = Splines`, these values must be in ascending order.

`t0, t1, ...` is equivalent to the attribute `TimeMesh`.

### **t<sub>start</sub>, t<sub>end</sub>, t<sub>step</sub>**

The time mesh: real numerical values. `tend` must be larger than `tstart` and `tstep` must be positive and should be smaller than `tend - tstart`.

`tstart, tend, tstep` are equivalent to the attribute `TimeMesh`.

## **$Y_0$**

The initial condition of the ODE: a list or a 1-dimensional array. See `numeric::odesolve`.

$Y_0$  is equivalent to the attribute `InitialConditions`.

## **$G_1, G_2, \dots$**

“generators of plot data”: procedures mapping a solution point  $(t, Y(t))$  to a list  $[x, y]$  or  $[x, y, z]$  representing a plot point in 2D or 3D, respectively.

$G_1, G_2, \dots$  is equivalent to the attribute `Projectors`.

## **method**

Use a specific numerical scheme (see `numeric::odesolve`)

## **a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## **Options**

### **Style**

Option, specified as `Style = style`

Sets the style in which the plot data are displayed. The following styles are available: `Points`, `Lines`, `Splines`, `[Lines, Points]`, and `[Splines, Points]`. The default style is `[Splines, Points]`.

### **Color**

Option, specified as `Color = c`

Sets the RGB color `c` in which the plot data are displayed. The default color of the  $i$ th generator is the  $i$ th entry of the attribute `Colors`.

### **RelErr**

Option, specified as `RelErr = rtol`

Sets a numerical discretization tolerance (see `numeric::odesolve`)

## **AbsErr**

Option, specified as `AbsErr = atol`

Sets a numerical discretization tolerance (see `numeric::odesolve`)

## **Stepsize**

Option, specified as `Stepsize = h`

Sets a constant stepsize (see `numeric::odesolve`)

# plot::Parallelogram2d

**Purpose** 2D parallelograms

**Syntax** `plot::Parallelogram2d([c_x, c_y], [u_x, u_y], [v_x, v_y],  
<a = a_min .. a_max>, options)`

**Description** `plot::Parallelogram2d(c, u, v)` defines a 2D parallelogram  $\{\vec{c} + \lambda \vec{u} + \mu \vec{v} \mid \lambda \in [-1, 1], \mu \in [-1, 1]\}$  with center  $\vec{c}$  and vectors  $\vec{u}, \vec{v}$  spanning the plane of the parallelogram. This is a rectangle with sides of length  $2|\vec{u}|, 2|\vec{v}|$  if the vectors  $\vec{u}$  and  $\vec{v}$  are orthogonal.

`plot::Parallelogram2d` creates a 2D parallelogram with center  $\vec{c} = [c_x, c_y]$  and sides given by the vectors  $2\vec{u} = [2u_x, 2u_y]$  and  $2\vec{v} = [2v_x, 2v_y]$ . The corners of the parallelogram are given by  $\vec{c} - \vec{u} - \vec{v}$ ,  $\vec{c} - \vec{u} + \vec{v}$ ,  $\vec{c} + \vec{u} - \vec{v}$ , and  $\vec{c} + \vec{u} + \vec{v}$ :

By default, the area of the parallelogram is filled with the color specified by the attribute `Color` or, equivalently, `FillColor`. With `Filled = False`, only the border lines of the parallelogram are visible. Their color is set by the attribute `LineColor`.

Alternatively, the center and the spanning vectors can be given as vectors.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE

## Examples

### Example 1

We plot several rectangles and parallelograms using different presentation styles:

```
plot(plot::Parallelogram3d([1, 1, 1], [0, 0, 2], [0, 3, 0]),
 plot::Parallelogram3d([2, 2, 2], [0, 1, 4], [0, 2, 0],
 FillColor = RGB::Red.[0.5]),
 plot::Parallelogram3d([3, 3, 3], [0, 1, 1], [0, 1, -1],
 Filled = FALSE, LineStyle = Dashed,
 LineColor = RGB::Black),
 plot::Parallelogram3d([4, 4, 4], [0, 1, 2], [0, 2, -2],
 Filled = FALSE, LineColor = RGB::Green)
):
```

## Example 2

We use `plot::Parallelogram3d` to visualize tangent planes of a surface. The first surface is the graph of the function  $f(x, y) = x^2 + y^2$ . At a point  $(x, y, f(x, y))$  on the graph, the tangent vectors in the  $x$  and  $y$  direction are given by  $(1, 0, 2x)$  and  $(0, 1, 2y)$ , respectively. After normalization to the length 0.4, they yield the tangent vectors  $u, v$  used in the construction of the tangent planes:

```
f := (x, y) -> x^2 + y^2:
c:= (x, y) -> [x, y, f(x, y)]:
u := (x, y) -> [0.4/sqrt(1+4*x^2), 0, 0.8*x/sqrt(1+4*x^2)]:
v := (x, y) -> [0, 0.4/sqrt(1+4*y^2), 0.8*y/sqrt(1+4*y^2)]:
plot(plot::Function3d(f(x, y), x = -1..1, y = -1..1),
 plot::Parallelogram3d(c(0, 0), u(0, 0), v(0, 0),
 Color = RGB::Grey.[0.5]),
 plot::Parallelogram3d(c(0, -1), u(0, -1), v(0, -1),
 Color = RGB::Grey.[0.5]),
 plot::Parallelogram3d(c(-1, 0), u(-1, 0), v(-1, 0),
```

## plot::Parallelogram2d

---

```
Color = RGB::Grey.[0.5]),
plot::Parallelogram3d(c(-1/2, -1/2), u(-1/2, -1/2),
v(-1/2, -1/2),
Color = RGB::Grey.[0.5]))):
```

The second surface is a sphere, parametrized by spherical coordinates  $p$  and  $t$  (polar and azimuth angle). At a point  $(x(p, t), y(p, t), z(p, t))$  on the sphere, the tangent vectors in the  $p$  and  $t$  direction are given by differentiation of  $x, y, z$  w.r.t.  $p$  and  $t$ , respectively. After normalization to the length 0.5, they yield the tangent vectors  $u, v$  used in the construction of the tangent planes:

```
x := (p, t) -> cos(p)*sin(t):
y := (p, t) -> sin(p)*sin(t):
z := (p, t) -> cos(t):
c := (p, t) -> [x(p, t), y(p, t), z(p, t)]:
u := (p, t) -> [-0.5*sin(p), 0.5*cos(p), 0]:
v := (p, t) -> [0.5*cos(p)*cos(t), 0.5*sin(p)*cos(t),
```

```
 -0.5*sin(t)]:
plot(plot::Surface(c(p, t), p = 0..2*PI, t = 0..PI),
 plot::Point3d(c(0, 0), Color = RGB::Black),
 plot::Parallelogram3d(c(0, 0), u(0, 0), v(0, 0),
 Color = RGB::Grey.[0.5]),
 plot::Point3d(c(-3*PI/4, PI/4), Color = RGB::Black),
 plot::Parallelogram3d(c(-3*PI/4, PI/4),
 u(-3*PI/4, PI/4),
 v(-3*PI/4, PI/4),
 Color = RGB::Grey.[0.5]),
 plot::Point3d(c(-PI/2, PI/3), Color = RGB::Black),
 plot::Parallelogram3d(c(-PI/2, PI/3),
 u(-PI/2, PI/3),
 v(-PI/2, PI/3),
 Color = RGB::Grey.[0.5]),
 plot::Point3d(c(PI, PI/2), Color = RGB::Black),
 plot::Parallelogram3d(c(PI, PI/2),
 u(PI, PI/2),
 v(PI, PI/2),
 Color = RGB::Grey.[0.5]),
 Scaling = Constrained):
```

# plot::Parallelogram2d

---

delete f, c, u, v, x, y, z:

## Parameters

**$c_x, c_y$**

Coordinates of the center: real numerical values or expressions of the animation parameter  $a$ .

$c_x, c_y$  are equivalent to the attributes CenterX, CenterY.

**$u_x, u_y$**

Components of the first vector spanning the parallelogram: real numerical values or expressions of the animation parameter  $a$ .

$u_x, u_y$  are equivalent to the attributes Tangent1X, Tangent1Y.

**$v_x, v_y$**

Components of the second vector spanning the parallelogram: real numerical values or expressions of the animation parameter  $a$ .

$v_x$ ,  $v_y$  are equivalent to the attributes Tangent2X, Tangent2Y.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Parallelogram3d

---

**Purpose** 3D parallelograms

**Syntax** `plot::Parallelogram3d([cx, cy, cz], [ux, uy, uz], [vx, vy, vz], <a = amin .. amax>, options)`

**Description** `plot::Parallelogram3d(c, u, v)` defines a 3D parallelogram  $\{\vec{c} + \lambda \vec{u} + \mu \vec{v} \mid \lambda \in [-1, 1], \mu \in [-1, 1]\}$  with center  $\vec{c}$  and vectors  $\vec{u}, \vec{v}$  spanning the plane of the parallelogram. This is a rectangle with sides of length  $2|\vec{u}|, 2|\vec{v}|$  if the vectors  $\vec{u}$  and  $\vec{v}$  are orthogonal.

`plot::Parallelogram3d` creates a 3D parallelogram with center  $\vec{c} = [c_x, c_y, c_z]$  and sides given by the vectors  $2\vec{u} = [2u_x, 2u_y, 2u_z]$  and  $2\vec{v} = [2v_x, 2v_y, 2v_z]$ . The corners of the parallelogram are given by  $\vec{c} - \vec{u} - \vec{v}, \vec{c} - \vec{u} + \vec{v}, \vec{c} + \vec{u} - \vec{v},$  and  $\vec{c} + \vec{u} + \vec{v}$ :

By default, the area of the parallelogram is filled with the color specified by the attribute `Color` or, equivalently, `FillColor`. With `Filled = False`, only the border lines of the parallelogram are visible. Their color is set by the attribute `LineColor`.

Alternatively, the center and the spanning vectors can be given as vectors.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Center</code>	center of objects, rotation center	[0, 0, 0]
<code>CenterX</code>	center of objects, rotation center, x-component	0
<code>CenterY</code>	center of objects, rotation center, y-component	0
<code>CenterZ</code>	center of objects, rotation center, z-component	0
<code>Color</code>	the main color	<code>RGB::LightBlue</code>
<code>Filled</code>	filled or transparent areas and surfaces	TRUE
<code>FillColor</code>	color of areas and surfaces	<code>RGB::LightBlue</code>
<code>FillColor2</code>	second color of areas and surfaces for color blends	<code>RGB::CornflowerBlue</code>

## plot::Parallelogram3d

---

Attribute	Purpose	Default Value
FillColorType	surface filling types	Flat
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Tangent1	first vector spanning parallelograms	[0, 1, 0]
Tangent2	second vector spanning parallelograms	[1, 0, 0]
Tangent1X	first vector spanning parallelograms, x component	0
Tangent1Y	first vector spanning parallelograms, y component	1
Tangent2X	second vector spanning parallelograms, x component	1
Tangent1Z	first vector spanning parallelograms, z component	0

## plot::Parallelogram3d

---

Attribute	Purpose	Default Value
Tangent2Y	second vector spanning parallelograms, y component	0
Tangent2Z	second vector spanning parallelograms, z component	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE

Attribute	Purpose	Default Value
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We plot several rectangles and parallelograms using different presentation styles:

```
plot(plot::Parallelogram3d([1, 1, 1], [0, 0, 2], [0, 3, 0]),
 plot::Parallelogram3d([2, 2, 2], [0, 1, 4], [0, 2, 0],
 FillColor = RGB::Red.[0.5]),
 plot::Parallelogram3d([3, 3, 3], [0, 1, 1], [0, 1, -1],
 Filled = FALSE, LineStyle = Dashed,
 LineColor = RGB::Black),
 plot::Parallelogram3d([4, 4, 4], [0, 1, 2], [0, 2, -2],
 Filled = FALSE, LineColor = RGB::Green)
):
```

# plot::Parallelogram3d

## Example 2

We use `plot::Parallelogram3d` to visualize tangent planes of a surface. The first surface is the graph of the function  $f(x, y) = x^2 + y^2$ . At a point  $(x, y, f(x, y))$  on the graph, the tangent vectors in the  $x$  and  $y$  direction are given by  $(1, 0, 2x)$  and  $(0, 1, 2y)$ , respectively. After normalization to the length 0.4, they yield the tangent vectors  $u, v$  used in the construction of the tangent planes:

```
f := (x, y) -> x^2 + y^2:
c := (x, y) -> [x, y, f(x, y)]:
u := (x, y) -> [0.4/sqrt(1+4*x^2), 0, 0.8*x/sqrt(1+4*x^2)]:
v := (x, y) -> [0, 0.4/sqrt(1+4*y^2), 0.8*y/sqrt(1+4*y^2)]:
plot(plot::Function3d(f(x, y), x = -1..1, y = -1..1),
 plot::Parallelogram3d(c(0, 0), u(0, 0), v(0, 0),
 Color = RGB::Grey.[0.5]),
 plot::Parallelogram3d(c(0, -1), u(0, -1), v(0, -1),
 Color = RGB::Grey.[0.5]),
 plot::Parallelogram3d(c(-1, 0), u(-1, 0), v(-1, 0),
```

```

Color = RGB::Grey.[0.5]),
plot::Parallelogram3d(c(-1/2, -1/2), u(-1/2, -1/2),
v(-1/2, -1/2),
Color = RGB::Grey.[0.5]))):

```

The second surface is a sphere, parametrized by spherical coordinates  $p$  and  $t$  (polar and azimuth angle). At a point  $(x(p, t), y(p, t), z(p, t))$  on the sphere, the tangent vectors in the  $p$  and  $t$  direction are given by differentiation of  $x, y, z$  w.r.t.  $p$  and  $t$ , respectively. After normalization to the length 0.5, they yield the tangent vectors  $u, v$  used in the construction of the tangent planes:

```

x := (p, t) -> cos(p)*sin(t):
y := (p, t) -> sin(p)*sin(t):
z := (p, t) -> cos(t):
c := (p, t) -> [x(p, t), y(p, t), z(p, t)]:
u := (p, t) -> [-0.5*sin(p), 0.5*cos(p), 0]:
v := (p, t) -> [0.5*cos(p)*cos(t), 0.5*sin(p)*cos(t),

```

## plot::Parallelogram3d

---

```
 -0.5*sin(t)]:
plot(plot::Surface(c(p, t), p = 0..2*PI, t = 0..PI),
 plot::Point3d(c(0, 0), Color = RGB::Black),
 plot::Parallelogram3d(c(0, 0), u(0, 0), v(0, 0),
 Color = RGB::Grey.[0.5]),
 plot::Point3d(c(-3*PI/4, PI/4), Color = RGB::Black),
 plot::Parallelogram3d(c(-3*PI/4, PI/4),
 u(-3*PI/4, PI/4),
 v(-3*PI/4, PI/4),
 Color = RGB::Grey.[0.5]),
 plot::Point3d(c(-PI/2, PI/3), Color = RGB::Black),
 plot::Parallelogram3d(c(-PI/2, PI/3),
 u(-PI/2, PI/3),
 v(-PI/2, PI/3),
 Color = RGB::Grey.[0.5]),
 plot::Point3d(c(PI, PI/2), Color = RGB::Black),
 plot::Parallelogram3d(c(PI, PI/2),
 u(PI, PI/2),
 v(PI, PI/2),
 Color = RGB::Grey.[0.5]),
 Scaling = Constrained):
```

delete f, c, u, v, x, y, z:

## Parameters

$c_x$ ,  $c_y$ ,  $c_z$

Coordinates of the center: real numerical values or expressions of the animation parameter a.

$c_x$ ,  $c_y$ ,  $c_z$  are equivalent to the attributes CenterX, CenterY, CenterZ.

$u_x$ ,  $u_y$ ,  $u_z$

Components of the first vector spanning the parallelogram: real numerical values or expressions of the animation parameter a.

$u_x$ ,  $u_y$ ,  $u_z$  are equivalent to the attributes Tangent1X, Tangent1Y, Tangent1Z.

$v_x$ ,  $v_y$ ,  $v_z$

# plot::Parallelogram3d

---

Components of the second vector spanning the parallelogram: real numerical values or expressions of the animation parameter  $a$ .

$v_x$ ,  $v_y$ ,  $v_z$  are equivalent to the attributes Tangent2X, Tangent2Y, Tangent2Z.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Parallelogram2d` | `plot::Box` | `plot::Line3d` |  
`plot::Polygon3d` | `plot::Rectangle`

**Purpose** 2D pie charts

**Syntax** `plot::Piechart2d([d1, d2, ], <a = amin .. amax>, options)`  
`plot::Piechart2d(A, <a = amin .. amax>, options)`

**Description** `plot::Piechart2d([d1, d2, d3, ])` creates a 2D pie chart with pieces of size ratios  $d_1 : d_2 : d_3 : \dots$

With the input data  $d_1, d_2$  etc., the  $i$ -th piece of the pie has the opening angle  $2 \cdot \text{PI} \cdot d_i / (d_1 + d_2 + \text{Symbol}::\text{dots})$ .

The attribute `Titles` allows to attach titles to the pieces of the pie. In contrast to the overall title of the pie chart (`Title`, `TitleFont`), the titles of the pieces react to `TextFont`.

The attribute `Moves` allows to move the pieces away from the pie center for highlighting.

The attributes `Center` and `Radius` allow to position and scale a pie chart relative to other graphical objects in the same scene.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Center</code>	center of objects, rotation center	[0, 0]

## Examples

### Example 1

We create a 2D pie chart with pieces of the size ratios 1 : 2 : 1 : 3 : 2.5.

```
p := plot::Piechart2d([1, 2, 1, 3, 2.5]):
plot(p)
```

We set titles for the pieces:

```
p::Titles := ["10.5%", "21.1%", "10.5%", "31.6%", "26.3%"]:
plot(p)
```

## plot::Piechart2d

---

Pieces can be moved away from the pie center with the attribute `Moves`. One or more moves can be given as a list of values `[f1, f2, ...]`. The “move factors” `f1, f2` etc. are positive real values that represent fractions of the pie radius. The *i*-th piece is moved away from the center by `fi`. If not all pieces are to be, one may specify `Moves = [n1 = f1, n2 = f2, ...]`, such that only the pieces with indices `n1, n2` etc. are moved:

```
p::Moves := [1 = 0.3, 3 = 0.5]:
plot(p)
```

`delete p:`

## Example 2

We create a 3D pie chart with pieces of the size ratios 1 : 2 : 1 : 3 : 2.5.

```
p := plot::Piechart3d([1, 2, 1, 3, 2.5]):
plot(p)
```

## plot::Piechart2d

---

We set titles for the pieces:

```
p::Titles := ["10.5%", "21.1%", "10.5%", "31.6%", "26.3%"]:
plot(p)
```

Some pieces are moved away from the center:

```
p::Moves := [1 = 0.3, 3 = 0.5]:
plot(p)
```

## plot::Piechart2d

---

The heights of the pieces in a 3D pie chart can vary:

```
p::Heights := [0.1, 0.2, 0.1, 0.3, 0.25]:
plot(p)
```

delete p:

### Example 3

A pie chart can be animated. We plot a pie chart with an animated radius. The pieces move in and out, changing their size:

```
m1 := piecewise([abs(a - PI/4) <= PI/4, sin(2*a)^2/3],
 [abs(a - PI/4) > PI/4, 0]):
m2 := piecewise([abs(a - 3*PI/4) <= PI/4, sin(2*a)^2/3],
 [abs(a - 3*PI/4) > PI/4, 0]):
m3 := piecewise([abs(a - 5*PI/4) <= PI/4, sin(2*a)^2/3],
 [abs(a - 5*PI/4) > PI/4, 0]):
m4 := piecewise([abs(a - 7*PI/4) <= PI/4, sin(2*a)^2/3],
 [abs(a - 7*PI/4) > PI/4, 0]):
p := plot::Piechart3d([5 + sin(a)/4, 2, 1 + sin(a)/2, 4],
 Title = "crazy pie chart",
 TitlePosition = [0, 15, 5],
 TitleFont = [Italic, 18],
```

# plot::Piechart2d

---

```
Center = [0, 0, 0],
Radius = 10 + sin(2*a),
Heights = [1.5 + sin(a), 1.5 + cos(2*a),
 1.5 + sin(a), 1.5 + cos(4*a)],
Titles = [1 = "piece 1", 2 = "piece 2",
 3 = "piece 3", 4 = "piece 4"],
Moves = [m1, m2, m3, m4],
a = 0..2*PI):
```

plot(p):

*crazy pie chart*

delete m1, m2, m3, m4, p:

## Parameters

$d_1, d_2, \dots$

The sizes of the pieces: non-negative real values or arithmetical expressions of the animation parameter  $a$ .

$d_1, d_2, \dots$  is equivalent to the attribute Data.

## A

A matrix or array containing the data  $d_1, d_2$  etc.

## a

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### Concepts

- “Create Bar Charts, Histograms, and Pie Charts”

**Purpose** Infinite plane in 3D

**Syntax**

```

plot::Plane([x, y, z], <[nx, ny, nz]>, <a =
amin .. amax>, options)
plot::Plane(X, <N>, <a = amin .. amax>, options)
plot::Plane(XN, <a = amin .. amax>, options)
plot::Plane(p1, p2, p3, <a = amin .. amax>, options)
plot::Plane(p123, <a = amin .. amax>, options)

```

**Description**

plot::Plane(x, n) creates the (infinite) plane with normal vector *n* passing through the point *x*.

plot::Plane provides a graphical plane in 3D that does not require a specification, which part of the plane is to be seen in the picture. The visible part of the plane is determined automatically by the ViewingBox of the entire 3D scene.

The contribution of a plane of type plot::Plane to the ViewingBox of a 3D scene consists only of the single point [x, y, z] (this is p<sub>1</sub>, if the plane is specified by three points p<sub>1</sub>, p<sub>2</sub>, p<sub>3</sub> on the plane).

Thus, two planes with the same normal but different points may be mathematically equivalent, but may produce different pictures due to different viewing boxes. Cf. “Example 3” on page 23-684.

By default, a mesh of lines is displayed on the plane. Use the attribute Mesh = [n<sub>1</sub>, n<sub>2</sub>] with positive integer values n<sub>1</sub>, n<sub>2</sub> to control the number of mesh lines.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::LightBlue

# plot::Plane

---

Attribute	Purpose	Default Value
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LinesVisible	visibility of lines	TRUE
Mesh	number of sample points	[15, 15]
Name	the name of a plot object (for browser and legend)	
Normal	normal vector of circles and discs, etc. in 3D	[0, 0, 1]
NormalX	normal vector of circles and discs, etc. in 3D, x-component	0
NormalY	normal vector of circles and discs, etc. in 3D, y-component	0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
NormalZ	normal vector of circles and discs, etc. in 3D, z-component	1
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Position	positions of cameras, lights, and text objects	[0, 0, 0]
PositionX	x-positions of cameras, lights, and text objects	0
PositionY	y-positions of cameras, lights, and text objects	0
PositionZ	z-positions of cameras, lights, and text objects	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

# plot::Plane

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
UMesh	number of sample points for parameter "u"	15
VMesh	number of sample points for parameter "v"	15
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We generate two spheres and a plane:

```
plot(plot::Sphere(1, [-1, -1, -1], Color = RGB::Red),
 plot::Sphere(1, [1, 1, 1], Color = RGB::Green),
 plot::Plane([0, 0, 0], [0, 0, 1], Color = RGB::Blue)):
```

We specify an explicit ViewingBox for the scene:

# plot::Plane

```
plot(plot::Sphere(1, [-1, -1, -1], Color = RGB::Red),
 plot::Sphere(1, [1, 1, 1], Color = RGB::Green),
 plot::Plane([0, 0, 0], [0, 0, 1], Color = RGB::Blue),
 ViewingBox = [-3..8, -3..8, -3..3]):
```

## Example 2

We demonstrate the effect of the attribute `Mesh` that controls the number of mesh lines displayed on planes:

```
plot(plot::Plane([0, 0, 0], [1, -1, 1], Color = RGB::Red,
 Mesh = [5, 5]),
 plot::Plane([0, 1, 0], [2, 1, -1], Color = RGB::Green,
 Mesh = [10, 10]),
 plot::Plane([1, -1, 0], [1, 1, 1], Color = RGB::Blue,
 Mesh = [20, 20]),
 ViewingBox = [-1..3, -2..2, -2..2])
```

We change the number of mesh lines:

```
plot(plot::Plane([0, 0, 0], [1, -1, 1], Color = RGB::Red,
 Mesh = [10, 10]),
 plot::Plane([0, 1, 0], [2, 1, -1], Color = RGB::Green,
 Mesh = [20, 10]),
 plot::Plane([1, -1, 0], [1, 1, 1], Color = RGB::Blue,
 Mesh = [15, 5]),
 ViewingBox = [-1..3, -2..2, -2..2])
```

### Example 3

The contribution of a plane to the automatic `ViewingBox` of the whole scene consists only of the point used to specify the plane. In the following scene, this point is the origin. It lies inside the `ViewingBox` generated by the two spheres. Thus, the `ViewingBox` of the scene is determined by the two spheres only:

```
plot(plot::Sphere(1, [1, 1, 1], Color = RGB::Red),
 plot::Sphere(1, [-1, -1, -1], Color = RGB::Green),
 plot::Plane([0, 0, 0], [0, 0, 1], Color = RGB::Blue)):
```

Now, a different point [5, 0, 0] is used to specify the same plane. It does not lie inside the ViewingBox generated by the two spheres and thus enlarges the ViewingBox of the scene:

```
plot(plot::Sphere(1, [1, 1, 1], Color = RGB::Red),
 plot::Sphere(1, [-1, -1, -1], Color = RGB::Green),
 plot::Plane([5, 0, 0], [0, 0, 1], Color = RGB::Blue)):
```

# plot::Plane

---

## Example 4

We create animated planes:

```
plot(plot::Plane([0, 0, 0], [cos(a), sin(a), 0], a = 0..PI,
 Color = RGB::Red),
 plot::Plane([0, 0, 0], [0, cos(a), sin(a)], a = 0..PI,
 Color = RGB::Green),
 plot::Plane([0, 0, a], [0, 0, 1], a = 0..1,
 Color = RGB::Blue),
 ViewingBox = [-1..1, -1..1, -1..1])
```

## Parameters

### **x, y, z**

The coordinates of a point on the plane: numerical real values or arithmetical expressions in the animation parameter *a*.

*x*, *y*, *z* are equivalent to the attributes PositionX, PositionY, PositionZ.

### **$n_x$ , $n_y$ , $n_z$**

The components of the normal vector;  $n_x$ ,  $n_y$ ,  $n_z$  must be numerical real values or arithmetical expressions in the animation parameter *a*. If no normal is specified, the normal (0, 0, 1) is used.

$n_x$ ,  $n_y$ ,  $n_z$  are equivalent to the attributes NormalX, NormalY, NormalZ.

### **x**

A matrix of category Cat::Matrix with three entries that provide the coordinates *x*, *y*, *z* of a point on the plane.

X is equivalent to the attribute `Position`.

## **N**

A matrix of category `Cat::Matrix` with three entries that provide the components  $n_x$ ,  $n_y$ ,  $n_z$  of the normal.

N is equivalent to the attribute `Normal`.

## **XN**

A matrix of category `Cat::Matrix` with 3 rows and 2 columns. The first column provides the coordinates  $x$ ,  $y$ ,  $z$  of a point on the plane, the second column provides the components  $n_x$ ,  $n_y$ ,  $n_z$  of the normal.

XN is equivalent to the attributes `Position`, `Normal`.

## **P<sub>1</sub>, P<sub>2</sub>, P<sub>3</sub>**

Three points on the plane: either lists with 3 entries each or matrices of category `Cat::Matrix` with 3 entries each. The point  $p_1$  corresponds to the attribute `Position`, the normal of the plane (the attribute `Normal`) is computed as the cross product  $(p_2 - p_1) \times (p_3 - p_1)$ .

## **P<sub>123</sub>**

A matrix of category `Cat::Matrix` with 3 rows and 3 columns. Each column corresponds to a point on the plane.

## **a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## MuPAD Functions

`plot` | `plot::copy`

**MuPAD  
Graphical  
Primitives**

`plot::Parallelogram3d` | `plot::Surface`

# plot::Point2d

---

**Purpose** 2D points

**Syntax**  
`plot::Point2d(x, y, <a = amin .. amax>, options)`  
`plot::Point2d([x, y], <a = amin .. amax>, options)`  
`plot::Point2d(matrix([x, y]), <a = amin .. amax>, options)`

**Description** `plot::Point2d(x, y)` creates a two-dimensional point with the coordinates  $(x, y)$ .

`plot::Point2d` creates graphical points in two dimensions.

Starting with MuPAD 3.0 software, each type of graphical elements has a fixed dimension. Therefore, `plot::Point2d` and `plot::Point3d` are distinct, but very similar, types.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE
Color	the main color	RGB::MidnightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
Name	the name of a plot object (for browser and legend)	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointColor	the color of points	RGB::MidnightBlue
PointStyle	the presentation style of points	FilledCircles
Position	positions of cameras, lights, and text objects	[0, 0]
PositionX	x-positions of cameras, lights, and text objects	0
PositionY	y-positions of cameras, lights, and text objects	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	

# plot::Point2d

Attribute	Purpose	Default Value
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We create three points:

```
p1 := plot::Point2d(1, 3, PointSize = 4*unit::mm);
p2 := plot::Point2d(2, 2, PointSize = 5*unit::mm);
p3 := plot::Point2d(3, 1, Color = RGB::Green,
```

```
PointSize = 6*unit::mm);
```

```
plot::Point2d(1, 3, PointSize = 4)
```

```
plot::Point2d(2, 2, PointSize = 5)
```

```
plot::Point2d(3, 1, PointColor = RGB::Green, PointSize = 6)
```

To have these points displayed, we use plot:

```
plot(p1, p2, p3)
```

It is possible to set global options directly in the call to plot:

```
plot(p1, p2, p3, PointStyle = FilledDiamonds)
```

## plot::Point2d

---

These options are regarded as the new *defaults*. This implies that objects having an option set explicitly will silently ignore these options. The green point stays green:

```
plot(p1, p2, p3, PointStyle = FilledDiamonds,
 PointColor = RGB::Red)
```

### Example 2

The point position can be animated. As an example, we combine a point with a curve that traces the path of the point:

```
x := t -> sin(3*t);
y := t -> cos(5*t);
p := plot::Point2d([x(t), y(t)], t = 0..2*PI);
c := plot::Curve2d([x(t), y(t)], t = 0..tmax, tmax = 0..2*PI)
```

$$t \rightarrow \sin(3 t)$$

$$t \rightarrow \cos(5 t)$$

$$\text{plot::Point2d}(\sin(3 t), \cos(5 t), t = 0..2 \pi)$$

# plot::Point2d

---

```
plot::Curve2d([sin(3 t), cos(5 t)], t = 0..tmax)
```

```
plot(c, p, PointSize = 3*unit::mm, LineWidth = 0.5*unit::mm)
```

## Parameters

**x, y**

Arithmetical expressions

x, y are equivalent to the attributes Position, PositionX, PositionY.

**a**

Animation parameter, specified as  $a = a_{\min}..a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Algorithms

For reasons of efficiency and clarity in the object browser, you should avoid generating large numbers of plot::Point2d and plot::Point3d

objects. None of the domains in the plot package do. For alternatives, consider `plot::PointList2d` and `plot::PointList3d`.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Point3d` | `plot::Polygon2d` | `plot::Polygon3d`

# plot::Point3d

---

**Purpose** 3D points

**Syntax**  
`plot::Point3d(x, y, z, <a = amin .. amax>, options)`  
`plot::Point3d([x, y, z], <a = amin .. amax>, options)`  
`plot::Point3d(matrix([x, y, z]), <a = amin .. amax>, options)`

**Description** `plot::Point3d(x, y, z)` creates a three-dimensional point with the coordinates  $(x, y, z)$ .

`plot::Point3d` creates graphical points in three dimensions.

Starting with MuPAD 3.0 software, each type of graphical elements has a fixed dimension. Therefore, `plot::Point2d` and `plot::Point3d` are distinct, but very similar, types.

## Examples

### Example 1

We create three points:

```
p1 := plot::Point2d(1, 3, PointSize = 4*unit::mm);
p2 := plot::Point2d(2, 2, PointSize = 5*unit::mm);
p3 := plot::Point2d(3, 1, Color = RGB::Green,
 PointSize = 6*unit::mm);
```

```
plot::Point2d(1, 3, PointSize = 4)
```

```
plot::Point2d(2, 2, PointSize = 5)
```

```
plot::Point2d(3, 1, PointColor = RGB::Green, PointSize = 6)
```

To have these points displayed, we use plot:

```
plot(p1, p2, p3)
```

## plot::Point3d

---

It is possible to set global options directly in the call to plot:

```
plot(p1, p2, p3, PointStyle = FilledDiamonds)
```

These options are regarded as the new *defaults*. This implies that objects having an option set explicitly will silently ignore these options. The green point stays green:

```
plot(p1, p2, p3, PointStyle = FilledDiamonds,
 PointColor = RGB::Red)
```

### Example 2

The point position can be animated. As an example, we combine a point with a curve that traces the path of the point:

```
x := t -> sin(3*t);
y := t -> cos(5*t);
p := plot::Point2d([x(t), y(t)], t = 0..2*PI);
c := plot::Curve2d([x(t), y(t)], t = 0..tmax, tmax = 0..2*PI)
```

$$t \rightarrow \sin(3 t)$$

$$t \rightarrow \cos(5 t)$$

$$\text{plot::Point2d}(\sin(3 t), \cos(5 t), t = 0..2 \pi)$$

# plot::Point3d

---

```
plot::Curve2d([sin(3 t), cos(5 t)], t = 0..tmax)
```

```
plot(c, p, PointSize = 3*unit::mm, LineWidth = 0.5*unit::mm)
```

## Parameters

**x, y, z**

Arithmetical expressions

x, y, z are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

**a**

Animation parameter, specified as  $a = a_{\min}..a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Algorithms

For reasons of efficiency and clarity in the object browser, you should avoid generating large numbers of `plot::Point2d` and `plot::Point3d`

objects. None of the domains in the plot package do. For alternatives, consider `plot::PointList2d` and `plot::PointList3d`.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Point2d` | `plot::Polygon2d` | `plot::Polygon3d`

# plot::PointList2d

---

**Purpose** Finite lists of 2D points

**Syntax**  
`plot::PointList2d(pts, <a = amin .. amax>, options)`  
`plot::PointList2d(M2d, <a = amin .. amax>, options)`

**Description** `plot::PointList2d` holds lists of points in 2D.

These types are containers for a (large) finite number of points. They let you avoid constructing large numbers of objects of type `plot::Point2d` for two reasons. First, the point types have non-negligible overhead and constructing and plotting a large number of them (say, five thousand) takes more time than plotting the same number of points in a single container object. Second, and this may be even more important, having five thousand points in the object browser takes a significant amount of memory and is not as lucid as having a single point list displayed there.

The attribute `Points2d` is displayed in the inspector in the user interface only for short lists.

`plot::PointList2d`, `PointList3d` internally use lists for storing the points. It is therefore not advisable to add a large number of points one-by-one. See “Example 2” on page 23-712 for a better method of collecting data.

If you specify the color of one point, you must specify the colors of all other points in the list. See “Example 3” on page 23-713.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Color</code>	the main color	<code>RGB::MidnightBlue</code>

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE

VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

plot::PointList3d provides a basic form of scatter plot:

```
plot(plot::PointList3d([[1,1,1], [1,2,2], [1,3,2], [1,3,4],
 [2,1,1], [2,2,3], [2,3.5, 4]],
 PointSize=5))
```

We can use this, for example, to get a visual test of random number generators:

```
r := frandom(0):
plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000])):
```

## plot::PointList2d

---

```
r := random(10^10)*1e-10:
plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000))):
```

frandom and random fill the cube nicely, without noticeable patterns. The following generator, however, should probably not be used:

```
randseed := 12345:
r := proc()
begin
 randseed := (randseed * 17 + 8) mod 10^10:
 1e-10 * randseed;
end:
plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000)):
```

## Example 2

The following iteration leads to the so-called Hénon attractor (from chaos theory):

```
c1 := 1.4:
c2 := 0.3:
henon_iter := (x, y) -> [c1*x^2+y-1, c2*x]:
```

We start at (0, 0), let hundred iteration cycles pass by (to only plot the attractor) and then collect the next three thousand points:

```
[x, y] := [0, 0]:
for i from 1 to 100 do
 [x, y] := henon_iter(x, y);
end_for:
data := {}:
for i from 1 to 3000 do
 [x, y] := henon_iter(x, y);
```

```
data := data union {[x, y]};
end_for:
```

Note that we collected the data in a set, because adding elements to a set is a fast operation, unlike changing the length of a list, and we don't care for the order in which points were reached. To plot the data, we must convert it to a list first:

```
data := coerce(data, DOM_LIST):
plot(plot::PointList2d(data))
```

We'd like to invite you to experiment with different values of  $c_1$  and  $c_2$  and see how they change the resulting image.

### Example 3

`plot::PointList2d` and `plot::PointList3d` allow you to specify the colors of the points. For example, the following list contains two points.

## plot::PointList2d

---

When you plot this list, the first point appears in red, and the second point appears in green:

```
Coords := [[3, 4, RGB::Red], [5, 5, RGB::Green]];
plotCoords := plot::PointList2d(Coords);
plot(plotCoords, PointSize=5)
```

```
[[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]
```

If you specify the color of one point, you must also specify the colors of all other points in the list:

```
Coords := [[3, 4, RGB::Red], [5, 5]];
plotCoords := plot::PointList2d(Coords)
```

```
[[3, 4, [1.0, 0.0, 0.0]], [5, 5]]
```

Error: The attribute 'Points2d' in the 'PointList2d' object must

## Example 4

(Feigenbaum's period doubling route to chaos)

We consider the iteration  $x_{n+1} = f_p(x_n)$  where  $f_p: X \rightarrow p X (1 - X)$  is the “logistic map” with a parameter  $p$ . The iteration map  $f_p$  maps the interval  $[0, 1]$  to itself for  $0 \leq p \leq 4$ . For small values of  $p$ , the sequence  $(x_n)$  has a finite number of accumulation points that are visited cyclically. Increasing  $p$ , the accumulation points split into 2 separate accumulation points for certain critical values of  $p$  (“period doubling”). For  $p \approx 3.569945672\dots$ , there are infinitely many accumulation points and the sequence  $(x_n)$  behaves chaotically.

We wish to visualize the accumulation points as functions of  $p$  (“Feigenbaum diagram”).

For  $P$  closely spaced values of  $p$ , we construct the sequence  $(x_n)$  starting with  $x_0 = 0.5$ . We ignore the first  $N$  values, expecting that the next  $M$  values cycle over the accumulation points. These points are added to a list `plotdata` that is finally fed into a `PointList2d` for plotting:

```
f:= (p, x) -> p*x*(1-x):

P:= 500: // number of steps in p direction
N:= 200: // transitional steps before we are close to the cycle
M:= 300: // maximal number of points on the cycle

pmin:= 2.8: // Consider p between
pmax:= 4.0: // pmin and pmax
plotdata:= []:
for p in [pmin + i*(pmax - pmin)/P $ i = 0..P] do
 // First, do N iterations to drive the
 // point x towards the limit cycle
 x:= 0.5:
 for i from 1 to N do
```

## plot::PointList2d

---

```

 x:= f(p, x):
end_for:

 // consider the next M iterates and use them as plot data:
xSequence:= table():
xSequence[1]:= x;
for i from 2 to M do
 x:= f(p, x):
 if abs(x - xSequence[1]) < 10^(-5) then
 // We are back at the beginning of the cycle;
 // the points will repeat. Go to the next p.
 break;
 else
 xSequence[i]:= x;
 end_if;
end_for:
plotdata:= plotdata . [[p, rhs(x)] $ x in xSequence];
end_for:

plot(plot::PointList2d(plotdata,
 PointColor = RGB::Black,
 PointSize = 0.5*unit::mm)):

```

```
delete f, P, N, M, pmin, pmax, plotdata, x, xSequence, i;
```

### Example 5

Create the following number spiral by plotting only prime numbers. This plot shows that primes cluster along particular curves called prime-generating curves.

```
plot(plot::PointList2d([[sqrt(n)*cos(2*PI*sqrt(n)), sqrt(n)*sin(
$ n in [ithprime(j) $ j = 1..2345]]], PointSize=1),
Axes = None, Scaling = Constrained, Height = 100, Width = 100)
```

## Parameters

**pts**

A list of points. A point must not be of type `plot::Point2d` or `plot::Point3d`, respectively. In 2D, each point must be a list of two real-valued expressions (the coordinates) and an optional RGB color. In 3D, each point must be a list of three expressions (the coordinates) and an optional RGB or RGBA color. The lists specifying the points and the colors must all have the same length.

`pts` is equivalent to the attributes `Points2d`, `Points3d`.

**$M_{2d}$**

An array or a matrix with 2 columns. Each row provides the coordinates of one point.

$M_{2d}$  is equivalent to the attribute `Points2d`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

`plot::Point3d` | `plot::Polygon2d` | `plot::Polygon3d` |  
`plot::Scatterplot`

# plot::PointList3d

---

**Purpose** Finite lists of 3D points

**Syntax**  
`plot::PointList3d(pts, <a = amin .. amax>, options)`  
`plot::PointList3d(M3d, <a = amin .. amax>, options)`

**Description** `plot::PointList3d` holds lists of points in 3D.

These types are containers for a (large) finite number of points. They let you avoid constructing large numbers of objects of type `plot::Point3d`, for two reasons. First, the point types have non-negligible overhead and constructing and plotting a large number of them (say, five thousand) takes more time than plotting the same number of points in a single container object. Second, and this may be even more important, having five thousand points in the object browser takes a significant amount of memory and is not as lucid as having a single point list displayed there.

The attribute `Points3d` is displayed in the inspector in the user interface only for short lists.

`plot::PointList2d`, `PointList3d` internally use lists for storing the points. It is therefore not advisable to add a large number of points one-by-one. See “Example 2” on page 23-726 for a better method of collecting data.

If you specify the color of one point, you must specify the colors of all other points in the list. See “Example 3” on page 23-727.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Color</code>	the main color	<code>RGB::MidnightBlue</code>
<code>Frames</code>	the number of frames in an animation	50
<code>Legend</code>	makes a legend entry	

Attribute	Purpose	Default Value
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Points3d	list of 3D points	
PointSize	the size of points	1.5
PointColor	the color of points	RGB::MidnightBlue
PointStyle	the presentation style of points	FilledCircles
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]

# plot::PointList3d

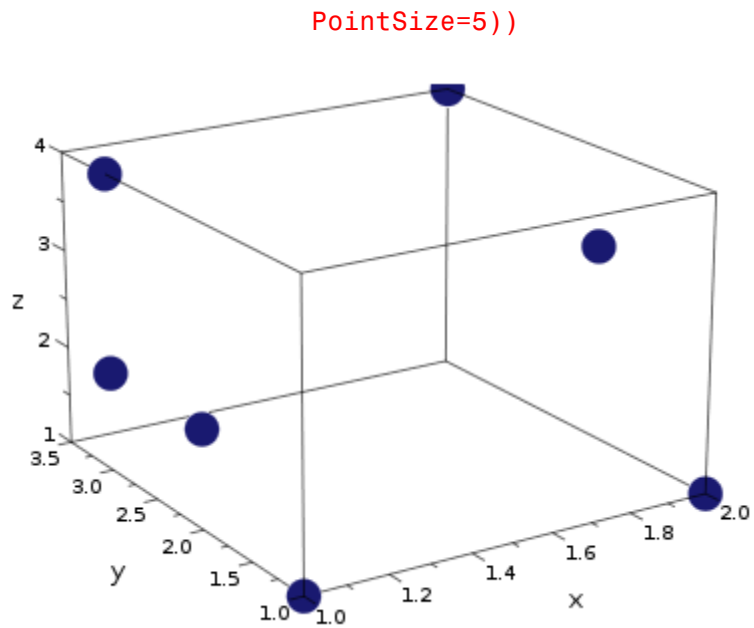

Attribute	Purpose	Default Value
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

plot::PointList3d provides a basic form of scatter plot:

```
plot(plot::PointList3d([[1,1,1], [1,2,2], [1,3,2], [1,3,4],
 [2,1,1], [2,2,3], [2,3.5, 4]]),
```

We can use this, for example, to get a visual test of random number generators:

```
r := frandom(0):
plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000)):
```

## plot::PointList3d

---

```
r := random(10^10)*1e-10:
plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000))):
```

frandom and random fill the cube nicely, without noticeable patterns. The following generator, however, should probably not be used:

```

randseed := 12345:
r := proc()
begin
 randseed := (randseed * 17 + 8) mod 10^10:
 1e-10 * randseed;
end:
plot(plot::PointList3d([[r(), r(), r()] $ i=1..10000)):
```

## Example 2

The following iteration leads to the so-called Hénon attractor (from chaos theory):

```
c1 := 1.4:
c2 := 0.3:
henon_iter := (x, y) -> [c1*x^2+y-1, c2*x]:
```

We start at (0, 0), let hundred iteration cycles pass by (to only plot the attractor) and then collect the next three thousand points:

```
[x, y] := [0, 0]:
for i from 1 to 100 do
 [x, y] := henon_iter(x, y);
end_for:
data := {}:
for i from 1 to 3000 do
 [x, y] := henon_iter(x, y);
```

```
data := data union {[x, y]};
end_for:
```

Note that we collected the data in a set, because adding elements to a set is a fast operation, unlike changing the length of a list, and we don't care for the order in which points were reached. To plot the data, we must convert it to a list first:

```
data := coerce(data, DOM_LIST):
plot(plot::PointList2d(data))
```

We'd like to invite you to experiment with different values of  $c_1$  and  $c_2$  and see how they change the resulting image.

### Example 3

`plot::PointList2d` and `plot::PointList3d` allow you to specify the colors of the points. For example, the following list contains two points.

## plot::PointList3d

---

When you plot this list, the first point appears in red, and the second point appears in green:

```
Coords := [[3, 4, RGB::Red], [5, 5, RGB::Green]];
plotCoords := plot::PointList2d(Coords);
plot(plotCoords, PointSize=5)
```

```
[[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]
```

If you specify the color of one point, you must also specify the colors of all other points in the list:

```
Coords := [[3, 4, RGB::Red], [5, 5]];
plotCoords := plot::PointList2d(Coords)
```

```
[[3, 4, [1.0, 0.0, 0.0]], [5, 5]]
```

Error: The attribute 'Points2d' in the 'PointList2d' object must

#### Example 4

(Feigenbaum's period doubling route to chaos)

We consider the iteration  $x_{n+1} = f_p(x_n)$  where  $f_p: X \rightarrow pX(1-X)$  is the “logistic map” with a parameter  $p$ . The iteration map  $f_p$  maps the interval  $[0, 1]$  to itself for  $0 \leq p \leq 4$ . For small values of  $p$ , the sequence  $(x_n)$  has a finite number of accumulation points that are visited cyclically. Increasing  $p$ , the accumulation points split into 2 separate accumulation points for certain critical values of  $p$  (“period doubling”). For  $p \approx 3.569945672\dots$ , there are infinitely many accumulation points and the sequence  $(x_n)$  behaves chaotically.

We wish to visualize the accumulation points as functions of  $p$  (“Feigenbaum diagram”).

For  $P$  closely spaced values of  $p$ , we construct the sequence  $(x_n)$  starting with  $x_0 = 0.5$ . We ignore the first  $N$  values, expecting that the next  $M$  values cycle over the accumulation points. These points are added to a list `plotdata` that is finally fed into a `PointList2d` for plotting:

```
f:= (p, x) -> p*x*(1-x):

P:= 500: // number of steps in p direction
N:= 200: // transitional steps before we are close to the cycle
M:= 300: // maximal number of points on the cycle

pmin:= 2.8: // Consider p between
pmax:= 4.0: // pmin and pmax
plotdata:= []:
for p in [pmin + i*(pmax - pmin)/P $ i = 0..P] do
 // First, do N iterations to drive the
 // point x towards the limit cycle
 x:= 0.5:
 for i from 1 to N do
```

## plot::PointList3d

---

```

 x:= f(p, x):
end_for:

 // consider the next M iterates and use them as plot data:
xSequence:= table():
xSequence[1]:= x;
for i from 2 to M do
 x:= f(p, x):
 if abs(x - xSequence[1]) < 10^(-5) then
 // We are back at the beginning of the cycle;
 // the points will repeat. Go to the next p.
 break;
 else
 xSequence[i]:= x;
 end_if;
end_for:
plotdata:= plotdata . [[p, rhs(x)] $ x in xSequence];
end_for:

plot(plot::PointList2d(plotdata,
 PointColor = RGB::Black,
 PointSize = 0.5*unit::mm)):

```

delete f, P, N, M, pmin, pmax, plotdata, x, xSequence, i;

## Parameters

### pts

A list of points. A point must not be of type `plot::Point2d` or `plot::Point3d`, respectively. In 2D, each point must be a list of two real-valued expressions (the coordinates) and an optional RGB color. In 3D, each point must be a list of three expressions (the coordinates) and an optional RGB or RGBA color. The lists specifying the points and the colors must all have the same length.

pts is equivalent to the attributes `Points2d`, `Points3d`.

### $M_{3d}$

An array or a matrix with 3 columns. Each row provides the coordinates of one point.

$M_{3d}$  is equivalent to the attribute `Points3d`.

# plot::PointList3d

---

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

`plot::PointList2d` | `plot::Listplot` | `plot::Point2d` |  
`plot::Point3d` | `plot::Polygon2d` | `plot::Polygon3d` |  
`plot::Scatterplot`

**Purpose** Curves in 2D parameterized in polar coordinates

**Syntax** `plot::Polar([r, ], u = umin .. umax, <a = amin .. amax>, options)`

**Description** `plot::Polar` creates parameterized curves in 2D, with parametrization in polar coordinates.

`plot::Polar` creates curves in one parameter, with parametrization in polar coordinates and possibly animated (see “Example 1” on page 23-737 and “Example 2” on page 23-741). The curves may contain poles, in which case automatic clipping is used by default, see “Example 4” on page 23-745.

Polar coordinates consist of a radius and an angle. The radius of a point is its distance from the origin (0, 0), while the angle is the angle between the positive “x”-axis (the ordinate) and the connection between the point and the origin, measured in radians and counter-clockwise.

By default, curves are sampled at equidistant values of the parameter `t`. The attribute `AdaptiveMesh` can be used to change this behavior, such that a denser sampling rate is used in areas of higher curvature. Cf. “Example 3” on page 23-742.

Curves are graphical objects that can be manipulated, see the examples and the documentation of the parameters listed below for details.

**Attributes**

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	0
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Color</code>	the main color	<code>RGB::Blue</code>

Attribute	Purpose	Default Value
DiscontinuitySearch	semi-symbolic search for discontinuities	TRUE
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Mesh	number of sample points	121

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Submesh	density of submesh (additional sample points)	0
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
UMax	final value of parameter “u”	
UMesh	number of sample points for parameter “u”	121
UMin	initial value of parameter “u”	
UName	name of parameter “u”	
URange	range of parameter “u”	
USubmesh	density of additional sample points for parameter “u”	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	

Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
YFunction	function for y values	

## Examples

### Example 1

The most basic example of a curve in polar coordinates is a circle: Using a constant radius, the angle goes from 0 to  $2\pi$ :

```
plot(plot::Polar([1, u], u = 0..2*PI))
```

## plot::Polar

---

A constant angle, on the other hand, means a straight line through the origin:

```
plot(plot::Polar([r, 1], r = 0..1))
```

plot::Polar accepts negative radii:

```
plot(plot::Polar([r, 1], r = -1..1))
```

# plot::Polar

---

The most simple “interesting” example is probably Archimedes’ spiral:

```
plot(plot::Polar([r, r], r = 0.5*PI))
```

### Example 2

Polar curves can be animated just like almost anything else:

```
plot(plot::Polar([r, a*r], r = 0..5*PI, a = -1..1))
```

### Example 3

In some cases, the default of 121 evaluations on the curve is not sufficient and causes visible artifacts:

```
plot(plot::Polar([r, 4*r^2], r = 0..PI))
```

One remedy for this problem is to increase the number of evaluation points:

```
plot(plot::Polar([r, 4*r^2], r = 0..PI, Mesh = 400))
```

## plot::Polar

---

This method is, however, wasteful: Near the center, the initial density was perfectly sufficient, while on the outer edge still more points would be desirable. `plot::Polar` offers adaptive mesh refinement for exactly these situations. In the following example, we switch on adaptive mesh refinement with up to  $2^4 = 16$  points introduced between each two consecutive points of the initial mesh:

```
plot(plot::Polar([r, 4*r^2], r = 0..PI, AdaptiveMesh=4))
```

#### Example 4

If the curve (i.e., the radius expression/function) contains poles, `plot::Polar` will use heuristics to clip the viewing box:

```
plot(plot::Polar([tan(t)+1, t], t = 0..2*PI))
```

# plot::Polar

---

To select a different area, use the attribute `ViewingBox`:

```
plot(plot::Polar([tan(t)+1, t], t = 0..2*PI,
ViewingBox = [-2..2, -2..2]))
```

### Example 5

plot::Polar creates objects that can be manipulated interactively and/or programmatically:

```
p := plot::Polar([tan(t)+1, t], t = 0..PI)
```

```
plot::Polar([tan(t) + 1, t], t = 0..π)
```

```
p::UMax := 2*PI:
p
```

```
plot::Polar([tan(t) + 1, t], t = 0..2 π)
```

```
p::ViewingBox := [-2..2, -2..2]:
p::LineColor := RGB::Blue:
```

# plot::Polar

---

```
p::LineWidth := 1*unit::mm:
plot(p)
```

## Parameters $r, \bullet$

The coordinate functions: arithmetical expressions or `piecewise` objects depending on the curve parameter  $u$  and the animation parameter  $a$ . Alternatively, procedures that accept 1 input parameter  $u$  or 2 input parameters  $u, a$  and return a real numerical value when the input parameters are numerical.

$r, \bullet$  are equivalent to the attributes `XFunction`, `YFunction`.

## $u$

The curve parameter: an identifier or an indexed identifier.

$u$  is equivalent to the attribute `UName`.

$u_{\min} \bullet \bullet u_{\max}$

The plot range for the parameter  $u$ :  $u_{\min}$ ,  $u_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ .

$u_{\min} .. u_{\max}$  is equivalent to the attributes `URange`, `UMin`, `UMax`.

**a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Curve2d` | `plot::Spherical` | `plot::Cylindrical`

# plot::Polygon2d

---

**Purpose** 2D polygons

**Syntax** `plot::Polygon2d([pt2d1, pt2d2, ...], <a = amin .. amax>, options)`  
`plot::Polygon2d(M2d, <a = amin .. amax>, options)`

**Description** `plot::Polygon2d` define polygons in 2D, by a given list of vertex points.

A polygon consists of points and edges. The edges are made up of the lines traversing from the first to the second point, the second to the third point, and so on. The last point is automatically connected with the first point if the attribute `Closed = TRUE` is specified.

Points and lines can be hidden via `PointsVisible = FALSE` and `LinesVisible = FALSE`. Per default the vertex points are hidden while the edges are visible.

All points as a whole can be manipulated via `PointStyle` and `PointSize`. The attribute `LineColor` sets the color for all points and all lines. Likewise all lines can be manipulated via `LineStyle` and `LineWidth`.

It is possible to vary the color of all lines and points via `LineColorType`. The default value is `Flat`. Specifying the values `Dichromatic` or `Rainbow`, a second color `LineColor2` can be set. With `Functional`, the colors are taken from a user defined `LineColorFunction`. Cf. “Example 2” on page 23-755.

The area of any closed 2D polygon can be filled by specifying `Filled = TRUE`. The filled area is defined by connecting the last and the first vertex. This additional edge itself, however, is only displayed if `Closed = TRUE` is set.

A fill color and a fill pattern can be chosen by `FillColor` and `FillPattern`.

In case of a self-intersecting polygon, a `FillStyle` can be selected. Cf. “Example 3” on page 23-757.

**Attributes**

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE
Closed	open or closed polygons	FALSE
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::Red
FillStyle	definition of inside/outside	EvenOdd
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid

# plot::Polygon2d

# plot::Polygon2d

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We create a polygon with vertices located at the 5 complex 5<sup>th</sup> roots of 1. The polygon consists of the 4 lines joining the 5 points in the order given:

```
p := plot::Polygon2d(
 [[cos(2*PI*k/5), sin(2*PI*k/5)] $ k = 0..4]):
plot(p, plot::Circle2d(1, [0, 0])):
```

In order to include the line connecting the last with the first point, pass the attribute `Closed` to the polygon:

```
p::Closed := TRUE:
plot(p, plot::Circle2d(1, [0, 0])):
```

```
delete p
```

## Example 2

We plot a closed star-shaped 3D polygon with various color attributes:

```
p := plot::Polygon3d(
 [([cos(PI*k/3), sin(PI*k/3), sin(PI*k/3)],
 [cos(PI*k/3 + PI/6)/2,
 sin(PI*k/3 + PI/6)/2,
 sin(PI*k/3 + PI/6)/2]) $k = 1..6
], Closed = TRUE):
S1 := plot::Scene3d(p, LineColorType = Flat):
```

## plot::Polygon2d

```
S2 := plot::Scene3d(p, LineColorType = Dichromatic):
S3 := plot::Scene3d(p, LineColorType = Dichromatic,
 LineColor = RGB::Blue,
 LineColor2 = RGB::Green):
S4 := plot::Scene3d(p, LineColorType = Rainbow,
 LineColor = RGB::Blue,
 LineColor2 = RGB::Green):
plot(S1, S2, S3, S4)
```

We plot the same polygon while animating its line color using a color function. The result is a dazzling star:

```
p := plot::Polygon3d(
 [([cos(PI*k/3), sin(PI*k/3), sin(PI*k/3)],
 [cos(PI*k/3 + PI/6)/2,
 sin(PI*k/3 + PI/6)/2,
 sin(PI*k/3 + PI/6)/2]) $k = 1..6
], Closed = TRUE,
```

```

LineColorFunction =
 proc(x, y, z, i, a) begin
 [sin(x + a*i)^2, sin(y + a*i)^2, sin(z + a*i)^2]:
 end_proc,
a = 0..10):
plot(p)

```

```
delete p, S1, S2, S3, S4
```

### Example 3

We plot a closed 2D polygon and fill the area inside. In fact, there are two possible interpretations of what “inside” really means. In the first plot, the complement of the unbound component of the complement of the polygon is filled. In the second plot only that area is filled that contains points with non-zero winding number with respect to the polygon. Cf. `FillStyle` for a detailed discussion.

```
p := plot::Polygon2d(
```

# plot::Polygon2d

```
[[cos(PI*k/3), sin(PI*k/3)] $k = 1..6,
 [cos(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2] $k = 1..6
], Closed = TRUE):
S1 := plot::Scene2d(p, Filled = TRUE):
S2 := plot::Scene2d(p, Filled = TRUE, FillStyle = Winding):
plot(S1, S2, Layout = Horizontal, Axes = Frame,
 Scaling = Constrained)
```

```
delete p, S1, S2:
```

## Parameters

**pt2d<sub>1</sub>, pt2d<sub>2</sub>, ...**

The 2D vertices. These must not be of type `plot::Point2d`, but lists of two numerical real values or arithmetical expressions of the animation parameter `a` (the coordinates).

`pt2d1, pt2d2, ...` is equivalent to the attribute `Points2d`.

**M<sub>2d</sub>**

An array or a matrix with 2 columns. Each row provides the coordinates of one point.

$M_{2d}$  is equivalent to the attribute `Points2d`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

`plot::Polygon3d(M3d, <a = amin .. amax>, options)`

**Description** `plot::Polygon3d` define polygons in 3D, by a given list of vertex points.

A polygon consists of points and edges. The edges are made up of the lines traversing from the first to the second point, the second to the third point, and so on. The last point is automatically connected with the first point if the attribute `Closed = TRUE` is specified.

Points and lines can be hidden via `PointsVisible = FALSE` and `LinesVisible = FALSE`. Per default the vertex points are hidden while the edges are visible.

All points as a whole can be manipulated via `PointStyle` and `PointSize`. The attribute `LineColor` sets the color for all points and all lines. Likewise all lines can be manipulated via `LineStyle` and `LineWidth`.

It is possible to vary the color of all lines and points via `LineColorType`. The default value is `Flat`. Specifying the values `Dichromatic` or `Rainbow`, a second color `LineColor2` can be set. With `Functional`, the colors are taken from a user defined `LineColorFunction`. Cf. “Example 2” on page 23-765.

A 3D polygon can only be filled if it is defined by 3 vertices (a triangle). The attribute `Filled = TRUE` is ignored for other 3D polygons.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Closed</code>	open or closed polygons	FALSE

Attribute	Purpose	Default Value
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0

# plot::Polygon3d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Points3d	list of 3D points	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We create a polygon with vertices located at the 5 complex 5<sup>th</sup> roots of 1. The polygon consists of the 4 lines joining the 5 points in the order given:

```
p := plot::Polygon2d(
 [[cos(2*PI*k/5), sin(2*PI*k/5)] $ k = 0..4]):
plot(p, plot::Circle2d(1, [0, 0])):
```

In order to include the line connecting the last with the first point, pass the attribute `Closed` to the polygon:

```
p::Closed := TRUE:
plot(p, plot::Circle2d(1, [0, 0])):
```

delete p

## Example 2

We plot a closed star-shaped 3D polygon with various color attributes:

```
p := plot::Polygon3d(
 [([cos(PI*k/3), sin(PI*k/3), sin(PI*k/3)],
 [cos(PI*k/3 + PI/6)/2,
 sin(PI*k/3 + PI/6)/2,
 sin(PI*k/3 + PI/6)/2]) $k = 1..6
], Closed = TRUE):
S1 := plot::Scene3d(p, LineColorType = Flat):
S2 := plot::Scene3d(p, LineColorType = Dichromatic):
S3 := plot::Scene3d(p, LineColorType = Dichromatic,
 LineColor = RGB::Blue,
 LineColor2 = RGB::Green):
S4 := plot::Scene3d(p, LineColorType = Rainbow,
 LineColor = RGB::Blue,
```

# plot::Polygon3d

```
LineColor2 = RGB::Green):
plot(S1, S2, S3, S4)
```

We plot the same polygon while animating its line color using a color function. The result is a dazzling star:

```
p := plot::Polygon3d(
 [([cos(PI*k/3), sin(PI*k/3), sin(PI*k/3)],
 [cos(PI*k/3 + PI/6)/2,
 sin(PI*k/3 + PI/6)/2,
 sin(PI*k/3 + PI/6)/2]) $k = 1..6
], Closed = TRUE,
 LineColorFunction =
 proc(x, y, z, i, a) begin
 [sin(x + a*i)^2, sin(y + a*i)^2, sin(z + a*i)^2]:
 end_proc,
 a = 0..10):
plot(p)
```

```
delete p, S1, S2, S3, S4
```

### Example 3

We plot a closed 2D polygon and fill the area inside. In fact, there are two possible interpretations of what “inside” really means. In the first plot, the complement of the unbound component of the complement of the polygon is filled. In the second plot only that area is filled that contains points with non-zero winding number with respect to the polygon. Cf. `FillStyle` for a detailed discussion.

```
p := plot::Polygon2d(
 [[cos(PI*k/3), sin(PI*k/3)] $k = 1..6,
 [cos(PI*k/3 + PI/6)/2, sin(PI*k/3 + PI/6)/2] $k = 1..6
], Closed = TRUE):
S1 := plot::Scene2d(p, Filled = TRUE):
S2 := plot::Scene2d(p, Filled = TRUE, FillStyle = Winding):
plot(S1, S2, Layout = Horizontal, Axes = Frame,
 Scaling = Constrained)
```

delete p, S1, S2:

## Parameters

**pt3d<sub>1</sub>, pt3d<sub>2</sub>, ...**

The 3D vertices. These must not be of type `plot::Point3d`, but lists of three numerical real values or arithmetical expressions of the animation parameter `a` (the coordinates).

`pt3d1, pt3d2, ...` is equivalent to the attribute `Points3d`.

**M<sub>3d</sub>**

An array or a matrix with 3 columns. Each row provides the coordinates of one point.

`M3d` is equivalent to the attribute `Points3d`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

plot::Polygon2d | plot::Line2d | plot::Line3d |  
plot::Listplot

# plot::Prism

---

**Purpose** Prisms

**Syntax** `plot::Prism(r, [x1, y1, z1], [x2, y2, z2], <a = amin .. amax>, options)`

**Description** `plot::Prism(r, [x1, y1, z1], [x2, y2, z2])` creates a prism with a regular base plane with a circumcircle of radius  $r$  and an axis from the point  $[x_1, y_1, z_1]$  to the point  $[x_2, y_2, z_2]$ .

The base center and top center of the prism can also be passed as vectors.

Note that only prisms with a regular base can be created with `plot::Prism`. For other bases, use a `plot::SurfaceSet` primitive.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Angle	rotation angle	0
Base	base center of cones, cylinders, pyramids and prisms	[0, 0, 0]
BaseX	x-coordinate of top center of cones, cylinders, pyramids and prisms	0
BaseY	y-coordinate of top center of cones, cylinders, pyramids and prisms	0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
BaseZ	z-coordinate of top center of cones, cylinders, pyramids and prisms	0
Color	the main color	RGB::Red
Edges	Number of Edges	3
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]

LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
Normal	normal vector of circles and discs, etc. in 3D	[0, 0, 0]
NormalX	normal vector of circles and discs, etc. in 3D, x-component	0
NormalY	normal vector of circles and discs, etc. in 3D, y-component	0
NormalZ	normal vector of circles and discs, etc. in 3D, z-component	0
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
PointsVisible	visibility of mesh points	FALSE
Radius	radius of circles, spheres etc.	1
Shading	smooth color blend of surfaces	Smooth
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Top	top center of cones, cylinders, pyramids and prisms	[0, 0, 1]

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
TopX	base and top center of cones, cylinders, pyramids and prisms	0
TopY	base and top center of cones, cylinders, pyramids and prisms	0
TopZ	base and top center of cones, cylinders, pyramids and prisms	1
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We plot three regular prisms with axes given by the coordinate axes:

```
plot(plot::Prism(1, [-3, 0, 0], [3, 0, 0], Color = RGB::Red),
 plot::Prism(1, [0, -4, 0], [0, 4, 0], Color = RGB::Green),
 plot::Prism(1, [0, 0, -5], [0, 0, 5], Color = RGB::Blue)):
```

## Example 2

All parameters of a prism can be animated:

```
plot(plot::Prism(a, [0, 0, a], [0, 0, 3-a], a = 1..2)):
```

### Example 3

The number of edges of the regular base plane of the prism are determined with the attribute Edges:

```
plot(plot::Prism(1, [0, 0, 0], [0, 0, 1], Edges = 7)):
```

## Example 4

To create a crooked regular prism, the normal vector of its base plane is specified with the attribute `Normal`. If this attribute is set to `[0, 0, 0]`, the axis between `Base` and `Top` is used as normal vector:

```
plot(plot::Scene3d(plot::Pyramid(2,[0,0,0],1,[0,4,4], Normal=[0,0,0],
plot::Scene3d(plot::Pyramid(2,[0,0,0],1,[0,4,4], Normal=[0,0,1]
```

### Example 5

Additionally, the orientation of the edges of the base can be changed with the rotation angle `Angle`:

```
plot(plot::Prism(1/2, Angle=0),
 plot::Prism(1/2, Angle=PI/4, FillColor2=RGB::Yellow))
```

## Parameters $r$

The radius of the circumcircle of the regular base plane: a real numerical value or an arithmetical expression of the animation parameter  $a$ .

$r$  is equivalent to the attribute `Radius`.

## $x_1, y_1, z_1$

Components of the base center: real numerical values or expressions of the animation parameter  $a$ .

$x_1, y_1, z_1$  are equivalent to the attributes `BaseX`, `BaseY`, `BaseZ`.

## $x_2, y_2, z_2$

Components of the top center: real numerical values or expressions of the animation parameter  $a$ .

$x_2, y_2, z_2$  are equivalent to the attributes `TopX`, `TopY`, `TopZ`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Pyramid

---

**Purpose** Pyramids and frustums of pyramids

**Syntax** `plot::Pyramid(br, [bx, by, bz], <tr>, [tx, ty, tz],  
<a = amin .. amax>, options)`

**Description** `plot::Pyramid(br, [ bx, by, bz], [ tx, ty, tz])` creates a pyramid stretching from the regular base plane with a circumcircle of radius *br* and center [b<sub>x</sub>, b<sub>y</sub>, b<sub>z</sub>] to the top [t<sub>x</sub>, t<sub>y</sub>, t<sub>z</sub>].

`plot::Pyramid(br, [ bx, by, bz], tr, [ tx, ty, tz])` creates a frustum of pyramid from the base with center [b<sub>x</sub>, b<sub>y</sub>, b<sub>z</sub>] to the top with center [t<sub>x</sub>, t<sub>y</sub>, t<sub>z</sub>]. The radius of the circumcircle of the regular base is *br*. The radius of the circumcircle of the regular top is *tr*.

The optional “top radius” *tr* for creating a frustum may also be specified as the attribute `TopRadius = tr`.

Note that only pyramids with a regular base can be created with `plot::Pyramid`. For other bases, use `plot::SurfaceSet` primitive.

## Attributes

Attribute	Purpose	Default Value

VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We draw a pyramid with base radius 6:

```
plot(plot::Pyramid(6, [0, 0, 0], [0, 0, 10])):
```

### Example 2

We create a frustum of pyramid by specifying a non-zero top radius:

```
br := 16: base := [3, 4, 5]:
tr:= 7: top := [11, 12, 13]:
plot(plot::Pyramid(br, base, tr, top)):
```

```
delete br, base, tr, top, n:
```

### Example 3

Bottom and top radii and centers can be animated:

```
plot(plot::Pyramid(sin(a)^2, [sin(2*a), cos(2*a), 0],
 cos(a)^2, [cos(2*a), sin(2*a), 1],
 a = 0..PI)):
```

# plot::Pyramid

---

## Example 4

Additionally, the orientation of the edges of the base can be changed with the rotation angle `Angle`:

```
plot(plot::Pyramid(1/2, Angle=0),
 plot::Pyramid(1/2, Angle=PI/4, FillColor2=RGB::Yellow))
```

## Parameters

### **br**

The radius of the circumcircle of the regular base. This must be a real numerical value or an arithmetical expression of the animation parameter  $a$ .

$br$  is equivalent to the attribute BaseRadius.

### **$b_x$ , $b_y$ , $b_z$**

The lower center point. The coordinates  $b_x$ ,  $b_y$ ,  $b_z$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$b_x$ ,  $b_y$ ,  $b_z$  are equivalent to the attributes BaseX, BaseY, BaseZ.

### **tr**

The radius of the circumcircle of the regular top of the frustum of pyramid. This must be a real numerical value or an arithmetical

# plot::Pyramid

---

expression of the animation parameter  $a$ . If no top radius is specified, a pyramid with top radius  $tr = 0$  is created.

$tr$  is equivalent to the attribute `TopRadius`.

**$t_x, t_y, t_z$**

The upper center point. The coordinates  $t_x, t_y, t_z$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$t_x, t_y, t_z$  are equivalent to the attributes `TopX, TopY, TopZ`.

**$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Prism` | `plot::Cone` | `plot::Cylinder`

**Purpose**

Statistical quantile-quantile plots

**Syntax**

```
plot::QQplot([a1, a2,], [b1, b2,], <a =
amin .. amax>, options)
plot::QQplot([[a1, a2,], [b1, b2,]], <a =
amin .. amax>, options)
plot::QQplot(A, <a = amin .. amax>, options)
plot::QQplot(s, <c1, c2>, <a = amin .. amax>, options)
plot::QQplot(s, <[c1, c2]>, <a = amin .. amax>, options)
```

**Description**

`plot::QQplot(data1, data2)` plots the quantiles of the first data set against the quantiles of the second data set.

`plot::QQplot` creates a quantile-quantile plot of two discrete data samples  $[a_1, a_2, \dots]$  and  $[b_1, b_2, \dots]$ . A QQ plot displays the collection of points with coordinates  $[x_1, y_1], [x_2, y_2]$  etc., where  $x_i = \text{stats::empiricalQuantile}([a_1, a_2, \dots])(i/(n - 1))$  and  $y_i = \text{stats::empiricalQuantile}([b_1, b_2, \dots])(i/(n - 1))$  with  $i$  running from 0 through  $n - 1$ . The number of plot points  $n$  is set by the attribute `Size = n`. If no value is specified by the user,  $n$  is chosen as the minimum of the lengths of the data lists  $[a_1, a_2, \dots]$  and  $[b_1, b_2, \dots]$ .

In addition, the diagonal reference line  $y = x$  is displayed in the plot. This line can be suppressed by the attribute `LinesVisible = FALSE`.

The samples  $[a_1, a_2, \dots]$  and  $[b_1, b_2, \dots]$  do not need to have the same length.

A QQ plot is a graphical technique for determining if two data sets come from populations with a common distribution.

If the two sets come from a population with the same distribution, the points of the QQ plot should fall approximately along the reference line  $y = x$ . The greater the departure from this reference line, the greater the evidence for the conclusion that the two data sets have come from populations with different distributions.

A specialized version of the QQ plot is the “probability plot”, where the quantiles of one of the data samples are replaced with the quantiles of a

# plot::QQplot

---

theoretical distribution. You can use `plot::QQplot` for this type of plot, too, by using a reference list such as

```
[stats::normalQuantile(0, 1)(i/n) $ i = 1 .. n-1]
```

as one of the data lists. In this particular case, data obeying a standard normal distribution should produce plot points close to the diagonal reference line  $y = x$ .

Cf. “Example 3” on page 23-799.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE

## Examples

### Example 1

We create a QQ plot of some data samples:

```
a := [6, 9, 17, 0, 13, 9, 9, 12, 12, 12]:
b := [7, 8, 20, 2, 11, 8, 9, 12, 13, 15, 2, 14]:
q := plot::QQplot(a, b):
plot(q)
```

We can modify the appearance of the QQ plot in various ways:

```
q::PointColor := RGB::Red:
q::PointSize := 3*unit::mm:
q::LineColor := RGB::Black:
q::LineWidth := 1*unit::mm:

plot(q)
```

# plot::QQplot

delete a, b, q:

## Example 2

We create some samples:

```
a := [stats::uniformRandom(-1, 1)() $ k = 1..100]:
b := [stats::normalRandom(0, 1)() $ k = 1..300]:
c := [stats::normalRandom(0, 1)() $ k = 1..500]:
```

The left QQ-plot shows a clear deviation from the reference line  $y = x$ . The samples  $a$  and  $b$  do not seem to be chosen from the same population. The QQ plot of the samples  $b$  and  $c$  (both normally distributed with mean 0 and variance 1), however, shows data points close to the reference line:

```
plot(plot::Scene2d(plot::QQplot(a, b)),
 plot::Scene2d(plot::QQplot(b, c)),
 Width = 20*unit::cm, Rows = 1)
```

delete a, b, c:

### Example 3

We create a normally distributed sample:

```
data1 := [stats::normalRandom(0, 1)() $ k = 1..100]:
```

We wish to investigate whether these data can indeed be regarded as normally distributed. We create a reference sample of data that are definitely normally distributed:

```
n:= nops(data1):
```

```
data2 := [stats::normalQuantile(0, 1)(i/n) $ i = 1 .. n-1]:
```

The QQ plot of the data shows plot points close to the reference line  $y = x$ :

```
plot(plot::QQplot(data1, data2))
```

# plot::QQplot

`delete data1, n, data2:`

## Parameters

$a_1, a_2, \dots, b_1, b_2, \dots$

The statistical data: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$a_1, a_2, \dots, b_1, b_2, \dots$  are equivalent to the attribute Data.

## A

An array of domain type `DOM_ARRAY` or a matrix of category `Cat::Matrix` (e.g., of type `matrix` or `densematrix`) providing numerical real values or arithmetical expressions of the animation parameter  $a$ . The array/matrix must have 2 columns. The first column is regarded as the data set  $[a_1, a_2, \dots]$  the second column is regarded as the data set  $[b_1, b_2, \dots]$ . If more columns are provided, the superfluous columns are ignored.

A is equivalent to the attribute Data.

**s**

A data collection of domain type `stats::sample`. Two columns in `s` are regarded as the data lists `[a1, a2, ...]` and `[b1, b2, ...]` respectively.

`s` is equivalent to the attribute `Data`.

**c<sub>1</sub>, c<sub>2</sub>**

Column indices into `s`: positive integers. These indices, if given, indicate that only the specified columns in `s` should be used. If no column indices are specified, the first two columns in `s` are used as the data sets `[a1, a2, ...]` and `[b1, b2, ...]`, respectively.

**a**

Animation parameter, specified as `a = amin . . amax`, where `amin` is the initial parameter value, and `amax` is the final parameter value.

Primitives**

`plot::Boxplot` | `plot::Bars2d` | `plot::Bars3d` |  
`plot::Histogram2d` | `plot::Listplot` | `plot::Scatterplot`

# plot::Raster

---

**Purpose** Raster plot

**Syntax**

```
plot::Raster(A, options)
plot::Raster(A, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
plot::Raster(L, options)
plot::Raster(L, x = x_min .. x_max, y = y_min .. y_max,
<a = a_min .. a_max>, options)
```

**Description** `plot::Raster(A, x = x_min..x_max, y = y_min..y_max)` translates a matrix  $A$  of RGB values into a regular 2D mesh of rectangles extending from the lower left corner  $(x_{\min}, y_{\min})$  to the upper right corner  $(x_{\max}, y_{\max})$ . The rectangles are colored according to the color entries in  $A$ .

`plot::Raster` serves for generating 2D raster objects such as bitmaps. External bitmap data can be imported to a MuPAD session via `import::readbitmap`. The resulting array of color values can be passed directly to `plot::Raster` to embed the imported bitmap in a 2D MuPAD scene.

When color values are specified by an array or a matrix  $A$ , the low indices correspond to the lower left corner of the graphics. The high indices correspond to the upper right corner.

---

**Note** Note that the bitmap data of most standard graphical formats are stored in the usual Western reading order: the first pixels correspond to the upper left corner, the last pixels correspond to the lower right corner. The utility `import::readbitmap` produces an array in which the first element corresponds to the lower left corner. Bitmap data imported this way can be passed directly to `plot::Raster`.

---

Arrays/matrices do not need to be indexed from 1. E.g.,  
 $A = \text{array}(i_{\min}..i_{\max}, j_{\min}..j_{\max}, [..RGB \text{ values}..])$   
yields a graphical array with

$XMesh = j_{max} - j_{min} + 1, YMesh = i_{max} - i_{min} + 1.$

If no plot range  $x_{min}..x_{max}, y_{min}..y_{max}$  is specified,

$x_{min} = j_{min} - 1, x_{max} = j_{max}, y_{min} = i_{min} - 1, y_{max} = i_{max}$

is used.

When color values are specified by a list of lists  $L$ , the first entries in the list correspond to the lower left corner of the graphics. The last entries correspond to the upper right corner.

If no plot range  $x_{min}..x_{max}, y_{min}..y_{max}$  is specified,

$x_{min} = 0, x_{max} = m, y_{min} = 0, y_{max} = n$

is used, where  $n$  is the length of  $L$  and  $m$  is the (common) length of the sublists in  $L$ . All sublists (“rows”) must have the same length.

Animations are triggered by specifying a range  $a = amin .. amax$  for a parameter  $a$  that is different from the variables  $x, y$ . Thus, in animations, both the ranges  $x = x_{min}..x_{max}, y = y_{min}..y_{max}$  as well as the animation range  $a = a_{min}..a_{max}$  must be specified.

The related plot routine `plot::Density` provides a similar functionality offering an automatic color scheme based on scalar density values.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	FALSE
Color	the main color	RGB::Blue
ColorData	color values of a raster plot	

## plot::Raster

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	FALSE
Mesh	number of sample points	[11, 11]
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

# plot::Raster

Attribute	Purpose	Default Value
XMax	final value of parameter “x”	
XMesh	number of sample points for parameter “x”	11
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YMax	final value of parameter “y”	
YMesh	number of sample points for parameter “y”	11
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

## Examples

### Example 1

We generate a raster plot:

```
checkerboard:= array(1..8, 1..8):
for i from 1 to 8 do
 for j from 1 to 8 do
 if i + j mod 2 = 0 then
```

```
 checkerboard[i,j] := RGB::Black;
 else
 checkerboard[i,j] := RGB::White;
 end_if;
end_for:
end_for:
p := plot::Raster(checkerboard):
```

The plot object is rendered:

```
plot(p):
```

```
delete checkerboard, p:
```

## Example 2

We import an external bitmap file:

```
[width, height, colordata] := import::readbitmap("Eva.jpeg");
```

# plot::Raster

---

The array `colordata` can be passed directly to `plot::Raster`:

```
scenewidth:= 80*unit::mm:
sceneheight:= height/width*scenewidth:
plot(plot::Raster(colordata),
 Width = scenewidth,
 Height = sceneheight,
 Footer = "This is Eva"):
```

This is Eva

```
delete width, height, colordata, scenewidth, sceneheight:
```

### Example 3

This is Tom:

```
[widthT, heightT, Tom] := import::readbitmap("Tom.jpeg", ReturnTypes
plot(plot::Raster(Tom), Width = widthT/3, Height = heightT/3):
```

This is Jerry:

```
[widthJ, heightJ, Jerry] := import::readbitmap("Jerry.jpeg", Ret
plot(plot::Raster(Jerry), Width = widthT/3, Height = heightT/3):
```

Although they look different, they are topologically equivalent. We demonstrate this by deforming Tom to Jerry via a smooth map  $(1 - a)T + aJ$ ,  $a \in [0, 1]$ :

```
blend := (T, J, a) -> zip(T, J, (t,j) -> (1-a)*t + a*j):
Tom2Jerry:= array(1..heightT, 1..widthT):
for i from 1 to heightT do
 for j from 1 to widthT do
 Tom2Jerry[i, j]:= blend(Tom[i, j], Jerry[i, j], a):
 end_for:
end_for:
```

The following call produces an animated plot of the deformation. Note that  $x$  and  $y$  ranges must be specified for an animation:

```
plot(plot::Raster(Tom2Jerry,
 x = 1..widthT,
 y = 1..heightT,
```

```
a = 0..1, Frames = 10,
Footer = "Tom & Jerry"),
Width = widthT/3, Height = heightT/3):
```

Tom & Jerry

This is the arithmetical mean of Tom and Jerry:

```
plot(plot::Raster(map(subs(Tom2Jerry, a = 0.5), eval)),
Footer = "(Tom + Jerry)/2", FooterFont = [12],
Width = widthT/3, Height = heightT/3):
```

(Tom + Jerry)/2

## Parameters

**A**

An array of domain type `DOM_ARRAY` or a matrix of category `Cat::Matrix` (e.g., of type `matrix` or `densematrix`) providing RGB values or color expressions of the animation parameter  $a$ . Rows/columns of the array, respectively matrix, correspond to rows/columns of the graphical array.

A is equivalent to the attribute `ColorData`.

**L**

A list of lists RGB values or color expressions of the animation parameter  $a$ . Each sublist of  $L$  represents a row of the graphical array.

L is equivalent to the attribute `ColorData`.

**x**

Name of the horizontal variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $x$  direction.

$x$  is equivalent to the attribute XName.

**$x_{\min}$  ..  $x_{\max}$**

The range of the horizontal variable:  $x_{\min}$ ,  $x_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$x_{\min}$  ..  $x_{\max}$  is equivalent to the attributes XRange, XMin, XMax.

**$y$**

Name of the vertical variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $y$  direction.

$y$  is equivalent to the attribute YName.

**$y_{\min}$  ..  $y_{\max}$**

The range of the vertical variable:  $y_{\min}$ ,  $y_{\max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$y_{\min}$  ..  $y_{\max}$  is equivalent to the attributes YRange, YMin, YMax.

**$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

`plot::Density` | `plot::Inequality`

# plot::Rectangle

---

**Purpose** Rectangles in 2D

**Syntax** `plot::Rectangle(xmin .. xmax, ymin .. ymax, <a = amin .. amax>, options)`

**Description** `plot::Rectangle( `x_{min}` .. `x_{max}` , `y_{min}` .. `y_{max}` )` generates the 2D rectangle with the corners (x<sub>min</sub>, y<sub>min</sub>), (x<sub>min</sub>, y<sub>max</sub>), (x<sub>max</sub>, y<sub>min</sub>), (x<sub>max</sub>, y<sub>max</sub>).

`plot::Rectangle` creates a 2D rectangle with edges parallel to the coordinate axes.

With `Filled = FALSE`, the rectangle consists only of its edges. With `Filled = TRUE`, it is a filled area.

The lines can be set as desired with `LineStyle`, `LineWidth`, and `LineColor`. Cf. “Example 1” on page 23-817.

With `LinesVisible = FALSE`, the edges are rendered invisible.

For filled rectangles, a `FillColor` and a `FillPattern` can be selected. Cf. “Example 2” on page 23-818.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	FALSE
<code>Color</code>	the main color	<code>RGB::Blue</code>
<code>Filled</code>	filled or transparent areas and surfaces	FALSE
<code>FillColor</code>	color of areas and surfaces	<code>RGB::Red</code>
<code>FillPattern</code>	type of area filling	<code>DiagonalLines</code>

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter "x"	1
XMin	initial value of parameter "x"	-1
XRange	range of parameter "x"	-1 .. 1
YMax	final value of parameter "y"	1
YMin	initial value of parameter "y"	-1
YRange	range of parameter "y"	-1 .. 1

## Examples

### Example 1

We plot two rectangles:

```
plot(plot::Rectangle(-2..2, -2..2, Filled = TRUE,
 FillColor = RGB::Red),
 plot::Rectangle(1..5, 1..5, Filled = FALSE,
 LineColor = RGB::Black,
 LineStyle = Dashed))
```

# plot::Rectangle

---

## Example 2

We plot rectangles with different fill patterns (FillPattern):

```
plot(plot::Rectangle(0..1, 2..3, Filled = TRUE,
 FillPattern = Solid,
 FillColor = RGB::Red),
 plot::Rectangle(1..2, 2..3, Filled = TRUE,
 FillPattern = CrossedLines,
 FillColor = RGB::Green),
 plot::Rectangle(2..3, 2..3, Filled = TRUE,
 FillPattern = XCrossedLines,
 FillColor = RGB::Blue),
 plot::Rectangle(0..1, 1..2, Filled = TRUE,
 FillPattern = HorizontalLines,
 FillColor = RGB::Orange),
 plot::Rectangle(1..2, 1..2, Filled = TRUE,
 FillPattern = VerticalLines,
 FillColor = RGB::Violet),
```

```
plot::Rectangle(0..1, 0..1, Filled = TRUE,
 FillPattern = DiagonalLines,
 FillColor = RGB::Brown),
plot::Rectangle(1..2, 0..1, Filled = TRUE,
 FillPattern = FDiagonalLines,
 FillColor = RGB::Cyan))
```

## Parameters

**$x_{\min}$  ..  $x_{\max}$**

The left and right border of the rectangle: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x_{\min}$  ..  $x_{\max}$  is equivalent to the attributes XRange, XMin, XMax.

**$y_{\min}$  ..  $y_{\max}$**

The lower and upper border of the rectangle: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$y_{\min}$  ..  $y_{\max}$  is equivalent to the attributes YRange, YMin, YMax.

# plot::Rectangle

---

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Purpose

Curves of roots of rational expressions

## Syntax

```
plot::Rootlocus(p(z, u), u = u_min .. u_max, <a =
a_min .. a_max>, options)
```

## Description

`plot::Rootlocus(p(z, u), u = u_min.. u_max)` creates a 2D plot of the curves in the complex plane given by the roots of  $p(z, u) = 0$  (solved for  $z$ ) as the parameter  $u$  varies between  $u_{\min}$  and  $u_{\max}$ .

For any given value of  $u$ , `plot::Rootlocus` solves the equation  $p(z, u) = 0$  for  $z$ . The solutions define points with coordinates  $x = \Re(z)$ ,  $y = \Im(z)$  in the complex plane. As the parameter  $u$  varies, the solutions form continuous curves that are depicted by `plot::Rootlocus`.

The roots of the numerator of  $p(z, u)$  are considered. All complex solutions of this polynomial in  $z$  are computed numerically via `numeric::polyroots`.

The polynomial is initially solved for some values  $u$  from the range  $u = u_{\min} \dots u_{\max}$ . The optional argument `Mesh = n` can be used to specify the number  $n$  of these initial points (the default value is 51). These points are not equally spaced, but accumulate close to the end of the range.

The routine then tries to pair up the roots for adjacent values of  $u$  by choosing those closest to each other.

Finally, the routine tries to trace out the different curves by joining up adjacent points with line segments. If adjacent line segments exhibit angles that are not close to 180 degrees, additional roots are computed for parameter values  $u$  between the values of the initial mesh. Up to  $m$  such bisectioning steps are possible, where  $m$  is specified by the optional argument `AdaptiveMesh = m` (the default value is 4). With `AdaptiveMesh = 0`, this adaptive mechanism may be switched off.

Sometimes, the matching up of the roots to continuous curves can be fooled and the result is a messy plot. In such a case, the user can take the following measures to improve the plot:

# plot::Rootlocus

---

- The parameter range  $u = `u_{\min}` .. `u_{\max}`$  may be unreasonably large. Reduce this range to a reasonable size!
- Increase the size  $n$  of the initial mesh using the option `Mesh = n`. Note that increasing  $n$  by some factor may increase the runtime of the plot by the same factor!
- Increase the number  $m$  of possible adaptive bisectioning steps using the option `AdaptiveMesh = m`. Note that increasing  $m$  by 1 may increase the runtime of the plot by a factor of 2!
- Using the options `LinesVisible = FALSE` in conjunction with `PointsVisible = TRUE`, the roots are displayed as separate points without joining line segments.

Cf. “Example 2” on page 23-830.

Animations are triggered by specifying a range  $a = `a_{\min}` .. `a_{\max}`$  for a parameter  $a$  that is different from the variables  $z$  and  $u$ . Cf. “Example 3” on page 23-834.

The curves can be colored by a user defined color scheme. Just pass the option `LineColorFunction = mycolor`, where `mycolor` is a user defined procedure that returns an RGB color value. The routine `plot::Rootlocus` calls `mycolor(u, x, y)`, where  $u$  is the parameter value and  $x, y$  are the real and imaginary parts of the root of  $p(x + iy, u) = 0$ . Cf. “Example 4” on page 23-836.

## Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	4
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
Mesh	number of sample points	51
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter

TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
UMax	final value of parameter "u"	

Attribute	Purpose	Default Value
UMesh	number of sample points for parameter "u"	51
UMin	initial value of parameter "u"	
UName	name of parameter "u"	
URange	range of parameter "u"	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

**Examples**

**Example 1**

The roots of the polynomial  $z^2 - 2uz + 1$  are given by  $z = u + \sqrt{u^2 - 1}$  and  $z = u - \sqrt{u^2 - 1}$ . We visualise these two curves via a rootlocus plot:

```
plot(plot::Rootlocus(z^2 - 2*u*z + 1, u = -1.5..1.5))
```

# plot::Rootlocus

---

For rational expressions, the roots of the numerator are considered. The following plot displays the roots of the numerator polynomial  $(z^2 - u)^2 + u(z - u)^3$ :

```
plot(plot::Rootlocus(1 + u * (z - u)^3/(z^2 - u)^2, u = -1..1)):
```

Here are various other examples:

```
plot(plot::Rootlocus((z^2 - 2*u*z + 1)^2 + u, u = -1..1))
```

# plot::Rootlocus

---

```
plot(plot::Rootlocus((z^2 - u)^6 + u^2, u = -2..2, Color = RGB::Red
```

```
plot(plot::Rootlocus((z^5 - 1)^3 + u, u = -1..1, PointsVisible,
```

# plot::Rootlocus

## Example 2

The following plot is rather messy, since the default mesh size of 51 initial points on each curve is not sufficient to obtain a good resolution:

```
plot(plot::Rootlocus((z-u)^3 - u/z^3, u = -10^3 .. 10^3)):
```

We obtain a better resolution by decreasing the range of the parameter  $u$  to a reasonable size. There are still a few points that are not properly matched up with the curves:

```
plot(plot::Rootlocus((z-u)^3 - u/z^3, u = -10 .. 10)):
```

# plot::Rootlocus

---

We increase the mesh size to cure this problem:

```
plot(plot::Rootlocus((z-u)^3 - u/z^3, u = -10 .. 10, Mesh = 251)):
```

We plot the roots as separate points without displaying connecting line segments:

```
plot(plot::Rootlocus((z-u)^3 - u/z^3, u = -10 .. 10, Mesh = 501,
LinesVisible = FALSE, PointsVisible)):
```

# plot::Rootlocus

---

### Example 3

We animate the expression whose roots are to plotted:

```
plot(plot::Rootlocus(z^2 - 2*u*z + a, u = -1..1, a = -0.2 .. 2, Mes
 plot::Text2d(a -> "a = ".stringlib::formatf(a, 2, 5), [1.2, 1.
```

We animate the parameter range:

```
plot(plot::Rootlocus(z^2 - 2*u*z + 0.81, u = -1 .. a, a = -1 ..
```

# plot::Rootlocus

---

## Example 4

We provide a color function: roots for small values of the parameter  $u$  are displayed in red, whereas roots for large parameter values are displayed in blue:

```
plot(plot::Rootlocus(z^2 - 2*u*z + 0.81, u = -1..1,
LineColorFunction = ((u, x, y) -> [(1 - u)/2,
```

## Parameters

### $p(z, u)$

An arithmetical expression in two unknowns  $z$  and  $u$  and, possibly, the animation parameter  $a$ . It must be a rational expression in  $z$ .

$p(z, u)$  is equivalent to the attribute `RationalExpression`.

### $z$

Name of the unknown: an identifier or an indexed identifier.

### $u$

Name of the curve parameter: an identifier or an indexed identifier.

$u$  is equivalent to the attribute `UName`.

### $u_{\min} .. u_{\max}$

The range of the curve parameter:  $u_{\min}, u_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ .

# plot::Rootlocus

---

$u_{\min} .. u_{\max}$  is equivalent to the attributes URange, UMin, UMax.

**a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

plot::Scatterplot(s, <c1, c2>, <a = amin .. amax>, options)
```

## Description

plot::Scatterplot creates a scatter plot of two discrete data samples [x<sub>1</sub>, x<sub>2</sub>, ] and [y<sub>1</sub>, y<sub>2</sub>, ]. A scatter plot displays the collection of points with coordinates [x<sub>1</sub>, y<sub>1</sub>], [x<sub>2</sub>, y<sub>2</sub>] etc.

In addition, a regression line  $y = a + bx$  through the given data pairs [x<sub>1</sub>, y<sub>1</sub>] etc. is computed and added to the plot. The estimators  $a$ ,  $b$  of the regression are computed by stats::linReg.

The regression line can be suppressed by specifying the attribute LinesVisible = FALSE.

The samples [x<sub>1</sub>, x<sub>2</sub>, ...] and [y<sub>1</sub>, y<sub>2</sub>, ...] should have the same number of elements. Otherwise, superfluous elements in the longer list are ignored.

There is an ambiguity between the various input formats if only 2 data points are provided:

---

**Note** For two data points the calls plot::Scatterplot([a, b], [c, d]) and plot::Scatterplot([[a, b], [c, d]]) both yield plots of the two points (x<sub>1</sub>, y<sub>1</sub>) = (a, b) and (x<sub>2</sub>, y<sub>2</sub>) = (c, d), not of the points (x<sub>1</sub>, y<sub>1</sub>) = (a, c) and (x<sub>2</sub>, y<sub>2</sub>) = (b, d)!

---

# plot::Scatterplot

---

The routines `plot::Listplot` and `plot::PointList2d` have a similar functionality. The main additional feature of `plot::Scatterplot` is the regression line.

Scatter plots are useful to visualize the relationship between two variables  $x$  (the “predictor”) and  $y$  (the “criterion”).

The variable regarded as a predictor corresponds to the horizontal axis while the variable regarded as the criterion corresponds to the vertical axis. The criterion variable represents the behavior to be predicted. The predictor variable represents the activity which is believed to be associated with the criterion.

The scatter plot consists of points  $(x, y)$  where  $x$  is a predictor value and  $y$  is the corresponding value of the criterion.

If there is a linear relation  $y = a + bx$  between  $x$  and  $y$ , the data points should form a line, potentially marred by statistical deviations. The regression line provided by the scatter plot allows a visual test of such a relation between  $x$  and  $y$ .

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Data</code>	the (statistical) data to plot	
<code>Frames</code>	the number of frames in an animation	50
<code>Legend</code>	makes a legend entry	
<code>LegendText</code>	short explanatory text for legend	

Attribute	Purpose	Default Value
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Red
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointColor	the color of points	RGB::Black
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	TRUE
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0

# plot::Scatterplot

---

Attribute	Purpose	Default Value
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We plot some data samples:

```
xdata := [6, 9, 17, 0, 13, 9, 9, 12, 12, 12]:
ydata := [7, 8, 20, 2, 11, 8, 9, 12, 13, 15]:
b := plot::Scatterplot(xdata, ydata):
plot(b)
```

We can modify the appearance of the scatter plot in various ways:

```
b::PointColor := RGB::Red:
b::PointSize := 3*unit::mm:
b::LineColor := RGB::Black:
b::LineWidth := 1*unit::mm:

plot(b)
```

# plot::Scatterplot

---

```
delete xdata, ydata, b:
```

## Example 2

We analyze the relationship between the time students spent on preparing for a test and the result of the test. We collect the data in a matrix. Each row corresponds to a student. The first column describes the numbers of hours spent for the preparation, the second column contains the corresponding test score (points out of 100):

```
TimesAndScores := matrix([[1, 61],
 [10, 75],
 [4, 55],
 [3, 18],
 [4, 77],
 [6, 72],
 [3, 18],
 [1, 25],
 [0, 50],
```

```
[4, 68],
[4, 68],
[8, 87],
[9, 74],
[11, 79],
[6, 28],
[4, 65],
[7, 52],
[8, 78],
[2, 36],
[3, 48],
[4, 39]
):
```

We draw a scatter plot to identify a possible relationship between the two variables:

```
plot(plot::Scatterplot(TimesAndScores))
```

# plot::Scatterplot

---

There seems to be a relationship, indeed.

`delete TimesAndScores:`

## Parameters

$x_1, y_1, x_2, y_2, \dots$

The statistical data: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$x_1, y_1, x_2, y_2, \dots$  is equivalent to the attribute `Data`.

**A**

An array of domain type `DOM_ARRAY` or a matrix of category `Cat::Matrix` (e.g., of type `matrix` or `densematrix`) providing numerical real values or arithmetical expressions of the animation parameter  $a$ . The  $i$ -th row is regarded as the data point  $(x_i, y_i)$ . The array/matrix must have 2 columns. If more columns are provided, the superfluous columns are ignored.

`A` is equivalent to the attribute `Data`.

**s**

A data collection of domain type `stats::sample`. The columns in `s` are regarded as  $x$ - and  $y$ -values, respectively.

`s` is equivalent to the attribute `Data`.

**c<sub>1</sub>, c<sub>2</sub>**

Column indices into `s`: positive integers. These indices, if given, indicate that only the specified columns in `s` should be used. If no column indices are specified, the first two columns in `s` are used as  $x$  and  $y$ -values, respectively.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Sequence

---

**Purpose** Sequences

**Syntax**  
`plot::Sequence(y, n = n1 .. n2, <a = amin .. amax>, options)`  
`plot::Sequence(x, y, n = n1 .. n2, <a = amin .. amax>, options)`

**Description** `plot::Sequence(y(n), n = n1 .. n2 )` creates the points

$$(n_1, y(n_1)), (n_1 + 1, y(n_1 + 1)), \dots, (n_2, y(n_2))$$

`plot::Sequence(x(n), y(n), n = n1 .. n2 )` creates the sequence of points

$$(x(n_1), y(n_1)), (x(n_1 + 1), y(n_1 + 1)), \dots, (x(n_2), y(n_2))$$

`plot::Sequence` creates graphs of sequences, i.e., functions and curves defined over (some subset of) the integers.

`plot::Sequence(y(n), n = n1..n2 )` is functionally equivalent to the call `plot::PointList2d([[n, y(n)] $ n = n1..n2 ])`, and `plot::Sequence(x(n), y(n), n = n1..n2 )` creates the same image as `plot::PointList2d([[x(n), y(n)] $ n = n1..n2 ])`. See “Example 2” on page 23-853 for some extra functionality.

## Attributes

VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
YFunction	function for y values	

## Examples

### Example 1

When given one expression and a range, `plot::Sequence` plots the sequence in function style:

```
plot(plot::Sequence((-1)^n/n, n=1..10))
```

# plot::Sequence

---

plot::Sequence accepts a variety of attributes to influence the appearance of the plot:

```
plot(plot::Sequence((-1)^n/n, n=1..10,
 PointStyle = FilledDiamonds,
 PointSize = 4*unit::mm,
 Color = RGB::Red),
 plot::Sequence(1/n, n=1..10,
 PointsVisible = FALSE,
 LinesVisible = TRUE),
 plot::Sequence(-1/n, n=1..10,
 PointsVisible = FALSE,
 LinesVisible = TRUE))
```

### Example 2

By giving two expressions, we can make `plot::Sequence` plot a sequence of points given by two expressions, for the  $x$ - and  $y$ -coordinate:

```
plot(plot::Sequence(sin(2*PI*n/60), cos(2*PI*n/60),
 n = 1..60), Scaling=Constrained)
```

# plot::Sequence

---

In contrast to the `plot::PointList2d` call listed above as equivalent, `plot::Sequence` allows to easily animate the number of points:

```
plot(plot::Sequence(sin(2*PI*n/60), cos(2*PI*n/60),
 n = 1..nmax, nmax = 1..60),
 Scaling=Constrained, Frames = 60, TimeRange = 1..60)
```

### Example 3

By including the animation parameter in the expressions  $x$  and  $y$ , more complex animations are possible. As an example, we animate Newton iteration for different starting values. First of all, we define the iteration step which maps an approximation to its refinement:

```
newton := x -> x - f(x)/f'(x):
```

For concrete calculations, we will need to use a specific function  $f$ :

```
f := x -> sin(2*x) + x^2:
```

To get successive iteration steps, we will employ the function iteration operator `@@`. For example, the third improvement of the starting value 1.0 is calculated as follows:

```
(newton@@3)(1.0)
```

## plot::Sequence

---

- 1.064963748

For our animation, we want to show the approximations, the corresponding function values, and the order in which the approximations are found. Additionally, we display the function itself:

```
function := plot::Function2d(f, x = -2..2):
steps := plot::Sequence((newton@@n)(x0), f((newton@@n)(x0)),
 n = 0..5, x0 = -1.25..1.5,
 Color = RGB::Green,
 LinesVisible = TRUE):
plot(function, steps,
 ViewingBox = [-2..2, -1..5], PointSize = 2.5)
```

To further increase the number of iteration steps, we should reuse previously computed approximations. To this end, we use a function with option `remember`:

```
newtonIter := proc(x0, n)
 option remember;
begin
 if domtype(n) <> DOM_INT then
 return(procname(args()));
 end_if;
 if iszero(n) then x0
 else newton(newtonIter(x0, n-1));
 end_if;
end_proc;
```

Additionally, we use `plot::Point2d` to display the initial point in a different color.

```
steps := plot::Sequence(newtonIter(x0, n), f(newtonIter(x0, n)),
 n = 0..10, x0 = -1.25..1.5,
 Color = RGB::Green,
 LinesVisible = TRUE);
start := plot::Point2d(x0, f(x0), x0 = -1.25..1.5);
plot(function, steps, start,
 ViewingBox = [-2..2, -1..5], PointSize = 2.5)
```

# plot::Sequence

---

Since  $f$  was evaluated in our object definitions, we will need to reissue the corresponding commands when changing  $f$ .

## Parameters

**$x, y$**

Real-valued arithmetical expressions in  $n$  and possibly the animation parameter  $a$ .

$x, y$  are equivalent to the attributes `XFunction`, `YFunction`.

**$n$**

The index of the sequence: an identifier or an indexed identifier.

$n$  is equivalent to the attribute `UName`.

**$n_1 .. n_2$**

The range of the index  $n$ : real-valued expressions, possibly of the animation parameter  $a$ .

$n_1 .. n_2$  is equivalent to the attributes `URange`, `UMin`, `UMax`.

**a**

Animation parameter, specified as  $a = a_{\min} . . a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Curve2d` | `plot::Function2d` | `plot::PointList2d`

# plot::SparseMatrixplot

---

**Purpose** Sparsity pattern of a matrix

**Syntax**

```
plot::SparseMatrixplot(A, options)
plot::SparseMatrixplot(A, x = x_min .. x_max, y = y_min ..
y_max, <a = a_min .. a_max>, options)
plot::SparseMatrixplot([row_1, row_2,], options)
plot::SparseMatrixplot([row_1, row_2,], x = x_min .. x_max,
y = y_min .. y_max, <a = a_min .. a_max>, options)
```

**Description** `plot::SparseMatrixplot(A)` creates a 2D plot with the axes representing the rows and columns of the matrix  $A$ . For each nonzero entry of  $A$  a point is plotted, thus displaying sparsity patterns in the matrix.

`plot::SparseMatrixplot` interprets the indices of a matrix as  $x$  and  $y$  coordinates, respectively. The indices are ordered according to the standard orientation of the axes, i.e., low matrix indices are found in the lower left corner of the plot.

If  $x = \text{'x\_min'} \dots \text{'x\_max'}$  is specified, the  $j$ -th column of an  $m \times n$

matrix  $A$  corresponds to the coordinate  $x = x_{\min} + \frac{(j-1)}{(n-1)} (x_{\max} - x_{\min})$ .

If  $y = \text{'y\_min'} \dots \text{'y\_max'}$  is specified, the  $i$ -th row corresponds

to the coordinate  $y = y_{\min} + \frac{(i-1)}{(m-1)} (y_{\max} - y_{\min})$ .

If no coordinate range is specified,  $x_{\min} = 1$ ,  $x_{\max} = n$ , and  $y_{\min} = 1$ ,  $y_{\max} = m$  is used, i.e., the coordinate  $x = j$  corresponds to the  $j$ -th column, the coordinate  $y = i$  corresponds to the  $i$ -th row.

A point is plotted for each non-zero matrix entry  $A_{ij}$ .

By default, the attribute `PointColorType = Flat` is used. The color of all points is given by `PointColor`.

With `PointColorType = Dichromatic`, a color blend from `PointColor` to `PointColor2` is used to indicate the size of the non-zero matrix entries. The color of points corresponding to small entries  $A_{ij}$  is `PointColor`. Large entries are colored with `PointColor2`.

Animations are triggered by specifying a range  $a = `a_{\min}` .. `a_{\max}`$  for a parameter  $a$  that is different from the variables  $x, y$ . Thus, in animations, both the ranges  $x = `x_{\min}` .. `x_{\max}`$ ,  $y = `y_{\min}` .. `y_{\max}`$  as well as the animation range  $a = `a_{\min}` .. `a_{\max}`$  must be specified.

## Attributes

Attribute	Purpose	Default Value

YMax	final value of parameter "y"	

# plot::SparseMatrixplot

Attribute	Purpose	Default Value
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

## Examples

### Example 1

We create a random matrix of dimension 100 200 with 1000 nonzero entries:

```
A := matrix::random(100, 200, 1000, frandom):
plot(plot::SparseMatrixplot(A))
```

With `PointColorType = Dichromatic`, the color of the points indicates the size of the matrix entries:

```
plot(plot::SparseMatrixplot(A, PointColorType = Dichromatic)):
```

```
delete A:
```

## Example 2

Choosing appropriate coordinate ranges, we let two sparse matrix plots overlap each other. The red points correspond to a sparse 10 10 matrix with 50 random entries. The blue points indicate the corresponding upper triangular form obtained by Gaussian elimination:

```
A := matrix::random(10, 10, 50, random(1..5)):
B := A::dom::gaussElim(A)[1]:
plot(plot::SparseMatrixplot(A, x = 1..10, y = 1..10,
 Color = RGB::Red),
 plot::SparseMatrixplot(B, x = 1.3..10.3, y = 1..10,
```

# plot::SparseMatrixplot

```
Color = RGB::Blue,
PointSize = 2*unit::mm, PointStyle = FilledCircles),
Axes = Frame)
```

delete A, B:

## Parameters A

A matrix of category `Cat::Matrix` or an array containing real numerical values or expressions of the animation parameter `a`.

A is equivalent to the attribute `Data`.

## row<sub>1</sub>, row<sub>2</sub>, ...

The matrix rows: each row must be a list of real numerical values or expressions of the animation parameter `a`. All rows must have the same length.

$row_1, row_2, \dots$  is equivalent to the attribute Data.

## **x**

Name of the horizontal coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $x$  direction.

$x$  is equivalent to the attribute XName.

## **$x_{min} .. x_{max}$**

The range of the horizontal coordinate:  $x_{min}, x_{max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$x_{min} .. x_{max}$  is equivalent to the attributes XRange, XMin, XMax.

## **y**

Name of the vertical coordinate: an identifier or an indexed identifier. It is used as the title of the coordinate axis in  $y$  direction.

$y$  is equivalent to the attribute YName.

## **$y_{min} .. y_{max}$**

The range of the vertical coordinate:  $y_{min}, y_{max}$  must be numerical real value or expressions of the animation parameter  $a$ .

$y_{min} .. y_{max}$  is equivalent to the attributes YRange, YMin, YMax.

## **a**

Animation parameter, specified as  $a = a_{min} .. a_{max}$ , where  $a_{min}$  is the initial parameter value, and  $a_{max}$  is the final parameter value.

## Examples

### Example 1

We create a blue sphere with center (9, 9, 9) and radius 3:

```
s := plot::Sphere(3, [9, 9, 9], Color = RGB::Blue)
```

```
plot::Sphere(3, [9, 9, 9])
```

# plot::Sphere

---

Call `plot` to plot the sphere:

```
plot(s)
```

Here is an ellipsoid around the origin with semi axes of lengths 1, 2, 3:

```
plot(plot::Ellipsoid(1, 2, 3, [0, 0, 0]))
```

```
delete s:
```

### Example 2

We create a sphere with center  $(-1, -1, 5)$  and radius 3. At two points on the sphere, we wish to add 3D discs indicating the tangent planes.

```
c := [-1, -1, 3]:
s := plot::Sphere(3, c):
p1 := [1, -3, 4]:
p2 := [-3, -2, 1]:
```

The discs are created via `plot::Circle3d` as filled 3D circles of radius 2.5, centered at the points  $p_1$  and  $p_2$ , respectively. The normals  $n_i$  are given by  $p_i - c$ . We compute them by subtracting the center  $c$  from the points  $p_i$  via `zip`:

```
n1 := zip(p1, c, _subtract):
n2 := zip(p2, c, _subtract):
```

# plot::Sphere

---

```
t1 := plot::Circle3d(2.5, p1, n1, Filled = TRUE,
 LineColor = RGB::Black,
 FillColor = RGB::Red.[0.5]):
t2 := plot::Circle3d(2.5, p2, n2, Filled = TRUE,
 LineColor = RGB::Black,
 FillColor = RGB::Red.[0.5]):
```

Finally, we convert the points  $p_i$  to graphical points and add them to the plot:

```
p1 := plot::Point3d(p1, PointColor = RGB::Red,
 PointSize = 2*unit::mm):
p2 := plot::Point3d(p2, PointColor = RGB::Red,
 PointSize = 2*unit::mm):
plot(s, p1, p2, t1, t2)
```

```
delete c, s, p1, p2, n1, n2, t1, t2:
```

**Example 3**

We consider the same sphere as in the previous example:

```
radius := 3: center := [-1, -1, 5]:
s := plot::Sphere(radius, center):
```

Using spherical coordinates, we define a curve on the sphere:

```
phi := a -> PI*sin(7*a):
thet := a -> PI/2 + 1.3*sin(5*a):
x := a -> center[1] + radius*cos(phi(a))*sin(thet(a)):
y := a -> center[2] + radius*sin(phi(a))*sin(thet(a)):
z := a -> center[3] + radius*cos(thet(a)):
```

The curve  $c$  is defined as an object of type `plot::Curve3d`. Further, we define an animated point  $p$  that will run along the curve. An animated filled disc of type `plot::Circle3d` indicating the tangent plane at the point  $p$  as well as the corresponding normal are added to the plot:

```
c := plot::Curve3d([x(t), y(t), z(t)], t = 0..2*PI,
 Mesh = 1000, Color = RGB::Black):
p := a -> [x(a), y(a), z(a)]:
n := a -> zip([x(a), y(a), z(a)], center, _subtract):
d := plot::Circle3d(2.5, p(a), n(a), a = 0..2*PI, Filled = TRUE,
 FillColor = RGB::BlueLight.[0.5],
 LinesVisible = FALSE):
n := plot::Arrow3d(p(a), [p(a)[i] + n(a)[i]/2 $ i=1..3],
 a = 0..2*PI, TipLength = 0.8*unit::mm):
p := plot::Point3d(p(a), a = 0..2*PI, PointColor = RGB::Black,
 PointSize = 2*unit::mm):

plot(s, c, p, n, d, Frames = 200, TimeEnd = 50):
```

# plot::Sphere

---

delete radius, center, s, phi, thet,  
x, y, z, c, p, n, d:

## Parameters **r**

The radius of the sphere: a real numerical value or an arithmetical expression of the animation parameter  $a$ .

$r$  is equivalent to the attribute Radius.

## **$c_x$ , $c_y$ , $c_z$**

The coordinates of the center: real numerical values or arithmetical expressions of the animation parameter  $a$ . If no center is specified, a sphere/ellipsoid centered at the origin is created.

$c_x$ ,  $c_y$ ,  $c_z$  are equivalent to the attributes Center, CenterX, CenterY, CenterZ.

**a**

Animation parameter, specified as  $a = a_{\min} . . a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Ellipsoid

---

**Purpose** Graphical primitive for ellipsoids

**Syntax** `plot::Ellipsoid(rx, ry, rz, <[cx, cy, cz]>, <a = amin .. amax>, options)`

**Description** `plot::Ellipsoid(rx, ry, rz, c)` creates an ellipsoid with the center `c` and symmetry axes parallel to the coordinate axes. The semi axes have the lengths `rx`, `ry`, `rz`.

Ellipsoids with arbitrary orientations of the symmetry axes can be generated via `plot::Rotate3d`.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Center	center of objects, rotation center	[0, 0, 0]
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
CenterZ	center of objects, rotation center, z-component	0
Color	the main color	RGB::LightBlue
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50

Attribute	Purpose	Default Value
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE

VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We create a blue sphere with center (9, 9, 9) and radius 3:

```
s := plot::Sphere(3, [9, 9, 9], Color = RGB::Blue)
```

```
plot::Sphere(3, [9, 9, 9])
```

Call plot to plot the sphere:

```
plot(s)
```

## plot::Ellipsoid

---

Here is an ellipsoid around the origin with semi axes of lengths 1, 2, 3:

```
plot(plot::Ellipsoid(1, 2, 3, [0, 0, 0]))
```

```
delete s:
```

### Example 2

We create a sphere with center  $(-1, -1, 5)$  and radius 3. At two points on the sphere, we wish to add 3D discs indicating the tangent planes.

```
c := [-1, -1, 3]:
s := plot::Sphere(3, c):
p1 := [1, -3, 4]:
p2 := [-3, -2, 1]:
```

The discs are created via `plot::Circle3d` as filled 3D circles of radius 2.5, centered at the points  $p_1$  and  $p_2$ , respectively. The normals  $n_i$  are given by  $p_i - c$ . We compute them by subtracting the center  $c$  from the points  $p_i$  via `zip`:

```
n1 := zip(p1, c, _subtract):
n2 := zip(p2, c, _subtract):
```

# plot::Ellipsoid

---

```
t1 := plot::Circle3d(2.5, p1, n1, Filled = TRUE,
 LineColor = RGB::Black,
 FillColor = RGB::Red.[0.5]):
t2 := plot::Circle3d(2.5, p2, n2, Filled = TRUE,
 LineColor = RGB::Black,
 FillColor = RGB::Red.[0.5]):
```

Finally, we convert the points  $p_i$  to graphical points and add them to the plot:

```
p1 := plot::Point3d(p1, PointColor = RGB::Red,
 PointSize = 2*unit::mm):
p2 := plot::Point3d(p2, PointColor = RGB::Red,
 PointSize = 2*unit::mm):
plot(s, p1, p2, t1, t2)
```

```
delete c, s, p1, p2, n1, n2, t1, t2:
```

### Example 3

We consider the same sphere as in the previous example:

```
radius := 3: center := [-1, -1, 5]:
s := plot::Sphere(radius, center):
```

Using spherical coordinates, we define a curve on the sphere:

```
phi := a -> PI*sin(7*a):
thet := a -> PI/2 + 1.3*sin(5*a):
x := a -> center[1] + radius*cos(phi(a))*sin(thet(a)):
y := a -> center[2] + radius*sin(phi(a))*sin(thet(a)):
z := a -> center[3] + radius*cos(thet(a)):
```

The curve  $c$  is defined as an object of type `plot::Curve3d`. Further, we define an animated point  $p$  that will run along the curve. An animated filled disc of type `plot::Circle3d` indicating the tangent plane at the point  $p$  as well as the corresponding normal are added to the plot:

```
c := plot::Curve3d([x(t), y(t), z(t)], t = 0..2*PI,
 Mesh = 1000, Color = RGB::Black):
p := a -> [x(a), y(a), z(a)]:
n := a -> zip([x(a), y(a), z(a)], center, _subtract):
d := plot::Circle3d(2.5, p(a), n(a), a = 0..2*PI, Filled = TRUE,
 FillColor = RGB::BlueLight.[0.5],
 LinesVisible = FALSE):
n := plot::Arrow3d(p(a), [p(a)[i] + n(a)[i]/2 $ i=1..3],
 a = 0..2*PI, TipLength = 0.8*unit::mm):
p := plot::Point3d(p(a), a = 0..2*PI, PointColor = RGB::Black,
 PointSize = 2*unit::mm):

plot(s, c, p, n, d, Frames = 200, TimeEnd = 50):
```

# plot::Ellipsoid

---

delete radius, center, s, phi, thet,  
x, y, z, c, p, n, d:

## Parameters

$r_x$ ,  $r_y$ ,  $r_z$

The length of the semi axes of the ellipsoid: real numerical values or arithmetical expressions of the animation parameter a.

$r_x$ ,  $r_y$ ,  $r_z$  are equivalent to the attributes SemiAxes, SemiAxisX, SemiAxisY, SemiAxisZ.

$c_x$ ,  $c_y$ ,  $c_z$

The coordinates of the center: real numerical values or arithmetical expressions of the animation parameter a. If no center is specified, a sphere/ellipsoid centered at the origin is created.

$c_x$ ,  $c_y$ ,  $c_z$  are equivalent to the attributes Center, CenterX, CenterY, CenterZ.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Spherical

---

## Purpose

Surfaces in 3D parameterized in spherical coordinates

## Syntax

```
plot::Spherical([r, , t], u = u_min .. u_max, v = v_min ..
v_max, <a = a_min .. a_max>, options)
```

## Description

plot::Spherical creates surfaces parametrized in spherical coordinates.

The surface given by a mapping (“parametrization”)

$(u, v) \rightarrow (r(u, v), \phi(u, v), \theta(u, v))$  is the set of all image points

$$\left\{ \begin{pmatrix} r(u, v) \\ \phi(u, v) \\ \theta(u, v) \end{pmatrix} \middle| u \in [u_{\min}, u_{\max}], v \in [v_{\min}, v_{\max}] \right\}$$

in spherical coordinates, which translate to the usual “Cartesian” coordinates as

$$\begin{aligned} x &= r \cos(\phi) \sin(\theta) \\ y &= r \sin(\phi) \sin(\theta) \\ z &= r \cos(\theta) \end{aligned}$$

$r$  is referred to as “radius”,  $\phi$  as “azimuthal angle”, and  $\theta$  is known as “polar angle.”

The functions  $r$ ,  $\phi$ ,  $\theta$  are evaluated on a regular equidistant mesh of sample points in the  $u$ - $v$  plane. This mesh is determined by the attributes UMesh, VMesh. By default, the attribute AdaptiveMesh = 0 is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of UMesh, VMesh or USubmesh, VSubmesh, or set AdaptiveMesh =  $n$  with some (small) positive integer

n. If necessary, up to  $2^n - 1$  additional points are placed in each direction of the  $u$ - $v$  plane between adjacent points of the initial equidistant mesh. Cf. “Example 3” on page 23-898.

“Coordinate lines” (“parameter lines”) are curves on the surface.

The phrase “ULines” refers to the curves  $(r(u, v_0), \varphi(u, v_0), \theta(u, v_0))$  with the parameter  $u$  running from  $u_{\min}$  to  $u_{\max}$ , while  $v_0$  is some fixed value from the interval  $[v_{\min}, v_{\max}]$ .

The phrase “VLines” refers to the curves  $(r(u_0, v), \varphi(u_0, v), \theta(u_0, v))$  with the parameter  $v$  running from  $v_{\min}$  to  $v_{\max}$ , while  $u_0$  is some fixed value from the interval  $[u_{\min}, u_{\max}]$ .

By default, the parameter curves are visible. They may be switched off by specifying `ULinesVisible = FALSE` and `VLinesVisible = FALSE`, respectively.

The coordinate lines controlled by `ULinesVisible = TRUE/FALSE` and `VLinesVisible = TRUE/FALSE` indicate the equidistant mesh in the  $u$ - $v$  plane set via the `UMesh`, `VMesh` attributes. If the mesh is refined by the `USubmesh`, `VSubmesh` attributes, or by the adaptive mechanism controlled by `AdaptiveMesh = n`, no additional parameter lines are drawn.

As far as the numerical approximation of the surface is concerned, the settings

$$\text{UMesh} = n_u, \text{VMesh} = n_v, \text{USubmesh} = m_u, \text{VSubmesh} = m_v$$

and

$$\text{UMesh} = (n_u - 1) (m_u + 1) + 1, \text{VMesh} = (n_v - 1) (m_v + 1) + 1,$$

$$\text{USubmesh} = 0, \text{VSubmesh} = 0$$

are equivalent. However, in the first setting,  $n_u$  parameter lines are visible in the  $u$  direction, while in the latter setting  $(n_u - 1) * (m_u + 1) + 1$  parameter lines are visible. Cf. “Example 3” on page 23-898.

Use `Filled = FALSE` to obtain a wireframe representation of the surface.

If the expression/function  $r$  contains singularities, it is recommended (but not strictly necessary) to use the attribute `ViewingBox` to set a suitable viewing box. No such precautions are necessary for  $\varphi$  and  $\theta$ , although singularities in these functions may result in poorly rendered surfaces – in many cases setting the attributes `Mesh` and/or `AdaptiveMesh` to higher values will help. Cf. “Example 6” on page 23-904.

## Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	0
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Color</code>	the main color	<code>RGB::Red</code>
<code>Filled</code>	filled or transparent areas and surfaces	TRUE
<code>FillColor</code>	color of areas and surfaces	<code>RGB::Red</code>
<code>FillColor2</code>	second color of areas and surfaces for color blends	<code>RGB::CornflowerBlue</code>
<code>FillColorType</code>	surface filling types	<code>Dichromatic</code>
<code>FillColorFunction</code>	functional area/surface coloring	
<code>FillColorDirection</code>	the direction of color transitions on surfaces	[0, 0, 1]
<code>FillColorDirectionX</code>	x-component of the direction of color transitions on surfaces	0

Attribute	Purpose	Default Value
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0

# plot::Spherical

---

Attribute	Purpose	Default Value
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[25, 25]
MeshVisible	visibility of irregular mesh lines in 3D	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Submesh	density of submesh (additional sample points)	[0, 0]

Attribute	Purpose	Default Value
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
ULinesVisible	visibility of parameter lines (u lines)	TRUE
UMax	final value of parameter "u"	
UMesh	number of sample points for parameter "u"	25
UMin	initial value of parameter "u"	

# plot::Spherical

---

Attribute	Purpose	Default Value
UName	name of parameter “u”	
URange	range of parameter “u”	
USubmesh	density of additional sample points for parameter “u”	0
VLinesVisible	visibility of parameter lines (v lines)	TRUE
VMax	final value of parameter “v”	
VMesh	number of sample points for parameter “v”	25
VMin	initial value of parameter “v”	
VName	name of parameter “v”	
VRange	range of parameter “v”	
VSubmesh	density of additional sample points for parameter “v”	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value

Attribute	Purpose	Default Value
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XContours	contour lines at constant x values	[]
XFunction	function for x values	
YContours	contour lines at constant y values	[]
YFunction	function for y values	
ZContours	contour lines at constant z values	[]
ZFunction	function for z values	

## Examples

### Example 1

Spherical coordinates get their name from the fact that, with a constant radius, they parameterize a sphere:

```
plot(plot::Spherical([1, u, v], u = 0..2*PI, v = 0..PI))
```

# plot::Spherical

---

```
plot(plot::Spherical([1, u, v], u = 0..PI, v = 0..2*PI))
```

### Example 2

The following plot demonstrates that spherical plots can exhibit singular surface features even with differentiable parameterizations; in this case, the rim in the middle is actually a border of both the left- and the right-hand part:

```
plot(plot::Spherical(
 [(phi^2*thet), phi, thet^2],
 phi = -PI..PI, thet=0..0.25*PI,
 Mesh = [40,40], Submesh=[3,0],
 Color = [0.9$3], FillColorType=Flat, LineColor=[0.8$3]),
 Axes = None, CameraDirection = [1, 0, 0])
```

### Example 3

For oscillating parameterizations or other surfaces with fine details, the default mesh may be too coarse. As stated above, the three attributes `Mesh`, `Submesh`, and `AdaptiveMesh` can be used for improving plots of these objects.

First, note that the following plot is not rendered with a sufficient resolution:

```
surf := plot::Spherical([4+sin(5*(u+v)), u, v], u = 0..PI, v = 0..2*PI)
plot(surf, Axes = None)
```

Setting `Mesh` to twice its default, we get a smoother surface with additional parameter lines:

```
surf::Mesh := [50, 50]:
plot(surf, Axes = None)
```

# plot::Spherical

---

Almost the same effect, but without the additional parameter lines, can be achieved by setting `Submesh = [1, 1]`:

```
delete surf::Mesh:
surf::Submesh := [1, 1]:
plot(surf, Axes = None)
```

It is also possible to use adaptive mesh refinement in areas where neighboring patches have an angle of more than 10 degrees. While this option is mostly useful for surfaces which require refinement only in some parts, it is certainly feasible with a plot like this, too (but increasing `Submesh` is faster):

```
delete surf::Submesh:
surf::AdaptiveMesh := 2:
plot(surf, Axes = None)
```

## Example 4

The radius function  $r$  may also take on negative values. With radius functions of changing sign, spherical surfaces often do self-intersect:

```
plot(plot::Spherical(
 [sin(phi^2*thet), phi, thet],
 phi = -PI..PI, thet = 0..0.5*PI,
 Mesh = [40, 20], Submesh=[0, 3]))
```

### Example 5

The angular functions ( $\varphi$  and  $\theta$ ) are not limited in value:

```
plot(plot::Spherical([r, r, thet], r = 0..9, thet = -PI..PI,
 Mesh = [60, 60], Filled = FALSE),
 Axes = None,
 plot::Camera([100, 100, 50], [0,0,0], 0.1))
```

Note that we used an explicit `plot::Camera` object here because the automatic camera is always placed such that all of an object is visible, even when using `CameraDirection`. To get a “closer” look, use the interactive manipulation possibilities or an explicit camera.

## Example 6

Singularities in the radius function are heuristically handled:

```
plot(plot::Spherical([1/(u + v), u, v], u = 0..PI, v = 0..PI))
```

However, the heuristics fails for some examples:

```
plot(plot::Spherical([1/(u + v)^2, u, v], u = 0..PI, v = 0..PI))
```

# plot::Spherical

---

In cases like this, we recommend setting a viewing box explicitly with the attribute `ViewingBox`:

```
plot(plot::Spherical([1/(u + v)^2, u, v], u = 0..PI, v = 0..PI),
 ViewingBox = [-1/10..0.7, 0..1/4, -0.2..0.3])
```

## Example 7

By setting one of the parameter ranges to a degenerate interval, it is possible to draw curves on a spherical surface:

```
f := (u, v) -> [1 + u/10, u, v]:
surface := plot::Spherical(f(u,v), u = 0..2, v = 0..2,
 FillColor = RGB::Grey, FillColorType
curve := plot::Spherical(f((1 + sin(u)), (1 + sin(2*u))),
 u = 0..2*PI, v = 0..0, Mesh = [200, 1],
 LineColor = RGB::Red, LineWidth = 1):
plot(surface, curve)
```

# plot::Spherical

---

## Example 8

While the transformation from spherical to Cartesian coordinates is not invertible, there are at least two ways of expressing each Cartesian point in spherical coordinates and any surface parameterizable in Cartesian coordinates can also be plotted using `plot::Spherical` (although this is probably more a curiosity than really useful):

```
trans := linalg::ogCoordTab[Spherical, InverseTransformation]:
spher := trans(x, y, sin(x^2+y^2))
```

$$\left[ \sqrt{x^2 + y^2 + \sin(x^2 + y^2)^2}, \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right) + \text{sign}(y) (\text{sign}(y) - 1) \left(\pi - \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right)\right) \right. \\ \left. \arccos\left(\frac{\sin(x^2 + y^2)}{\sqrt{x^2 + y^2 + \sin(x^2 + y^2)^2}}\right) \right]$$

```
plot(plot::Spherical(spher, x = -2..2, y = -2..2))
```

### Example 9

Last but not least we can also produce animations with the help of `plot::Spherical`. The following shows a deformation from a general spherical object to a sphere. We have used the animation parameter a

# plot::Spherical

---

inside of the argument for the sine function to obtain a slight rotation during the deformation process:

```
plot(
 plot::Spherical(
 [1+a*sin(3*Phi+a)*sin(2*Theta),Phi,Theta],
 Theta=0..PI, Phi=0..2*PI, a=5..0
)
)
```

## Parameters $r, \bullet,$

The coordinate functions: arithmetical expressions or piecewise objects depending on the surface parameters  $u, v$  and the animation parameter  $a$ . Alternatively, procedures that accept 2 input parameters  $u, v$  or 3 input parameters  $u, v, a$  and return a real numerical value when the input parameters are numerical.

$r$ ,  $\phi$ ,  $\xi$  are equivalent to the attributes XFunction, YFunction, ZFunction.

## **u**

The first surface parameter: an identifier or an indexed identifier.

$u$  is equivalent to the attribute UName.

## **u<sub>min</sub> .. u<sub>max</sub>**

The plot range for the parameter  $u$ :  $u_{\min}$ ,  $u_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ .

$u_{\min} .. u_{\max}$  is equivalent to the attributes URange, UMin, UMax.

## **v**

The second surface parameter: an identifier or an indexed identifier.

$v$  is equivalent to the attribute VName.

## **v<sub>min</sub> .. v<sub>max</sub>**

The plot range for the parameter  $v$ :  $v_{\min}$ ,  $v_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ .

$v_{\min} .. v_{\max}$  is equivalent to the attributes VRange, VMin, VMax.

## **a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

**Syntax**

```
plot::Streamlines2d([v1, v2], x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
plot::Streamlines2d(v1, v2, x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
plot::Streamlines2d(V, x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
```

**Description** `plot::Streamlines2d( [v1, v2] , x = `x_{min}` .. `x_{max}` ,  
y = `y_{min}` .. `y_{max}` )` creates streamlines of the vector field  
defined by  $(X, Y) \rightarrow (V_1(X, Y), V_2(X, Y))$  with  $(x, y) [x_{min}, x_{max}] [y_{min},$   
 $y_{max}]$ .

A vector field is defined by a function  $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ . `plot::Streamlines2d`  
displays a vector field by drawing almost evenly spaced streamlines  
of the vector field, i.e., curves to which the vector field is tangential  
at every point. The density of stream lines (and the time needed for  
calculation) is controlled with the attribute `MinimumDistance`.

As a rule of thumb: decreasing the value of `MinimumDistance` by a  
factor of 2 leads to an increase of the runtime by a factor of 4.

A user defined color scheme may be specified by `LineColorFunction`  
`= color`, where `color` is a MuPAD procedure accepting 6 input  
parameters and returning a list of RGB values. During plotting, this  
function is called in the form `color(x, y, v1, v2, t, l, n)`:

The values `x, y` are the coordinates of the current point.

The values `v1, v2` are the components of the vector field at the current  
point.

The value `t` is the “time” of the current point  $(x, y)$  on the current  
streamline. The scaling of this parameter depends on the vector field.

The value `l` is the curve length of the current streamline from its  
starting point the current point  $(x, y)$ , as a Euclidean distance. This

parameter is invariant with respect to scalar changes of the vector field (up to changing the direction of the streamline).

The integer value  $n$  is a count of the current streamline. Each separate streamline has a different value.

Cf. “Example 3” on page 23-921.

## Attributes

Attribute	Purpose	Default Value
AbsoluteError	maximal absolute discretization error	
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	TRUE
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black
LineWidth	width of lines	0.35*unit::mm
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat

## plot::Streamlines2d

XFunction	function for x values	
XMax	final value of parameter "x"	
XMin	initial value of parameter "x"	
XName	name of parameter "x"	
XRange	range of parameter "x"	
YFunction	function for y values	
YMax	final value of parameter "y"	
YMin	initial value of parameter "y"	
YName	name of parameter "y"	
YRange	range of parameter "y"	

## Examples

### Example 1

plot::Streamlines2d depicts vector fields by (more or less) equidistant stream lines:

```
plot(plot::Streamlines2d(-x, -y, x=-2..2, y=-2..2))
```

Note that this style of display necessarily breaks symmetries, in this case the perfect rotational symmetry of the vector field.

Additionally, cycles will not be closed, but leave a gap:

```
plot(plot::Streamlines2d(-y, x, x=-2..2, y=-2..2))
```

## plot::Streamlines2d

---

### Example 2

Apart from the “usual” parameters such as parameter ranges, line color, or line width, `plot::Streamlines2d` can be controlled with the attribute `MinimumDistance`, which sets the minimum distance between stream lines:

```
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2),
x = -3..3, y = -2..2))
```

```
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2),
x = -3..3, y = -2..2,
MinimumDistance = 0.2))
```

## plot::Streamlines2d

---

```
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2),
x = -3..3, y = -2..2,
MinimumDistance = 0.05))
```

### Example 3

A line color function for `plot::Streamlines2d` has access to the current coordinates, to the components of the vector field at the current point, to the current length on the curve (both in terms of the “time” parameter and Euclidean distance) and an integer count of the current curve (which are not found in some predefined order). We use the curve number to generate a colorful display:

```
num2col := (x, y, vx, vy, t, l, n) -> RGB::fromHSV([111*n, 1, 1])
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2),
 x = -3..3, y = -2..2,
 LineColorFunction = num2col))
```

## plot::Streamlines2d

---

Using the curve length information allows us to include directional information in the visual display:

```
l2col := (x, y, vx, vy, t, l) -> [frac(5*t) $ 3]:
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2+y^2),
 x = -3..3, y = -2..2,
 LineWidth = 0.75,
 LineColorFunction = l2col))
```

Often, an easier way of plotting the orientation of the stream lines is to activate the arrow heads `plot::Streamlines2d` plots at the middle of each sufficiently long) stream line. These are made invisible by the default tip length of 0:

```
plot(plot::Streamlines2d(0.3*x-y, 0.3*y+x,
 x = -3..3, y = -2..2,
 TipLength = 3*unit::mm))
```

## plot::Streamlines2d

---

### Example 4

Since the placement of stream lines is hard to predict, `plot::Streamlines2d` is not really suitable for animations. It is possible to animate `plot::Streamlines2d`, but coherence between the animation frames is less than usual:

```
plot(plot::Streamlines2d(sin(x^2+y^2), cos(x^2-y^2+a),
 x = -2..2, y = -2..2, a = -PI..PI,
 MinimumDistance = 0.1,
 Frames=10))
```

### Example 5

With the default settings, `plot::Streamlines2d` is not able to plot the vector field  $[1, 3^{2/y}]$  (which is not Lipschitz continuous) in a satisfying way:

```
plot(plot::Streamlines2d([1, surd(3,y)^2],
 x=-3..3, y=-2..2))
```

## plot::Streamlines2d

---

By using a different numerical integrator, the problems can be overcome (at the cost of longer computation):

```
plot(plot::Streamlines2d([1, surd(3,y)^2],
 x=-3..3, y=-2..2,
 ODEMethod=RKF43,
 RelativeError=1e-3))
```

## Parameters

**$v_1, v_2$**

The  $x$ - and  $y$ -component of the vector field: arithmetical expressions in  $x$ ,  $y$ , and, possibly, the animation parameter  $a$ .

$v_1, v_2$  are equivalent to the attributes `XFunction`, `YFunction`.

**$V$**

A matrix of category `Cat::Matrix` with two entries that provide the components  $v_1, v_2$  of the vector field.

**$x, y$**

Identifiers.

$x, y$  are equivalent to the attributes `XName`, `YName`.

**$x_{\min} \dots x_{\max}, y_{\min} \dots y_{\max}$**

Real numerical values.

# plot::Streamlines2d

---

$x_{\min} \dots x_{\max}$ ,  $y_{\min} \dots y_{\max}$  are equivalent to the attributes XRange, YRange, XMin, XMax, YMin, YMax.

**a**

Animation parameter, specified as  $a = a_{\min} \dots a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Algorithms

The algorithm used in `plot::Streamlines2d` has been published in “Creating Evenly-Spaced Streamlines of Arbitrary Density” by Bruno Jobard and Wilfrid Lefer at the Eurographics Workshop in Boulogne-sur-Mer, France.

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::Ode2d` | `plot::Ode3d` | `plot::VectorField2d` |  
`plot::VectorField3d`

## Purpose

Graphical primitive for symbolic sums

## Syntax

```
plot::Sum(ex, i = m .. n, <a = amin .. amax>, options)
plot::Sum(sum(ex, i = m .. n), <a = amin .. amax>, options)
```

## Description

`plot::Sum(ex, i = m..n)` creates a plot of summing `ex` over the range `m..n`.

`plot::Sum` creates a visual display of partial sums over a finite interval. Mathematically, `plot::Sum(ex, i = m..n)` plots the function

$$x \rightarrow \sum_{i=m} (m + [x - m]) ex.$$

To ease the use of `plot::Sum` in programs, symbolic sums are accepted in the input and `plot::Sum` takes care not to evaluate these. It is highly recommended, though, not to use this syntax in interactive applications, to avoid premature evaluation.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AntiAliased	antialiased lines and points?	FALSE
Color	the main color	RGB::Blue
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	Solid
Frames	the number of frames in an animation	50

Attribute	Purpose	Default Value

# plot::Sum

Attribute	Purpose	Default Value
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XMax	final value of parameter "x"	
XMin	initial value of parameter "x"	
XName	name of parameter "x"	
XRange	range of parameter "x"	

## Examples

### Example 1

It is well known that  $\sum_{j=1}^{\infty} \frac{1}{j^2} = \frac{\pi^2}{6}$ . We use `plot::Sum` to display the first 100 partial sums:

```
plot(plot::Sum(1/j^2, j = 1..100),
 plot::Function2d(PI^2/6, x=1..101, LineStyle = Dashed))
```

With more partial sums, the steps approximate points:

```
plot(plot::Sum(sin(j^2)/j, j=1..500))
```

# plot::Sum

---

## Example 2

To show some of the formatting options of `plot::Sum`, we use the following sum:

```
s := plot::Sum(1/j, j = 1..20)
```

```
plot::Sum($\frac{1}{j}$, j = 1..20)
```

By default, this object is displayed as follows:

```
plot(s)
```

To change parameters, we can select them in the inspector and change the values, we can give other values directly in the plot command or we can set the new values in our object `s`:

```
s::PointsVisible := TRUE:
s::LinesVisible := FALSE:
s::PointColor := RGB::Green:
plot(s)
```

# plot::Sum

---

### Example 3

`plot::Sum` allows animation in the usual way, for example, in the term  
to sum:

```
plot(plot::Sum(sin(a*i^2)/i, i = 1..50, a = 0..PI))
```

Another interesting parameter to animate is the summation range:

```
plot(plot::Sum((-1)^j/j, j = 1..jmax, jmax = 1..50))
```

# plot::Sum

---

## Parameters

**ex**

Arithmetical expression in **i** and the animation parameter **a**, if that is used.

**ex** is equivalent to the attribute **Function**.

**i**

An identifier or indexed identifier.

**i** is equivalent to the attribute **XName**.

**m .. n**

The range of **i**. **m** and **n** may be expressions in the animation parameter **a**. Summation goes over  $m + \text{integer}$ . If  $n - m$  is not an integer, **n** will not be reached.

**m .. n** is equivalent to the attributes **XRange**, **XMin**, **XMax**.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Graphical Primitives

[plot::Function2d](#) | [plot::PointList2d](#)

# plot::Surface

---

**Purpose** Parametrized surfaces in 3D

**Syntax**

```
plot::Surface([x, y, z], u = u_min .. u_max, v = v_min .. v_max, <a = a_min .. a_max>, options)
plot::Surface(xyz, u = u_min .. u_max, v = v_min .. v_max, <a = a_min .. a_max>, options)
plot::Surface(A, u = u_min .. u_max, v = v_min .. v_max, <a = a_min .. a_max>, options)
```

**Description** plot::Surface creates a parametrized surface in 3D.

The surface given by a mapping (“parametrization”)  $(u, v) \rightarrow (x(u, v), y(u, v), z(u, v))$  is the set of all image points

$$\left\{ \begin{pmatrix} x(u, v) \\ y(u, v) \\ z(u, v) \end{pmatrix} \middle| u \in [u_{\min}, u_{\max}], v \in [v_{\min}, v_{\max}] \right\} \in \mathbb{R}^3$$

The expressions/functions  $x, y, z$  may have singularities in the plot range. Although a heuristics is used to find a reasonable viewing range when singularities are present, it is highly recommended to specify a viewingbox via the attribute

```
ViewingBox = [`x_{min}` .. `x_{max}` , `y_{min}` .. `y_{max}` , `z_{min}` .. `z_{max}`]
```

with suitable numerical real values  $x_{\min}, x_{\max}, y_{\min}, y_{\max}, z_{\min}, z_{\max}$ . See “Example 3” on page 23-950.

Animations are triggered by specifying a range  $a = `a_{\min}` .. `a_{\max}`$  for a parameter  $a$  that is different from the surface parameters  $u, v$ . See “Example 5” on page 23-953.

The functions  $x, y, z$  are evaluated on a regular equidistant mesh of sample points in the  $u$ - $v$  plane. This mesh is determined by the

attributes `UMesh`, `VMesh`. By default, the attribute `AdaptiveMesh = 0` is set, i.e., no adaptive refinement of the equidistant mesh is used.

If the standard mesh does not suffice to produce a sufficiently detailed plot, one may either increase the value of `UMesh`, `VMesh` or `USubmesh`, `VSubmesh`, or set `AdaptiveMesh = n` with some (small) positive integer  $n$ . If necessary, up to  $2^n - 1$  additional points are placed in each direction of the  $u$ - $v$  plane between adjacent points of the initial equidistant mesh. See “Example 6” on page 23-954.

The “coordinate lines” (“parameter lines”) are curves on the surface.

The phrase “ULines” refers to the curves  $(x(u, v_0), y(u, v_0), z(u, v_0))$  with the parameter  $u$  running from  $u_{\min}$  to  $u_{\max}$ , while  $v_0$  is some fixed value from the interval  $[v_{\min}, v_{\max}]$ .

The phrase “VLines” refers to the curves  $(x(u_0, v), y(u_0, v), z(u_0, v))$  with the parameter  $v$  running from  $v_{\min}$  to  $v_{\max}$ , while  $u_0$  is some fixed value from the interval  $[u_{\min}, u_{\max}]$ .

By default, the parameter curves are visible. They may be “switched off” by specifying `ULinesVisible = FALSE` and `VLinesVisible = FALSE`, respectively.

The coordinate lines controlled by `ULinesVisible = TRUE/FALSE` and `VLinesVisible = TRUE/FALSE` indicate the equidistant mesh in the  $u$ - $v$  plane set via the `UMesh`, `VMesh` attributes. If the mesh is refined by the `USubmesh`, `VSubmesh` attributes, or by the adaptive mechanism controlled by `AdaptiveMesh = n`, no additional parameter lines are drawn.

As far as the numerical approximation of the surface is concerned, the settings `UMesh =  $n_u$` , `VMesh =  $n_v$` , `USubmesh =  $m_u$` , `VSubmesh =  $m_v$`  and `UMesh =  $(n_u - 1) (m_u + 1) + 1$` , `VMesh =  $(n_v - 1) (m_v + 1) + 1$` , `USubmesh = 0`, `VSubmesh = 0` are equivalent. However, in the first setting,  $n_u$  parameter lines are visible in the  $u$  direction, while in the latter setting  $(n_u - 1) (m_u + 1) + 1$  parameter lines are visible. See “Example 7” on page 23-957.

Use `Filled = FALSE` to render the surface as a wireframe.

# plot::Surface

## Examples

### Example 1

Using standard spherical coordinates, a parametrization of a sphere of radius  $r$  by the azimuth angle  $u$   $[0, 2\pi]$  and the polar angle  $v$   $[0, \pi]$  is given by:

```
x := r*cos(u)*sin(v):
y := r*sin(u)*sin(v):
z := r*cos(v):
```

We fix  $r = 1$  and create the surface object:

```
r := 1:
s := plot::Surface([x, y, z], u = 0 .. 2*PI, v = 0 .. PI)
```

# plot::Surface

---

```
plot::Surface([cos(u) sin(v), sin(u) sin(v), cos(v)], u = 0..2 π, v = 0..π)
```

We call plot to plot the surface:

```
plot(s, Scaling = Constrained):
```

```
delete x, y, z, r, s:
```

## Example 2

The parametrization can also be specified by piecewise objects or procedures:

```
x := u*cos(v):
y := piecewise([u <= 1, u*sin(v)], [u >= 1, u^2*sin(v)]):
z := proc(u, v)
begin
```

```
if u <= 1 then
 0
else
 cos(4*v)
end_if:
end_proc:
plot(plot::Surface([x, y, z], u = 0 .. sqrt(2), v = 0 .. 2*PI)):
```

We enable adaptive sampling to get a smoother graphical result:

```
plot(plot::Surface([x, y, z], u = 0 .. sqrt(2), v = 0 .. 2*PI),
 AdaptiveMesh = 3):
```

# plot::Surface

---

```
delete x, y, z, s, r:
```

### Example 3

We plot a surface with singularities:

```
s := plot::Surface([u*cos(v), u*sin(v), 1/u^2],
 u = 0 .. 1, v = 0 .. 2*PI):
plot(s):
```

We specify an explicit viewing range for the  $z$  coordinate:

```
plot(s, ViewingBox = [Automatic, Automatic, 0 .. 10]):
```

# plot::Surface

---

delete s:

## Example 4

By introducing non-real function evaluations, we can plot surfaces with holes:

```
chi := piecewise([sin(4*u) < cos(3*v)+0.5, 1]):
plot(plot::Surface([cos(u)*sin(v),
 sin(u)*sin(v),
 chi*cos(v)],
 u = 0 .. 2*PI, v = 0 .. PI,
 AdaptiveMesh=2), Scaling = Constrained)
```

### Example 5

We generate an animation of a surface of revolution. The graph of the

function  $f(u) = \frac{1}{(1+u^2)}$  is rotated around the  $x$ -axis:

```
f := u -> 1/(1 + u^2):
plot(plot::Surface([u, f(u)*sin(v), f(u)*cos(v)], u = -2 .. 2,
 v = 0 .. a*2*PI, a = 0 .. 1)):
```

# plot::Surface

---

See `plot::XRotate`, `plot::ZRotate` for an alternative way to create surfaces of revolution.

`delete f:`

## Example 6

The standard mesh for the numerical evaluation of a surface does not suffice to generate a satisfying plot in the following case:

```
r := 2 + sin(7*u + 5*v):
x := r*cos(u)*sin(v):
y := r*sin(u)*sin(v):
z := r*cos(v):
plot(plot::Surface([x, y, z], u = 0 .. 2*PI, v = 0 .. PI)):
```

We increase the number of mesh points. Here, we use `USubmesh`, `VSubmesh` to place 2 additional points in each direction between each pair of neighboring points of the default mesh. This increases the runtime for computing the plot by a factor of 9:

```
plot(plot::Surface([x, y, z], u = 0 .. 2*PI, v = 0 .. PI,
 USubmesh = 2, VSubmesh = 2)):
```

# plot::Surface

---

Alternatively, we enable adaptive sampling by setting the value of `AdaptiveMesh` to some positive value:

```
plot(plot::Surface([x, y, z], u = 0 .. 2*PI, v = 0 .. PI,
AdaptiveMesh = 2)):
```

```
delete r, x, y, z:
```

### Example 7

By default, the parameter lines of a parametrized surface are “switched on”:

```
x := r*cos(phi):
y := r*sin(phi):
z := r^2:
plot(plot::Surface([x, y, z], r = 1/3 .. 1, phi = 0 .. 2*PI)):
```

## plot::Surface

---

The parameter lines are “switched off”:

```
plot(plot::Surface([x, y, z], r = 1/3 .. 1, phi = 0 .. 2*PI,
 ULinesVisible = FALSE,
 VLinesVisible = FALSE)):
```

The number of parameter lines are determined by the attributes UMesh and VMesh:

```
plot(plot::Surface([x, y, z], r = 1/3 .. 1, phi = 0 .. 2*PI,
 UMesh = 5, VMesh = 12)):
```

# plot::Surface

---

When the mesh is refined via the attributes USubmesh, VSubmesh, the numerical approximation of the surface becomes smoother. However, the number of parameter lines is determined by the values of UMesh, VMesh and is not increased:

```
plot(plot::Surface([x, y, z], r = 1/3 .. 1, phi = 0 .. 2*PI,
 UMesh = 5, VMesh = 12,
 USubmesh = 1, VSubmesh = 2)):
```

### Example 8

Klein's bottle is a surface without orientation. There is no "inside" and no "outside" of the following object:

```

bx := u -> -6*cos(u)*(1 + sin(u)):
by := u -> -14*sin(u):
r := u -> 4 - 2*cos(u):
x := (u, v) -> piecewise([u <= PI, bx(u) - r(u)*cos(u)*cos(v)],
 [PI < u, bx(u) + r(u)*cos(v)]):
y := (u, v) -> r(u)*sin(v):
z := (u, v) -> piecewise([u <= PI, by(u) - r(u)*sin(u)*cos(v)],
 [PI < u, by(u)]):
KleinBottle:= plot::Surface(
 [x, y, z], u = 0 .. 2*PI, v = 0 .. 2*PI,
 Mesh = [35, 31], LineColor = RGB::Black.[0.2],
 FillColorFunction = RGB::MuPADGold):
plot(KleinBottle, Axes = None, Scaling = Constrained,
 Width = 60*unit::mm, Height = 72*unit::mm,

```

BackgroundStyle = Pyramid):

```
delete bx, by, r, x, y, z, KleinBottle:
```

## Example 9

Finally we create an animated surface plot of  $(u, v) \rightarrow (\sin(u), \sin(v), a \sin(u + v))$  where  $a$  is the animation parameter:

```
plot(
 plot::Surface(
 [sin(u),sin(v),a*sin(u+v)],
 u=0..2*PI, v=0..2*PI, a=1..0,
 AnimationStyle = BackAndForth
)
)
```

## Parameters

### **x, y, z**

The coordinate functions: arithmetical expressions or piecewise objects depending on the surface parameters  $u$ ,  $v$  and the animation parameter  $a$ . Alternatively, procedures that accept 2 input parameters  $u$ ,  $v$  or 3 input parameters  $u$ ,  $v$ ,  $a$  and return a numerical value when the input parameters are numerical.

$x$ ,  $y$ ,  $z$  are equivalent to the attributes XFunction, YFunction, ZFunction.

### **xyz**

The parametrization: a procedure that accepts 2 input parameters  $u$ ,  $v$  or 3 input parameters  $u$ ,  $v$ ,  $a$  and returns a list of 3 numerical values  $[x, y, z]$ .

### **A**

# plot::Surface

---

A matrix of category `Cat::Matrix` with three entries that provide the parametrization  $x, y, z$

## **u**

The first surface parameter: an identifier or an indexed identifier. `u` is equivalent to the attribute `UName`.

## **u<sub>min</sub> .. u<sub>max</sub>**

The plot range for the parameter  $u$ : `umin`, `umax` must be numerical real values or expressions of the animation parameter  $a$ .

`umin .. umax` is equivalent to the attributes `URange`, `UMin`, `UMax`.

## **v**

The second surface parameter: an identifier or an indexed identifier.

`v` is equivalent to the attribute `VName`.

## **v<sub>min</sub> .. v<sub>max</sub>**

The plot range for the parameter  $v$ : `vmin`, `vmax` must be numerical real values or expressions of the animation parameter  $a$ .

`vmin .. vmax` is equivalent to the attributes `VRange`, `VMin`, `VMax`.

## **a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where `amin` is the initial parameter value, and `amax` is the final parameter value.

### MuPAD Functions

`plot` | `plot::copy` | `plotfunc3d`

### MuPAD Graphical Primitives

`plot::Function3d` | `plot::Matrixplot`

## Purpose

Triangle and quad surface meshes

## Syntax

```
plot::SurfaceSet(meshlist, <MeshListType = t>,
<MeshListNormals = n>, <UseNormals = b>, <a =
amin .. amax>, options)
```

## Description

`plot::SurfaceSet(MeshList)` creates a 3D graphical object from a given list of triangle or quad coordinates.

`MeshList` contains coordinates of points (and optional normals) of either triangles or quads which define a mesh of a 3D surface. The points must be given homogenous: If a normal is given, it must be given for all points or facets, respectively. The attribute `MeshListType` specifies how these points are to be interpreted for plotting the surface. The attribute `MeshListNormals` specifies whether the list contains normal vectors and at which positions they located.

`MeshListType` specifies how the points in `MeshList` are to be interpreted for plotting the surface. See `MeshList` for more information about mesh list types. Cf. “Example 4” on page 23-975.

`MeshListNormals` specifies whether `MeshList` contains normals and at which positions they are located. See `MeshList` for more information about normals and facet orientation.

When setting the attribute `UseNormals` to `FALSE` the normals defined in `MeshList` are ignored when plotting the object in MuPAD. This reduces the data volume of the graphics object and the computing time as well. However, it leads to a less brilliant image.

User-defined color functions `LineColorFunction` and `FillColorFunction` will be called with the index of the current point as its first parameter, followed by the  $x$ ,  $y$ , and  $z$  coordinate of the current point.

The transformation objects `plot::Rotate3d`, `plot::Scale3d`, `plot::Translate3d` and `plot::Transform3d` can be applied to the imported STL object. Cf. “Example 8” on page 23-988.

# plot::SurfaceSet

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
MeshList	triangulation data	

## plot::SurfaceSet

---

Attribute	Purpose	Default Value
MeshVisible	visibility of irregular mesh lines in 3D	FALSE
MeshListType	triangulation data	Triangles
MeshListNormals	triangulation data	None
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Shading	smooth color blend of surfaces	Smooth
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
UseNormals	use pre-defined normals?	TRUE
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

# plot::SurfaceSet

---

## Examples

### Example 1

When given a list of real numbers, `plot::SurfaceSet` by default considers them as the coordinates of points in 3D forming triangles. Note that we are using `FillColorFunction` here to make the triangles easier to see and that the number of values must be divisible by 9, since each triangle needs 9 numbers to be specified:

```
plot(plot::SurfaceSet([frandom() $ i = 1..9*5],
 FillColorFunction = (i -> RGB::ColorList[floor((i+2)/3)]))):
```

### Example 2

This examples demonstrates how surface sets can be created and animated in MuPAD. First we create a mesh of points:

```
delete cx, cy, cz, r:
F:= [[[cx-r ,cy-r+a,cz+r], [cx-r+a,cy-r ,cz+r],
 [cx+r-a,cy-r ,cz+r], [cx+r ,cy-r+a,cz+r],
```

```

 [cx+r ,cy+r-a,cz+r], [cx+r-a,cy+r ,cz+r],
 [cx-r+a,cy+r ,cz+r], [cx-r ,cy+r-a,cz+r]],
[[cx+r,cy-r ,cz-r+a], [cx+r,cy-r+a,cz-r],
 [cx+r,cy+r-a,cz-r], [cx+r,cy+r ,cz-r+a],
 [cx+r,cy+r ,cz+r-a], [cx+r,cy+r-a,cz+r],
 [cx+r,cy-r+a,cz+r], [cx+r,cy-r ,cz+r-a]],
[[cx-r ,cy+r,cz-r+a], [cx-r+a,cy+r,cz-r],
 [cx+r-a,cy+r,cz-r], [cx+r ,cy+r,cz-r+a],
 [cx+r ,cy+r,cz+r-a], [cx+r-a,cy+r,cz+r],
 [cx-r+a,cy+r,cz+r], [cx-r ,cy+r,cz+r-a]]]:

F:= F.[subs(F[1], cz+r=cz-r),
 subs(F[2], cx+r=cx-r),
 subs(F[3], cy+r=cy-r)]:

T:= [[cx+r,cy-r+a,cz+r], [cx+r-a,cy-r,cz+r], [cx+r,cy-r,cz+r-a]]
T:= T.subs(T, cx+r-a=cx-r+a, cx+r=cx-r):
T:= T.subs(T, cy-r+a=cy+r-a, cy-r=cy+r):
T:= T.subs(T, cz+r-a=cz-r+a, cz+r=cz-r):

```

Then we create plot objects using the mesh above:

```

cx := 0: cy := 0: cz := 0:
r := 1:
P := range ->
 plot::Group3d(
 plot::Group3d(
 plot::SurfaceSet(map(F[i], op), a = range,
 MeshListType = TriangleFan)
 $ i=1..6),
 plot::Group3d(
 plot::Polygon3d(F[i], a = range, Closed) $ i=1..6,
 LineWidth = 1.5,
 LineColor = RGB::Grey,
 PointsVisible,
 PointSize = 3),
 plot::Group3d(

```

## plot::SurfaceSet

---

```
 plot::SurfaceSet(map(T, op), a = range),
 FillColorType = Flat,
 FillColor=RGB::Yellow,
 Filled)
):

plot(P(0..r),
 Scaling = Constrained,
 Width = 120, Height = 120,
 Axes = None):
```

The first half of this animation is plotted again. In the left image we can see how parts of the surface set are constructed as triangle fan. In the right image parts of the surface are displayed as wireframe:

```
plot(
 plot::Scene3d(P(0..r/2), MeshVisible = TRUE),
 plot::Scene3d(P(0..r/2), Filled = FALSE),
 Scaling = Constrained, Width = 150, Height = 75,
 Axes = None, Layout = Horizontal
```

):

### Example 3

A second animation demonstrates the fold back of a cube:

```
r := 1:
bottom := [[0, 0, 0], [r, 0, 0],
 [r, r, 0], [0, r, 0]]:
left := [[0, 0, 0], [0, -r*sin(a), r*cos(a)],
 [r, -r*sin(a), r*cos(a)], [r, 0, 0]]:
right := map(left, l -> [l[1], r-l[2], l[3]]):
front := map(left, l -> [l[2], l[1], l[3]]):
back := map(right, l -> [l[2], l[1], l[3]]):
top := [left[3], left[2],
 zip(left[2], [0, -r*sin(2*a-PI/2), r*cos(2*a-PI/2)], `+`),
 zip(left[3], [0, -r*sin(2*a-PI/2), r*cos(2*a-PI/2)], `+`)]

plot(plot::SurfaceSet(map(bottom.left.top.right.front.back, op),
 MeshListType = Quads,
```

```
PointsVisible = TRUE,
PointSize = 3,
MeshVisible = TRUE,
LineWidth = 1.5,
LineColor = RGB::Grey,
a=0..PI/2),
plot::MuPADCube(Radius = r/3, Center = [r/2 $ 3]),
Scaling = Constrained)
```

```
delete r, bottom, left, right, front, back, top:
```

#### Example 4

Let's have a deeper look on the different kind of mesh types. We create a mesh of points first and then plot it using the different mesh types available. The first point will always be plotted in red color:

```
PL:= [((0,i,0.5-0.1*i), (1,i,0.5-0.1*i)) $ i = 0..5]:
S0:= FillColorFunction =
```

## plot::SurfaceSet

---

```
((n,x,y,z)->[RGB::Blue,RGB::Red,RGB::Green][(n mod 3)+1]),
LineColorFunction =
((n,x,y,z)-> if n=1 then RGB::Red else RGB::Black end_if),
PointsVisible:
V0:= plot::Camera([0.5,2.5,4.5], [0.5,2.51,0], 0.2),
ViewingBox = [0..1,0..5,0..0.5],
Axes = None:
```

We tell MuPAD to interpret the given mesh list as a set of separate triangles. The corresponding plot looks like this:

```
plot(plot::SurfaceSet(PL, S0, MeshListType = Triangles), V0):
```

We tell MuPAD to interpret the given mesh list as a triangle fan. The corresponding plot looks like this:

```
plot(plot::SurfaceSet(PL, S0, MeshListType = TriangleFan), V0):
```

The plot above looks a little bit confusing, thus we let MuPAD plot the first four triangles step by step in order to learn how the whole fan will be created:

```
plot(
 plot::Scene3d(
 plot::SurfaceSet(PL[1..3*n], S0, MeshListType = TriangleFan)
 V0
) $ n=3..6
):
```

# plot::SurfaceSet

---

We tell MuPAD to interpret the given mesh list as a triangle strip. The corresponding plot looks like this:

```
plot(plot::SurfaceSet(PL, S0, MeshListType = TriangleStrip), V0):
```

We tell MuPAD to interpret the given mesh list as a set of separate quads. The corresponding plot looks like this:

```
plot(plot::SurfaceSet(PL, S0, MeshListType = Quads), V0):
```

# plot::SurfaceSet

---

The reason for plotting triangles instead of (the expected) rectangles is the order of the points in the point list. Changing the order of the second and third point, we get the expected result:

```
PK:= PL: tmp:= PK[7]: PK[7]:= PK[10]: PK[10]:=tmp:
plot(plot::SurfaceSet(PK, S0, MeshListType = Quads), V0):
delete PK, tmp:
```

We tell MuPAD to interpret the given mesh list as a quad strip. The corresponding plot looks like this:

```
plot(plot::SurfaceSet(PL, S0, MeshListType = QuadStrip), V0):
delete PL, S0, V0:
```

## Example 5

It is possible to include normals to give smooth shading for surfaces that are not supposed to look like flat triangles. In the following example, we use a triangulation of a rectangle:

```
trias := [[(x, y], [(x+1), y], [x , (y+1)],
 [x, (y+1)], [(x+1), y], [(x+1), (y+1)]]
$ x = 1..4 $ y = 1..4]:
```

Mapping the function  $(x, y) \rightarrow \sin(x) \cos(y)$  to these points, we get the following surface plot:

```
f := (x,y) -> sin(x)*cos(y):
meshList := map(trias, l -> [l[1], l[2], f(l[1], l[2])]):
plot(plot::SurfaceSet(meshList, MeshListType = Triangles))
```

The triangulation is clearly visible. One way to reduce this would be to refine the mesh, but this may take a lot of time with more complicated functions or be completely impossible for measurement data. It is much faster to give MuPAD more information on the surface, namely, the direction of the tangent planes at the points we evaluated:

```
normals := map(trias, l -> [D([1], f)(l[1], l[2]),
 D([2], f)(l[1], l[2]), 1]):
plot(plot::SurfaceSet(zip(meshList, normals, _exprseq),
 MeshListType = Triangles,
 MeshListNormals = BehindPoints))
```

As you can see (especially at the border; otherwise, switch on `LinesVisible`), MuPAD still draws the triangles at exactly the same places, but uses a color shading to create the illusion of a smooth surface.

## Example 6

We create a triangle mesh with normals in front of each triangle and plot this object, a tetrahedron, afterwards:

```
meshList:= [
 0.0 , 0.0 , -1.0 ,
 -1.5 , -1.5 , 1.4 , 0.0 , 1.7 , 1.4 , 1.5 , -1.5 , 1.4 ,
 0.0 , 0.88 , 0.47 ,
 -1.5 , -1.5 , 1.4 , 1.5 , -1.5 , 1.4 , 0.0 , 0.0 , -1.4 ,
 -0.88 , -0.41 , 0.25 ,
 1.5 , -1.5 , 1.4 , 0.0 , 1.7 , 1.4 , 0.0 , 0.0 , -1.4 ,
 0.88 , -0.41 , 0.25 ,
 0.0 , 1.7 , 1.4 , -1.5 , -1.5 , 1.4 , 0.0 , 0.0 , -1.4
]:
```

```
plot(
 plot::SurfaceSet(meshList,
 MeshListType = Triangles,
 MeshListNormals = BeforeFacets
)
):
```

## Example 7

A color function `FillColorFunction` can be specified. The procedure is called for each vertex: the parameters are the index of the current triangle followed by the x-, y- and z-coordinate of the current vertex:

```
plot(
 plot::Scene3d(
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets,
 MeshVisible = TRUE,
 LineColor = RGB::Black,
 FillColorFunction =
```

# plot::SurfaceSet

---

```
(n ->[RGB::Red,RGB::Blue,RGB::Green,RGB::Yellow]
 [n+2 div 3])
),
plot::Scene3d(
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets,
 MeshVisible = TRUE,
 LineColor = RGB::Black,
 FillColorFunction = ((n,x,y,z) -> [x/2,y/2,z/2])
)
),
Axes = None, Layout = Horizontal
):
```

The same is true for a LineColorFunction:

```
plot(
 plot::Scene3d(
```

```
plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets,
 MeshVisible = TRUE,
 PointsVisible = TRUE,
 Filled = FALSE,
 LineWidth = 2,
 LineColorFunction =
 (n -> [RGB::Red,RGB::Blue,RGB::Green,RGB::Yellow][n+2 div
)
),
plot::Scene3d(
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets,
 MeshVisible = TRUE,
 PointsVisible = TRUE,
 Filled = FALSE,
 LineWidth = 2,
 LineColorFunction = ((n,x,y,z) -> [x/4,y/4,z/4])
)
),
Axes = None, Layout = Horizontal
):
```

## Example 8

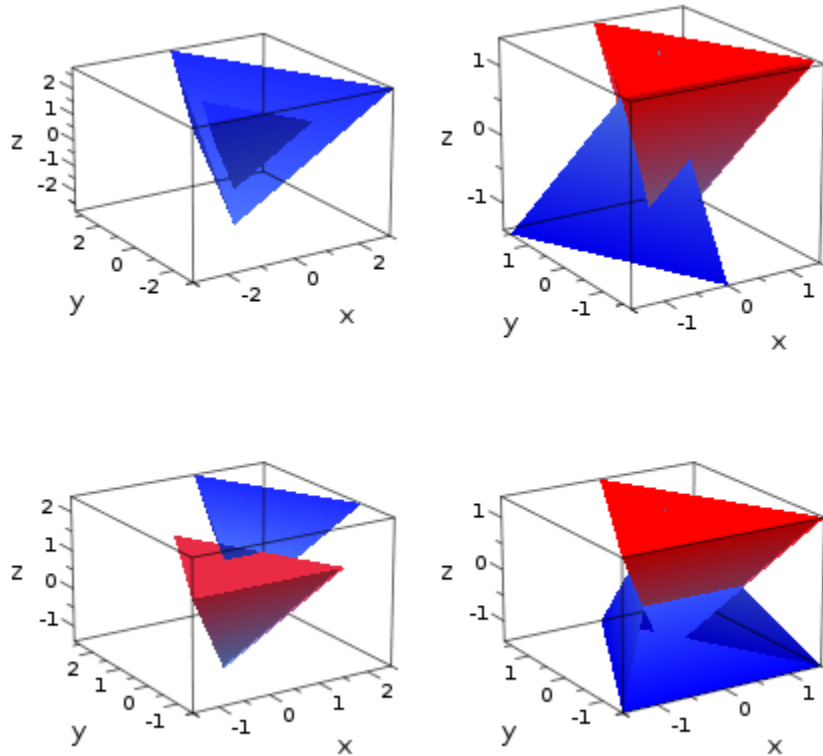

Again we plot the object defined in “Example 6” on page 23-984, but now we add a rotated, scaled and translated copy of it:

```
plot(
 plot::Scene3d(
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets),
 plot::Scale3d([2,2,2],
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets,
 Color = RGB::Blue.[0.1])
)
),
 plot::Scene3d(
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets),
 plot::Rotate3d(PI, Axis=[1,0,0],
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets,
 Color = RGB::Blue.[0.1])
)
)
)
```

```
),
plot::Scene3d(
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets),
 plot::Translate3d([1,1,1],
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets,
 Color = RGB::Blue.[0.1])
)
),
plot::Scene3d(
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets),
 plot::Transform3d([0,0,0], [1,0,0, 0,1,0, 0,0,-1],
 plot::SurfaceSet(meshList, MeshListNormals = BeforeFacets,
 Color = RGB::Blue.[0.1])
)
),
Width = 120, Height = 120
):
```

# plot::SurfaceSet

---

## Parameters

### meshlist

The point list: a list of coordinates of type DOM\_FLOAT.

meshlist is equivalent to the attribute MeshList.

### a

Animation parameter, specified as  $a = a_{\min} \dots a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Options

### MeshListType

Option, specified as `MeshListType = t`

`t` may be `Triangles`, `TriangleFan`, `TriangleStrip`, `Quads` or `QuadStrip`. This attribute specifies the kind of surface mesh given in `MeshList`. This means it specifies how the point coordinates in `MeshList` are to be interpreted.

### MeshListNormals

Option, specified as `MeshListNormals = n`

`n` may be `None`, `BeforePoints`, `BehindPoints`, `BeforeFacets` or `BehindFacets`. This attribute specifies whether `MeshList` contains normal vectors and at which positions they are located.

### UseNormals

Option, specified as `UseNormals = b`

`b` may be `TRUE` or `FALSE`. This attribute specifies whether the normals defined in the STL file are used for the MuPAD plot.

## Algorithms

The normal of a facet (a triangle or quad) given in `MeshList` is used for all its vertices when plotting this object. Due to the fact that some facets may share points with other facets, these points may be specified with different normals.

`plot::Surface` | `plot::SurfaceSTL` | `plot::Rotate3d` |  
`plot::Scale3d` | `plot::Translate3d` | `plot::Transform3d`

# plot::SurfaceSTL

---

**Purpose** Import of STL graphics files

**Syntax** `plot::SurfaceSTL(filename, <UseNormals = b>, <a = amin .. amax>, options)`

**Description** `plot::SurfaceSTL(filename)` creates a 3D surface object from the data of a given STL graphics file named "filename".

Stereolithography (STL) files were introduced in software by 3D Systems of Valencia, CA, as a simple method of storing information about 3D objects.

STL files contain triangulation data of 3D surfaces. Each triangle is stored as a unit normal and three vertices. The normal and the vertices are specified by three coordinates each, so there is a total of 12 numbers stored for each triangle. Read the 'Background' section of this help page for further details.

Depending on your hardware we recommend to plot STL objects with no more than 50.000 to 150.000 facets (triangles). You should activate the option 'Accelerate OpenGL<sup>®</sup>' in the VCam options menu.

`plot::SurfaceSTL` reacts to the MuPAD environment variable `READPATH`. For example, after

```
>> READPATH := READPATH, "C:\\STLFILES":
```

the file 'C:\\STLFILES\\xyz.stl' is found by the command

```
>> S := plot::SurfaceSTL("xyz.stl"):
```

Alternatively, the file name can be specified as an absolute pathname:

```
>> S := plot::SurfaceSTL("C:\\STLFILES\\xyz.stl"):
```

If a MuPAD notebook was saved to a file, its location is available inside the notebook as the environment variable `NOTEBOOKPATH`. If your STL file is in the same folder as the notebook, you may call

```
>> S := plot::SurfaceSTL(NOTEBOOKPATH."xyz.stl"):
```

When setting the attribute `UseNormals` to `FALSE`, the normals defined in the STL graphics file are ignored when plotting the object in MuPAD.

This reduces the data volume of the graphics object in the MuPAD session and improves the computing time as well. However, it leads to a slightly less brilliant image. Cf. “Example 2” on page 23-998.

The STL data do not include any color information. Hence, the imported graphics reacts to the usual settings of `FillColor`, `FillColorType` etc. for MuPAD surfaces.

Also user-defined color functions `LineColorFunction` and `FillColorFunction` can be used to color the imported surface. These functions are called with the index of the current triangle as its first parameter, followed by the  $x$ ,  $y$ , and  $z$  coordinate of the current point.

The transformation objects `plot::Rotate3d`, `plot::Scale3d`, `plot::Translate3d` and `plot::Transform3d` can be applied to the imported STL object. Cf. “Example 7” on page 23-1007.

If an object of type `plot::SurfaceSTL` is to be plotted together with other objects, one needs to know the coordinates of the surface objects. To this end, an object `S := plot::SurfaceSTL(...)` provides the methods `S::center` and `S::boundingBox`.

The call `S::center()` returns a list of 3 floating-point values representing the 3D center of the STL object.

The call `S::boundingBox()` returns a list of 3 ranges of floating-point values representing the ranges for the  $x$ ,  $y$ , and  $z$  coordinates of the STL surface.

See “Example 2” on page 23-998 and “Example 5” on page 23-1004.

`plot::SurfaceSTL::center(S)` and `plot::SurfaceSTL::boundingBox(S)`, respectively, are alternative calls.

Note that the STL graphics file must be read completely for computing these data. Also note that after a first call to `S::center()` or `S::boundingBox()`, the data are not recomputed by these functions even if the STL object `S` has changed. Use `plot::SurfaceSTL::center(S)`, `plot::SurfaceSTL::boundingBox(S)` in such a case.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Frames	the number of frames in an animation	50
InputFile	input file for import functions	
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LineColorType	line coloring types	Flat
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1

# plot::SurfaceSTL

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
MeshVisible	visibility of irregular mesh lines in 3D	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
PointsVisible	visibility of mesh points	FALSE
Shading	smooth color blend of surfaces	Smooth
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
UseNormals	use pre-defined normals?	TRUE
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

The following imported STL graphics consists of about 110.000 triangles:

```
plot(plot::SurfaceSTL("hand.stl"),
 CameraDirection = [15, 13, 22])
```

### Example 2

By default, the normals defined in an STL graphics file are used when plotting the object in MuPAD. Suppressing the use of these normals may reduce the data volume of the graphical object and speed up plotting. However, in general, this leads to slightly less brilliant images. For comparison, the following STL graphics is plotted with and without using its normals:

```
S1 := plot::SurfaceSTL("skin.stl");
S2 := plot::SurfaceSTL("skin.stl", UseNormals = FALSE);
```

```
plot(plot::Scene3d(S1), plot::Scene3d(S2), Layout = Vertical,
 Width = 120*unit::mm, Height = 140*unit::mm,
 Axes = None, BackgroundStyle = Pyramid):
```

# plot::SurfaceSTL

---

We compute the center and the bounding box of the surface:

```
S1::center()
```

```
[-422.035, 0.0, 282.1]
```

```
S1::boundingBox()
```

```
[-738.07..-106.0, -401.5..401.5, 156.0..408.2]
```

We rotate the object around its center:

```
plot(plot::Rotate3d(a, S1::center(), [0, 0, 1], S1,
a = 0..2*PI), Axes = None)
```

```
delete S1, S2:
```

### Example 3

The following STL graphics is displayed as a surface model and as a wireframe model:

```
nut := plot::SurfaceSTL("nut.stl"):
plot(plot::Scene3d(nut, CameraDirection = [10, 15, 30]),
 plot::Scene3d(nut, CameraDirection = [10, 15, 30],
 MeshVisible = TRUE, Filled = FALSE,
 LineColor = RGB::Black),
 Axes = None, Layout = Horizontal,
 BackgroundStyle = Pyramid):
```

```
delete nut:
```

## Example 4

For demonstrating further features of STL file import, we first create our own STL graphics file which defines a tetrahedron:

```
stlFile := "demo.stl":

fprintf(Unquoted, Text, stlFile,
 "SOLID TRI
 FACET NORMAL 0.0 0.0 -1.0
 OUTER LOOP
 VERTEX -1.5 -1.5 1.4
 VERTEX 0.0 1.7 1.4
 VERTEX 1.5 -1.5 1.4
 ENDOLOOP
 ENDFACET
 FACET NORMAL 0.0 0.88148 0.472221
 OUTER LOOP
 VERTEX -1.5 -1.5 1.4
 VERTEX 1.5 -1.5 1.4
 VERTEX 0.0 0.0 -1.4
 ENDOLOOP
 ENDFACET
 FACET NORMAL -0.876814 -0.411007 0.24954
 OUTER LOOP
 VERTEX 1.5 -1.5 1.4
 VERTEX 0.0 1.7 1.4
 VERTEX 0.0 0.0 -1.4
 ENDOLOOP
 ENDFACET
 FACET NORMAL 0.876814 -0.411007 0.24954
 OUTER LOOP
 VERTEX 0.0 1.7 1.4
 VERTEX -1.5 -1.5 1.4
 VERTEX 0.0 0.0 -1.4
 ENDOLOOP
 ENDFACET
 ENDSOLID")
```

```
ENDSOLID TRI"
)
```

This STL graphics file is imported as a MuPAD plot object and rendered:

```
plot(plot::SurfaceSTL(stlFile, MeshVisible = TRUE)):
```

We create another STL file using `export::stl`. It contains a sphere of radius 1 parametrized by spherical coordinates:

```
export::stl("sphere.stl", [cos(u)*sin(v), sin(u)*sin(v), cos(v)]
 u = 0 .. 2*PI, v = 0 .. 2*PI, Mesh = [50, 50], Scali
 OutputBox = [-1 .. 1, -1 .. 1, -1 .. 1]):

plot(plot::SurfaceSTL("sphere.stl", Scaling = Constrained)):
```

## Example 5

We plot the object defined in the STL graphics file of “Example 4” on page 23-1002 with its bounding box:

```
S := plot::SurfaceSTL(stlFile):
plot(S, plot::Box(op(S::boundingBox()),
Color = RGB::Blue.[0.1])):
```

`delete S:`

## Example 6

A color function `FillColorFunction` can be specified. This will be called with the index of the current facet as its first parameter followed by the x-, y- and z-coordinate of the current point.

We use the object defined in the STL graphics file of “Example 4” on page 23-1002:

```
mycolorlist:= [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Scene3d(plot::SurfaceSTL(stlFile,
 FillColorFunction =
 proc(n, x, y, z) begin
 mycolorlist[n]
 end_proc)),
 plot::Scene3d(plot::SurfaceSTL(stlFile,
 FillColorFunction =
```

# plot::SurfaceSTL

---

```
proc(n, x, y, z) begin
 [abs(x)/2, abs(y)/2, abs(z)/2]
end_proc)),
Axes = None, Layout = Horizontal):
```

We define a LineColorFunction:

```
plot(plot::Scene3d(plot::SurfaceSTL(stlFile,
 LineColorFunction =
 proc(n, x, y, z) begin
 mycolorlist[n]
 end_proc)),
 plot::Scene3d(plot::SurfaceSTL(stlFile,
 LineColorFunction =
 proc(n, x, y, z) begin
 [abs(x)/2, abs(y)/2, abs(z)/2]
 end_proc)),
 Axes = None, Filled = FALSE, MeshVisible = TRUE,
```

```
LineWidth = 2*unit::mm, Layout = Horizontal):
```

```
delete mycolorlist:
```

## Example 7

Again, we plot the object of the STL graphics file defined in “Example 4” on page 23-1002. Here, we add rotated, scaled and translated copies:

```
plot(
 plot::Scene3d(
 plot::SurfaceSTL(stlFile),
 plot::Scale3d([2, 2, 2],
 plot::SurfaceSTL(stlFile, Color = RGB::Blue.[0.1])
)
),
 plot::Scene3d(
 plot::SurfaceSTL(stlFile),
 plot::Rotate3d(PI, Axis = [1, 0, 0],
```

# plot::SurfaceSTL

---

```
 plot::SurfaceSTL(stlFile, Color = RGB::Blue.[0.1])
)
),
plot::Scene3d(
 plot::SurfaceSTL(stlFile),
 plot::Translate3d([1, 1, 1],
 plot::SurfaceSTL(stlFile, Color = RGB::Blue.[0.1])
)
),
plot::Scene3d(
 plot::SurfaceSTL(stlFile),
 plot::Transform3d([0, 0, 0], [1, 0, 0, 0, 1, 0, 0, 0, -1],
 plot::SurfaceSTL(stlFile, Color = RGB::Blue.[0.1])
)
),
Width = 120*unit::mm, Height = 120*unit::mm):
```

### Example 8

STL objects can be animated. The tetrahedron defined in “Example 4” on page 23-1002 moves around a box:

```

S0 := plot::SurfaceSTL(stlFile):
B0 := plot::Box(op(S0::boundingBox(S0)), Color = RGB::Blue.[0.1])
GO := [6*sin(a), -6*cos(a), 4*cos(2*a)], a = 0..2*PI:
CU := plot::Curve3d(GO):

```

# plot::SurfaceSTL

---

```
plot(B0, CU, plot::Translate3d(G0, S0),
 ViewingBox = [-8..8, -8..8, -6..6]):
```

Below, the color function FillColorFunction of an STL object is animated:

```
plot(plot::SurfaceSTL(stlFile,
 MeshVisible = TRUE,
 LineColor = RGB::Black,
 FillColorFunction =
 proc(n, x, y, z) begin
 [sin(x + a)^2 ,sin(y + a)^2, sin(z + a)^2]
 end_proc,
 a = 0..2*PI, TimeRange = 1..4),
 Axes = None, Layout = Horizontal)
```

`delete S0, B0, G0, CU, stlFile:`

## Parameters

### **filename**

The file name: a character string of type DOM\_STRING.

filename is equivalent to the attribute InputFile.

### **a**

Animation parameter, specified as  $a = a_{\min}..a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Options

### **UseNormals**

Option, specified as `UseNormals = b`

b may be TRUE or FALSE. This attribute specifies whether the normals defined in the STL file are used for the MuPAD plot.

## Algorithms

The STL sample files presented on this help page were taken from the ftp site of the Clemson University, South Carolina, USA:

[ftp.vr.clemson.edu/pub/rp/STL\\_objects](ftp.vr.clemson.edu/pub/rp/STL_objects).

There are two storage formats available for STL files, which are ASCII and BINARY. ASCII files are human-readable while BINARY files are smaller and faster to process. Both formats can be read by `plot::SurfaceSTL`. A typical ASCII STL file looks like this:

```
solid sample
facet normal -4.470293E-02 7.003503E-01 -7.123981E-01
 outer loop
 vertex -2.812284E+00 2.298693E+01 0.000000E+00
 vertex -2.812284E+00 2.296699E+01 -1.960784E-02
 vertex -3.124760E+00 2.296699E+01 0.000000E+00
 endloop
endfacet
...
endsolid sample
```

STL BINARY files have the following format:

Bytes	Type	Description
80	ASCII	header, no data significance
4	uint	number of facets in file
4	float	normal x - start of facet
4	float	normal y
4	float	normal z
4	float	vertex1 x
4	float	vertex1 y
4	float	vertex1 z
4	float	vertex2 x
4	float	vertex2 y
4	float	vertex2 z

```
4 float vertex3 x
4 float vertex3 y
4 float vertex3 z
2 byte not used - end of facet
...

```

Facet orientation: The facets define the surface of a 3D object. As such, each facet is part of the boundary between the interior and the exterior of the object. The orientation of the facets (which way is "out" and which way is "in") is specified redundantly in two ways which should be consistent. First, the direction of the normal is outward. Second, which is most commonly used nowadays, the facet vertices are listed in counterclockwise order when looking at the object from the outside (right-hand rule).

Vertex-to-vertex rule: Each triangle must share two vertices with each of its adjacent triangles. In other words, a vertex of one triangle cannot lie on the side of another.

Axes: The format specifies that all vertex coordinates must be strictly positive numbers. However, it seems that — with a few exceptions — most software used today (MuPAD included) allow negative coordinates as well.

Units: The STL file does not contain any scale information; the coordinates may be interpreted in arbitrary units.

Further details about the STL file format are available in the web, e.g., at:

- [www.ennex.com/fabbers/StL.asp](http://www.ennex.com/fabbers/StL.asp),
- [www.math.iastate.edu/burkardt/data/stl/stl.html](http://www.math.iastate.edu/burkardt/data/stl/stl.html) and
- [rpdrc.ic.polyu.edu.hk/content/stl/stl\\_introduction.htm](http://rpdrc.ic.polyu.edu.hk/content/stl/stl_introduction.htm).

Collections of STL sample files can be found in the web, e.g., at:

# plot::SurfaceSTL

---

- [www.wohlersassociates.com/Software-for-Rapid-Prototyping.html](http://www.wohlersassociates.com/Software-for-Rapid-Prototyping.html) and
- [www.cs.duke.edu/~edels/Tubes](http://www.cs.duke.edu/~edels/Tubes).

Information about rapid prototyping technologies is available in the web, e.g., at:

[www.cs.hut.fi/~ado/rp/rp.html](http://www.cs.hut.fi/~ado/rp/rp.html).

Note that MuPAD only accepts the following notations for the keywords “facet” and “vertex” in STL ASCII files: facet, FACET, Facet and vertex, VERTEX, Vertex, respectively.

The normal of a facet defined in an STL file is used for all its vertices when plotting this object. Due to the fact that some facets (triangles) share points with other ones, these points are plotted with different normals.

## Purpose

Sweep surface from the deformation of a 3D curve

## Syntax

```
plot::Sweep([x1, y1, z1], <Ground = g>, u = umin ..
umax, <a = amin .. amax>, options)
plot::Sweep(A1, <Ground = g>, u = umin .. umax, <a
= amin .. amax>, options)
plot::Sweep(C1, <Ground = g>, options)
plot::Sweep([x1, y1, z1], [x2, y2, z2], u = umin ..
umax, <a = amin .. amax>, options)
plot::Sweep(A1, A2, u = umin .. umax, <a = amin ..
amax>, options)
plot::Sweep(C1, C2, options)
```

## Description

`plot::Sweep([x1(u), y1(u), z1(u)], u = `umin` .. `umax`)` creates the surface swept out by the (linear) deformation of the parameterized curve  $(x_1(u), y_1(u), z_1(u))$  to its projection  $(x_1(u), y_1(u), 0)$  to the  $x$ - $y$ -plane.

`plot::Sweep([x1(u), y1(u), z1(u)], [x2(u), y2(u), z2(u)], u = `umin` .. `umax`)` creates the surface swept out by the (linear) deformation of the parameterized curve  $(x_1(u), y_1(u), z_1(u))$  to the parameterized curve  $(x_2(u), y_2(u), z_2(u))$ .

`plot::Sweep` creates the parametrized surface

$$\begin{aligned} X(u, v) &= X_1(u) + v (X_2(u) - X_1(u)) \\ Y(u, v) &= Y_1(u) + v (Y_2(u) - Y_1(u)) \\ Z(u, v) &= Z_1(u) + v (Z_2(u) - Z_1(u)) \end{aligned}$$

with the two surface parameters  $u$  (ranging from  $u_{\min}$  to  $u_{\max}$ ) and  $v$  (ranging from 0 to 1). This is the linear deformation of the curve  $(x_1(u), y_1(u), z_1(u))$  defining one border of the surface to the curve  $(x_2(u), y_2(u), z_2(u))$  defining the other border of the surface.

If no “target curve”  $(x_2(u), y_2(u), z_2(u))$  is specified, the projection  $x_2(u) = x_1(u), y_2(u) = y_1(u), z_2(u) = g$  of the “source curve”  $(x_1(u), y_1(u), z_1(u))$  to

# plot::Sweep

---

the  $x$ - $y$ -plane with constant value  $z = g$  is used. The value  $g$  is set by the attribute `Ground = g`. The default value is  $g = 0$ .

When a target curve  $[x_2(u), y_2(u), z_2(u)]$  is specified, the `Ground` attribute does not have any effect.

If the curves are specified by objects  $C_1, C_2$  of type `plot::Curve3d`, the graphical attributes of the object created by `plot::Sweep` are copied from  $C_1$ . The parametrization of  $C_2$  is automatically rewritten in terms of the curve parameter used in the definition of  $C_1$ . This, however, will only work if the parametrization of  $C_2$  is defined by symbolic expressions.

---

**Note** If the parametrization of  $C_2$  is defined by procedures, make sure that the parameter ranges of  $C_1$  and  $C_2$  coincide!

---

## Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	0

## Examples

### Example 1

We deform a 3D spiral to its projection to the  $x$ - $y$ -plane:

```
plot(plot::Sweep([u*cos(u), u*sin(u), u], u = 0..4*PI),
 CameraDirection = [90, 50, 120])
```

# plot::Sweep

---

We use the `Ground` attribute to project the spiral to the  $x$ - $y$ -plane with  $z = 9$ :

```
plot(plot::Sweep([u*cos(u), u*sin(u), u], u = 0..4*PI, Ground = 9),
 CameraDirection = [130, 60, 45])
```

### Example 2

We deform a circle in the  $x$ - $y$ -plane to a planar spiral:

```
plot(plot::Sweep([cos(u), sin(u), 0], [u*cos(u), u*sin(u), 0],
 u = PI/3..7/3*PI), Scaling = Constrained)
```

# plot::Sweep

---

With `Filled = FALSE`, only the lines are visible along which the mesh points of the curves are moved:

```
plot(plot::Sweep([cos(u), sin(u), 0], [u*cos(u), u*sin(u), 0],
 u = PI/3..7/3*PI), Scaling = Constrained,
 Filled = FALSE)
```

We increase the number of mesh points:

```
plot(plot::Sweep([cos(u), sin(u), 0], [u*cos(u), u*sin(u), 0],
 u = PI/3..7/3*PI, Mesh = 50),
 Scaling = Constrained, Filled = FALSE)
```

### Example 3

We deform a circle to an animated point. The resulting sweep surface is an animated cone:

```
plot(plot::Sweep([cos(u), sin(u), 0], [a, 0, a],
 u = 0..2*PI, a = 0..2))
```

## Parameters

### $x_1, y_1, z_1$

The parametrization of the initial 3D curve: real-valued expressions in  $u$  (and possibly the animation parameter).

$x_1, y_1, z_1$  are equivalent to the attributes XFunction1, YFunction1, ZFunction1.

### $x_2, y_2, z_2$

The parametrization of the “target curve”: real-valued expressions in  $u$  (and possibly the animation parameter).

$x_2, y_2, z_2$  are equivalent to the attributes XFunction2, YFunction2, ZFunction2.

### $u$

The curve parameter: an identifier or an indexed identifier.

$u$  is equivalent to the attribute UName.

# plot::Sweep

---

**$u_{\min}$ ,  $u_{\max}$**

Real-valued expressions (possibly in the animation parameter).

$u_{\min}$ ,  $u_{\max}$  are equivalent to the attributes UMin, UMax.

**$g$**

Real-valued expression (possibly in the animation parameter).

$g$  is equivalent to the attribute Ground.

**$A_1$ ,  $A_2$**

matrices of category `Cat::Matrix` with three entries that provide the parametrizations  $x_1$ ,  $y_1$ ,  $z_1$  and  $x_2$ ,  $y_2$ ,  $z_2$ , respectively.

**$C_1$ ,  $C_2$**

Curves of type `plot::Curve3d`.  $C_1$  provides the “initial curve” [ $x_1$ ,  $y_1$ ,  $z_1$ ],  $C_2$  provides the “target curve” [ $x_2$ ,  $y_2$ ,  $z_2$ ].

**$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

`plot::Curve3d` | `plot::Polygon3d` | `plot::Surface` |  
`plot::Hatch`

**Purpose** Regular Tetrahedra

**Syntax** `plot::Tetrahedron(<a = amin .. amax>, options)`

**Description** `plot::Tetrahedron()` creates regular polyhedra.

Per default, all polyhedra are centered at the origin. The attribute `Center` allows to choose a different center. This is helpful to align the polyhedra relative to other objects in the graphical scene. Cf. “Example 1” on page 23-1034.

All polyhedra fit into a box extending from -1 to 1 in all coordinate directions. Their size can be changed by the attribute `Radius`. In case of a hexahedron (a box), this attribute represents the radius of the inscribed sphere. For the other polyhedra, it is the radius of the circumscribed sphere.

The default value of `Radius` is 1 for all polyhedra.

Further to the attributes `Center` and `Radius`, you can modify the polyhedra by applying transformation objects of type `plot::Rotate3d`, `plot::Scale3d`, `plot::Translate3d`, and `plot::Transform3d`. Cf. “Example 3” on page 23-1037.

User-defined color functions (`LineColorFunction`, `FillColorFunction`) are called with the index of the current facet as its first parameter, followed by the  $x$ ,  $y$ , and  $z$  coordinate of the current point, followed by the current value of the animation parameter (if animated). Cf. “Example 4” on page 23-1038.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	<code>TRUE</code>
<code>Center</code>	center of objects, rotation center	<code>[0, 0, 0]</code>

# plot::Tetrahedron

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
CenterZ	center of objects, rotation center, z-component	0
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0

Attribute	Purpose	Default Value
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend

TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

# plot::Tetrahedron

---

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

Using different Centers, the five regular polyhedra are placed side by side:

```
plot(plot::Hexahedron (Center = [0, 0, 0]),
 plot::Tetrahedron (Center = [3, 0, 0]),
 plot::Octahedron (Center = [6, 0, 0]),
 plot::Icosahedron (Center = [9, 0, 0]),
 plot::Dodecahedron(Center = [12, 0, 0]),
 Axes = Frame);
```

With the attribut `Radius`, the size of the polyhydra can be changed:

```
plot(plot::Hexahedron (Radius = 1.0, Center = [0, 0, 0]),
 plot::Tetrahedron (Radius = 1.5, Center = [4, 0, 0]),
 plot::Octahedron (Radius = 2.0, Center = [8, 0, 0]),
 plot::Icosahedron (Radius = 2.5, Center = [13, 0, 0]),
 plot::Dodecahedron(Radius = 3.0, Center = [19, 0, 0]),
 Axes = Frame);
```

# plot::Tetrahedron

---

## Example 2

A tetrahedron and an octahedron are embedded in a hexahedron:

```
plot(plot::Hexahedron (FillColorFunction = RGB::Red.[0.2],
 VisibleFromTo = 0..8),
 plot::Tetrahedron(FillColorFunction = RGB::Green.[0.2],
 VisibleFromTo = 1..5),
 plot::Octahedron (FillColorFunction = RGB::Blue.[0.2],
 VisibleFromTo = 3..7),
 Axes = None)
```

### Example 3

Transformation objects can be applied to polyhedra as demonstrated below:

```
H := plot::Hexahedron(Color = RGB::Blue.[0.2],
 FillColorType = Flat):
T := plot::Tetrahedron(Color = RGB::Red):
plot(plot::Rotate3d(a, [0, 0, 0], [0, 0, 1], a = 0..2*PI,
 H,
 plot::Translate3d([0, 0, a], T, a = 0..2)
), Axes = None)
```

# plot::Tetrahedron

---

```
delete T, H:
```

## Example 4

A `FillColorFunction` can be specified. This will be called with the index of the current facet as its first parameter, followed by the  $x$ -,  $y$ - and  $z$ -coordinate of the current point:

```
mycolorlist := [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Dodecahedron(Center = [0, 0, 0],
 FillColorFunction =
 proc(n, x, y, z) begin
 [(1 + x)/2, (1 + y)/2, (1 + z)/2]
 end_proc),
 plot::Dodecahedron(Center = [3, 0, 0],
 FillColorFunction =
 proc(n, x, y, z) begin
 mycolorlist[(n mod 4)+1]
 end_proc),
```

Axes = None):

The same holds true for a LineColorFunction:

```
plot(plot::Icosahedron(Center = [0, 0, 0],
 LineColorFunction =
 proc(n, x, y, z) begin
 [(1 + x)/2, (1 + y)/2, (1 + z)/2]
 end_proc),
 plot::Icosahedron(Center = [3, 0, 0],
 LineColorFunction =
 proc(n, x, y, z) begin
 mycolorlist[(n mod 4)+1]
 end_proc),
 Axes = None, LineWidth = 1.0*unit::mm,
 FillColor = RGB::Grey80, FillColorType = Flat):
```

# plot::Tetrahedron

---

If the polyhedron is animated, the color functions are called with an additional argument: the current value of the animation parameter:

```
plot(plot::Octahedron(FillColorFunction =
 proc(n, x, y, z, a)
 begin
 [sin(n*a)^2, cos(n*a)^2, 1]:
 end_proc,
 a = 0..2*PI))
```

`delete mycolorlist:`

## Algorithms

A polyhedron is called regular if all its facets consist of the same regular polygon and each vertex has the same number of coincidence polygons.

Since Plato we know that only five regular polyhedrons exist:

- the tetrahedron with 4 (greek *tetra*) triangles,
- the hexahedron with 6 (greek *hexa*) squares,
- the octahedron with 8 (greek *okta*) triangles,
- the dodecahedron with 12 (greek *dodeka*) pentagons and
- the icosahedron with 20 (greek *eikosi*) triangles.

The following table lists some important geometrical data of the polyhedra with the edge length  $a$ . Where  $R$  is the radius of the outer

# plot::Tetrahedron

sphere  $r$  the radius of the inner sphere,  $A$  the surface area and  $V$  the volume:

Ratio	Tetrahedron	Hexahedron	Octahedron	Dodecahedron	Icosahedron
$\frac{R}{a}$	$\frac{\sqrt{6}}{4}$	$\frac{\sqrt{3}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{3}(1+\sqrt{5})}{4}$	$\frac{\sqrt{10+2\sqrt{5}}}{4}$
$\frac{r}{a}$	$\frac{\sqrt{6}}{12}$	$\frac{1}{2}$	$\frac{\sqrt{6}}{6}$	$\frac{\sqrt{250+110\sqrt{5}}}{20}$	$\frac{\sqrt{5}\sqrt{3(3+\sqrt{5})}}{12}$
$\frac{A}{a^2}$	$\sqrt{3}$	6	$2\sqrt{3}$	$3\sqrt{25+10\sqrt{5}}$	$5\sqrt{3}$
$\frac{V}{a^3}$	$\frac{\sqrt{2}}{12}$	1	$\frac{\sqrt{2}}{3}$	$\frac{(15+7\sqrt{5})}{4}$	$\frac{5(3+\sqrt{5})}{12}$

 plot::Translate3d([0, 0, a], T, a = 0..2)
), Axes = None)
```

# plot::Octahedron

---

```
delete T, H:
```

## Example 4

A `FillColorFunction` can be specified. This will be called with the index of the current facet as its first parameter, followed by the  $x$ -,  $y$ - and  $z$ -coordinate of the current point:

```
mycolorlist := [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Dodecahedron(Center = [0, 0, 0],
 FillColorFunction =
 proc(n, x, y, z) begin
 [(1 + x)/2, (1 + y)/2, (1 + z)/2]
 end_proc),
 plot::Dodecahedron(Center = [3, 0, 0],
 FillColorFunction =
 proc(n, x, y, z) begin
 mycolorlist[(n mod 4)+1]
 end_proc),
```

Axes = None):

The same holds true for a LineColorFunction:

```
plot(plot::Icosahedron(Center = [0, 0, 0],
 LineColorFunction =
 proc(n, x, y, z) begin
 [(1 + x)/2, (1 + y)/2, (1 + z)/2]
 end_proc),
 plot::Icosahedron(Center = [3, 0, 0],
 LineColorFunction =
 proc(n, x, y, z) begin
 mycolorlist[(n mod 4)+1]
 end_proc),
 Axes = None, LineWidth = 1.0*unit::mm,
 FillColor = RGB::Grey80, FillColorType = Flat):
```

# plot::Octahedron

---

If the polyhedron is animated, the color functions are called with an additional argument: the current value of the animation parameter:

```
plot(plot::Octahedron(FillColorFunction =
 proc(n, x, y, z, a)
 begin
 [sin(n*a)^2, cos(n*a)^2, 1]:
 end_proc,
 a = 0..2*PI))
```

```
delete mycolorlist:
```

## Algorithms

A polyhedron is called regular if all its facets consist of the same regular polygon and each vertex has the same number of coincidence polygons.

Since Plato we know that only five regular polyhedrons exist:

- the tetrahedron with 4 (greek *tetra*) triangles,
- the hexahedron with 6 (greek *hexa*) squares,
- the octahedron with 8 (greek *okta*) triangles,
- the dodecahedron with 12 (greek *dodeka*) pentagons and
- the icosahedron with 20 (greek *eikosi*) triangles.

The following table lists some important geometrical data of the polyhedra with the edge length  $a$ . Where  $R$  is the radius of the outer

# plot::Octahedron

sphere  $r$  the radius of the inner sphere,  $A$  the surface area and  $V$  the volume:

Ratio	Tetrahedron	Hexahedron	Octahedron	Dodecahedron	Icosahedron
$\frac{R}{a}$	$\frac{\sqrt{6}}{4}$	$\frac{\sqrt{3}}{2}$	$\frac{\sqrt{2}}{2}$	$\frac{\sqrt{3}(1+\sqrt{5})}{4}$	$\frac{\sqrt{10+2\sqrt{5}}}{4}$
$\frac{r}{a}$	$\frac{\sqrt{6}}{12}$	$\frac{1}{2}$	$\frac{\sqrt{6}}{6}$	$\frac{\sqrt{250+110\sqrt{5}}}{20}$	$\frac{\sqrt{5}\sqrt{3(3+\sqrt{5})}}{12}$
$\frac{A}{a^2}$	$\sqrt{3}$	6	$2\sqrt{3}$	$3\sqrt{25+10\sqrt{5}}$	$5\sqrt{3}$
$\frac{V}{a^3}$	$\frac{\sqrt{2}}{12}$	1	$\frac{\sqrt{2}}{3}$	$\frac{(15+7\sqrt{5})}{4}$	$\frac{5(3+\sqrt{5})}{12}$

plot::Tetrahedron | plot::Hexahedron | plot::Dodecahedron | plot::Icosahedron | plot::Box | plot::Cone | plot::Cylinder | plot::Sphere | plot::Parallelogram3d | plot::Transform3d

**Purpose** Regular Dodecahedra

**Syntax** `plot::Dodecahedron(<a = amin .. amax>, options)`

**Description** `plot::Dodecahedron()` creates regular polyhedra.

Per default, all polyhedra are centered at the origin. The attribute `Center` allows to choose a different center. This is helpful to align the polyhedra relative to other objects in the graphical scene. Cf. “Example 1” on page 23-1076.

All polyhedra fit into a box extending from -1 to 1 in all coordinate directions. Their size can be changed by the attribute `Radius`. In case of a hexahedron (a box), this attribute represents the radius of the inscribed sphere. For the other polyhedra, it is the radius of the circumscribed sphere.

The default value of `Radius` is 1 for all polyhedra.

Further to the attributes `Center` and `Radius`, you can modify the polyhedra by applying transformation objects of type `plot::Rotate3d`, `plot::Scale3d`, `plot::Translate3d`, and `plot::Transform3d`. Cf. “Example 3” on page 23-1079.

User-defined color functions (`LineColorFunction`, `FillColorFunction`) are called with the index of the current facet as its first parameter, followed by the  $x$ ,  $y$ , and  $z$  coordinate of the current point, followed by the current value of the animation parameter (if animated). Cf. “Example 4” on page 23-1080.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	<code>TRUE</code>
<code>Center</code>	center of objects, rotation center	<code>[0, 0, 0]</code>

# plot::Dodecahedron

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
CenterZ	center of objects, rotation center, z-component	0
Color	the main color	RGB::Red
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0

Attribute	Purpose	Default Value
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]

TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

# plot::Dodecahedron

---

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

Using different Centers, the five regular polyhedra are placed side by side:

```
plot(plot::Hexahedron (Center = [0, 0, 0]),
 plot::Tetrahedron (Center = [3, 0, 0]),
 plot::Octahedron (Center = [6, 0, 0]),
 plot::Icosahedron (Center = [9, 0, 0]),
 plot::Dodecahedron(Center = [12, 0, 0]),
 Axes = Frame);
```

With the attribut `Radius`, the size of the polyhydra can be changed:

```
plot(plot::Hexahedron (Radius = 1.0, Center = [0, 0, 0]),
 plot::Tetrahedron (Radius = 1.5, Center = [4, 0, 0]),
 plot::Octahedron (Radius = 2.0, Center = [8, 0, 0]),
 plot::Icosahedron (Radius = 2.5, Center = [13, 0, 0]),
 plot::Dodecahedron(Radius = 3.0, Center = [19, 0, 0]),
 Axes = Frame);
```

# plot::Dodecahedron

---

## Example 2

A tetrahedron and an octahedron are embedded in a hexahedron:

```
plot(plot::Hexahedron (FillColorFunction = RGB::Red.[0.2],
 VisibleFromTo = 0..8),
 plot::Tetrahedron(FillColorFunction = RGB::Green.[0.2],
 VisibleFromTo = 1..5),
 plot::Octahedron (FillColorFunction = RGB::Blue.[0.2],
 VisibleFromTo = 3..7),
 Axes = None)
```

### Example 3

Transformation objects can be applied to polyhedra as demonstrated below:

```
H := plot::Hexahedron(Color = RGB::Blue.[0.2],
 FillColorType = Flat):
T := plot::Tetrahedron(Color = RGB::Red):
plot(plot::Rotate3d(a, [0, 0, 0], [0, 0, 1], a = 0..2*PI,
 H,
 plot::Translate3d([0, 0, a], T, a = 0..2)
), Axes = None)
```

# plot::Dodecahedron

---

```
delete T, H:
```

## Example 4

A `FillColorFunction` can be specified. This will be called with the index of the current facet as its first parameter, followed by the  $x$ -,  $y$ - and  $z$ -coordinate of the current point:

```
mycolorlist := [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Dodecahedron(Center = [0, 0, 0],
 FillColorFunction =
 proc(n, x, y, z) begin
 [(1 + x)/2, (1 + y)/2, (1 + z)/2]
 end_proc),
 plot::Dodecahedron(Center = [3, 0, 0],
 FillColorFunction =
 proc(n, x, y, z) begin
 mycolorlist[(n mod 4)+1]
 end_proc),
```

Axes = None):

The same holds true for a LineColorFunction:

```
plot(plot::Icosahedron(Center = [0, 0, 0],
 LineColorFunction =
 proc(n, x, y, z) begin
 [(1 + x)/2, (1 + y)/2, (1 + z)/2]
 end_proc),
 plot::Icosahedron(Center = [3, 0, 0],
 LineColorFunction =
 proc(n, x, y, z) begin
 mycolorlist[(n mod 4)+1]
 end_proc),
 Axes = None, LineWidth = 1.0*unit::mm,
 FillColor = RGB::Grey80, FillColorType = Flat):
```

# plot::Dodecahedron

---

If the polyhedron is animated, the color functions are called with an additional argument: the current value of the animation parameter:

```
plot(plot::Octahedron(FillColorFunction =
 proc(n, x, y, z, a)
 begin
 [sin(n*a)^2, cos(n*a)^2, 1]:
 end_proc,
 a = 0..2*PI))
```

`delete mycolorlist:`

## Algorithms

 plot::Dodecahedron(Center = [12, 0, 0]),
 Axes = Frame);
```

With the attribut `Radius`, the size of the polyhydra can be changed:

```
plot(plot::Hexahedron (Radius = 1.0, Center = [0, 0, 0]),
 plot::Tetrahedron (Radius = 1.5, Center = [4, 0, 0]),
 plot::Octahedron (Radius = 2.0, Center = [8, 0, 0]),
 plot::Icosahedron (Radius = 2.5, Center = [13, 0, 0]),
 plot::Dodecahedron(Radius = 3.0, Center = [19, 0, 0]),
 Axes = Frame);
```

# plot::Icosahedron

---

## Example 2

A tetrahedron and an octahedron are embedded in a hexahedron:

```
plot(plot::Hexahedron (FillColorFunction = RGB::Red.[0.2],
 VisibleFromTo = 0..8),
 plot::Tetrahedron(FillColorFunction = RGB::Green.[0.2],
 VisibleFromTo = 1..5),
 plot::Octahedron (FillColorFunction = RGB::Blue.[0.2],
 VisibleFromTo = 3..7),
 Axes = None)
```

### Example 3

Transformation objects can be applied to polyhedra as demonstrated below:

```
H := plot::Hexahedron(Color = RGB::Blue.[0.2],
 FillColorType = Flat):
T := plot::Tetrahedron(Color = RGB::Red):
plot(plot::Rotate3d(a, [0, 0, 0], [0, 0, 1], a = 0..2*PI,
 H,
 plot::Translate3d([0, 0, a], T, a = 0..2)
), Axes = None)
```

```
delete T, H:
```

## Example 4

A `FillColorFunction` can be specified. This will be called with the index of the current facet as its first parameter, followed by the  $x$ -,  $y$ - and  $z$ -coordinate of the current point:

```
mycolorlist := [RGB::Red, RGB::Blue, RGB::Green, RGB::Yellow]:
plot(plot::Dodecahedron(Center = [0, 0, 0],
 FillColorFunction =
 proc(n, x, y, z) begin
 [(1 + x)/2, (1 + y)/2, (1 + z)/2]
 end_proc),
 plot::Dodecahedron(Center = [3, 0, 0],
 FillColorFunction =

 plot::Cylinder | plot::Sphere | plot::Parallelogram3d |  
 plot::Transform3d

**Purpose** 2D text

**Syntax** `plot::Text2d(text, [x, y], <a = amin .. amax>, options)`

**Description** `plot::Text2d` draws a text at a given position  $(x, y)$  (the “anchor point”). The attributes `VerticalAlignment` and `HorizontalAlignment` determine the alignment of the text w.r.t. its anchor.

Size, text color, font type etc. are controlled by the attribute `TextFont`.

A text may consist of several lines. The newline character in MuPAD strings is `\n`. For example: "first line\nsecond line".

The attribute `TextRotation` allows to rotate the text on the screen.

The text of a text object can be animated if it is passed as a procedure that returns the text string during runtime. Cf. “Example 5” on page 23-1105.

## Attributes

Attribute	Purpose	Default Value

# plot::Text2d

---

## Examples

### Example 1

We draw the text string 'Hello world!' at the anchor point (1, 2) which is indicated by a red dot:

```
plot(plot::Rectangle(0..2, 0..4),
 plot::Point2d([1, 2]),
 plot::Text2d("Hello world!", [1, 2],
 HorizontalAlignment = Center),
 Axes = Frame, TextFont = [24],
 PointColor = RGB::Red, PointSize = 3*unit::mm)
```

### Example 2

We animate the anchor points of the following texts and demonstrate various alignment possibilities:

```
plot(plot::Circle2d(1),
 plot::Point2d([sin(a), cos(a)], a = 0..2*PI),
```

```

plot::Point2d([cos(a), -sin(a)], a = 0..2*PI),
plot::Point2d([-sin(a), -cos(a)], a = 0..2*PI),
plot::Point2d([-cos(a), sin(a)], a = 0..2*PI),
PointColor = RGB::Red, PointSize = 3*unit::mm,
plot::Text2d("Hello (1)", [sin(a), cos(a)], a = 0..2*PI),
plot::Text2d("Hello (2)", [cos(a), -sin(a)], a = 0..2*PI,
 HorizontalAlignment = Left,
 VerticalAlignment = BaseLine),
plot::Text2d("Hello (3)", [-sin(a), -cos(a)], a = 0..2*PI,
 HorizontalAlignment = Center,
 VerticalAlignment = Top),
plot::Text2d("Hello (4)", [-cos(a), sin(a)], a = 0..2*PI,
 HorizontalAlignment = Right,
 VerticalAlignment = Bottom),
TextFont = [Italic, 24], Axes = Frame)

```

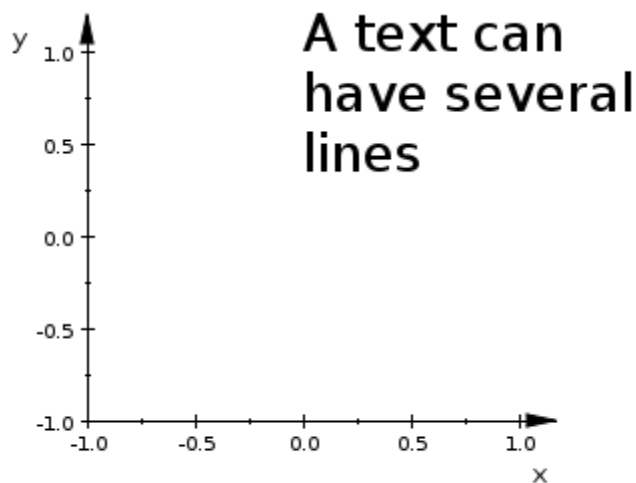

# plot::Text2d

---

## Example 3

A text may consist of several lines. The newline character in MuPAD strings is `\n`:

```
plot(plot::Text2d("A text can\nhave several\nlines",
 [sin(a), cos(a)], a = 0..2*PI),
 Axes = Frame, TextFont = [20])
```

## Example 4

The attribute `TextRotation` allows to rotate a 2D text on the screen:

```
plot(plot::Circle2d(sqrt(2)),
 plot::Text2d("Hello (1)", [1, 1],
 HorizontalAlignment = Left,
 TextRotation = PI/4),
 plot::Text2d("Hello (2)", [1, -1],
 HorizontalAlignment = Left,
```

```

 TextRotation = -PI/4),
plot::Text2d("Hello (3)", [-1,-1],
 HorizontalAlignment = Right,
 TextRotation = PI/4),
plot::Text2d("Hello (4)", [-1, 1],
 HorizontalAlignment = Right,
 TextRotation = -PI/4),
 HorizontalAlignment = Left, TextFont = [20])

```

### Example 5

The text of a text object can be animated if the text string is provided by a procedure. We use `stringlib::formatf` to format the animation parameter that is passed to the procedure as a floating-point number for each frame of the animation:

```

plot(plot::Rectangle(-1..1, -1..1),
 plot::Text2d(a -> stringlib::formatf(a, 2, 5)." sec",
 [0, 0], a = 0..20),

```

# plot::Text2d

---

```
TextFont = [60],
HorizontalAlignment = Center, VerticalAlignment = Center,
Axes = Frame, Frames = 201, TimeRange = 0..20)
```

## Parameters

### text

The text: a string. Alternatively, a procedure that accepts one input parameter  $a$  (the animation parameter) and returns a string.

text is equivalent to the attribute Text.

### x, y

The position of the text. The coordinates  $x$  and  $y$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x$ ,  $y$  are equivalent to the attributes Position, PositionX, PositionY.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Functions

`plot` | `plot::copy` | `stringlib::formatf`

### MuPAD Graphical Primitives

`plot::Text3d`

# plot::Text3d

---

**Purpose** 3D text

**Syntax** `plot::Text3d(text, [x, y, z], <a = amin .. amax>, options)`

**Description** `plot::Text3d` draws a text at a given position  $(x, y, z)$  (the “anchor point”). The attributes `VerticalAlignment` and `HorizontalAlignment` determine the alignment of the text w.r.t. its anchor.

Size, text color, font type etc. are controlled by the attribute `TextFont`.

In contrast to `plot::Text2d`, a 3D text cannot consist of several lines. The newline character `\n` in MuPAD strings does not have an effect.

By default, a 3D text uses `Billboarding = TRUE`, i.e., the text is automatically oriented such that it is readable by the observer. When setting `Billboarding = FALSE`, the attribute `TextOrientation` allows to fix the orientation of the text arbitrarily in space. See the help page of `TextOrientation` for details.

The text of a text object can be animated if it is passed as a procedure that returns the text string during runtime. Cf. “Example 5” on page 23-1116.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Billboarding</code>	text orientation in space or towards observer	TRUE
<code>Frames</code>	the number of frames in an animation	50
<code>HorizontalAlignment</code>	horizontal alignment of text objects w.r.t. their coordinates	Left

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Position	positions of cameras, lights, and text objects	
PositionX	x-positions of cameras, lights, and text objects	
PositionY	y-positions of cameras, lights, and text objects	
PositionZ	z-positions of cameras, lights, and text objects	

# plot::Text3d

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Text	the text of a text object	
TextFont	font of text objects	[" sans-serif ", 11]
TextOrientation	orientation of a 3D text	[1, 0, 0, 0, 0, 1]
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
VerticalAlignment	vertical alignment of text objects w.r.t. their coordinates	BaseLine
Visible	visibility	TRUE

Attribute	Purpose	Default Value
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

We draw the text string 'Hello world' at the anchor point (1, 2, 3) which is indicated by a red dot:

```
plot(plot::Circle3d(3, [1, 2, 3], [0, 0, 1]),
 plot::Point3d([1, 2, 3]),
 plot::Text3d("Hello world!", [1, 2, 3],
 HorizontalAlignment = Center),
 Axes = Frame, TextFont = [24],
 PointColor = RGB::Red, PointSize = 3*unit::mm)
```

# plot::Text3d

---

## Example 2

We animate the anchor points of the following texts and demonstrate various alignment possibilities:

```
plot(plot::Circle3d(1, [0, 0, 0], [0, 0, 1]),
 plot::Point3d([sin(a), cos(a), 0], a = 0..2*PI),
 plot::Point3d([cos(a), -sin(a), 0], a = 0..2*PI),
 plot::Point3d([-sin(a), -cos(a), 0], a = 0..2*PI),
 plot::Point3d([-cos(a), sin(a), 0], a = 0..2*PI),
 PointColor = RGB::Red, PointSize = 3*unit::mm,
 plot::Text3d("Hello (1)", [sin(a), cos(a), 0], a = 0..2*PI),
 plot::Text3d("Hello (2)", [cos(a), -sin(a), 0], a = 0..2*PI,
 HorizontalAlignment = Left,
 VerticalAlignment = BaseLine),
 plot::Text3d("Hello (3)", [-sin(a), -cos(a), 0], a = 0..2*PI,
 HorizontalAlignment = Center,
 VerticalAlignment = Top),
 plot::Text3d("Hello (4)", [-cos(a), sin(a), 0], a = 0..2*PI,
```

```

 HorizontalAlignment = Right,
 VerticalAlignment = Bottom),
 TextFont = [Italic, 24], Axes = Frame,
 CameraDirection = [0, -1, 10])

```

### Example 3

In contrast to `plot::Text2d`, a 3D text may not consist of several lines. The newline character `\n` in MuPAD strings does not have any effect:

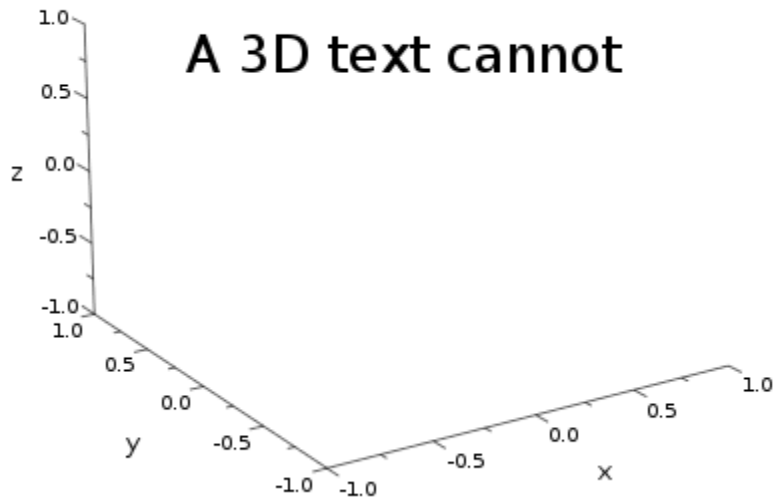

```

plot(plot::Text3d("A 3D text cannot \nhave several\nlines",
 HorizontalAlignment = Center,
 [0, 0, 0]),
 Axes = Frame, TextFont = [20])

```

# plot::Text3d

---

## Example 4

Per default, the attribute `Billboarding = TRUE` is set. The text always faces the observer:

```
plot(plot::Circle3d(1, [0, 0, 0], [0, 0, 1]),
 plot::Point3d([-cos(a), -sin(a), 0], a = 0 .. 2*PI),
 plot::Point3d([cos(a), sin(a), 0], a = 0 .. 2*PI),
 plot::Text3d("Hello (1)", [-cos(a), -sin(a), 0],
 a = 0 .. 2*PI),
 plot::Text3d("Hello (2)", [cos(a), sin(a), 0],
 a = 0 .. 2*PI),
 Axes = Frame, TextFont = [20],
 PointColor = RGB::Red, PointSize = 2*unit::mm)
```

We use `TextOrientation` to fix the orientation of the texts in space. The first text lies in a plane parallel to the  $x$ - $y$  plane, the second text is parallel to the  $x$ - $z$  plane. Note that we have to specify `Billboarding = FALSE` for `TextOrientation` to have an effect:

```
plot(plot::Circle3d(1, [0, 0, 0], [0, 0, 1]),
 plot::Point3d([-cos(a), -sin(a), 0], a = 0 .. 2*PI),
 plot::Point3d([cos(a), sin(a), 0], a = 0 .. 2*PI),
 PointColor = RGB::Red, PointSize = 2*unit::mm,
 plot::Text3d("Hello (1)", [-cos(a), -sin(a), 0],
 a = 0 .. 2*PI,
 TextOrientation = [1, 0, 0, 0, 1, 0]),
 plot::Text3d("Hello (2)", [cos(a), sin(a), 0],
 a = 0 .. 2*PI,
 TextOrientation = [1, 0, 0, 0, 0, 1]),
 Billboarding = FALSE, TextFont = [20], Axes = Frame)
```

# plot::Text3d

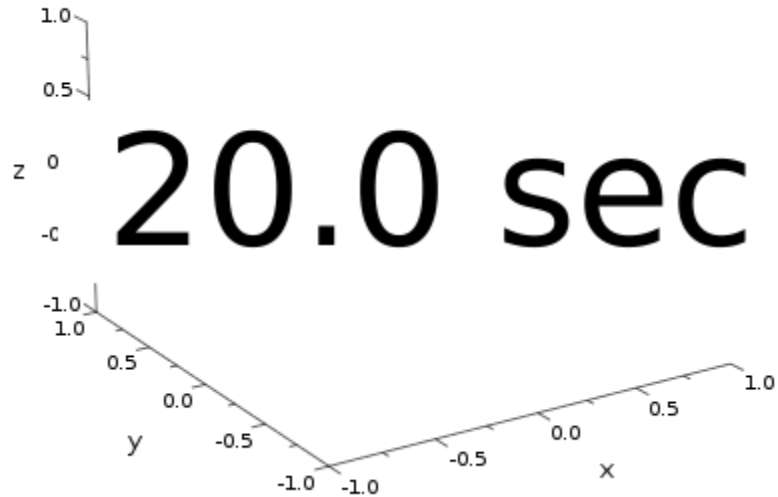

---

## Example 5

The text of a text object can be animated if the text string is provided by a procedure. We use `stringlib::formatf` to format the animation parameter that is passed to the procedure as a floating-point number for each frame of the animation:

```
plot(plot::Text3d(a -> stringlib::formatf(a, 2, 5)." sec",
 [0, 0, 0], a = 0..20),
 TextFont = [60],
 HorizontalAlignment = Center, VerticalAlignment = Center,
 Axes = Frame, Frames = 201, TimeRange = 0..20)
```

## Parameters

### text

The text: a string. Alternatively, a procedure that accepts one input parameter  $a$  (the animation parameter) and returns a string.

text is equivalent to the attribute Text.

### x, y, z

The position of the text. The coordinates  $x$ ,  $y$ ,  $z$  must be real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x$ ,  $y$ ,  $z$  are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

### a

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Text3d

### MuPAD Functions

`plot` | `plot::copy` | `stringlib::formatf`

### MuPAD Graphical Primitives

`plot::Text2d`

**Purpose** Generalized tubular plots (canal surfaces)

**Syntax** `plot::Tube([x, y, z], <r>, t = t_min .. t_max, <a = a_min .. a_max>, options)`

**Description** `plot::Tube` creates generalized tubular plots, known as “canal surfaces”, with special cases known as “tube surface”, “pipe surface” or “tubular surfaces.”

Intuitively, canal surfaces are space curves with thickness. More formally, a canal surface `plot::Tube([x(t), y(t), z(t)], r(t), t = t_min..t_max)` is the envelope of spheres with center  $[x(t), y(t), z(t)]$  and radius  $r(t)$ , i.e., the thickness of the curve can vary with the curve parameter  $t$ .

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
AngleEnd	end of angle range	2*PI
AngleBegin	begin of angle range	0
AngleRange	angle range	0 .. 2*PI
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	TRUE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineColorType	line coloring types	Flat

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
LineColorFunction	functional line coloring	
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Mesh	number of sample points	[60, 11]
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointsVisible	visibility of mesh points	FALSE
RadiusFunction	radius of a tube plot	1/10

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Shading	smooth color blend of surfaces	Smooth
Submesh	density of submesh (additional sample points)	[0, 1]
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
ULinesVisible	visibility of parameter lines (u lines)	TRUE
UMax	final value of parameter "u"	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
UMesh	number of sample points for parameter “u”	60
UMin	initial value of parameter “u”	
UName	name of parameter “u”	
URange	range of parameter “u”	
USubmesh	density of additional sample points for parameter “u”	0
VLinesVisible	visibility of parameter lines (v lines)	TRUE
VMesh	number of sample points for parameter “v”	11
VSubmesh	density of additional sample points for parameter “v”	1
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	

# plot::Tube

---

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XFunction	function for x values	
YFunction	function for y values	
ZFunction	function for z values	

## Examples

### Example 1

A torus can be drawn as a tube around a circle:

```
plot(plot::Tube([cos(t), sin(t), 0], 0.4,
 t = 0..2*PI))
```

Varying the diameter of the tube, we deform the torus into a cyclide:

```
plot(plot::Tube([cos(t), sin(t), 0], 0.4 + 0.3*cos(t),
t = 0..2*PI))
```

## Example 2

All surfaces of revolution are special cases of canal surfaces:

```
plot(plot::Scene3d(plot::XRotate(sin(u), u = 0..10)),
 plot::Scene3d(plot::ZRotate(sin(u), u = 0..10)),
 plot::Scene3d(plot::Tube([u, 0, 0], sin(u), u = 0..10)),
 plot::Scene3d(plot::Tube([0, 0, sin(u)], u, u = 0..10)),
 Width = 180 * unit::mm)
```

The last image shows that the defaults for the mesh are not always adequate and should be changed:

```
plot(plot::Tube([0, 0, sin(u)], u, u = 0..10,
 Mesh = [20, 20]))
```

# plot::Tube

---

### Example 3

The famous Klein bottle can be obtained from a “drop silhouette” by using an appropriate radius parametrization:

```
plot(plot::Tube([6*cos(u)*(sin(u) - 1), 0, 14*sin(u)],
 4 - 2*cos(u), u = -PI..PI))
```

#### Example 4

Re-using the cyclide from above, we demonstrate coloring a canal surface:

```
color := (t, phi) -> RGB::fromHSV([(t+sin(4*phi))*180/PI, 1, 1])
plot(plot::Tube([sin(t), cos(t), 0], 0.4 + 0.3*cos(t), t=0..2*PI
 FillColorFunction = color))
```

## Example 5

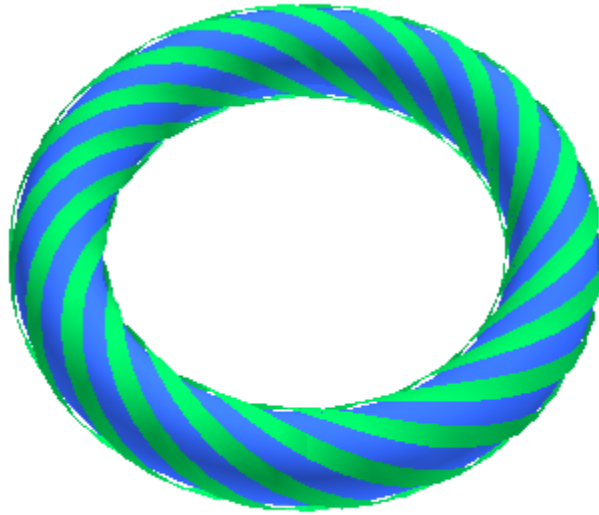

Yet another variation of the cyclide, we use a non-constant AngleRange to “slice” it:

```
plot(plot::Tube([sin(t), cos(t), 0], 0.4 - 0.3*sin(t), t=0..2*PI,
 AngleRange = 0 .. 2*PI*sin(abs(t-PI/2)/2)),
 Axes = None, CameraDirection = [14, 1, 5])
```

Combining more than one tubular plot with identical spine curves but different angle ranges, we can achieve a braid-like effect:

```
braid := i ->
 plot::Tube([sin(u), cos(u), 0], 0.2, u=0..2*PI,
 AngleRange = i*PI/3 + 3*u .. i*PI/3 + 3*u + 1/2,
 Color = RGB::EmeraldGreen, Mesh = [60, 2]):
torus := plot::Tube([sin(u), cos(u), 0], 0.18, u=0..2*PI,
 Color = RGB::BlueLight,
 Name = "Torus"):
plot(braid(i) $ i = 0..5,
 torus,
 ULinesVisible = FALSE, VLinesVisible = FALSE,
 FillColorType = Flat,
 Axes = None, CameraDirection = [0, 7, 10])
```

## Example 6

The spine curve, the radius function, color functions etc. can be animated as usual:

```
plot(plot::Tube([sin(t)*sin(a), cos(t)*cos(a), sin(a)],
 0.4 - 0.3*sin(t-a),
 t = 0..2*PI, a = 0..2*PI,
 Frames = 20, TimeRange = 0..5))
```

### Example 7

Note that in the presence of a sharp bend (in relation to the tube diameter), the surface plotted by `plot::Tube` may self-intersect:

```
plot(plot::Tube([x, 0, x^2], 1.2, x = -1.4..1.4,
 Mesh = [20, 10]),
 Axes = None, CameraDirection = [-3, 1, 2])
```

## plot::Tube

---

This effect is unavoidable. Sharp bends also cause another effect which can be avoided by increasing the mesh density: The tube might not follow the curve quickly enough:

```
plot(plot::Tube([sin(x^2), x, 0], x = -5..0))
```

In this situation, you can set `USubmesh` to a positive value to request additional function evaluations:

```
plot(plot::Tube([sin(x^2), x, 0], x = -5..0, USubmesh = 5))
```

# plot::Tube

---

## Parameters

**x, y, z**

The spine curve coordinates: real-valued expressions in  $t$  and the animation parameter.

$x$ ,  $y$ ,  $z$  are equivalent to the attributes `XFunction`, `YFunction`, `ZFunction`.

**r**

The tube radius: a real-valued expression in  $t$  and the animation parameter. Default is the constant  $\frac{1}{10}$ .

$r$  is equivalent to the attribute `RadiusFunction`.

**t**

The curve parameter: an (indexed) identifier.

$t$  is equivalent to the attribute `UName`.

**$t_{\min} .. t_{\max}$** 

The range of the curve parameter: real-valued expressions in the animation parameter.

$t_{\min} .. t_{\max}$  is equivalent to the attributes URange, UMin, UMax.

 **$a$** 

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Turtle

---

<b>Purpose</b>	“turtle graphics” (imperative drawings)
<b>Syntax</b>	<code>plot::Turtle(commands, &lt;a = a<sub>min</sub> .. a<sub>max</sub>&gt;, options)</code>
<b>Description</b>	<p>Turtle graphics define a line drawing by a sequence of commands to an abstract robot.</p> <p><code>plot::Turtle</code> defines a graphic by sending movement commands to an abstract robot. This robot starts heading up and standing at the origin, with its pen ready for drawing (“down”) and the line color taken from the attribute <code>LineColor</code>.</p> <p>The following commands are known to the robot:</p> <ul style="list-style-type: none"><li>• <b>Left</b>(<math>\alpha</math>) Turn left by the angle <math>\alpha</math> (in radians).</li><li>• <b>Right</b>(<math>\alpha</math>) Turn right by the angle <math>\alpha</math> (in radians).</li><li>• <b>Forward</b>(<math>d</math>) Move forward distance <math>d</math>.</li><li>• <b>Up</b> Lift the “pen”, i.e., subsequent movement commands do not draw lines.</li><li>• <b>Down</b> Lower the “pen”, i.e., subsequent movement commands do draw lines.</li><li>• <b>Push</b> Remember the current state (position, angle, line color).</li><li>• <b>Pop</b> Restore the last remembered state and remove it from the list of remembered states.</li><li>• <b>Noop</b></li></ul>

This command is ignored.

- `LineColor(c)`

Set the line color to the `colorc`.

The commands not taking an argument may also be entered with empty parentheses `()` after, e.g., `Push()`.

A `plot::Turtle`-object can be manipulated dynamically by calling its methods `left`, `right`, `forward`, `penUp`, `penDown`, `push`, `pop`, and `setLineColor`, with the obvious connections to the commands above. These methods append a new command to the end of the list. Cf. “Example 3” on page 23-1146.

---

**Note** For long command sequences, it is highly recommended to give the commands directly using the syntax above or by setting the `CommandList` attribute directly.

---

Both angles and distances can be animated. Colors can not.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	<code>TRUE</code>
<code>AntiAliased</code>	antialiased lines and points?	<code>TRUE</code>
<code>Color</code>	the main color	<code>RGB::Blue</code>
<code>CommandList</code>	turtle movement commands	<code>[]</code>
<code>Frames</code>	the number of frames in an animation	<code>50</code>

# plot::Turtle

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter

VisibleBeforeBegin	object visible before its animation time starts?	TRUE

# plot::Turtle

---

## Examples

### Example 1

A square can be drawn by four times moving forward, each time turning right 90°:

```
plot(plot::Turtle([Forward(1), Right(PI/2),
 Forward(1), Right(PI/2),
 Forward(1), Right(PI/2),
 Forward(1), Right(PI/2)]))
```

Using the \$ operator, this command list can be written much shorter:

```
plot(plot::Turtle([(Forward(1), Right(PI/2))$4]))
```

In the same fashion, we can draw any regular  $n$ -sided polygon:

```
n := 7:
plot(plot::Turtle([(Forward(1), Right(2*PI/n)) $ n]))
```

## Example 2

The distance to move may contain an animation parameter:

```
plot(plot::Turtle([Forward(1+a), Right(PI/2),
 Forward(1-2*a), Right(PI/2),
 Forward(1+3*a), Right(PI/2),
 Forward(1-4*a), Right(PI/2),
 Forward(1+5*a)], a=0..2))
```

Likewise, the angle can be animated:

```
plot(plot::Turtle([(Forward(1), Right(a))$10],
a = 0.25..2.5))
```

### Example 3

It is also possible to successively append commands to the list:

```
t := plot::Turtle()
```

```
plot::Turtle([])
```

```
t::forward(1)
```

```
plot::Turtle([Forward(1)])
```

```
for i from 1 to 9 do
 t::left(3*PI/5);
 t::forward(1);
end_for
```

```
plot::Turtle([Forward(1), Left((3*PI)/...5), Forward(1)])
```

```
plot(t)
```

#### Example 4

As an extension to the original turtle model, the line color may be changed while plotting:

```
t := plot::Turtle():
t::setLineColor(RGB::Red):
t::forward(1):
p := float(PI/5):
for i from 1 to 9 do
 t::left(108*PI/180);
 t::setLineColor([cos(i*p), sin(i*p), 0.0]);
 t::forward(1);
```

```
end_for;

plot::Turtle([LineColor([1.0, 0.0, 0.0...]), Forward(1)])

plot(t)
```

Note that the color within one line segment is constant.

## Example 5

Another extension to the turtle model is that `plot::Turtle` supports a stack of saved states, enabling the robot to return to previous positions:

```
t := plot::Turtle():
t::forward(5):
for i from -3 to 4 do
 t::push();
 t::left(PI/18*i);
```

```
t::forward(3);
t::pop();
end_for:
plot(t)
```

### Example 6

Using small steps, it is possible to create appealing curves with `plot::Turtle`:

```
t := plot::Turtle(LineColor = RGB::Green):
t::forward(2):
for dir in [-1, 1] do
 t::push();
 t::left(dir*PI/30);
 for i from 1 to 10 do
 t::forward(0.2);
 t::left(dir*PI/30);
 end_for;
end_for;
```

# plot::Turtle

---

```
 t::left(dir*2/3*PI);
 for i from 1 to 10 do
 t::forward(0.2);
 t::left(dir*PI/30);
 end_for;
 t::pop()
end_for:
t::forward(3):
t::setLineColor(RGB::Red):
for dir from -5 to 5 do
 t::push();
 t::left(dir*2*PI/11);
 for i from 1 to 10 do
 t::forward(0.1);
 t::left(PI/30);
 end_for;
 t::left(2*PI/3);
 for i from 1 to 10 do
 t::forward(0.1);
 t::left(PI/30);
 end_for;
 t::pop()
end_for:
plot(t)
```

## Parameters

### commands

A list of commands. See below for command definitions.

`commands` is equivalent to the attribute `CommandList`.

### **a**

Animation parameter, specified as  $\mathbf{a} = \mathbf{a}_{\min} \cdot \mathbf{a}_{\max}$ , where  $\mathbf{a}_{\min}$  is the initial parameter value, and  $\mathbf{a}_{\max}$  is the final parameter value.

plot::Lsys

## Purpose

2D vector field

## Syntax

```
plot::VectorField2d([v1, v2], x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
plot::VectorField2d(v1, v2, x = xmin .. xmax, y = ymin ..
ymax, <a = amin .. amax>, options)
```

## Description

`plot::VectorField2d([v1, v2], x = `x_{min}` .. `x_{max}``, y = `y_{min}` .. `y_{max}``)` represents a plot of the vector field defined by  $(x, y) \rightarrow (v_1(x, y), v_2(x, y))$  with  $(x, y)$   $[x_{min}, x_{max}] [y_{min}, y_{max}]$ .

A vector field is defined by a function  $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ . `plot::VectorField2d` displays a vector field by placing arrows at regular intervals with the arrow at  $(x, y)$  pointing in direction  $f(x, y)$ .

The length of the arrows depend on  $|f(x, y)|$  and the setting of the attribute `ArrowLength`: By default, arrow lengths are proportional to the magnitude of  $f$ , but can be set to be of fixed length or to scale logarithmically.

The density of arrows placed can be controlled with the attributes `XMesh`, `YMesh`, and `Mesh`. See the examples below.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>ArrowLength</code>	scaling of arrows in a vector field	Proportional
<code>Color</code>	the main color	RGB::Blue

## plot::VectorField2d

XRange	range of parameter "x"	
YFunction	function for y values	
YMax	final value of parameter "y"	

Attribute	Purpose	Default Value
YMesh	number of sample points for parameter “y”	11
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

## Examples

### Example 1

We demonstrate a plot of the vector field  $v(x, y) = (1, \sin(x) + \cos(y))$ :

```
field := plot::VectorField2d([1, sin(x) + cos(y)],
 x = 0..6, y = 0..2.5,
 Mesh = [31, 26]):
```

It is the directional field associated with the ode

$y'(x) = \sin(x) + \cos(y)$ . We insert curves representing numerical solutions of this ode into this plot. We use `numeric::odesolve2` to compute the numerical solutions for the initial values  $y(0) = 0.4$ ,  $y(0.5) = 1.5$ , and  $y(1) = 1.2$ :

```
f := (x, y) -> [sin(x) + cos(y[1])]:
solution1 := numeric::odesolve2(f, 0, [0.4]):
curve1 := plot::Function2d(solution1(x)[1], x = 0 .. 6,
 LineColor = RGB::Blue):
solution2 := numeric::odesolve2(f, 0.5, [1.5]):
curve2 := plot::Function2d(solution2(x)[1], x = 0.5 .. 6,
 LineColor = RGB::Black):
solution3 := numeric::odesolve2(f, 1, [1.2]):
curve3 := plot::Function2d(solution3(x)[1], x = 1 .. 6,
 LineColor = RGB::GreenDark):
```

# plot::VectorField2d

We plot the three objects in a single graphical scene:

```
plot(field, curve1, curve2, curve3, GridVisible = TRUE):
```

```
delete field, curve1, curve2, curve3:
```

## Example 2

Assume you want to plot an electrostatic potential field. The following routine generates the necessary formula in a format accepted by `plot::VectorField2d`:

```
potentialE :=
 proc(l)
 local p, x0, y0, f0, fx, fy, dist;
 begin
 fx := 0; fy := 0;
 for p in [args()] do
 [x0, y0, f0] := p;
```

```

 dist := sqrt((x-x0)^2 + (y-y0)^2);
 fx := fx + f0*(x-x0)/dist;
 fy := fy + f0*(y-y0)/dist;
 end_for;
 [fx, fy];
end_proc:

plot(plot::VectorField2d(potentialE([-1, -2, -1],
 [1, 3, 0.5],
 [2, -1, 0.5]),
 x = -3..3, y = -3..3,
 XMesh = 30, YMesh = 30)):

```

### Example 3

Like most other objects, `plot::VectorField2d` can be animated by supplying an extra parameter:

```
field := plot::VectorField2d([1, a*sin(x) + (a-1)*cos(y)],
```

# plot::VectorField2d

```
text := plot::Text2d(a -> "a = ".stringlib::formatf(a, 2, 5), [2, -
x = 0..6, y = 0..2.5, a=-1..1):
a = -1..1, HorizontalAlignment = Left):
plot(field, text)
```

```
delete field, text:
```

## Parameters

**$v_1, v_2$**

The  $x$ - and  $y$ -component of the vector field: arithmetical expressions in  $x$ ,  $y$ , and, possibly, the animation parameter  $a$ .

$v_1, v_2$  are equivalent to the attributes `XFunction`, `YFunction`.

**$x, y$**

Identifiers.

$x, y$  are equivalent to the attributes `XName`, `YName`.

$x_{\min} \dots x_{\max}, y_{\min} \dots y_{\max}$

Real numerical values.

$x_{\min} \dots x_{\max}, y_{\min} \dots y_{\max}$  are equivalent to the attributes XRange, YRange, XMin, XMax, YMin, YMax.

**a**

Animation parameter, specified as  $a = a_{\min} \dots a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Examples

### Example 1

We demonstrate a plot of the vector field  $v(x, y, z) = (1, \sin(x) + \cos(y), \sin(z))$ ,  $\sin(z)$ :

```
field := plot::VectorField3d([1, sin(x) + cos(y), sin(z)],
 x = 0..6, y = 0..2.5, z = 0..5,
 Mesh = [7, 7, 7]):
plot(field):
```

# plot::VectorField3d

delete field:

## Example 2

Like most other objects, `plot::VectorField3d` can be animated by supplying an extra parameter:

```
mycolor := (x, y, z, vx, vy, vz, a) -> [a, a*z, 1 - a]:
field := plot::VectorField3d([a*y + (1-a)*x ,
 -a*x + (1-a)*y,
 a*sin(PI*z)],
 x = -1..1, y = -1..1, z = 0..1,
 LineColorFunction = mycolor,
 Mesh = [7, 7, 7], a = 0..1):
text := plot::Text3d(a -> "a = ".stringlib::formatf(a, 2, 5),
 [1, 0.7, 1.2], a = 0..1):
plot(field, text, Axes = Frame)
```

delete field, text:

## Parameters

$v_1, v_2, v_3$

The  $x$ -,  $y$ -, and  $z$ -component of the vector field: arithmetical expressions in  $x$ ,  $y$ ,  $z$  and, possibly, the animation parameter  $a$ .

$v_1, v_2, v_3$  are equivalent to the attributes XFunction, YFunction, ZFunction.

$x, y, z$

Identifiers.

$x, y, z$  are equivalent to the attributes XName, YName, ZName.

$x_{\min} \dots x_{\max}, y_{\min} \dots y_{\max}, z_{\min} \dots z_{\max}$

Real numerical values.

$x_{\min} \dots x_{\max}, y_{\min} \dots y_{\max}, z_{\min} \dots z_{\max}$  are equivalent to the attributes XRange, YRange, ZRange, XMin, XMax, YMin, YMax, ZMin, ZMax.

$a$

Animation parameter, specified as  $a = a_{\min} \dots a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Waterman

---

**Purpose** Waterman polyhedra

**Syntax** `plot::Waterman(r, <a = amin .. amax>, options)`

**Description** `plot::Waterman(r)` creates the Waterman polyhedron of radius  $r$ .

Waterman polyhedra, invented around 1990 by Steve Waterman, form a vast family of polyhedra. Some of them have a number of nice properties like multiple symmetries, or very interesting and regular shapes. Some other are just a bunch of faces formed out of irregular convex polygons.

Waterman polyhedra result from the examination of balls in face-centered cubic close packing (which is one of the two densest packings of equally sized balls in 3D space, according to the Kepler Conjecture, proofed by Hales and Ferguson, 1997-2005). A single layer

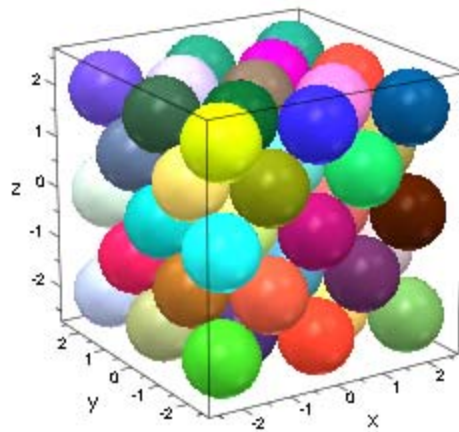

of spheres (of radius  $\frac{1}{\sqrt{2}}$ ) in this packing looks like this:

The close packing results from placing several of these layers over one another, shifted to optimally fill the gaps (in very much the same way your grocery store puts apples and oranges on display):

Given a radius  $r$  and a center  $c$  (which we let default to  $[0, 0, 0]$ ), now consider all those centers of spheres in this packing which fall into the sphere of radius  $r$  around  $c$ :

The convex hull of these points is the Waterman polyhedron of the given radius and center:

# plot::Waterman

---

**Attributes**

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Center	center of objects, rotation center	[0, 0, 0]

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

## Examples

### Example 1

With increasing radius, Waterman polyhedra get ever closer to spheres:

```
plot(plot::Waterman(r, r=0..10,
 PointsVisible, PointSize=1,
 LineColor=RGB::Black,
 Color=RGB::Red.[0.75]),
 plot::Sphere(r, [0,0,0], r=0..10,
 Color=RGB::Yellow.[0.3]),
 CameraDirection=[2,10,1])
```

# plot::Waterman

---

## Example 2

Waterman polyhedra have a rather general definition and can be made from spheres centered anywhere:

```
plot(plot::Waterman(5, Center=[0,0,0]))
```

```
plot(plot::Waterman(5, Center=[0,0,1]))
```

# plot::Waterman

---

To translate or scale a Waterman polyhedron, use `plot::Translate3d` and `plot::Scale3d`:

```
n := 3:
r := i -> 3/2+sqrt(i+1):
plot(plot::Translate3d([i mod n, i div n, 0],
 plot::Scale3d([1/(3*r(i)) $ 3],
 plot::Waterman(r(i), Color=RGB::random()))))
$ i = 0..n^2-1, Axes=None)
```

### Example 3

As usual, many attributes can be animated, although by the nature of Waterman polyhedra, the resulting animation will not be smooth:

```
plot(plot::Waterman(5, Center=[a/PI, cos(a), 0],
a=0..2*PI),
AnimationStyle=BackAndForth, CameraDirection=[0,0.1,1])
```

## Example 4

The `LineColorFunction` and `FillColorFunction` attributes can be set to functions which get indices of the currently painted surface polygon and its current vertex as fourth and fifth argument, respectively. This allows to color the polygons individually:

```
colors := [RGB::random() $ i = 1..42]:
plot(plot::Waterman(5, FillColorFunction=((x,y,z,i) -> colors[i])))
```

Another way of getting random colors which remain constant for each polygon is to use a procedure with option remember:

```
col :=
proc(n)
 option remember;
begin
 RGB::fromHSV([360*frandom(), 1, 1]);
end;
plot(plot::Waterman(7, FillColorFunction=((x,y,z,i) -> col(i))))
```

# plot::Waterman

---

## Parameters **r**

An arithmetical expression: the radius of the polyhedron (see below for details).

`r` is equivalent to the attribute `Radius`.

## **a**

Animation parameter, specified as `a = amin..amax`, where `amin` is the initial parameter value, and `amax` is the final parameter value.

## Algorithms

`plot::Waterman` uses `plot::hull` (and therefore, the Geometry Centre's `qhull` code) to compute the convex hull of the coordinates. Most of the remaining code has been contributed by Mirek Majewski.

# plot::XRotate

---

**Purpose** Surfaces of revolution around x-axis

**Syntax** `plot::XRotate(f, x = xmin .. xmax, <a = amin .. amax>, options)`

**Description** `plot::XRotate(f, x = `x_{min}` .. xmax)` creates a surface of revolution by rotating the function graph  $y = f(x)$  with  $x$   $[x_{min}, x_{max}]$  around the  $x$ -axis.

`plot::XRotate` rotates the graph of the function  $y = f(x)$  around the  $x$ -axis, creating a surface of revolution. The slice of the surface parallel to the  $y$ - $z$  plane at a point  $x$  is a circle of radius  $f(x)$ .

The range of the rotation can be restricted with the attributes `AngleBegin`, `AngleEnd`, `AngleRange`. The surface of revolution will only span over the given range of the rotation angle.

Surfaces of revolution are parametrized surfaces. The first surface parameter is  $x$ , the second is the rotation angle. Surfaces of revolution react to most of the graphical attributes that surfaces of type `plot::Surface` react to. For example, use `Mesh`, `Submesh` to control the numerical mesh or use `ULinesVisible`, `VLinesVisible` to switch the parameter lines on/off.

## Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	0
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE

ZContours	contour lines at constant z values	[]

# plot::XRotate

---

## Examples

### Example 1

By default, `plot::XRotate` displays a complete revolution, just as if an object was created on a lathe:

```
plot(plot::XRotate(2 - sin(x), x = 0..2*PI))
```

This rotation is insensitive to negative values: The surfaces of revolution of  $f(x)$  and  $|f(x)|$  are identical:

```
plot(plot::Scene3d(plot::XRotate(sin(x), x = 0..2*PI)),
 plot::Scene3d(plot::XRotate(abs(sin(x)), x = 0..2*PI)),
 Layout = Horizontal)
```

This symmetry is broken when not performing a whole revolution:

```
plot(plot::Scene3d(plot::XRotate(sin(x), x = 0..2*PI,
 AngleRange = -PI/2..PI/2)),
 plot::Scene3d(plot::XRotate(abs(sin(x)), x = 0..2*PI,
 AngleRange = -PI/2..PI/2)),
 Layout = Horizontal)
```

# plot::XRotate

---

`plot::XRotate` can be animated, like almost every plot object:

```
plot(plot::XRotate(sin(x + a), x = 0 .. 2*a + PI,
 AngleRange = 0 .. PI + a/2,
 a = 0..2*PI))
```

### Example 2

As for `plot::ZRotate`, most of the points from above hold here, too. Obviously, the symmetry for a whole revolution is now with respect to the  $x$  values, not the function values:

```
plot(plot::Scene3d(plot::ZRotate(exp(x), x = -1..1)),
 plot::Scene3d(plot::ZRotate(exp(-x), x = -1..1)),
 Layout = Horizontal)
```

# plot::XRotate

---

```
plot(plot::Scene3d(plot::ZRotate(exp(x), x = -1..1,
 AngleRange = -a..a,
 a = 0..PI)),
plot::Scene3d(plot::ZRotate(exp(-x), x = -1..1,
 AngleRange = -a..a,
 a = 0..PI)),
Layout = Horizontal)
```

## Parameters **f**

The function: an arithmetical expression or a piecewise object in the independent variable  $x$  and the animation parameter  $a$ . Alternatively, a procedure that accepts 1 input parameter  $x$  or 2 input parameters  $x, a$  and returns a real numerical value when the input parameters are numerical.

$f$  is equivalent to the attribute Function.

## **x**

The independent variable: an identifier or an indexed identifier.

$x$  is equivalent to the attribute XName.

## **$x_{\min}$ .. $x_{\max}$**

The plot range:  $x_{\min}, x_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ .

# plot::XRotate

---

$x_{\min} .. x_{\max}$  is equivalent to the attributes XRange, XMin, XMax.

**a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### MuPAD Functions

[plot](#) | [plot::copy](#)

### MuPAD Graphical Primitives

[plot::ZRotate](#) | [plot::Function2d](#) | [plot::Function3d](#) |  
[plot::Surface](#)

## Purpose

Surfaces of revolution around z-axis

## Syntax

`plot::ZRotate(f, x = xmin .. xmax, <a = amin .. amax>, options)`

## Description

`plot::ZRotate(f, x = `x_{min}` .. xmax)` creates a surface of revolution by rotating the function graph  $z = f(x)$  with  $x$   $[x_{min}, x_{max}]$  around the z-axis.

`plot::ZRotate` rotates the graph of the given function  $z = f(x)$  around the z-axis, creating another surface of revolution. The slice of the surface parallel to the x-y plane at a point  $z$  consists of circles with radii  $|x_i|$  given by the solutions of  $f(x) = z$ .

The range of the rotation can be restricted with the attributes `AngleBegin`, `AngleEnd`, `AngleRange`. The surface of revolution will only span over the given range of the rotation angle.

Surfaces of revolution are parametrized surfaces. The first surface parameter is  $x$ , the second is the rotation angle. Surfaces of revolution react to most of the graphical attributes that surfaces of type `plot::Surface` react to. For example, use `Mesh`, `Submesh` to control the numerical mesh or use `ULinesVisible`, `VLinesVisible` to switch the parameter lines on/off.

## Attributes

Attribute	Purpose	Default Value
<code>AdaptiveMesh</code>	adaptive sampling	0
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AngleEnd</code>	end of angle range	$2 \cdot \text{PI}$
<code>AngleBegin</code>	begin of angle range	0
<code>AngleRange</code>	angle range	$0 .. 2 \cdot \text{PI}$
<code>Color</code>	the main color	<code>RGB::Red</code>

## plot::ZRotate

---

Attribute	Purpose	Default Value
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::Red
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Dichromatic
FillColorFunction	functional area/surface coloring	
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]

VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XContours	contour lines at constant x values	[]
XMax	final value of parameter "x"	5
XMin	initial value of parameter "x"	0
XName	name of parameter "x"	
XRange	range of parameter "x"	0 .. 5
YContours	contour lines at constant y values	[]
ZContours	contour lines at constant z values	[]

## Examples

### Example 1

By default, `plot::XRotate` displays a complete revolution, just as if an object was created on a lathe:

```
plot(plot::XRotate(2 - sin(x), x = 0..2*PI))
```

This rotation is insensitive to negative values: The surfaces of revolution of  $f(x)$  and  $|f(x)|$  are identical:

```
plot(plot::Scene3d(plot::XRotate(sin(x), x = 0..2*PI)),
 plot::Scene3d(plot::XRotate(abs(sin(x)), x = 0..2*PI)),
 Layout = Horizontal)
```

# plot::ZRotate

---

This symmetry is broken when not performing a whole revolution:

```
plot(plot::Scene3d(plot::XRotate(sin(x), x = 0..2*PI,
 AngleRange = -PI/2..PI/2)),
 plot::Scene3d(plot::XRotate(abs(sin(x)), x = 0..2*PI,
 AngleRange = -PI/2..PI/2)),
 Layout = Horizontal)
```

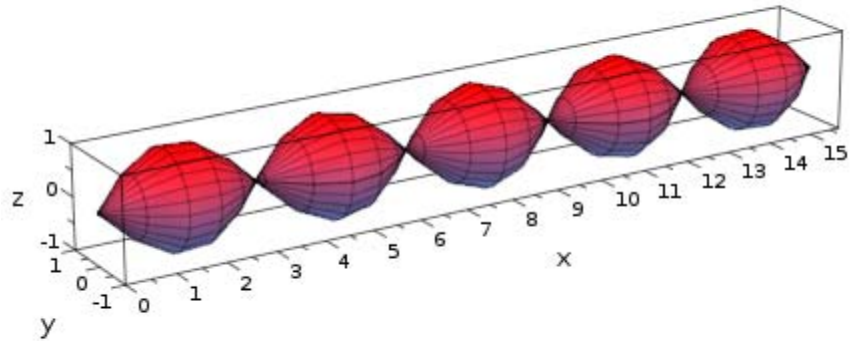

`plot::XRotate` can be animated, like almost every plot object:

```
plot(plot::XRotate(sin(x + a), x = 0 .. 2*a + PI,
 AngleRange = 0 .. PI + a/2,
 a = 0..2*PI))
```

# plot::ZRotate

---

## Example 2

As for `plot::ZRotate`, most of the points from above hold here, too. Obviously, the symmetry for a whole revolution is now with respect to the  $x$  values, not the function values:

```
plot(plot::Scene3d(plot::ZRotate(exp(x), x = -1..1)),
 plot::Scene3d(plot::ZRotate(exp(-x), x = -1..1)),
 Layout = Horizontal)
```

```
plot(plot::Scene3d(plot::ZRotate(exp(x), x = -1..1,
 AngleRange = -a..a,
 a = 0..PI)),
plot::Scene3d(plot::ZRotate(exp(-x), x = -1..1,
 AngleRange = -a..a,
 a = 0..PI)),
Layout = Horizontal)
```

# plot::ZRotate

---

## Parameters **f**

The function: an arithmetical expression or a *piecewise* object in the independent variable  $x$  and the animation parameter  $a$ . Alternatively, a procedure that accepts 1 input parameter  $x$  or 2 input parameters  $x, a$  and returns a real numerical value when the input parameters are numerical.

$f$  is equivalent to the attribute `Function`.

## **x**

The independent variable: an identifier or an indexed identifier.

$x$  is equivalent to the attribute `XName`.

## **$x_{\min}$ .. $x_{\max}$**

The plot range:  $x_{\min}, x_{\max}$  must be numerical real values or expressions of the animation parameter  $a$ .

$x_{\min} .. x_{\max}$  is equivalent to the attributes XRange, XMin, XMax.

**a**

Animation parameter, specified as  $a = a_{\min} .. a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Canvas

---

<b>Purpose</b>	Drawing area
<b>Syntax</b>	<code>plot::Canvas(object<sub>1</sub>, object<sub>2</sub>, , &lt;a = a<sub>min</sub> .. a<sub>max</sub>&gt;, options)</code>
<b>Description</b>	<p><code>plot::Canvas</code> is the top level element of the hierarchy of graphical objects. It represents the 2 dimensional drawing area into which 2D and 3D plots are painted.</p> <p>The user does not need to create a canvas object explicitly, because a <code>plot</code> command such as <code>plot(object<sub>1</sub>, object<sub>2</sub>, )</code> implicitly creates a default canvas object to display the graphical objects in.</p> <p>Strictly speaking, a canvas object is a container for scenes of type <code>plot::Scene2d</code> or <code>plot::Scene3d</code>, respectively. The user, however, does not have to bother about this technicality, because a suitable default scene is created internally, when graphical primitives are passed to <code>plot::Canvas</code>.</p> <p>A canvas can display several scenes simultaneously. However, all scenes must be of the same dimension. A mixture of 2D and 3D is not supported!</p> <p>See the help page of the canvas attribute <code>Layout</code> for details on the layout of a canvas containing several scenes.</p> <p>The canvas object is always visible in the interactive object browser of the MuPAD graphics tool (see section <code>Viewer, Browser, and Inspector: Interactive Manipulation</code> of this document). It can contain one or more scenes as its children. When the canvas object is selected, it provides access to a variety of attributes that are associated with the canvas. The canvas attributes allow to</p> <ul style="list-style-type: none"><li>• set <code>Height</code> and <code>Width</code> of the plot,</li><li>• set a <code>Header</code> and/or a <code>Footer</code>,</li><li>• control the layout (<code>Layout</code>, <code>Rows</code>, <code>Columns</code>),</li><li>• set various style parameters such as <code>BorderWidth</code>, <code>BorderColor</code>, <code>BackgroundColor</code> etc.</li></ul>

A complete listing of the attributes associated with a canvas is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the canvas object, also attributes for scenes, coordinate systems and graphical objects inside the canvas can be specified when generating a canvas object. These attribute values are inherited to the objects inside the canvas as new default values.

## Attributes

Attribute	Purpose	Default Value
AnimationStyle	behaviour of the animation toolbar	RunOnce
AutoPlay	start animations automatically	TRUE
BackgroundColor	background color	RGB::White
BorderColor	color of frame/border around canvas and scenes	RGB::Grey50
BorderWidth	width of frame/border around canvas and scenes	0
BottomMargin	bottom margin width	1
Columns	number of columns of scenes	0
Footer	footer text	
FooterFont	font of footers (scene and canvas)	[" sans-serif ", 12]
FooterAlignment	alignment of footer of canvas and scenes	Center
Header	header text	

# plot::Canvas

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
HeaderFont	font of headers (scene and canvas)	[" sans-serif ", 12]
HeaderAlignment	alignment of header of canvas and scenes	Center
Height	heights of canvas/scenes	80
InitialTime	initial time of the animation slider	
Layout	arrangement/layout of several scenes in a canvas	Tabular
LeftMargin	left margin width	1
Margin	margins around canvas and scenes	1
Name	the name of a plot object (for browser and legend)	
OutputUnits	the physical length unit used by the inspector	unit::mm
RightMargin	right margin width	1
Rows	number of rows of scenes	0
Spacing	space between scenes	1.0
TopMargin	top margin width	1
Width	widths of canvas/scenes	120

## Examples

### Example 1

We display several scenes in a canvas. Various canvas attributes are passed when creating the canvas object:

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI),
 Header = "the sine function"):
S2 := plot::Scene2d(plot::Function2d(cos(x), x = 0..2*PI),
 Header = "the cosine function"):
S3 := plot::Scene2d(plot::Function2d(tan(x), x = 0..PI),
 Header = "the tan function"):
S4 := plot::Scene2d(plot::Function2d(cot(x), x = 0..PI),
 Header = "the cot function"):
C := plot::Canvas(S1, S2, S3, S4,
 Width = 80*unit::mm, Height = 80*unit::mm,
 BorderWidth = 0.5*unit::mm,
 Header = "trigonometric functions",
 HeaderFont = ["Times New Roman", Bold, 18]):
plot(C)
```

delete S1, S2, S3, S4, C:

**object<sub>1</sub>, object<sub>2</sub>, ...**

Graphical objects

## See Also

### MuPAD Functions

plot | plot::copy

### MuPAD Graphical Primitives

plot::Scene2d | plot::Scene3d | plot::CoordinateSystem2d |  
plot::CoordinateSystem3d

**Purpose**

Coordinate system to display 2D objects in

**Syntax**

```
plot::CoordinateSystem2d(object1, object2, , <a
= amin .. amax>, options)
```

**Description**

`plot::CoordinateSystem2d` is a container to display graphical 2D objects within. Usually, the user does not need to create such an object explicitly, because a `plot` command such as `plot(object1, object2, )` creates a default object of type `plot::CoordinateSystem2d` implicitly to display the graphical objects in.

The `plot::CoordinateSystem2d` object is always visible in the interactive object browser of the MuPAD graphics tool (see [Viewer](#), [Browser](#), and [Inspector: Interactive Manipulation](#) of this document). It contains the graphical objects as its children. When the coordinate system object is selected, it provides access to a variety of attributes that are associated with the coordinate system. These attributes allow to manipulate:

- the `CoordinateType` (linear vs. logarithmic coordinates),
- the `ViewingBox` (visibility range),
- the coordinate axes (axes titles, visibility, alignment, type, tips etc.),
- the ticks along the coordinate axes (number of tick marks, visibility, tick labels etc.),
- the coordinate grid (visibility, color, line width etc.),
- the scaling ratios of the coordinate directions (`Constrained` vs. `UnConstrained`).

A complete listing of the attributes associated with the coordinate system is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the coordinate system, also attributes for the graphical objects inside the coordinate system can be specified when generating an object of type `plot::CoordinateSystem2d`. These

# plot::CoordinateSystem2d

---

attribute values are inherited to the graphical objects as new default values.

A graphical scene may contain more than one coordinate system. Each coordinate system provides separate coordinate axes, ticks, grid lines etc.

In such a case, separate `plot::CoordinateSystem2d` containers must be created explicitly by the user and passed to a `plot` command (or inserted into a scene of type `plot::Scene2d`). Cf. “Example 2” on page 23-1225.

## Attributes

Attribute	Purpose	Default Value
Axes	type of the coordinate axes	Automatic
AxesTips	arrow tips at the coordinate axes?	TRUE
AxesOrigin	crosspoint of the coordinate axes	[0, 0]
AxesTitles	titles for the coordinate axes	[" x ", " y "]
AxesInFront	coordinate axes in front of or behind graphical objects?	FALSE
AxesOriginX	crosspoint of the coordinate axes, x-coordinate	0
AxesOriginY	crosspoint of the coordinate axes, y-coordinate	0
AxesVisible	display coordinate axes?	TRUE

Attribute	Purpose	Default Value
AxesLineColor	color of the coordinate axes	RGB::Black
AxesLineWidth	width of the coordinate axes	0.18
AxesTitleFont	font of axes titles	[" sans-serif ", 10]
AxesTitleAlignment	alignment of axes titles	End
CoordinateType	linear versus logarithmic plots in 2D	LinLin
GridInFront	coordinate grid in front of or behind graphical objects?	FALSE
GridVisible	display a coordinate grid?	FALSE
GridLineColor	line color of the coordinate grid	RGB::Grey60
GridLineWidth	width of coordinate grid lines	0.1
GridLineStyle	line style of the coordinate grid	Solid
Name	the name of a plot object (for browser and legend)	
Scaling	scaling ratios	Unconstrained
SubgridVisible	display a coordinate subgrid?	FALSE
SubgridLineColor	line color of the coordinate subgrid	RGB::Grey80

# plot::CoordinateSystem2d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
SubgridLineWidth	width of coordinate subgrid lines	0.1
SubgridLineStyle	line style of the coordinate subgrid	Solid
TicksAt	special axes tick marks	
TicksAnchor	user defined start of axes tick marks	0
TicksLength	length of axes tick marks	2
TicksNumber	number of axes tick marks	Normal
TicksBetween	number of minor (unlabeled) axes tick marks between major (labeled) axes tick marks	1
TicksVisible	display axes tick marks?	TRUE
TicksDistance	user defined axes tick mark distance	0
TicksLabelFont	font of tick labels	[" sans-serif ", 8]
TicksLabelStyle	display style of axes tick labels	Horizontal
TicksLabelsVisible	display axes tick labels?	TRUE

Attribute	Purpose	Default Value
ViewingBox	the visible coordinate range	[Automatic .. Automatic, Automatic .. Automatic]
ViewingBoxXMin	the smallest visible x-values	Automatic
ViewingBoxYMin	the smallest visible y-values	Automatic
ViewingBoxXMax	the largest visible x-values	Automatic
ViewingBoxYMax	the largest visible y-values	Automatic
ViewingBoxXRange	the range of x-values visible	Automatic .. Automatic
ViewingBoxYRange	the range of y-values visible	Automatic .. Automatic
XAxisTitle	title for the x axis	" x "
XAxisVisible	display x axis?	TRUE
XAxisTitleAlignment	alignment of x axis title	End
XGridVisible	display a coordinate grid in x-direction?	FALSE
XSubgridVisible	display a coordinate subgrid in x-direction?	FALSE
XTicksAt	special x axis tick marks	
XTicksAnchor	user defined start of x axis tick marks	0

# plot::CoordinateSystem2d

---

Attribute	Purpose	Default Value
XTicksNumber	number of x axis tick marks	Normal
XTicksBetween	number of minor (unlabeled) x axis tick marks between major (labeled) x axis tick marks	1
XTicksVisible	display x axis tick marks?	TRUE
XTicksDistance	distance of tick marks on x axis	0
XTicksLabelStyle	display style of x axis tick labels	Horizontal
XTicksLabelsVisible	display x axis tick labels?	TRUE
YAxisTitle	title for the y axis	" y "
YAxisVisible	display y axis?	TRUE
YAxisTitleAlignment	alignment of y axis title	End
YAxisTitleOrientation	orientation of the vertical axis title in 2D	Horizontal
YGridVisible	display a coordinate grid in y-direction?	FALSE
YSubgridVisible	display a coordinate subgrid in y-direction?	FALSE
YTicksAt	special y axis tick marks	

Attribute	Purpose	Default Value
YTicksAnchor	user defined start of y axis tick marks	0
YTicksNumber	number of y axis tick marks	Normal
YTicksBetween	number of minor (unlabeled) y axis tick marks between major (labeled) y axis tick marks	1
YTicksVisible	display y axis tick marks?	TRUE
YTicksDistance	distance of tick marks on y axis	0
YTicksLabelStyle	display style of y axis tick labels	Horizontal
YTicksLabelsVisible	display y axis tick labels?	TRUE

## Examples

### Example 1

When executing a plot command, a default `plot::CoordinateSystem2d` is created implicitly which contains the specified graphical objects:

```
f := plot::Function2d(sin(x)^2, x = -PI..PI):
g := plot::Function2d(cos(x)^2, x = -PI..PI):
plot(f, g)
```

## plot::CoordinateSystem2d

---

We can also create the coordinate system explicitly. The result is the same:

```
plot(plot::CoordinateSystem2d(f, g))
```

delete f, g:

## Example 2

We present the yearly sales of pears and apples in one scene. Different coordinate systems are used to obtain separate axes. We set various attributes to determine the positioning of the axes and their titles:

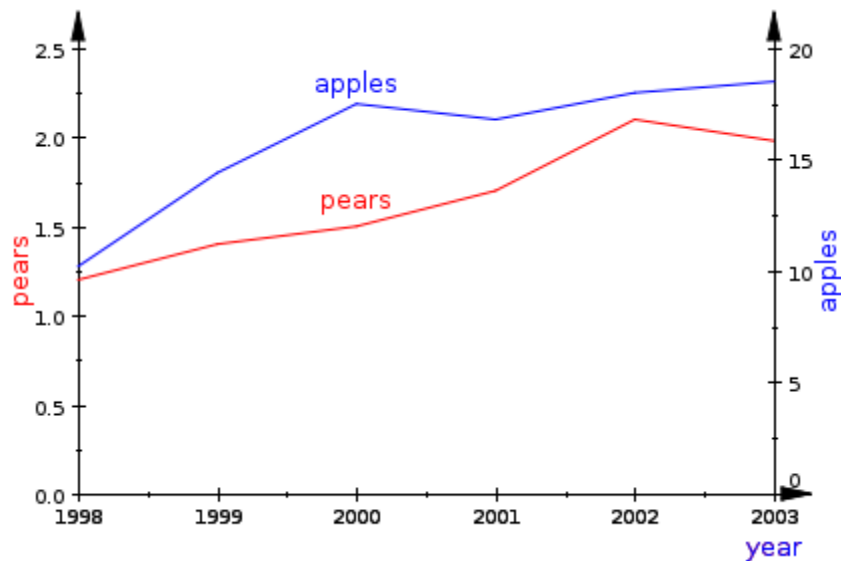

```
pears := plot::Polygon2d(
 [[1998, 1.2], [1999, 1.4], [2000, 1.5],
 [2001, 1.7], [2002, 2.1], [2003, 1.98]],
 Color = RGB::Red, Title = "pears",
 TitlePosition = [2000, 1.6],
 TitleFont = [RGB::Red]):
apples := plot::Polygon2d(
 [[1998, 10.2], [1999, 14.4], [2000, 17.5],
 [2001, 16.8], [2002, 18.0], [2003, 18.5]],
 Color = RGB::Blue, Title = "apples",
 TitlePosition = [2000, 18.0],
```

# plot::CoordinateSystem2d

```
TitleFont = [RGB::Blue]):

CS1 := plot::CoordinateSystem2d(pears):
CS1::AxesOriginX := 1998:
CS1::ViewingBox := [1998..2003, 0..2.5]:
CS1::AxesTitleFont := [RGB::Red]:
CS1::XAxisTitle := "year":
CS1::YAxisTitle := "pears":

CS2 := plot::CoordinateSystem2d(apples):
CS2::AxesOriginX := 2003:
CS2::ViewingBox := [1998..2003, 0..20]:
CS2::AxesTitleFont := [RGB::Blue]:
CS2::XAxisTitle := "year":
CS2::YAxisTitle := "apples":
plot(CS1, CS2, Axes = Origin, YAxisTitleAlignment = Center,
 YAxisTitleOrientation = Vertical)
```

`delete pears, apples, CS1, CS2:`

`plot::Canvas` | `plot::CoordinateSystem2d` | `plot::Scene2d`

# plot::CoordinateSystem3d

---

**Purpose** Coordinate system to display 3D objects in

**Syntax** `plot::CoordinateSystem3d(object1, object2, , <a  
= amin .. amax>, options)`

**Description** `plot::CoordinateSystem3d` is a container to display graphical 3D objects within. Usually, the user does not need to create such an object explicitly, because a `plot` command such as `plot(object1, object2, )` creates a default object of type `plot::CoordinateSystem3d` implicitly to display the graphical objects in.

The `plot::CoordinateSystem3d` object is always visible in the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). It contains the graphical objects as its children. When the coordinate system object is selected, it provides access to a variety of attributes that are associated with the coordinate system. These attributes allow to manipulate:

- the `CoordinateType` (linear vs. logarithmic coordinates),
- the `ViewingBox` (visibility range),
- the coordinate axes (axes titles, visibility, alignment, type, tips etc.),
- the ticks along the coordinate axes (number of tick marks, visibility, tick labels etc.),
- the coordinate grid (visibility, color, line width etc.),
- the scaling ratios of the coordinate directions (`Constrained` vs. `UnConstrained`).

A complete listing of the attributes associated with the coordinate system is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the coordinate system, also attributes for the graphical objects inside the coordinate system can be specified when generating an object of type `plot::CoordinateSystem3d`. These

attribute values are inherited to the graphical objects as new default values.

A graphical scene may contain more than one coordinate system. Each coordinate system provides separate coordinate axes, ticks, grid lines etc.

In such a case, separate `plot::CoordinateSystem3d` containers must be created explicitly by the user and passed to a `plot` command (or inserted into a scene of type `plot::Scene3d`). Cf. “Example 2” on page 23-1237.

## Attributes

Attribute	Purpose	Default Value
Axes	type of the coordinate axes	Boxed
AxesTips	arrow tips at the coordinate axes?	FALSE
AxesOrigin	crosspoint of the coordinate axes	[0, 0, 0]
AxesTitles	titles for the coordinate axes	[" x ", " y ", " z "]
AxesOriginX	crosspoint of the coordinate axes, x-coordinate	0
AxesOriginY	crosspoint of the coordinate axes, y-coordinate	0
AxesOriginZ	crosspoint of the coordinate axes, z-coordinate	0
AxesVisible	display coordinate axes?	TRUE

# plot::CoordinateSystem3d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
AxesLineColor	color of the coordinate axes	RGB::Black
AxesLineWidth	width of the coordinate axes	0.18
AxesTitleFont	font of axes titles	[" sans-serif ", 10]
AxesTitleAlignment	alignment of axes titles	Center
GridVisible	display a coordinate grid?	FALSE
GridLineColor	line color of the coordinate grid	RGB::Grey60
GridLineWidth	width of coordinate grid lines	0.1
GridLineStyle	line style of the coordinate grid	Solid
Name	the name of a plot object (for browser and legend)	
Scaling	scaling ratios	Unconstrained
SubgridVisible	display a coordinate subgrid?	FALSE
SubgridLineColor	line color of the coordinate subgrid	RGB::Grey80
SubgridLineWidth	width of coordinate subgrid lines	0.1
SubgridLineStyle	line style of the coordinate subgrid	Solid

Attribute	Purpose	Default Value
TicksAt	special axes tick marks	
TicksAnchor	user defined start of axes tick marks	0
TicksLength	length of axes tick marks	2
TicksNumber	number of axes tick marks	Normal
TicksBetween	number of minor (unlabeled) axes tick marks between major (labeled) axes tick marks	1
TicksVisible	display axes tick marks?	TRUE
TicksDistance	user defined axes tick mark distance	0
TicksLabelFont	font of tick labels	[" sans-serif ", 8]
TicksLabelStyle	display style of axes tick labels	Horizontal
TicksLabelsVisible	display axes tick labels?	TRUE
ViewingBox	the visible coordinate range	[Automatic .. Automatic, Automatic .. Automatic, Automatic .. Automatic]
ViewingBoxXMin	the smallest visible x-values	Automatic

# plot::CoordinateSystem3d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ViewingBoxYMin	the smallest visible y-values	Automatic
ViewingBoxXMax	the largest visible x-values	Automatic
ViewingBoxZMin	the smallest visible z-values	Automatic
ViewingBoxYMax	the largest visible y-values	Automatic
ViewingBoxZMax	the largest visible z-values	Automatic
ViewingBoxXRange	the range of x-values visible	Automatic .. Automatic
ViewingBoxYRange	the range of y-values visible	Automatic .. Automatic
ViewingBoxZRange	the range of z-values visible	Automatic .. Automatic
XAxisTitle	title for the x axis	" x "
XAxisVisible	display x axis?	TRUE
XAxisTitleAlignment	alignment of x axis title	Center
XGridVisible	display a coordinate grid in x-direction?	FALSE
XSubgridVisible	display a coordinate subgrid in x-direction?	FALSE
XTicksAt	special x axis tick marks	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
XTicksAnchor	user defined start of x axis tick marks	0
XTicksNumber	number of x axis tick marks	Normal
XTicksBetween	number of minor (unlabeled) x axis tick marks between major (labeled) x axis tick marks	1
XTicksVisible	display x axis tick marks?	TRUE
XTicksDistance	distance of tick marks on x axis	0
XTicksLabelStyle	display style of x axis tick labels	Horizontal
XTicksLabelsVisible	display x axis tick labels?	TRUE
YAxisTitle	title for the y axis	" y "
YAxisVisible	display y axis?	TRUE
YAxisTitleAlignment	alignment of y axis title	Center
YGridVisible	display a coordinate grid in y-direction?	FALSE
YSubgridVisible	display a coordinate subgrid in y-direction?	FALSE
YTicksAt	special y axis tick marks	

# plot::CoordinateSystem3d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
YTicksAnchor	user defined start of y axis tick marks	0
YTicksNumber	number of y axis tick marks	Normal
YTicksBetween	number of minor (unlabeled) y axis tick marks between major (labeled) y axis tick marks	1
YTicksVisible	display y axis tick marks?	TRUE
YTicksDistance	distance of tick marks on y axis	0
YTicksLabelStyle	display style of y axis tick labels	Horizontal
YTicksLabelsVisible	display y axis tick labels?	TRUE
ZAxisTitle	title for the z axis	" z "
ZAxisVisible	display z axis?	TRUE
ZAxisTitleAlignment	alignment of z axis title	Center
ZGridVisible	display a coordinate grid in z-direction?	FALSE
ZSubgridVisible	display a coordinate subgrid in z-direction?	FALSE
ZTicksAt	special z axis tick marks	

Attribute	Purpose	Default Value
ZTicksAnchor	user defined start of z axis tick marks	0
ZTicksNumber	number of z axis tick marks	Normal
ZTicksBetween	number of minor (unlabeled) z axis tick marks between major (labeled) z axis tick marks	1
ZTicksVisible	display z axis tick marks?	TRUE
ZTicksDistance	distance of tick marks on z axis	0
ZTicksLabelStyle	display style of z axis tick labels	Horizontal
ZTicksLabelsVisible	display z axis tick labels?	TRUE

## Examples

### Example 1

When executing a plot command, a default `plot::CoordinateSystem3d` is created implicitly which contains the specified graphical objects:

```
f := plot::Function3d(sin(x - y)^2, x = -PI..PI, y = -PI..PI):
g := plot::Function3d(cos(x - y)^2, x = -PI..PI, y = -PI..PI):
plot(f, g)
```

## plot::CoordinateSystem3d

---

We can also create the coordinate system explicitly. The result is the same:

```
plot(plot::CoordinateSystem3d(f, g))
```

delete f, g:

## Example 2

The functions  $f_1 = \sin(x - y)$  and  $f_2 = \sin(h)(x + y)$  cannot be plotted simultaneously in one coordinate system over the range  $x \in [-10, 10]$ ,  $y \in [-10, 10]$ , because they produce function values of different orders of magnitude. To plot them together, we use two different coordinate systems. We request explicit vertical ranges for the (rather different) viewing boxes by the attribute `ViewingBoxZRange`.

We set various attributes of the coordinate systems to determine the positioning of the axes and their titles:

```
f1 := plot::Function3d(sin(x - y), x = -10..10, y = -10..10,
 Submesh = [2, 2],
 Color = RGB::Red, FillColorType = Flat,
 Legend = "sin(x - y)"):
CS1 := plot::CoordinateSystem3d(f1):
```

# plot::CoordinateSystem3d

```
CS1::Axes := Origin:
CS1::AxesOrigin := [-10, 10, -3]:
CS1::ViewingBoxZRange := -3..3:
CS1::ZAxisTitle := "sin":

f2 := plot::Function3d(sinh(x + y), x = -10..10, y = -10..10,
 Color = RGB::Blue, FillColorType = Flat,
 Legend = "sinh(x + y)":
CS2 := plot::CoordinateSystem3d(f2):
CS2::Axes := Origin:
CS2::AxesOrigin := [10, -10, -3*10^8]:
CS2::ViewingBoxZRange := -3*10^8..3*10^8:
CS2::ZAxisTitle := "sinh":

plot(CS1, CS2):
```

```
delete f1, CS1, f2, CS2:
```

**Parameters**     `object1, object2, ...`  
                    Graphical 3D objects

**See Also**

**MuPAD  
Functions**     `plot` | `plot::copy`

**MuPAD  
Graphical  
Primitives**     `plot::Canvas` | `plot::CoordinateSystem3d` | `plot::Scene3d`

# plot::Group2d

---

**Purpose** Groups of 2D objects

**Syntax** `plot::Group2d(object2d1, object2d2, ..., <a = amin .. amax>, options)`

**Description** `plot::Group2d` forms a group of any number of graphical 2D objects.

Grouping together a larger number of graphical objects and accessing the group as a whole simplifies their handling. In particular, the main purpose of a group is to inherit graphical attributes that are shared by all members of the group.

If you wish to change the inherited attributes interactively, you should not select the group itself in the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). Underneath the group object, you find 'defaults' branches for the objects in the group. Select the 'defaults' branch for the object type that you wish to set attributes for.

A group may again contain groups.

---

**Note** When working with groups of points, it is more efficient to use the specialized grouping constructs `plot::PointList2d` and `plot::PointList3d` instead of generic groups of points!

---

## Attributes

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
Visible	visibility	TRUE

**Examples****Example 1**

We plot two groups of bubbles. Some bubbles are not visible as they are inside larger bubbles:

```
G1 := plot::Group3d(plot::Sphere(1/n, [0, 0, n/2 + 1/n]
) $ n = 1..10):
G2 := plot::Group3d(plot::Sphere(1/(3*n), [0, 0, n/2 + 1/n]
) $ n = 2..10):
plot(G1, G2)
```

We wish to increase transparency of all bubbles in the first group, but keep the bubbles in the second group opaque. Since the bubbles are grouped, it is easy to set different attribute values for the two groups:

```
G1::Color := RGB::SkyBlue.[0.25]:
G2::Color := RGB::Red:
plot(G1, G2)
```

```
delete G1, G2:
```

## Example 2

Consider a group G1 consisting of two triangles inscribed in an ellipse. We form a new group G2 consisting of the group G1, the ellipse and its focal points. The entire figure given by the group G2 is rotated by an animated `plot::Rotate2d`:

```
G1 := plot::Group2d(
 plot::Polygon2d([[0, -1], [0, 1], [-2, 0]]),
 plot::Polygon2d([[0, -1], [0, 1], [2, 0]]),
 Closed = TRUE, Filled = TRUE, Color = RGB::Blue):
G2 := plot::Group2d(
 G1,
 plot::Ellipse2d(2, 1,[0, 0]),
 plot::PointList2d([[-sqrt(3), 0], [sqrt(3), 0]]),
 PointSize = 2*unit::mm,
 PointColor = RGB::Red,
```

```
LineColor = RGB::Black):
plot(plot::Rotate2d(a, [0, 0], a = 0..2*PI, G2))
```

```
delete G1, G2:
```

**Concepts**

- “Groups of Primitives”

# plot::Scene2d

---

**Purpose** 2D scenes

**Syntax** `plot::Scene2d(object2d1, object2d2, ..., <a = amin .. amax>, options)`

**Description** `plot::Scene2d` is a container to display one or more coordinate systems containing graphical objects. Scene objects must be created when several graphical scenes are to be displayed simultaneously in a plot.

Usually, you do not need to create a scene object explicitly, because a `plot` command such as `plot(object1, object2, ...)` creates a default scene object implicitly to display the graphical objects in.

The need for creating scene objects explicitly arises only when several scenes are to be displayed simultaneously in one plot.

The MuPAD graphics makes a clear division between 2D and 3D. Scene objects of type `plot::Scene2d` do not accept 3D objects and `plot::Scene3d` objects do not accept 2D objects. When several scenes are displayed simultaneously in a single plot, all scenes must be of the same dimension.

Strictly speaking, a 2D scene object is a container for coordinate systems of type `plot::CoordinateSystem2d`. However, you do not have to bother about this technicality because a suitable default coordinate system is created internally, when graphical primitives are passed to `plot::Scene2d`.

Scene objects are always visible in the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). Each scene contains one or more coordinate systems as its children. When the scene object is selected, it provides access to a variety of attributes that are associated with scenes. The scene attributes allow to

- set annotations (Header, Footer) and control the Legend,
- set layout parameters such as height and width (if the canvas attribute Layout is set to Absolute or Relative),

- set various style parameters such as BackgroundColor etc.

A complete listing of the attributes associated with a 2D scene is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the scene object, also attributes for the coordinate system and the graphical objects inside the scene can be specified when generating a scene object. These attribute values are inherited to the coordinate system and the graphical objects as new default values.

A plot may contain more than one graphical scene. In such a case, separate scene objects must be created explicitly by the user and passed to a plot command (or inserted into an object of type `plot::Canvas`). For details on the layout of scenes inside the drawing area (“canvas”), see the help page of the canvas attribute `Layout`.

See “Example 1” on page 23-1253.

## Attributes

Attribute	Purpose	Default Value
BackgroundColor	background color	RGB::White
BackgroundTransparent	plot a scene on a transparent background	FALSE
BorderColor	color of frame/border around canvas and scenes	RGB::Grey50
BorderWidth	width of frame/border around canvas and scenes	0
Bottom	distance of bottom of scene to bottom of canvas	0

## plot::Scene2d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
BottomMargin	bottom margin width	1
Footer	footer text	
FooterFont	font of footers (scene and canvas)	[" sans-serif ", 12]
FooterAlignment	alignment of footer of canvas and scenes	Center
Header	header text	
HeaderFont	font of headers (scene and canvas)	[" sans-serif ", 12]
HeaderAlignment	alignment of header of canvas and scenes	Center
Height	heights of canvas/scenes	80
Left	distance of left of scene to left of canvas	0
LeftMargin	left margin width	1
LegendFont	font of legend entries	[" sans-serif ", 8]

RightMargin	right margin width	1

Attribute	Purpose	Default Value
TopMargin	top margin width	1
Width	widths of canvas/scenes	120

## Examples

### Example 1

Scene objects have to be created explicitly only when several scenes are to be displayed simultaneously in one plot. The following call uses the automatic layout of several scenes in a canvas:

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI),
 Header = "the sine function"):
S2 := plot::Scene2d(plot::Function2d(cos(x), x = 0..2*PI),
 Header = "the cosine function"):
S3 := plot::Scene2d(plot::Function2d(tan(x), x = 0..PI),
 Header = "the tan function"):
S4 := plot::Scene2d(plot::Function2d(cot(x), x = 0..PI),
 Header = "the cot function"):
plot(S1, S2, S3, S4, BorderWidth = 0.5*unit::mm)
```

# plot::Scene2d

We use the canvas attribute `Layout = Relative` to position 3 of these scenes in the canvas. The size of the scenes is set with the attributes `Width` and `Height`, specifying multiples of the canvas' width and height. The bottom left corner of each scene is positioned with the scene attributes `Bottom` and `Left`:

```
S1::Width := 0.475: S1::Height := 0.42:
S2::Width := 0.475: S2::Height := 0.42:
S3::Width := 0.475: S3::Height := 0.42:
S1::Bottom := 0.46: S1::Left := 0.02:
S2::Bottom := 0.02: S2::Left := 0.02:
S3::Bottom := 0.26: S3::Left := 0.51:
S3::HeaderFont := ["Times New Roman", Italic, 12]:
plot(S1, S2, S3, Layout = Relative,
 BorderWidth = 0.5*unit::mm,
 plot::Scene2d::BorderWidth = 0.2*unit::mm,
 Header = "trigonometric functions",
 HeaderFont = ["Times New Roman", Bold, 18]):
```

delete S1, S2, S3, S4:

### Example 2

Conic sections are the curves that you get when intersecting a cone and a plane. The first scene displays a plane and a rotating cone, the second the corresponding conic section:

```
c := plot::Cone(1, [-sin(a), 0, -cos(a)], [sin(a), 0, cos(a)],
 a = 0..2*PI):
s := plot::Surface([x, y, 0], x = -1..1, y = -1..1):
S1 := plot::Scene3d(c, s):
S2 := plot::Scene3d(c, ViewingBoxZRange = -0.01 .. 0.01):
plot(S1, S2, Layout = Horizontal)
```

# plot::Scene2d

---

delete c, s, S1, S2:

```

## Description

`plot::Scene3d` is a container to display one or more coordinate systems containing graphical objects. Scene objects must be created when several graphical scenes are to be displayed simultaneously in a plot.

Usually, you do not need to create a scene object explicitly, because a `plot` command such as `plot(object1, object2, )` creates a default scene object implicitly to display the graphical objects in.

The need for creating scene objects explicitly arises only when several scenes are to be displayed simultaneously in one plot.

The MuPAD graphics makes a clear division between 2D and 3D. Scene objects of type `plot::Scene2d` do not accept 3D objects and `plot::Scene3d` objects do not accept 2D objects. When several scenes are displayed simultaneously in a single plot, all scenes must be of the same dimension.

Strictly speaking, a 3D scene object is a container for coordinate systems of type `plot::CoordinateSystem3d`. However, you do not have to bother about this technicality because a suitable default coordinate system is created internally, when graphical primitives are passed to `plot::Scene3d`.

Scene objects are always visible in the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). Each scene contains one or more coordinate systems as its children. When the scene object is selected, it provides access to a variety of attributes that are associated with scenes. The scene attributes allow to

- set annotations (Header, Footer) and control the Legend,
- set layout parameters such as height and width (if the canvas attribute `Layout` is set to `Absolute` or `Relative`),

# plot::Scene3d

---

- set a direction for the automatic camera in 3D (`CameraDirection`),
- set various style parameters such as `BackgroundColor` etc.

A complete listing of the attributes associated with a scene is given below. Follow the links to the help pages of the attributes to find more detailed information.

Apart from these attributes of the scene object, also attributes for the coordinate system and the graphical objects inside the scene can be specified when generating a scene object. These attribute values are inherited to the coordinate system and the graphical objects as new default values.

A plot may contain more than one graphical scene. In such a case, separate scene objects must be created explicitly by the user and passed to a plot command (or inserted into an object of type `plot::Canvas`). For details on the layout of scenes inside the drawing area (“canvas”), see the help page of the canvas attribute `Layout`.

Cf. “Example 1” on page 23-1261.

## Attributes

Attribute	Purpose	Default Value
<code>BackgroundColor</code>	background color	<code>RGB::White</code>
<code>BackgroundColor2</code>	second background color for color blends	<code>RGB::Grey75</code>
<code>BackgroundStyle</code>	color blends in the background	<code>Flat</code>
<code>BackgroundTransparent</code>	plot a scene on a transparent background	<code>FALSE</code>
<code>BorderColor</code>	color of frame/border around canvas and scenes	<code>RGB::Grey50</code>

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
BorderWidth	width of frame/border around canvas and scenes	0
Bottom	distance of bottom of scene to bottom of canvas	0
BottomMargin	bottom margin width	1
CameraDirection	the direction of the automatic camera	
CameraDirectionX	the direction of the automatic camera, x-component	
CameraDirectionY	the direction of the automatic camera, y-component	
CameraDirectionZ	the direction of the automatic camera, z-component	
Footer	footer text	
FooterFont	font of footers (scene and canvas)	[" sans-serif ", 12]
FooterAlignment	alignment of footer of canvas and scenes	Center
Header	header text	
HeaderFont	font of headers (scene and canvas)	[" sans-serif ", 12]
HeaderAlignment	alignment of header of canvas and scenes	Center

## plot::Scene3d

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Height	heights of canvas/scenes	80
Left	distance of left of scene to left of canvas	0
LeftMargin	left margin width	1
LegendFont	font of legend entries	[" sans-serif ", 8]
LegendVisible	switch legend on/off	FALSE
LegendPlacement	legend above or below	Bottom
LegendAlignment	legend at left, center, or right	Center
Lighting	light schemes for 3D graphics	Automatic
Margin	margins around canvas and scenes	1
Name	the name of a plot object (for browser and legend)	
RightMargin	right margin width	1
TopMargin	top margin width	1
Width	widths of canvas/scenes	120
YXRatio	scaling ratio between y and x axes	1
ZXRatio	scaling ratio between z and x axes	2/3

## Examples

### Example 1

Scene objects have to be created explicitly only when several scenes are to be displayed simultaneously in one plot. The following call uses the automatic layout of several scenes in a canvas:

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI),
 Header = "the sine function"):
S2 := plot::Scene2d(plot::Function2d(cos(x), x = 0..2*PI),
 Header = "the cosine function"):
S3 := plot::Scene2d(plot::Function2d(tan(x), x = 0..PI),
 Header = "the tan function"):
S4 := plot::Scene2d(plot::Function2d(cot(x), x = 0..PI),
 Header = "the cot function"):
plot(S1, S2, S3, S4, BorderWidth = 0.5*unit::mm)
```

We use the canvas attribute `Layout = Relative` to position 3 of these scenes in the canvas. The size of the scenes is set with the attributes `Width` and `Height`, specifying multiples of the canvas' width and height.

# plot::Scene3d

The bottom left corner of each scene is positioned with the scene attributes `Bottom` and `Left`:

```
S1::Width := 0.475: S1::Height := 0.42:
S2::Width := 0.475: S2::Height := 0.42:
S3::Width := 0.475: S3::Height := 0.42:
S1::Bottom := 0.46: S1::Left := 0.02:
S2::Bottom := 0.02: S2::Left := 0.02:
S3::Bottom := 0.26: S3::Left := 0.51:
S3::HeaderFont := ["Times New Roman", Italic, 12]:
plot(S1, S2, S3, Layout = Relative,
 BorderWidth = 0.5*unit::mm,
 plot::Scene2d::BorderWidth = 0.2*unit::mm,
 Header = "trigonometric functions",
 HeaderFont = ["Times New Roman", Bold, 18]):
```

```
delete S1, S2, S3, S4:
```

**Example 2**

Conic sections are the curves that you get when intersecting a cone and a plane. The first scene displays a plane and a rotating cone, the second the corresponding conic section:

```
c := plot::Cone(1, [-sin(a), 0, -cos(a)], [sin(a), 0, cos(a)],
 a = 0..2*PI):
s := plot::Surface([x, y, 0], x = -1..1, y = -1..1):
S1 := plot::Scene3d(c, s):
S2 := plot::Scene3d(c, ViewingBoxZRange = -0.01 .. 0.01):
plot(S1, S2, Layout = Horizontal)
```

```
delete c, s, S1, S2:
```

**Parameters**

**Purpose** Clipping of 3D objects

**Syntax** `plot::ClippingBox(xmin .. xmax, ymin .. ymax, zmin .. zmax, <a = amin .. amax>, options)`

**Description** A `plot::ClippingBox` defines a cubic box with edges parallel to the coordinate axes. When a clipping box is inserted in a 3D scene, only the parts of the graphical objects in the scene are visible that lie inside the coordinate range defined by the clipping box.

Inserting a `plot::ClippingBox` into a 3D scene has a similar effect as specifying a viewing box for the scene by the attribute `ViewingBox`.

However, the specified viewing box fills the entire drawing region of the plot, whereas a `plot::ClippingBox` preserves the space in the drawing region that the invisible parts would fill if no clipping box was used.

Moreover, in contrast to `plot::ClippingBox`, the visibility range defined by the `ViewingBox` cannot be animated.

In fact, the main purpose of `plot::ClippingBox` is to provide an animated version of the `ViewingBox`.

Size and location of the `ViewingBox` remain unaffected by the presence of a clipping box. Also coordinate axes are not clipped.

Only one single `plot::ClippingBox` should be used inside a 3D scene.

## Attributes

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

# plot::ClippingBox

---

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Visible	visibility	TRUE
XMax	final value of parameter "x"	
XMin	initial value of parameter "x"	
XRange	range of parameter "x"	
YMax	final value of parameter "y"	
YMin	initial value of parameter "y"	
YRange	range of parameter "y"	
ZMax	final value of parameter "z"	

Attribute	Purpose	Default Value
ZMin	initial value of parameter "z"	
ZRange	range of parameter "z"	

## Examples

### Example 1

We plot a full sphere yet rendering only a part of it visible. This is done by passing a suitable `plot::ClippingBox` to the `plot` command. Note that the viewing box remains unaffected:

```
plot(plot::Sphere(1, [0, 0, 0]),
 plot::ClippingBox(-1 + a .. 1 - a,
 -1 + a .. 1 - a,
 -1 .. 1, a = 0..1))
```

## Example 2

We plot a Klein bottle. By chopping off the upper parts, one can have a look inside:

```
KleinBottle := plot::Tube([6*cos(u)*(sin(u)-1), 0, 14*sin(u)],
 4 - 2*cos(u), u = -PI..PI):
C := plot::ClippingBox(-15..15, -10..10, -20.. a,
 a = 15 .. -20):
plot(KleinBottle, C, Axes = None)
```

```
delete KleinBottle, C:
```

## Parameters

$x_{\min}$ ,  $x_{\max}$

The borders of the visible range of the  $x$  coordinate: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$x_{\min}$ ,  $x_{\max}$  are equivalent to the attributes XMin, XMax.

**$y_{\min}$ ,  $y_{\max}$** 

The borders of the visible range of the  $y$  coordinate: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$y_{\min}$ ,  $y_{\max}$  are equivalent to the attributes YMin, YMax.

 **$z_{\min}$ ,  $z_{\max}$** 

The borders of the visible range of the  $z$  coordinate: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$z_{\min}$ ,  $z_{\max}$  are equivalent to the attributes ZMin, ZMax.

 **$a$** 

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

Graphical  
Primitives**

plot::CoordinateSystem3d

# plot::Reflect2d

---

**Purpose** Reflection about a 2D point or a line

**Syntax** `plot::Reflect2d([x1, y1], <[x2, y2>, obj1, obj2, ,  
<a = amin .. amax>, options)`

**Description** `plot::Reflect2d([ x1, y1], object)` reflects a 2D object about the point  $(x_1, y_1)$ .

`plot::Reflect2d([ x1, y1], [ x2, y2], object)` reflects a 2D object about the line through the points  $(x_1, y_1)$  and  $(x_2, y_2)$ .

Reflections are transformation objects that mirror their contents about a straight line (in 2D) or a plane (in 3D). In the degenerate case where both points on the line coincide, or the normal vector is given as  $[0, 0, 0]$ , or if only one point is specified, they reflect about a point.

Like all transformation objects, reflections may contain any number of objects of the appropriate dimension. Plotting the reflection object renders the reflections of all graphical objects inside.

Reflections can be animated. If the contained objects are animated, too, the animations will run simultaneously.

Animated reflection objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated reflection object than to redefine the object for each frame.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Frames	the number of frames in an animation	50
From	starting point of arrows and lines	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
FromX	starting point of arrows and lines, x-coordinate	
FromY	starting point of arrows and lines, y-coordinate	
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
To	end point of arrows and lines	

# plot::Reflect2d

Attribute	Purpose	Default Value
ToX	end point of arrows and lines, x-coordinate	
ToY	end point of arrows and lines, y-coordinate	

## Examples

### Example 1

We plot the reflection of a function graph about the origin:

```
plot(plot::Reflect2d([0, 0],
 plot::Function2d(x^2, x=-2..2)))
```

Reflecting a function about the main diagonal (the line through the origin and the point (1, 1)) shows the (multivalued) inverse function:

```
plot(plot::Reflect2d([0, 0], [1, 1],
 plot::Function2d(x^2, x=-2..2)))
```

To display both an object and its mirror image, assign the object to some variable and plot both:

```
f := plot::Function2d(x^2, x=-2..2, LineWidth = 0.5):
plot(f, plot::Reflect2d([0, 0], [1, 1], f))
```

## plot::Reflect2d

---

The following command shows two more useful variations: First, we use `plot::Line2d` to display the line of reflection. Second, we employ `plot::modify` to change the line color of the mirrored function graph:

```
g := plot::Line2d([0, 0], [1, 1],
 Color = RGB::Red,
 LineStyle = Dashed,
 Extension = Infinite):
f1 := plot::Reflect2d([0, 0], [1, 1],
 plot::modify(f, LineColor = RGB::Green)):
plot(f, g, f1)
```

### Example 2

A 3D function graph and its reflection about the point (0, 0, 2):

```
f := plot::Function3d(sin(cos(x) - cos(y)), x = 0..PI, y = -2..5)
p := plot::Point3d([0, 0, 2], PointSize=2):
plot(f, plot::Reflect3d([0, 0, 2], f), p,
 CameraDirection=[30, -50, 20])
```

## plot::Reflect2d

---

The same function graph and its reflection at a plane through the point  $(0, 0, 2)$  with an animated normal vector:

```
pl := plot::Plane([0, 0, 2], [a, 0, 1-a], a=0..1, Color=RGB::Green.
plot(f, plot::Reflect3d([0, 0, 2], [a, 0, 1-a], a=0..1, f), p, pl,
 CameraDirection=[30, -50, 20])
```

**Parameters**

**$x_1, y_1, x_2, y_2$**

The coordinates of two points on a line: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x_1, y_1, x_2, y_2$  are equivalent to the attributes From, To, FromX, FromY, ToX, ToY.

**obj1, obj2, ...**

Arbitrary plot objects of the appropriate dimension

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Reflect2d

### MuPAD Graphical Primitives

`plot::Reflect3d` | `plot::Line2d` | `plot::Plane` |  
`plot::Transform2d` | `plot::Transform3d`

## Purpose

Reflection about a 3D point or a plane

## Syntax

```
plot::Reflect3d([x, y, z], <[nx, ny, nz]>, obj1, obj2,
, <a = amin .. amax>, options)
```

## Description

`plot::Reflect3d([x, y, z], object)` reflects a 3D object about the point  $(x, y, z)$ .

`plot::Reflect3d([x, y, z], [nx, ny, nz], object)` reflects a 3D object about the plane through the point  $(x, y, z)$  with normal  $(n_x, n_y, n_z)$ .

Reflections are transformation objects that mirror their contents about a straight line (in 2D) or a plane (in 3D). In the degenerate case where both points on the line coincide, or the normal vector is given as  $[0, 0, 0]$ , or if only one point is specified, they reflect about a point.

Like all transformation objects, reflections may contain any number of objects of the appropriate dimension. Plotting the reflection object renders the reflections of all graphical objects inside.

Reflections can be animated. If the contained objects are animated, too, the animations will run simultaneously.

Animated reflection objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated reflection object than to redefine the object for each frame.

## Attributes

## Examples

### Example 1

We plot the reflection of a function graph about the origin:

```
plot(plot::Reflect2d([0, 0],
 plot::Function2d(x^2, x=-2..2)))
```

## plot::Reflect3d

---

Reflecting a function about the main diagonal (the line through the origin and the point (1, 1)) shows the (multivalued) inverse function:

```
plot(plot::Reflect2d([0, 0], [1, 1],
 plot::Function2d(x^2, x=-2..2)))
```

To display both an object and its mirror image, assign the object to some variable and plot both:

```
f := plot::Function2d(x^2, x=-2..2, LineWidth = 0.5):
plot(f, plot::Reflect2d([0, 0], [1, 1], f))
```

## plot::Reflect3d

---

The following command shows two more useful variations: First, we use `plot::Line2d` to display the line of reflection. Second, we employ `plot::modify` to change the line color of the mirrored function graph:

```
g := plot::Line2d([0, 0], [1, 1],
 Color = RGB::Red,
 LineStyle = Dashed,
 Extension = Infinite):
f1 := plot::Reflect2d([0, 0], [1, 1],
 plot::modify(f, LineColor = RGB::Green)):
plot(f, g, f1)
```

### Example 2

A 3D function graph and its reflection about the point (0, 0, 2):

```
f := plot::Function3d(sin(cos(x) - cos(y)), x = 0..PI, y = -2..5)
p := plot::Point3d([0, 0, 2], PointSize=2):
plot(f, plot::Reflect3d([0, 0, 2], f), p,
 CameraDirection=[30, -50, 20])
```

## plot::Reflect3d

---

The same function graph and its reflection at a plane through the point  $(0, 0, 2)$  with an animated normal vector:

```
pl := plot::Plane([0, 0, 2], [a, 0, 1-a], a=0..1, Color=RGB::Green.
plot(f, plot::Reflect3d([0, 0, 2], [a, 0, 1-a], a=0..1, f), p, pl,
 CameraDirection=[30, -50, 20])
```

**Parameters**

**$x, y, z$**

The coordinates of the mirror point or a point on the mirror plane, respectively: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$x, y, z$  are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

**$n_x, n_y, n_z$**

The coordinates of the normal of the mirror plane: real numerical values or arithmetical expressions of the animation parameter  $a$ .

$n_x, n_y, n_z$  are equivalent to the attributes Normal, NormalX, NormalY, NormalZ.

**obj1, obj2, ...**

Arbitrary plot objects of the appropriate dimension

# plot::Reflect3d

---

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

[plot::Reflect2d](#) | [plot::Line2d](#) | [plot::Plane](#) |  
[plot::Transform2d](#) | [plot::Transform3d](#)

**Purpose** Rotations of 2D objects

**Syntax** `plot::Rotate2d(angle, <[cx, cy>, obj1, <obj2, >, <a = amin .. amax>, options)`

**Description** `plot::Rotate2d(angle, [cx, cy], object)` rotates a 2D object counter clockwise by the given angle around the rotation center [c<sub>x</sub>, c<sub>y</sub>].

In 2D, the direction of the rotation is counter clock wise. Use negative angles to rotate clock wise.

Rotate objects can rotate several graphical objects simultaneously. Plotting the rotate object renders all graphical objects inside.

Rotated objects have a tendency to overestimate their `ViewingBox`. Cf. the help page of `ViewingBox`. In such a case, you should specify a suitable `ViewingBox` explicitly.

Transformation objects can be used inside rotate objects. If they are animated, the animations run simultaneously.

Animated rotate objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated rotate object than to redefine the object for each frame.

The function `op` allows to extract the graphical objects inside a rotate object.

## Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>Angle</code>	rotation angle	0
<code>Center</code>	center of objects, rotation center	[0, 0]

# plot::Rotate2d

---

Attribute	Purpose	Default Value
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
Frames	the number of frames in an animation	50
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

## Examples

### Example 1

Ellipses of type `plot::Ellipse2d` have symmetry axes parallel to the coordinate axes. You can use `plot::Rotate2d` to obtain ellipses with other orientations:

```
e0 := plot::Ellipse2d(3, 1, [0, 0]):
e1 := plot::Rotate2d(PI/4, [0, 0], e0):
e2 := plot::Rotate2d(-PI/4, [0, 0], e0):
plot(e0, e1, e2):
```

Similarly, 3D boxes with arbitrary orientation can be generated via `plot::Rotate3d`. We use several animated rotation objects:

```
b0 := plot::Box(-3..3, -2..2, -1..1):
b1 := plot::Rotate3d(a, [0, 0, 0], [0, 0, 1], b0,
 a = 0..PI/2, TimeRange = 0..3):
b2 := plot::Rotate3d(a, [0, 0, 0], [0, 1, 0], b1,
 a = 0..PI/2, TimeRange = 3..6):
b3 := plot::Rotate3d(a, [0, 0, 0], [1, 0, 0], b2,
 a = 0..PI/2, TimeRange = 6..9):
plot(b0, b3):
```

# plot::Rotate2d

---

```
delete e0, e1, e2, b0, b1, b2, b3:
```

## Example 2

We plot several copies of a function plot, rotated by different angles:

```
f := plot::Function2d(sin(x^3)/(x^2+1), x = -5..5, Mesh = 300):
plot(plot::Rotate2d(f, Angle = PI/11*a) $ a = 0..10):
```

delete f:

### Example 3

We plot turning cogs. Each animated rotate object rotates a curve and a line simultaneously:

```

r1 := 2: x1 := -r1: y1 := 0:
r2 := 1: x2 := r2: y2 := 0:
dr := 0.2:
cog1 := plot::Curve2d([x1 + (r1 + dr*cos(36*u))*cos(u),
 y1 + (r1 + dr*cos(36*u))*sin(u)],
 u = 0..2*PI, Mesh = 360):
cog2 := plot::Curve2d([x2 + (r2 - dr*cos(18*u))*cos(u),
 y2 + (r2 - dr*cos(18*u))*sin(u)],
 u = 0..2*PI, Mesh = 360):
line1 := plot::Line2d([x1, y1], [x1 + r1 + dr, y1],
 Color = RGB::Red):
line2 := plot::Line2d([x2, y2], [x2 - r2 + dr, y2],

```

# plot::Rotate2d

```
Color = RGB::Red):
Cog1 := plot::Rotate2d(-a, [x1, y1], cog1, line1,
a = 0..2*PI, Frames = 180):
Cog2 := plot::Rotate2d(2*a, [x2, y2], cog2, line2,
a = 0..2*PI, Frames = 180):
plot(Cog1, Cog2, Scaling = Constrained):
```

```
delete r1, x1, y1, r2, x2, y2, dr, cog1, cog2,
line1, line2, Cog1, Cog2:
```

## Example 4

We use an animated rotation inside another animated rotation:

```
L1 := plot::Line2d([0, 0], [0, 1]):
L2 := plot::Rotate2d(a, [0, 1], a = 0..2*PI,
plot::Line2d([0, 1], [1, 1]))):
plot(plot::Rotate2d(a, [0, 0], L1, L2, a = 0..PI/2))):
```

delete L1, L2:

## Parameters

### angle

The rotation angle in radians: a numerical real value or an arithmetical expression of the animation parameter  $a$ .

`angle` is equivalent to the attribute `Angle`.

### $c_x$ , $c_y$

The components of the rotation center: numerical real values or arithmetical expressions of the animation parameter  $a$ . If no rotation center is specified, the center  $[0, 0, 0]$  is used.

$c_x$ ,  $c_y$  are equivalent to the attributes `Center`, `CenterX`, `CenterY`.

### `obj1`, `obj2`, ...

Arbitrary plot objects of the appropriate dimension

# plot::Rotate2d

---

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Purpose

Rotations of 3D objects

## Syntax

```
plot::Rotate3d(angle, <[cx, cy, cz], [dx, dy, dz], obj1,
<obj2, >, <a = amin .. amax>, options)
```

## Description

`plot::Rotate3d`(angle, [c<sub>x</sub>, c<sub>y</sub>, c<sub>z</sub>], [d<sub>x</sub>, d<sub>y</sub>, d<sub>z</sub>], object) rotates a 3D object by the given angle around the rotation axis defined by the point [c<sub>x</sub>, c<sub>y</sub>, c<sub>z</sub>] and the direction [d<sub>x</sub>, d<sub>y</sub>, d<sub>z</sub>].

In 3D, the rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation.

Use negative angles to rotate in the opposite direction.

Rotate objects can rotate several graphical objects simultaneously. Plotting the rotate object renders all graphical objects inside.

Rotated objects have a tendency to overestimate their `ViewingBox`. Cf. the help page of `ViewingBox`. In such a case, you should specify a suitable `ViewingBox` explicitly.

Transformation objects can be used inside rotate objects. If they are animated, the animations run simultaneously.

Animated rotate objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated rotate object than to redefine the object for each frame.

The function `op` allows to extract the graphical objects inside a rotate object.

plot(e0, e1, e2):
```

## plot::Rotate3d

---

Similarly, 3D boxes with arbitrary orientation can be generated via `plot::Rotate3d`. We use several animated rotation objects:

```
b0 := plot::Box(-3..3, -2..2, -1..1):
b1 := plot::Rotate3d(a, [0, 0, 0], [0, 0, 1], b0,
 a = 0..PI/2, TimeRange = 0..3):
b2 := plot::Rotate3d(a, [0, 0, 0], [0, 1, 0], b1,
 a = 0..PI/2, TimeRange = 3..6):
b3 := plot::Rotate3d(a, [0, 0, 0], [1, 0, 0], b2,
 a = 0..PI/2, TimeRange = 6..9):
plot(b0, b3):
```

```
delete e0, e1, e2, b0, b1, b2, b3:
```

## Example 2

We plot several copies of a function plot, rotated by different angles:

```
f := plot::Function2d(sin(x^3)/(x^2+1), x = -5..5, Mesh = 300):
plot(plot::Rotate2d(f, Angle = PI/11*a) $ a = 0..10):
```

# plot::Rotate3d

delete f:

### Example 3

We plot turning cogs. Each animated rotate object rotates a curve and a line simultaneously:

```
r1 := 2: x1 := -r1: y1:= 0:
r2 := 1: x2 := r2: y2:= 0:
dr := 0.2:
cog1 := plot::Curve2d([x1 + (r1 + dr*cos(36*u))*cos(u),
 y1 + (r1 + dr*cos(36*u))*sin(u)],
 u = 0..2*PI, Mesh = 360):
cog2 := plot::Curve2d([x2 + (r2 - dr*cos(18*u))*cos(u),
 y2 + (r2 - dr*cos(18*u))*sin(u)],
 u = 0..2*PI, Mesh = 360):
line1 := plot::Line2d([x1, y1], [x1 + r1 + dr, y1],
 Color = RGB::Red):
line2 := plot::Line2d([x2, y2], [x2 - r2 + dr, y2],
```

```

Color = RGB::Red):
Cog1 := plot::Rotate2d(-a, [x1, y1], cog1, line1,
a = 0..2*PI, Frames = 180):
Cog2 := plot::Rotate2d(2*a, [x2, y2], cog2, line2,
a = 0..2*PI, Frames = 180):
plot(Cog1, Cog2, Scaling = Constrained):

```

```

delete r1, x1, y1, r2, x2, y2, dr, cog1, cog2,
line1, line2, Cog1, Cog2:

```

#### Example 4

We use an animated rotation inside another animated rotation:

```

L1 := plot::Line2d([0, 0], [0, 1]):
L2 := plot::Rotate2d(a, [0, 1], a = 0..2*PI,
plot::Line2d([0, 1], [1, 1])):
plot(plot::Rotate2d(a, [0, 0], L1, L2, a = 0..PI/2)):

```

# plot::Rotate3d

---

delete L1, L2:

## Parameters

### angle

The rotation angle in radians: a numerical real value or an arithmetical expression of the animation parameter  $a$ .

`angle` is equivalent to the attribute `Angle`.

### $c_x$ , $c_y$ , $c_z$

The components of the rotation center: numerical real values or arithmetical expressions of the animation parameter  $a$ . If no rotation center is specified, the center  $[0, 0, 0]$  is used.

$c_x$ ,  $c_y$ ,  $c_z$  are equivalent to the attributes `Center`, `CenterX`, `CenterY`, `CenterZ`.

### $d_x$ , $d_y$ , $d_z$

The components of the direction of the rotations axis: numerical real values or arithmetical expressions of the animation parameter  $a$ . If no direction is specified, the direction  $[0, 0, 1]$  is used.

$d_x$ ,  $d_y$ ,  $d_z$  are equivalent to the attributes `Axis`, `AxisX`, `AxisY`, `AxisZ`.

**obj<sub>1</sub>**, **obj<sub>2</sub>**, ...

Arbitrary plot objects of the appropriate dimension

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

`plot::Transform3d`

# plot::Scale2d

---

**Purpose**            Scaling of 2D objects

**Syntax**            `plot::Scale2d([sx, sy], obj1, <obj2, >, <a = amin .. amax>, options)`

**Description**       `plot::Scale2d([sx, sy], objects)` applies the scaling transformation  $X \rightarrow A X$  with the diagonal matrix  $A = \text{diag}(s_x, s_y)$  to 2D objects.

Scale objects can scale several graphical objects simultaneously. Plotting the scale object renders all graphical objects inside.

Transformation objects can be used inside scale objects. If they are animated, the animations run simultaneously.

Animated scale objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated scale object than to redefine the object for each frame.

The function `op` allows to extract the graphical objects inside a scale object.

## Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Frames	the number of frames in an animation	50
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	

Attribute	Purpose	Default Value
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Scale	scaling factors	[1, 1]
ScaleX	scaling factor in x-direction	1
ScaleY	scaling factor in y-direction	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0

## Examples

### Example 1

A scaling transformation turns a sphere into an ellipsoid:

```
plot(plot::Scale3d([1 + 3*a, 1 + 2*a, 1 + a],
 plot::Sphere(1, [0, 0, 0]),
 a = 0..1))
```

## plot::Scale2d

---

We plot a (southern) hemisphere and two scaled copies:

```
A0 := plot::Spherical([1, u, v], u = 0..2*PI, v = PI/2 .. PI):
A1 := plot::Scale3d([0.5, 0.4, 0.5], A0):
A2 := plot::Scale3d([0.2, 0.3, 0.2], A0):
plot(A0, A1, A2, CameraDirection = [-1, -2, 2.5]):
```

delete A0, A1, A2:

## Parameters

$s_x, s_y$

The scaling factors: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$s_x, s_y$  are equivalent to the attributes Scale, ScaleX, ScaleY.

$obj_1, obj_2, \dots$

Arbitrary plot objects of the appropriate dimension

$a$

Animation parameter, specified as  $a = a_{\min} + a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::Scale2d

`plot::Translate2d` | `plot::Translate3d` | `plot::Transform2d` |  
`plot::Transform3d`

# plot::Transform2d

---

**Purpose** Affine linear transformation of 2D objects

**Syntax** `plot::Transform2d(<b2d>, A2d, obj1, <obj2>, <a  
= amin .. amax>, options)`

**Description** `plot::Transform2d(b, A, objects)` with a vector  $b$  and a matrix  $A$  applies the affine linear transformation  $x \rightarrow Ax + b$  to 2D objects.

The transformation matrix  $A$  can be specified by a list of lists

`[[A1, 1, A1, 2, ], [A2, 1, A2, 2, ], ]`

with the sublists representing the rows.

A plain list

`[A1, 1, A1, 2, A2, 1, A2, 2]`

represents the matrix row by row in 2D.

Transform objects can transform several graphical objects simultaneously. Plotting the transform object renders all graphical objects inside.

Transformed objects have a tendency to overestimate their `ViewingBox`. Cf. the help page of `ViewingBox`. In such a case, you should specify a suitable `ViewingBox` explicitly.

Transformation objects can be used inside transformation objects. If they are animated, the animations run simultaneously.

Animated transform objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated transform object than to redefine the object for each frame.

The function `op` allows to extract the graphical objects inside a transformation object.

## Attributes

# plot::Transform2d

## Examples

### Example 1

We visualize a linear transformation  $X \rightarrow A X$  without shift:

```
x1 := plot::Arrow2d([0, 0], [1/3, 1], Color = RGB::Red):
x2 := plot::Arrow2d([0, 0], [1, 1], Color = RGB::Green):
x3 := plot::Arrow2d([0, 0], [1, 1/3], Color = RGB::Blue):
A := matrix([[1, -2], [-2, 1]]):
plot(plot::Scene2d(x1, x2, x3),
 plot::Scene2d(plot::Transform2d(A, x1, x2, x3)),
 Scaling = Constrained, Layout = Horizontal):
```

```
delete x1, x2, x3, A:
```

### Example 2

For some applications, it is very popular to plot a function in 3D together with a projection of its contour lines onto the lower or upper bounding plane. MuPAD has no direct option for this, but with

`plot::Transform3d`, it is possible to achieve the same effect. Assume you have the function under consideration in a `plot::Function3d` object:

```
f := plot::Function3d(sin(x*y)+cos(x^2-y),
 x=-3..3, y=-3..3, Submesh=[1,1]):
```

To plot contour lines at all, we use the attribute `ZContours`. Since we don't want to change our `f`, we create a modified *copy* using `plot::modify`:

```
plot(plot::modify(f, ZContours = [Automatic, 10]))
```

To only get contour lines, we have to change a few more parameters: We need to switch off the surface and the parameter lines. Then, we add height coloring to our lines and use `plot::Transform3d` to *project* them onto the plane  $z = -2.5$ . Finally, we plot these lines together with the original function:

# plot::Transform2d

---

```
plot(f,
 plot::Transform3d([0, 0, -2.5], // shift vector
 [1, 0, 0, // transformation matrix
 0, 1, 0,
 0, 0, 0],
 plot::modify(f,
 Filled = FALSE,
 XLinesVisible = FALSE, YLinesVisible = FALSE,
 ZContours = [Automatic, 10],
 LineColorFunction = // height coloring
 ((x, y, z) -> [(z+2)/4, 0, (2-z)/4])))
```

## Parameters $\mathbf{b}_{2d}$

The 2D shift vector: a list with 2 entries. Also vectors generated by matrix and arrays are accepted. The entries must be numerical values or arithmetical expressions of the animation parameter  $a$ .

$b_{2d}$  is equivalent to the attribute Shift.

## **$A_{2d}$**

The 2D transformation matrix: a 2 2 matrix, a 2 2 array, a list of 2 lists, or a plain list with 4 entries. The entries must be numerical values or arithmetical expressions of the animation parameter  $a$ .

$A_{2d}$  is equivalent to the attribute Matrix2d.

## **obj1, obj2, ...**

Plot objects of the appropriate dimension

## **$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

plot::Translate3d

# plot::Transform3d

---

## Purpose

Affine linear transformation of 3D objects

## Syntax

```
plot::Transform3d(<b3d>, A3d, obj1, <obj2, >, <a
= amin .. amax>, options)
```

## Description

`plot::Transform3d(b, A, objects)` transforms 3D objects accordingly.

The transformation matrix  $A$  may be specified by a list of lists

```
[[A1, 1, A1, 2,], [A2, 1, A2, 2,],]
```

with the sublists representing the rows.

A plain list

```
[A1, 1, A1, 2, , A3, 2, A3, 3]
```

represents the matrix row by row in 3D.

Transform objects can transform several graphical objects simultaneously. Plotting the transform object renders all graphical objects inside.

Transformed objects have a tendency to overestimate their `ViewingBox`. Cf. the help page of `ViewingBox`. In such a case, you should specify a suitable `ViewingBox` explicitly.

Transformation objects can be used inside transformation objects. If they are animated, the animations run simultaneously.

Animated transform objects are rather “cheap” concerning computing and storing costs. For more complex graphical objects, it is more efficient to use an animated transform object than to redefine the object for each frame.

The function `op` allows to extract the graphical objects inside a transformation object.

## Attributes

A := matrix([[1, -2], [-2, 1]]):
plot(plot::Scene2d(x1, x2, x3),
 plot::Scene2d(plot::Transform2d(A, x1, x2, x3)),
 Scaling = Constrained, Layout = Horizontal):
```

```
delete x1, x2, x3, A:
```

### Example 2

For some applications, it is very popular to plot a function in 3D together with a projection of its contour lines onto the lower or upper bounding plane. MuPAD has no direct option for this, but with

`plot::Transform3d`, it is possible to achieve the same effect. Assume you have the function under consideration in a `plot::Function3d` object:

```
f := plot::Function3d(sin(x*y)+cos(x^2-y),
 x=-3..3, y=-3..3, Submesh=[1,1]):
```

To plot contour lines at all, we use the attribute `ZContours`. Since we don't want to change our `f`, we create a modified *copy* using `plot::modify`:

```
plot(plot::modify(f, ZContours = [Automatic, 10]))
```

To only get contour lines, we have to change a few more parameters: We need to switch off the surface and the parameter lines. Then, we add height coloring to our lines and use `plot::Transform3d` to *project* them onto the plane  $z = -2.5$ . Finally, we plot these lines together with the original function:

# plot::Transform3d

---

```
plot(f,
 plot::Transform3d([0, 0, -2.5], // shift vector
 [1, 0, 0, // transformation matrix
 0, 1, 0,
 0, 0, 0],
 plot::modify(f,
 Filled = FALSE,
 XLinesVisible = FALSE, YLinesVisible = FALSE,
 ZContours = [Automatic, 10],
 LineColorFunction = // height coloring
 ((x, y, z) -> [(z+2)/4, 0, (2-z)/4])))
```

## Parameters $\mathbf{b}_{3d}$

The 3D shift vector: a list with 3 entries. Also vectors generated by matrix or arrays are accepted. The entries must be numerical values or arithmetical expressions of the animation parameter  $a$ .

$b_{3d}$  is equivalent to the attribute Shift.

## **$A_{3d}$**

The 3D transformation matrix: a 3 3 matrix, a 3 3 array, a list of 3 lists, or a plain list with 9 entries. The entries must be numerical values or arithmetical expressions of the animation parameter  $a$ .

$A_{3d}$  is equivalent to the attribute Matrix3d.

## **obj1, obj2, ...**

Plot objects of the appropriate dimension

## **$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## Examples

### Example 1

We use an animated translation object to shift a vector to the tip of another vector:

```
A1 := plot::Arrow2d([0, 0], [2, 1], Color = RGB::Red):
A2 := plot::Arrow2d([0, 0], [2, 3], Color = RGB::Green):
plot(A1, plot::Translate2d([2*a, a], A2, a = 0..1,
 TimeRange = 0..4),
 plot::Arrow2d([0, 0], [4, 4], Color = RGB::Blue,
 VisibleFromTo = 4..6),
 Header = "how to add 2 vectors"):
```

# plot::Translate2d

```
delete A1, A2:
```

## Example 2

Note that `plot::Translate2d` and `plot::Translate3d` do not actually change the objects translated, so it is possible to use the same object in different places in the same plot. As an example, we show an intuitive way of constructing the Sierpinski carpet, a flat version of the Menger sponge.

The Sierpinski carpet is a fractal with the general shape of a square and the property that the following operation maps it onto itself: Take eight copies, scale them by  $\frac{1}{3}$ , and arrange them in a square with the middle left unfilled. Now, this can be directly written in MuPAD code:

```
Carpet := proc(iter)
 local square;
begin
 if iter <= 1 then
```

```
 return(plot::Polygon2d([[0,0], [0,1], [1,1], [1,0]],
 Closed, Filled, FillPattern = Solid,
 FillColor = [0.2234, 0.4563, 0.4568],
 LinesVisible, LineColor = RGB::White,
 Scaling = Constrained, Axes = None));
 else
 square := plot::Scale2d([1/3, 1/3], Carpet(iter-1));
 return(plot::Group2d(
 plot::Translate2d([0, 0], square),
 plot::Translate2d([0, 1/3], square),
 plot::Translate2d([0, 2/3], square),
 plot::Translate2d([1/3, 0], square),
 // plot::Translate2d([1/3, 1/3], square),
 plot::Translate2d([1/3, 2/3], square),
 plot::Translate2d([2/3, 0], square),
 plot::Translate2d([2/3, 1/3], square),
 plot::Translate2d([2/3, 2/3], square)));
 end_if;
end_proc;

plot(Carpet(3))
```

# plot::Translate2d

---

## Parameters

**$d_x$ ,  $d_y$**

The components of the shift vector: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$d_x$ ,  $d_y$  are equivalent to the attribute `Shift`.

**$obj_1$ ,  $obj_2$ , ...**

Arbitrary plot objects of the appropriate dimension

**$a$**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

plot::Transform3d

# plot::AmbientLight

---

**Purpose** Ambient light

**Syntax** `plot::AmbientLight(<intensity>, <a = amin .. amax>, options)`

**Description** `plot::AmbientLight(intensity)` generates undirected ambient light of the given intensity.

Each 3D scene is illuminated by several light sources that are set automatically and cannot be controlled by the user. Cf. the help page of `Lighting`.

If special light effects are desired, the user can create alternative light sources of various types such as `plot::AmbientLight`, `plot::DistantLight`, `plot::PointLight`, and `plot::SpotLight`.

If at least one user defined light source is inserted into the scene (e.g., by simply passing the light objects as input parameters to the `plot` command), the automatic lights are switched off and the user defined lights are used to illuminate the scene.

While directed lights such as `plot::DistantLight` etc. create shading effects that add depth to the picture, a certain amount of undirected ambient light is usually needed.

`plot::AmbientLight(intensity)` creates ambient light whose intensity is given by the parameter `intensity`. When the intensity is 1, the ambient light dominates all other light sources.

By default, white light is created. Other colours can be chosen by the attribute `LightColor`.

It does not make sense to have more than one ambient light object in a scene.

## Attributes

Attribute	Purpose	Default Value
Frames	the number of frames in an animation	50
LightColor	the color of light	RGB::White

Attribute	Purpose	Default Value
LightIntensity	intensity of light	1.0
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Visible	visibility	TRUE

## Examples

### Example 1

We create a 3D function graph in flat white and use ambient white light to illuminate it:

```
f := plot::Function3d(sin(x + y) + cos(x - y),
 x = -PI..PI, y = -PI..PI,
 FillColorType = Flat,
 Color = RGB::White):
ambientlight := plot::AmbientLight(0.7):
plot(f, ambientlight):
```

## plot::AmbientLight

---

We create another ambient light with animated intensity:

```
ambientlight := plot::AmbientLight(a, a = 0..1):
plot(f, ambientlight)
```

We add directed yellow light to the scene and study the mixture between the “sunlight” and an increasing amount of ambient light. When the ambient light is at full intensity, it dominates the directed light completely:

```
sunlight := plot::DistantLight([0, 0, 0], [5, 1, -3], 1,
 LightColor = RGB::Yellow):
plot(f, ambientlight, sunlight)
```

# plot::AmbientLight

---

```
delete f, ambientlight, sunlight:
```

## Parameters

### intensity

The intensity of the light: a numerical value between 0 and 1 or an arithmetical expression of the animation parameter  $a$ .

`intensity` is equivalent to the attribute `LightIntensity`.

### $a$

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

plot::PointLight | plot::DistantLight | plot::SpotLight

# plot::Camera

---

**Purpose** Camera

**Syntax** `plot::Camera([px, py, pz], [fx, fy, fz], angle, <a = amin .. amax>, options)`

**Description** `plot::Camera([px, py, pz], [fx, fy, fz], angle)` creates a camera at the position  $[p_x, p_y, p_z]$  pointing towards the focal point  $[f_x, f_y, f_z]$ . The opening angle of its lense is given by angle.

When creating a 3D scene, an “automatic camera” is used. Its location can be controlled by the attribute `CameraDirection`, but there are now further means of manipulating its parameters.

If the automatic camera does not suffice for your purposes, you may define your own camera by `plot::Camera`. Inserting such a camera object in your scene (for example, just by passing the camera as an argument to the `plot` command), the automatic camera is switched off and the new camera determines the view.

A camera of type `plot::Camera` allows to set all parameters determining the view and its perspective. Further, all parameters can be animated such that an animated “flight” through a 3D scene can be realized.

The first argument  $[p_x, p_y, p_z]$  in the call generating a camera is the `Position` of the camera in 3-space. The second argument  $[f_x, f_y, f_z]$  is the point the camera is aimed at (`FocalPoint`).

The optical axis is given by the vector `FocalPoint - Position`.

Together with the opening angle of the zoom lense (`ViewingAngle`), these parameters determine the view of the scene.

The `FocalPoint` vector can be replaced by any other point on the optical axes without changing the view. (`FocalPoint` and `Position` should not coincide, though.)

By default, the  $z$ -direction in 3-space corresponds to the vertical direction of the final picture. If this is not desired, the camera can be rotated around its optical axes using the attribute `UpVector`.

Depending on the distance of the camera to the graphical scene and the opening angle of the lense, the scene may fill only a small portion of the viewing area if the camera is too far away. If the camera is too close, only some parts of the scene may be visible

Just as for a real camera, you will have to move closer to or farther away from the scene to make it fill the drawing area as desired. Alternatively, you may keep the camera position fixed and use the zoom lense by choosing an appropriate `ViewingAngle`.

As in real life, you have to find appropriate parameters experimentally by looking at the picture and changing the parameters interactively.

Alternatively, you may define the camera with the attribute `OrthogonalProjection = TRUE`. This has the same effect as positioning the camera at a large distance from the scene using a powerful tele lense.

In this case, the camera ignores the `ViewingAngle` and the `Position` in 3-space. It is moved along the optical axis `FocalPoint - Position` to infinity and chooses an infinitesimal small viewing angle such that the scene fills the drawing area optimally.

Several cameras can be present simultaneously in a graphical scene. The first camera specified in the `plot` command determines the views.

One may switch between the cameras by clicking on the corresponding camera in the interactive “object browser” of the MuPAD graphics tool (see section `Viewer, Browser, and Inspector: Interactive Manipulation` of this document).

You may place your own light sources in the scene. When specifying the attribute `CameraCoordinates = TRUE` in the definition of the lights, they are attached to the camera and move automatically, when the camera is moved.

# plot::Camera

---

## Attributes

Attribute	Purpose	Default Value
FocalPoint	the focal point of a camera	
FocalPointX	the focal point of a camera, x-coordinate	
FocalPointY	the focal point of a camera, y-coordinate	
FocalPointZ	the focal point of a camera, z-coordinate	
Frames	the number of frames in an animation	50
KeepUpVector	keep the UpVector constant when moving the camera?	TRUE
Name	the name of a plot object (for browser and legend)	
OrthogonalProjection	parallel projection without perspective distortion	FALSE
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
Position	positions of cameras, lights, and text objects	
PositionX	x-positions of cameras, lights, and text objects	
PositionY	y-positions of cameras, lights, and text objects	
PositionZ	z-positions of cameras, lights, and text objects	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
UpVector	“up direction” of a camera	[0.0, 0.0, 1.0]
UpVectorX	x-component of the “up vector” of the camera	0.0
UpVectorY	y-component of the “up vector” of the camera	0.0
UpVectorZ	z-component of the “up vector” of the camera	1.0

# plot::Camera

Attribute	Purpose	Default Value
ViewingAngle	opening angle of the camera lense	
Visible	visibility	TRUE

## Examples

### Example 1

We use our own camera to view the 3D graph of a function:

```
f := plot::Function3d(sin(x) + y^3 + 2*exp(-3*x^2 - 20*y^2),
 x = -PI..PI, y = -1 .. 1,
 Submesh = [2, 2]):
camera := plot::Camera([-12, -4, 14], [0, 0, 0], PI/7):
plot(f, camera):
```

We move the camera to another position:

```
camera::Position := [7, -5, 6]:
plot(f, camera):
```

We turn the camera towards the central peak and zoom in by decreasing the opening angle of the zoom lens:

```
camera::FocalPoint := [0, 0, 1]:
camera::ViewingAngle := PI/20:
plot(f, camera):
```

## plot::Camera

---

We create an animated camera and fly through the scene:

```
camera := plot::Camera([-15 + 3*a, 4 - a, 3 + (a - 4)^2],
 [0, 0, 1.5], PI/6, a = 0..8,
 Frames = 100, TimeRange = 0..20):
plot(f, camera):
```

delete f, camera:

## Parameters

**$p_x$ ,  $p_y$ ,  $p_z$**

Coordinates of the camera position: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$p_x$ ,  $p_y$ ,  $p_z$  are equivalent to the attributes PositionX, PositionY, PositionZ.

**$f_x$ ,  $f_y$ ,  $f_z$**

Coordinates of the the focal point: numerical real values or arithmetical expressions of the animation parameter  $a$ .

$f_x$ ,  $f_y$ ,  $f_z$  are equivalent to the attributes FocalPointX, FocalPointY, FocalPointZ.

**angle**

# plot::Camera

---

The opening angle of the lense in radians: a numerical real value or an arithmetical expression of the animation parameter  $a$  representing a value between 0 and  $\pi$ .

`angle` is equivalent to the attribute `ViewingAngle`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

### Concepts

- “Cameras in 3D”

**Purpose** Directed distant light (“sunlight”)

**Syntax** `plot::DistantLight([px, py, pz], [tx, ty, tz], <intensity>, <a = amin .. amax>, options)`

**Description** `plot::DistantLight([px, py, pz], [tx, ty, tz], intensity)` creates a distant light source emitting parallel light shining into the direction  $[t_x - p_x, t_y - p_y, t_z - p_z]$

Each 3D scene is illuminated by several light sources that are set automatically and cannot be controlled by the user. Cf. the help page of `Lighting`.

If special light effects are desired, the user can create alternative light sources of various types such as `plot::AmbientLight`, `plot::DistantLight`, `plot::PointLight`, and `plot::SpotLight`.

If at least one user defined light source is inserted into the scene (e.g., by simply passing the light objects as input parameters to the `plot` command), the automatic lights are switched off and the user defined lights are used to illuminate the scene.

---

**Note** The vector  $[p_x, p_y, p_z]$  does *not* represent the position of a distant light in space. The light source is infinitely far away.

---

When using  $[t_x, t_y, t_z] = [0, 0, 0]$ , you may think of  $[p_x, p_y, p_z]$  as the *direction* where the light source is located.

When using  $[p_x, p_y, p_z] = [0, 0, 0]$ , you may think of  $[t_x, t_y, t_z]$  as the *direction* into which the light is shining.

By default, white light is created. Other colors can be chosen by the attribute `LightColor`.

When using the attribute `CameraCoordinates = TRUE`, the light source is fixed to the camera. It moves automatically, when the camera is moved.

# plot::DistantLight

---

Directed light such as `plot::DistantLight` create shading effects that add depth to the picture. Usually, a certain amount of undirected ambient light of type `plot::AmbientLight` enhances the picture.

## Attributes

Attribute	Purpose	Default Value
CameraCoordinates	position of light sources relative to the camera?	FALSE
Frames	the number of frames in an animation	50
LightColor	the color of light	RGB::White
LightIntensity	intensity of light	1.0
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Position	positions of cameras, lights, and text objects	
PositionX	x-positions of cameras, lights, and text objects	

<b>Attribute</b>	<b>Purpose</b>	<b>Default Value</b>
PositionY	y-positions of cameras, lights, and text objects	
PositionZ	z-positions of cameras, lights, and text objects	
Target	the target point of a light	
TargetX	the target point of a light, x component	
TargetY	the target point of a light, y component	
TargetZ	the target point of a light, z component	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Visible	visibility	TRUE

## Examples

### Example 1

We create a white sphere and use a single directed white light to illuminate it:

```
f := plot::Surface(
 [cos(u)*sin(v), sin(u)*sin(v), cos(v)],
 u = 0..2*PI, v = 0..PI,
 FillColorType = Flat,
```

# plot::DistantLight

---

```
FillColorFunction = RGB::White,
Scaling = Constrained):
sunlight1 := plot::DistantLight([1, -2, 3], [0, 0, 0], 1/2):
plot(f, sunlight1):
```

We create another distant light source shining from another direction, of yellow color and with animated intensity:

```
sunlight2 := plot::DistantLight([-2, 1, 3], [0, 0, 0], a,
LightColor = RGB::Yellow,
a = 0..1):
plot(f, sunlight2)
```

We use both lights simultaneously:

```
plot(f, sunlight1, sunlight2)
```

# plot::DistantLight

---

`delete f, sunlight1, sunlight2:`

## Parameters

### $p_x$ , $p_y$ , $p_z$

The coordinates of the sun's "position": numerical values or arithmetical expressions of the animation parameter  $a$ .

$p_x$ ,  $p_y$ ,  $p_z$  are equivalent to the attributes PositionX, PositionY, PositionZ.

### $t_x$ , $t_y$ , $t_z$

The coordinates of the point the light is shining to: numerical values or arithmetical expressions of the animation parameter  $a$ .

$t_x$ ,  $t_y$ ,  $t_z$  are equivalent to the attributes TargetX, TargetY, TargetZ.

### intensity

The intensity of the light: a numerical value between 0 and 1 or an arithmetical expression of the animation parameter  $a$ .

`intensity` is equivalent to the attribute `LightIntensity`.

**a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

## See Also

### MuPAD Functions

`plot` | `plot::copy`

### MuPAD Graphical Primitives

`plot::AmbientLight` | `plot::PointLight` | `plot::SpotLight`

# plot::PointLight

---

## Purpose

Point light

## Syntax

```
plot::PointLight([x, y, z], <intensity>, <a =
amin .. amax>, options)
```

## Description

`plot::PointLight([x, y, z], intensity)` generates a point light at the position  $(x, y, z)$ .

Each 3D scene is illuminated by several light sources that are set automatically and cannot be controlled by the user. Cf. the help page of `Lighting`.

If special light effects are desired, the user can create alternative light sources of various types such as `plot::AmbientLight`, `plot::DistantLight`, `plot::PointLight`, and `plot::SpotLight`.

If at least one user defined light source is inserted into the scene (e.g., by simply passing the light objects as input parameters to the `plot` command), the automatic lights are switched off and the user defined lights are used to illuminate the scene.

`plot::PointLight([x, y, z], intensity)` creates a point light at the position  $(x, y, z)$ . It emits light into all directions.

Unlike in real life, the light flux of a point light does not decrease with the distance to the light source.

By default, white light is created. Other colors can be chosen by the attribute `LightColor`.

When using the attribute `CameraCoordinates = TRUE`, the light source is fixed to the camera. It moves automatically, when the camera is moved.

Light sources such as `plot::PointLight` create shading effects that add depth to the picture.

Usually, you will use point lights to highlight special details of the scene. For the illumination of the entire scene you will usually need additional undirected ambient light of type `plot::AmbientLight`, too.

Note that all light sources create a homogeneous lighting effect for a 3D triangle. Thus, realistic shading effects can only be achieved for

surfaces with a sufficiently fine triangulation. For function graphs (`plot::Function3d`) and parametrized surfaces (`plot::Surface`), a fine triangulation is created by sufficiently high values of `XMesh`, `YMesh` or `UMesh`, `VMesh`, respectively.

## Attributes

Attribute	Purpose	Default Value
CameraCoordinates	position of light sources relative to the camera?	FALSE
Frames	the number of frames in an animation	50

Attribute	Purpose	Default Value
PositionY	y-positions of cameras, lights, and text objects	
PositionZ	z-positions of cameras, lights, and text objects	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Visible	visibility	TRUE

## Examples

### Example 1

We create three blue surfaces and illuminate them by an animated point light. The position of the point light is indicated by a white point:

```
s1 := plot::Surface([1, y, z], y = 0..1, z = 0..1):
s2 := plot::Surface([x, 1, z], x = 0..1, z = 0..1):
s3 := plot::Surface([x, y, 0], x = 0..1, y = 0..1):
p := plot::Point3d([a, 0.9, 0.2], a = 0..1,
 PointSize = 2.0*unit::mm,
 PointColor = RGB::White):
light := plot::PointLight([a, 0.9, 0.2], 1, a = 0..1):
plot(s1, s2, s3, p, light, Axes = Frame,
 FillColor = RGB::Blue, FillColorType = Flat):
```

```
delete s1, s2, s3, p, light:
```

## Parameters

### **x, y, z**

The coordinates of the point light: numerical values or arithmetical expressions of the animation parameter *a*.

*x*, *y*, *z* are equivalent to the attributes `Position`, `PositionX`, `PositionY`, `PositionZ`.

### **intensity**

The intensity of the light: a numerical value between 0 and 1 or an arithmetical expression of the animation parameter *a*.

*intensity* is equivalent to the attribute `LightIntensity`.

### **a**

Animation parameter, specified as  $a = a_{\min} + a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

# plot::PointLight

---

## Purpose

Spot light

## Syntax

```
plot::SpotLight([px, py, pz], [tx, ty, tz], angle,
<intensity>, <a = amin .. amax>, options)
```

## Description

`plot::SpotLight([px, py, pz], [tx, ty, tz], angle, intensity)` generates a spot light at the position p<sub>x</sub>, p<sub>y</sub>, p<sub>z</sub>, aimed at the point t<sub>x</sub>, t<sub>y</sub>, t<sub>z</sub>. The opening angle of the light cone is given by angle.

Each 3D scene is illuminated by several light sources that are set automatically and cannot be controlled by the user. Cf. the help page of `Lighting`.

If special light effects are desired, the user can create alternative light sources of various types such as `plot::AmbientLight`, `plot::DistantLight`, `plot::PointLight`, and `plot::SpotLight`.

If at least one user defined light source is inserted into the scene (e.g., by simply passing the light objects as input parameters to the `plot` command), the automatic lights are switched off and the user defined lights are used to illuminate the scene.

`plot::SpotLight([px, py, pz], [tx, ty, tz], angle)` creates a spot light source at the point [p<sub>x</sub>, p<sub>y</sub>, p<sub>z</sub>] emitting a light cone towards the point [t<sub>x</sub>, t<sub>y</sub>, t<sub>z</sub>]. In contrast to real life, the light flux of a spot light does not decrease with the distance to the light source.

By default, white light is created. Other colours can be chosen by the attribute `LightColor`.

When using the attribute `CameraCoordinates = TRUE`, the light source is fixed to the camera. It moves automatically, when the camera is moved.

Directed light such as `plot::SpotLight` create shading effects that add depth to the picture.

Usually, you will use spot lights to highlight special details of the scene. For the illumination of the entire scene you will usually need additional undirected ambient light of type `plot::AmbientLight`, too.

## Examples

### Example 1

We create three white surfaces and illuminate them by two animated white spot lights and some ambient light. The spot lights are indicated by little cones:

```
s1 := plot::Surface([1, y, z], y = 0..1, z = 0..1):
s2 := plot::Surface([x, 1, z], x = 0..1, z = 0..1,
 Submesh = [2, 2]):
s3 := plot::Surface([x, y, 0], x = 0..1, y = 0..1,
 Submesh = [2, 2]):
ambientlight:= plot::AmbientLight(0.4):
spotlight1 := plot::SpotLight([1/3, a, 1/3], [1/3, 1, 1/3],
 PI/5, a = 0..0.8):
c1 := plot::Cone(0, [1/3, a, 1/3],
 0.2*tan(PI/10), [1/3, a + 0.2, 1/3],
 a = 0..0.8, Color = RGB::Orange.[0.5]):
spotlight2 := plot::SpotLight([2/3, a, 2/3], [2/3, a, 0],
 PI/4, a = 0.15..0.95):
c2 := plot::Cone(0, [2/3, a, 2/3],
 0.2*tan(PI/8), [2/3, a, 2/3 - 0.2],
 a = 0.15..0.95, Color = RGB::Orange.[0.5]):
plot(s1, s2, s3, FillColor = RGB::White,
 FillColorType = Flat,
 ambientlight, c1, spotlight1,
 c2, spotlight2, Axes = Frame):
```

delete s1, s2, s3, c1, c2, ambientlight,  
spotlight1, spotlight2:

## Parameters

**$p_x$ ,  $p_y$ ,  $p_z$**

The coordinates of the position: numerical values or arithmetical expressions of the animation parameter  $a$ .

$p_x$ ,  $p_y$ ,  $p_z$  are equivalent to the attributes Position, PositionX, PositionY, PositionZ.

**$t_x$ ,  $t_y$ ,  $t_z$**

The coordinates of the point the light is shining to: numerical values or arithmetical expressions of the animation parameter  $a$ .

$t_x$ ,  $t_y$ ,  $t_z$  are equivalent to the attributes Target, TargetX, TargetY, TargetZ.

**angle**

# plot::SpotLight

---

The opening angle of the light cone in radians: a numerical value between 0 and  $\pi$  or an arithmetical expression of the animation parameter  $a$ .

`angle` is equivalent to the attribute `SpotAngle`.

## **intensity**

The intensity of the light: a numerical value between 0 and 1 or an arithmetical expression of the animation parameter  $a$ .

`intensity` is equivalent to the attribute `LightIntensity`.

## **a**

Animation parameter, specified as  $a = a_{\min} \cdot a_{\max}$ , where  $a_{\min}$  is the initial parameter value, and  $a_{\max}$  is the final parameter value.

<b>Purpose</b>	File name to plot into		
<b>Value Summary</b>	OutputFile, OutputOptions	Optional	See below
<b>Description</b>	<p>The attribute <code>OutputFile</code> allows to specify a file name to direct the plot output into an external file instead of rendering the plot on the screen. The extension of the file name indicates the export format.</p> <p>The available formats include <code>.xvz</code> and <code>.xvc</code> (the MuPAD proprietary XML format) as well as various standard bitmap formats such as <code>.bmp</code>, <code>.gif</code>, <code>.jpg</code> etc. and vector formats such as <code>.eps</code>, <code>.svg</code> etc. Animated MuPAD graphics can be exported to animated GIF files. On Windows systems, it also can be exported to <code>.avi</code> format.</p> <p>Some of the export formats allow to specify certain parameters such as “resolution,” “quality” etc. Such parameters may be specified by the attribute <code>OutputOptions</code>.</p> <p>MuPAD plots can be saved in “batch mode” by specifying the attribute <code>OutputFile = filename</code> in a <code>plot</code> call or in <code>plotfunc2d</code>, <code>plotfunc3d</code>. The file name must be a MuPAD string. For example:</p> <pre>plot(..graphical objects.., OutputFile = "mypicture.xvz");</pre> <p>(Here, the extension <code>.xvz</code> of the file name <code>"mypicture.xvz"</code> indicates that the MuPAD XML data are to be written).</p> <p>If the MuPAD environment variable <code>WRITEPATH</code> does not have a value, the previous call creates the file in the directory where MuPAD is running. (On Windows and Macintosh systems, this is, by default, the directory where it is installed).</p> <p>After setting <code>WRITEPATH</code> to the absolute path of a folder, the file is created in that folder. For example, after</p> <pre>WRITEPATH := "C:\\Documents":</pre>		

# OutputFile, OutputOptions

---

the command

```
plot(..graphical objects.., OutputFile = "mypicture.xvz");
```

stores the plot data in the file "C:\Documents\mypicture.xvz."

Alternatively, the file name can be specified as an absolute pathname:

```
plot(..objects.., OutputFile = "C:\\Documents\\mypicture.xvz");
```

If a MuPAD notebook was saved to a file, its location is available inside the notebook as the environment variable NOTEBOOKPATH. If you wish to save your plot in the same folder as the notebook, you may call

```
plot(..objects.., OutputFile = NOTEBOOKPATH."mypicture.xvz");
```

The plot data can be stored in various formats indicated by the extension of the file name. In particular, there are the MuPAD proprietary XML formats. The file extension .xvz indicates that XML data are to be written and, finally, the file is to be compressed. Alternatively, the extension .xvc may be used to write the XML data without final compression (the resulting text file can be read with any text editor). Files in both formats can be inserted into a MuPAD notebook and freely manipulated.

Apart from saving files as XML data, MuPAD pictures can also be saved in a variety of standard bitmap formats such as .bmp, .gif, .jpg etc. Also .svg and .eps export is available. Just use an appropriate extension of the file name indicating the format.

---

**Note** Only XML files .xvz and .xvc retain the information necessary for interactive manipulation in a MuPAD notebook. All other formats are intended for exporting graphics to other programs.

---

If no file extension is specified in the file name, the default extension .xvz is used, i.e., XML data are written.

On Windows systems, animated MuPAD plots can be exported to .avi format. Cf. “Example 2” on page 23-1377.

In addition to `OutputFile`, there is the attribute `OutputOptions` to specify parameters for some of the export formats. The admissible value for this attribute is a list of equations:

```
OutputOptions = [<ReduceTo256Colors = b >, <DotsPerInch = n1>, <Quality = n2>, <JPEGMode = n3>, <EPSMode = n4>, <AVIMode = n5>, <WMFMode = n6>, <FramesPerSecond = n7>, <PlotAt = l1>]
```

Each entry of the list is optional. The parameters are

- |                |                                                                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| b              | TRUE or FALSE. Has an effect for export to some raster formats only. With TRUE, only 256 different colors are stored in the raster file. The default value is FALSE.                                      |
| n <sub>1</sub> | Positive integer setting the resolution in DPI (dots per inch). Has an effect for export to raster formats only. The default value depends on the hardware.                                               |
| n <sub>2</sub> | One of the integers 1, 2, ..., 100. This integer represents a percentage value determining the quality of the export. Has an effect for JPG, 3D EPS, 3D WMF and AVI export only. The default value is 75. |

## OutputFile, OutputOptions

---

$n_3$	0, 1, or 2. Has an effect for JPG export only. The flag 0 represents the JPG mode 'Baseline Sequential', 1 represents 'Progressive', 2 represents 'Sequential Optimized'. The default value is 0.
$n_4$	0 or 1. Has an effect for EPS export only. The flag 0 represents the EPS mode 'Painter's Algorithm', 1 represents 'BSP Tree Algorithm'. The default value is 0.
$n_5$	0, 1 or 2. Has an effect for AVI export only. With 0, the 'Microsoft Video 1 Codec' is used. With 1, the 'Uncompressed Single Frame Codec' is used. With 2, the 'Radius Cinepak Codec' is used. The default value is 0.
$n_6$	0, 1 or 2. Has an effect for WMF export only. With 0, the 'Painter's Algorithm' is used. With 1, the 'BSP Tree Algorithm' is used. With 2, a 'embedded bitmap' is created. The default value is 0.

$n_7$	Positive integer setting the frames per second for the AVI to be generated. Has an effect for AVI and animated GIF export only. The default value is 15.
$l_1$	List of real values between TimeBegin and TimeEnd which determines the times at which pictures should be saved from an animation.

## Examples

### Example 1

The following commands save the plot in four different files in JPG, EPS, SVG, and BMP format, respectively:

```
f1 := plot::Function2d(sin(x), x = 0..PI, Color = RGB::Red):
f2 := plot::Function2d(cos(x), x = 0..PI, Color = RGB::Blue):
plot(f1, f2, OutputFile = "mypicture.jpg"):
plot(f1, f2, OutputFile = "mypicture.eps"):
plot(f1, f2, OutputFile = "mypicture.svg"):
plot(f1, f2, OutputFile = "mypicture.bmp"):
```

If no file extension is specified in the file name, the default extension .xvz is used, i.e., XML data are written. The following command creates the file mypicture.xvz:

```
plot(f1, f2, OutputFile = "mypicture"):
```

### Example 2

An animated MuPAD plot can be exported to .avi format:

```
plotfunc2d(sin(x - a), x = 0 .. 2*PI, a = 0 .. 5,
 OutputFile = "myanimation.avi"):
```

# OutputFile, OutputOptions

---

## Example 3

An animated MuPAD plot can be exported to several single images at given times:

```
plotfunc2d(sin(x - a), x = 0 .. 2*PI, a = 0 .. 5,
 OutputFile = "someName.png",
 OutputOptions=[PlotAt = [i $ i = 0..10 step 0.5]]):
```

## Concepts

- “Save in Batch Mode”

**Purpose** Influence of objects on the ViewingBox of a scene

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	AffectViewingBox Default Values
plot::Arc2d, plot::Arc3d, plot::Arrow2d, plot::Arrow3d, plot::Bars2d, plot::Bars3d, plot::Box, plot::Boxplot, plot::Circle2d, plot::Circle3d, plot::Cone, plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylinder, plot::Cylindrical, plot::Density, plot::Dodecahedron, plot::Ellipse2d, plot::Ellipse3d, plot::Ellipsoid, plot::Function2d, plot::Function3d, plot::Hatch, plot::Hexahedron, plot::Histogram2d, plot::Icosahedron, plot::Implicit2d, plot::Implicit3d, plot::Inequality, plot::Integral, plot::Iteration, plot::Line2d, plot::Line3d,	TRUE

# AffectViewingBox

---

Objects	AffectViewingBox Default Values
<pre>plot::Listplot, plot::Lsys, plot::Matrixplot, plot::MuPADCube, plot::Octahedron, plot::Ode2d, plot::Ode3d, plot::Parallelogram2d, plot::Parallelogram3d, plot::Piechart2d, plot::Piechart3d, plot::Plane, plot::Point2d, plot::Point3d, plot::PointList2d, plot::PointList3d, plot::Polar, plot::Polygon2d, plot::Polygon3d, plot::Prism, plot::Pyramid, plot::QQplot, plot::Raster, plot::Rectangle, plot::Reflect2d, plot::Reflect3d, plot::Rootlocus, plot::Rotate2d, plot::Rotate3d, plot::Scale2d, plot::Scale3d, plot::Scatterplot, plot::Sequence, plot::SparseMatrixplot, plot::Sphere, plot::Spherical, plot::Streamlines2d, plot::Sum, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep,</pre>	

Objects	AffectViewingBox Default Values
plot::Tetrahedron, plot::Text2d, plot::Text3d, plot::Transform2d, plot::Transform3d, plot::Translate2d, plot::Translate3d, plot::Tube, plot::Turtle, plot::VectorField2d, plot::VectorField3d, plot::Waterman, plot::XRotate, plot::ZRotate	

## Description

AffectViewingBox determines whether the ViewingBox of an object should be taken into account for the total ViewingBox of the graphical scene.

Usually, the visible area/volume of a graphical scene is automatically chosen as the smallest box containing all objects of the scene. Objects with AffectViewingBox = FALSE are ignored in the computation of this box.

## Examples

### Example 1

We plot the sine and the exponential function in one scene:

```
plot(plot::Function2d(sin(x), x = -PI..PI),
 plot::Function2d(exp(x), x = -PI..PI))
```

# AffectViewingBox

---

The exponential function dominates the sine. We set `AffectViewingBox = FALSE` for `exp`. Now, only the sine function determines the visible area and `exp` is only visible where it is in the `ViewingBox` of the sine function:

```
plot(plot::Function2d(sin(x), x = -PI..PI),
 plot::Function2d(exp(x), x = -PI..PI,
 AffectViewingBox = FALSE))
```

**See Also**

**MuPAD  
Functions**

ViewingBox

# Angle

**Purpose** Rotation angle

**Value Summary** Optional MuPAD expression

## Graphics Primitives

Objects	Angle Default Values
plot::Arc2d, plot::Arc3d, plot::Prism, plot::Pyramid, plot::Rotate2d, plot::Rotate3d	0

## Description

Angle determines the rotation angle in transformation objects of type `plot::Rotate2d` and `plot::Rotate3d`, respectively, and other graphical objects. The angle has to be specified in radians.

In 2D, the direction of the rotation is counter clock wise. Use negative angles to rotate clock wise.

In 3D, the rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation. Use negative angles to rotate in the opposite direction.

## Examples

### Example 1

Rectangles of type `plot::Rectangle` are always parallel to the coordinate axes. To have one with a different orientation, we must rotate it:

```
r0 := plot::Rectangle(0..2, 1..3):
r1 := plot::Rotate2d(r0, Center = [1, 2], Angle = PI/6)
```

```
plot::Rotate2d($\frac{\pi}{6}$, Center = [1, 2], plot::Rectangle(0..2, 1..3))
```

As you can see in the output above, the rotate object *contains* the rotated object and acts as a grouping construct. This means that we only need to plot `r1` to see the rotated object:

```
plot(r1)
```

Plotting both `r0` and `r1` yields a plot showing the rotated rectangle together with the unrotated one:

```
plot(r0, r1)
```

# Angle

---

```
delete r0, r1:
```

## Example 2

Using `plot::Rotate2d`, we plot several copies of a function plot, rotated at different angles:

```
f := plot::Function2d(sin(x^3)/(x^2+1), x = -5..5, Mesh = 300):
plot(plot::Rotate2d(f, Angle = PI/11*a) $ a = 0..10):
```

`delete f:`

### Example 3

The rotation angle can be animated. We use an animated `plot::Rotate2d` object to rotate a square around a center that moves along a circle around the origin:

```

p := plot::Point2d([cos(a), sin(a)], a = 0..2*PI,
 Frames = 100):
r := plot::Rotate2d(plot::Rectangle(0..2, -1..1), Angle = a,
 Center = [0, 0], a = 0..2*PI):
q := plot::Rotate2d(r, Angle = 4*a, Center = [cos(a), sin(a)],
 a = 0..2*PI, Frames = 200):
plot(p, q)

```

# Angle

---

```
delete p, r, q:
```

## Example 4

This is the 3D analogue of “Example 1” on page 23-1384. Boxes of type `plot::Box` are always parallel to the coordinate axes. To have one with a different orientation, we must rotate it:

```
b0 := plot::Box(0..2, 1..3, 2..3):
b1 := plot::Rotate3d(b0, Center = [1, 2, 2.5],
 Axis = [1, 1, 1], Angle = PI/5)
```

```
plot::Rotate3d($\frac{\pi}{5}$, Center = [1, 2, 2.5], Axis = [1, 1, 1], plot::Box(0..2, 1..3, 2..3))
```

```
plot(b0, b1)
```

```
delete b0, b1:
```

## Example 5

Some graphic objects, e.g. `plot::Arc2d` and `plot::Pyramid`, also accept a rotation angle:

```
arc:= [3, 1], [0, 0], -PI/4..PI/4, Filled:
plot(
 plot::Arc2d(arc, Angle=0, FillColor=RGB::Red),
 plot::Arc2d(arc, Angle=1/2*PI, FillColor=RGB::Green),
 plot::Arc2d(arc, Angle=PI, FillColor=RGB::Yellow),
 plot::Arc2d(arc, Angle=3/2*PI, FillColor=RGB::Blue)
)
```

# Angle

---

```
plot(plot::Pyramid(1/2, Angle=0),
 plot::Pyramid(1/2, Angle=PI/4, FillColor2=RGB::Yellow))
```

delete arc:

## MuPAD Functions

Axis | Center

# AngleRange, AngleBegin, AngleEnd

**Purpose** Angle range

**Value Summary**

AngleRange	[AngleBegin .. AngleEnd]	Range of arithmetical expressions
AngleBegin, AngleEnd	Optional	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Tube, plot::XRotate, plot::ZRotate	AngleRange: 0 .. 2*PI AngleBegin: 0 AngleEnd: 2*PI
plot::Arc2d, plot::Arc3d	AngleRange: 0 .. PI/2 AngleBegin: 0 AngleEnd: PI/2

## Description

AngleRange, AngleBegin, AngleEnd define a range for the angle in circular arcs and surfaces of revolution.

For circular arcs of type plot::Arc2d, the attributes AngleBegin and AngleEnd define the starting point and the end point of the arc. The values are the usual polar angles measuring the angle to the positive  $x$ -axis in radians.

For surfaces of revolution of type plot::XRotate or plot::ZRotate, respectively, the attributes AngleBegin and AngleEnd define the starting point and the end point of the revolution.

For plot::XRotate, the values are the polar angles to the positive  $y$ -axis, specified in radians.

For plot::ZRotate, the values are the usual angles to the positive  $x$ -axis in radians, known from cylindrical coordinates.

# AngleRange, AngleBegin, AngleEnd

Values for `AngleBegin` and `AngleEnd` may depend on the animation parameter and must evaluate to real numbers for any given time stamp.

`AngleRange` provides a shortcut for setting `AngleBegin` and `AngleEnd`. The attribute `AngleRange = a_1..a_2` is equivalent to `AngleBegin = a_1, AngleEnd = a_2`.

## Examples

### Example 1

We define a semi-circle as a circular arc with a range of the polar angle from 0 to 180 degrees (i.e.,  $\pi$  in radians):

```
arc := plot::Arc2d(1, 0 .. PI):
plot(arc)
```

The range is stored as the attribute `AngleRange` in the object and can be accessed and changed:

```
arc::AngleBegin, arc::AngleEnd, arc::AngleRange
```

# AngleRange, AngleBegin, AngleEnd

---

`0,  $\pi$ , 0.. $\pi$`

```
arc::AngleRange := PI/2 .. 2*PI:
plot(arc)
```

```
delete arc:
```

## Example 2

We leave gaps in the following surfaces of revolution by restricting the revolution angle:

```
plot(plot::XRotate(sin(x), x = 0 .. PI/2,
AngleRange = -0.8*PI .. 0.8*PI)):
```

# AngleRange, AngleBegin, AngleEnd

---

```
plot(plot::ZRotate(sin(x), x = 0 .. PI/2,
 AngleRange = 0.3*PI .. 2*PI)):
```

# AngleRange, AngleBegin, AngleEnd

---

**Purpose** Area of a histogram plot

**Value Summary** Optional Non-negative real number

### Graphics Primitives

Objects	Area Default Values
plot::Histogram2d	0

### Description

Area determines whether bars of a histogram plot are scaled with respect to their heights or with respect to their areas, and by how much.

By default, the bars of a histogram plot use a height that is equal to the absolute number of data points in the corresponding cell. Using Area, the user can change this behavior to make the *areas* of the bars proportional to this number.

### Examples

#### Example 1

For any distribution with a continuous quantile, we can define, using `stats::equiprobableCells`, a list of  $n$  cells where each cell is “hit” with the same probability,  $\frac{1}{n}$ . By the law of large numbers, we expect the number of elements in each cell to be approximating  $\frac{N}{n}$  for large values of  $N$ , the number of samples:

```
X := stats::normalRandom(10, 1):
cells := stats::equiprobableCells(40,
 stats::normalQuantile(10, 1)):

N := 1000:
data := [X() $ i = 1..N]:
plot(plot::Histogram2d(data, Cells = cells))
```

# Area

---

```
N := 10000:
data := [X() $ i = 1..N]:
plot(plot::Histogram2d(data, Cells = cells))
```

On the other hand, if we want to display a histogram as an approximation to the probability distribution, we want not the height, but rather the area of the rectangles to correspond to our measurements. Moreover, the sum of all areas should be 1, so we set `Area` to this value:

```
plot(plot::Histogram2d(data, Cells = cells, Area = 1))
```

# Area

---

```
plot(plot::Histogram2d(data, Cells = cells, Area = 1),
 plot::Function2d(stats::normalPDF(10,1)(x), x = 7..13,
 Color = RGB::Black, LineWidth = 0.5))
```

**MuPAD  
Functions**

Cells

# Averaged

---

**Purpose** Mode for computing quantile lines in box plots

**Value Summary** Optional TRUE or FALSE

## Graphics Primitives

Objects	Averaged Default Values
<code>plot::Boxplot</code>	TRUE

## Description

Statistical box plots indicate the 25%/50%/75% quantiles of data samples by horizontal lines. With the default `Averaged = TRUE`, the quantile lines are computed using `stats::empiricalQuantile` using the option `Averaged`.

A plot of type `plot::Boxplot` serves for visualizing and comparing statistical data samples. The plot reduces the data to few simple descriptive parameters.

A typical notched box looks like this:

The location of the 25%/50%/75% quantile lines are computed internally via `stats::empiricalQuantile`. When using `Averaged = TRUE` in the box plot, the quantile function is called with the option `Averaged` (see the help page of `stats::empiricalQuantile` for details).

## Examples

### Example 1

By default, the quantile lines of the boxes are computed with the option `Averaged`. When using `Averaged = FALSE`, the quantiles are computed without this option:

```
r := random(0..10):
SEED := 123:
data := [r() $ k = 1..250]:
```

# Averaged

```
plot(plot::Boxplot(data, Averaged = TRUE, BoxCenters = 0.5, Color =
 plot::Boxplot(data, Averaged = FALSE, BoxCenters = 1.5, Color =
))):
```

```
delete r, SEED, data:
```

## MuPAD Functions

[BoxCenters](#) | [BoxWidths](#) | [DrawMode](#) | [Notched](#)

## Purpose

Rotation axis

## Value Summary

Axis	Library wrapper for “[AxisX, AxisY, AxisZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
AxisX, AxisY, AxisZ	Optional	MuPAD expression

## Graphics Primitives

Objects	Default Values
<code>plot::Rotate3d</code>	Axis: [0, 0, 1] AxisX, AxisY: 0 AxisZ: 1

## Description

Axis is a vector determining the direction of the rotation axis in rotation objects of type `plot::Rotate3d`. It is given by a list of 3 components.

AxisX etc. refer to the  $x$ ,  $y$ ,  $z$  components of this vector.

A rotation in 3D is determined by a line around which is rotated. The line is given by a point on the line (the `Center`) and a direction vector (the `Axis`). The rotation angle is given by the attribute `Angle`.

The length of the `Axis` vector is of no relevance. However, it should not be zero.

The rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation. Use negative angles to rotate in the opposite direction or replace the `Axis` vector by its negative.

# Axis, AxisX, AxisY, AxisZ

---

## Examples

### Example 1

A cone is first rotated around the  $x$ -axis. The rotated cone is then rotated around the  $z$ -axis:

```
c0 := plot::Cone(1, [0, 0, 1], [0, 0, 2]):
c1 := plot::Rotate3d(c0, Center = [0, 0, 0],
 Axis = [1, 0, 0], Angle = PI/2):
c2 := plot::Rotate3d(c1, Center = [0, 0, 0],
 Axis = [0, 0, 1], Angle = PI/2):
plot(plot::Scene3d(c0, Axes = Origin,
 ViewingBox = [-2..2, -2..2, -2..2]),
 plot::Scene3d(c1, Axes = Origin,
 ViewingBox = [-2..2, -2..2, -2..2]),
 plot::Scene3d(c2, Axes = Origin,
 ViewingBox = [-2..2, -2..2, -2..2]),
 TicksNumber = None,
 Width = 120*unit::mm, Height = 40*unit::mm,
 Layout = Horizontal):
```

```
delete c0, c1, c2:
```

### Example 2

We illustrate the “right hand rule”. A small box  $b0$  is rotated. The rotated copies  $b1$ ,  $b2$ ,  $b3$  are plotted together with the original box:

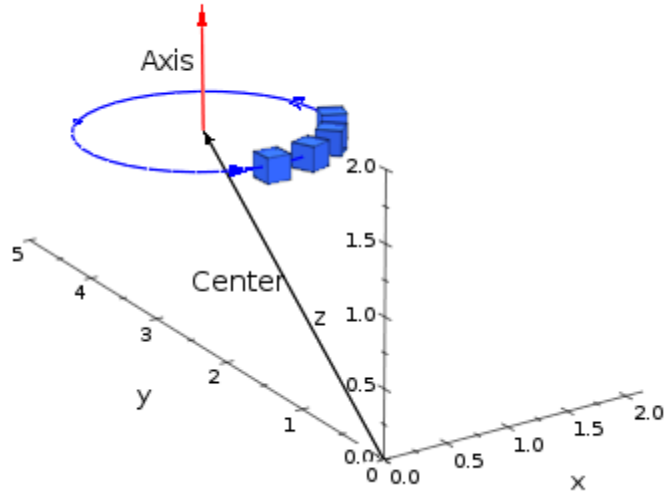

```
center := [1, 4, 1]:
```

```
axis := [0, 0, 1]:
b0 := plot::Box(0.9..1.1, 2.9 .. 3.1, 0.9 .. 1.1):
b1 := plot::Rotate3d(b0, Center = center, Axis = axis,
 Angle = PI/8):
b2 := plot::Rotate3d(b1, Center = center, Axis = axis,
 Angle = PI/8):
b3 := plot::Rotate3d(b2, Center = center, Axis = axis,
 Angle = PI/8):
centerplusaxis := [center[i] + axis[i] $ i = 1..3]:
plot(b0, b1, b2, b3,
 plot::Arrow3d([0, 0, 0], center, Color = RGB::Black,
 Title = "Center",
 TitlePosition = [0.1, 2, 0.5]),
 plot::Arrow3d(center, centerplusaxis,
 Title = "Axis", Color = RGB::Red,
 TitlePosition = [0.7, 4, 1.5]),
 plot::Circle3d(1, center, axis),
 plot::Rotate3d(plot::Arrow3d([0, 4, 1], [0, 3.9, 1],
 Color = RGB::Blue),
 Axis = axis, Center = center,
 Angle = 0.43*PI + a*2*PI/3) $ a = 1..3,
 Axes = Origin
):
```

# Axis, AxisX, AxisY, AxisZ

---

`delete center, axis, b0, b1, b2, b3, centerplusaxis:`

# Base, Top, BaseX, TopX, BaseY, TopY, BaseZ, TopZ

**Purpose** Base center of cones, cylinders, pyramids and prisms

## Value Summary

Base	Library wrapper for “[BaseX, BaseY]” (2D), “[BaseX, BaseY, BaseZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
Top	Library wrapper for “[TopX, TopY]” (2D), “[TopX, TopY, TopZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
BaseX, BaseY, BaseZ, TopX, TopY, TopZ	Mandatory	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Cone, plot::Cylinder, plot::Prism, plot::Pyramid	Base: [0, 0, 0] Top: [0, 0, 1] BaseX, TopX, BaseY, TopY, BaseZ: 0 TopZ: 1

## Description

Base is a vector determining the position of the base center of cones/conical frustums, cylinders, pyramids/frustums of pyramids and prisms. It is given by a list or vector of 3 components.

BaseX etc. refer to the  $x$ ,  $y$ ,  $z$  components of this vector.

Top is a vector determining the position of the top center of cones/conical frustums, cylinders, pyramids/frustums of pyramids and prisms. For a cone, this is the tip. The vector is given by a list or vector of 3 components.

TopX etc. refer to the  $x$ ,  $y$ ,  $z$  components of this vector.

# Base, Top, BaseX, TopX, BaseY, TopY, BaseZ, TopZ

---

The values of these attributes can be animated.

## Examples

### Example 1

We define a cone:

```
c := plot::Cone(1, [0, 0, 0], [0, 0, 1]):
plot(c)
```

The second and third argument are the base center and the top center, respectively. Internally, they are stored as the attributes `Bottom` and `Top`. We can access the object's attributes and change them:

```
c::Base, c::Top
```

```
[0, 0, 0], [0, 0, 1]
```

```
c::Top := [0, 1, 1]:
plot(c):
```

```
delete c:
```

## Example 2

The values of Bottom and Top can be animated:

```
plot(plot::Cylinder(3, [2, 2, 2], [2, 2, a], a = 7..12)):
```

# Base, Top, BaseX, TopX, BaseY, TopY, BaseZ, TopZ

---

**MuPAD  
Functions**

BaseRadius | TopRadius

**Purpose** Base and top radius of cones/conical frustums and pyramids/frustums of pyramids

**Value Summary** BaseRadius, TopRadius Mandatory MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Cone, plot::Pyramid	BaseRadius: 1 TopRadius: 0

## Description

BaseRadius defines the radius of the base of a cone or the radius of the circumcircle of the regular base of a pyramid. TopRadius defines the radius  $r$  of the top of a conical frustum and the radius of the circumcircle of the top of a frustum of pyramid. With the default  $r = 0$ , a cone or pyramid, respectively, is created. You get a frustum for  $r > 0$ .

The values of these attributes can be animated.

## Examples

### Example 1

We draw two cones forming an hour glass:

```
c := plot::Cone(3, [2, 2, 2], [2, 2, 6]):
d := plot::Cone(3, [2, 2, 10], [2, 2, 6]):
plot(c, d)
```

# BaseRadius, TopRadius

---

The first argument is the base radius of the cone. Internally, it is stored as the attribute `BaseRadius`. We can access the objects' attributes and change them:

```
c::BaseRadius, d::TopRadius
```

```
3, 0
```

```
c::BaseRadius := 0: c::TopRadius := 3:
d::BaseRadius := 0: d::TopRadius := 3:
plot(c, d):
```

`delete c, d:`

## Example 2

The values of BaseRadius and TopRadius can be animated:

```
plot(plot::Cone(a, [0, 0, 0], 1 - a, [0, 0, 1], a = 0..1)):
```

# BaseRadius, TopRadius

---

### Example 3

For a pyramid and a frustum of pyramid, the attributes BaseRadius and TopRadius determine the radius of the circumcircle of its regular base and top:

```
plot(plot::Prism(1,Edges=5), plot::Circle3d(1)):
```

# Cells

---

**Purpose** Classes of histogram plots

**Value Summary** Mandatory List of arithmetical expressions

**Graphics Primitives**

Objects	Cells Default Values
plot::Histogram2d	[7]

**Description**

Cells determines the number and position of the classes used in a histogram.

Cells accepts either a single positive integer (or, equivalently, a list of one positive integer) or a list of cells given as ranges or lists of two elements.

A single integer  $n$  in the specification `Cells = n` or `Cells = [n]` is interpreted as “subdivide the range of data into  $n$  cells of equal size.”

The number  $n$  can be animated. In this case,  $n$  may be a symbolic expression of the animation parameter.

The cells may be specified directly as in `Cells = [[a1, b1], [a2, b2], ...]` or `Cells = [a1..b1, a2..b2, Symbol::dots]`.

---

**Note** The  $i$ -th cell is the semi-open interval  $(a_i, b_i]$ , i.e., a datum  $x$  is tallied into the  $i$ -th cell if  $a_i < x \leq b_i$  is satisfied.

---

The cell boundaries must satisfy  $a_1 < b_1 \leq a_2 < b_2 \leq a_3 < \dots$ . In most applications,  $b_1 = a_2$ ,  $b_2 = a_3$  etc. is appropriate.

If giving cells directly, the leftmost border may be `-infinity` and the rightmost border may be `infinity`. These rectangles will then be adjusted according to the average widths of the other rectangles for display purposes.

With the attribute `CellsClosed = Left`, the cells `[a_1..b_1, a_2..b_2, Symbol::dots]` are interpreted as the semi-open intervals  $[a_i, b_i)$ .

## Examples

### Example 1

We create a sample of 1000 data points and plot a histogram of them:

```
X := stats::fRandom(100, 10):
data := [X() $ i = 1..1000]:
plot(plot::Histogram2d(data))
```

The shape of the distribution becomes much better visible when we increase the number of cells:

```
plot(plot::Histogram2d(data, Cells = 40))
```

# Cells

---

```
plot(plot::Histogram2d(data, Cells = [40], Area = 1),
 plot::Function2d(stats::fPDF(100,10)(x), x = 0 .. 5,
 Color = RGB::Black))
```

With cells of different widths, setting Area to a positive value is highly recommended, to still have the histogram follow the probability distribution:

```
cells := stats::equiprobableCells(50,
 stats::fQuantile(100, 10))

plot(plot::Histogram2d(data, Cells = cells)):
```

# Cells

---

```
plot(plot::Histogram2d(data, Cells = cells, Area = 1),
 plot::Function2d(stats::fPDF(100, 10)(x), x = 0 .. 5,
 Color = RGB::Black))
```

Area | CellsClosed

# CellsClosed, ClassesClosed

**Purpose** Interpretation of the classes in histogram plots

**Value Summary**

CellsClosed	Optional	Left, or Right
ClassesClosed	[[CellsClosed]]	See below

## Graphics Primitives

Objects	Default Values
plot::Histogram2d	CellsClosed, ClassesClosed: Right

## Description

CellsClosed determines whether the classes used in a histogram are interpreted as semi-open intervals that are closed at the left or the right boundary.

The graphical primitive plot::Histogram2d tallies numerical data into cells (“classes”) that are defined by the attribute Cells = [a\_1 .. b\_1, a\_2 .. b\_2, dots]. By default, these classes are interpreted as a collection of semi-open intervals  $(a_i, b_i]$  that are closed at the right boundary. A data item  $x$  is tallied into the  $i$ -th cell if it satisfies  $a_i < x \leq b_i$ . With the option CellsClosed = Left or the equivalent ClassesClosed = Left the classes are interpreted as the semi-open intervals  $[a_i, b_i)$  that are closed at the left boundary.

## Examples

### Example 1

We create a sample of 15 data points:

```
data := [1, 2, 2, 3, 3, 3, 4, 4, 4, 4, 5, 5, 5, 5, 5]:
```

These data are to be tallied into the following cells (classes):

```
cells := [0 .. 1, 1 .. 2, 2 .. 3, 3 .. 4, 4 .. 5, 5 .. 6]:
```

With the default setting `CellsClosed = Right`, the 6 classes are the intervals  $(0, 1]$ ,  $(1, 2]$ ,  $(2, 3]$  etc. The interval  $(0, 1]$  contains one of the data items, the interval  $(1, 2]$  contains two, etc.:

```
plot(plot::Histogram2d(data, Cells = cells))
```

Using `CellsClosed = Left`, the 6 classes are interpreted as the intervals  $[0, 1)$ ,  $[1, 2)$ ,  $[2, 3)$  etc. Now, the first class  $[0, 1)$  contains none of the data items, the second class  $[1, 2)$  contains one item, etc.:

```
plot(plot::Histogram2d(data, Cells = cells, CellsClosed = Left))
```

# CellsClosed, ClassesClosed

---

`delete data, cells:`

## MuPAD Functions

Area | Cells

# Center, CenterX, CenterY, CenterZ

---

**Purpose** Center of objects, rotation center

**Value Summary**

Center	Library wrapper for “[CenterX, CenterY]” (2D), “[CenterX, CenterY, CenterZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
CenterX, CenterY, CenterZ	Mandatory	MuPAD expression

**Graphics Primitives**

Objects	Default Values
plot::Arc3d, plot::Circle3d, plot::Dodecahedron, plot::Ellipse3d, plot::Ellipsoid, plot::Hexahedron, plot::Icosahedron, plot::MuPADCube, plot::Octahedron, plot::Parallelogram3d, plot::Piechart3d, plot::Rotate3d, plot::Sphere, plot::Tetrahedron, plot::Waterman	Center: [0, 0, 0]  CenterX, CenterY, CenterZ: 0
plot::Arc2d, plot::Circle2d, plot::Ellipse2d, plot::Parallelogram2d, plot::Piechart2d, plot::Rotate2d	Center: [0, 0]  CenterX, CenterY: 0

**Description**

The vector Center determines the center of various objects such a circles, spheres, pie charts etc. In rotation objects, it refers to the center of rotation.

# Center, CenterX, CenterY, CenterZ

---

Depending on the dimension of the object, it is given by a list or vector of 2 or 3 components.

CenterX etc. refer to the  $x$ ,  $y$ ,  $z$  components of this vector.

Center, CenterX etc. also denotes the rotation center in rotation objects of type `plot::Rotate2d` or `plot::Rotate3d`.

The values of these attributes can be animated.

## Examples

### Example 1

We create circles around the origin:

```
c1 := plot::Circle2d(1, [0, 0]):
c2 := plot::Circle2d(2, [0, 0]):
```

The second argument in `plot::Circle2d` is the center. Internally, it is stored as the attribute `Center` and can be changed by assigning a new value:

```
c1::Center := [1, 0]:
c2::Center := [-1, 1]:
plot(c1, c2):
```

```
delete c1, c2:
```

## Example 2

We create an ellipse with an animated center. A copy of it is rotated around this center:

```
e1 := plot::Ellipse2d(1, 3, Center = [a, a], a = 0..5):
e2 := plot::Rotate2d(e1, Angle = a*PI/2,
 Center = e1::Center, a = 0..5):
plot(e1, e2)
```

# Center, CenterX, CenterY, CenterZ

---

```
delete e1, e2:
```

### Example 3

We create a sphere of radius 2 and change the default center  $[0, 0, 0]$  to  $[1, 2, 3]$ :

```
s := plot::Sphere(2):
s::Center := [1, 2, 3]:
plot(s)
```

delete s:

**See Also**

**MuPAD  
Functions**

Radius | SemiAxes

# Closed

---

**Purpose** Open or closed polygons

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	Closed Default Values
plot::Arc2d, plot::Arc3d, plot::Polygon2d, plot::Polygon3d	FALSE

**Description** Closed switches between open and closed polygons.

Closed determines whether objects of type `plot::Polygon2d` and `plot::Polygon3d` are drawn as “real” polygons (i.e., closed) or as broken lines (open polygons).

Open polygons can be filled, too. The filled area is exactly the same as if the polygon were closed.

## Examples **Example 1**

By default, polygons are not closed automatically:

```
p := plot::Polygon2d([[1, 2], [3, 4], [5, -6]]):
plot(p)
```

```
p := plot::Polygon2d([[1, 2], [3, 4], [5, -6]], Closed = TRUE):
plot(p)
```

# Closed

---

Note that Filled and Closed are independent:

```
p::Closed := FALSE:
p::Filled := TRUE:
plot(p)
```

delete p:

**See Also**

**MuPAD  
Functions**

Filled

# ColorData

---

**Purpose** Color values of a raster plot

**Value Summary** Mandatory List of arithmetical expressions

## Graphics Primitives

Objects	ColorData Default Values
plot::Raster	

**Description** ColorData is a nested list of RGB color values visualized by a plot::Raster object.

The internal representation of the ColorData entry of a plot::Raster object is a list of lists of color values. Also a matrix or a 2-dimensional array of color values can be assigned to this entry: they are converted to a list of lists.

## Examples

### Example 1

We create a raster plot object:

```
colordata := [[RGB::Red, RGB::Green, RGB::Blue],
 [RGB::Black, RGB::Cyan, RGB::White]]:
r := plot::Raster(colordata, x = 0..3, y = 0..2):
plot(r):
```

The color data of the raster object can be accessed via the ColorData slot:

```
colordata := r::ColorData
```

```
[[[1.0, 0.0, 0.0], [0.0, 1.0, 0.0], [0.0, 0.0, 1.0]], [[0.0, 0.0, 0.0], [0.0, 1.0, 1.0], [1.0, 1.0, 1.0]]]
```

The list of list of color values is turned into an array. After changing one entry, the new colors are written back into the raster object:

```
colordata := array(1..2, 1..3, colordata):
colordata[2, 3] := RGB::Magenta:
colordata
```

# ColorData

---

```
([1.0, 0.0, 0.0] [0.0, 1.0, 0.0] [0.0, 0.0, 1.0]
 [0.0, 0.0, 0.0] [0.0, 1.0, 1.0] [1.0, 0.0, 1.0])
```

```
r::ColorData := colordata:
plot(r)
```

Although the color values were assigned as an array, they are internally stored as a list of lists:

```
r::ColorData
```

```
[[[1.0, 0.0, 0.0], [0.0, 1.0, 0.0], [0.0, 0.0, 1.0]], [[0.0, 0.0, 0.0], [0.0, 1.0, 1.0], [1.0, 0.0, 1.0]]]
```

```
delete colordata, r:
```

**Purpose** Turtle movement commands

**Value Summary** Mandatory List of arithmetical expressions

**Graphics Primitives**

Objects	CommandList Default Values
plot::Turtle	[]

**Description** CommandList stores the command sequence of a plot::Turtle. See the documentation of plot::Turtle for admissible commands and examples.

# Contours

---

**Purpose** Contours of an implicit function

**Value Summary** Mandatory List of arithmetical expressions

## Graphics Primitives

Objects	Contours Default Values
plot::Implicit2d, plot::Implicit3d	[0]

**Description** With Contours, you can set the contour(s) of an implicit function. By default, plot::Implicit2d and plot::Implicit3d plot the set  $f^{-1}(0) = \{X \mid f(X) = 0\}$ . Using Contours, you can instead plot the set  $f^{-1}(c)$  for any real  $c$  or for a sequence of such values.

## Examples **Example 1**

The following command plots a series of cuts through a sphere:

```
plot(plot::Implicit2d(x^2+y^2, x = -1..1, y = -1..1,
Contours = [0, 0.25^2, 0.5^2,
0.75^2, 1.0])):
```

## Example 2

Being an expression attribute, Contours can be animated:

```
plot(plot::Implicit2d(x^2-y^2, x = -1..1, y = -1..1,
 Contours = [1/2*cos(a)], a=0..2*PI)):
```

# Contours

---

### Example 3

The contour currently plotted is passed to the color functions and can be used to distinguish them visually:

```
plot(plot::Implicit3d(x^y - y*z, x=1..4, y=1..4, z=-2..2,
 Contours = [$0..5],
 FillColorFunction = ((x,y,z,dx,dy,dz,c) ->
 RGB::ColorList[round(c)+
```

# CoordinateType

---

**Purpose** Linear versus logarithmic plots in 2D

**Value Summary** Inherited See below

## Graphics Primitives

Objects	CoordinateType Default Values
plot::CoordinateSystem2d	LinLin

## Description

CoordinateType allows to switch between linear and logarithmic 2D plots.

By default, a linear (Cartesian) scaling of all coordinate axes is used in 2D. This corresponds to `CoordinateType = LinLin`. Logarithmic plots are created by choosing a `CoordinateType` different from `LinLin`.

In 2D, the following coordinate types are available:

- `LinLin`: Straight lines given by  $y = c_1x + c_2$  are rendered as straight lines on the screen.
- `LinLog`: Linear coordinates are plotted along the horizontal axis, logarithmic coordinates along the vertical axis. The curves  $y = e^{c_1x + c_2}$  are rendered as straight lines on the screen.
- `LogLin`: Logarithmic coordinates are plotted along the horizontal axis, linear coordinates along the vertical axis. The curves  $y = c_1 \ln(x) + c_2$  are rendered as straight lines on the screen.
- `LogLog`: Logarithmic coordinates are plotted along both axes. The curves  $y = c_1x^{c_2}$  are rendered as straight lines on the screen.

The objects to be plotted must have strictly positive coordinate values in “logarithmic directions”.

## Examples

### Example 1

We consider an exponential function:

```
plot(plot::Function2d(5*exp(x/4), x = -10 .. 100),
 CoordinateType = LinLin):
```

In a singly logarithmic plot, the graph is a straight line:

```
plot(plot::Function2d(5*exp(x/4), x = 0 .. 100),
 CoordinateType = LinLog):
```

# CoordinateType

---

## Example 2

We render the function  $y = \sqrt{x} + x^2$  in a log-log plot:

```
plot(plot::Function2d(sqrt(x) + x^2, x = 10^(-3) .. 10^3),
 CoordinateType = LogLog):
```

# Data

---

**Purpose** The (statistical) data to plot

**Value Summary** Mandatory List of arithmetical expressions

## Graphics Primitives

Objects	Data Default Values
plot::Bars2d, plot::Bars3d, plot::Boxplot, plot::Histogram2d, plot::Listplot, plot::Matrixplot, plot::QQplot, plot::Scatterplot, plot::SparseMatrixplot	
plot::Piechart2d, plot::Piechart3d	[1]

## Description

Data is used internally to store the statistical data displayed, for example, in a pie-chart diagram. While it is possible to manipulate this data (as shown in “Example 2” on page 23-1449), Data is mostly seen as a storage space irrelevant to the user.

For speed and clarity, Data will be displayed in the object inspector only if the amount of data is small. This may cause problems when using the “recalculate” feature. In such a case, the remedy is to assign the plot object in question to an identifier before plotting.

## Examples

### Example 1

All object types listed above store the data given in Data:

```
X := stats::normalRandom(0, 1):
h := plot::Histogram2d([X() $ i = 1..30])
```

```
plot::Histogram2d(...)
```

```
h::Data
```

```
[- 0.5297400457, - 0.5694234147, - 0.5161446272, - 1.090814471, ..., - 0.3119111074,
 0.1868437371, - 0.7818045527]
```

## Example 2

It is possible to change the data in an object using Data:

```
p := plot::Piechart2d([1, 2, 3, 4]):
plot(p)
```

```
p::Data := [1, 1, 3, 2, 3]:
plot(p)
```

**See Also**

**MuPAD  
Functions**

Cells

**Purpose** Density values for a density plot

**Value Summary** DensityData, DensityFunction Optional List of arithmetical expressions

## Graphics Primitives

Objects	Default Values
plot::Density	

## Description

DensityData is a nested list of “density values” visualized by a plot::Density object.

DensityFunction is a symbolic expression or a procedure defining the “density values” of a plot::Density object.

Density objects of type plot::Density can be defined either by discrete density data or by a density function. In the first case, the object has the slot DensityData. In the latter case, the function describing the densities is stored in the slot DensityFunction.

The internal representation of the DensityData entry of a plot::Density object is a list of lists of density values. Also a matrix or a 2-dimensional array of density values can be assigned to this entry: they are converted to a list of lists.

The DensityFunction of a density object can be a symbolic expression, a procedure or a piecewise object.

Assigning a value to the DensityData entry deletes an existing DensityFunction entry and vice versa.

## Examples

### Example 1

We create a density plot object defined by a density function:

```
d := plot::Density(sin(x^2 + y^2), x = -2..2, y = -2..2):
plot(d, Scaling = Constrained):
```

# DensityData, DensityFunction

---

The density function of this object can be accessed via the DensityFunction slot:

```
d::DensityFunction
```

```
sin(x2 + y2)
```

We change the density function by assigning a new value to the DensityFunction slot:

```
d::DensityFunction := exp(-(x2 + y2)/2):
plot(d, Scaling = Constrained)
```

`delete d:`

## **Example 2**

We create a density plot object defined by discrete density data:

```
densitydata := [[0.1, 0.2, 0.3],
 [0.4, 0.5, 0.6]]:
d := plot::Density(densitydata, x = 0..3, y = 0..2):
plot(d):
```

# DensityData, DensityFunction

---

The density data of the density object can be accessed via the DensityData slot:

```
densitydata := d::DensityData
```

```
[[0.1, 0.2, 0.3], [0.4, 0.5, 0.6]]
```

The list of list of density values is turned into a matrix. After changing one entry, the new density values are written back into the density object:

```
densitydata := matrix(densitydata):
densitydata[2, 3] := 0.2:
densitydata
```

```
(0.1 0.2 0.3)
(0.4 0.5 0.2)
```

```
d::DensityData := densitydata:
plot(d)
```

Although the density values were assigned as a matrix, they are internally stored as a list of lists:

```
d::DensityData
```

```
[[0.1, 0.2, 0.3], [0.4, 0.5, 0.2]]
```

```
delete densitydata, d:
```

# Edges

---

**Purpose** Number of Edges

**Value Summary** Mandatory MuPAD expression

## Graphics Primitives

Objects	Edges Default Values
plot::Pyramid	4
plot::Prism	3

**Description** Edges determines the number of edges for the regular base plane of a prism or pyramid. Edges is a positive integer number.

## Examples

### Example 1

The default values for the attribute Edges are:

```
plot::Prism();
plot::Pyramid();
```

```
plot::Prism(1, [0, 0, 0], [0, 0, 1], Edges = 3)
```

```
plot::Pyramid(1, [0, 0, 0], 0, [0, 0, 1], Edges = 4)
```

### Example 2

The attribute Edges can be animated:

```
plot(plot::Pyramid(Edges=a, a=3..13)):
```

# Extension

---

**Purpose** Line extensions

**Value Summary** Inherited Finite, Infinite, or SemiInfinite

## Graphics Primitives

Objects	Extension Default Values
plot::Line2d, plot::Line3d	Finite

## Description

Extension allows to extent a line segment to an infinite ray or an infinite line.

Lines of type `plot::Line2d` and `plot::Line3d` are defined by specifying two points through which the line passes. For example: `plot::Line2d([x1, y1], [x2, y2])`. The first point `[x1, y1]` corresponds to the attribute `From`, the second point `[x2, y2]` corresponds to the attribute `To`.

With `Extension = Finite`, a line segment from `From` to `To` is drawn.

With `Extension = SemiInfinite`, an infinite ray is drawn starting at `From` passing through `To`. The ray extends to the border of the `ViewingBox`.

With `Extension = Infinite`, an infinite line is drawn passing through `From` and `To`. The line extends in both directions to the border of the `ViewingBox`.

## Examples

### Example 1

We plot two lines with the default value `Extension = Finite`:

```
plot(plot::Line2d([0, 0], [1, 1], Color = RGB::Blue),
 plot::Line2d([1, 0], [2, 1], Color = RGB::Red),
 ViewingBox = [-1..3, -1..3])
```

Now, with `Extension = SemiInfinite`, the blue line becomes a ray extending to the `ViewingBox` in one direction:

```
plot(plot::Line2d([0, 0], [1, 1], Color = RGB::Blue,
 Extension = SemiInfinite),
 plot::Line2d([1, 0], [2, 1], Color = RGB::Red),
 ViewingBox = [-1..3, -1..3])
```

# Extension

---

With `Extension = Infinite`, the blue line extends to the `ViewingBox` in both directions:

```
plot(plot::Line2d([0, 0], [1, 1], Color = RGB::Blue,
 Extension = Infinite),
 plot::Line2d([1, 0], [2, 1], Color = RGB::Red),
 ViewingBox = [-1..3, -1..3])
```

## Example 2

Here we define a finite line segment and use `plot::modify` to create an extended copy. It is drawn as an infinite dashed line:

```
line := plot::Line2d([0, 0], [1, 1]):
plot(plot::modify(line, Extension = Infinite,
 LineStyle = Dashed),
 line, ViewingBox = [-1..2, -1..2]):
```

# Extension

---

delete line:

## See Also

### MuPAD Functions

[AffectViewingBox](#) | [From](#) | [To](#)

# From, To, FromX, FromY, FromZ, ToX, ToY, ToZ

**Purpose** Starting point of arrows and lines

## Value Summary

From	Library wrapper for “[FromX, FromY]” (2D), “[FromX, FromY, FromZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
To	Library wrapper for “[ToX, ToY]” (2D), “[ToX, ToY, ToZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
FromX, FromY, FromZ, ToX, ToY, ToZ	Mandatory	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Arrow2d, plot::Line2d	From: [0, 0] To: [1, 0] FromX, FromY, ToY: 0 ToX: 1
plot::Arrow3d, plot::Line3d	From: [0, 0, 0] To: [1, 0, 0] FromX, FromY, FromZ, ToY, ToZ: 0 ToX: 1
plot::Reflect2d	

## Description

The vectors From and To determine the starting point and the end point, respectively, of arrows and lines.

# From, To, FromX, FromY, FromZ, ToX, ToY, ToZ

---

From is a vector determining the position of the starting point of arrows and lines. Depending on the dimension, it is given by a list or vector of 2 or 3 components.

FromX etc. refer to the  $x$ ,  $y$ ,  $z$  components of this vector.

To is a vector determining the position of the end point of arrows and lines. Depending on the dimension, it is given by a list or vector of 2 or 3 components.

To etc. refer to the  $x$ ,  $y$ ,  $z$  components of this vector.

The values of these attributes can be animated.

## Examples

### Example 1

We define an arrow:

```
p := plot::Arrow2d([0, 0], [1, 2]):
plot(p):
```

# From, To, FromX, FromY, FromZ, ToX, ToY, ToZ

The arguments are the starting point and the end point of the arrow. Internally, they are stored as the attributes From and To. We can access the object's attributes and change them:

```
p::From, p::To
```

```
[0, 0], [1, 2]
```

```
p::From := [1, 0]:
p::To := [0, 1]:
plot(p):
```

```
delete p:
```

## Example 2

The values of From and To can be animated. Here is a simple clock:

# From, To, FromX, FromY, FromZ, ToX, ToY, ToZ

---

```
plot(plot::Circle2d(1, [0, 0], Color = RGB::Black),
 plot::Line2d([0.9*cos(a*PI/6), 0.9*sin(a*PI/6)],
 [1.0*cos(a*PI/6), 1.0*sin(a*PI/6)],
 Color = RGB::Black, LineWidth = 0.8*unit::mm)
 $ a = 0 .. 11,
 plot::Line2d([0.95*cos(a*PI/30), 0.95*sin(a*PI/30)],
 [1.0*cos(a*PI/30), 1.0*sin(a*PI/30)],
 Color = RGB::Black, LineWidth = 0.5*unit::mm)
 $ a = 0 .. 59,
 plot::Arrow2d([0, 0], [0.85*sin(12*a), 0.85*cos(12*a)],
 a = 0 .. 2*PI, LineWidth = 2*unit::mm),
 plot::Arrow2d([0, 0], [0.6*sin(a), 0.6*cos(a)],
 a = 0 .. 2*PI, LineWidth = 3*unit::mm),
 Axes = None, Frames = 600, TimeRange = 0..120):
```

# Function, XFunction, YFunction, ZFunction

**Purpose** Function expression or procedure

**Value Summary** Function, XFunction, YFunction, ZFunction      Mandatory      MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylindrical, plot::Function2d, plot::Function3d, plot::Implicit2d, plot::Implicit3d, plot::Iteration, plot::Ode2d, plot::Ode3d, plot::Polar, plot::Sequence, plot::Spherical, plot::Streamlines2d, plot::Sum, plot::Surface, plot::Tube, plot::VectorField2d, plot::VectorField3d, plot::XRotate, plot::ZRotate	

**Description** Function, XFunction, YFunction, ZFunction correspond to function expressions or procedures in various plot objects given by a mathematical function.

The attribute Function is used for graphs of functions in 2D and 3D, implicit plots, conformal plots etc. which are characterized by a single function.

# Function, XFunction, YFunction, ZFunction

---

The attributes XFunction etc. refer to the parametrization of the  $x$ ,  $y$  or  $z$ -coordinate of parametrized curves and surfaces. In vector field plots they correspond to the components of the vector field.

When defining a graphical primitive such as a function plot, the mathematical expression defining the function is passed directly to the plot routine generating this object. E.g., one calls `plot::Function2d(x*sin(x), x = -5 .. 5)` to define the graph of  $f(x) = x\sin(x)$ . Internally, the attribute `Function = x*sin(x)` is associated with the graphical object.

Wherever function expressions are expected, also `piecewise` objects or MuPAD procedures can be used. E.g., the calls `plot::Function2d(sin(x), x = 0..PI)` and `plot::Function2d(x -> sin(x), x = 0..PI)` are equivalent and associate the attributes `Function = sin(x)` or `Function = x -> sin(x)`, respectively, with the plot objects.

## Examples

### Example 1

We define an object of type `plot::Function2d` representing the graph of  $f(x) = x\sin(x)$ :

```
f := plot::Function2d(x*sin(x), x = -4 .. 4):
plot(f)
```

# Function, XFunction, YFunction, ZFunction

---

Internally, the expression defining the function is turned into the attribute `Function = x*sin(x)`. It is accessible via a corresponding slot of the object:

```
f::Function
```

```
x sin(x)
```

One can change the object by reassigning a new value to this attribute:

```
f::Function := 1/x:
plot(f):
```

# Function, XFunction, YFunction, ZFunction

---

`delete f:`

## Example 2

For implicit plots as produced by `plot::Implicit2d` and `plot::Implicit3d`, the attribute `Function` refers to the function whose zero set is to be plotted:

```
p := plot::Implicit2d(y*sin(x) - x*cos(y), x=-5..5, y=-5..5):
```

Internally, the expression defining the function is turned into the attribute `Function = y*sin(x) - x*cos(y)`. It is accessible via a corresponding slot of the object:

```
p::Function
```

```
y sin(x) - x cos(y)
```

# Function, XFunction, YFunction, ZFunction

---

```
delete p:
```

## Example 3

For parametrized curves and surfaces, the attributes XFunction, YFunction etc. correspond to the parametrization of the coordinates  $x, y$  etc:

```
c2 := plot::Curve2d([u*cos(u), u*sin(u)], u = 0..5*PI):
c2::XFunction, c2::YFunction
```

$u \cos(u), u \sin(u)$

```
c3 := plot::Curve3d([u*cos(u), u*sin(u), u^2], u = 0..5*PI):
c3::XFunction, c3::YFunction, c3::ZFunction
```

$u \cos(u), u \sin(u), u^2$

```
s := plot::Surface([u*cos(v), u*sin(v), u^2*sin(2*v)],
 u = 0..1, v = 0..2*PI):
s::XFunction, s::YFunction, s::ZFunction
```

$u \cos(v), u \sin(v), u^2 \sin(2 v)$

```
delete c2, c3, s:
```

## Example 4

Wherever a function expression is expected, also a piecewise object or a procedure can be used:

```
f1 := piecewise([x < 0, 0], [x >= 0, x]):
f2 := proc(x) begin
 if x < 0 then
 1
```

# Function, XFunction, YFunction, ZFunction

---

```
 else 1 - x^2/2
 end_if;
 end_proc;
F1 := plot::Function2d(f1, x = -1..PI/2):
F2 := plot::Function2d(f2, x = -1..PI/2):
F1::Function, F2::Function
```

```
{ 0 if x < 0
 x if 0 ≤ x, proc f2(x) ... end
```

```
plot(F1, F2)
```

```
delete f1, f2, F1, F2:
```

### MuPAD Functions

Function1 | Function2

# Function 1, Function2, Baseline

---

**Purpose** First function/curve delimiting hatch

**Value Summary** Baseline, Mandatory Text string  
Function1,  
Function2

## Graphics Primitives

Objects	Default Values
plot::Hatch, plot::Integral	

## Description

Function1 and Function2 refer to the functions that define the borders of a hatched 2D region of type plot::Hatch.

Baseline is the  $y$  value of a straight horizontal border line of a hatch.

Function1, Function2 are very technical attributes that a user will hardly ever use.

If  $f_1, f_2$  are function objects of type plot::Function2d, the hatch object  $h := \text{plot::Hatch}(f_1, f_2)$  stores references to the objects  $f_1, f_2$  as the slots  $h::\text{Function1}, h::\text{Function2}$ . These are text references (i.e., strings) by which the function objects  $f_1, f_2$  can be identified, but not the function objects themselves.

Function1 points to a function object of type plot::Function2d or a curve object of type plot::Curve2d.

Function1 is usually set implicitly by plot::Hatch to the Name attribute of its first argument.

When Function1 refers to a curve of type plot::Curve2d, Function2 and Baseline are ignored.

Function2 is the (optional) second border function of a hatch. In the plot, the hatched area is bounded by the two functions referred to by Function1 and Function2.

# Function1, Function2, Baseline

If Function2 is given, Function1 must refer to a function graph of type `plot::Function2d`, too.

Function2 is usually set implicitly by `plot::Hatch` to the Name attribute of its second argument.

Baseline is an alternative second delimiter of a hatch. It defines a horizontal border line of the hatch with a y-value given by Baseline. The Baseline expression may be animated.

## Examples

### Example 1

We hatch the area between the functions  $\sqrt{x}$  and  $x^2$ :

```
f1 := plot::Function2d(sqrt(x), x = 0..2, Color = RGB::Black):
f2 := plot::Function2d(x^2, x = 0..2, Color = RGB::Blue):
h := plot::Hatch(f1, f2):
plot(f1, f2, h)
```

# Function1, Function2, Baseline

---

The references to the border functions are stored as strings in the hatch object h:

```
h::Function1, h::Function2
```

```
"Function2d(LineColor = [0.0, 0.0, 0.0], XMin = 0, XMax = 2, XName = x, Function = x^(1/2) x)", "Function2d(LineColor = [0.0, 0.0, 1.0], XMin = 0, XMax = 2, XName = x, Function = x = "x")"
```

Baseline serves as an alternative for the special case of a constant border function. The Baseline value can be animated:

```
h := plot::Hatch(f1, sqrt(2)*a, a = 0 .. 1):
h::Baseline
```

$\sqrt{2} a$

```
plot(f1, h)
```

# Function 1, Function 2, Baseline

A (closed) curve of type `plot::Curve2d` may be used as the boundary of the hatch:

```
f1 := plot::Curve2d([sin(2*x), cos(3*x)], x = 0..2*PI,
 Color = RGB::Black):
h := plot::Hatch(f1):
h::Function1
```

```
"Curve2d(LineColor = [0.0, 0.0, 0.0], UMin = 0, UMax = 2*PI, UName = x, XFunction = sin(2*x),
 YFunction = cos(3*x))"
```

```
plot(f1, h)
```

# Function 1, Function 2, Baseline

---

```
delete f1, f2, h, c:
```

**See Also**

**MuPAD  
Functions**

Name

**Purpose** Initial conditions of the ODE

**Value Summary** InitialConditions, Mandatory List of arithmetical  
TimeMesh expressions

## Graphics Primitives

Objects	Default Values
plot::Ode2d, plot::Ode3d	

## Description

InitialConditions = [y<sub>1</sub>(t<sub>0</sub>), y<sub>2</sub>(t<sub>0</sub>), ] sets the initial conditions for the initial value problem

$$\frac{\partial}{\partial t} \begin{pmatrix} y_1(t) \\ y_2(t) \\ \vdots \end{pmatrix} = \begin{pmatrix} f_1(t, y_1(t), y_2(t), \dots) \\ f_2(t, y_1(t), y_2(t), \dots) \\ \vdots \end{pmatrix}$$

TimeMesh = [t<sub>0</sub>, t<sub>1</sub>, t<sub>2</sub>, ] sets the values of the independent variable *t* (the “time”) of the ODE at which graphical points of the solution curve are plotted. The first entry t<sub>0</sub> is the initial time for which initial conditions are set by InitialConditions.

Internally, plot::Ode2d and plot::Ode3d call the routine numeric::odesolve for solving the given ODE numerically.

The list of initial conditions set by InitialConditions is forwarded to numeric::odesolve. See the corresponding help page for further details.

## Examples

### Example 1

We solve the initial value problem  $y'(t) = -y(t)$ ,  $y(0) = 1$  numerically:

# InitialConditions, TimeMesh

---

```
f := (t, Y) -> [-Y[1]]:
Y0 := [1]:
timemesh:= [0, 0.2, 0.5, 1, 1.5, 2, 3, 5]:
plot(plot::Ode2d(f, InitialConditions = Y0,
 TimeMesh = timemesh))
```

```
delete f, Y0, timemesh:
```

**Purpose** Method for integral approximation

**Value Summary** Optional Exact, RiemannLeft, RiemannRight, RiemannLower, RiemannUpper, RiemannMiddle, RiemannLowerAbs, RiemannUpperAbs, Simpson, or Trapezoid

## Graphics Primitives

Objects	IntMethod Default Values
plot::Integral	Exact

## Description

IntMethod determines the method of the visualization of plot::Integral objects.

Following methods are implemented:

- Exact  
the area between x-axis and function graph is colored
- RiemannLower  
display boxes between x-axis and function graph using the smallest value of the function in each subinterval
- RiemannLowerAbs  
display boxes between x-axis and function graph using the smallest absolut value of the function in each subinterval
- RiemannUpper  
display boxes between x-axis and function graph using the greatest value of the function in each subinterval
- RiemannUpperAbs

# IntMethod

---

display boxes between x-axis and function graph using the greatest absolute value of the function in each subinterval

- RiemannLeft

display boxes between x-axis and function graph using the function value of the left border in each subinterval

- RiemannMiddle

display boxes between x-axis and function graph using the function value of the middle in each subinterval

- RiemannRight

display boxes between x-axis and function graph using the function value of the right border in each subinterval

- Trapezoid

display an approximation of the integral using the Trapezoidal rule

- Simpson

interpolate the graph of the function using Simpsons rule

## Examples

### Example 1

The following example shows all implemented methods:

```
f := plot::Function2d(x*(x-3)*(x+4), Color = RGB::Black):
plot(plot::Scene2d(plot::Integral(f, 7, IntMethod = method, Color =
 ShowInfo = [IntMethod, Integral,

# Generations, RotationAngle, IterationRules, StartRule, StepLength, TurtleRules

---

**Purpose** Number of iterations of L-system rules

**Value Summary** Generations, Optional MuPAD expression  
IterationRules,  
RotationAngle,  
StartRule,  
StepLength,  
TurtleRules

## Graphics Primitives

Objects	Default Values
plot::Lsys	Generations: 5 StepLength: 1.0

**Description** Generations, RotationAngle, IterationRules, StartRule, StepLength, and TurtleRules define a Lindenmayer system. The attribute meanings and examples of their use can be found in the documentation of plot::Lsys.

**Purpose** Base value

**Value Summary** Optional MuPAD expression

## Graphics Primitives

Objects	Ground Default Values
plot::Bars3d, plot::Sweep	0

## Description

In bar charts, the attribute `Ground = g` determines the vertical coordinate value of one end of the bars. Data values  $m > g$  are displayed as bars stretching in the vertical direction from the lower end  $g$  up to the upper end  $m$ . Data values  $m < g$  are displayed as bars stretching in the vertical direction from the upper end  $g$  down to the lower end  $m$ .

In sweep surfaces of type `plot::Sweep`, a parametrized space curve  $(x(u), y(u), z(u))$  is projected to the  $x$ - $y$ -plane with constant  $z = g$ , where  $g$  is set by the `Ground` attribute.

The parameter  $g$  has to be a numerical real value or an expression of the animation parameter.

If the attribute `Ground = g` is not specified, the default value  $g = 0$  is used.

## Examples

### Example 1

We plot the same data with different `Ground` values:

```
A := matrix::random(5, 5, frandom):
plot(plot::Scene3d(plot::Bars3d(A, Ground = 0,
 Color = RGB::Grey)),
 plot::Scene3d(plot::Bars3d(A, Ground = 0.5,
 Color = RGB::Grey)),
 Layout = Horizontal):
```

# Ground

---

In the next call, the ground level is animated. Note that in animations one must specify ranges for the  $x$  and  $y$  coordinates. We include a transparent plane visualizing the ground level:

```
plot(plot::Bars3d(A, x = 0 .. 1, y = 0 .. 1, a = 0 .. PI,
 Color = RGB::Grey,
 Gap = [0.5, 0.5],
 Ground = sin(a)),
 plot::Surface([x, y, sin(a) + 0.001],
 x = 0 .. 1, y = 0 .. 1, a = 0 .. PI,
 Mesh = [2, 2], Color = RGB::Blue.[0.5])
):
```

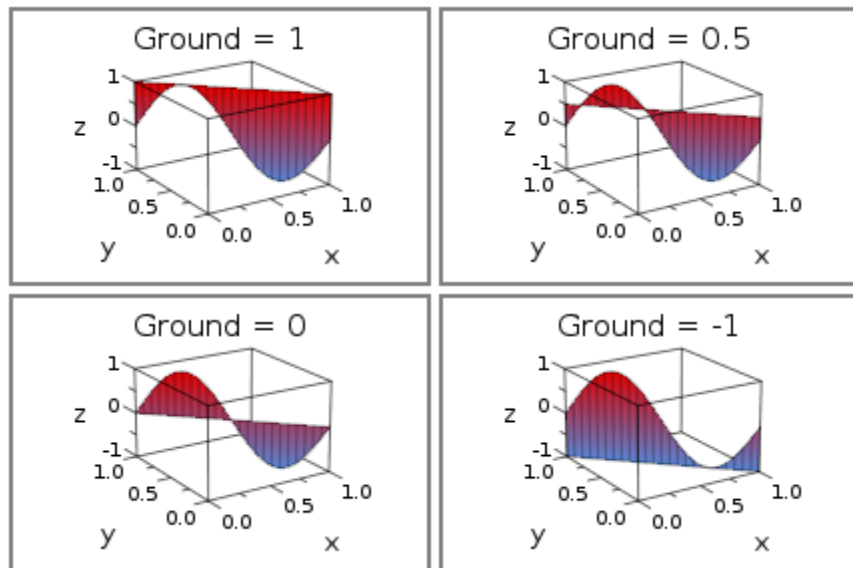

`delete A:`

## Example 2

We use different Ground values to project a space curve to the  $x$ - $y$ -plane:

```
plot(plot::Scene3d(plot::Sweep([u, 1-u, sin(2*PI*u)], u = 0..1,
 Ground = 1), Header = "Ground = 1"),
 plot::Scene3d(plot::Sweep([u, 1-u, sin(2*PI*u)], u = 0..1,
 Ground = 0.5), Header = "Ground = 0.5"),
 plot::Scene3d(plot::Sweep([u, 1-u, sin(2*PI*u)], u = 0..1,
 Ground = 0), Header = "Ground = 0"),
 plot::Scene3d(plot::Sweep([u, 1-u, sin(2*PI*u)], u = 0..1,
 Ground = -1), Header = "Ground = -1"),
 plot::Scene3d::BorderWidth = 0.5*unit::mm,
 Layout = Tabular, Rows = 2)
```

# Ground

**Purpose** Heights of pieces in pie charts

**Value Summary** Heights, Moves      Optional      List of arithmetical expressions

## Graphics Primitives

Objects	Default Values
<code>plot::Piechart3d</code>	Heights: [0.3] Moves: [0]
<code>plot::Piechart2d</code>	Moves: [0]

## Description

Heights, Moves determine the heights and displacements of the single pieces in a pie chart.

Heights determines the heights of the pieces in a `plot::Piechart3d`. If no height value is given for a piece, 0.3 is used. The given values have to be real numbers or expressions of the animation parameter.

Moves determines the movements of pieces away from the pie chart center. If no move value is given for a piece, 0 is used. The given values have to be non-negative real numbers or expressions of the animation parameter. The values are fractions of the Radius of the pie chart. A value of 1 means a full pie chart radius, 0.5 half the radius of the pie chart etc.

Heights, Moves accept its input in two formats:

- The values can be given as a flat list of values with entries of the type specified above. The first list entry will be used for the first piece etc. If the list contains less values than the data set of the pie chart, the last value is repeated. Superfluous entries are ignored.
- The values can be given as a list of equations with positive integers on the left hand side and values – as specified above – on the right hand side. The integers are interpreted as indices of the pieces.

# Heights, Moves

---

## Examples

### Example 1

We move the third piece of the following pie chart away from the center by half the radius of the pie chart:

```
plot(plot::Piechart2d([1, 2, 1, 3],
 Moves = [3 = 0.5]))
```

The pieces are moved away from the center by different amounts:

```
plot(plot::Piechart2d([1, 2, 1, 3],
 Moves = [0, 0.5, 0.2, 0.1]))
```

## Example 2

We plot an analogous 3D pie chart:

```
plot(plot::Piechart3d([1, 2, 1, 3],
 Moves = [3 = 0.5]))
```

# Heights, Moves

---

The pieces are moved away from the center by different amounts:

```
plot(plot::Piechart3d([1, 2, 1, 3],
 Moves = [0, 0.5, 0.2, 0.1]))
```

In 3D, the pieces of a pie chart can have different heights:

```
plot(plot::Piechart3d([1, 2, 1, 3],
 Heights = [0.4, 0.5, 0.2, 0.1]))
```

# Heights, Moves

---

## Example 3

Here is a `plot::Piechart3d` with animated Heights, Moves, and Radius:

```
plot(plot::Piechart3d([4, 3, 2, 1],
 Radius = 3 + sin(a),
 Heights = [cos(a)^2, cos(2*a)^2,
 cos(3*a)^2, cos(4*a)^2],
 Moves = [0.3*sin(a)^2, a = 0..PI]):
```

# Inequalities

---

**Purpose** Inequalities displayed in inequality plots

**Value Summary** Mandatory List of arithmetical expressions

## Graphics Primitives

Objects	Inequalities Default Values
<code>plot::Inequality</code>	

**Description** `Inequalities` is the attribute used by `plot::Inequality` to store the inequalities to plot.

`plot::Inequality` is used to plot the areas where one or more inequalities are fulfilled. `Inequalities` is the internal attribute where the inequalities are stored. Most users will never access this attribute directly; it exists for technical reasons only.

**Purpose** Input file for import functions

**Value Summary** Mandatory Text string

**Graphics Primitives**

Objects	InputFile Default Values
plot::SurfaceSTL	

**Description**

InputFile specifies the name of the input file for import functions.

InputFile can either be an absolute pathname or a pathname relative to the current working directory or one of the directories specified by the MuPAD variable READPATH.

Note that some MuPAD functions do not react to the MuPAD variable READPATH. In this case it might be necessary to specify InputFile as an absolute pathname.

Note that the current working directory of a MuPAD session may depend on how and from where MuPAD has been started. Be careful when making assumptions about this.

See plot::SurfaceSTL for examples.

**See Also**

**MuPAD Functions** OutputFile

# Iterations, StartingPoint

---

**Purpose** Number of iterations in plot::Iteration

**Value Summary** Iterations, StartingPoint Optional MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Iteration	Iterations: 10

## Description

Iterations and StartingPoints are special attributes for iteration objects of type plot::Iteration. StartingPoint sets the starting point, Iterations sets the number of iteration steps.

The call `it := plot::Iteration(f, x_0, n, x = `x_{min}` .. `x_{max}`)` yields a visualization of the iteration  $x_i = f(x_{i-1})$  of the starting point  $x_0$  with  $i = 1, \dots, n$ . The values  $x_0$  and  $n$  are stored as the attributes `StartingPoint = x_0` and `Iterations = n` in the iteration object `it`. The values can be accessed and changed as the slots `it::StartingPoint` and `it::Iterations`, respectively.

These attributes can be animated.

## Examples

### Example 1

We define and plot an iteration object:

```
f := plot::Function2d(exp(-2*x), x = 0..1):
g := plot::Function2d(x, x = 0..1):
it := plot::Iteration(exp(-2*x), 0.2, 5, x = 0..1):
plot(f, g, it)
```

The starting point  $x_0 = 0.2$  and the number of iteration steps 5 are stored inside the iteration object:

```
it::StartingPoint, it::Iterations
```

```
0.2, 5
```

We change these values:

```
it::StartingPoint := 0.1:
it::Iterations := 30:
plot(f, g, it)
```

# Iterations, StartingPoint

---

delete f, g, it:

# LineColorFunction, FillColorFunction

## Description

Objects	Default Values
---------	----------------

<code>plot::VectorField2d,</code> <code>plot::VectorField3d,</code> <code>plots::Waterman,</code> <code>plot::XRotate,</code> <code>plot::ZRotate</code>	These objects are color functions that define the color of a plot at arbitrary points. Using <code>FillColorType</code> and <code>LineColorType</code> , the user can control the
-------------------------------------------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

color of many graphical objects. The setting providing the most detailed (and most complicated) control is `Functional`. In this case, a *color function* must be provided using one of `LineColorFunction`, `FillColorFunction`.

A color function can be a list of three or four expressions.

If three expressions are given, they specify RGB colors. If four expressions are given, they specify RGBA colors. See the introduction for more details on color specifications.

The expressions may contain the identifiers bound in the corresponding object. For example, in a `plot::Function2d(sin(x), x=0..PI)`, the color function may refer to `x`. More formally, the expressions may contain the identifiers found in the attributes `XName`, `YName`, `ZName`, `UName`, `VName`, and `ParameterName` of the plot object they are found in.

All of these expressions must, for values in the given ranges, evaluate to real numbers in the range `0..1`. Real values outside this range do not yield errors, they are simply clipped.

See also “Example 1” on page 23-1504.

Alternatively, a color function can be a procedure or function environment.

A procedure (or a function environment) used as a color function must return lists of three or four real numbers in the range `0..1`. Real values outside this range are clipped. (If this function ever returns a list of four numbers, it must always do so.) A list of three numbers is interpreted as an RGB color, while a list of four values is interpreted as an RGBA color. See the introduction for more details on color specifications.

# LineColorFunction, FillColorFunction

The number and meaning of arguments a color function is called with depends on the object type. Informally, we have:

Type (abbreviated)	Parameters
Conformal( $f(z)$ )	$z$ , $\text{Re}(f(z))$ , $\text{Im}(f(z))$ , flag (with flag = 1 or flag = 2)
Curve2d( $x(u), y(u)$ )	$u$ , $x(u)$ , $y(u)$
Curve3d( $x(u), y(u), z(u)$ )	$u$ , $x(u)$ , $y(u)$ , $z(u)$
Cylindrical( $r(u, v), \text{phi}(u, v), z(u, v)$ )	$u, v, r(u, v), \text{phi}(u, v), z(u, v), x(u), y(u), z(u)$
Density( $f(x, y)$ )	$x, y, f(x, y)$
Dodecahedron	See below.

Tube	See below.
VectorField2d( $v(x,y), w(x,y)$ )	$x, y, v(x,y), w(x,y)$
XRotate( $f(x)$ )	$x, \text{phi}, x, y(x,\text{phi}), z(x,\text{phi})$
ZRotate( $f(t)$ )	$t, \text{phi}, x(t,\text{phi}), y(t,\text{phi}), f(t)(=z(t,\text{phi}))$

Additionally, for animated objects, the current value of the animation parameter is provided.

Dodecahedron, Hexahedron, Icosahedron, SurfaceSTL, SurfaceSet, and Tetrahedron are built from triangles; the color functions are called once for each vertex of these triangles and are passed the number of the triangle (an integer count starting at 1), the coordinates of the vertex and the animation parameter, if that is used.

For `plot::Tube`, the color functions are given the coordinates of the currently visited point on the central curve, followed by the coordinates of the point on the surface, followed by the animation parameter, if any. (That makes seven arguments altogether.)

The examples below show different usage environments of color functions for some of the object types listed above.

## Examples

### Example 1

By default, most 3D-objects in MuPAD get “height coloring”:

```
plot(plot::Function3d(sin(x)*y^3))
```

# LineColorFunction, FillColorFunction

To change the direction of this color, you can use `FillColorFunction`:

```
xmin := -5:
xmax := 5:
color := zip(RGB::Red, RGB::CornflowerBlue,
 (a, b) -> (x-xmin)/(xmax-xmin)*a
 +(xmax-x)/(xmax-xmin)*b)
```

```
[0.0607807 x + 0.6960965, 0.2921535 - 0.0584307 x, 0.4646975 - 0.0929395 x]
```

```
plot(plot::Function3d(sin(x)*y^3,
 FillColorFunction = color))
```

# LineColorFunction, FillColorFunction

---

## Example 2

Animated color functions can be combined with static objects:

```
plot(plot::Curve2d([sin(3*x), sin(4*x+1)], x=0..2*PI,
 LineColorFunction = ((u, x, y, a) -> [(u-a)/5
 a = -5..6))
```

# LineColorFunction, FillColorFunction

```
cf := (i, x, y, z, a) -> [RGB::Red,
 RGB::Green,
 RGB::Blue][(floor(a*i)
 mod 3) + 1]:
plot(plot::Icosahedron(FillColorFunction = cf,
 a = 0..9))
```

# LineColorFunction, FillColorFunction

---

## Example 3

A color function should generate values in RGB color space. Since a `plot::Box` does not allow a `FillColorFunction`, we use six (trivial) `Surface` objects to show the outside of this color space:

```
rgb := (u, v, x, y, z) -> [x, y, z]:
plot(plot::Surface(formula, u = 0..1, v = 0..1,
 FillColorFunction = rgb)
 $ formula in [[0, u, v], [1, u, v],
 [u, 0, v], [u, 1, v],
 [u, v, 0], [u, v, 1]],
 plot::Box(0..1, 0..1, 0..1, Filled = FALSE,
 LineColor = RGB::Black.[0.25]),
 Scaling = Constrained, Axes = None,
 ULinesVisible = FALSE, VLinesVisible = FALSE,
 Lighting = None, CameraDirection = [4, 7, 3])
```

# LineColorFunction, FillColorFunction

---

RGB colors are a very technical way of defining a color. The HSV color space is more popular with designers, since there the “hue” (i.e., the perceived color type) is not a combination of three numbers but rather one of the numbers making up a color:

```
hsv := (u, v, r, phi, z) -> RGB::fromHSV([180/PI*phi, r, z]):
plot(plot::Cylindrical([z, phi, z], z = 0..1, phi = 0..2*PI,
 FillColorFunction = hsv),
 plot::Cylindrical([r, phi, 1], r = 0..1, phi = 0..2*PI,
 FillColorFunction = hsv),
 plot::Circle3d(1, [0, 0, 1], [0, 0, 1],
 Color = RGB::Black.[0.25]),
 ZXRatio = 1.5, Scaling = Unconstrained,
 Axes = None, Lighting = None,
 ULinesVisible = FALSE, VLinesVisible = FALSE,
 CameraDirection = [-17, -12, 3])
```

# LineColorFunction, FillColorFunction

---

## Example 4

HSV color space is especially suitable for quick coloring of cylindrical, polar, or spherical plots, due to its circular nature:

```
hsv := (u, v, r, phi, thet) ->
 RGB::fromHSV([180/PI*(phi+(thet+2)^3/PI^2),
 3/4+sin(u)/4, 1]):
plot(plot::Spherical([1, u, v], u = 0..2*PI, v = 0..PI,
 FillColorFunction = hsv))
```

# LineColorFunction, FillColorFunction

There are other examples, where the cyclic nature comes in handy, too:

```
hsv := (x, y, z) -> RGB::fromHSV([150*z, 1, 1]):
plot(plot::Function3d(sin(x*y)*(x-y), x = -3..3, y = -3..3,
 Submesh = [2, 2], FillColorFunction = hsv)
```

# LineColorFunction, FillColorFunction

The following example takes a long time to compute. Reducing the values set for Mesh results in a shorter computation, while higher values lead to an image with finer details:

```
c := 0.377+0.2*I;
julia := proc(x, y)
 local i, z;
 begin
 i := 0;
 z := float(x + I*y);
 while i < 1000 and abs(z) < 4 do
 z := z^2 + c;
 i := i + 1;
 end_while;
 i;
 end_proc;
Jcol := (x, y, i) -> if i >= 1000 then
 RGB::Black
```

# LineColorFunction, FillColorFunction

```
else
 RGB::fromHSV([i, 1, 3/4+i/2000])
end:
plot(plot::Density(julia, x = 0..0.5, y=0.25..0.75,
 FillColorFunction = Jcol,
 Mesh = [100,75]))
```

## Example 5

Another way of getting a smooth color transition is to use a periodic function in between, for example trigonometric ones (note the  $(1+\sin(a))/2$ : we need values between 0 and 1):

```
plot(plot::Polar([r*surd(r, 3), r], r = -4*PI..4*PI, AdaptiveMes
 LineColorFunction = [(sin(r)+1)/2, (cos(r/2)+1)
 LineWidth = 1*unit::mm))
```

# LineColorFunction, FillColorFunction

---

This also applies for cyclic colors in terms of time:

```
plot(plot::Function3d(sin(x)+sin(y), x = -5..5, y = -5..5,
 FillColorFunction = [(x+5)/10, (y+5)/10,
 abs(x+y+5*cos(a))/15,
 (1+cos(x+y^2-a))/2],
 a = 0..2*PI),
 CameraDirection = [-1, -3, 3],
 Scaling = Constrained)
```

## Algorithms

Animation is handled by the general framework, not the individual objects. Therefore, the framework also supplies the animation parameter to the color functions.

# MeshList, MeshListType, MeshListNormals

**Purpose** Triangulation data

**Value Summary**

MeshList	Mandatory	List of arithmetical expressions
MeshListType	Optional	ColorQuads, Quads, QuadStrip, Triangles, TriangleFan, or TriangleStrip
MeshListNormals	Optional	BeforeFacets, BeforePoints, BehindFacets, BehindPoints, or None

## Graphics Primitives

Objects	Default Values
plot::SurfaceSet	MeshListType: Triangles MeshListNormals: None

## Description

**MeshList** is a list of data defining the triangulation of a 3D surface of type `plot::SurfaceSet`.

**MeshListType** specifies how the data in the list **MeshList** are to be interpreted.

**MeshListNormals** specifies which of the data in the list **MeshList** are to be interpreted as normals.

**MeshList** contains coordinates of points (and optional normals) of either triangles or quads which define a mesh of a 3D surface. The points must be given homogenous: If a normal is given, it must be given for all points or facets, respectively. The attribute **MeshListType** specifies how these points are to be interpreted for plotting the surface. The attribute **MeshListNormals** specifies whether the list contains normal vectors and at which positions they located.

About normals and facet orientation: The facets (triangles or quads) define the surface of a 3D object. As such, each facet is part of the boundary between the interior and the exterior of the object. The

# MeshList, MeshListType, MeshListNormals

orientation of the facets (which way is "out" and which way is "in") is specified redundantly in two ways which should be consistent: First, the direction of the normal is outward. Second, which is most commonly used now-a-day, the facet vertices are listed in counter-clockwise order when looking at the object from the outside (right-hand rule). Normals must be given as unit vectors.

`MeshList` must not contain color values. Use the color functions `LineColorFunction` and `FillColorFunction` instead.

`MeshListType` specifies how the points in `MeshList` are to be interpreted. Supported mesh list types are:

Value	Info	Description
Triangles	Set of separate	Each tuple of three points define one new triangle.
TriangleFan	Triangle fan	The first triangle is defined by the first three points. The next triangles are defined by the first point, the previous point and the current point.
TriangleStrip	Triangle strip	The first triangle is defined by the first three points. The next triangles are defined by the two previous points and the current point.
Quads	Set of separate quads	Each tuple of four points define one new quad.
QuadStrip	Strip of quads	The first quad is defined by the first four points. The next quads are defined by the two previous points and the next two points.

`MeshListNormals` specifies whether `MeshList` contains normal vectors and at which positions they are located. Valid options are:

# MeshList, MeshListType, MeshListNormals

---

Value	Description
None	No normals are specified.
BeforePoints	A normal is given before each point.
BehindPoints	A normal is given behind each point.
BeforeFacets	A normal is given before each triangle or quad, respectively. This option is only valid for MeshListType = Triangles and MeshListType = Quads.
BehindFacets	A normal is given behind each triangle or quad, respectively. This option is only valid for MeshListType = Triangles and MeshListType = Quads.

## Examples

### Example 1

We create a triangle set with normals in front of each triangle and plot this object, a tetrahedron, afterwards:

```
meshList:= [
 0.0 , 0.0 , -1.0 ,
 -1.5 , -1.5 , 1.4 , 0.0, 1.7, 1.4, 1.5, -1.5, 1.4,
 0.0 , 0.88, 0.47,
 -1.5 , -1.5 , 1.4 , 1.5, -1.5, 1.4, 0.0, 0.0, -1.4,
 -0.88, -0.41, 0.25,
 1.5 , -1.5 , 1.4 , 0.0, 1.7, 1.4, 0.0, 0.0, -1.4,
 0.88, -0.41, 0.25,
 0.0 , 1.7 , 1.4 , -1.5, -1.5, 1.4, 0.0, 0.0, -1.4
]:
plot(plot::SurfaceSet(meshList,
 MeshListType = Triangles,
 MeshListNormals = BeforeFacets)):
```

# MeshList, MeshListType, MeshListNormals

`delete meshList:`

## Example 2

The object is displayed in the legend and the interactive object browser of the graphics tool.</p> <p>Giving a name to a graphical object has no significance whatsoever for the graphical appearance of the object. The main purpose of the name is to make it easier to identify the object in the interactive “object browser” of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document).</p> <p>If no name is specified, the type of the object is displayed in the object browser.</p> <p>If the legend is “switched on” by setting <code>LegendVisible</code> to <code>TRUE</code>, the name slot of an object is used (if it exists), unless the object has a specific <code>LegendText</code>.</p> <p>Name has a special technical semantics for objects of type <code>plot::Hatch</code>. The bounding functions or curves of the hatch are referenced via the <code>Name</code> slot. If the bounding function or curve has no name slot, it is set to <code>plot::Hatch</code> to the output of <code>expr2text</code> of the function <code>Curve</code>, cf. Example 2 on page 23-1524.</p>
<b>Examples</b>	<p><b>Example 1</b></p> <p>The first two of the following function objects are given the names <code>Sin</code> and <code>Cos</code>, respectively. Generate the graphics and doubleclick on the plot. The two function objects are visible under their names in the object browser. The third function is just labeled as a ‘Function2d’ object. Also the legend uses this labeling:</p>

# Name

## Example 2

By default, an object does not have a Name entry:

```
f := plot::Function2d(cos(x), x=0..PI):
f::Name
```

FAIL

When creating a `plot::Hatch` object, the Name slot is set implicitly for the border function(s):

```
h := plot::Hatch(f):
h::Name
```

```
"Function2d(XMin = 0, XMax = PI, XName = x, Function = cos(x), XAxisTitle = "x")"
```

We plot the hatch with its bounding function:

```
plot(h, f)
```

Doubleclick on the graphics and observe the way the objects are labeled in the object inspector.

```
delete f, h:
```

# Nodes

---

**Purpose** Number of subintervals or list of x-values for subintervals

**Value Summary** Optional List of arithmetical expressions

## Graphics Primitives

Objects	Nodes Default Values
<code>plot::Integral</code>	[10]

## Description

`Nodes` is a positive number of subintervals for numeric approximation of integrals. The given interval for approximation is divided into the given number of subintervals, all of the same width.

Otherwise, `Nodes` can be a list of x-values for dividing the given interval. The interval is divided into subintervals at the given x-values.

When a number is given for `Nodes`, the number can be given as a list with this one number, too.

When a list with x-values is given, the left and right border of the whole (approximation) interval can be omitted. In this case, the number of subintervals is the number of given x-values plus one.

`Nodes` outside the approximation interval are ignored. Duplicate values are ignored.

The nodes need not be ordered.

## Examples

### Example 1

`Nodes` determines the number of rectangles for Riemann sums:

```
f := plot::Function2d(x*(x+4)*(x-4)):
plot(plot::Integral(f, Nodes = 25, IntMethod = RiemannLower), f)
```

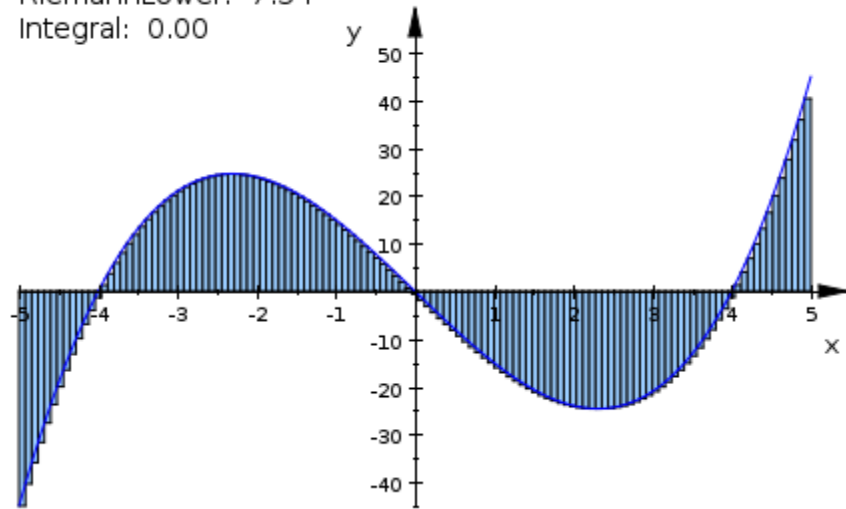

Increasing of Nodes decreases the error or the approximation:

```
plot(plot::Integral(f, Nodes = 125, IntMethod = RiemannLower), f
```

# Nodes

RiemannLower: -7.54  
Integral: 0.00

```
delete f:
```

## Example 2

We request a specific division into subintervals:

```
f := plot::Function2d(sin(x), x = -2*PI..2*PI):
plot(plot::Integral(f, Nodes = [i*PI/2 $ i = -4..4], IntMethod = Tr
```

Trapezoid: 0.00  
Integral: 0.00

The subintervals do not need to be of equal width:

```
f := plot::Function2d(sin(x), x = 0..PI):
plot(plot::Integral(f, [PI/3, PI/2, 2*PI/3], IntMethod = Trapezo
```

# Nodes

---

delete f:

## See Also

## MuPAD Functions

IntMethod

# Normal, NormalX, NormalY, NormalZ

**Purpose** Normal vector of circles and discs, etc. in 3D

## Value Summary

Normal	Library wrapper for “[NormalX, NormalY]” (2D), “[NormalX, NormalY, NormalZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
NormalX, NormalY, NormalZ	Mandatory	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Prism, plot::Pyramid	Normal: [0, 0, 0] NormalX, NormalY, NormalZ: 0
plot::Arc3d, plot::Circle3d, plot::Ellipse3d, plot::Plane, plot::Reflect3d	Normal: [0, 0, 1] NormalX, NormalY: 0 NormalZ: 1

## Description

Normal determines the normal vector of the plane of the 3D circle, prism or pyramid. It is given by a list or vector of 3 components.

NormalX etc. refer to the  $x$ ,  $y$ ,  $z$  components of this vector.

The values of these attributes can be animated.

With Filled = TRUE, a circle becomes a disc.

## Examples

### Example 1

We create a circle around the origin lying in the  $x$ - $y$  plane:

```
c := plot::Circle3d(1, [0, 0, 0], [0, 0, 1])
```

# Normal, NormalX, NormalY, NormalZ

---

```
plot::Circle3d(1, [0, 0, 0], [0, 0, 1])
```

The second argument in `plot::Circle3d` is the center, the third argument is the normal. Internally, these vectors are stored as the attributes `Center` and `Normal` and can be changed by assigning a new value:

```
c::Normal := [-0.5, 0.5, 1]:
plot(c):
```

```
delete c:
```

## Example 2

Normal can be animated:

```
plot(plot::Circle3d(1, [0, 0, 0], [cos(a), sin(a), 0]),
```

# Normal, NormalX, NormalY, NormalZ

```
 a = 0 .. 2*PI, Filled = TRUE),
Axes = Origin):
```

## Example 3

Normal can be used to create crooked prisms, pyramids and frustums of pyramids. If this attribute is set to  $[0, 0, 0]$ , the axis between Base and Top is used as normal vector:

```
plot(plot::Scene3d(plot::Pyramid(2,[0,0,0],1,[0,4,4], Normal=[0,
plot::Scene3d(plot::Pyramid(2,[0,0,0],1,[0,4,4], Normal=[0,
```

# Normal, NormalX, NormalY, NormalZ

---

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

## Purpose

Name of the animation parameter

## Value Summary

ParameterBegin, ParameterEnd, ParameterName	Optional	MuPAD expression
ParameterRange	[ParameterBegin .. ParameterEnd]	Range of arithmetical expressions

## Description

Typically, animations are triggered by passing an equation of the form  $a = `a_{\min}` .. `a_{\max}`$  in the definition of an object.

This is equivalent to passing the attributes  $\text{ParameterName} = a$ ,  $\text{ParameterBegin} = a_{\min}$ , and  $\text{ParameterEnd} = a_{\max}$  in the definition of the object.

The attribute  $\text{ParameterRange} = `a_{\min}` .. `a_{\max}`$  is equivalent to setting both  $\text{ParameterBegin} = a_{\min}$  and  $\text{ParameterEnd} = a_{\max}$ .

Animations are defined object by object, not frame by frame.

In most cases, the user will define animations by passing an equation of the form  $a = `a_{\min}` .. `a_{\max}`$  in the definition of an object. Any equation of this form that is not essential for the definition of a static version of the object is interpreted as an animation parameter and an animation range.

Passing such an equation is equivalent to setting the three attributes  $\text{ParameterName} = a$ ,  $\text{ParameterBegin} = a_{\min}$ ,  $\text{ParameterEnd} = a_{\max}$ .

The attribute  $\text{ParameterRange} = `a_{\min}` .. `a_{\max}`$  serves as a short cut for setting both  $\text{ParameterBegin} = a_{\min}$  and  $\text{ParameterEnd} = a_{\max}$ .

The values  $a_{\min}$  and  $a_{\max}$  are the parameter values at the beginning and the end of the real time range in which an object is animated. This time range is set by the attributes  $\text{TimeBegin}$  and  $\text{TimeEnd}$ , respectively.

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

The parameter range ``a_{min}` .. `a_{max}`` is mapped linearly to this time interval.

The name of the animation parameter may be an identifier or an indexed identifier. This parameter is a 'global variable' that may be present in other quantities or attributes defining the object.

The definition of an object may involve procedures rather than symbolic expressions. E.g., a 2D function plot may be defined by `plot::Function2d(f, x = x_0..x_1)`, where  $f$  is a procedure accepting one numerical argument  $x$  from the plot range between  $x_0$  and  $x_1$ .

In an animated version `plot::Function2d(f, x = x_0..x_1, a = `a_{min}` .. `a_{max}`)`, the function  $f$  will be called with two arguments  $x$  and  $a$ . Thus,  $f$  may be defined as a function accepting two parameters  $x, a$  or as a function with one parameter  $x$ , using the animation parameter  $a$  as a global variable.

Each animated object has its own animation parameter and range ``a_{min}` .. `a_{max}``. It is not necessary that several animated objects in a scene use the same parameter name. It is not used to synchronize the animations.

The synchronization is determined uniquely by the linear correspondence between the animation range ``a_{min}` .. `a_{max}`` and the real time span of the animation set by the attributes `TimeBegin` and `TimeEnd` of the object.

## Examples

### Example 1

The definition of a static 2D function plot involves the specification of one range (for the  $x$  variable):

```
plot(plot::Function2d(sin(x), x = 0 .. 2*PI))
```

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

When a “surplus equation”  $a = \text{'a\_min'} \dots \text{'a\_max'}$  is passed, this is interpreted as a call to animate the function. The animation parameter may turn up in the expression defining the function:

```
plot(plot::Function2d(sin(x + a), x = a .. 2*PI, a = 0..PI))
```

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

A static function plot in 3D requires two ranges (for the  $x$  and the  $y$  variable):

```
plot(plot::Function3d(sin(x)*sin(y), x = 0 .. PI, y = 0..PI))
```

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

Now, a third equation  $a = \text{'a\_min'} \dots \text{'a\_max'}$  triggers an animation:

```
plot(plot::Function3d(sin(x + a)*sin(y - a), x = 0 .. PI,
y = 0..PI, a = 0..PI))
```

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

## Example 2

We define an animated 2D function plot:

```
f := plot::Function2d(x^3 + a*x, x = -1..1, a = 0..2):
plot(f):
```

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

We swap the role of the independent variable  $x$  and the animation parameter  $a$ :

```
[f::XName, f::ParameterName] := [f::ParameterName, f::XName]:
[f::XRange, f::ParameterRange] :=
 [f::ParameterRange, f::XRange]:
```

The function now is drawn as a function of  $a$  for various values of the “time”  $x$ :

```
plot(f)
```

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

delete f:

### Example 3

We demonstrate the use of procedures in the definition of animated functions.

We wish to plot the eigenvalues of a matrix that depends on two parameters  $x$  and  $a$ . The eigenvalues are computed numerically in the procedure `eigenvals`. This procedure uses option `remember`, because it is called thrice with the same arguments by the procedures  $f_1$ ,  $f_2$ ,  $f_3$  that produce the smallest, the middle, and the largest eigenvalue, respectively, as functions of the parameters  $x$  and  $a$ :

```
eigenvals :=
 proc(x, a)
 option remember;
 local A;
 begin
```

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

```
A:= matrix([[1, a, x],
 [a, 2, a*x],
 [x, a*x, 3]]):
sort(numeric::eigenvalues(A)):
end_proc:
f1:= (x, a) -> eigenvals(x, a)[1]:
f2:= (x, a) -> eigenvals(x, a)[2]:
f3:= (x, a) -> eigenvals(x, a)[3]:

plot(plot::Function2d(f1, x = -2..2, a = 0..2,
 Color = RGB::Red),
 plot::Function2d(f2, x = -2..2, a = 0..2,
 Color = RGB::Green),
 plot::Function2d(f3, x = -2..2, a = 0..2,
 Color = RGB::Blue)):
```

```
delete eigenvals, f1, f2, f3:
```

# ParameterName, ParameterBegin, ParameterEnd, ParameterRange

---

### Concepts

- “The Number of Frames and the Time Range”

**Purpose** List of 2D points

**Value Summary** Points2d, Points3d Mandatory List of 2D points

**Graphics Primitives**

Objects	Default Values
plot::PointList2d, plot::PointList3d, plot::Polygon2d, plot::Polygon3d	

**Description**

Points2d is the list of 2D points in objects of type plot::PointList2d and plot::Polygon2d, respectively.

Points3d is the list of 3D points in objects of type plot::PointList3d and plot::Polygon3d, respectively.

One usually defines such an object p, say, via

`p := plot::PointList2d([[x1, y1], [x2, y2], ])` or

`p := plot::Polygon2d([[x1, y1], [x2, y2], ])`, respectively.

Internally, the points are stored as the attribute

`Points2d = [[x1, y1], [x2, y2], ]`

and can be accessed via the slot call `p::Points2d`. Assigning a new list to `p::Points2d` changes the object p accordingly.

The corresponding statements hold for 3D point lists and polygons.

The points in the list Points2d may consist of lists with 2 elements (the x and y coordinates) or of lists with 3 elements (the x and y coordinates and the RGB color of the point).

The points in the list Points3d may consist of lists with 3 elements (the x, y, and z coordinates) or of lists with 4 elements (the x, y, z coordinates and the RGB/RGBA color of the point).

# Points2d, Points3d

---

If you specify the color of one point, you must specify the colors of all other points in the list. See “Example 2” on page 23-1547.

The points in the lists `Points2d` and `Points3d` can be animated.

## Examples

### Example 1

We define a 2D polygon with 5 points:

```
p := plot::Polygon2d([[0, 0], [1, 1], [1, 2], [2, 2], [2, 1]]):
plot(p):
```

The points in the polygon can be accessed as the `Points2d` attribute:

```
pts := p::Points2d

[[0, 0], [1, 1], [1, 2], [2, 2], [2, 1]]
```

We change the polygon by assigning a new point list:

```
p::Points2d := [pts[1], pts[5], pts[2], pts[4], pts[3]]:
plot(p):
```

```
delete p, pts:
```

## Example 2

Points2d and Points3d allow you to specify the colors of the points. For example, the following list contains two points. The plot function uses the default color for both points on the plot:

```
Coords := [[3, 4], [5, 5]];
plotCoords := plot::PointList2d(Coords):
plot(plotCoords, PointSize = 5)
```

# Points2d, Points3d

---

```
[[3, 4], [5, 5]]
```

To access and modify the list of points, use `Points2d`. For example, include the color of each point in the list:

```
plotCoords::Points2d := [[3, 4, RGB::Red], [5, 5, RGB::Green]]
```

```
[[3, 4, [1.0, 0.0, 0.0]], [5, 5, [0.0, 1.0, 0.0]]]
```

Now the first point appears in red, and the second point appears in green:

```
plot(plotCoords, PointSize = 5)
```

If you specify the color of one point, you must also specify the colors of all other points in the list:

```
plotCoords::Points2d := [[3, 4, RGB::Red], [5, 5]]
```

Error: The attribute 'Points2d' in the 'PointList2d' object must

# Position, PositionX, PositionY, PositionZ

---

**Purpose**                      Positions of cameras, lights, and text objects

**Value Summary**

Position	Library wrapper for “[PositionX, PositionY]” (2D), “[PositionX, PositionY, PositionZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
PositionX, PositionY, PositionZ	Mandatory	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Camera, plot::DistantLight, plot::PointLight, plot::SpotLight, plot::Text2d, plot::Text3d	
plot::Point2d	Position: [0, 0] PositionX, PositionY: 0
plot::Plane, plot::Point3d, plot::Reflect3d	Position: [0, 0, 0] PositionX, PositionY, PositionZ: 0

**Description**                      Position determines the positions of cameras, lights, and text objects. PositionX etc. refer to the single coordinate values of the position. The attribute Position refers to the location of a camera taking pictures of a 3D scene. Its a value is a list or vector of coordinates. Also the position of light sources illuminating the 3D scene is set by Position.

Further, `Position` determines the coordinates where text objects are to be placed.

These attributes can be animated. Animating a camera position one can realize a flight through a 3D scene.

By default, the position of lights is given in model coordinates that have nothing to do with the camera that is used to view the scene.

The attribute `CameraCoordinates` also allows to position a light relative to the camera. In particular, the light moves automatically, when the camera is moved.

## Examples

### Example 1

We define a 3D scene consisting of a function, a distant light, and a camera. The light shines from the direction of the camera:

```
f := plot::Function3d(sin(x^2 - y^2), x = -2..2, y = -2..2,
 Color = RGB::White):
light := plot::DistantLight([3, 4, 5], [0, 0, 0], 0.75,
 Color = RGB::Yellow):
camera := plot::Camera([3, 4, 5], [0, 0, 0], 0.25*PI):
plot(f, light, camera)
```

# Position, PositionX, PositionY, PositionZ

---

We animate the camera position but keep the light position fixed:

```
camera::Position := [3*sqrt(2)*cos(a + PI/4),
 4*sqrt(2)*sin(a + PI/4),
 5*(0.7 + 0.3*cos(2*a))]:
camera::ParameterName := a:
camera::ParameterRange := 0..2*PI:
plot(f, light, camera)
```

Using the same objects, we fix the camera and animate the light position:

```
camera::Position := [3, 4, 5]:
camera::Frames := 1:
light::Position := [3*sqrt(2)*cos(a + PI/4),
 4*sqrt(2)*sin(a + PI/4),
 5]:
light::ParameterName := a:
light::ParameterRange := 0..2*PI:
plot(f, light, camera)
```

# Position, PositionX, PositionY, PositionZ

---

```
delete f, light, camera:
```

## See Also

### MuPAD Functions

CameraCoordinates | CameraDirection | FocalPoint |  
SpotAngle | Target | ViewingAngle

**Purpose** Radius of circles, spheres etc.

**Value Summary** Mandatory MuPAD expression

**Graphics Primitives**

Objects	Radius Default Values
plot::Circle2d, plot::Circle3d, plot::Cylinder, plot::Dodecahedron, plot::Hexahedron, plot::Icosahedron, plot::MuPADCube, plot::Octahedron, plot::Piechart2d, plot::Piechart3d, plot::Prism, plot::Sphere, plot::Tetrahedron	1
plot::Waterman	

**Description** Radius defines the radius of circles (plot::Circle2d and plot::Circle3d, respectively), spheres (plot::Sphere), cylinders (plot::Cylinder), circumcircles of regular bases of prisms (plot::Prism) and pie charts (plot::Piechart2d and plot::Piechart3d, respectively). Also polyhedra such as plot::Dodecahedron use this attribute to set their size.

**Examples Example 1**

We generate a sphere around the origin with radius 2:

```
s := plot::Sphere(2, [0, 0, 0])
```

# Radius

---

```
plot::Sphere(2, [0, 0, 0])
```

The first argument in `plot::Sphere` is the radius, the second argument is the center. Internally, these values are stored as the attributes `Radius` and `Center`, respectively. We can access the objects' attributes and change them:

```
s::Radius, s::Center
```

```
2, [0, 0, 0]
```

```
s2 := plot::copy(s):
s2::Center := [4, 0, 0]:
s2::Radius := 1:
plot(s, s2):
```

```
delete s, s2:
```

## Example 2

The attribute Radius can be animated:

```
plot(plot::Sphere(a, [0, 0, 0], a = 1..2)):
```

## Example 3

For a prism, the attribute Radius determines the radius of the circumcircle of its regular bases:

```
plot(plot::Prism(1,Edges=5), plot::Circle3d(1)):
```

# Radius

---

## See Also

### MuPAD Functions

[Base](#) | [Center](#) | [Normal](#) | [SemiAxes](#) | [Top](#)

**Purpose** Radius of a tube plot

**Value Summary** Mandatory                      Arithmetical expression or function

## Graphics Primitives

Objects	RadiusFunction Default Values
plot::Tube	1/10

## Description

RadiusFunction is the internal name of the radius function in plot::Tube.

With RadiusFunction =  $r(t)$ , plot::Tube will draw (part of) a circle of radius  $r(t)$  at the point  $(x(t), y(t), z(t))$  around the central curve.

Usually, a user will have no need to access RadiusFunction directly, since it is set by plot::Tube directly.

## Examples

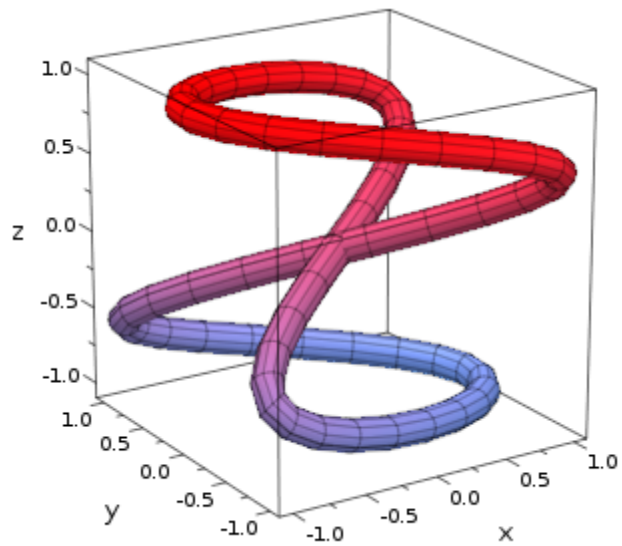

### Example 1

By default, plot::Tube uses a constant radius of  $\frac{1}{10}$ :

```
t := plot::Tube([sin(3*x), sin(2*x), sin(x)], x = 0..2*PI):
plot(t)
```

# RadiusFunction

---

To change this default, either set some other radius when creating the tube plot (see the documentation of `plot::Tube` for this) or set `RadiusFunction`:

```
t::RadiusFunction := (1+sin(3*x))/2/10:
plot(t)
```

# RationalExpression

---

**Purpose** Rational expression in a rootlocus plot

**Value Summary** Mandatory MuPAD expression

## Graphics Primitives

Objects	RationalExpression Default Values
plot::Rootlocus	

**Description** RationalExpression is the internal name of the expression whose roots are depicted by plot::Rootlocus.

A rootlocus plot depicts the roots of a rational function  $p(z, u)$  in the complex plane, depending on a parameter  $u$ . The expression  $p(z, u)$  is stored as the attribute RationalExpression in the rootlocus object.

Usually, a user will have no need to access the attribute RationalExpression, since it is set by plot::Rootlocus directly.

## Examples

### Example 1

We define a rootlocus plot:

```
r:= plot::Rootlocus(z^2 - 2*u*z + 0.81, u = -1..1):
plot(r)
```

The function  $z^2 - 2uz + 0.81$  is stored as the attribute `r::RationalExpression` in the object `r`:

```
r::RationalExpression
```

$$z^2 - 2uz + 0.81$$

We can redefine this attribute:

```
r::RationalExpression:= z^3 - 2*u*z + 0.81:
plot(r)
```

# RationalExpression

---

**Purpose** Scaling factors

**Value Summary**

Scale	Library wrapper for “[ScaleX, ScaleY]” (2D), “[ScaleX, ScaleY, ScaleZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
ScaleX, ScaleY, ScaleZ	Optional	MuPAD expression

**Graphics Primitives**

Objects	Default Values
plot::Scale2d	Scale: [1, 1] ScaleX, ScaleY: 1
plot::Scale3d	Scale: [1, 1, 1] ScaleX, ScaleY, ScaleZ: 1

**Description**

Scale defines the scaling factors used by plot::Scale2d and plot::Scale3d.

ScaleX etc. correspond to the factors in the single coordinate directions.

The scaling objects plot::Scale2d and plot::Scale3d apply the scaling transformation  $\mathbf{X} \rightarrow \mathbf{A} \mathbf{X}$  with the matrix  $A = \text{diag}(s_x, s_y)$  in 2D and  $A = \text{diag}(s_x, s_y, s_z)$  in 3D, respectively.

Scale is the list  $[s_x, s_y]$  resp.  $[s_x, s_y, s_z]$  of the scaling factors. The attributes ScaleX etc. correspond to  $s_x$  etc.

These attributes can be animated.

**Examples**

**Example 1**

We start with a 2D circle:

# Scale, ScaleX, ScaleY, ScaleZ

---

```
c := plot::Circle2d(3, [3, 3]):
```

We apply a scaling transformation:

```
S := plot::Scale2d([2, 3], c):
plot(c, S):
```

The scaling factors are stored as the `Scale` attribute in the scaling object `S`:

```
S::Scale, S::ScaleX, S::ScaleY
```

```
[2, 3], 2, 3
```

We change the scaling factors:

```
S::Scale := [-2, -3]:
```

`plot(c, S):`

`delete c, S:`

# SemiAxes, SemiAxisX, SemiAxisY, SemiAxisZ

---

**Purpose** Semi axes of ellipses and ellipsoids

**Value Summary**

SemiAxes	Library wrapper for “[SemiAxisX, SemiAxisY]” (2D), “[SemiAxisX, SemiAxisY, SemiAxisZ]” (3D)	List of two or three real-valued expressions
SemiAxisX, SemiAxisY, SemiAxisZ	Mandatory	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Ellipsoid	SemiAxes: [1, 2, 3] SemiAxisX: 1 SemiAxisY: 2 SemiAxisZ: 3
plot::Ellipse2d	SemiAxes: [2, 1] SemiAxisX: 2 SemiAxisY: 1
plot::Ellipse3d	SemiAxisX: 2 SemiAxisY: 1
plot::Arc2d	SemiAxes: [1, 1] SemiAxisX, SemiAxisY: 1
plot::Arc3d	SemiAxisX, SemiAxisY: 1

**Description** SemiAxes determines the lengths of the semi axes of ellipses in 2D and ellipsoids in 3D.

# SemiAxes, SemiAxisX, SemiAxisY, SemiAxisZ

---

`SemiAxes = [rx, ry]` sets the lengths  $r_x$ ,  $r_y$  of the semi axes of an ellipse in 2D.

`SemiAxes = [rx, ry, rz]` sets the lengths  $r_x$ ,  $r_y$ ,  $r_z$  of the semi axes of an ellipsoid in 3D.

`SemiAxisX = rx`, `SemiAxisY = ry`, `SemiAxisZ = rz` refer to the semi axis in the  $x$ ,  $y$ , and  $z$  direction, respectively.

The values of these attributes can be animated.

## Examples

### Example 1

We create an ellipse around the origin with semi axes 1 and 2:

```
e := plot::Ellipse2d(1, 2, [0, 0]):
```

The first two arguments in `plot::Ellipse2d` are the semi axes. Internally, they are stored as the attributes `SemiAxisX` and `SemiAxisY` and can be changed by assigning new values:

```
e::SemiAxisX, e::SemiAxisY, e::SemiAxes
```

```
1, 2, [1, 2]
```

```
e::SemiAxes := [3, 2]:
plot(e):
```

# SemiAxes, SemiAxisX, SemiAxisY, SemiAxisZ

---

delete e:

## Example 2

SemiAxes can be animated:

```
plot(plot::Ellipse2d(a, 3 - a, [3, 3], a = 1..2)):
```

# SemiAxes, SemiAxisX, SemiAxisY, SemiAxisZ

---

**See Also**

**MuPAD  
Functions**

Radius

# Shift, ShiftX, ShiftY, ShiftZ

---

## Purpose

Shift vector

## Value Summary

Shift

Library wrapper for “[ShiftX, ShiftY]” (2D), “[ShiftX, ShiftY, ShiftZ]” (3D)

List of 2 or 3 expressions, depending on the dimension

ShiftX, ShiftY, ShiftZ

Optional

MuPAD expression

## Description

Shift is the shift vector in transformation objects. ShiftX etc. refer to the single components of this vector.

The general transformation objects `plot::Transform2d` and `plot::Transform3d` allow to apply the affine-linear transformation  $X \rightarrow A X + b$  to 2D and 3D objects, respectively. The shift vector  $b$  can be accessed and changed via the attribute `Shift`.

Special transformation objects such as `plot::Translate2d`, `plot::Translate3d` correspond to special matrices  $A$  and shifts  $b$ . They also allow to access and change the shift vector by the attribute `Shift`.

When setting the `Shift` attribute, matrices, arrays, and lists with 2 or 3 elements are accepted. Internally, however, the shift data are always stored as the list  $[b_1, b_2]$  in 2D or  $[b_1, b_2, b_3]$  in 3D, respectively. When reading the vector by a slot access, this list is returned.

The entries of `Shift` can be animated.

## Examples

### Example 1

We move an arrow along the  $y$ -axis:

```
T := plot::Translate2d([0, a], a = 0..5,
 plot::Arrow2d([0, 0], [1, 1])):
plot(T)
```

The `Shift` vector is the first argument in the call above. It is stored in the corresponding slot of the translation object `T`:

```
T::Shift
```

```
[0, a]
```

We change the shift vector:

```
T::Shift := [a, 0]:
plot(T)
```

# Shift, ShiftX, ShiftY, ShiftZ

---

delete T:

## See Also

## MuPAD Functions

[Matrix2d](#) | [Matrix3d](#) | [Scale](#)

**Purpose** Size of a point list

**Value Summary** Optional MuPAD expression

### Graphics Primitives

Objects	Size Default Values
plot::QQplot	

**Description** Size represents the number of plot points in a plot::QQplot.

A plot::QQplot accepts two data lists, displaying a set of plot points with coordinate values given by quantile values of the data. By default, the number of plot points is chosen as the minimum of the sizes of the two data lists. In principle, however, the number of plot points can be chosen independently of the data sizes. With Size =  $n$ , the number of plot points of the QQ plot can be set to any positive integer value  $n$ .

The value of Size can be animated.

### Examples

#### Example 1

We create a QQ plot:

```
data1 := [stats::normalRandom(0, 1)() $ k = 1..100]:
data2 := [stats::normalRandom(0, 1)() $ k = 1..200]:
qq := plot::QQplot(data1, data2):
plot(qq)
```

# Size

---

By default, the minimum of the data sizes is chosen as the number of plot points in the plot (i.e., `Size = 100` in this case). We reduce the number of plot points by setting the value of `Size` explicitly:

```
qq::Size := 30:
plot(qq)
```

The number of plot points can also be specified directly by passing the attribute `Size = n`. In the following graphics, this value is animated:

```
plot(plot::QQplot(data1, data2, Size = n, n = 10..200));
```

# Size

---

```
delete data1, data2, qq:
```

# Tangent1, Tangent1X, Tangent1Y, Tangent1Z, Tangent2, Tangent2X, Tangent2Y, Tangent2Z

## Purpose

First vector spanning parallelograms

## Value Summary

Tangent1	Library wrapper for “[Tangent1X, Tangent1Y]” (2D), “[Tangent1X, Tangent1Y, Tangent1Z]” (3D)	List of 2 or 3 expressions, depending on the dimension
Tangent1X, Tangent1Y, Tangent1Z, Tangent2X, Tangent2Y, Tangent2Z	Mandatory	MuPAD expression
Tangent2	Library wrapper for “[Tangent2X, Tangent2Y]” (2D), “[Tangent2X, Tangent2Y, Tangent2Z]” (3D)	List of 2 or 3 expressions, depending on the dimension

## Graphics Primitives

Objects	Default Values
plot::Parallelogram3d	Tangent1: [0, 1, 0] Tangent1X, Tangent1Z, Tangent2Y, Tangent2Z: 0 Tangent1Y, Tangent2X: 1 Tangent2: [1, 0, 0]
plot::Parallelogram2d	Tangent1: [0, 1] Tangent1X, Tangent2Y: 0 Tangent1Y, Tangent2X: 1 Tangent2: [1, 0]

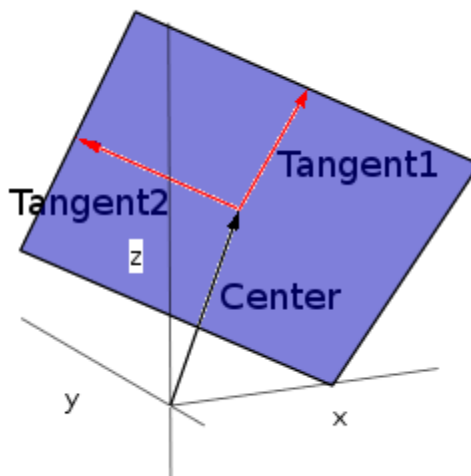

# Tangent1, Tangent1X, Tangent1Y, Tangent1Z, Tangent2, Tangent2X, Tangent2Y, Tangent2Z

---

## Description

Tangent1 and Tangent2 determine the vectors spanning the parallelograms created by `plot::Parallelogram2d` and `plot::Parallelogram3d`.

Parallelograms created by `plot::Parallelogram2d` and `plot::Parallelogram3d` are specified by a vector defining the Center and two vectors Tangent1 and Tangent2 which span the plane of the parallelogram. The lengths of the “tangent” vectors are half the side lengths of the parallelogram:

Depending on the dimension, the vectors Tangent1, Tangent2 are given by lists or vectors of two or three components.

The attributes Tangent1X etc. represent the x, y, z coordinates of these vectors.

The values of these attributes can be animated.

# Tangent1, Tangent1X, Tangent1Y, Tangent1Z, Tangent2, Tangent2X, Tangent2Y, Tangent2Z

## Examples

### Example 1

The “tangent vectors” of a parallelogram are accessible via the slots Tangent1 and Tangent2:

```
p := plot::Parallelogram3d([1, 1, 1], [0, 1, 0], [0, 0, 1],
 Color = RGB::Blue):
```

```
p::Tangent1, p::Tangent2
```

```
[0, 1, 0], [0, 0, 1]
```

```
plot(p,
 plot::Arrow3d([1, 1, 1], [1, 2, 1], Color = RGB::Red),
 plot::Arrow3d([1, 1, 1], [1, 1, 2], Color = RGB::Red),
 Axes = Origin, Scaling = Constrained):
```

We change the “tangent vectors”:

# Tangent1, Tangent1X, Tangent1Y, Tangent1Z, Tangent2, Tangent2X, Tangent2Y, Tangent2Z

---

```
p::Tangent1 := [1, 0, 0]: p::Tangent2 := [1, 1, 0]:
plot(p,
 plot::Arrow3d([1, 1, 1], [2, 1, 1], Color = RGB::Red),
 plot::Arrow3d([1, 1, 1], [2, 2, 1], Color = RGB::Red),
 Axes = Origin, Scaling = Constrained):
```

```
delete p:
```

**See Also**

**MuPAD  
Functions**

Center

**Purpose** Text of a text object

**Value Summary** Mandatory String or function

### Graphics Primitives

Objects	Text Default Values
plot::Text2d, plot::Text3d	

### Description

The attribute `Text` represents the text of a text object. It may be a text string or a function generating a text string at runtime.

The `Text` attribute represents the text in text objects of type `plot::Text2d` and `plot::Text3d`. When creating a text object such as

```
t := plot::Text2d("hello world", [0, 0]),
```

the text is the first argument. Internally, it is stored as the attribute `Text = "hello world"` and can be accessed and changed via a slot call `t::Text`.

In most cases, the text is given as a string.

---

**Note** Note that this string has to be quoted when changing it in the “property inspector” of the interactive graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document). If the string contains white space and the quotes are removed, the recalculation following the change will produce a syntax error!

---

A text given by a fixed string cannot be animated. Use a procedure to create animated texts.

The attribute `Text` can be a procedure that is called at runtime with the animation parameter as the only input parameter. The return value is used as the text of the text object in the corresponding frame

# Text

---

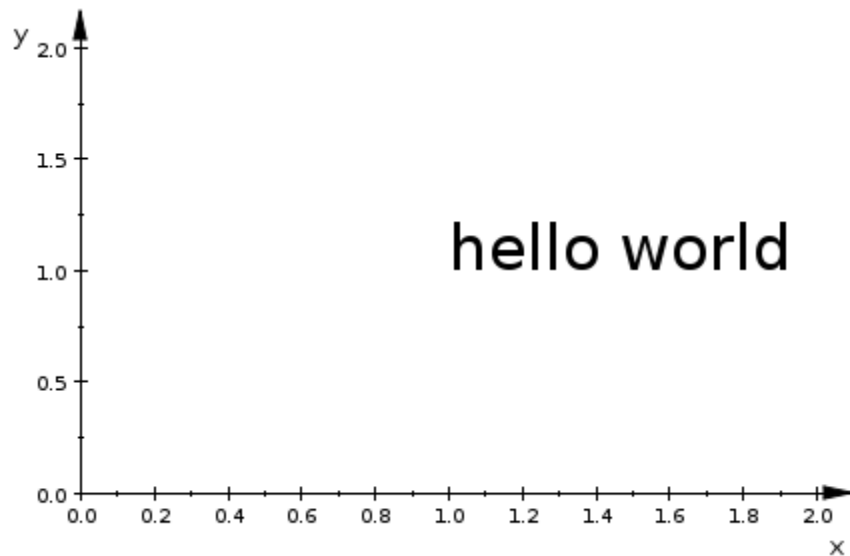

of the animation. If the result is not a string, `expr2text` is applied to the return value.

## Examples

### Example 1

Usually, a text is given by a string:

```
t := plot::Text2d("hello world", [1, 1], TextFont = [24]):
plot(t)
```

We access and change the text:

```
t::Text
```

```
"hello world"
```

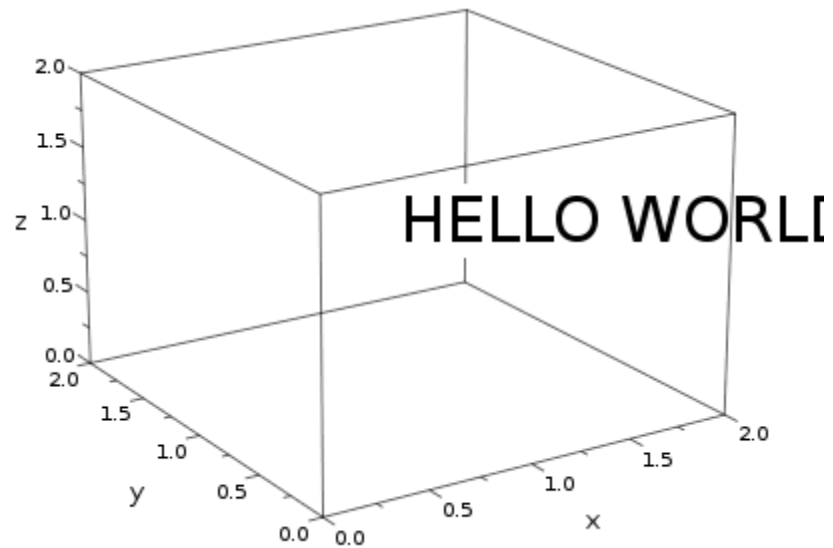

```
t::Text := "HELLO WORLD":
```

```
plot(t)
```

The same message in 3D:

```
plot(plot::Text3d("HELLO WORLD", [1, 1, 1],
 TextFont = [24]))
```

```
delete t:
```

## Example 2

The text of a text object can be animated if the text string is provided by a procedure. We use `stringlib::formatf` to format the animation parameter that is passed to the procedure as a floating-point number for each frame of the animation:

```
plot(plot::Rectangle(-1..1, -1..1),
 plot::Text2d(a -> stringlib::formatf(a, 2, 5)." sec",
 [0, 0], a = 0..20,
 TextFont = [60],
 HorizontalAlignment = Center,
 VerticalAlignment = Center),
 Axes = Frame, Frames = 201, TimeRange = 0..20)
```

Here is the corresponding example in 3D:

```
plot(plot::Text3d(a -> stringlib::formatf(a, 2, 5)." sec",
 [0, 0, 0], a = 0..20,
 TextFont = [60],
 HorizontalAlignment = Center,
 VerticalAlignment = Center),
 Axes = Frame, Frames = 201, TimeRange = 0..20)
```

### MuPAD Functions

[Billboarding](#) | [HorizontalAlignment](#) | [TextFont](#) |  
[VerticalAlignment](#) | [stringlib::formatf](#)

**Purpose** Orientation of a 3D text

**Value Summary** Optional List of six real-valued expressions

## Graphics Primitives

Objects	TextOrientation Default Values
<code>plot::Text3d</code>	[1, 0, 0, 0, 0, 1]

## Description

`TextOrientation` defines the orientation of a text object of type `plot::Text3d`. Its orientation in 3 space is given by 2 directions. There is the “writing direction” from the first character of the text to the last. The direction from the bottom of the characters to their top shall be referred to as the “up direction”.

Together with the anchor point of the text (the attribute `Position` of a `plot::Text3d` object), these two directions define a 2 dimensional plane in 3D. You may regard this plane as the sheet onto which the text is written.

The value of `TextOrientation` has to be a list of 6 numerical values or expressions of the animation parameter. The first 3 components of this list define the “writing direction”, the last 3 components the “up direction”.

The length of these two vectors is irrelevant, only their directions matter. The lengths should not be zero, though.

Further, the “up direction” should be orthogonal to the “writing direction”. If this is not the case, the “up direction” is automatically replaced by the vector orthogonal to the “writing direction” that lies in the plane given by the original directions.

“Writing direction” and “up direction” should not be parallel.

# TextOrientation

---

---

**Note** TextOrientation only has an effect in conjunction with the attribute Billboarding = FALSE.

---

TextOrientation can be animated.

The effect of TextOrientation is independent of the HorizontalAlignment and VerticalAlignment of the text relative to its anchor point (Position).

While TextOrientation is used for orienting 3D texts, TextRotation is used for rotating a 2D text of type plot::Text2d.

## Examples

### Example 1

The “writing direction” of the text object text1 is rotated around an axis parallel to the  $z$ -axis. The “up direction” of its characters is the  $z$  direction.

The “writing direction” of the text object text2 is parallel to the  $x$  axis. The animated “up direction” is rotated around an axis pointing into the  $x$  direction:

```
p1 := plot::Point3d([1, 2, 3], PointSize = 3*unit::mm):
text1 := plot::Text3d("Hello world!", [1, 2, 3],
 TextOrientation = [cos(a), sin(a), 0, 0, 0, 1],
 a = 0..2*PI, TextFont = [24],
 Billboarding = FALSE):
p2 := plot::Point3d([3, 6, 9], PointSize = 3*unit::mm):
text2 := plot::Text3d("MuPAD", [3, 6, 9],
 TextOrientation = [1, 0, 0, 0, sin(a), cos(a)],
 a = 0..2*PI, TextFont = [24],
 Billboarding = FALSE):
plot(p1, text1, p2, text2)
```

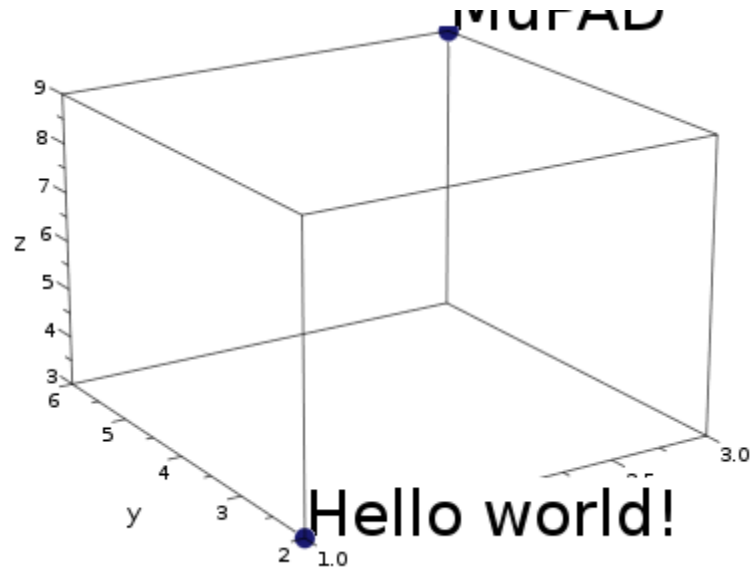

When Billboarding is set to TRUE, TextOrientation does not have any effect:

```
text1::Billboarding := TRUE:
text2::Billboarding := TRUE:
plot(p1, text1, p2, text2)
```

# TextOrientation

---

```
delete p1, text1, p2, text2:
```

## See Also

### MuPAD Functions

TextRotation

**Purpose** Rotation of a 2D text

**Value Summary** Optional Real-valued expression (interpreted in radians)

**Graphics Primitives**

Objects	TextRotation Default Values
plot::Integral, plot::Text2d	0

**Description**

TextRotation sets the rotation angle of a 2D text object relative to the horizontal axis.

TextRotation rotates a text object of type plot::Text2d. around its anchor point (the attribute Position of a plot::Text2d object). Note that a plot::Text2d allows different alignments (HorizontalAlignment, VerticalAlignment) relative to this point.

The rotation angle in TextRotation = angle has to be entered in radians. If positive, the rotation is counterclockwise.

The rotation of the text refers to 'rotation on the screen'. It is invariant w.r.t. rescaling of the canvas, aspect ratio etc.

While TextRotation is used for rotating 2D texts, TextOrientation is used for rotating a 3D text of type plot::Text3d.

TextRotation can be animated.

**Examples**

**Example 1**

We draw a rectangle and a rotating text inside:

```
r := plot::Rectangle(0..4, 0..4):
p := plot::Point2d([2, 2], PointSize = 3*unit::mm):
text := plot::Text2d("Hello world!", [2, 2],
 HorizontalAlignment = Center,
 TextRotation = a, a = 0..2*PI,
```

# TextRotation

---

```
plot(r, p, text):
 TextFont = [24]):
```

We change the alignment of the text w.r.t. its anchor point [2, 2]:

```
text:: HorizontalAlignment := Left:
text:: VerticalAlignment := Top:
plot(r, p, text):
```

```
text:: HorizontalAlignment := Center:
text:: VerticalAlignment := Center:
plot(r, p, text):
```

# TextRotation

---

```
delete r, p, text:
```

# **UName, URange, UMin, UMax, VName, VRange, VMin, VMax, XName, XRange, XMin, XMax, YName, YRange, YMin, YMax, ZName, ZRange, ZMin, ZMax**

## **Description**

UName, VName, XName, YName, ZName specify the names of parameters defining parametrized objects such as functions, curves and surfaces.

UMin, UMax, VMin, VMax, XMin, XMax, YMin, YMax, ZMin, ZMax specify the minimal and maximal values of the range of the parameters.

URange, VRange, XRange, YRange, ZRange serve as shortcuts for setting UMin, UMax etc.

In most cases, the user has no need for using these attributes explicitly, because parameter ranges are set implicitly during creation of plot objects. For example, the definition

```
f := plot::Function2d(sin(x), x = 0 .. 2*PI)
```

sets the attribute values XName = x, XMin = 0, XMax = 2\*PI automatically for the function object f. In fact, you can define f by the equivalent call

```
f := plot::Function2d(sin(x), XName = x, XMin = 0, XMax = 2*PI).
```

In the interactive object browser of the MuPAD graphics tool (see section Viewer, Browser, and Inspector: Interactive Manipulation of this document), you will not see a specification such as  $x = 0 \dots 2\pi$ , but you find separate entries for XName, XMin, XMax.

The use of 'X', 'Y', 'Z' as opposed to 'U', 'V' depends on the type of the object.

Functions of type plot::Function2d refer to the independent variable ("the parameter") as XName.

Functions of type plot::Function3d refer to the two independent variables as XName, YName.

Parametrized curve of type plot::Curve2d or plot::Curve3d refer to the curve parameter as UName.

Parametrized surfaces of type plot::Surface, plot::XRotate etc. refer to the two surface parameters as UName, VName.

# UName, URange, UMin, UMax, VName, VRange, VMin, VMax, XName, XRange, XMin, XMax, YName, YRange, YMin, YMax, ZName, ZRange, ZMin, ZMax

---

Various other plot objects of type `plot::Implicit2d`, `plot::VectorField2d` etc. also use the attributes `XName` etc. Here, the ranges from `XMin` to `XMax` etc. denote the coordinate range in which the objects are placed.

After a definition such as `f := plot::Function2d(sin(x), x = 0 .. 2*PI)`, the parameter and its range can be accessed as the slots `f::XName`, `f::XMin`, `f::XMax`.

The slot `f::XRange` yields the range `0 .. 2*PI` consisting of the values of `XMin` and `XMax`. Setting the attribute `XRange` is a short cut for setting `XMin` and `XMax` simultaneously. For example, setting `f::XRange := -PI .. PI` is equivalent to setting `f::XMin := -PI` and `f::XMax := PI`.

Of course, the analogous statements hold for `YRange`, `ZRange`, `URange`, `VRange`, too.

## Examples

### Example 1

We define a function object:

```
f1 := plot::Function2d(sin(x), x = 0.. 2*PI)
```

```
plot@"Function2d(sin(x),x = 0..2 p)
```

This is equivalent to:

```
f2 := plot::Function2d(sin(x), XName = x, XMin = 0, XMax = 2*PI)
```

```
plot@"Function2d(sin(x),x = 0..2 p)
```

The objects `f1` and `f2` have the same entries for the parameter `x`:

```
f1::XName = f1::XMin .. f1::XMax, f2::XName = f2::XRange
```

# UName, URange, UMin, UMax, VName, VRange, VMin, VMax, XName, XRange, XMin, XMax, YName, YRange, YMin, YMax, ZName, ZRange, ZMin, ZMax

---

```
x = 0..2 p, x = 0..2 p
```

Changing the  $x$  range via XRange is equivalent to changing XMin and XMax separately:

```
f1::XRange := -PI..PI:
f2::XMin := -PI:
f2::XMax := PI:
f1, f2
```

```
plot@"Function2d(sin(x),x = p..p),plot@"Function2d(sin(x),x = p..p)
```

```
delete f1, f2:
```

# ViewingBox, ViewingBoxXMin, ViewingBoxXMax, ViewingBoxXRange, ViewingBoxYMin, ViewingBoxYMax, ViewingBoxYRange, ViewingBoxZMin, ViewingBoxZMax, ViewingBoxZRange

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	ViewingBox: [Automatic .. Automatic, Automatic .. Automatic]  ViewingBoxXMin, ViewingBoxXMax, ViewingBoxYMin, ViewingBoxYMax: Automatic  ViewingBoxXRange, ViewingBoxYRange: Automatic .. Automatic
plot::CoordinateSystem3d	ViewingBox: [Automatic .. Automatic, Automatic .. Automatic]  ViewingBoxXMin, ViewingBoxXMax, ViewingBoxYMin, ViewingBoxYMax, ViewingBoxZMin, ViewingBoxZMax: Automatic  ViewingBoxXRange, ViewingBoxYRange, ViewingBoxZRange: Automatic .. Automatic

## Description

The ViewingBox attributes set the coordinate range that is visible in a plot.

ViewingBoxXMin =  $x_{\min}$ , ViewingBoxXMax =  $x_{\max}$ , equivalent to ViewingBoxXRange =  $x_{\min} .. x_{\max}$ , restricts the visibility to  $x$  values between  $x_{\min}$  and  $x_{\max}$ . ViewingBoxYMin etc. work analogously.

# ViewingBox, ViewingBoxXMin, ViewingBoxXMax, ViewingBoxXRange, ViewingBoxYMin, ViewingBoxYMax, ViewingBoxYRange, ViewingBoxZMin, ViewingBoxZMax, ViewingBoxZRange

Setting ViewingBox = [x<sub>min</sub> .. x<sub>max</sub>, y<sub>min</sub> .. y<sub>max</sub>] in 2D and  
ViewingBox = [x<sub>min</sub> .. x<sub>max</sub>, y<sub>min</sub> .. y<sub>max</sub>, z<sub>min</sub> .. z<sub>max</sub>] in 3D

---

respectively, serves as a short cut for setting the single entries ViewingBoxXMin etc.

The ViewingBox of a plot is computed automatically by default. It is chosen as the smallest box containing all graphical objects in the coordinate system.

The values x<sub>min</sub> etc. of the ViewingBox attributes must be real numerical expressions or the special flag Automatic. With Automatic, the system chooses appropriate values automatically.

When plotting a function or a curve with singularities, a heuristics is used to set a “reasonable” restricted viewing box for the plot. This heuristics sometimes fails to produce a pleasing picture. We recommended to request an explicit ViewingBox in such a case.

When using plot::Rotate2d or plot::Rotate3d, the ViewingBox may be larger than necessary. Its size is computed by rotating the common viewing box of all objects in the rotation object. See “Example 4” on page 23-1612.

The ViewingBox of an animation is automatically chosen as the union of all viewing boxes of the frames of the animation.

The ViewingBox itself cannot be animated. However, the object plot::ClippingBox may be used to implement animated visibility regions.

## Examples

### Example 1

In the following plot, the horizontal axis is placed at the minimal y-value produced by the function:

```
f := plot::Function2d(exp(-x^2), x = -1.7 .. 1.7):
plot(f)
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,**

inge

We wish to make the  $x$ -axis appear at  $y = 0$ . To this end, we request the  $y$  range to start with  $y = 0$  and use `Automatic` to let MuPAD find the maximal  $y$ -value automatically:

```
plot(f, ViewingBoxYRange = 0..Automatic)
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,  
ViewingBoxZR**

The previous command is equivalent to:

```
plot(f, ViewingBoxYMin = 0)
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,**

inge

```
delete f:
```

### **Example 2**

Here is a 3D plot of a singular function:

```
f := plot::Function3d((sin(x) + cos(y))/(x^2 + y^2),
 x = -PI..PI, y = -PI..PI):
plot(f)
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,  
ViewingBoxZR**

We specify the upper z value of the visible volume:

```
plot(f, ViewingBoxZRange = Automatic..3)
```

# ViewingBox, ViewingBoxXMin, ViewingBoxXMax, ViewingBoxXRange, ViewingBoxYMin, ViewingBoxYMax, ViewingBoxYRange, ViewingBoxZMin, ViewingBoxZMax, inge

```
delete f:
```

### Example 3

Usually, a plot uses the whole drawing area:

```
f := plot::Function2d(ln(x), x = 0..2):
plot(f)
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,  
ViewingBoxZR**

We extend the viewing box in  $x$  direction to make it symmetric w.r.t.  $x$ :

```
plot(f, ViewingBoxXRange = -2..2)
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,**

We specify the viewing box both in  $x$  and  $y$  direction:

```
plot(f, ViewingBox = [-2..2, -2..2])
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,  
ViewingBoxZR**

```
delete f:
```

#### **Example 4**

The following viewing box is larger than expected:

```
c := plot::Ellipse2d(1, 0.5, [0, 0]):
r := plot::Rotate2d(c, PI/3):
plot(r)
```

# ViewingBox, ViewingBoxXMin, ViewingBoxXMax, ViewingBoxXRange, ViewingBoxYMin, ViewingBoxYMax, ViewingBoxYRange, ViewingBoxZMin, ViewingBoxZMax,

inge

The reason is how the viewing box of the rotation is computed. The blue rectangle is the viewing box of the ellipse. The rotated viewing box is the black rectangle. The viewing box of the rotation is the smallest rectangle containing the rotated viewing box of the ellipse (the dashed black rectangle):

```
rect1 := plot::Rectangle(-1..1, -0.5..0.5, Color = RGB::Black):
rect2 := plot::modify(rect1, Color = RGB::Blue):
r := plot::Rotate2d(c, rect1, a, a = 0..PI/2):
X := cos(a) + 0.5*sin(a):
Y := 0.5*cos(a) + sin(a):
rect3 := plot::Rectangle(-X..X, -Y..Y, a = 0..PI/2,
 Color = RGB::Black,
 LineStyle = Dashed):

plot(r, rect2, rect3)
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,  
ViewingBoxZR**

```
delete c, r, rect1, rect2, rect3, X, Y:
```

### **Example 5**

The  $x$ -range from  $-\pi$  to  $\pi$  is generated by *all* frames of the following animation and does not change from frame to frame:

```
plot(plot::Function2d(sin(x), x = -PI + a .. a, a = 0 .. PI)):
```

**ViewingBox, ViewingBoxXMin, ViewingBoxXMax,  
ViewingBoxXRange, ViewingBoxYMin,  
ViewingBoxYMax, ViewingBoxYRange,  
ViewingBoxZMin, ViewingBoxZMax,**

### MuPAD Functions

[VisibleAfter](#) | [VisibleAfterEnd](#) | [VisibleBefore](#) |  
[VisibleBeforeBegin](#)

# XFunction1, YFunction1, ZFunction1, XFunction2, YFunction2, ZFunction2

**Purpose** Parametrization of the curves in sweep surfaces

**Value Summary**

XFunction1, XFunction2, YFunction1, YFunction2, ZFunction1, ZFunction2	Mandatory	Arithmetical expression or function
---------------------------------------------------------------------------------------	-----------	----------------------------------------

## Graphics Primitives

Objects	Default Values
plot::Sweep	

## Description

XFunction1 etc. are the parametrization functions of the curves delimiting a surface of type plot::Sweep.

In most cases, the user passes parametrizations  $[x_1(u), y_1(u), z_1(u)]$  and  $[x_2(u), y_2(u), z_2(u)]$  as expressions of a curve parameter  $u$  directly to plot::Sweep. Internally, these expressions are stored as the attributes XFunction1 =  $x_1(u)$ , ..., ZFunction2 =  $z_2(u)$  in the sweep object. They can be accessed and changed via the corresponding slots "XFunction1" etc. of the sweep object.

The attributes XFunction1 etc. can also be defined by procedures instead of symbolic expressions.

## Examples

### Example 1

Typically, the user sets the parametrization of the bounding curves directly by passing lists of corresponding expressions to plot::Sweep. Here, XFunction1 =  $u$ , YFunction1 =  $1 - u^2$ , ZFunction1 =  $u^3$ , XFunction2 =  $u$ , YFunction2 =  $1 - u^2$ , ZFunction2 =  $0$ :

```
s := plot::Sweep([u, 1 - u^2, u^3], [u, 1 - u^2, 0], u = 0..1)
```

# XFunction1, YFunction1, ZFunction1, XFunction2, YFunction2, ZFunction2

---

```
plot::Sweep([u, 1 - u2, u3], [u, 1 - u2, 0], u = 0..1)
```

```
plot(s):
```

```
s::XFunction1, s::YFunction1, s::ZFunction1
```

```
u, 1 - u2, u3
```

```
s::XFunction2, s::YFunction2, s::ZFunction2
```

```
u, 1 - u2, 0
```

We change the z-component of the “target curve”:

# XFunction1, YFunction1, ZFunction1, XFunction2, YFunction2, ZFunction2

```
s::ZFunction2 := s::ZFunction1 / 2:
s
```

```
plot::Sweep([u, 1 - u2, u3], [u, 1 - u2, $\frac{u^3}{2}$], u = 0..1)
```

```
plot(s)
```

Instead of expressions, the attributes XFunction1 etc. can be defined by procedures:

```
s::ZFunction2 := u -> u:
s
```

```
plot::Sweep([u, 1 - u2, u3], [u, 1 - u2, u → u], u = 0..1)
```

# XFunction1, YFunction1, ZFunction1, XFunction2, YFunction2, ZFunction2

---

`plot(s)`

`delete s:`

**Purpose** Type of the coordinate axes

**Value Summary** Inherited Automatic, Boxed, Frame, None, or Origin

**Graphics Primitives**

Objects	Axes Default Values
plot::CoordinateSystem2d	Automatic
plot::CoordinateSystem3d	Boxed

**Description**

Axes determines the type of the coordinate axes.

The following types of coordinate axes are available:

- **Automatic:** The axes are displayed as a coordinate cross. The cross point is not taken from the attribute `AxesOrigin`, but is chosen automatically.
- **Origin:** The axes are displayed as a coordinate cross. The cross point is set by the attribute `AxesOrigin`. If `AxesOrigin` is not set, the origin of the coordinate system is used as the default cross point. If the `AxesOrigin` is not inside the “viewing box” of the scene, parts of the axes may not be visible (cf. “Example 4” on page 23-1629).
- **Boxed:** The axes are displayed as a box around the graphical scene. It corresponds to the “viewing box” of the scene and may be set explicitly by the attribute `ViewingBox`.
- **Frame:** As with `Axes = Boxed`, the edges of the “viewing box” are used. However, only the labeled edges are displayed.
- **None:** No coordinate axes are displayed.

As an alternative to `Axes = None`, you may also “switch the axes off” by setting `AxesVisible = FALSE` in the plot command or via

# Axes

---

the interactive object inspector (see Viewer, Browser, and Inspector: Interactive Manipulation in this document).

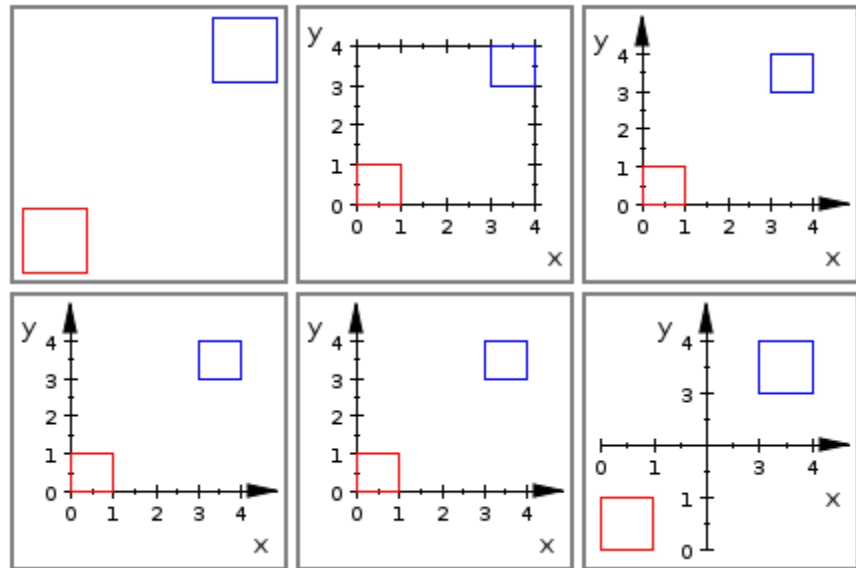

Single coordinate axes can also be “switched off” separately via `XAxisVisible = FALSE` etc.

## Examples

### Example 1

We demonstrate the axes styles in 2D:

```
b1 := plot::Rectangle(0..1, 0..1, Color = RGB::Red):
b2 := plot::Rectangle(3..4, 3..4, Color = RGB::Blue):
plot(plot::Scene2d(b1, b2, Axes = None),
 plot::Scene2d(b1, b2, Axes = Boxed),
 plot::Scene2d(b1, b2, Axes = Frame),
 plot::Scene2d(b1, b2, Axes = Automatic),
 plot::Scene2d(b1, b2, Axes = Origin),
 plot::Scene2d(b1, b2, Axes = Origin,
 AxesOrigin = [2, 2]),
 plot::Scene2d::BorderWidth = 0.5*unit::mm,
 Rows = 2):
```

delete b1, b2:

## Example 2

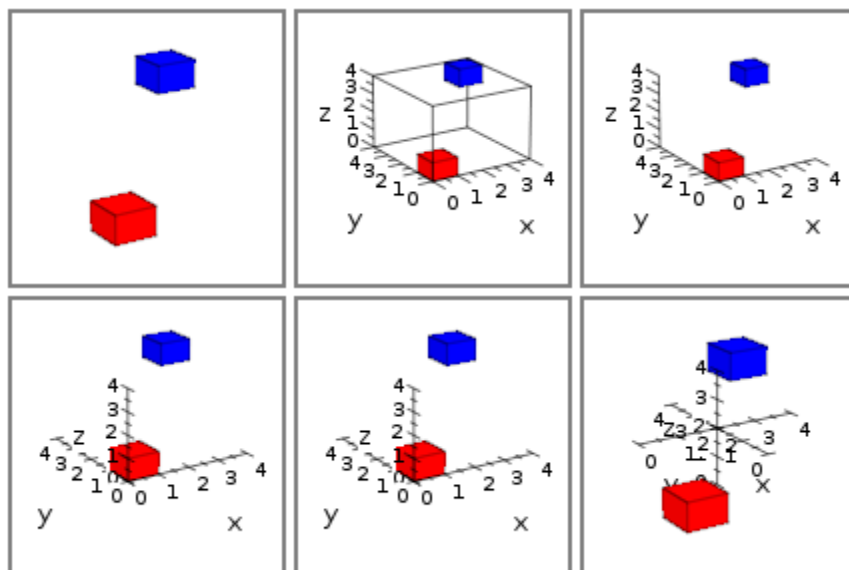

We demonstrate the axes styles in 3D:

```

b1 := plot::Box(0..1, 0..1, 0..1, Color = RGB::Red):
b2 := plot::Box(3..4, 3..4, 3..4, Color = RGB::Blue):
plot(plot::Scene3d(b1, b2, Axes = None),
 plot::Scene3d(b1, b2, Axes = Boxed),
 plot::Scene3d(b1, b2, Axes = Frame),
 plot::Scene3d(b1, b2, Axes = Automatic),
 plot::Scene3d(b1, b2, Axes = Origin),
 plot::Scene3d(b1, b2, Axes = Origin,
 AxesOrigin = [2, 2, 2]),
 plot::Scene3d::BorderWidth = 0.5*unit::mm,
 Rows = 2):

```

# Axes

delete b1, b2:

### Example 3

Here is a hyperboloid with various axes:

```
f1 := plot::Function3d(sqrt(0.2 + x^2 + y^2),
 x = -1..2, y = -1..2):
f2 := plot::Function3d(-sqrt(0.2 + x^2 + y^2),
 x = -1..2, y = -1..2):
plot(f1, f2):
```

```
plot(f1, f2, Axes = Origin,
 AxesOrigin = [-1, -1, 0]):
```

# Axes

---

```
plot(f1, f2, Axes = Frame):
```

```
delete f1, f2:
```

#### Example 4

We draw a portion of the normal distribution density:

```
F := plot::Function2d(stats::normalPDF(0, 1)(x),
 x = -2.5 .. 2.5):
plot(F)
```

# Axes

---

Note that with the default setting `Axes = Automatic`, the  $x$ -axis does not pass through the origin but is shifted along the  $y$ -axis to fit into the viewing box of the scene.

With `Axes = Origin`, the  $x$ -axis passes through the origin, but is outside the viewing box:

```
plot(F, Axes = Origin)
```

We extend the viewing box in the  $y$  direction:

```
plot(F, Axes = Origin, ViewingBoxYRange = 0 .. Automatic):
```

# Axes

---

delete F:

[AxesInFront](#) | [AxesLineColor](#) | [AxesLineWidth](#) | [AxesOrigin](#) | [AxesTips](#) | [AxesTitleAlignment](#) | [AxesTitleFont](#) | [AxesTitles](#) | [AxesVisible](#) | [YAxisTitleOrientation](#)

**Purpose** Coordinate axes in front of or behind graphical objects?

**Value Summary** Inherited FALSE, or TRUE

**Graphics Primitives**

Objects	AxesInFront Default Values
plot::CoordinateSystem2d	FALSE

**Description**

AxesInFront = TRUE versus AxesInFront = FALSE places 2D axes in front of or behind the graphical objects in the scene.

By default, the coordinate axes are plotted behind the graphical objects in a scene. Consequently, the objects may cover the axes. If only line objects and points are present in a 2D scene, this is desirable in most cases.

However, if there are filled areas such as filled polygons in the scene, the view to the axes, tick marks, and tick labels may be totally blocked. In such a situation, you may want to draw the axes in front of the objects to guarantee visibility of the axes.

Although the default setting is AxesInFront = FALSE, some objects which create filled areas send AxesInFront = TRUE as a “hint” (see the section Primitives Requesting Special Scene Attributes: “Hints” of this documentation).

This attribute is available only in 2D.

**Examples**

**Example 1**

It is usually desirable to let line objects and points cover the axes:

```
p1 := plot::Point2d(0, 0.62, PointSize = 3*unit::mm,
 Color = RGB::Green):
p2 := plot::Point2d(0, 0.93, PointSize = 3*unit::mm,
 Color = RGB::Green):
```

# AxesInFront

```
f1 := plot::Function2d(x^5*heaviside(x), x = -1 .. 1,
 Color = RGB::Blue):
f2 := plot::Function2d(x^2, x = -1 .. 1, Color = RGB::Red):
plot(plot::Scene2d(p1, p2, f1, f2, AxesInFront = FALSE),
 plot::Scene2d(p1, p2, f1, f2, AxesInFront = TRUE)):
```

However, you probably want to have the axes visible in front of the following density plot:

```
d := plot::Density(exp(-x^2 - y^2), x = -1..1, y = -1 .. 1,
 FillColor = RGB::White):
plot(plot::Scene2d(d, AxesInFront = FALSE),
 plot::Scene2d(d, AxesInFront = TRUE),
 Layout = Horizontal):
```

Note that density objects of type `plot::Density` automatically send the “hint” `AxesInFront = TRUE`, so there is no need to set this attribute explicitly:

```
plot(d):
```

# AxesInFront

---

`delete p1, p2, f1, f2, d:`

### MuPAD Functions

[Axes](#) | [AxesLineColor](#) | [AxesLineWidth](#) | [AxesOrigin](#) |  
[AxesTips](#) | [AxesTitleAlignment](#) | [AxesTitleFont](#) | [AxesTitles](#)  
| [AxesVisible](#) | [YAxisTitleOrientation](#)

**Purpose** Color of the coordinate axes

**Value Summary** Inherited Color

**Graphics Primitives**

Objects	AxesLineColor Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	RGB::Black

**Description** AxesLineColor sets the RGB color for the coordinate axes and the tick marks.

The color of the axes titles and the tick labels are *not* set by AxesLineColor. Choose an appropriate color for the corresponding fonts via the attributes AxesTitleFont and TicksLabelFont.

**Examples** **Example 1**

The black axes are not appropriate for the following density graphics:

```
d := plot::Density(exp(-x^2 - y^2), x = -1..1, y = -1 ..1,
 FillColor = RGB::Black):
plot(d)
```

# AxesLineColor

---

We change the axes color to 'white' via `AxesLineColor`. The titles and the tick labels along the axes do not turn white, automatically, so we choose white font colors as well:

```
plot(d,
 AxesLineColor = RGB::White,
 AxesTitleFont = [RGB::White],
 TicksLabelFont = [RGB::White],
 plot::Scene2d::BackgroundColor = RGB::Black)
```

`delete d:`

## Example 2

We display the axes as a blue box:

```
plot(plot::Sphere(1, [0, 0, 0]), AxesLineColor = RGB::Blue):
```

# AxisLineColor

---

| [AxesTitleAlignment](#) | [AxesTitleFont](#) | [AxesTitles](#) |  
[AxesVisible](#) | [YAxisTitleOrientation](#)

**Purpose** Width of the coordinate axes

**Value Summary** Inherited Positive output size

## Graphics Primitives

Objects	AxesLineWidth Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	0.18

## Description

AxesLineWidth sets the width for the coordinate axes, the ticks, and the AxesTips. The value should be specified as an absolute physical length including a length unit such as AxesLineWidth = 0.5\*unit::mm. Numbers without a physical unit give the size in mm.

The length of the ticks is not affected by AxesLineWidth and can be set separately via TicksLength.

Note that the graphics cannot always react to small changes of the line width because of the discretization into pixels.

## Examples

### Example 1

We create a graticule with “thick” wiring. Note that LineWidth refers to the circles, whereas AxesLineWidth relates to the coordinate axes:

```
plot(plot::Circle2d(1, [0, 0]),
 TicksDistance = 0.2, TicksLength = 5*unit::mm,
 LineWidth = 0.5*unit::mm, AxesLineWidth = 1*unit::mm):
```

# AxesLineWidth

---

[AxesVisible](#) | [TicksLength](#) | [YAxisTitleOrientation](#)

# AxesOrigin, AxesOriginX, AxesOriginY, AxesOriginZ

**Purpose** Crosspoint of the coordinate axes

**Value Summary**

AxesOrigin	Library wrapper for “[AxesOriginX, AxesOriginY]” (2D), “[AxesOriginX, AxesOriginY, AxesOriginZ]” (3D)	See below
AxesOriginX, AxesOriginY, AxesOriginZ	Optional	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	AxesOrigin: [0, 0] AxesOriginX, AxesOriginY: 0
plot::CoordinateSystem3d	AxesOrigin: [0, 0, 0] AxesOriginX, AxesOriginY, AxesOriginZ: 0

## Description

AxesOrigin determines the crosspoint of the coordinate axes.

These attributes only have an effect with Axes = Origin. The coordinate axes are displayed as a cross.

The vector AxesOrigin determines the point where the coordinate axes cross. Depending on the dimension of the scene, it is given by a list of 2 or 3 components.

AxesOriginX etc. refer to the  $x$ ,  $y$ ,  $z$  components of this point.

# AxesOrigin, AxesOriginX, AxesOriginY, AxesOriginZ

---

---

**Note** If the crosspoint of the axes is not inside the “viewing box” of the scene, parts of the axes may not be visible.

---

The viewing box may be set explicitly via the attribute `ViewingBox`. With `Axes = Automatic`, the point given by `AxesOrigin` is ignored; the crosspoint of the axes is chosen automatically inside the viewing box.

## Examples

### Example 1

We plot two spheres representing a planet with a moon. The coordinate axes cross at their common center of gravity:

```
m1 := 1: x1 := 0:
x2 := 1: m2 := 0.2:
earth := plot::Sphere(0.1, [x1, 0, 0],
 FillColor = RGB::SkyBlue):
moon := plot::Sphere(0.03, [x2, 0, 0],
 FillColor = RGB::Grey):
plot(earth, moon, Axes = Origin,
 YTicksNumber = None, ZTicksNumber = None,
 AxesOrigin = [(m1*x1 + m2*x2)/(m1 + m2), 0, 0],
 ViewingBox = [-0.2 .. 1.1, -0.2..0.2, -0.2..0.2]):
```

# AxesOrigin, AxesOriginX, AxesOriginY, AxesOriginZ

---

```
delete m1, m2, x1, x2, earth, moon:
```

| [AxesVisible](#) | [YAxisTitleOrientation](#)

# AxesTips

---

**Purpose** Arrow tips at the coordinate axes?

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	AxesTips Default Values
plot::CoordinateSystem2d	TRUE
plot::CoordinateSystem3d	FALSE

**Description** With `AxesTips = TRUE`, the coordinate axes are drawn with arrow tips. This attribute only has an effect with `Axes = Automatic` or `Axes = Origin`. In both cases the coordinate axes are displayed as a cross. With `AxesTips = TRUE`, little arrows are drawn on the end of the coordinate axes pointing into the positive direction. The size of the arrow tips that are displayed as lines is controlled by `AxesLineWidth`. `AxesTips = FALSE` suppresses any coordinate axes tips.

## Examples

### Example 1

In order to emphasize on `AxesTips`, we plot empty scenes. The tick marks are “switched off” via `TicksNumber = None`:

```
S1 := plot::Scene2d(AxesTips = FALSE):
S2 := plot::Scene2d(AxesTips = TRUE):
plot(S1, S2, TicksNumber = None, Layout = Horizontal):
```

```
S1 := plot::Scene3d(AxesTips = FALSE):
S2 := plot::Scene3d(AxesTips = TRUE):
plot(S1, S2, Axes = Origin, TicksNumber = None,
 Layout = Horizontal):
```

# AxesTips

---

# AxesTitleAlignment, XAxisTitleAlignment, YAxisTitleAlignment, ZAxisTitleAlignment

## Purpose

Alignment of axes titles

## Value Summary

AxesTitleAlignment Library wrapper for See below  
“{XAxisTitleAlignment,  
YAxisTitleAlignment}”  
(2D),  
“{XAxisTitleAlignment,  
YAxisTitleAlignment,  
ZAxisTitleAlignment}”  
(3D)

XAxisTitleAlignment, Inherited Begin, Center, or End  
YAxisTitleAlignment,  
ZAxisTitleAlignment

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	AxesTitleAlignment, XAxisTitleAlignment, YAxisTitleAlignment: End
plot::CoordinateSystem3d	AxesTitleAlignment, XAxisTitleAlignment, YAxisTitleAlignment, ZAxisTitleAlignment: Center

## Description

AxesTitleAlignment governs the alignment of axes titles along the coordinate axes.

With AxesTitleAlignment = End, titles for all coordinate axes are displayed at that end of the axes with higher coordinate values.

With AxesTitleAlignment = Begin, titles are displayed at that end of the axes with lower coordinate values.

With AxesTitleAlignment = Center, titles are centered along the axes.

# AxisTitleAlignment, XAxisTitleAlignment, YAxisTitleAlignment, ZAxisTitleAlignment

---

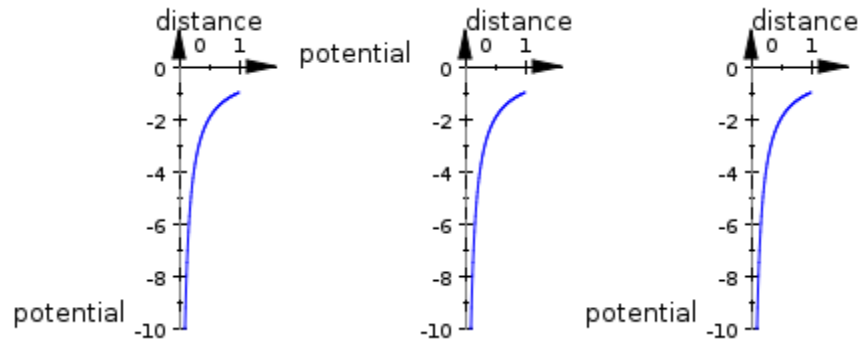

XAxisTitleAlignment etc. allow to set the title alignments separately for each single axis.

## Examples

### Example 1

We plot the Coulomb potential of a charged particle:

```
F := plot::Function2d(-1/r, r = 0..1,
 ViewingBoxYRange = -10..0):
S1 := plot::Scene2d(F, AxesTitles = ["distance", "potential"],
 XAxisTitleAlignment = Center,
 YAxisTitleAlignment = Begin):
S2 := plot::Scene2d(F, AxesTitles = ["distance", "potential"],
 XAxisTitleAlignment = Begin,
 YAxisTitleAlignment = End):
S3 := plot::Scene2d(F, AxesTitles = ["distance", "potential"],
 XAxisTitleAlignment = Begin,
 YAxisTitleAlignment = Begin):
plot(S1, S2, S3, Layout = Horizontal,
 Width = 120*unit::mm, Height = 50*unit::mm):
```

```
delete F, S1, S2, S3:
```

# AxisTitleAlignment, XAxisTitleAlignment, YAxisTitleAlignment, ZAxisTitleAlignment

---

## Example 2

We use the 3D analogue of the previous example to demonstrate the alignment of axes titles in 3D:

```
F := plot::Function3d(-1/sqrt(x^2 + y^2), x = -1..1, y = -1..1,
 ViewingBoxZRange = -10 .. 0):
S1 := plot::Scene3d(F, AxesTitles = ["x", "y", "potential"],
 XAxisTitleAlignment = Begin,
 YAxisTitleAlignment = Center,
 ZAxisTitleAlignment = End):
S2 := plot::Scene3d(F, AxesTitles = ["x", "y", "potential"],
 XAxisTitleAlignment = Center,
 YAxisTitleAlignment = End,
 ZAxisTitleAlignment = Begin):
plot(S1, S2, Layout = Vertical,
 Width = 80*unit::mm, Height = 120*unit::mm):
```

# AxisTitleAlignment, XAxisTitleAlignment, YAxisTitleAlignment, ZAxisTitleAlignment

---

delete F, S1, S2:

AxesOrigin | AxesTips | AxesTitleFont | AxesTitles |  
AxesVisible | YAxisTitleOrientation

# AxesTitles, XAxisTitle, YAxisTitle, ZAxisTitle

## Purpose

Titles for the coordinate axes

## Value Summary

AxesTitles	Library wrapper for “[XAxisTitle, YAxisTitle]” (2D), “[XAxisTitle, YAxisTitle, ZAxisTitle]” (3D)	See below
XAxisTitle, YAxisTitle, ZAxisTitle	Optional	Text string

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	AxesTitles: [ " x ", " y " ] XAxisTitle: " x " YAxisTitle: " y "
plot::CoordinateSystem3d	AxesTitles: [ " x ", " y ", " z " ] XAxisTitle: " x " YAxisTitle: " y " ZAxisTitle: " z "

## Description

AxesTitles sets the titles attached to the coordinate axes.

Depending on the dimension of the coordinate system, the value of the attribute AxisTitles must be a list with two or three strings.

Per default, the coordinate axes titles are [ "x", "y" ] in 2D and [ "x", "y", "z" ] in 3D regardless of the names of involved parameters. Cf. “Example 1” on page 23-1654.

# AxesTitles, XAxisTitle, YAxisTitle, ZAxisTitle

---

Using `AxesTitles`, axes titles can be edited as desired.

With `XAxisTitle` etc., the titles can be edited separately for the different coordinate directions.

Set empty strings `AxesTitles = [ "", "" ]` in 2D or `AxesTitles = [ "", "", "" ]` in 3D, respectively, if no axes titles shall be displayed.

Some objects in the MuPAD `plot` library override the default setting via the “hint mechanism” (see the section `Primitives Requesting Special Scene Attributes: “Hints”` in this document). Whenever such an object is plotted in a scene, the axes titles chosen by the object are used. A complete list of these objects is given further up on this help page.

You can still override these titles via `AxesTitles` etc.

The attribute `AxisTitleAlignment` can be used to change the default alignment of the titles along the axes.

The attribute `YAxisTitleOrientation` can be used in 2D to rotate the title of the vertical axis.

## Examples

### Example 1

We set appropriate axes titles for a damped vibration given by a plot of the “amplitude over time”:

```
F := plot::Function2d(exp(-t)*cos(PI*t), t = 0 .. 4):
plot(F, AxesTitles = ["time", "amplitude"]):
```

# AxesTitles, XAxisTitle, YAxisTitle, ZAxisTitle

---

It might be desirable to use the attribute `YAxisTitleOrientation` to twist the title for the vertical axis:

```
plot(F, AxesTitles = ["time", "amplitude"],
 YAxisTitleOrientation = Vertical):
```

# AxesTitles, XAxisTitle, YAxisTitle, ZAxisTitle

---

## See Also

### MuPAD Functions

[Axes](#) | [AxesInFront](#) | [AxesLineColor](#) | [AxesLineWidth](#) |  
[AxesOrigin](#) | [AxesTips](#) | [AxesTitleAlignment](#) | [AxesTitleFont](#)  
| [AxesVisible](#) | [YAxisTitleOrientation](#)

# AxesVisible, XAxisVisible, YAxisVisible, ZAxisVisible

**Purpose** Display coordinate axes?

**Value Summary**

AxesVisible	Library wrapper for “{XAxisVisible, YAxisVisible}” (2D), “{XAxisVisible, YAxisVisible, ZAxisVisible}” (3D)	TRUE, FALSE, or list of 2 or 3 of these, depending on the dimension
XAxisVisible, YAxisVisible, ZAxisVisible	Inherited	FALSE, or TRUE

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	AxesVisible, XAxisVisible, YAxisVisible: TRUE
plot::CoordinateSystem3d	AxesVisible, XAxisVisible, YAxisVisible, ZAxisVisible: TRUE

## Description

With `AxesVisible = TRUE` versus `AxesVisible = FALSE` all coordinate axes are “switched on” or “off”.

With `XAxisVisible` etc., the coordinate axes in the different coordinate directions can be switched on and off, separately.

With `Axes = Box`, the coordinate axes are displayed as a box about the scene. With `XAxisVisible = FALSE` etc., the four edges of this box parallel to the respective axis are suppressed.

Alternatively to `AxesVisible = FALSE`, you may switch the axes off by setting `Axes = None`, too.

# AxesVisible, XAxisVisible, YAxisVisible, ZAxisVisible

---

## Examples

### Example 1

In the following illustration, you probably do not want any axes:

```
plot(
 plot::Arrow2d([1.5, 1], [2.5, 3],
 Title = "a", TitlePosition = [2.05, 1.9],
 LineStyle = Dashed, Color = RGB::Red),
 plot::Arrow2d([1, 2], [2.5, 3],
 Title = "b", TitlePosition = [1.6, 2.5],
 LineStyle = Dashed, Color = RGB::Blue),
 plot::Arrow2d([0, 0], [1, 2], Color = RGB::Red,
 Title = "a", TitlePosition = [0.4, 1.0]),
 plot::Arrow2d([0, 0], [1.5, 1], Color = RGB::Blue,
 Title = "b", TitlePosition = [0.8, 0.3]),
 plot::Arrow2d([0, 0], [2.5, 3], Color = RGB::Black,
 Title = "a + b", TitlePosition = [1.35, 1.3]),
 AxesVisible = FALSE, TitleFont = [14],
 TipLength = 5.0*unit::mm, LineWidth = 1.0*unit::mm,
 HeaderFont = [20], Header = "how to add two vectors"
)
```

how to add two vectors

## Example 2

Using the default axes style `Axes = Box` in 3D, we suppress all parts of the axes box in the  $x$  direction:

```
plot(plot::Sphere(1, [0, 0, 0]), XAxisVisible = FALSE):
```

# AxesVisible, XAxisVisible, YAxisVisible, ZAxisVisible

---

## See Also

### MuPAD Functions

[Axes](#) | [AxesInFront](#) | [AxesLineColor](#) | [AxesLineWidth](#) |  
[AxesOrigin](#) | [AxesTips](#) | [AxesTitleAlignment](#) | [AxesTitleFont](#)  
| [AxesTitles](#) | [YAxisTitleOrientation](#)

**Purpose** Orientation of the vertical axis title in 2D

**Value Summary** Inherited Horizontal, or Vertical

## Graphics Primitives

Objects	YAxisTitleOrientation Default Values
plot::CoordinateSystem2d	Horizontal

## Description

YAxisTitleOrientation determines whether the title of the vertical axis in 2D is plotted horizontally or vertically.

If the title of the vertical axis in 2D is long, it uses up a lot of horizontal space when rendered from left to right with YAxisTitleOrientation = Horizontal. This space may be taken away from the drawing region for the graphical objects. In such a case it might be desirable to use YAxisTitleOrientation = Vertical to let the title be rendered from bottom to top instead, parallel to the vertical axis.

This attribute is ignored in 3D.

## Examples

### Example 1

We plot the density of the normal distribution function:

```
f := plot::Function2d(stats::normalPDF(0, 1)(x), x = -3 .. 3):
plot(f, Axes = Automatic,
 AxesTitles = ["x", "normal distribution"],
 YAxisTitleOrientation = Horizontal):
```

# YAxisTitleOrientation

---

There is plenty of room to draw the long title "normal distribution", because the vertical axis is placed in the middle of the plot. In the next plot, however, the vertical axis is flushed left and a lot of space is "wasted" for the axis title:

```
plot(f, Axes = Frame,
 AxesTitles = ["x", "normal distribution"],
 YAxisTitleOrientation = Horizontal):
```

You make better use of the drawing area by plotting the title of the vertical axis parallel to this axis:

```
plot(f, Axes = Frame,
 AxesTitles = ["x", "normal distribution"],
 YAxisTitleOrientation = Vertical):
```

# YAxisTitleOrientation

---

`delete f:`

## See Also

### MuPAD Functions

# TicksAnchor, XTicksAnchor, YTicksAnchor, ZTicksAnchor

**Purpose** User defined start of axes tick marks

**Value Summary**

TicksAnchor	Library wrapper for “{XTicksAnchor, YTicksAnchor}” (2D), “{XTicksAnchor, YTicksAnchor, ZTicksAnchor}” (3D)	MuPAD expression
XTicksAnchor, YTicksAnchor, ZTicksAnchor	Optional	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	TicksAnchor, XTicksAnchor, YTicksAnchor: 0
plot::CoordinateSystem3d	TicksAnchor, XTicksAnchor, YTicksAnchor, ZTicksAnchor: 0

## Description

With  $\text{TicksAnchor} = t_0$ ,  $\text{TicksDistance} = d$ , the automatic ticks along the coordinate axes are switched off and replaced by equidistant ticks with distance  $d$  at the positions  $t_j = t_0 + jd, j$ .

With  $\text{TicksAnchor} = t_0$ ,  $\text{TicksDistance} = d$ , these ticks are used for all coordinate axes.

With  $\text{XTicksAnchor} = t_0$ ,  $\text{XTicksDistance} = d$  etc., these ticks may be defined separately for each single coordinate axis.

When executing a plot command, per default a “reasonable” placing for tick marks on coordinate axes is automatically computed. Through this process tick marks may not come to lie on desired positions. The attributes  $\text{TicksAnchor}$  and  $\text{TicksDistance}$  allow to generate an alternative mesh of equidistant tick marks.

# TicksAnchor, XTicksAnchor, YTicksAnchor, ZTicksAnchor

---

---

**Note** The attributes `TicksAnchor`, `XTicksAnchor` etc. only have an effect when a positive distance  $d > 0$  between major ticks marks is set explicitly via `TicksDistance = d`, `XTicksDistance = d` etc.

---

The ticks set by `TicksAnchor` and `TicksDistance` are “major” tick marks bearing labels. Depending on the value of `TicksBetween`, there may be additional “minor” ticks without labels between each pair of major tick marks.

Additional tick marks at specific positions can be inserted with `TicksAt`.

## Examples

### Example 1

For the following plot of the sine function, the tick marks along the  $x$ -axis are chosen to match the period:

```
plot(plot::Function2d(sin(x), x = 0..4*PI),
 XTicksAnchor = 0, XTicksDistance = PI):
```

# TicksAnchor, XTicksAnchor, YTicksAnchor, ZTicksAnchor

---

The ticks along the  $y$ -axis are re-defined with a distance of  $0.2$ :

```
plot(plot::Function2d(sin(x), x = 0..4*PI),
 XTicksAnchor = 0, XTicksDistance = PI,
 YTicksAnchor = 0, YTicksDistance = 0.2):
```

# TicksAnchor, XTicksAnchor, YTicksAnchor, ZTicksAnchor

---

We increase the number of “minor” ticks along the x-axis:

```
plot(plot::Function2d(sin(x), x = 0..4*PI),
 XTicksAnchor = 0, XTicksDistance = PI,
 XTicksBetween = 4,
 YTicksAnchor = 0, YTicksDistance = 0.2):
```

# TicksAnchor, XTicksAnchor, YTicksAnchor, ZTicksAnchor

## Example 2

We plot the two-dimensional normal distribution centered around the mean  $(m_1, m_2) = (3.2, 4.9)$ . This point is used as the anchor for the tick marks along the  $x$ -axis and the  $y$ -axis, respectively. Ticks are positioned at distances that are integer multiples of the standard deviations  $(s_1, s_2) = (0.8, 1.2)$ :

```
m1:= 3.2: s1 := 0.8:
m2:= 4.9: s2 := 1.1:
plot(plot::Function3d(stats::normalPDF(m1, s1^2)(x)
 *stats::normalPDF(m2, s2^2)(y),
 x = 0 .. 10, y = 0 .. 10,
 Submesh = [3, 3]),
 TicksBetween = 0,
 XTicksAnchor = m1, XTicksDistance = s1,
 YTicksAnchor = m2, YTicksDistance = s2,
 XTicksLabelStyle = Vertical,
 YTicksLabelStyle = Diagonal,
```

# TicksAnchor, XTicksAnchor, YTicksAnchor, ZTicksAnchor

---

`GridVisible = TRUE):`

`delete m1, s1, m2, s2:`

[TicksAt](#) | [TicksBetween](#) | [TicksDistance](#) | [TicksLabelFont](#)  
| [TicksLabelStyle](#) | [TicksLabelsVisible](#) | [TicksLength](#) |  
[TicksNumber](#) | [TicksVisible](#)

# TicksAt, XTicksAt, YTicksAt, ZTicksAt

**Purpose** Special axes tick marks

## Value Summary

TicksAt	Library wrapper for “[XTicksAt, YTicksAt]” (2D), “[XTicksAt, YTicksAt, ZTicksAt]” (3D)	See below
XTicksAt, YTicksAt, ZTicksAt	Optional	See below

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	

## Description

`XTicksAt = [x1, x2, ...]` allows to set additional tick marks on the *x*-axis at the positions *x*<sub>1</sub>, *x*<sub>2</sub> etc. With `XTicksAt = [x1 = L1, x2 = L2, ...]`, the special tick marks at the positions *x*<sub>1</sub>, *x*<sub>2</sub> etc. are labeled with the strings *L*<sub>1</sub>, *L*<sub>2</sub> etc.

`YTicksAt`, `ZTicksAt` work analogously for the other coordinate directions.

`TicksAt = [[x1, x2, ...], [y1, y2, ...]]` in 2D and `TicksAt = [[x1, x2, ...], [y1, y2, ...], [z1, z2, ...]]` in 3D serve as shortcuts for setting `XTicksAt`, `YTicksAt` etc.

Per default, equidistant tick marks along the coordinate axes are chosen automatically.

With `XTicksAt = [x1, x2, ...]`, *additional* tick marks are inserted along the *x*-axis at arbitrary positions *x*<sub>1</sub>, *x*<sub>2</sub> etc. These values must be numbers or exact numerical expressions such as `PI` or `sqrt(2)` that can be converted to floating-point numbers via `float`.

# TicksAt, XTicksAt, YTicksAt, ZTicksAt

---

The special ticks set by `XTicksAt` are labeled automatically by floating-point numbers approximating  $x_1$ ,  $x_2$  etc.

Special labels for these ticks may be requested by replacing the coordinate values  $x_1$ ,  $x_2$  etc. by equations  $x_1 = L_1$ ,  $x_2 = L_2$  etc., where  $L_1$ ,  $L_2$  etc. are strings to be used as the labels. Note that MuPAD strings have to be enclosed by the string delimiters ". For example, `XTicksAt = [3.14 = "pi"]` adds a single tick at the position  $x = 3.14$  with the label `pi`. Cf. "Example 1" on page 23-1672.

With `YTicksAt = [y_1, y_2, ...]` or `YTicksAt = [y_1 = L_1, y_2 = L_2, ...]` etc., special ticks can be inserted along the  $y$ -axis.

In 3D, `ZTicksAt` allows to insert special ticks along the  $z$ -axis.

If no automatic tick marks are desired, set `TicksNumber = None` or `XTicksNumber = None` etc. to switch them off on all coordinate axes or on single coordinate axes, respectively.

Use `TicksAt`, `XTicksAt` etc. to set alternative tick marks.

## Examples

### Example 1

We plot the cosine function. The automatic tick marks along the  $x$ -axis are suppressed via `XTicksNumber = None`. Points of special interest such as the extrema and the zeroes of the function are set as special tick marks:

```
plot(plot::Function2d(cos(x), x = -PI..PI),
 XTicksNumber = None,
 XTicksAt = [-PI = "-PI", -PI/2 = "-PI/2",
 0 = "0", PI/2 = "PI/2", PI = "PI"])
```

# TicksAt, XTicksAt, YTicksAt, ZTicksAt

We improve the labeling of the tick marks by using the font Symbol. This font allows to typeset Greek characters such as  $\pi$ , addressed by the character "p":

```
plot(plot::Function2d(cos(x), x = -PI..PI),
 XTicksNumber = None, TicksLabelFont = ["Symbol"],
 XTicksAt = [-PI = "-p", -PI/2 = "-p/2",
 0 = "0", PI/2 = "p/2", PI = "p"]):
```

# TicksAt, XTicksAt, YTicksAt, ZTicksAt

---

## Example 2

The Newton iteration  $x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)}$  finds successive approximations to a zero of a function  $f(x)$ . We switch the automatic ticks along the  $x$ -axis off via `XTicksNumber = None` and display some elements of the Newton sequence as tick marks:

```
f := x -> x^4/10 - 2:
x[0] := 4.12:
for i from 0 to 3 do
 x[i + 1] := x[i] - f(x[i])/f'(x[i]);
end_for:
plot(plot::Function2d(f(X), X = 1..4.5),
 plot::Line2d([x[i], f(x[i])], [x[i+1], 0],
 Color = RGB::Black) $ i = 0..3,
 plot::Line2d([x[i], 0], [x[i], f(x[i])]),
 Color = RGB::Black,
```

# TicksAt, XTicksAt, YTicksAt, ZTicksAt

```
LineStyle = Dashed) $ i = 0..4,
XTicksNumber = None, XTicksAt = [x[i] $ i = 0..3])
```

```
delete f, x, i:
```

**Purpose**                      Number of minor (unlabeled) axes tick marks between major (labeled) axes tick marks

**Value Summary**

TicksBetween	Library wrapper for “{XTicksBetween, YTicksBetween}” (2D), “{XTicksBetween, YTicksBetween, ZTicksBetween}” (3D)	Non-negative integer
XTicksBetween, YTicksBetween, ZTicksBetween	Inherited	Non-negative integer

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	TicksBetween, XTicksBetween, YTicksBetween: 1
plot::CoordinateSystem3d	TicksBetween, XTicksBetween, YTicksBetween, ZTicksBetween: 1

## Description

The tick marks along the coordinate axes consist of “major” tick marks bearing labels and of “minor” tick marks without labels.

TicksBetween sets the number of minor ticks between each pair of major ticks for all coordinate axes.

With XTicksBetween etc., the number of minor ticks may be set separately for each single coordinate axis.

Per default between every two major tick marks one minor tick mark is rendered. Via TicksBetween this number can be increased or set to zero. In contrast to major tick marks, minor tick marks are never labelled.

# TicksBetween, XTicksBetween, YTicksBetween, ZTicksBetween

Minor tick marks are rendered always with half the length of the major tick marks. Cf. TicksLength.

## Examples

### Example 1

We request few “major” tick marks in the  $x$  direction and place 9 “minor” tick marks between each pair. The ticks in  $y$  direction are chosen automatically:

```
plot(plot::Curve2d([u*cos(u*PI), u*sin(u*PI)], u = 0..2),
 XTicksNumber = Low, XTicksBetween = 9)
```

### Example 2

We request few “major” tick marks in all directions. In the horizontal directions, we place 4 “minor” tick marks between each pair. The ticks in  $z$  direction consist of the the labeled ticks only:

```
plot(plot::Function3d(exp(-x^2 - y^2), x = -3..3, y = -3..3,
```

# TicksBetween, XTicksBetween, YTicksBetween, ZTicksBetween

---

```
Submesh = [2, 2]),
TicksNumber = Low, XTicksBetween = 4, YTicksBetween = 4,
ZTicksBetween = 0, GridVisible = TRUE)
```

| [TicksLabelStyle](#) | [TicksLabelsVisible](#) | [TicksLength](#) |  
[TicksNumber](#) | [TicksVisible](#)

# TicksDistance, XTicksDistance, YTicksDistance, ZTicksDistance

**Purpose** User defined axes tick mark distance

**Value Summary**

TicksDistance	Library wrapper for “{XTicksDistance, YTicksDistance}” (2D), “{XTicksDistance, YTicksDistance, ZTicksDistance}” (3D)	MuPAD expression
XTicksDistance, YTicksDistance, ZTicksDistance	Optional	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	TicksDistance, XTicksDistance, YTicksDistance: 0
plot::CoordinateSystem3d	TicksDistance, XTicksDistance, YTicksDistance, ZTicksDistance: 0

## Description

With `TicksAnchor =  $t_0$` , `TicksDistance = d`, the automatic ticks along the coordinate axes are switched off and replaced by equidistant ticks with distance `d` at the positions  $t_j = t_0 + jd, j$ .

With `TicksAnchor =  $t_0$` , `TicksDistance = d`, these ticks are used for all coordinate axes.

With `XTicksAnchor =  $t_0$` , `XTicksDistance = d` etc., these ticks may be defined separately for each single coordinate axis.

# TicksDistance, XTicksDistance, YTicksDistance, ZTicksDistance

---

When executing a plot command, per default a “reasonable” placing for tick marks on coordinate axes is automatically computed. Through this process tick marks may not come to lie on desired positions. The attributes `TicksAnchor` and `TicksDistance` allow to generate an alternative mesh of equidistant tick marks.

---

**Note** The attributes `TicksAnchor`, `XTicksAnchor` etc. only have an effect when a positive distance  $d > 0$  between major ticks marks is set explicitly via `TicksDistance = d`, `XTicksDistance = d` etc.

---

The ticks set by `TicksAnchor` and `TicksDistance` are “major” tick marks bearing labels. Depending on the value of `TicksBetween`, there may be additional “minor” ticks without labels between each pair of major tick marks.

Additional tick marks at specific positions can be inserted with `TicksAt`.

## Examples

### Example 1

For the following plot of the sine function, the tick marks along the  $x$ -axis are chosen to match the period:

```
plot(plot::Function2d(sin(x), x = 0..4*PI),
 XTicksAnchor = 0, XTicksDistance = PI):
```

# TicksDistance, XTicksDistance, YTicksDistance, ZTicksDistance

---

The ticks along the  $y$ -axis are re-defined with a distance of  $0.2$ :

```
plot(plot::Function2d(sin(x), x = 0..4*PI),
 XTicksAnchor = 0, XTicksDistance = PI,
 YTicksAnchor = 0, YTicksDistance = 0.2):
```

# TicksDistance, XTicksDistance, YTicksDistance, ZTicksDistance

---

We increase the number of “minor” ticks along the x-axis:

```
plot(plot::Function2d(sin(x), x = 0..4*PI),
 XTicksAnchor = 0, XTicksDistance = PI,
 XTicksBetween = 4,
 YTicksAnchor = 0, YTicksDistance = 0.2):
```

# TicksDistance, XTicksDistance, YTicksDistance, ZTicksDistance

---

## Example 2

We plot a hyperbolic spiral about the point (1.07, 1.07) which is not included in the automatic tick marks. We increase the number of ticks along the vertical axis and position the ticks relative to this point. Note that the tick marks along the horizontal axis miss the center of the spiral:

```
plot(plot::Point2d(1.07, 1.07),
 plot::Curve2d([1.07 - cos(t)/t, 1.07 + sin(t)/t],
 t = 2*PI..50*PI, Submesh = 20),
 YTicksDistance = 0.025, YTicksAnchor = 1.07)
```

# TicksDistance, XTicksDistance, YTicksDistance, ZTicksDistance

### Example 3

We plot the two-dimensional normal distribution centered around the mean  $(m_1, m_2) = (3.2, 4.9)$ . This point is used as the anchor for the tick marks along the  $x$ -axis and the  $y$ -axis, respectively. Ticks are positioned at distances that are integer multiples of the standard deviations  $(s_1, s_2) = (0.8, 1.2)$ :

```
m1:= 3.2: s1 := 0.8:
m2:= 4.9: s2 := 1.2:
plot(plot::Function3d(stats::normalPDF(m1, s1^2)(x)
 *stats::normalPDF(m2, s2^2)(y),
 x = 0 .. 10, y = 0 .. 10,
 Submesh = [3, 3]),
 XTicksAnchor = m1, XTicksDistance = s1,
 YTicksAnchor = m2, YTicksDistance = s2,
 TicksBetween = 0, GridVisible = TRUE):
```

# TicksDistance, XTicksDistance, YTicksDistance, ZTicksDistance

---

```
delete m1, s1, m2, s2:
```

[TicksNumber](#) | [TicksVisible](#)

# TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle

---

**Purpose**                      Display style of axes tick labels

**Value Summary**

TicksLabelStyle	Library wrapper for “{XTicksLabelStyle, YTicksLabelStyle}” (2D), “{XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle}” (3D)	See below
XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle	Inherited	Diagonal, Horizontal, Shifted, or Vertical

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle: Horizontal
plot::CoordinateSystem3d	TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle: Horizontal

## Description

TicksLabelStyle allows to modify the display style of the tick labels on all coordinate axes.

XTicksLabelStyle etc. allow to set the label styles separately for each single coordinate axis.

It may occur that tick labels overlap if too many tick marks along the coordinate axes are requested. The following styles for the tick labels are available to deal with this problem:

# TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle

---

**Horizontal:** The labels are displayed in the usual horizontal reading order from left to right.

**Vertical:** The labels are tilted 90 degrees counter clockwise, i.e., they have to be read from bottom to top.

**Diagonal:** The labels are tilted 45 degrees counter clockwise.

**Shifted:** Each second label is shifted to avoid overlapping.

Note that also in 3D the orientation **Horizontal**, **Diagonal**, **Vertical** refers to the screen output irrespectively of the 3D orientation of the corresponding axis.

**TicksLabelStyle** sets the display style for the ticks labels along *all* coordinate axes.

With **XTicksLabelStyle** etc. the style may be set separately for each single axis.

Independently from **TicksLabelStyle**, the titles of the axes are rendered horizontally. In 2D, the attribute **YAxisTitleOrientation** is available to tilt the title of the vertical axis by 90 degrees.

## Examples

### Example 1

We demonstrate the styles for the ticks labels:

```
f := plot::Function2d(sin(x), x = 0 .. 2*PI):
S1 := plot::Scene2d(f, TicksLabelStyle = Horizontal):
S2 := plot::Scene2d(f, TicksLabelStyle = Vertical):
S3 := plot::Scene2d(f, TicksLabelStyle = Diagonal):
S4 := plot::Scene2d(f, TicksLabelStyle = Shifted):
plot(S1, S2, S3, S4, Height = 10*unit::cm,
 Width = 10*unit::cm):
```

# TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle

---

Here is a corresponding picture in 3D:

```
f := plot::Function3d(exp(-x^2 - y^2), x = -3..3,
 y = -3..3, Submesh = [2, 2]):
S1 := plot::Scene3d(f, TicksLabelStyle = Horizontal):
S2 := plot::Scene3d(f, TicksLabelStyle = Vertical):
S3 := plot::Scene3d(f, TicksLabelStyle = Diagonal):
S4 := plot::Scene3d(f, TicksLabelStyle = Shifted):
plot(S1, S2, S3, S4, Height = 10*unit::cm,
 Width = 10*unit::cm):
```

# TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle

---

`delete f, S1, S2, S3, S4:`

## Example 2

The tick labels along the x-axis nearly collide in the following plot:

```
f := plot::Function2d(exp(30*x)*sin(x*100*PI),
 x = 10.04 .. 10.05):
plot(f, GridVisible = TRUE, XTicksNumber = High):
```

# TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle

---

Tilting the labels yields a more tidy looking graphics:

```
plot(f, GridVisible = TRUE, XTicksNumber = High,
 XTicksLabelStyle = Diagonal):
```

# TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle

### Example 3

In the following graphics, there is not enough space to squeeze in the requested high number of ticks in the  $x$  and  $y$  direction:

```
plot(plot::Function3d(exp(-x^2 - y^2), x = -2..2, y = -2..2,
 Submesh = [2, 2]),
 TicksNumber = High,
 AxesTitles = ["North <--> South",
 "East <--> West",
 "Heaven <--> Earth"]):
```

# TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle

---

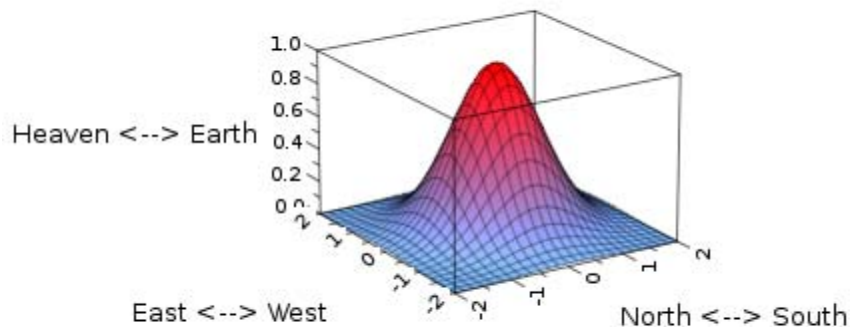

The tick labels fit with Vertical and Diagonal orientation:

```
plot(plot::Function3d(exp(-x^2 - y^2), x = -2..2, y = -2..2,
 Submesh = [2, 2]),
 TicksNumber = High,
 XTicksLabelStyle = Vertical,
 YTicksLabelStyle = Diagonal,
 ZTicksLabelStyle = Horizontal,
 AxesTitles = ["North <--> South",
 "East <--> West",
 "Heaven <--> Earth"]):
```

# TicksLabelStyle, XTicksLabelStyle, YTicksLabelStyle, ZTicksLabelStyle

---

### MuPAD Functions

TicksAnchor | TicksAt | TicksBetween | TicksDistance  
| TicksLabelFont | TicksLabelsVisible | TicksLength |  
TicksNumber | TicksVisible

# TicksLength

---

**Purpose** Length of axes tick marks

**Value Summary** Inherited Positive output size

## Graphics Primitives

Objects	TicksLength Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	2

## Description

The tick marks along the coordinate axes consist of “major” tick marks bearing labels and of “minor” tick marks without labels.

TicksLength sets the length for the major tick marks on all coordinate axes. The length of minor tick marks (cf. TicksBetween) is half of TicksLength .

The value should be specified as an absolute physical length including a length unit such as `TicksLength = 2.5*unit::mm`. Numbers without a physical unit give the length in mm.

TicksLength sets the length of automatic tick marks (cf. TicksNumber) as well of special tick marks set via TicksAt.

It is not possible to change the length of tick marks on any single axis alone.

## Examples

### Example 1

We plot the density of the standard normal distribution. Compared to the default length of 2 mm, the ticks length is increased by 50%:

```
plot(plot::Function2d(stats::normalPDF(0, 1)(x), x = -4..4),
 TicksLength = 3*unit::mm):
```

A corresponding plot in 3D:

```
plot(plot::Function3d(exp(-x^2 - y^2), x = -3..3, y = -3..3,
 Submesh = [2, 2]),
 TicksLength = 3*unit::mm)
```

# TicksLength

---

## Example 2

In the following plot of the sine function, we switch the automatic tick marks along the  $x$ -axis off via `XTicksNumber = None`. Some extra ticks are set via `XTicksAt`:

```
plot(plot::Function2d(sin(x), x = 0 .. PI),
 XTicksAt = [0 = "0", PI/2 = "p/2", PI = "p"],
 XTicksNumber = None, TicksLength = 4*unit::mm,
 TicksLabelFont = ["Symbol"], YAxisVisible = FALSE)
```

**Purpose**                      Number of axes tick marks

**Value Summary**

<p>TicksNumber</p> <p>XTicksNumber, YTicksNumber, ZTicksNumber</p>	<p>Library wrapper for “{XTicksNumber, YTicksNumber}” (2D), “{XTicksNumber, YTicksNumber, ZTicksNumber}” (3D)</p> <p>Inherited</p>	<p>See below</p> <p>High, Low, None, or Normal</p>
----------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	TicksNumber, XTicksNumber, YTicksNumber: Normal
plot::CoordinateSystem3d	TicksNumber, XTicksNumber, YTicksNumber, ZTicksNumber: Normal

## Description

TicksNumber directs the internal routine that chooses tick marks along coordinate axes to produce no, few, or many ticks.

With XTicksNumber etc., the number of tick marks can be controlled separately for each single axis.

The tick marks along the coordinate axes consist of “major” tick marks bearing labels and of “minor” tick marks without labels.

The attributes TicksNumber, XTicksNumber etc. only refer to the labeled “major” tick marks. The “minor” tick marks are governed by the attribute TicksBetween.

Automatically generated equidistant tick marks are displayed along the coordinate axes, unless the user specifies the ticks explicitly via the attributes TicksAnchor and TicksDistance.

# TicksNumber, XTicksNumber, YTicksNumber, ZTicksNumber

---

TicksNumber provides a hint for the automatic computation process, how many tick marks are to be displayed. The possible values are None, Low, Normal, and Many.

With XTicksNumber etc., ticks numbers may be controlled separately for each single axis.

If equidistant tick marks are set explicitly via TicksAnchor and TicksDistance, the attributes TicksNumber, XTicksNumber etc. are ignored.

There is no influence on special tick marks set via TicksAt, XTicksAt etc. either.

With TicksNumber = None, XTicksNumber = None etc., no automatically generated tick marks are displayed.

Tick marks may also be suppressed via TicksVisible = FALSE, XTicksVisible = FALSE etc. However, in contrast to TicksNumber = None, XTicksNumber = None etc., this also suppresses equidistant tick marks set explicitly via TicksAnchor, TicksDistance as well as special tick marks set via TicksAt, XTicksAt etc.

## Examples

### Example 1

We demonstrate the effect of various TicksNumber values:

```
f := plot::Function2d(sinh(x), x = -5 .. 5):
S1 := plot::Scene2d(f, TicksNumber = None):
S2 := plot::Scene2d(f, TicksNumber = Low):
S3 := plot::Scene2d(f, TicksNumber = Normal):
S4 := plot::Scene2d(f, TicksNumber = High):
plot(S1, S2, S3, S4):
```

# TicksNumber, XTicksNumber, YTicksNumber, ZTicksNumber

---

```
delete f, S1, S2, S3, S4:
```

## Example 2

We demonstrate the effect of various TicksNumber values in a 3D plot:

```
s := plot::Function3d(x^2 + y^2, x = -1..1, y = -2..2):
plot(s):
```

# TicksNumber, XTicksNumber, YTicksNumber, ZTicksNumber

---

```
plot(s, XTicksNumber = High, YTicksNumber = Normal,
 ZTicksNumber = Low):
```

# TicksNumber, XTicksNumber, YTicksNumber, ZTicksNumber

---

All tick marks are suppressed:

```
plot(s, TicksNumber = None)
```

# TicksNumber, XTicksNumber, YTicksNumber, ZTicksNumber

---

`delete s:`

## See Also

### MuPAD Functions

`TicksAnchor` | `TicksAt` | `TicksBetween` | `TicksDistance` |  
`TicksLabelFont` | `TicksLabelStyle` | `TicksLabelsVisible` |  
`TicksLength` | `TicksVisible`

# TicksVisible, XTicksVisible, YTicksVisible, ZTicksVisible

**Purpose** Display axes tick marks?

**Value Summary**

TicksVisible	Library wrapper for “{XTicksVisible, YTicksVisible}” (2D), “{XTicksVisible, YTicksVisible, ZTicksVisible}” (3D)	TRUE, FALSE, or list of 2 or 3 of these, depending on the dimension
XTicksVisible, YTicksVisible, ZTicksVisible	Inherited	FALSE, or TRUE

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d	TicksVisible, XTicksVisible, YTicksVisible: TRUE
plot::CoordinateSystem3d	TicksVisible, XTicksVisible, YTicksVisible, ZTicksVisible: TRUE

## Description

TicksVisible = TRUE versus TicksVisible = FALSE switches tick marks along all coordinate axes on or off.

With XTicksVisible = TRUE/FALSE etc., the tick marks can be switched on or off separately for each single axis.

With TicksVisible = FALSE, the tick marks along all coordinate axes are switched off. The labels of the tick marks, however, remain visible.

TicksVisible etc. refers to automatically generated tick marks (cf. TicksNumber), to equidistant tick marks that are requested explicitly via TicksAnchor, TicksDistance as well as to special tick marks set via TicksAt.

# TicksVisible, XTicksVisible, YTicksVisible, ZTicksVisible

Ticks can also be suppressed via `TicksNumber = None`, `XTicksNumber = None` etc. In contrast to `TicksVisible = FALSE`, however, this affects only the automatically generated ticks and their labels. Ticks set by `TicksAnchor`, `TicksDistance`, `TicksAt` are not affected.

## Examples

### Example 1

Visualizing that the sine function is nearly linear near its zeroes, we suppress the automatic tick marks along the  $x$ -axis via `XTicksNumber = None`. Three special ticks are set via `XTicksAt`:

```
f := plot::Function2d(sin(x), x = 3.0 .. 3.3):
plot(f, XTicksNumber = None, XTicksAt = [3.1, PI = "p", 3.2],
 TicksLabelFont = ["Symbol"])
```

The tick marks along the  $x$ -axis are switched off:

```
plot(f, XTicksNumber = None, XTicksAt = [3.1, PI = "p", 3.2],
```

# TicksVisible, XTicksVisible, YTicksVisible, ZTicksVisible

```
TicksLabelFont = ["Symbol"], XTicksVisible = FALSE)
```

The labels of the ticks are switched off, too:

```
plot(f, XTicksNumber = None, XTicksAt = [3.1, PI = "p", 3.2],
 TicksLabelFont = ["Symbol"], XTicksVisible = FALSE,
 XTicksLabelsVisible = FALSE)
```

# TicksVisible, XTicksVisible, YTicksVisible, ZTicksVisible

`delete f:`

 ZTicksLabelsVisible

**Graphics Primitives**

Objects	Default Values
plot::CoordinateSystem2d	TicksLabelsVisible, XTicksLabelsVisible, YTicksLabelsVisible: TRUE
plot::CoordinateSystem3d	TicksLabelsVisible, XTicksLabelsVisible, YTicksLabelsVisible, ZTicksLabelsVisible: TRUE

**Description**

TicksLabelsVisible = TRUE versus TicksLabelsVisible = FALSE switches the labeling of the tick marks along all coordinate axes on or off.

With TicksLabelsVisible = FALSE, the labeling of the tick marks along all coordinate axes is switched off. The tick marks themselves, however, remain visible. They are switched off via TicksVisible = FALSE.

With XTicksLabelsVisible = TRUE/FALSE etc., the tick labeling can be switched on or off separately for each single axis.

# TicksLabelsVisible, XTicksLabelsVisible, YTicksLabelsVisible, ZTicksLabelsVisible

---

TicksLabelsVisible, XTicksLabelsVisible etc. refer to automatically generated tick marks (cf. TicksNumber), to equidistant tick marks that are requested explicitly via TicksAnchor, TicksDistance as well as to special tick marks set via TicksAt.

Ticks can also be suppressed via TicksNumber = None, XTicksNumber = None etc. In contrast to TicksLabelsVisible = FALSE, however, this affects only the automatically generated ticks and their labels. Ticks set by TicksAnchor, TicksDistance, TicksAt are not affected.

## Examples

### Example 1

We approximate the cosine function by a fourth order polynomial (a Taylor polynomial around the expansion point 0). The automatic tick marks along the  $x$ -axis are suppressed via XTicksNumber = None. Some special tick marks including the zero of the cosine function at  $x = \frac{\pi}{2}$  are inserted via XTicksAt:

```
f1 := plot::Function2d(cos(x), x = 0..2):
f2 := plot::Function2d(1 - x^2 + x^4/4!, x = 0..2,
 LineColor = RGB::Blue):
plot(f1, f2, XTicksNumber = None,
 XTicksAt = [1, PI/2 = "p/2", 2],
 TicksLabelFont = ["Symbol"])
```

# TicksLabelsVisible, XTicksLabelsVisible, YTicksLabelsVisible, ZTicksLabelsVisible

---

The labeling of the tick marks along the  $x$ -axis is switched off:

```
plot(f1, f2, XTicksNumber = None,
 XTicksAt = [1, PI/2 = "p/2", 2],
 TicksLabelFont = ["Symbol"],
 XTicksLabelsVisible = FALSE)
```

# TicksLabelsVisible, XTicksLabelsVisible, YTicksLabelsVisible, ZTicksLabelsVisible

---

The ticks themselves are switched off, too:

```
plot(f1, f2, XTicksNumber = None,
 XTicksAt = [1, PI/2 = "p/2", 2],
 TicksLabelFont = ["Symbol"], XTicksLabelsVisible = FALSE,
 XTicksVisible = FALSE)
```

# TicksLabelsVisible, XTicksLabelsVisible, YTicksLabelsVisible, ZTicksLabelsVisible

---

```
delete f1, f2:
```

Objects	GridInFront Default Values
plot::CoordinateSystem2d	FALSE

## Description

GridInFront = TRUE versus GridInFront = FALSE places 2D coordinate lines in front of or behind the graphical objects in the scene.

Setting GridVisible = TRUE, SubgridVisible = TRUE, one can display a coordinate grid extending the tick marks on the coordinate axes. See the help page of GridVisible for further information.

By default, the lines of the coordinate grid are plotted behind the graphical objects in a scene. Consequently, the objects may cover the coordinate grid. If only line objects and points are present in a 2D scene, this is desirable in most cases.

However, if there are filled areas such as filled polygons in the scene, the view to the coordinate grid may be totally blocked. In such a situation, you may want to draw the grid lines in front of the objects to guarantee visibility of the coordinate grid.

Although the default setting is GridInFront = FALSE, some objects which create filled areas send GridInFront = TRUE as a “hint” (see the section Primitives Requesting Special Scene Attributes: “Hints” of this documentation).

This attribute is available only in 2D.

## Examples

### Example 1

It is usually desirable to let line objects and points cover the coordinate grid:

# GridInFront

```
p1 := plot::Point2d(0.5, 0.5, PointSize = 3*unit::mm,
 Color = RGB::Green):
p2 := plot::Point2d(0.5, 1.0, PointSize = 3*unit::mm,
 Color = RGB::Green):
f1 := plot::Function2d(cos(x*PI), x = -1 .. 1,
 Color = RGB::Blue):
f2 := plot::Function2d(sin(x*PI), x = -1 .. 1, Color = RGB::Red):
plot(plot::Scene2d(p1, p2, f1, f2,
 AxesInFront = FALSE, GridInFront = FALSE),
 plot::Scene2d(p1, p2, f1, f2,
 AxesInFront = TRUE, GridInFront = TRUE),
 GridVisible = TRUE, SubgridVisible = TRUE):
```

However, you probably want to have the coordinate grid visible in front of the following density plot:

```
d := plot::Density(exp(-x^2 - y^2), x = -1..1, y = -1 .. 1,
 FillColor = RGB::Blue):
```

```
plot(
 plot::Scene2d(d, AxesInFront = FALSE, GridInFront = FALSE),
 plot::Scene2d(d, AxesInFront = TRUE, GridInFront = TRUE),
 GridVisible = TRUE, SubgridVisible = TRUE,
 Layout = Horizontal
):
```

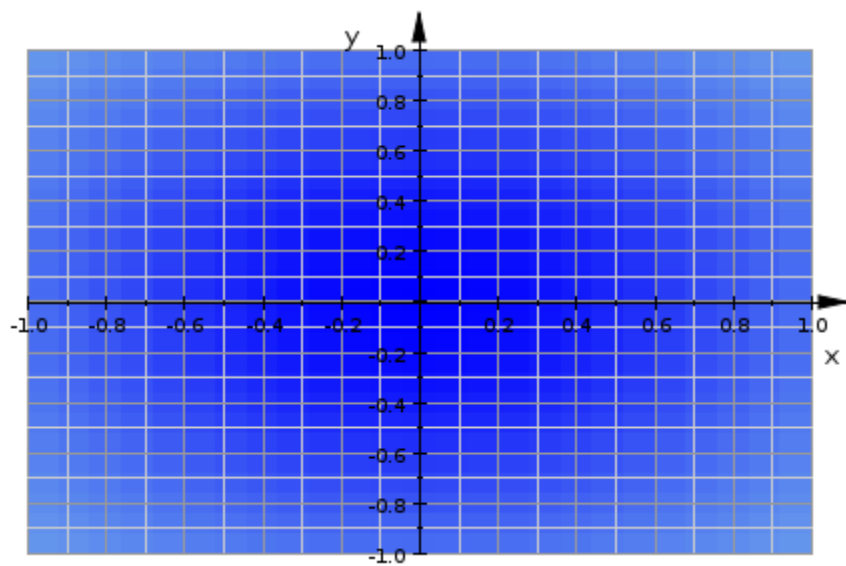

Note that density objects of type `plot::Density` automatically send the “hint” `GridInFront = TRUE`, so there is no need to set this attribute explicitly:

```
plot(d, GridVisible = TRUE, SubgridVisible = TRUE):
```

# GridInFront

---

`delete p1, p2, f1, f2, d:`

`GridLineColor` | `GridLineStyle` | `GridLineWidth` | `GridVisible`

# GridLineColor, SubgridLineColor

**Purpose** Line color of the coordinate grid

**Value Summary** GridLineColor, SubgridLineColor Inherited Color

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	GridLineColor: RGB::Grey60 SubgridLineColor: RGB::Grey80

## Description

GridLineColor, SubgridLineColor govern the color of coordinate grid and subgrid lines extending the tick marks on coordinate axes.

Setting GridVisible = TRUE, SubgridVisible = TRUE, one can display a coordinate grid extending the tick marks on the coordinate axes. See the help page of GridVisible for further information.

GridLineColor, SubgridLineColor set the RGB color for the coordinate grid and subgrid lines.

The color of the coordinate grid lines cannot be specified separately for the single coordinate directions.

## Examples

### Example 1

The usual grey lines of the coordinate grid are not appropriate for the following density graphics:

```
d := plot::Density(exp(-x^2 - y^2), x = -1..1, y = -1 ..1,
 FillColor = RGB::White):
plot(d, TicksNumber = Normal, TicksBetween = 4,
 GridVisible = TRUE, SubgridVisible = TRUE)
```

# GridLineColor, SubgridLineColor

---

We change the grid color to a darker grey:

```
plot(d, TicksNumber = Normal, TicksBetween = 4,
 GridVisible = TRUE, SubgridVisible = TRUE,
 GridLineColor = RGB::SlateGreyDark,
 SubgridLineColor = RGB::SlateGreyDark,
 GridLineWidth = 0.5*unit::mm)
```

# GridLineColor, SubgridLineColor

---

`delete d:`

**Purpose** Line style of the coordinate grid

**Value Summary** GridLineStyle, SubgridLineStyle Inherited Dashed, Dotted, or Solid

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	GridLineStyle, SubgridLineStyle: Solid

## Description

GridLineStyle, SubgridLineStyle govern the style of the coordinate grid lines and subgrid lines extending the tick marks on coordinate axes.

Setting GridVisible = TRUE, SubgridVisible = TRUE, one can display a coordinate grid extending the tick marks on the coordinate axes. See the help page of GridVisible for further information.

Styles for coordinate grid and subgrid lines can be either Solid, Dashed, or Dotted.

The line style of the coordinate grid cannot be specified separately for the single coordinate directions.

## Examples

### Example 1

We use horizontal coordinate lines to visualize quantiles for the normal distribution:

```
plot(plot::Function2d(stats::normalCDF(0, 1)(x), x = -3..3),
 Axes = Frame, TicksBetween = 4,
 YGridVisible = TRUE, YSubgridVisible = TRUE,
 GridLineStyle = Solid, SubgridLineStyle = Dashed):
```

## Example 2

Here is an example of a function graph in 3D with different style settings for the coordinate grid and subgrid:

```
plot(plot::Function3d(sin(x*y), x = -2..2, y = -2..2),
 GridVisible = TRUE, SubgridVisible = TRUE,
 GridLineStyle = Dashed, SubgridLineStyle = Dotted):
```

# GridLineStyle, SubgridLineStyle

---

## See Also

### MuPAD Functions

`GridInFront` | `GridLineColor` | `GridLineWidth` | `GridVisible`

# GridLineWidth, SubgridLineWidth

**Purpose** Width of coordinate grid lines

**Value Summary** GridLineWidth, SubgridLineWidth Inherited Positive output size

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	GridLineWidth, SubgridLineWidth: 0.1

## Description

GridLineWidth, SubgridLineWidth govern the width of coordinate grid lines and subgrid lines extending the tick marks on coordinate axes.

Setting GridVisible = TRUE, SubgridVisible = TRUE, one can display a coordinate grid extending the tick marks on the coordinate axes. See the help page of GridVisible for further information.

GridLineWidth, SubgridLineWidth set the linewidth for the coordinate grid and the subgrid, respectively. The values should be specified as absolute physical lengths including a length unit such as GridLineWidth = 0.5\*unit::mm. Numbers without a physical unit give the size in mm.

GridLinesWidth and SubgridLinesWidth set a common line width for the grid lines in all coordinate directions.

XGridLinesWidth and XSubgridLinesWidth set the line width only for the grid lines extending the axes tick marks on the *x*-axis.

YGridLinesWidth etc. work correspondingly for the other coordinate directions.

Note that the graphics cannot always react to small changes of the line width because of the discretization into pixels.

# GridLineWidth, SubgridLineWidth

## Examples

### Example 1

We use the coordinate lines to plot the sine function on “lined paper”. Because of the rather high number of subgrid lines set by `TicksBetween = 10`, we use extra fine lines for the subgrid:

```
plot(plot::Function2d(sin(x), x = 0 .. 2*PI),
 TicksNumber = Normal, TicksBetween = 10,
 GridVisible = TRUE, SubgridVisible = TRUE,
 GridLineWidth = 0.5*unit::mm,
 SubgridLineWidth = 0.1*unit::mm)
```

Here is a corresponding plot in 3D:

```
plot(plot::Function3d(cos(x*PI)*cos(y*PI), x = 0 .. 2,
 y = 0 .. 2),
 TicksNumber = Low, TicksBetween = 9,
 GridVisible = TRUE, SubgridVisible = TRUE,
 GridLineWidth = 0.5*unit::mm,
```

`SubgridLineWidth = 0.1*unit::mm)`

Alternatively, use TicksAnchor, TicksDistance to specify the major tick marks explicitly.</p> <p>Use TicksBetween to control the number of minor tick marks.</p> <p>Non-regular tick marks added via TicksAt do not generate additional grid lines.</p>

# GridVisible, SubgridVisible, XGridVisible, XSubgridVisible, YGridVisible, YSubgridVisible, ZGridVisible, ZSubgridVisible

---

## Examples

### Example 1

We plot the graph of the sine function without grid lines:

```
plot(plot::Function2d(sin(x), x = 0..2*PI),
 XTicksNumber = Normal, YTicksNumber = High)
```

The grid lines are “switched on”:

```
plot(plot::Function2d(sin(x), x = 0..2*PI),
 XTicksNumber = Normal, YTicksNumber = High,
 GridVisible = TRUE):
```

# GridVisible, SubgridVisible, XGridVisible, XSubgridVisible, YGridVisible, YSubgridVisible, ZGridVisible, ZSubgridVisible

The subgrid lines are switched on as well:

```
plot(plot::Function2d(sin(x), x = 0..2*PI),
 XTicksNumber = Normal, YTicksNumber = High,
 GridVisible = TRUE, SubgridVisible = TRUE):
```

# GridVisible, SubgridVisible, XGridVisible, XSubgridVisible, YGridVisible, YSubgridVisible, ZGridVisible, ZSubgridVisible

---

We refine the subgrid in the  $x$ -direction via `XTicksBetween`:

```
plot(plot::Function2d(sin(x), x = 0..2*PI),
 XTicksNumber = Normal, XTicksBetween = 4,
 YTicksNumber = High,
 GridVisible = TRUE, SubgridVisible = TRUE):
```

# GridVisible, SubgridVisible, XGridVisible, XSubgridVisible, YGridVisible, YSubgridVisible, ZGridVisible, ZSubgridVisible

## Example 2

We consider the probability of at least  $k$  successes when performing 10 independent experiments each with a 50% chance of success. Consider for this the cumulative density of the binomial distribution given by `stats::binomialCDF`. Quantiles are visualized by introducing horizontal grid lines:

```
f := stats::binomialCDF(10, 0.5):
plot(plot::Bars2d([f(k) $ k = 0..10]),
 XTicksDistance = 1, XTicksBetween = 0,
 XAxisVisible,
 YTicksDistance = 0.1, YTicksBetween = 4,
 YGridVisible, YSubgridVisible)
```

# GridVisible, SubgridVisible, XGridVisible, XSubgridVisible, YGridVisible, YSubgridVisible, ZGridVisible, ZSubgridVisible

---

`delete f:`

### Example 3

Consider a curve in 3D with two of its projections to the coordinate planes. We render the coordinate grid visible:

```
c1 := plot::Curve3d([t, cos(t)/t, sin(t)], t = 1..10,
 LineColor = RGB::Red):
c2 := plot::Curve3d([1, cos(t)/t, sin(t)], t = 1..10,
 LineColor = RGB::ForestGreen):
c3 := plot::Curve3d([t, cos(t)/t, -1], t = 1..10,
 LineColor = RGB::Blue):
plot(c1,c2, c3, TicksBetween = 4, GridVisible = TRUE,
 SubgridVisible = TRUE)
```

# GridVisible, SubgridVisible, XGridVisible, XSubgridVisible, YGridVisible, YSubgridVisible, ZGridVisible, ZSubgridVisible

```
delete c1, c2, c3:
```

## Example 4

Because of the rather large number of grid lines in the following plot, we use extra fine lines to render the subgrid:

```
plot(plot::Function3d(cos(x*PI)*cos(y*PI), x = 0 .. 2,
 y = 0 .. 2),
 TicksNumber = Low, TicksBetween = 9,
 GridVisible = TRUE, SubgridVisible = TRUE,
 GridLineWidth = 0.5*unit::mm,
 SubgridLineWidth = 0.1*unit::mm)
```

# **GridVisible, SubgridVisible, XGridVisible, XSubgridVisible, YGridVisible, YSubgridVisible, ZGridVisible, ZSubgridVisible**

---

## **See Also**

## **MuPAD Functions**

`GridInFront` | `GridLineColor` | `GridLineStyle` | `GridLineWidth`

**Purpose** Behaviour of the animation toolbar

**Value Summary** Inherited BackAndForth, Loop, or RunOnce

## Graphics Primitives

Objects	AnimationStyle Default Values
plot::Canvas	RunOnce

**Description** AnimationStyle determines how an animation is played in VCam once it is activated.

AnimationStyle determines what has to be done when an animation reaches the end of its playing time. With RunOnce the animation stops, with BackAndForth the animation reverts and runs through to the beginning and with Loop it jumps back to the beginning and runs on from there on.

AnimationStyle sets the initial value of the Animation Style menu in the animation toolbar according to its value.

## Examples

### Example 1

This examples shows an animation which builds up a picture frame by frame and at the end of the animation time the complete picture is visible. For this kind of animation the value RunOnce is a good choice for AnimationStyle:

```
plot(plot::Line2d([a/36, 0], [sin(a/18*PI), cos(a/18*PI)],
 VisibleAfter = a/7.2,
 Color = [sin(a/18*PI), sin(a/18*PI), cos(a/18*PI)],
 $ a = -36..36,
 AnimationStyle = RunOnce)
```

# AnimationStyle

---

## Example 2

This example plays in an endless loop and the value `Loop` is chosen because first frame is the natural successor of the last frame of the animation:

```
plot(plot::Function2d(sin(a*x), x = -PI..PI, a = -PI..PI),
 AnimationStyle = Loop)
```

### Example 3

In this example the circle grows from radius 0 to radius 1. With `AnimationStyle = BackAndForth` the circle grows and shrinks in an endless loop:

```
plot(plot::Circle2d(a, a = 0..1),
 AnimationStyle = BackAndForth)
```

**Value Summary** Optional FALSE, or TRUE

**Graphics Primitives**

Objects	AutoPlay Default Values
plot::Canvas	TRUE

**Description** When plotting with `AutoPlay = TRUE`, animations will start automatically when the plot is activated. This is the default setting. Animations created with `AutoPlay = FALSE` start when the corresponding button is pressed.

# Frames

---

## Purpose

Number of frames in an animation

## Value Summary

Inherited

Positive integer

## Description

Frames determines the number of frames in the animation of an object.

Frames =  $n$  with a positive integer  $n$  sets the number of frames for the animation of an object to  $n$ .

These frames are played during the real time period given by TimeBegin =  $t_0$  and TimeEnd =  $t_1$  (in seconds).

The resulting frame rate is  $n/(t_1 - t_0)$  (frames per second).

Increasing the number of frames does not mean that the animation lasts longer, because the renderer does not work with a fixed number of frames per second.

Keeping the play period from TimeBegin =  $t_0$  to TimeEnd =  $t_1$  fixed, an increased number of frames just produces a higher frame rate leading to a smoother animation.

Note that the human eye cannot distinguish between different frames if they change with a rate of more than 25 frames per second. Thus, the number of frames  $n$  for an animation should satisfy  $n < 25 (t_1 - t_0)$ .

With the default time range TimeBegin =  $t_0 = 0$ , TimeEnd =  $t_1 = 10$  (seconds), it does not make sense to specify Frames =  $n$  with  $n > 250$ . If a higher  $n$  is required to obtain a sufficient resolution of the animated object, one should increase the time for the animation by a sufficiently high value of TimeEnd.

Since the values of Frames, TimeBegin, TimeEnd may be set separately for different objects, it is possible to animate objects in a scene with different frame rates. Cf. "Example 2" on page 23-1741.

## Examples

### Example 1

We set the number of frames for the following animation to 40. The default animation range of 10 seconds is used. This results in a frame rate of 4 frames per second:

```
plot(plot::Function2d(sin(a*x), x = -PI..PI,
 a = 1..2, Frames = 40)):
```

### Example 2

Here is an example of different frame rates in one plot. The default animation range of 10 seconds is used.

The red point is sampled with 30 frames in 10 seconds, the blue one with 100 frames in 10 seconds. The animation of the blue point is much smoother:

```
plot(plot::Function2d(sin(x), x = 0..PI,
 Color = RGB::Black),
```

# Frames

---

```
plot::Point2d([a , sin(a) + 0.07], a = 0 .. PI,
 Color = RGB::Red, Frames = 30),
plot::Point2d([a , sin(a) - 0.07], a = 0 .. PI,
 Color = RGB::Blue, Frames = 100),
PointSize = 4*unit::mm):
```

## Concepts

- “The Number of Frames and the Time Range”

# TimeBegin, TimeEnd, TimeRange, InitialTime

**Purpose** Time of the animation

**Value Summary**

InitialTime, TimeBegin, TimeEnd	Inherited	Real number
TimeRange	[TimeBegin .. TimeEnd]	Range of arithmetical expressions

**Graphics Primitives**

Objects	Default Values
plot::Canvas	

**Description**

TimeBegin =  $t_0$  defines the starting time  $t_0$  of the animation of an object.

TimeEnd =  $t_1$  defines the time  $t_1$  for the end of the animation.

TimeRange =  $t_0 .. t_1$  is a short cut for setting both TimeBegin =  $t_0$  and TimeEnd =  $t_1$ .

InitialTime =  $t_2$  defines the time  $t_2$  for the initial position of the animation slider.

Animations are defined object by object. Each animated object is animated for a certain time span specified by TimeBegin and TimeEnd setting the real start and end time in seconds.

The total real time span of an animated plot is the physical real time given by the minimum of the TimeBegin values of all animated objects in the plot to the maximum of the TimeEnd values of all the animated objects:

- When a plot containing animated objects is created, the real time clock is set to the minimum of the TimeBegin values of all animated objects in the plot. The real time clock is started when pushing the 'play' button for animations in the graphical user interface.
- Before the real time reaches the TimeBegin value  $t_0$  of an animated object, this object is static in the state corresponding to the begin of

# TimeBegin, TimeEnd, TimeRange, InitialTime

---

its animation. Depending on the attribute `VisibleBeforeBegin`, it may be visible or invisible before  $t_0$ .

- During the time from  $t_0$  to  $t_1$ , the object changes from its original to its final state.
- After the real time reaches the `TimeEnd` value  $t_1$ , the object stays static in the state corresponding to the end of its animation. Depending on the attribute `VisibleAfterEnd`, it may stay visible or become invisible after  $t_1$ .
- The animation of the entire plot ends with the physical time given by the maximum of the `TimeEnd` values of all animated objects in the plot.

If all animated objects in a plot share the same values `TimeBegin` =  $t_0$  and `TimeEnd` =  $t_1$ , the physical time span of the animation is  $t_1 - t_0$  (in seconds). During this time, all animated objects change from their initial to their final state.

Separate settings for `TimeBegin` and `TimeEnd` in different animated objects allow to synchronize the animations.

With the optional attribute `InitialTime` the initial position of the animation slider can be set to any time value  $t_2$  between  $t_0$  and  $t_1$ . If `InitialTime` is not set, the slider will be placed at the beginning of the animation.

The attributes `VisibleAfter`, `VisibleBefore`, and `VisibleFromTo` allow special “visibility animations” in which objects are visible for a limited time only.

---

**Note** The attributes `VisibleAfter`, `VisibleBefore`, and `VisibleFromTo` implicitly set values for `TimeBegin` and `TimeEnd` (and, therefore, also for `TimeRange`). Consequently, these attributes should not be used simultaneously in the definition of an animated object.

---

# TimeBegin, TimeEnd, TimeRange, InitialTime

## Examples

### Example 1

By default, an animation plays for 10 seconds. Keeping the default value `TimeBegin = 0`, this time can be reduced to 5 seconds by setting `TimeEnd = 5`:

```
plot(plot::Function2d(sin(a*x), x = -PI .. PI, a = -PI..PI,
 TimeEnd = 5)):
```

The total time of the animation is the difference between `TimeEnd` and `TimeBegin`. Hence, the following animation plays 5 seconds as well:

```
plot(plot::Function2d(sin(a*x), x = -PI..PI, a = -PI..PI,
 TimeRange = 5..10)):
```

# TimeBegin, TimeEnd, TimeRange, InitialTime

---

## Example 2

Using different time ranges allows to synchronize the animations of different objects. Here we plot two functions. The first function is animated from 0 to 5 (seconds) and then stays static in its final state. The second function stays static in its initial state for 5 seconds and is then animated in the range from 5 to 10 (seconds):

```
f1 := plot::Function2d(a*sin(x), x = -PI..PI, a = -1..1,
 Color = RGB::Red, TimeRange = 0..5):
f2 := plot::Function2d(a*cos(x), x = -PI..PI, a = -1..1,
 Color = RGB::Blue, TimeRange = 5..10):
plot(f1 ,f2):
```

# TimeBegin, TimeEnd, TimeRange, InitialTime

Both functions are visible outside the time range of their animations. We use the attributes `VisibleAfterEnd` and `VisibleBeforeBegin` to make them visible only during their animations:

```
f1::VisibleAfterEnd := FALSE:
f2::VisibleBeforeBegin := FALSE:
plot(f1, f2):
```

# TimeBegin, TimeEnd, TimeRange, InitialTime

---

```
delete f1, f2:
```

### Example 3

The following animation uses the implicitly given `TimeRange` from 0 to 10 seconds, but the first image shown is at the time 5:

```
plot(plot::Function2d(a*sin(x), x = -PI..PI, a = -1..1),
 InitialTime=5):
```

# TimeBegin, TimeEnd, TimeRange, InitialTime

---

## Concepts

- “The Number of Frames and the Time Range”
- “Advanced Animations: The Synchronization Model”

# VisibleAfter, VisibleBefore, VisibleFromTo

---

## Purpose

Object visible at time value

## Value Summary

VisibleAfter,  
VisibleBefore,  
VisibleFromTo

Library wrapper for  
“TimeEnd, TimeBegin,  
VisibleAfterEnd,  
and  
VisibleBeforeBegin”

Non-negative real  
number

## Description

`VisibleAfter = t0` renders an object invisible until the real time  $t_0$  has elapsed in an animation. Then the object becomes visible.

`VisibleBefore = t1` renders an object visible until the time  $t_1$ . Then the object becomes invisible.

`VisibleFrom = t0 .. t1` renders an object invisible until the time  $t_0$ . Then the object becomes visible. After the time  $t_1$  it becomes invisible again.

`VisibleAfter`, `VisibleBefore`, `VisibleFromTo` allow to implement animated visibility of objects. This also includes otherwise static objects, which become animated objects when one of these attributes is used.

The attributes `VisibleBeforeBegin` and `VisibleAfterEnd` control the visibility of objects outside the time range of their animation set by `TimeBegin` and `TimeEnd`. See `TimeBegin`, `TimeEnd` for details.

`VisibleAfter`, `VisibleBefore`, `VisibleFromTo` provide short cuts for suitable settings of the attributes `TimeBegin`, `VisibleBeforeBegin`, `TimeEnd`, `VisibleAfterEnd` that produce the desired visibility effects.

`VisibleAfter = t0` is a short cut for setting the following attribute values:

`TimeBegin = t0`, `VisibleBeforeBegin = FALSE`,

`TimeEnd = t0`, `VisibleAfterEnd = TRUE`.

The resulting effect is that the corresponding object is invisible at the beginning of the animation. It becomes visible at the time  $t_0$ , staying visible until the end of the animation.

# VisibleAfter, VisibleBefore, VisibleFromTo

---

The time  $t_0$  has to be a real numerical value giving the real time in seconds.

`VisibleBefore = t1` is a short cut for setting the following attribute values:

`TimeBegin = t1, VisibleBeforeBegin = TRUE,`

`TimeEnd = t1, VisibleAfterEnd = FALSE.`

The resulting effect is that the corresponding object is visible at the beginning of the animation. At the time  $t_1$  it becomes invisible, staying invisible until the end of the animation.

The time  $t_1$  has to be a real numerical value giving the real time in seconds.

`VisibleFromTo = t0 .. t1` is a short cut for setting the following attribute values:

`TimeBegin = t0, VisibleBeforeBegin = FALSE,`

`TimeEnd = t1, VisibleAfterEnd = FALSE.`

The resulting effect is that the corresponding object is visible only from the time  $t_0$  until the time  $t_1$ .

---

**Note** The attributes `VisibleAfter = t0` and `VisibleBefore = t1` should not be combined to create visibility for the time range between  $t_0$  and  $t_1$ . (Conflicting values are set implicitly for `VisibleBeforeBegin` etc.) Use `VisibleFromTo = t0 .. t1` instead.

---

---

**Note** `VisibleAfter`, `VisibleBefore`, `VisibleFromTo` should not be combined with any of the the attributes `TimeBegin`, `TimeEnd`, `VisibleBeforeBegin` or `VisibleAfterEnd`, since implicit values for these attributes are set.

---

# VisibleAfter, VisibleBefore, VisibleFromTo

## Examples

### Example 1

The following animation consists of 100 pieces of the graph of the function  $x\sin(x)$ . At the times  $t = 0.1, 0.2$  etc., an additional piece of the function becomes visible until, finally, the whole graph is built up:

```
plot(plot::Function2d(x*sin(x), x = (i - 1)*PI/100 .. i*PI/100,
 VisibleAfter = i/10) $ i = 1..100)
```

### Example 2

This example creates an animated “spider net”. It consists of several lines which appear one after the other at the times given by `VisibleAfter` until the full net is visible at the end of the animation:

```
SpiderNet :=
proc(move, move1, rc, gc, bc)
 local r, lines, x, y, x1, y1;
begin
```

# VisibleAfter, VisibleBefore, VisibleFromTo

---

```
r := 1.0:
lines := [FAIL $ 361]:
for i from 0 to 360 do
 thet := float(i*PI/180);
 x := r * cos(move * thet);
 y := r * sin(move * thet);
 x1 := r * cos(move1 * thet);
 y1 := r * sin(move1 * thet);
 lines[i+1] :=
 plot::Line2d([x, y] , [x1, y1],
 Color = [abs(rc*sin(i*PI/360)),
 abs(gc*sin(i*PI/360 + PI/4)),
 abs(bc*sin(i*PI/360 + PI/2))],
 VisibleAfter = i/36
);
end_for:
plot::Group2d(op(lines), Name = "SpiderNet",
 Axes = None, Scaling = Constrained)
end_proc:

plot(SpiderNet(3, 7, 0.9, 0.1, 0.5))
```

# VisibleAfter, VisibleBefore, VisibleFromTo

---

```
delete SpiderNet:
```

### Example 3

This example creates an animated “Maurer rose”. Here the animation starts with the full object. During the animation the lines disappear at the times given by `VisibleBefore`:

```
MaurerRose := proc(n, b, rc, gc, bc)
 local lines, i, thet, r, x, y, x1, y1;
begin
 r := 1.0;
 lines := [FAIL $ 361];
 b := float(b*PI/180);
 for i from 0 to 360 do
 thet := float(i*PI/180);
 x := r * sin(n*thet) * cos(thet);
 y := r * sin(n*thet) * sin(thet);
 x1 := r * sin(n*(thet+b)) * cos(thet+b);
```

# VisibleAfter, VisibleBefore, VisibleFromTo

---

```
y1 := r * sin(n*(thet+b)) * sin(thet+b);
lines[i+1] :=
 plot::Line2d([x, y], [x1, y1],
 Color = [abs(rc*sin(i*PI/360)),
 abs(gc*sin(i*PI/360 + PI/4)),
 abs(bc*sin(i*PI/360 + PI/2))],
 VisibleBefore = i/36
);
end_for:
plot::Group2d(op(lines), Name = "MaurerRose",
 Axes = None, Scaling = Constrained):
end_proc:

plot(MaurerRose(4, 120, 0.1, 0.5, 0.9)):
```

```
delete MaurerRose:
```

# VisibleAfter, VisibleBefore, VisibleFromTo

---

## Example 4

This example creates an animated “Lissajous net”. It is built up from lines that have a life span of only 2 seconds each, set by `VisibleFromTo`:

```
LissajousNet := proc(r, a, b, R, A, B, rc, gc, bc)
 local lines, i, thet;
begin
 lines := [FAIL $ 361]:
 for i from 0 to 360 do
 thet := float(i*PI/180);
 x := r * cos(a*thet);
 y := r * sin(b*thet);
 x1 := R * cos(A*thet);
 y1 := R * sin(B*thet);
 lines[i+1] :=
 plot::Line2d([x, y], [x1, y1],
 Color = [abs(rc*sin(i*PI/360)),
 abs(gc*sin(i*PI/360 + PI/4)),
 abs(bc*sin(i*PI/360 + PI/2))],
 VisibleFromTo = i/36 .. i/36 + 2
);
 end_for:
 plot::Group2d(op(lines), Name = "LissajousNet",
 Axes = None, Scaling = Constrained):
end_proc:

plot(LissajousNet(2, 3, 4, 1, 6, 3, 0.7, 0.1, 0.99))
```

```
delete LissajousNet:
```

## Example 5

Here is a 3D example of an animation. A “spider net” is built up with lines that have a life span of 4 seconds each:

```
SpiderNet3d := proc(a, b, c, rc, gc, bc)
 local r, lines, i, x, x1, y, y1, thet, z1, z;
begin
 r := 1.0;
 lines := [FAIL $ 361]:
 for i from 0 to 360 do
 thet := float(i*PI/180);
 x := r * cos(thet)*cos(thet);
 y := r * sin(thet)*cos(thet);
 z := r * sin(thet);
 x1 := r * cos(a*thet)*cos(a*thet);
 y1 := r * sin(b*thet)*cos(b*thet);
```

# VisibleAfter, VisibleBefore, VisibleFromTo

---

```
z1 := r * sin(c*thet):
lines[i+1] :=
 plot::Line3d([x,y,z],[x1,y1,z1],
 Color = [abs(rc*sin(i*PI/360)),
 abs(gc*sin(i*PI/360 + PI/4)),
 abs(bc*sin(i*PI/360 + PI/2))],
 VisibleFromTo = i/36 .. i/36 + 4
);
end_for:
plot::Group3d(op(lines), Name = "SpiderNet3d"):
end_proc:

plot(SpiderNet3d(2, 1, 3, 0.99, 0.9, 0.1))
```

## Algorithms

The last examples on this page are taken from the mathPAD Online Edition (<http://www.mupad.com/mathpad/recreations.html>) written

# VisibleAfter, VisibleBefore, VisibleFromTo

---

by Prof. Mirek Majewski. See there for details about the mathematics behind the examples above.

- “Frame by Frame Animations”

# VisibleBeforeBegin, VisibleAfterEnd

---

<b>Purpose</b>	Object visible before or after its animation time starts?
<b>Value Summary</b>	VisibleAfterEnd, Inherited FALSE, or TRUE VisibleBeforeBegin
<b>Description</b>	<p>VisibleBeforeBegin, VisibleAfterEnd determine the visibility of an object before the begin and after the end of its own animation time span, respectively.</p> <p>Animations are defined object by object. Each animated object is animated for a certain time span specified by TimeBegin and TimeEnd setting the real start and end time in seconds.</p> <p>The total real time span of an animated plot is the physical real time given by the minimum of the TimeBegin values of all animated objects in the plot to the maximum of the TimeEnd values of all the animated objects.</p> <p>Thus, the time span of an animated plot may be larger than the time spans of the animations of individual objects.</p> <p>With VisibleBeforeBegin = TRUE, an object is visible as a static object when the animation of the entire plot starts. Its state corresponds to the start of its own animation. It begins to change, when the starting time of its own animation set by TimeBegin is reached.</p> <p>With VisibleBeforeBegin = FALSE, an object is invisible when the animation of the entire plot starts. It becomes visible when the starting time of its own animation is reached.</p> <p>With VisibleAfterEnd = TRUE, an object stays visible in the final state of its animation after the end of its own animation time span set by TimeEnd.</p> <p>With VisibleAfterEnd = FALSE, an object becomes invisible at the end of its own animation.</p>

# VisibleBeforeBegin, VisibleAfterEnd

`VisibleBeforeBegin`, `VisibleAfterEnd` is useful only in plots consisting of several animated objects with different time spans of their animations.

Also consider the attributes `VisibleAfter`, `VisibleBefore`, and `VisibleFromTo` to animate the visibility of objects.

## Examples

### Example 1

In the first 5 seconds of the following animation, the sine function draws itself. Afterwards, a point wanders along the graph:

```
f := plot::Function2d(sin(x), x = -PI..a, a = -PI..PI,
 TimeRange = 0..5):
p := plot::Point2d(a, sin(a), PointSize = 5*unit::mm,
 a = -PI..PI, TimeRange = 5..10):
plot(f, p)
```

# VisibleBeforeBegin, VisibleAfterEnd

The point is visible for the first 5 seconds, too, because it used the default setting `VisibleBeforeBegin = TRUE`. With `VisibleBeforeBegin = FALSE`, the point is invisible at the start of the animation. It appears after 5 seconds, when its own animation begins:

```
p::VisibleBeforeBegin := FALSE:
plot(f, p)
```

```
delete p, f:
```

## Example 2

The `plot::Polar` object in the following animation is only visible in its `TimeRange` from the 3rd to the 7th second:

```
Speaker :=
 plot::Polygon2d([[0.5, -1], [0.5, 1], [0, 0.3],
 [-0.5, 0.3], [-0.5, -0.3], [0, -0.3],
 [0.5, -1]], Color = RGB::Black, Filled):
```

# VisibleBeforeBegin, VisibleAfterEnd

---

```
Point := plot::Point2d([2, a], a = -2.5..2.5,
 PointSize = 3*unit::mm):

plot(plot::Polar([1 + 0.1*(2 + sin(20*a))*cos(20*phi)], phi],
 phi = -1..1, a = 0..3, TimeRange = 3..7,
 VisibleBeforeBegin = FALSE,
 VisibleAfterEnd = FALSE),
 Speaker, Point, Axes = None)
```

The previous command is equivalent to:

```
plot(plot::Polar([1 + 0.1*(2 + sin(20*a))*cos(20*phi)], phi],
 phi = -1..1, a = 0..3, VisibleFromTo = 3..7),
 Speaker, Point, Axes = None)
```

# VisibleBeforeBegin, VisibleAfterEnd

---

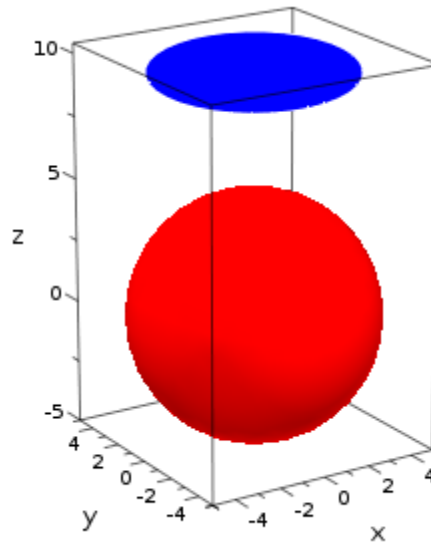

```
delete Speaker, Point:
```

## Example 3

A circle is tumbling around in 3D. After 3 seconds, a growing sphere becomes visible. From the 5th second through to the end of the animation, the sphere stays visible with the constant radius 5, while the circle moves further out:

```
plot(plot::Circle3d(4, [sin(a), cos(a), a],
 [sin(a), cos(a), a], a = 0..10,
 Frames = 100, TimeRange = 0..10,
 Filled = TRUE, FillColor = RGB::Blue),
 plot::Sphere(a, [0, 0, 0], Color=RGB::Red,
 a = 3..5, TimeRange = 3 .. 5, Frames = 20,
 VisibleBeforeBegin = FALSE)):
```

# Footer, Header

---

**Purpose** Footer text

**Value Summary** Footer, Header Optional Text string

## Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	

**Description** Footer = " " sets a text to be displayed at the bottom of a scene or canvas.  
Header = " " sets a text to be displayed at the top of a scene or canvas.  
As described in the introduction, each plot consists of a canvas containing one or more scenes. Using Header and Footer, you can set captions for both levels of nesting, above and/or below the contents.  
To change the appearance of the captions, please use the attributes FooterAlignment and HeaderAlignment for positioning and FooterFont and HeaderFont to control fonts and sizes.

## Examples **Example 1**

The easiest way of setting a caption is to include a canvas-caption in a plot command:

```
plot(plot::Function2d(sin(x), x = 0..2*PI),
 Footer = "the sine function");
```

the sine function

You can also set style controlling attributes in this context:

```
plot(plot::Function2d(sin(x), x = 0..2*PI),
 Header = "the sine function",
 HeaderFont = ["Monotype Corsiva", 17, RGB::Red],
 HeaderAlignment = Left):
```

## the sine function

### Example 2

Advanced users may want to plot several scenes together. These can be given individual captions:

```
f1 := plot::Function3d(sin(x^2 + y^2)*(x^2 + y^2),
 x = -3..3, y = -3 ..3,
 AdaptiveMesh = 0):
f2 := plot::modify(f1, AdaptiveMesh = 2):

s1 := plot::Scene3d(f1, Footer = "AdaptiveMesh = 0"):
s2 := plot::Scene3d(f2, Footer = "AdaptiveMesh = 2"):
plot(s1, s2, Layout = Horizontal)
```

AdaptiveMesh = 0

AdaptiveMesh = 2

| [Title](#)

# FooterAlignment, HeaderAlignment

---

**Purpose** Alignment of footer of canvas and scenes

**Value Summary** FooterAlignment, HeaderAlignment Inherited Center, Left, or Right

## Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	FooterAlignment, HeaderAlignment: Center

**Description** Using the attributes Footer and Header, a canvas or scene can be given a caption. FooterAlignment and HeaderAlignment control the horizontal alignment of these captions.

## Examples

### Example 1

Using the default placement, a footer is centered:

```
plot(plot::Point2d([1,1]), Footer="Point2d")
```

# FooterAlignment, HeaderAlignment

---

We may want to place the footer more to the right:

```
plot(plot::Point2d([1,1]), Footer="Point2d",
 FooterAlignment = Right)
```

# FooterAlignment, HeaderAlignment

---

Point2d

[HorizontalAlignment](#) | [VerticalAlignment](#) | [LegendAlignment](#)

# HorizontalAlignment, TitleAlignment, VerticalAlignment

**Purpose** Horizontal alignment of text objects w.r.t. their coordinates

**Value Summary**

HorizontalAlignment, Inherited	Center, Left, or Right
TitleAlignment	
VerticalAlignment Inherited	BaseLine, Bottom, Center, or Top

## Graphics Primitives

Objects	Default Values
plot::Text2d, plot::Text3d	HorizontalAlignment: Left TitleAlignment: Center VerticalAlignment: BaseLine
plot::Integral	HorizontalAlignment: Left TitleAlignment: Center VerticalAlignment: Bottom

**Description** TitleAlignment controls the interpretation of the TitlePosition of the titles of graphical objects.

HorizontalAlignment and VerticalAlignment control the interpretation of the coordinates of text objects.

Titles of graphical objects are placed at the position defined by TitlePosition. TitleAlignment determines whether the beginning, the center, or the end of the title text is aligned at this position. See “Example 1” on page 23-1774.

Text objects (i.e., objects of type plot::Text2d or plot::Text3d) carry, in their Position attribute, a position. HorizontalAlignment and VerticalAlignment together determine which point of the text this position refers to. For example, with HorizontalAlignment = Left and VerticalAlignment = Bottom, the given position is the lower left corner of the rendered text.

# HorizontalAlignment, TitleAlignment, VerticalAlignment

## Examples

### Example 1

We plot three points with title positions 0.1 above each point. The titles are aligned such that the beginning of the text (Left), the center of the text (Center), or the end of the text (Right) is at the TitlePosition:

```
plot(plot::Point2d(0, 0, Title = "Point 1",
 TitlePosition = [0, 0.1],
 TitleAlignment = Left),
 plot::Point2d(1, 1, Title = "Point 2",
 TitlePosition = [1, 1.1],
 TitleAlignment = Center),
 plot::Point2d(2, 2, Title = "Point 2",
 TitlePosition = [2, 2.1],
 TitleAlignment = Right),
 PointSize = 2.5*unit::mm)
```

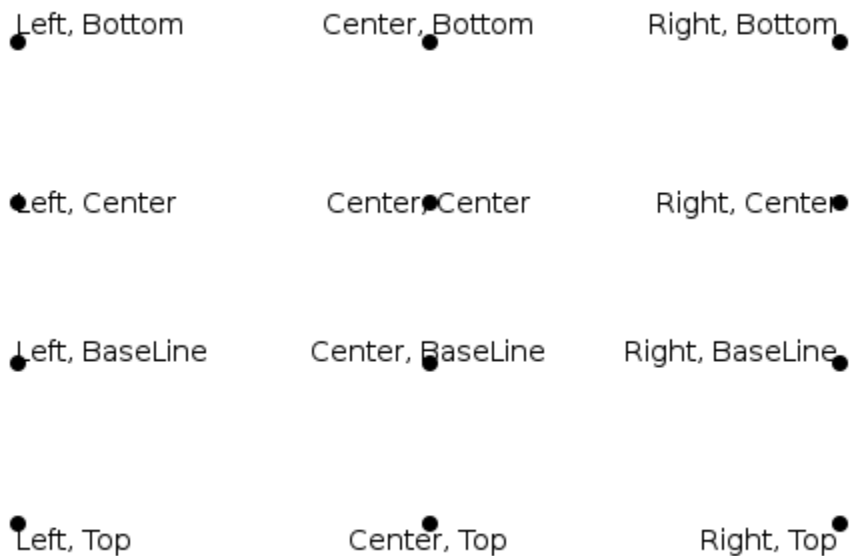

# HorizontalAlignment, TitleAlignment, VerticalAlignment

---

## Example 2

The following call generates a table showing all the combinations of HorizontalAlignment and VerticalAlignment:

```
Hor := [Left, Center, Right]:
Vert := [Top, BaseLine, Center, Bottom]:
plot((plot::Text2d(expr2text(Hor[i], Vert[j]), [i, j],
 HorizontalAlignment = Hor[i],
 VerticalAlignment = Vert[j]),
 plot::Point2d([i, j], Color = RGB::Black))
 $ i = 1..3 $ j = 1..4, Axes = None,
 TitleFont = [13], PointSize = 2.5*unit::mm)
```

```
delete Hor, Vert:
```

# HorizontalAlignment, TitleAlignment, VerticalAlignment

---

## See Also

## MuPAD Functions

Position | Title | TitlePosition

**Purpose** Makes a legend entry

**Value Summary** Library wrapper for LegendText, LegendEntry, and LegendVisible See below

**Description** Legend makes a legend entry and activates the legend. Legend is a library wrapper which sets a LegendText and simultaneously switches the legend on by setting LegendEntry and LegendVisible to TRUE.

**Examples** **Example 1**

Legend is used to set a LegendText for the function and activate the legend. The line does not appear in the legend:

```
plot(plot::Function2d(cos(x), x = 0..2*PI, Legend = "cos(x)"),
 plot::Line2d([0, 1], [4, cos(4)], Color = RGB::Black))
```

# Legend

---

## See Also

## MuPAD Functions

[LegendAlignment](#) | [LegendEntry](#) | [LegendPlacement](#) |  
[LegendText](#) | [LegendVisible](#)

## Concepts

- “Legends”

**Purpose** Add this object to the legend?

**Value Summary** Inherited FALSE, or TRUE

**Description** LegendEntry turns legend entries of individual objects on and off, if LegendVisible is TRUE.

---

**Note** LegendEntry is a technical internal attribute. You will most likely want to use the library interface attribute Legend in order to set legend entries.

---

If legends are active (i.e., LegendVisible is set to TRUE), LegendEntry controls which objects have entries in the legend. Only objects with LegendEntry = TRUE show up there.

As long as LegendVisible has its default value of FALSE, LegendEntry has no effect whatsoever.

## Examples

### Example 1

By default, functions have LegendEntry = TRUE, while, e.g., lines do not:

```
plot(plot::Function2d(cos(x), x = 0..2*PI, Name = "cos(x)"),
 plot::Line2d([0, 1], [4, cos(4)], Name = "cos(0) .. cos(4)"
 Color = RGB::Black),
 LegendVisible)
```

# LegendEntry

---

Use LegendEntry to turn on the legend entry for the line:

```
plot(plot::Function2d(cos(x), x = 0..2*PI, Name = "cos(x)"),
 plot::Line2d([0, 1], [4, cos(4)], Name = "cos(0) .. cos(4)",
 Color = RGB::Black, LegendEntry = TRUE),
 LegendVisible)
```

## See Also

## MuPAD Functions

[Legend](#) | [LegendAlignment](#) | [LegendPlacement](#) | [LegendText](#) | [LegendVisible](#)

## Concepts

- “Legends”

# LegendAlignment, LegendPlacement, LegendVisible

---

**Purpose** Legend at left, center, or right

**Value Summary**

LegendAlignment	Inherited	Center, Left, or Right
LegendPlacement	Inherited	Bottom, or Top
LegendVisible	Inherited	FALSE, or TRUE

## Graphics Primitives

Objects	Default Values
plot::Scene2d, plot::Scene3d	LegendAlignment: Center LegendPlacement: Bottom LegendVisible: FALSE

## Description

LegendVisible activates a legend identifying the individual objects in a plot.

LegendAlignment and LegendPlacement control the placement of this legend.

For complex plots with multiple objects, it is often helpful to include an explanation in form of a legend that states the connection from object color to object meaning.

The entry for “object meaning” is usually not provided automatically but must be given using LegendText. As an exception, plotfunc2d and plotfunc3d set the function terms as “meaning”. Cf. “Example 1” on page 23-1783.

Using LegendPlacement, the legend can be moved from below the plot to above it. LegendAlignment controls whether the legend is displayed flush left, flush right, or centered (which is the default).

# LegendAlignment, LegendPlacement, LegendVisible

## Examples

### Example 1

When plotting more than one object, `plotfunc2d` and `plotfunc3d` set `LegendVisible = TRUE`:

```
plotfunc2d(sin(x), cos(x))
```

It is possible to explicitly switch this automatic legend off:

```
plotfunc2d(sin(x), cos(x), LegendVisible = FALSE)
```

# LegendAlignment, LegendPlacement, LegendVisible

---

Using `LegendPlacement` and `LegendAlignment`, we place the legend in the upper right corner of the graphics:

```
plotfunc2d(sin(x), cos(x),
 LegendPlacement = Top, LegendAlignment = Right)
```

# LegendAlignment, LegendPlacement, LegendVisible

## Example 2

When plotting many objects with active legend entries, the legend is abbreviated: It will never take up more than half of the scene height and it will not contain more than 20 entries:

```
plotfunc2d(-i*x^3+i/10*x^2+x-i $ i = -15..15, x=-1..1)
```

# LegendAlignment, LegendPlacement, LegendVisible

```
plotfunc2d(-i*x^3+i/10*x^2+x-i $ i = -15..15, x=-1..1,
Height = 15*unit::cm)
```

# LegendAlignment, LegendPlacement, LegendVisible

- 15\*x^3 - (3\*x^2)/2 + x + 15
- 14\*x^3 - (7\*x^2)/5 + x + 14
- 13\*x^3 - (13\*x^2)/10 + x + 13
- 12\*x^3 - (6\*x^2)/5 + x + 12
- 11\*x^3 - (11\*x^2)/10 + x + 11
- 10\*x^3 - x^2 + x + 10
- 9\*x^3 - (9\*x^2)/10 + x + 9
- 8\*x^3 - (4\*x^2)/5 + x + 8
- 7\*x^3 - (7\*x^2)/10 + x + 7
- 6\*x^3 - (3\*x^2)/5 + x + 6
- 5\*x^3 - x^2/2 + x + 5
- 4\*x^3 - (2\*x^2)/5 + x + 4
- 3\*x^3 - (3\*x^2)/10 + x + 3
- 2\*x^3 - x^2/5 + x + 2
- x^3 - x^2/10 + x + 1
- x
- x^3 + x^2/10 + x - 1
- 2\*x^3 + x^2/5 + x - 2
- 3\*x^3 + (3\*x^2)/10 + x - 3
- 4\*x^3 + (2\*x^2)/5 + x - 4

# LegendAlignment, LegendPlacement, LegendVisible

---

## See Also

## MuPAD Functions

[Legend](#) | [LegendFont](#) | [LegendText](#)

**Purpose** Short explanatory text for legend

**Value Summary** Optional Text string

**Description** LegendText sets the text for the legend entry of an object.

---

**Note** LegendText is a technical internal attribute. You will most likely want to use the library interface attribute Legend in order to set legend entries.

---

To have a legend entry, the object must have Legend set to TRUE and LegendVisible must be TRUE for the enclosing scene. Cf. “Example 1” on page 23-1789.

If LegendText is unset, but Legend and LegendVisible are TRUE, the legend entry is taken from the attribute Name. If that is unset, too, the name of the object type is displayed. Cf. “Example 2” on page 23-1791.

## Examples

### Example 1

We create a few objects with values for LegendText set:

```
f := plot::Function2d(sin(x), x = 0..PI,
 LegendText = "f(x)", Color = RGB::Red):
g := plot::Function2d(cos(x), x = 0..PI,
 LegendText = "f'(x)", Color = RGB::Blue):
p := plot::Point2d([2, sin(2)], PointSize = 3*unit::mm,
 LegendText = "(2; f(2))", Color = RGB::Black)
```

Switching on the legend, we plot these objects:

```
plot(f, g, p, LegendVisible = TRUE)
```

# LegendText

---

As we can see, only the function objects show up in the legend. If  $p$  is supposed to be shown there, too, we must explicitly set `LegendEntry` to `TRUE`:

```
p::LegendEntry := TRUE:
plot(f, g, p, LegendVisible = TRUE)
```

### Example 2

If an object has a legend entry, but `LegendText` is not set, the first fall-back is the `Name` attribute of the object:

```
plot(plot::Function3d(sin(x^2 + y^2), x = -2..2, y = -2..2,
 Color = RGB::Green, FillColorType = Flat,
 LegendText = "LegendText: sin",
 Name = "Name: sin"),
 plot::Function3d(cos(x + y), x = -2..2, y = -2..2,
 Color = RGB::Blue, FillColorType = Flat,
 Name = "Name: cos"),
 LegendVisible)
```

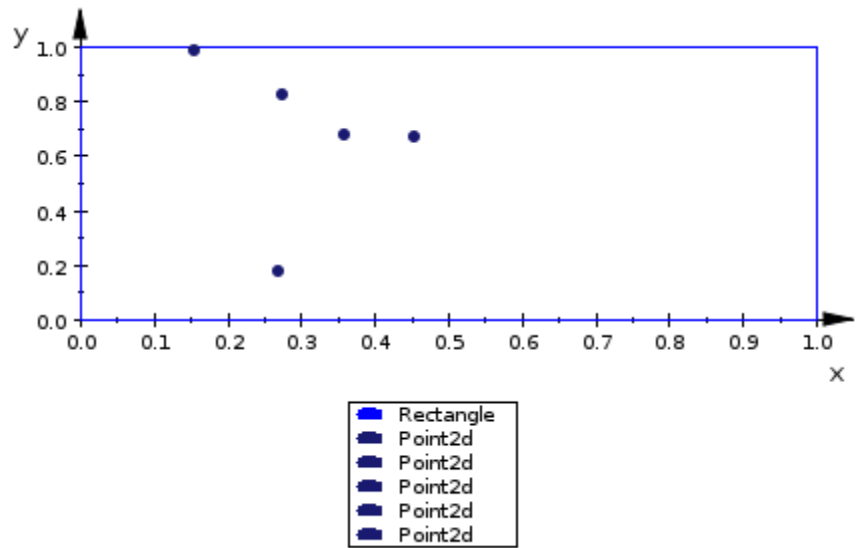

# LegendText

---

As a last resort, the name of the type of object is used:

```
plot(plot::Rectangle(0..1, 0..1),
 plot::Point2d(frandom(), frandom()),
 plot::Point2d(frandom(), frandom()),
 plot::Point2d(frandom(), frandom()),
 plot::Point2d(frandom(), frandom()),
 plot::Point2d(frandom(), frandom()),
 LegendEntry = TRUE, LegendVisible = TRUE)
```

# ShowInfo

---

**Purpose** Information about integral approximation

**Value Summary** Optional List of arithmetical expressions

## Graphics Primitives

Objects	ShowInfo Default Values
<code>plot::Integral</code>	<code>[2, IntMethod, Integral]</code>

## Description

ShowInfo defines the text information displayed by `plot::Integral`.

In `plot::Integral`, text information about the used approximation method, the values of the approximation and the exact integral, the number of subintervals and the error of the approximation can be displayed within the approximation object.

The attribute is specified by `ShowInfo = [entry1, entry2, ...]` with a list of various entries. The user may specify the entries in arbitrary order.

If the list is empty, no text information is displayed.

Each entry in the list can be of one of the following types:

- an arbitrary string

In the text, this entry is appended to the current line. No white space or line break is prepended or appended. The string itself, however, may contain white space or a line break (given by `\n`).

- "" (empty string)

This inserts an empty line in the text.

- IntMethod

In the text, this creates a new line

`name: float_value,`

where `name` is the value of the attribute `IntMethod` and `float_value` is the numerical value of the integral approximation. This value is computed internally and inserted in the text, automatically.

- `IntMethod = name`

In the text, this creates a new line

```
name: float_value,
```

where `float_value` is the numerical value of the integral approximation.

If `name` is one of the flags `RiemannLower` etc. listed on the help page of the attribute `IntMethod`, this flag is displayed in the text.

Alternatively, `name` may be a string. When `name` is the empty string `" "`, only the numerical approximation of the integral value is displayed.

- `Integral`

In the text, this creates a new line

```
Integral: float_value,
```

where `float_value` is a high precision float approximation of the exact integral value.

- `Integral = string`

In the text, this creates a new line

```
string: float_value,
```

where `string` is an arbitrary text string and `float_value` is a high precision float approximation of the exact integral value .

When `string` is the empty string `" "`, only the high precision approximation `float_value` is displayed.

- `Error`

In the text, this creates a new line

```
Error: float_value,
```

# ShowInfo

---

where `float_value` is the absolute difference between the numerical value obtained by the chosen approximation method and a high precision float approximation of the exact integral value.

- `Error = string`

In the text, this creates a new line

```
string: float_value,
```

where `string` is an arbitrary text string and `float_value` is the absolute difference between the numerical value obtained by the chosen approximation method and a high precision float approximation of the exact integral value.

When `string` is the empty string "", only the absolute quadrature error `float_value` is displayed.

- `Nodes`

In the text, this creates a new line

```
Nodes: n,
```

where the integer `n` is the number of intervals used for the integral approximation.

- `Nodes = string`

In the text, this creates a new line

```
string: n,
```

where `string` is an arbitrary text string and the integer `n` is the number of intervals used for the integral approximation.

When `string` is the empty string "", only the integer `n` is displayed.

- `Position = [X, Y]`

This entry determines the position of the text information. `X` and `Y` are the coordinates of the anchor point of the text. The alignment of the text with respect to the anchor point can be chosen by the attributes `HorizontalAlignment` and `VerticalAlignment`.

- a positive integer `digits`

The integer `digits` determines the number of digits after the decimal point for all following float values.

Different float values can be displayed with a different number of digits by inserting several `digits` entries at appropriate positions in the list.

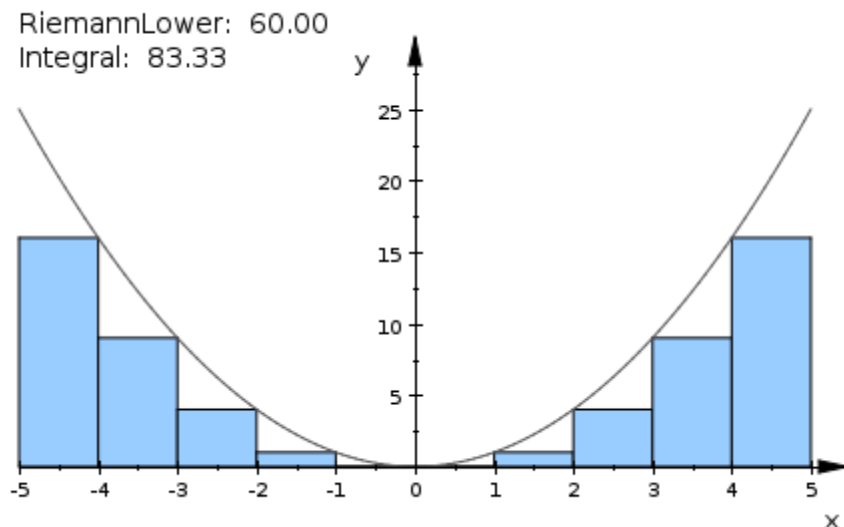

Without an explicit specification of `Position = [X, Y]`, the text is positioned automatically.

## Examples

### Example 1

By default, the approximation method, the value of approximation and the integral is displayed with 2 digits after the decimal point:

```
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannLower), f)
```

# ShowInfo

This call is equivalent to:

```
plot(plot::Integral(f, IntMethod = RiemannLower,
 ShowInfo = [2, IntMethod, Integral]), f):
```

The text can be changed:

```
plot(plot::Integral(f, IntMethod = RiemannLower,
 ShowInfo = [IntMethod = "value of the lower Riemann sum",
 Integral = "exact numerical value",
 Error = "difference"]), f)
```

```
value of the lower Riemann sum: 60.00
exact numerical value: 83.33
difference: 23.33
```

```
delete f:
```

## Example 2

The position can be specified explicitly. In this case, the entries to be displayed must be specified explicitly, too. The text attribute `VerticalAlignment` aligns the text object:

```
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannUpper, Color = RGB::Li
 ShowInfo = [IntMethod, Integral,
 Position = [-5, -1]],
 VerticalAlignment = Top),
 plot::Integral(f, IntMethod = RiemannLower, Color = RGB::Go
 ShowInfo = [IntMethod,
 Position = [0, -1]],
 VerticalAlignment = Top),
 f)
```

delete f:

### Example 3

The number of digits after the decimal point can be specified for each value. In the following example all values are displayed with four digits:

```
f := plot::Function2d(x^2*(x-4)*(x+2), x = -3..5,
```

# ShowInfo

```
Color = RGB::Black):
plot(plot::Integral(f, 4, IntMethod = Simpson,
LineColor = RGB::Red,
ShowInfo = [4, IntMethod, Integral, Error]),
f)
```

```
Simpson: -2.6667
Integral: -3.7333
Error: 1.0667
```

Only the error shall be displayed with four digits after the decimal point. All other values are shown with only one digit:

```
plot(plot::Integral(f, 4, IntMethod = Simpson, LineColor = RGB::Red,
ShowInfo = [1, IntMethod, Integral, 4, Error]),
f)
```

delete f:

#### Example 4

Two approximation objects shall be displayed in one plot. To prevent collision of the automatically positioned texts, we insert an empty line into the text of one of the objects to prevent collision of the automatically positioned texts:

```
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannUpper, Color = RGB::Ro
 ShowInfo = [IntMethod, "", Integral]),
 plot::Integral(f, IntMethod = RiemannLower,
 ShowInfo = [IntMethod, Integral]),
 f)
```

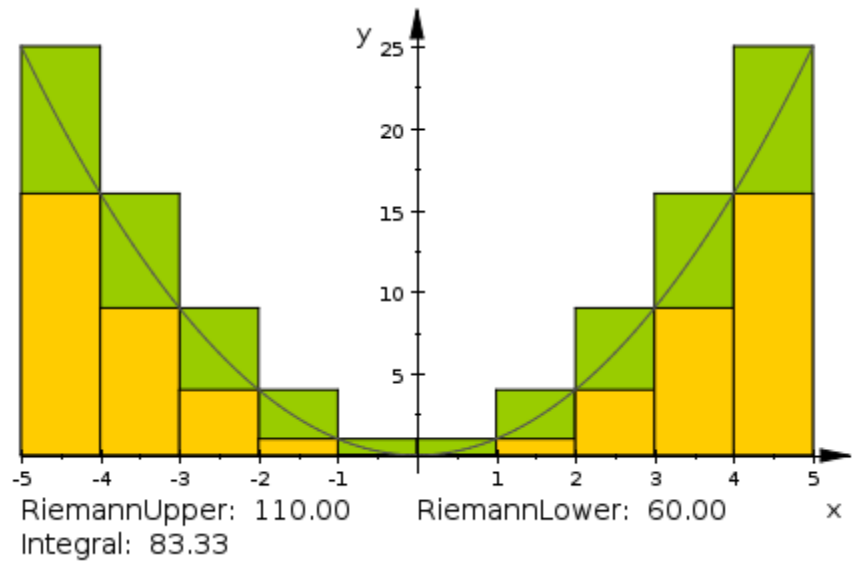

# ShowInfo

RiemannUpper: 110.00  
RiemannLower: 60.00  
Integral: 83.33

Alternatively, the position can be given explicitly:

```
f := plot::Function2d(x^2, x = -5..5, Color = RGB::DarkGrey):
plot(plot::Integral(f, IntMethod = RiemannUpper, Color = RGB::Lime,
 ShowInfo = [IntMethod, Integral,
 Position = [-5, -1]],
 VerticalAlignment = Top),
 plot::Integral(f, IntMethod = RiemannLower, Color = RGB::Gold,
 ShowInfo = [IntMethod,
 Position = [0, -1]],
 VerticalAlignment = Top),
 f)
```

`delete f:`

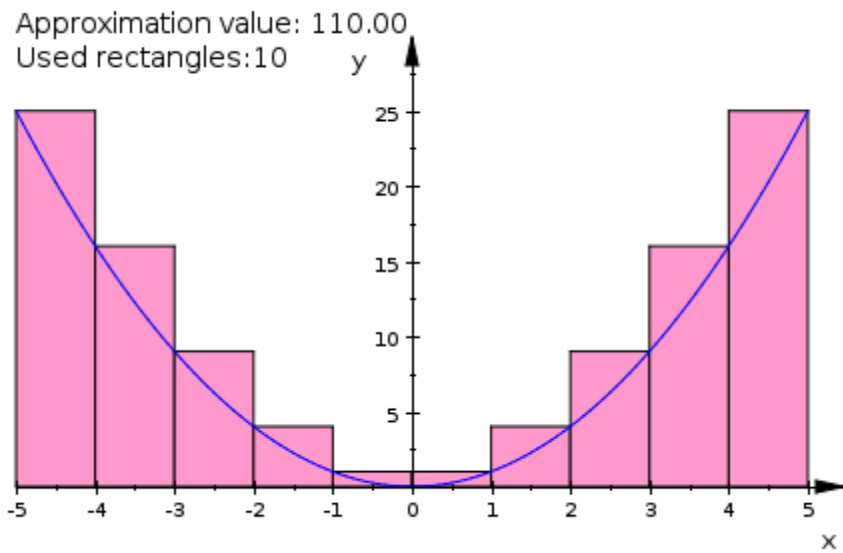

### Example 5

The text may contain additional messages:

```
f := plot::Function2d(x^2, x = -5..5):
plot(plot::Integral(f, IntMethod = RiemannUpper,
 ShowInfo = ["Approximation value:", IntMethod = "",
 "\nUsed rectangles:", Nodes = ""],
 Color = RGB::Rose),
 f)
```

# ShowInfo

---

delete f:

### MuPAD Functions

IntMethod | TextFont | TextRotation | HorizontalAlignment |  
VerticalAlignment

**Purpose** Object title

**Value Summary** Title, Titles Optional Text string

## Graphics Primitives

Objects	Default Values
plot::Piechart2d, plot::Piechart3d	Titles: [" "]

## Description

Title sets the title of an object to be displayed in the graphics.

Titles is a list of titles for parts of an object, e.g., the pieces of a pie chart.

Using Title, any graphical object can be given a title that will be displayed at the position given by the TitlePosition attribute.

The Title can additionally be horizontally aligned at the TitlePosition via TitleAlignment.

The object attribute Visible also affects the object's title: Invisible objects do not show their titles.

Titles is used to set a number of titles for sub-objects, such as the bars of a bar plot or the segments of a pie chart. These do not react to TitlePosition.

Title and Titles cannot be animated. But note that TitlePosition can.

## Examples

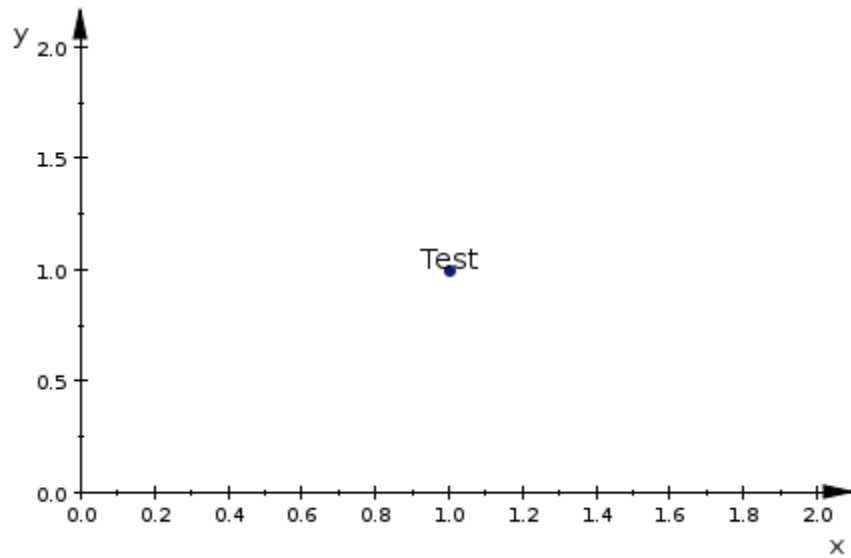

### Example 1

The default positioning of a title relative to TitlePosition is to have the lower left corner of the title at this place:

```
plot(plot::Point2d(1, 1, Title = "Test",
 TitlePosition = [1, 1]))
```

# Title, Titles

---

This position depends on the title alignment:

```
plot(plot::Point2d(1, 1, Title = "Test",
 TitlePosition = [1, 1],
 TitleAlignment = Left))
```

## Example 2

In 3D, titles have so-called “bill-boarding”: Instead of having a fixed orientation, they are always drawn in a readable orientation and their sizes are not affected by zooming and perspective scaling:

```
plot(plot::Point3d(1, 1, 1,
 Title = "Nr. 1",
 TitlePosition = [1, 1, 1]),
 plot::Point3d(2, 20, 2,
 Title = "Nr. 2",
 TitlePosition = [2, 20, 2]),
 plot::Point3d(10, 10, 10,
 Title = "Nr. 3",
 TitlePosition = [10, 10, 10]),
 TitleFont = [30])
```

# Title, Titles

---

## Example 3

Titles of invisible objects are invisible themselves. This also applies to objects that are temporarily invisible:

```
plot(plot::Point2d(i, i,
 Title = expr2text(i), TitlePosition = [i+1/10, i],
 VisibleAfter = i) $ i = 1..5,
 TimeRange = 0..5,
 ViewingBox = [0..5, 0..5])
```

## Example 4

Use Titles to label individual parts of statistical plots such as pie charts:

```
plot(plot::Piechart2d([3267, 2629, 4970, 18094,
 4189, 1236, 4003, 297],
 Titles = ["<= 1900", "1901-1918",
 "1919-1948", "1949-1978",
 "1979-1986", "1987-1990",
 "1991-2000", ">= 2001"]))
```

# Title, Titles

---

Note that pie charts with many pies are in general tricky to label nicely:

```
p := plot::Piechart3d([10601, 12330, 3388, 2593, 660, 1726,
 6078, 1760, 7956, 18052, 4049, 1066,
 4384, 2581, 2804, 2411],
 Titles = ["Baden-W rttemberg", "Bayern", "Berlin",
 "Brandenburg", "Bremen",
 "Hamburg", "Hessen",
 "Mecklenburg-Vorpommern",
 "Niedersachsen", "Nordrhein-Westfalen",
 "Rheinland-Pfalz", "Saarland", "Sachsen",
 "Sachsen-Anhalt", "Schleswig-Holstein",
 "Th ringen"]):
plot(p, Header = "Einwohner 2001")
```

```
p::Moves := [0.3]:
plot(p, Header = "Einwohner 2001")
```

# Title, Titles

---

## See Also

## MuPAD Functions

TitleAlignment | TitleFont | TitlePosition

# TitlePosition, TitlePositionX, TitlePositionY, TitlePositionZ

---

## Purpose

Position of object titles

## Value Summary

TitlePosition	Library wrapper for “[TitlePositionX, TitlePositionY]” (2D), “[TitlePositionX, TitlePositionY, TitlePositionZ]” (3D)	See below
TitlePositionX, TitlePositionY, TitlePositionZ	Optional	MuPAD expression

## Description

TitlePosition sets the position where the object title is displayed.

TitlePositionX, TitlePositionY, and TitlePositionZ refer to the individual components of TitlePosition.

An object can be given a title to be displayed in the graphic with the attribute Title. TitlePosition, TitlePositionX, TitlePositionY, TitlePositionZ determines the position of this title.

TitlePosition, TitlePositionX, TitlePositionY, TitlePositionZ determines the anchor point of the title, which is in 3D displayed in “bill-boarding mode,” which means that the text will always face the observer and will always be displayed in the same size, regardless of zooming or perspective. The alignment of the text w.r.t. the anchor point is further determined by the setting of TitleAlignment, cf. “Example 1” on page 23-1814.

MuPAD does not have automatic positioning of titles; to have a title properly positioned, TitlePosition must be set.

# TitlePosition, TitlePositionX, TitlePositionY, TitlePositionZ

---

## Examples

### Example 1

We plot three points with titles attached to them, changing the alignment. For demonstration purposes, the title positions coincide with the points:

```
plot(plot::Point2d(0, 3, Title = "Left", TitlePosition = [0, 3],
 TitleAlignment = Left),
 plot::Point2d(0, 2, Title = "Center", TitlePosition = [0, 2],
 TitleAlignment = Center),
 plot::Point2d(0, 1, Title = "Right", TitlePosition = [0, 1],
 TitleAlignment = Right),
 Axes = None, PointSize = 2.0*unit::mm,
 ViewingBox = [-1..1, 0..4])
```

### Example 2

A more realistic placement of titles is to separate them slightly from the points:

# TitlePosition, TitlePositionX, TitlePositionY, TitlePositionZ

---

```
plot(plot::Polygon2d([[0, 0], [5, 0], [9/5, 12/5]], Closed),
 plot::Point2d([0, 0], Title = "A",
 TitlePosition = [-0.2, -0.1]),
 plot::Point2d([5, 0], Title = "B",
 TitlePosition = [5.2, -0.1]),
 plot::Point2d([9/5, 12/5], Title = "C",
 TitlePosition = [2.0, 2.5]),
 Axes = None, TitleFont = [15], LineColor = RGB::Black,
 LineWidth = 0.5*unit::mm, PointSize = 3*unit::mm)
```

# Bottom, Left

---

**Purpose** Positioning of a scene in a canvas

**Value Summary** Bottom, Left      Optional      See below

## Graphics Primitives

Objects	Default Values
plot::Scene2d, plot::Scene3d	Bottom, Left: 0

## Description

With the canvas attribute `Layout` set to `Absolute` or `Relative`, scenes in the canvas can be scaled and positioned freely.

`Bottom = b` places the bottom side of a scene at a distance  $b$  above the bottom side of the canvas.

`Left = l` places the left hand side of a scene at a distance  $l$  to the right of the left hand side of the canvas.

The automatic layout schemes `Layout = Horizontal`, `Layout = Vertical`, and `Layout = Tabular` are available for a canvas that contains several scenes.

The canvas settings `Layout = Absolute` and `Layout = Relative` switch the automatic layout mode off and allow to position each scene freely via the attributes `Bottom` and `Left`, respectively. These attributes set the distances of the lower left corner of the scene to the bottom, respectively left hand side of the canvas. These values can be set separately for each scene.

---

**Note** `Bottom` and `Left` are only respected for plots with `Layout = Absolute` or `Layout = Relative`.

---

The following pictures illustrates the positioning of scenes in a canvas via the scene attributes `Bottom` and `Left`:

With `Layout = Absolute`, the distance of the lower left corner of the scene to the lower left corner of the canvas must be specified via physical lengths with a unit, e.g., `Bottom = 2*unit::mm`, `Left = 0.1*unit::inch`. Missing units are assumed to be mm.

With `Layout = Relative`, the distance of the bottom side of the scene to the bottom side of the canvas must be specified as a fraction of the canvas height, i.e., as a number between 0 and 1. The distance of the left hand side of the scene to the left hand side of the canvas must be specified as a fraction of the canvas width, i.e., as a number between 0 and 1.

The lower left corner of a scene may be placed outside the canvas. The parts of a scene outside the canvas are clipped.

## Bottom, Left

---

Overlapping scenes can be created. In such a situation it may be useful to create transparent scenes (without a background) via `BackgroundTransparent = TRUE`.

### Examples

#### Example 1

We demonstrate the layout of the canvas with `Layout = Absolute`. The scene `S1` is positioned automatically in the canvas using the default values `Bottom = 0`, `Left = 0`. The smaller scenes `S2` and `S3` are positioned explicitly via `Bottom` and `Left`:

```
S1 := plot::Scene3d(plot::Sphere(1, [0, 0, 0],
 Color = RGB::Red),
 Width = 70*unit::mm, Height = 70*unit::mm,
 BackgroundColor = RGB::Grey):
S2 := plot::Scene3d(plot::Box(-1..1, -1..1, -1..1,
 Color = RGB::Green),
 Width = 30*unit::mm, Height = 30*unit::mm,
 Left = 60*unit::mm, Bottom = 3*unit::mm):
S3 := plot::Scene3d(plot::Cone(1, [0, 0, 0], [0, 0, 1],
 Color = RGB::Blue),
 Width = 30*unit::mm, Height = 30*unit::mm,
 Left = 60*unit::mm, Bottom = 36*unit::mm):
plot(S1, S2, S3, Layout = Absolute,
 plot::Canvas::BorderWidth = 1.0*unit::mm,
 plot::Canvas::BorderColor = RGB::Black,
 plot::Canvas::Width = 92*unit::mm,
 plot::Canvas::Height = 72*unit::mm,
 plot::Scene3d::BorderWidth = 0.5*unit::mm,
 plot::Scene3d::BorderColor = RGB::Black):
```

We make the background of the small scenes transparent and switch the axes off:

```

S2::BackgroundTransparent := TRUE:
S2::Axes := None:
S3::BackgroundTransparent := TRUE:
S3::Axes := None:
plot(S1, S2, S3, Layout = Absolute,
 plot::Canvas::BorderWidth = 1.0*unit::mm,
 plot::Canvas::BorderColor = RGB::Black,
 plot::Canvas::Width = 92*unit::mm,
 plot::Canvas::Height = 72*unit::mm,
 plot::Scene3d::BorderWidth = 0.5*unit::mm,
 plot::Scene3d::BorderColor = RGB::Black):

```

## Bottom, Left

---

```
delete S1, S2, S3:
```

### Example 2

We demonstrate the layout of the canvas with `Layout = Relative`. Apart from the scene headers and the positioning via `Bottom` and `Left`, all scene attributes are set in the `plot` call via specifications such as `plot::Scene2d::Width` etc. This distinguishes the scene attributes from the canvas attributes `Width`, `BorderWidth` etc.

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI),
 Left = 0.02, Bottom = 0.46,
 Header = "the sine function");
S2 := plot::Scene2d(plot::Function2d(cos(x), x = 0..2*PI),
 Left = 0.51, Bottom = 0.46,
 Header = "the cosine function");
S3 := plot::Scene2d(plot::Function2d(tan(x), x = 0..PI),
 Left = 0.02, Bottom = 0.02,
 Header = "the tan function");
S4 := plot::Scene2d(plot::Function2d(cot(x), x = 0..PI),
```

```

Left = 0.51, Bottom = 0.02,
Header = "the cot function"):
plot(S1, S2, S3, S4, Layout = Relative,
Width = 120*unit::mm, Height = 80*unit::mm,
BorderWidth = 0.5*unit::mm,
HeaderFont = ["Times New Roman", 18, Bold],
Header = "trigonometric functions",
plot::Scene2d::Width = 0.475,
plot::Scene2d::Height = 0.42,
plot::Scene2d::BorderWidth = 0.2*unit::mm,
plot::Scene2d::HeaderFont =
["Times New Roman", Italic, 12]):

```

```

delete S1, S2, S3, S4:

```

## Bottom, Left

---

### See Also

**MuPAD  
Functions**

Layout

**Purpose** Heights and widths of canvases and scenes

**Value Summary** Height, Width      Inherited      Positive output size

## Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	Height: 80 Width: 120

## Description

Height = h and Width = w set the size of the canvas or scene to the height h and the width w.

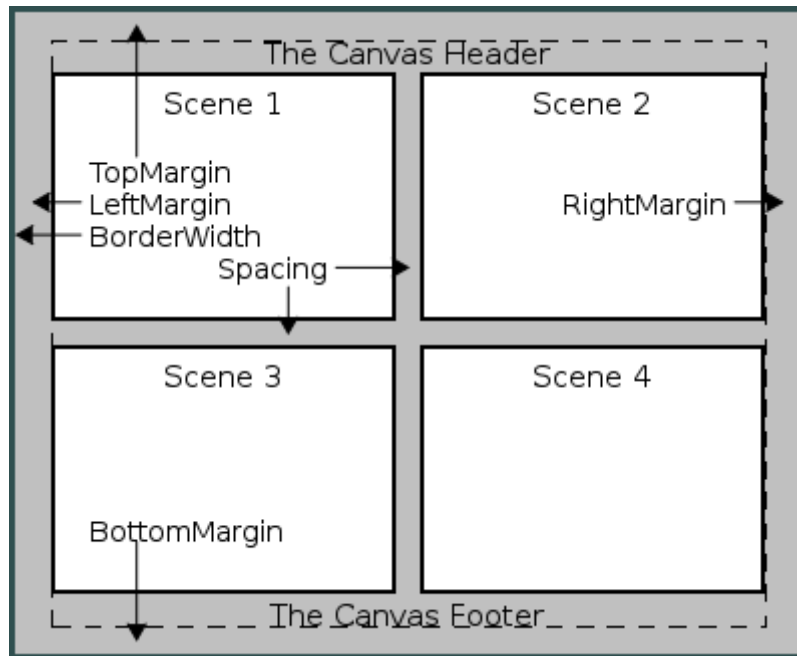

For the canvas, the width and the height should be specified as physical lengths with a unit, e.g., Width = 120\*unit::mm, Height = 4.72\*unit::inch. Numbers without a physical unit give the size in mm.

These values specify the (approximate) physical size of the canvas, with which the graphics appears on the screen. A printout of the MuPAD graphics will have this physical size precisely.

The following picture illustrates the layout of the canvas:

# Height, Width

---

The width and height of the canvas include the margin set by `Margin` and the border set by `BorderWidth`.

When only one scene is displayed in the canvas, this scene fills the canvas, i.e., the scene size coincides with the canvas size. When the canvas contains several scenes, there are various layout schemes, set by the canvas attribute `Layout`, to arrange the scenes in the canvas. Two schemes allow to set the size of the scenes independently of the canvas size:

---

**Note** For scenes, the attributes `Width` and `Height` are only used when plotting with the canvas attribute `Layout` set to `Absolute` or `Relative`.

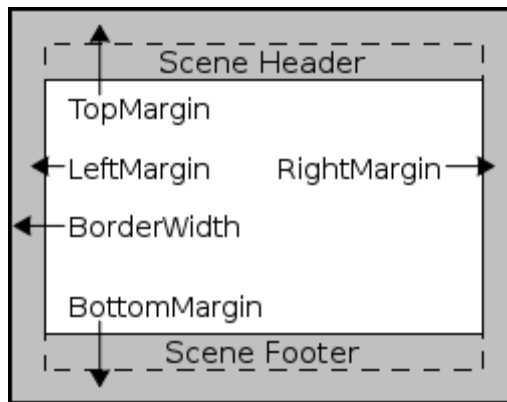

---

With `Layout = Absolute`, width and height of a scene must be specified as physical lengths with a unit, e.g., `Height = 40*unit::mm`, `Width = 2.4*unit::inch` (missing units are assumed to be mm).

With `Layout = Relative`, width and height of a scene must be specified as fractions of the canvas width and height, i.e., as numbers between 0 and 1.

The lower left corner of a scene can be moved to any position via the attributes `Bottom` and `Left`.

The following picture illustrates the layout of a scene:

The width and height of the scene include the margin set by `Margin` and the border set by `BorderWidth`.

If a scene exceeds the canvas, the corresponding parts of the scene are clipped.

## Examples

### Example 1

The following calls produce plots of the physical sizes 8.4 cm and 11.7 cm, respectively.

```
f := plot::Function2d(sin(x), x = 0..2*PI):
plot(f, Width = 80*unit::mm, Height = 4*unit::cm,
```

# Height, Width

---

```
BorderWidth = 1.0*unit::mm):
```

```
plot(f, Width = 110*unit::mm, Height = 7*unit::cm,
 BorderWidth = 1.0*unit::mm):
```

```
delete f:
```

## Example 2

In the following graphics, we place two scenes in one canvas:

```
f1 := plot::Function2d(sin(x), x = 0..2*PI):
f2 := plot::Function2d(cos(x), x = 0..2*PI):
S1 := plot::Scene2d(f1, BorderWidth = 0.5*unit::mm,
 Height = 7*unit::cm, Width = 11*unit::cm):
S2 := plot::Scene2d(f2, BorderWidth = 0.5*unit::mm,
 Height = 3*unit::cm, Width = 5*unit::cm):
plot(S1, S2, Layout = Horizontal, BorderWidth = 1.0*unit::mm,
 Height = 7*unit::cm, Width = 11*unit::cm):
```

Note that with `Layout = Horizontal`, the size attributes of the scenes were ignored in the plot above. They affect the graphic when switching `Layout` to `Absolute`, either interactively in the inspector or directly in the plot call:

```
plot(S1, S2, Layout = Absolute, BorderWidth = 1.0*unit::mm,
 Height = 7*unit::cm, Width = 11*unit::cm):
```

# Height, Width

---

Note that we did not set the attributes `Bottom` and `Left` of the scenes, so the bottom left corners of the scenes are placed in the bottom left corner of the canvas.

We make the background of the scene `S2` transparent via `BackgroundTransparent = TRUE` and shift this scene via suitable values of `Bottom` and `Left`:

```
S2::BackgroundTransparent := TRUE:
S2::Bottom := 3.7*unit::cm:
S2::Left := 5.4*unit::cm:
plot(S1, S2, Layout = Absolute, BorderWidth = 1.0*unit::mm,
 Height = 7*unit::cm, Width = 11*unit::cm):
```

delete f1, f2, S1, S2:

## See Also

## MuPAD Functions

BorderWidth | Bottom | Layout | Left | Margin

# Layout, Rows, Columns

---

**Purpose** Arrangement/layout of several scenes in a canvas

**Value Summary**

Layout	Optional	Absolute, Horizontal, Relative, Tabular, or Vertical
Columns, Rows	Optional	Positive integer

## Graphics Primitives

Objects	Default Values
plot::Canvas	Layout: Tabular Rows, Columns: 0

## Description

Layout determines the arrangement of several scenes in a canvas.

Rows determines the number of scene rows in a tabular arrangement of several scenes.

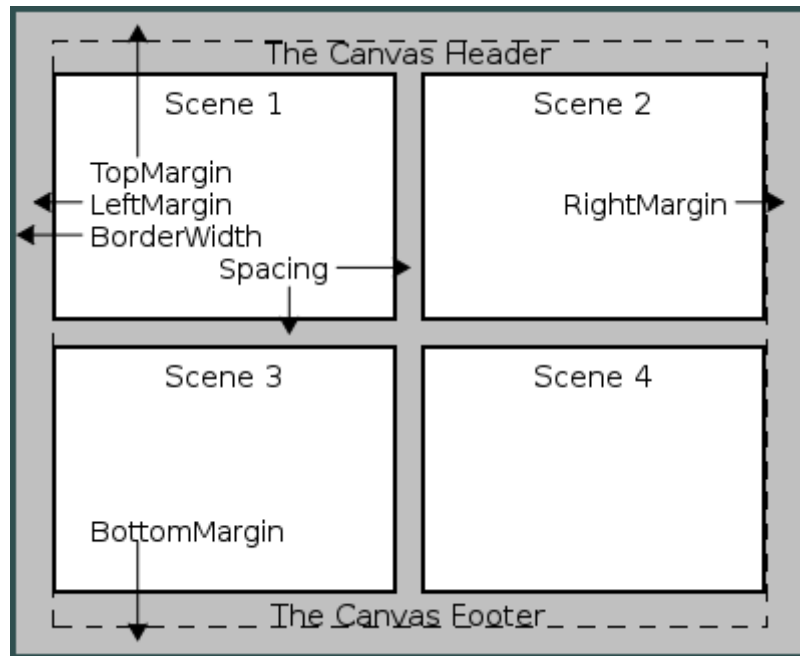

Columns determines the number of scene columns in a tabular arrangement of several scenes.

If a canvas contains more than one scene, the `Layout` attribute determines how the scenes are arranged in the canvas:

- With the default setting `Layout = Tabular`, a sequence of scenes in a canvas is arranged like a table with several columns and rows. The number of columns or rows may be chosen via the attributes `Columns` or `Rows`, respectively. If none of these attributes is given, the tabular layout scheme chooses some suitable values, automatically.

The scenes are filled into the table according to standard western reading order, filling the upper row from left to right, then proceeding to the next row etc:

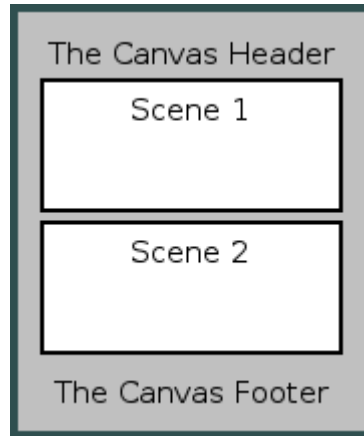

- `Layout = Horizontal` is a shortcut for `Layout = Tabular, Rows = 1`. The scenes are placed side by side in a single row.

- `Layout = Vertical` is a shortcut for `Layout = Tabular, Columns = 1`. The scenes are placed below each other in a single column.

# Layout, Rows, Columns

---

The settings `Layout = Absolute` and `Layout = Relative` switch the automatic layout mode off and allow to position each scene via the scene attributes `Left` and `Bottom`. These attributes determine the position of the lower left corner of the scene and can be set separately for each scene.

- With `Layout = Absolute`, the values for the lower left corner of the scene as well as its width and height must be specified as absolute physical lengths such as `Left = 3.0*unit::mm`, `Bottom = 4.5*unit::mm`, `Width = 10*unit::cm`, `Height = 4*unit::inch`.
- With `Layout = Relative`, these values must be specified as fractions of the canvas height and width. E.g.,

`Layout = Relative,`

`Left = 0.3, Bottom = 0.2, Width = 0.5, Height = 0.5`

is equivalent to

`Layout = Absolute,`

`Left = 0.3*canvaswidth, Bottom = 0.2*canvasheight,`

`Width = 0.5*canvaswidth, Height = 0.5*canvasheight,`

where `canvaswidth` and `canvasheight` are the physical width and height of the canvas.

With `Layout = Absolute` and `Layout = Relative` overlapping scenes can be created. In such a situation it may be useful to create transparent scenes (without a background) via `BackgroundTransparent = TRUE`.

## Examples

### Example 1

We define four scenes:

```
S1 := plot::Scene3d(plot::Sphere(1, [0, 0, 0],
 Color = RGB::Red),
 BorderWidth = 0.2*unit::mm,
 BorderColor = RGB::Black);
S2 := plot::Scene3d(plot::Box(-1..1, -1..1, -1..1,
```

# Layout, Rows, Columns

---

```
 Color = RGB::Green),
 BorderWidth = 0.2*unit::mm,
 BorderColor = RGB::Black):
S3 := plot::Scene3d(plot::Cone(1, [0, 0, -1], [0, 0, 1],
 Color = RGB::Blue),
 BorderWidth = 0.2*unit::mm,
 BorderColor = RGB::Black):
S4 := plot::Scene3d(plot::Cone(1, [0, 0, 1], [0, 0, -1],
 Color = RGB::Orange),
 BorderWidth = 0.2*unit::mm,
 BorderColor = RGB::Black):
```

These scenes are positioned in the canvas in various ways:

```
plot(S1, S2, S3, S4, Layout = Tabular,
 Height = 80*unit::mm, Width = 80*unit::mm):
```

```
plot(S1, S2, Layout = Horizontal,
```

```
Height = 40*unit::mm, Width = 80*unit::mm):
```

```
plot(S1, S2, Layout = Vertical,
 Height = 80*unit::mm, Width = 40*unit::mm):
```

For explicit placement of the scenes, we set values for the Left, Bottom, Width, and Height attributes of the scenes:

# Layout, Rows, Columns

```
S1::Left := 0: S1::Bottom := 15*unit::mm:
S1::Width := 60*unit::mm: S1::Height:= 60*unit::mm:
S2::Left := 60*unit::mm: S2::Bottom := 0*unit::mm:
S2::Width := 40*unit::mm: S2::Height:= 30*unit::mm:
S3::Left := 60*unit::mm: S3::Bottom := 30*unit::mm:
S3::Width := 40*unit::mm: S3::Height:= 30*unit::mm:
S4::Left := 60*unit::mm: S4::Bottom := 60*unit::mm:
S4::Width := 40*unit::mm: S4::Height:= 30*unit::mm:
```

We use `Layout = Absolute`:

```
plot(S1, S2, S3, S4, Layout = Absolute,
 BorderWidth = 0.5*unit::mm, BorderColor = RGB::Black,
 BackgroundColor = RGB::LightGrey,
 Height = 90*unit::mm, Width = 100*unit::mm):
```

For `Layout = Relative`, the scene attributes `Left`, `Width`, `Bottom`, `Height` must be given as fractions of the canvas width and height, respectively:

```
S1::Left := 0: S1::Width := 0.6:
S1::Bottom := 0: S1::Height := 0.6:
S2::Left := 0: S2::Width := 0.5:
S2::Bottom := 0.6: S2::Height := 0.4:
S3::Left := 0.5: S3::Width := 0.5:
S3::Bottom := 0.6: S3::Height := 0.4:
S4::Left := 0.58: S4::Width := 0.4:
S4::Bottom := 0.35: S4::Height := 0.4:
S4::BackgroundTransparent := TRUE:

plot(S1, S2, S3, S4, Layout = Relative,
 BorderWidth = 0.5*unit::mm, BorderColor = RGB::Black,
 BackgroundColor = RGB::LightGrey,
 Height = 87*unit::mm, Width = 104*unit::mm):
```

# Layout, Rows, Columns

delete S1, S2, S3, S4:

## Example 2

We demonstrate the layout of the canvas with `Layout = Relative`. Apart from the scene headers and the positioning via `Bottom` and `Left`, all scene attributes are set in the plot call via specifications such as `plot::Scene2d::Width` etc. This distinguishes the scene attributes from the canvas attributes `Width`, `BorderWidth` etc.

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0..2*PI),
 Left = 0.02, Bottom = 0.46,
 Header = "the sine function");
S2 := plot::Scene2d(plot::Function2d(cos(x), x = 0..2*PI),
 Left = 0.51, Bottom = 0.46,
 Header = "the cosine function");
S3 := plot::Scene2d(plot::Function2d(tan(x), x = 0..PI),
```

```
Left = 0.02, Bottom = 0.02,
Header = "the tan function");
S4 := plot::Scene2d(plot::Function2d(cot(x), x = 0..PI),
Left = 0.51, Bottom = 0.02,
Header = "the cot function");
plot(S1, S2, S3, S4, Layout = Relative,
Width = 120*unit::mm, Height = 80*unit::mm,
BorderWidth = 0.5*unit::mm,
HeaderFont = ["Times New Roman", 18, Bold],
Header = "trigonometric functions",
plot::Scene2d::Width = 0.475,
plot::Scene2d::Height = 0.42,
plot::Scene2d::BorderWidth = 0.2*unit::mm,
plot::Scene2d::HeaderFont =
["Times New Roman", Italic, 12]);
```

# Layout, Rows, Columns

---

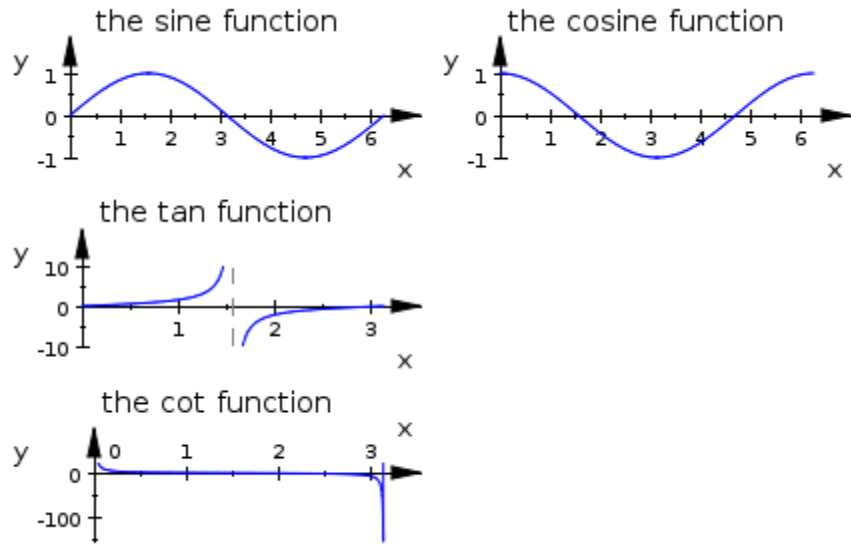

Finally, we demonstrate the attributes `Rows` and `Columns`. The automatic tabular layout ignores the explicit positioning of the scenes and chooses the following arrangement:

```
plot(S1, S2, S3, S4)
```

We explicitly request three rows:

```
plot(S1, S2, S3, S4, Rows = 3)
```

We explicitly request three columns:

```
plot(S1, S2, S3, S4, Columns = 3)
```

# Layout, Rows, Columns

---

We generate an empty scene:

```
empty := plot::Scene2d(Axes = None):
```

The tabular layout is filled in with empty scenes:

```
plot(S1, S2, empty, S3, empty, S4, Rows = 3)
```

```
plot(S1, S2, S3, empty, S4, empty, Columns = 3)
```

# Layout, Rows, Columns

---

delete S1, S2, S3, S4, empty:

# Margin, BottomMargin, TopMargin, LeftMargin, RightMargin

**Purpose** Margins around canvas and scenes

**Value Summary**

Margin	{BottomMargin, LeftMargin, RightMargin, TopMargin}	Non-negative output size
BottomMargin, LeftMargin, RightMargin, TopMargin	Inherited	Non-negative output size

## Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	Margin, BottomMargin, TopMargin, LeftMargin, RightMargin: 1

## Description

Margin = d sets a margin of size d around a canvas or scene. The margins at the bottom, to the left etc. can also be specified separately via BottomMargin = d<sub>1</sub>, LeftMargin = d<sub>2</sub> etc.

The canvas as well as the scenes have a margin that is not used for displaying graphical objects or captions. Its color coincides with the background color of the canvas or the scenes, respectively.

The size d of this margin is set by specifying Margin = d in a canvas or in a scene (of type plot::Scene2d or plot::Scene3d), respectively. Here, d is the physical width of the margin, e.g., Margin = 0.5\*unit::mm.

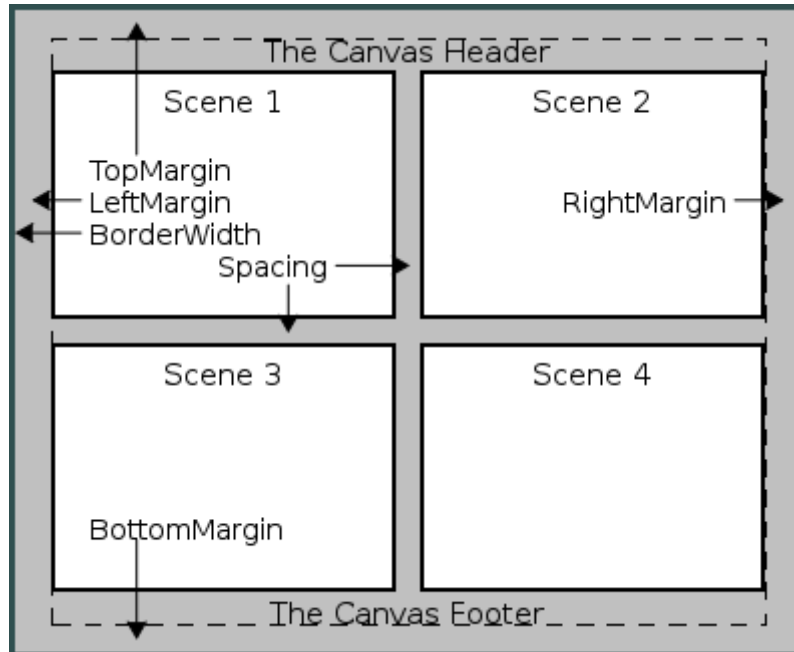

The margin sizes at the bottom, left, right, top of the canvas or the scenes can be specified separately via BottomMargin = d<sub>1</sub>, LeftMargin = d<sub>2</sub>, RightMargin = d<sub>3</sub>, TopMargin = d<sub>4</sub>.

The attribute Margin = d is a shortcut for BottomMargin = d, LeftMargin = d, RightMargin = d, TopMargin = d.

# Margin, BottomMargin, TopMargin, LeftMargin, RightMargin

---

The following picture illustrates the layout of the canvas:

The following picture illustrates the layout of a scene:

# Margin, BottomMargin, TopMargin, LeftMargin, RightMargin

The size of a canvas, set by the attributes `Width` and `Height`, includes the width of the margin set by `Margin`. The same holds for the scenes.

With `BackgroundTransparent = TRUE`, transparent scenes (without a background) can be created. The margin becomes transparent as well.

The margins do not react to `Layout = Relative`. One always has to specify the margin width as absolute physical lengths such as `0.5*unit::mm`.

Scenes do *not* inherit margin widths from the enclosing canvas. You can set margin widths for all scenes simultaneously by specifying them in `plot::setDefault` as `plot::Scene2d::Margin` or `plot::Scene3d::Margin`, respectively. Cf. “Example 2” on page 23-1848.

## Examples

### Example 1

The following two scenes display the same function graph using different margins:

```
f := plot::Function2d(exp(-x^2), x = -3..3):
plot(plot::Scene2d(f, Margin = 2*unit::mm,
 BackgroundColor = RGB::Grey),
 plot::Scene2d(f, Margin = 8*unit::mm,
 BackgroundColor = RGB::Grey),
```

# Margin, BottomMargin, TopMargin, LeftMargin, RightMargin

---

```
Layout = Horizontal, Axes = Frame,
Width = 120*unit::mm, Height = 60*unit::mm):
```

delete f:

## Example 2

We use `plot::setDefault` to define new default values for the layout and style parameters `BorderWidth`, `BorderColor`, `Margin`, and `BackgroundColor`:

```
plot::setDefault(
 plot::Canvas::BorderWidth = 0.5*unit::mm,
 plot::Canvas::BorderColor = RGB::Black,
 plot::Canvas::Margin = 1.5*unit::mm,
 plot::Canvas::BackgroundColor = RGB::SlateGrey,
 plot::Scene2d::BorderWidth = 0.5*unit::mm,
 plot::Scene2d::BorderColor = RGB::Black,
 plot::Scene2d::Margin = 2*unit::mm,
 plot::Scene2d::BackgroundColor = RGB::Grey
):
```

# Margin, BottomMargin, TopMargin, LeftMargin, RightMargin

The following canvas contains two scenes. This plot uses the new defaults:

```
plot(plot::Scene2d(plot::Rectangle(-1..1, -1..1,
 Filled = TRUE, FillColor = RGB::Red,
 Header = "Scene 1")),
 plot::Scene2d(plot::Rectangle(-1..1, -1..1,
 Filled = TRUE, FillColor = RGB::Blue,
 Header = "Scene 2")),
 Layout = Horizontal, Axes = None,
 Header = "Canvas Header"):
```

# OutputUnits

---

**Purpose** Physical length unit used by the inspector

**Value Summary** Optional unit::cm, unit::dm, unit::inch, unit::km, unit::m, unit::mm, or unit::pt

## Graphics Primitives

Objects	OutputUnits Default Values
plot::Canvas	unit::mm

## Description

Various length parameters in the MuPAD graphics such as the width and the height of the canvas, the length of tick marks, the width of lines, the size of points etc. may be specified as physical lengths with a length unit. The inspector allows to display a physical length in the physical unit set by OutputUnits.

For example, when specifying the canvas size by the attributes `Width = 120*unit::mm`, `Height = 80*unit::mm`, the MuPAD graphics will appear on the screen in a canvas of 120 80 mm (approximately). A printout of the MuPAD graphics will have this physical size precisely.

One may also specify these lengths as pure numbers such as `Width = 120`, `Height = 80`. In this case, the physical length unit is given in mm.

In the “object inspector” of the MuPAD Graphics Tool (see the section Viewer, Browser, and Inspector: Interactive Manipulation of this document), lengths are displayed as numbers without unit. The actual physical length is given by these numbers times the physical length unit given by OutputUnits.

---

**Note** Note that the specification `Width = 10, OutputUnit = unit::inch` does not mean `Width = 10*unit::inch`, but `Width = 10*unit::mm`, displayed as 0.3937... inches.

It is recommended to specify output sizes always as products of the numerical values times the unit.

---

Changing the value of `OutputUnits` does not change the physical lengths! When changing `OutputUnits = unit::mm` to `OutputUnits = unit::inch`, say, the numbers in the object inspector such as `Width = 120` (corresponding to a canvas size of 120 mm in the real world) change automatically to `Width = 4.7244...` (corresponding to the same canvas size `120 mm = 4.7244... inches`).

If you want to change the physical length, you need to change the number in the input region of `Width` in the object inspector.

Switching between different output units via `OutputUnits` is convenient if physical conditions such as the real world size of a printout have to be met. Depending on your nationality, you will have a preference for inches or millimeters.

## Examples

### Example 1

The following calls all produce graphical output of the same physical size:

```
f := plot::Function2d(sin(x), x = 0..PI):
plot(f, Width = 90*unit::mm, Height = 40*unit::mm):
```

# OutputUnits

---

```
plot(f, Width = 90, Height = 40, OutputUnits = unit::mm):
```

```
plot(f, Width = 90, Height = 40, OutputUnits = unit::inch):
```

```
plot(f, Width = 3.544*unit::inch, Height = 40*unit::mm):
```

```
plot(f, Width = 3.544*unit::inch, Height = 1.575*unit::inch):
```

In the following plot command, the size of graphical points is specified in millimeters. The specification of `OutputUnits = unit::inch` does not change the physical point size of  $2\text{ mm} = 0.07874\dots\text{ inch}$ . It just means that the value of the point size is displayed as 0.07874 in the object inspector of the MuPAD Graphics Tool, not as 2:

```
plot(plot::Function2d(sin(x), x = 0..PI, Mesh = 30),
 PointsVisible = TRUE, PointSize = 2*unit::mm,
 Width = 90*unit::mm, Height = 40*unit::mm,
 OutputUnits = unit::inch):
```

# OutputUnits

---

delete f:

## Example 2

The conversion between the output sizes can be computed via MuPAD:

```
120.0*unit::mm = unit::convert(120.0*unit::mm, unit::inch),
4.7244*unit::inch = unit::convert(4.7244*unit::inch, unit::pt)
```

```
120.0 mm = 4.724409449 inch, 4.7244 inch = 341.4323914 pt
```

### MuPAD Functions

AxesLineWidth | Bottom | BottomMargin | GridLineWidth  
| Height | Left | LeftMargin | LineWidth | PointSize  
| RightMargin | Spacing | SubgridLineWidth |  
TicksLength | TipLength | TopMargin | TubeDiameter |  
VerticalAsymptotesWidth | Width

**Purpose** Space between scenes

**Value Summary** Optional Non-negative output size

**Graphics Primitives**

Objects	Spacing Default Values
plot::Canvas	1.0

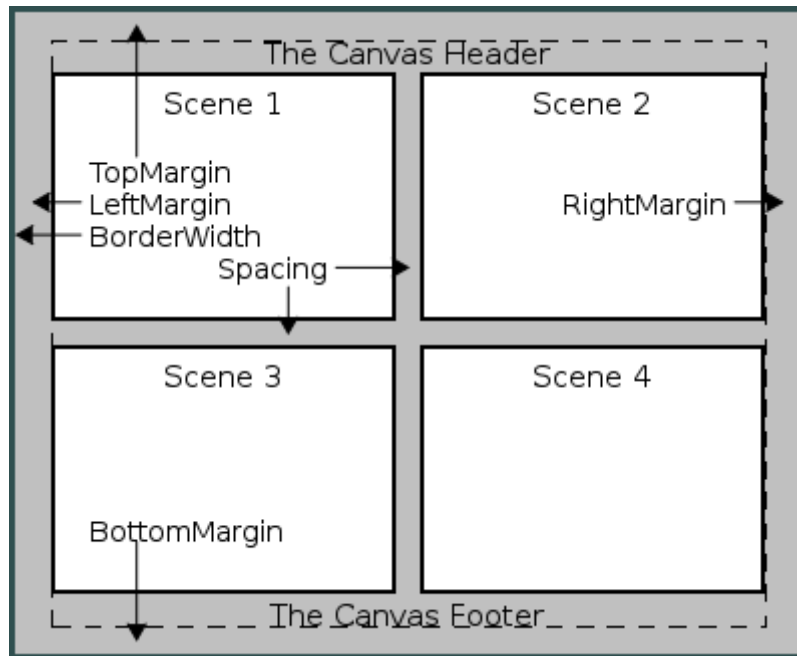

**Description** Spacing =  $d$  sets a gap of size  $d$  between neighboring scenes in a canvas.

If a canvas contains several scenes, an automatic layout of the canvas may be requested by `Layout = Horizontal`, `Layout = Tabular`, or `Layout = Vertical`. In these modes, the scenes are separated by a gap that is set by `Spacing = d`. Here,  $d$  is the physical width of the gap, e.g., `Spacing = 0.5*unit::mm`.

The `Spacing` attribute has an effect only in conjunction with the automatic layout modes `Layout = Horizontal`, `Layout = Tabular`, or `Layout = Vertical`, respectively.

The following picture illustrates the layout of the canvas:

# Spacing

## Examples

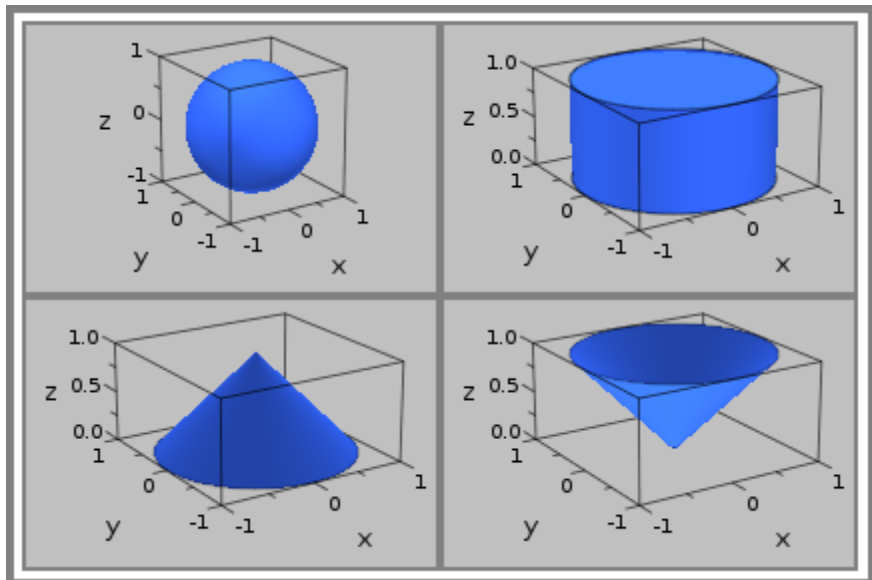

### Example 1

We define four scenes:

```
S1 := plot::Scene3d(plot::Sphere(1, [0, 0, 0]),
 BackgroundColor = RGB::Grey,
 BorderWidth = 0.5*unit::mm):
S2 := plot::Scene3d(plot::Cylinder(1, [0, 0, 0], [0, 0, 1]),
 BackgroundColor = RGB::Grey,
 BorderWidth = 0.5*unit::mm):
S3 := plot::Scene3d(plot::Cone(1, [0, 0, 0], [0, 0, 1]),
 BackgroundColor = RGB::Grey,
 BorderWidth = 0.5*unit::mm):
S4 := plot::Scene3d(plot::Cone(1, [0, 0, 1], [0, 0, 0]),
 BackgroundColor = RGB::Grey,
 BorderWidth = 0.5*unit::mm):
```

These scenes are positioned in the canvas with no gap between them (Spacing = 0). By default, the automatic layout mode Layout = Tabular is used:

```
plot(S1, S2, S3, S4, Spacing = 0,
 BorderWidth = 1.0*unit::mm):
```

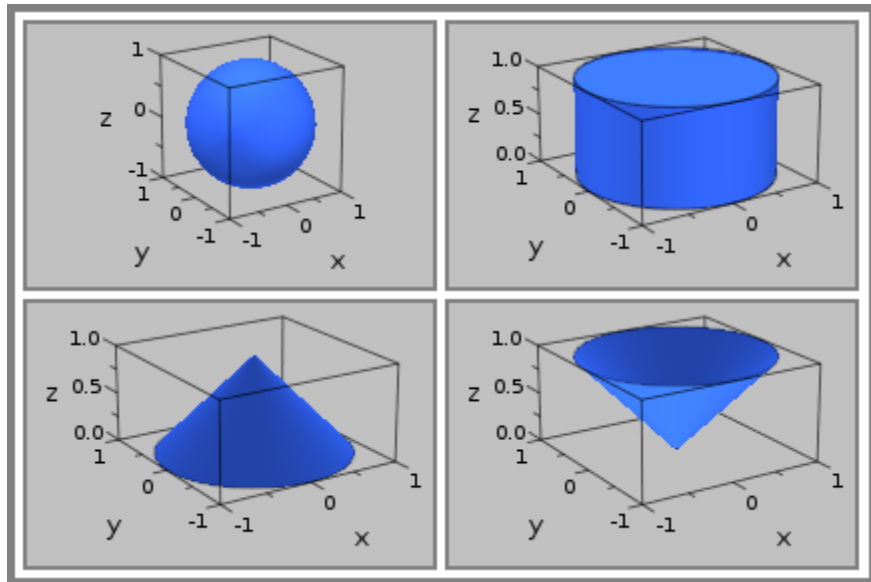

We introduce a gap of 1 mm:

```
plot(S1, S2, S3, S4, Spacing = 1.0*unit::mm,
 BorderWidth = 1.0*unit::mm):
```

# Spacing

---

delete S1, S2, S3, S4:

### MuPAD Functions

BottomMargin | LeftMargin | Margin | RightMargin |  
TopMargin | Layout | Left | Bottom

**Purpose** Maximal absolute discretization error

**Value Summary** AbsoluteError, RelativeError      Optional      MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Ode2d, plot::Ode3d	
plot::Streamlines2d	RelativeError: 1/100000

## Description

`AbsoluteError = atol` sets the tolerance `atol` for the maximal absolute discretization error in the numerical solution of ODEs.

`RelativeError = rtol` sets the tolerance `rtol` for the maximal relative discretization error.

Internally, `plot::Ode2d` and `plot::Ode3d` call the routine `numeric::odesolve` for solving the given ODE numerically. The attributes `AbsoluteError`, `RelativeError` are forwarded to `numeric::odesolve`. See the corresponding help page for further details.

## Examples

### Example 1

We consider the initial value problem

$y'(t) = -t \cos(y(t))$ ,  $y(0) = 4.7$ . The ODE is solved numerically with different tolerances for the relative discretization error.

The 'oscillating' behaviour of the red solution curve is a numerical artifact. The blue solution curve, computed with a smaller tolerance, is more precise:

```
f := (t, Y) -> [-t*cos(Y[1])]:
Y0 := [4.7]:
plot(plot::Ode2d(f, [i $ i = 0..20], Y0, Color = RGB::Blue,
 RelativeError = 0.0001),
```

# AbsoluteError, RelativeError

```
plot::Ode2d(f, [i $ i = 0..20], Y0, Color = RGB::Red,
RelativeError = 0.001))
```

```
delete f, Y0:
```

## MuPAD Functions

[InitialConditions](#) | [ODEMethod](#) | [Projectors](#) | [Stepsize](#) | [TimeMesh](#)

**Purpose** Adaptive sampling

**Value Summary** Inherited Non-negative integer

**Graphics Primitives**

Objects	AdaptiveMesh Default Values
plot::Function2d	2
plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylindrical, plot::Function3d, plot::Implicit3d, plot::Polar, plot::Spherical, plot::Surface, plot::Sweep, plot::XRotate, plot::ZRotate	0
plot::Rootlocus	4

**Description**

AdaptiveMesh =  $n$  controls the adaptive sampling in the numerical evaluation of functions, curves and surfaces. With  $n = 0$ , adaptive sampling is disabled. With  $n > 0$ , adaptive sampling is enabled.

The “depth”  $n$  of the adaptive sampling should be a *small* integer such as 0, 1, 2, or 3.

Continuous graphical objects such as function graphs, parameterized curves and surfaces are approximated by a discrete mesh of numerical points.

This mesh may be controlled by the user via the attributes Mesh, Submesh, and AdaptiveMesh. (Depending on the object, the Mesh attribute splits into more specific versions such as UMesh and VMesh for curve and surface plots, or XMesh, YMesh, ZMesh for function and implicit plots.)

# AdaptiveMesh

---

First, the object is evaluated numerically on an equidistant “initial mesh” set via the attribute `Mesh` (or the more specific versions mentioned above).

With `AdaptiveMesh = 0`, the numerical data over the initial mesh are used to render the object without any further adaptive refinement.

With `AdaptiveMesh = n`,  $n > 0$ , further numerical data are computed before the renderer is called. In particular, the data of neighboring points on the initial mesh are investigated. If a point is not reasonably represented by a straight line connecting the neighboring points, the corresponding intervals of the initial mesh are sub-divided recursively. The adaptive mechanism descends into the sub-intervals of the initial mesh if consecutive line segments of the discretized plot object deviate from a straight line by a “bend angle” of more than 10 degrees. The intervals involved in such a situation are split into halves, recursively.

The value of  $n$  should be a *small* integer that determines the recursive depth of the adaptive refinement. In each direction, up to  $2^n - 1$  additional points are placed between the points of the initial mesh.

If the object looks smooth on the initial mesh set via the attribute `Mesh` or its more detailed variants, the adaptive mechanism does *not* descend into the intervals of the initial mesh. If there are fine structures hidden inside these intervals, specifying `AdaptiveMesh = n` with  $n > 0$  will *not* help to improve the plot. In such a case, the initial mesh should be refined via the appropriate attribute for the initial mesh.

On the other hand, if the initial mesh is fine enough to indicate finer internal structures via the “max bend angle” criterion, it is often more efficient to use `AdaptiveMesh = n` than to refine the initial mesh, because the adaptive mechanism refines only those parts of the object that do need refinement. This effect can be seen in “Example 3” on page 23-1869.

---

**Note** Note that increasing the recursive depth  $n$  by 1 may increase the run time by a factor of 2 for line objects (2D function graphs and curves) and by a factor of 4 for surface objects (3D function graphs and surfaces). In most cases, a *small* value such as  $n \in \{1, 2, 3\}$  suffices to obtain a reasonably smooth plot object.

---

---

**Note** Note that the adaptive algorithm for surface objects in 3D is *very expensive!* As an alternative to values  $n > 0$  in `AdaptiveMesh = n`, you may experiment with `AdaptiveMesh = 0, Submesh = [2n- 1, 2n- 1]` in 3D function graphs or surfaces. The granularity of the “initial mesh” generated with these attribute values is approximately of the same size as the adaptive mesh generated with `AdaptiveMesh = n, Submesh = [0, 0]`. The non-adaptive evaluation on the refined regular mesh may still be more efficient than the evaluation on the (irregular) non-adaptive mesh.

---

## Examples

### Example 1

The following function plot contains areas of high variation. Without a specification of `AdaptiveMesh`, the default mode `AdaptiveMesh = 0` is used and we clearly see artifacts caused by the evaluation on a discrete mesh:

```
plot(plot::Function2d(
 sin(x) + exp(-5*(x - PI/2)^2)*sin(110*x)/10, x = 0..PI)):
```

# AdaptiveMesh

---

We activate the adaptive refinement with a high level of 3:

```
plot(plot::Function2d(
 sin(x) + exp(-5*(x - PI/2)^2)*sin(110*x)/10, x = 0..PI,
 AdaptiveMesh = 3)):
```

We set the attribute `PointsVisible = TRUE` so that the points of the adaptive mesh become visible:

```
plot(plot::Function2d(
 sin(x) + exp(-5*(x - PI/2)^2)*sin(110*x)/10, x = 0..PI,
 AdaptiveMesh = 3, PointsVisible = TRUE)):
```

# AdaptiveMesh

---

## Example 2

The default value of Mesh does not provide a sufficient resolution for the following spiral:

```
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI)):
```

Increasing the Mesh value improves the plot:

```
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI,
Mesh = 1000)):
```

# AdaptiveMesh

---

Alternatively, adaptive plotting can be used:

```
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI,
AdaptiveMesh = 3)):
```

### Example 3

In 3D the typical artifacts caused by the rectilinear initial mesh are “dents” on surface features that are not parallel to a parameter axis. Without a specification of `AdaptiveMesh`, the default mode `AdaptiveMesh = 0` is used:

```
f := plot::Function3d(sin(x*y)/(abs(x*y) + 1),
 x = -4 .. 4, y = -4 .. 4):
plot(f):
```

# AdaptiveMesh

---

Activating the adaptive refinement, we get a much more accurate plot. However, the computation takes *much longer*:

```
plot(f, AdaptiveMesh = 2):
```

To see how local the refinement is, we set the attribute `MeshVisible = TRUE` so that the internal triangulation of the adaptive mesh becomes visible:

```
plot(f, AdaptiveMesh = 2, MeshVisible = TRUE):
```

# AdaptiveMesh

---

We use a non-adaptive evaluation, but refine the regular mesh by setting Submesh values  $2^n - 1$  that correspond to the adaptive depth  $n = 2$  used above. The result is of a similar quality as before:

```
plot(plot::Function3d(sin(x*y)/(abs(x*y) + 1),
 x = -4 .. 4, y = -4 .. 4,
 Submesh = [3, 3])):
```

`delete f:`

# DiscontinuitySearch

---

**Purpose** Semi-symbolic search for discontinuities

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	DiscontinuitySearch Default Values
plot::Curve2d, plot::Curve3d, plot::Function2d, plot::Polar, plot::Sweep	TRUE

## Description

DiscontinuitySearch = TRUE versus DiscontinuitySearch = FALSE determines whether a graphical object is checked (semi-)symbolically for discontinuities and singularities.

Certain graphical objects such as function graphs or parametrized curves may have singularities. This may create graphical artifacts such as spurious lines between numerical sample points that enclose a singularity. With DiscontinuitySearch = TRUE, the object is pre-processed to find potential singularities. If singular points are found, the object is split into several disjoint sub-objects ("branches"), each of which is smooth.

---

**Note** DiscontinuitySearch is only available for line objects (2D function graphs and parametrized curves in 2D and 3D). It is not available for surface objects such as 3D function graphs and parametrized surfaces!

---

Discontinuities will only be detected if they are caused by system functions that are implemented as a function environment with an appropriate "realDiscont" or "numericDiscont" slot.

The search for discontinuities uses interval arithmetic. If special functions are involved that do not support this kind of arithmetic, the search will not succeed.

For efficiency reasons, it is recommended to disable the search for discontinuities with `DiscontinuitySearch = FALSE` when it is known that the graphical object is continuous.

## Examples

### Example 1

The following plot contains first order poles. When the discontinuity search is disabled, spurious vertical lines occur connecting sample points to the left of a pole with neighbouring sample points to the right of the pole. Further, the neighbourhood of the poles is poorly sampled:

```
plot(plot::Function2d(tan(x^2), x=-3..3,
 ViewingBoxYRange = -10..10,
 DiscontinuitySearch = FALSE)):
```

# DiscontinuitySearch

Without specification of `DiscontinuitySearch`, the default setting `DiscontinuitySearch = TRUE` is used. The spurious lines disappear. With the default `VerticalAsymptotesVisible = TRUE`, they are replaced by dashed vertical asymptotes indicating the poles. Also note that the numerical sampling near the poles is better, because the existence of the singularities and their positions is known before the numerical evaluation of the function graph starts:

```
plot(plot::Function2d(tan(x^2), x=-3..3,
 ViewingBoxYRange = -10..10)):
```

## Example 2

The Heaviside function has a jump discontinuity. Without a discontinuity search, a spurious line connecting the left and the right limit points of the jump appears:

```
plot(plot::Function2d(heaviside(x-1), x = -1..3,
 DiscontinuitySearch = FALSE)):
```

This spurious line disappears with the default setting  
`DiscontinuitySearch = TRUE`:

```
plot(plot::Function2d(heaviside(x-1), x = -1..3),
 VerticalAsymptotesVisible = FALSE):
```

# DiscontinuitySearch

---

### Example 3

Without a discontinuity search, the poles of the following singular 3D curve are poorly presented graphically:

```
plot(plot::Curve3d([cos(u), sin(u), tan(2*u)], u = 0..2*PI,
ViewingBox = [-1..1, -1..1, -10..10],
DiscontinuitySearch = FALSE)):
```

The default setting `DiscontinuitySearch = TRUE` produces a better graphical presentation:

```
plot(plot::Curve3d([cos(u), sin(u), tan(2*u)], u = 0..2*PI,
 ViewingBox = [-1..1, -1..1, -10..10])):
```

# DiscontinuitySearch

---

## Description

The attributes `Mesh` and `Submesh` determine the number of sample points used for the numerical approximation of plot objects.

Many plot objects have to be evaluated numerically on a discrete mesh. Depending on the object type, there are type specific attributes such as `XMesh` (for 2D function graphs), `UMesh`, `VMesh` (for parametrized surfaces), `XMesh`, `YMesh`, `ZMesh` (for implicit plots in 3D) etc. setting the number of sample points of the numerical mesh.

The `Mesh` attribute unifies these more specific attributes and can be set for all objects that use a discrete numerical mesh. Depending on the object, the values for `Mesh` must be integer numbers or lists of such numbers. The more specific attributes are set automatically when `Mesh` values are specified.

E.g., in a 2D function plot of type `plot::Function2d`, `Mesh = 200` is equivalent to `XMesh = 200`. In a 3D surface plot of type `plot::Surface`, `Mesh = [40, 50]` is equivalent to `UMesh = 40`, `VMesh = 50`.

In the “object inspector” of the interactive graphics tool (see section `Viewer, Browser, and Inspector: Interactive Manipulation` in this document), only the type specific attributes are visible, not the `Mesh` attribute.

Roughly speaking, high Mesh values yield smooth plots but cost run time.

With the attribute `Submesh = m`, additional  $m$  equidistant sample points are inserted between each pair of adjacent sample points set by the Mesh attribute. This smoothens the object.

Like Mesh, the attribute Submesh unifies type specific attributes such as XSubmesh, USubmesh etc. Depending on the object, the values of Submesh have to be integers or lists of integers.

There is a semantical difference between the “major” mesh points set by Mesh and the “minor” mesh points inserted by Submesh. There are coordinate lines associated with the (regular) numerical mesh. See XLinesVisible, ULinesVisible etc. The coordinate lines are available only for the mesh given by the “major” mesh points, whereas Submesh does not influence the number of coordinate lines. Thus, increased Mesh values yield a smoother plot with more coordinate lines, whereas Submesh can be used to smoothen the plot without adding further coordinate lines.

Apart from this effect, the pair `Mesh = n`, `Submesh = m` corresponds to the combination `Mesh = (n - 1) (m + 1) + 1`, `Submesh = 0`.

If adaptive sampling is enabled, further non-equidistant sample points are chosen automatically between the equidistant points of the ‘initial mesh’ set via the Mesh and Submesh attributes.

## Examples

### Example 1

In the following plot, the default value of Mesh does not suffice to produce a sufficiently exact picture:

```
plot(plot::Function2d(sin(x^2), x = 0..10)):
```

# Mesh, Submesh

---

A mesh with more sample points yields a higher resolution graphics:

```
plot(plot::Function2d(sin(x^2), x = 0..10, Mesh = 500)):
```

## Example 2

The default value of Mesh does not provide a sufficient resolution for the following spiral:

```
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI)):
```

# Mesh, Submesh

---

The spiral winds around the origin 25 times. We wish to have approximately 40 sample points per revolution, so we need to use a total of 1000 sample points:

```
plot(plot::Curve2d([x*cos(x), x*sin(x)], x = 0..50*PI,
Mesh = 1000)):
```

### Example 3

Note the difference between increased Mesh values and additional sample points inserted via Submesh. Submesh does not introduce additional coordinate lines:

```
S1 := plot::Scene3d(plot::Function3d(
 x^2 + y^2, x = 0..1/2, y = 0..1, Mesh = [4, 4])):
S2 := plot::Scene3d(plot::Function3d(
 x^2 + y^2, x = 0..1/2, y = 0..1, Mesh = [4, 4],
 Submesh = [2, 2])):
S3 := plot::Scene3d(plot::Function3d(
 x^2 + y^2, x = 0..1/2, y = 0..1, Mesh = [10, 10])):
plot(S1, S2, S3, Layout = Horizontal,
 Height = 5*unit::cm, Width = 12*unit::cm,
 LineColor = RGB::Black):
```

# Mesh, Submesh

---

delete S1, S2, S3:

### MuPAD Functions

[AdaptiveMesh](#) | [UMesh](#) | [USubmesh](#) | [VMesh](#) | [VSubmesh](#) | [XMesh](#)  
| [YMesh](#) | [ZMesh](#)

**Purpose** Space between stream lines

**Value Summary** Optional MuPAD expression

## Graphics Primitives

Objects	MinimumDistance Default Values
plot::Streamlines2d	

## Description

MinimumDistance determines how closely spaced the stream lines generated by a plot::Streamlines2d object are.

plot::Streamlines2d displays orbits (stream lines) of ODEs which are at least  $m$  and at most  $2m$  units apart from one another, if MinimumDistance has been set to  $m$ .

The distance of stream lines is taken as the Euclidean distance, measured in coordinate units. If MinimumDistance is not set, it defaults to 0.02 times the maximum extent in either direction.

## Examples

### Example 1

The default setting is adequate for many stream lines plots:

```
plot(plot::Streamlines2d([sin(x)^2-cos(y)^2,
 sin(x^2)-cos(y)^2],
 x=0..4, y=0..4))
```

# MinimumDistance

---

To display simple ODEs, you may wish to reduce the number of stream lines:

```
plot(plot::Streamlines2d([1, 1], x=0..4, y=0..4))
```

```
plot(plot::Streamlines2d([1, 1], x=0..4, y=0..4, MinimumDistance
```

# MinimumDistance

---

**Purpose** Numerical scheme used for solving the ODE

**Value Summary** ODEMethod, Stepsize Optional MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Ode2d, plot::Ode3d	ODEMethod: DOPRI78
plot::Streamlines2d	ODEMethod: ABM4

## Description

ODEMethod = method determines the numerical scheme for solving the ODE. The parameter method is a name such as EULER1, RK4, RKF78 etc.

Stepsize = h sets a constant step size  $h$  that is used to compute the numerical solution.

Internally, plot::Ode2d, plot::Ode3d, and plot::Streamlines2d call the routine numeric::odesolve for solving the given ODE numerically. The method set by the attribute ODEMethod = method and/or the step size set by Stepsize = h are forwarded to numeric::odesolve. See the corresponding help page for a complete list of all methods available and for further details on the step size.

The setting ODEMethod = ABM4 is an exception to the above: It is only available with plot::Streamlines2d and makes the plot use a fast Adams-Bashforth-Moulton predictor corrector integrator of fourth order with fixed step size. It ignores the settings of RelativeError and AbsoluteError.

## Examples

### Example 1

We solve the initial value problem  $y'(t) = -y(t)$ ,  $y(0) = 1$  numerically by the classical 4th order Runge-Kutta scheme RK4 using a constant step size 0.1:

```
f := (t, Y) -> [-Y[1]]:
```

# ODEMethod, Stepsize

---

```
Y0 := [1]:
timemesh:= [0, 1, 2, 3, 4, 5]:
plot(plot::Ode2d(f, timemesh, Y0, ODEMethod = RK4,
 StepSize = 0.1))
```

```
delete f, Y0, timemesh:
```

## Example 2

With the default settings, `plot::Streamlines2d` is not able to plot the vector field  $[1, 3^{2/y}]$  (which is not Lipschitz continuous) in a satisfying way:

```
plot(plot::Streamlines2d([1, surd(3,y)^2],
 x=-3..3, y=-2..2))
```

By using a different numerical integrator, the problems can be overcome (at the cost of longer computation):

```
plot(plot::Streamlines2d([1, surd(3,y)^2],
 x=-3..3, y=-2..2,
 ODEMethod=RKF43,
 RelativeError=1e-3))
```

# ODEMethod, StepSize

---

plot::Ode2d, plot::Ode3d	USubmesh: 4

## Description

The attributes UMesh etc. determine the number of sample points used for the numerical approximation of parameterized plot objects such as curves and surfaces.

Many plot objects have to be evaluated numerically on a discrete mesh. The attributes described on this help page serve for setting the number of sample points of the numerical mesh.

# UMesh, VMesh, USubmesh, VSubmesh

---

For curves in 2D and 3D given by a parametrization  $x(u)$ ,  $y(u)$  and, possibly,  $z(u)$  with the curve parameter  $u$ , the attribute `UMesh = n` creates a numerical mesh of  $n$  equidistant  $u$  values. The attribute `USubmesh = m` inserts additional  $m$  mesh points between each pair of adjacent points set by `UMesh`.

The combinations `UMesh = n`, `USubmesh = m` and `UMesh = (m + 1) (n - 1) + 1`, `USubmesh = 0` are equivalent.

Specifying `Mesh`, `Submesh` has the same effect as specifying `UMesh`, `USubmesh`.

The sample points of a curve can be made visible by setting `PointsVisible = TRUE`.

Surface objects in 3D are parameterized by coordinate functions  $x(u, v)$ ,  $y(u, v)$ ,  $z(u, v)$  of two surface parameters  $u$ ,  $v$ .

The attribute `UMesh =  $n_u$`  sets the number  $n_u$  of sample points for the first surface parameter. The attribute `VMesh =  $n_v$`  sets the number  $n_v$  of sample points for the second surface parameter. The parametrization is evaluated on a regular mesh of  $n_u n_v$  values of the surface parameters  $u$ ,  $v$ .

With the `USubmesh`, `VSubmesh` attributes, additional equidistant sample points can be inserted between each pair of adjacent sample points set by the `UMesh`, `VMesh` attributes.

With `ULinesVisible = TRUE` and `VLinesVisible = TRUE`, respectively, the parameter lines of the regular mesh set by the attributes `UMesh`, `VMesh` are displayed on the surface. Additional points inserted via `USubmesh`, `VSubmesh` do *not* create additional parameter lines.

You can also specify `UMesh =  $n_u$` , `VMesh =  $n_v$` , `USubmesh =  $m_u$` , `VSubmesh =  $m_v$`  in the shorter form `Mesh = [ $n_u$ ,  $n_v$ ]`, `Submesh = [ $m_u$ ,  $m_v$ ]`.

If adaptive sampling is enabled, further non-equidistant sample points are chosen automatically between the equidistant points of the 'initial mesh' set via the `UMesh`, `USubmesh`, `VMesh`, `VSubmesh` attributes.

## Examples

### Example 1

It is possible to use low settings of mesh parameters to achieve special effects. As an example, we draw a parametrization of a circle with just six evaluation points:

```
plot(plot::Curve2d([cos(t), sin(t)], t = 0..2*PI, UMesh = 6,
Scaling = Constrained))
```

The reason we get a pentagon here and not a hexagon is that the first and the last evaluation points coincide: six points in a line means five line segments.

With `UMesh = 30`, the circle looks like a circle:

```
plot(plot::Curve2d([cos(t), sin(t)], t = 0..2*PI, UMesh = 30,
Scaling = Constrained))
```

# UMesh, VMesh, USubmesh, VSubmesh

---

## Example 2

The default values of UMesh, VMesh do not provide a sufficient resolution for the following graphics:

```
plot(plot::Surface([r*cos(phi), r*sin(phi), r*phi],
 r = 0..1, phi = 0..10*PI)):
```

# UMesh, VMesh, USubmesh, VSubmesh

The spiral winds around the  $z$ -axis 5 times. We wish to have approximately 40 sample points per revolution, so we need to use a total of 200 sample points with respect to the angle parameter  $\phi$ . The coordinate lines related to the radial parameter  $r$  are straight lines, so a very low resolution in this direction suffices:

```
plot(plot::Surface([r*cos(phi), r*sin(phi), r*phi],
 r = 0..1, phi = 0..10*PI,
 UMesh = 2, VMesh = 200)):
```

# UMesh, VMesh, USubmesh, VSubmesh

---

When refining the mesh via VSubmesh, no additional parameter lines are created:

```
plot(plot::Surface([r*cos(phi), r*sin(phi), r*phi],
 r = 0..1, phi = 0..10*PI,
 UMesh = 2, VMesh = 25, VSubmesh = 8)):
```

plot::Inequality	XMesh, YMesh: 256
plot::Density	XMesh, YMesh: 25
plot::Matrixplot	XSubmesh, YSubmesh: 2
plot::Listplot	XSubmesh: 6

**Description** The attributes XMesh etc. determine the number of sample points used for the numerical approximation of plot objects such as function graphs, implicit plots etc.

Various object types use numerical function evaluations on a discrete equidistant mesh. XMesh, YMesh, and for plot::Implicit3d also

# XMesh, XSubmesh, YMesh, YSubmesh, ZMesh

---

ZMesh set the number of points of this mesh. An exception of this are parameterized curves and surfaces, which use the attributes UMesh, USubmesh, VMesh, and VSubmesh.

For most of the object types listed above, the interpretation of the integers set by these attributes is as follows: In each of XRange, YRange, ZRange, the corresponding number of points is spread out equidistantly. For XMesh = 2 and XRange = 0..1, for example, evaluation takes place for  $x = 0$  and  $x = 1$ . For XMesh = 3, a further mesh point at  $x = \frac{1}{2}$  is used.

The exception to this rule is `plot::Implicit2d`: Here, the values of XMesh and YMesh determine the density of the grid *used for finding components* and increasing their values helps exactly in those cases where components (i.e., lines) are missing from the plot. Decreasing XMesh and YMesh in a 2D implicit plot will not make the curves appear rougher; it may result in curves missing.

For types reacting to AdaptiveMesh and for `plot::Implicit3d`, this mesh is used to find *initial* values that can be refined further. See the documentation of the specific types and of AdaptiveMesh for details.

In general, a finer mesh (higher values) leads to a longer computation, while a coarser mesh may cause details being missed.

One may specify XMesh =  $n_x$ , YMesh =  $n_y$ , XSubmesh =  $m_x$ , YSubmesh =  $m_y$ , also in the shorter Form Mesh = [ $n_x$ ,  $n_y$ ], Submesh = [ $m_x$ ,  $m_y$ ].

## Examples

### Example 1

The notorious function  $\sin(\frac{1}{x})$  oscillates wildly near the origin. The standard mesh values do not suffice to resolve the behavior of the function near the critical point:

```
plot(plot::Function2d(sin(1/x), x = -1 .. 1))
```

# XMesh, XSubmesh, YMesh, YSubmesh, ZMesh

---

We get a better result with an increased value of XMesh:

```
plot(plot::Function2d(sin(1/x), x = -1 .. 1), XMesh = 1000)
```

## Example 2

In the following plot, the default values of XMesh, YMesh do not suffice to produce a sufficiently smooth function graph:

```
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)),
 x = -20 .. 20, y = -20 .. 20)):
```

# XMesh, XSubmesh, YMesh, YSubmesh, ZMesh

---

Increasing the default values `XSubmesh = 0`, `YSubmesh = 0` yields a higher resolution plot. Note that this does not influence the number of mesh lines that are displayed:

```
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)),
 x = -20 .. 20, y = -20 .. 20,
 XSubmesh = 2, YSubmesh = 2)):
```

# XMesh, XSubmesh, YMesh, YSubmesh, ZMesh

Alternatively, we increase the values of XMesh, YMesh and use the default values XSubmesh = 0, YSubmesh = 0. This, however, increases the number of mesh lines that are displayed:

```
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)),
 x = -20 .. 20, y = -20 .. 20,
 XMesh = 73, YMesh = 73)):
```

# XMesh, XSubmesh, YMesh, YSubmesh, ZMesh

---

Yet another possibility is to use the default values of XMesh, YMesh, XSubmesh, YSubmesh and activate the adaptive mechanism to smoothen the critical regions of the plot. However, this plot consists almost completely of critical regions and the adaptive mechanism will therefore be slower than a direct calculation with a finer mesh that leads to almost the same result:

```
plot(plot::Function3d(besselJ(0, sqrt(x^2 + y^2)),
 x = -20 .. 20, y = -20 .. 20,
 AdaptiveMesh = 2)):
```

### Example 3

For two-dimensional implicit plots, XMesh and YMesh determine the mesh of “seed points” that are used to find components (see the documentation of `plot::Implicit2d` for more details). In effect, this means that if some components are missing from a plot, the values of these attributes should be increased:

```
plot(plot::Implicit2d(sin(2*x*y), x = -3..3, y = -3..3))
```

# XMesh, XSubmesh, YMesh, YSubmesh, ZMesh

---

```
plot(plot::Implicit2d(sin(2*x*y), x = -3..3, y = -3..3,
XMesh = 20, YMesh = 20))
```

# CameraCoordinates

---

**Purpose** Position of light sources relative to the camera?

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	CameraCoordinates Default Values
plot::DistantLight, plot::PointLight, plot::SpotLight	FALSE

## Description

With `CameraCoordinates = FALSE`, the coordinates defining the position of a light are interpreted as model coordinates in 3 space. Thus, the lights are positioned relative to the objects in the scene. They do not move when the camera moves.

With `CameraCoordinates = TRUE`, these coordinates are interpreted as “camera coordinates”. Thus, the lights are attached to the camera and move automatically with the camera when it is moved.

A vector  $(x, y, z)$  in “camera coordinates” has to be interpreted as follows:

The  $x$ -coordinate refers to the horizontal axis of the picture that you see in the finder of the camera. Positive  $x$  values are to your right hand side, negative  $x$  values to your left hand side.

The  $y$ -coordinate refers to the vertical axis of the picture that you see in the finder. Positive  $y$  values are above you, negative  $y$  values below you.

The  $z$ -coordinate refers to the position along the optical axis of the camera. Positive  $z$  values refer to points in front of you, negative  $z$  values to points behind you.

In camera coordinates, the camera position is  $(0, 0, 0)$ .

For example, a point light positioned at the point  $(0, 1, 0)$  in camera coordinates is a “head lamp” fixed at a distance of 1 above the camera.

A 3D plot may contain several cameras. Changing the state of `CameraCoordinates` for a light affects its relation to *all* cameras of a scene. With `CameraCoordinates = TRUE`, the position of the light in 3 space changes, when a new camera is chosen interactively.

## Examples

### Example 1

We define a sphere:

```
sphere := plot::Spherical(
 [1, u, v], u = 0..2*PI, v = 0..PI,
 FillColorType = Functional,
 FillColorFunction =
 proc(u, v) begin
 [(2 + cos(2*u))/3, (2 + sin(2*u))/3, 0]
 end_proc):
```

We define sunlight shining from above:

```
sunlight := plot::DistantLight([0, 0, 1], [0, 0, 0]):
plot(sphere, sunlight):
```

# CameraCoordinates

---

Next, the sunlight is defined relative to the camera. In camera coordinates, “above the camera” is given by the Position[0, 1, 0]. Because the camera points downwards, we set the direction of the sunlight “behind” the camera as well by choosing the direction [0, 1, -1.5] w.r.t. the camera:

```
sunlight := plot::DistantLight([0, 1, -1.5], [0, 0, 0],
 CameraCoordinates = TRUE):
plot(sphere, sunlight):
```

```
delete sphere, sunlight, pointlight:
```

## Example 2

We define the same sphere as in the previous example:

```
sphere := plot::Spherical(
 [1, u, v], u = 0..2*PI, v = 0..PI,
 FillColorType = Functional,
 FillColorFunction =
 proc(u, v) begin
 [(2 + cos(2*u))/3, (2 + sin(2*u))/3, 0]
 end_proc):
```

We define an animated camera. First, we use sunlight fixed in space:

```
camera := plot::Camera([-3*sin(a), -3*cos(a), 2],
 [0, 0, 0], 0.3*PI, a = 0..2*PI):
sunlight:= plot::DistantLight([0, -2, 3], [0, 0, 0]):
```

# CameraCoordinates

---

```
plot(sphere, camera, sunlight):
```

Next, we use sunlight moving with the camera:

```
sunlight:= plot::DistantLight([0, 3, -2], [0, 0, 0],
 CameraCoordinates = TRUE):
plot(sphere, camera, sunlight):
```

We define a point light that is fixed to some point above the camera:

```
pointlight := plot::PointLight([0, 1, 0],
 CameraCoordinates = TRUE):
plot(sphere, camera, pointlight):
```

# CameraCoordinates

---

```
delete sphere, camera, sunlight, pointlight:
```

### Example 3

We define the same sphere as in the previous examples:

```
sphere := plot::Spherical(
 [1, u, v], u = 0..2*PI, v = 0..PI,
 FillColorType = Functional,
 FillColorFunction =
 proc(u, v) begin
 [(2 + cos(2*u))/3, (2 + sin(2*u))/3, 0]
 end_proc):
```

We define an animated point light that is positioned below the camera initially. It moves to some point above the camera during the animation:

```
pointlight := plot::PointLight([0, 10*a, 0], a = -1..1,
 CameraCoordinates = TRUE):
```

```
plot(sphere, pointlight):
```

We define an animated point light that is positioned to the left of the camera initially. It moves to the right of the camera:

```
pointlight := plot::PointLight([10*a, 0, 0], a = -1 .. 1,
 CameraCoordinates = TRUE):
plot(sphere, pointlight):
```

# CameraCoordinates

---

`delete sphere, pointlight:`

### MuPAD Functions

`LightColor` | `LightIntensity` | `Position` | `SpotAngle` | `Target`

# CameraDirection, CameraDirectionX, CameraDirectionY, CameraDirectionZ

---

**Purpose** Direction of the automatic camera

**Value Summary**

CameraDirection	Library wrapper for “[CameraDirectionX, CameraDirectionY, CameraDirectionZ]” (3D)	See below
CameraDirectionX, CameraDirectionY, CameraDirectionZ		See below

**Graphics Primitives**

Objects	Default Values
plot::Scene3d	

**Description**

CameraDirection controls the direction where the automatically set camera is positioned.

CameraDirectionX etc. refer to the single coordinates of this direction.

When creating a 3D scene, an “automatic camera” is used. It is placed somewhere along the ray starting at the center of the scene (or the center of an explicitly requested ViewingBox, respectively) with the direction given by CameraDirection.

The distance to the scene is chosen automatically such that the graphical scene or ViewingBox fills the drawing area optimally.

The CameraDirection value is a list or vector of numbers.

---

**Note** This vector represents a direction, where the camera is found when starting at the center of the scene or viewing box. It is not the position of the camera!

---

# CameraDirection, CameraDirectionX, CameraDirectionY, CameraDirectionZ

---

The length of the CameraDirection does not matter, only its direction. The length should not be zero, though.

CameraDirection = [0, 0, 1] (looking straight down onto the  $x$ - $y$  plane along the  $z$ -axis) does not yield a well defined camera view. This direction is automatically replaced by a direction that is close to, but not exactly equal to the  $z$  direction and orients the scene similar to a 2D plot.

The CameraDirection attributes cannot be animated.

The automatic camera is designed to produce a picture of the entire scene or viewing box, filling the drawing area optimally. CameraDirection is the only means to control it.

If only parts of a scene shall be visible, or if the camera is not to aim at the center of the scene, or if large perspective distortions are desired, or if the camera position is to be animated, one has to define one's own camera of type `plot::Camera`. It can be placed at an arbitrary Position with an arbitrary FocalPoint and can have an arbitrary ViewingAngle. Further, it can be animated (allowing to realize a flight through a 3D scene).

When such a camera object is inserted in a graphical scene, the automatic camera is switched off and the user defined camera takes over, automatically. It uses its own perspective parameters and ignores the attribute CameraDirection.

## Examples

### Example 1

We look at a function with the default direction of the automatic camera:

```
f := plot::Function3d(x^2 + y^3, x = 0..1, y = -1 ..1):
plot(f):
```

# CameraDirection, CameraDirectionX, CameraDirectionY, CameraDirectionZ

---

We look from different directions:

```
S1 := plot::Scene3d(f, CameraDirection = [-3,-4, 5]):
S2 := plot::Scene3d(f, CameraDirection = [3,-4, 5]):
S3 := plot::Scene3d(f, CameraDirection = [3, 4, 5]):
S4 := plot::Scene3d(f, CameraDirection = [-3, 4, 5]):
plot(S1, S2, S3, S4)
```

# CameraDirection, CameraDirectionX, CameraDirectionY, CameraDirectionZ

---

We look straight down onto the  $x$ - $y$  plane along the  $z$ -axis:

```
plot(f, CameraDirection = [0, 0, 1])
```

# CameraDirection, CameraDirectionX, CameraDirectionY, CameraDirectionZ

---

delete f, S1, S2, S3:

## MuPAD Functions

FocalPoint | OrthogonalProjection | Position | ViewingAngle

# FocalPoint, FocalPointX, FocalPointY, FocalPointZ

**Purpose** Focal point of a camera

**Value Summary**

FocalPoint	Library wrapper for “[FocalPointX, FocalPointY, FocalPointZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
FocalPointX, FocalPointY, FocalPointZ	Optional	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Camera	

## Description

The attribute `FocalPoint` refers to the point a camera taking pictures of a 3D scene is aimed at. Its value is a list or vector of coordinates (numerical values or symbolic expressions of an animation parameter).

`FocalPointX` etc. refer to the single coordinates `x` etc.

The optical axis of the camera is given by the vector from the camera `Position` to its `FocalPoint`.

When creating a camera by

```
camera := plot::Camera(camera_position, focal_point, opening_angle),
```

the focal point is the second argument. Internally, this point is stored as the attribute `FocalPoint` and can be accessed and changed as `camera::FocalPoint`.

The focal point attributes can be animated.

Of course, the focal point should be set such that the camera points into the direction of the objects that are to be rendered. Typically, for a

# FocalPoint, FocalPointX, FocalPointY, FocalPointZ

---

camera positioned outside the graphical scene, a good focal point is the center of the scene.

## Examples

### Example 1

We define a scene consisting of 4 geometric objects:

```
b := plot::Box(4..5, -1..1, -1..1, Filled = FALSE,
 LineColor = RGB::Red):
c1 := plot::Cone(1, [0, 4, 0], [0, 4, 1], Color = RGB::Green):
s := plot::Sphere(1, [-4, 0, 0], Color = RGB::Blue):
c2 := plot::Cone(1, [0, -4, 1], [0, -4, 0],
 Color = RGB::Orange):
```

We use a small black object to mark the point (0, 0, 0.5), where we wish to place an animated camera:

```
cameraposition := plot::Group3d(
 plot::Box(-0.1..0.1, -0.3..0.3, 0.3..0.7,
 Color = RGB::Black),
 plot::Cone(0.1, [0, 0, 0.5], 0.3, [0.5, 0, 0.5],
 Color = RGB::DarkGrey)):
plot(b, c1, s, c2, cameraposition)
```

# FocalPoint, FocalPointX, FocalPointY, FocalPointZ

---

When defining the camera, the second argument is the FocalPoint. In this case, it is animated: The camera is to turn around the z-axis.

```
camera := plot::Camera([0, 0, 0.5], [4*cos(a), 4*sin(a), 0],
 PI/4, a = 0..2*PI):
camera::FocalPoint

[4 cos(a), 4 sin(a), 0]
```

We insert the animated camera:

```
plot(b, c1, s, c2, camera)
```

# FocalPoint, FocalPointX, FocalPointY, FocalPointZ

---

```
delete b, c1, s, c2, cameraposition, camera:
```

## Example 2

We define a function and a camera with an animated focal point:

```
f := plot::Function3d(sin(x^2-y^2), x = -2..2, y = -2..2,
 Submesh = [2, 2]):
camera := plot::Camera([3, 3, 3], [sin(a), cos(a), 0],
 PI/6, a = 0..2*PI):
plot(f, camera)
```

# FocalPoint, FocalPointX, FocalPointY, FocalPointZ

---

`delete f, camera:`

### MuPAD Functions

[CameraDirection](#) | [OrthogonalProjection](#) | [Position](#) | [ViewingAngle](#)

**Purpose** Color of light

**Value Summary** Inherited Color

**Description** `LightColor` sets the color of user-defined light sources such as `plot::AmbientLight`, `plot::DistantLight` etc.

The value of `LightColor` must be an RGB or RGBA color, i.e., a list of three or four numerical values between 0 and 1. (The fourth value is the opacity entry of an RGBA color. It is accepted but does not have any effect on the light color.)

The RGB library provides many predefined colors such as `RGB::Blue` etc. See Section of this document for more information on colors.

`LightColor` cannot be animated.

## Examples **Example 1**

We define a white box and illuminate it by a yellow distant light:

```
b := plot::Box(-1..1, -1..1, -1..1, Color = RGB::White):
light := plot::DistantLight([-1, -2, 3], [0, 0, 0],
 Color = RGB::Yellow):
plot(b, light, Axes = None)
```

# LightColor

---

We change the color of the light source:

```
light::LightColor := RGB::Blue:
plot(b, light, Axes = None)
```

```
delete b, light:
```

## See Also

### MuPAD Functions

CameraCoordinates | LightIntensity | Position | SpotAngle |  
Target

# Lighting

---

**Purpose** Light schemes for 3D graphics

**Value Summary** Inherited Automatic, Explicit, or None

## Graphics Primitives

Objects	Lighting Default Values
plot::Scene3d	Automatic

## Description

Lighting determines the light scheme used to illuminate a 3D scene.

With the default `Lighting = Automatic`, several light sources are set automatically to illuminate a 3D scene. Firstly, there is ambient white light of type `plot::AmbientLight`:

- Light 0: `LightIntensity = 0.25`, `LightColor = RGB::White`

In addition, there are 6 directed lights of type `plot::DistantLight` with `LightColor = RGB::White`. Their directions is given as follows: Think of the graphical scene as being scaled to a standard box extending from -1 to 1 in each coordinate direction. In these scaled coordinates, the directed lights shine into the directions given by the following Target attributes:

- Light 1: Target = [-5, -6, -8], `LightIntensity = 0.50`,
- Light 2: Target = [ 5, 6, 8], `LightIntensity = 0.60`,
- Light 3: Target = [ 5, -6, -8], `LightIntensity = 0.20`,
- Light 4: Target = [-5, 6, 8], `LightIntensity = 0.25`,
- Light 5: Target = [-5, 6, -8], `LightIntensity = 0.20`,
- Light 6: Target = [ 5, -6, 8], `LightIntensity = 0.25`.

User-defined lights in the scene are ignored with `Lighting = Automatic`.

With `Lighting = Explicit`, the light sources set via `Lighting = Automatic` are switched off and user-defined light sources are switched on.

A `plot` command searches for light objects set by the user. If `Lighting` is not specified and any kind of user-defined light object is found in the scene, `Lighting = Explicit` is set automatically.

Switching between `Lighting = Automatic` and `Lighting = Explicit` in the inspector, one can easily compare the effect of the automatic lights with the effect of ones own lights.

With `Lighting = None`, the 3D shading algorithm based on reflections of light emitted from light sources in the graphical scene is switched off. This does not mean that the graphical scene turns black: all objects are painted in the color they are defined with. However, the scene will appear flat, because the depth of a 3D scene is created via the shading caused by different reflections of light at different points of the scene.

The maximal number of lights that can be used to illuminate a 3D scene depends on the OpenGL driver installed on the computer.

---

**Note** Some OpenGL drivers do not allow more than 6 light sources. If there are more light sources in the scene, the surplus lights are ignored. Lights that are switched off via `Visible = FALSE` are not counted.

---

After activating a 3D plot (by clicking it), the “Help” menu contains an item “OpenGL Info” that provides information about the maximal number of lights.

## Examples

### Example 1

In our first scene, no lights are specified. The default setting `Lighting = Automatic` is used:

```
f := plot::Function3d(sin(x^2 + y^2), x = -2..2, y = -2..2):
plot(f):
```

# Lighting

---

When specifying `Lighting = Explicit`, the lights set by the user are used. Since the scene does not contain any lights, the scene turns dark:

```
plot(f, Lighting = Explicit):
```

Lights are specified in the next scene. The setting `Lighting = Explicit` is used automatically:

```
Light0 := plot::AmbientLight(0.25):
Light1 := plot::DistantLight([1, 0, 1], [0, 0, 0], 0.3):
Light2 := plot::DistantLight([-1, 0, 1], [0, 0, 0], 0.3):
Light3 := plot::DistantLight([0, 1, 1], [0, 0, 0], 0.3):
Light4 := plot::DistantLight([0, -1, 1], [0, 0, 0], 0.3):
plot(f, Light0, Light1, Light2, Light3, Light4):
```

# Lighting

---

We switch off the parameter lines:

```
plot(f, Light0, Light1, Light2, Light3, Light4,
 XLinesVisible = FALSE, YLinesVisible = FALSE,
 Axes = None):
```

In the next scene, the 3D shading model is switched off via `Lighting = None`:

```
plot(f, Lighting = None):
```

# Lighting

---

In the previous picture, the axes box and the mesh lines are switched on and create a certain 3D effect. After switching the box and the mesh lines off, the scene appears flat when rendered without shading:

```
plot(f, Lighting = None, Axes = None,
 XLinesVisible = FALSE, YLinesVisible = FALSE):
```

```
delete f, Light0, Light1, Light2, Light3, Light4:
```

Target

# OrthogonalProjection

---

**Purpose** Parallel projection without perspective distortion

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	OrthogonalProjection Default Values
plot::Camera	FALSE

## Description

Setting `OrthogonalProjection = TRUE`, a camera uses parallel projection without perspective distortion.

By default, a camera uses `OrthogonalProjection = FALSE`. Depending on the distance of the camera to the graphical scene (set by the attribute `Position`), the scene is subject to some natural perspective distortion. The distortion is large when the camera is near the scene. It is small when the camera is far away.

In principle, using parallel projection is equivalent to placing a camera at a very large distance from the scene, looking through a very powerful tele lens.

For technical reasons, however, you should *not* suppress perspective distortion by placing the camera yourself somewhere far away via the attribute `Position` and turning the camera's lens into a tele lens by setting a small value for its opening angle (cf. `ViewingAngle`). This may lead to problems with the hidden line algorithm used by the 3D renderer. Further, a suitable opening angle has to be found experimentally such that the scene fills a reasonable portion of the drawing area.

Use `OrthogonalProjection = TRUE` instead. The scaling of the scene is done automatically to fill the drawing area optimally.

With `OrthogonalProjection = TRUE`, the view is only determined by the direction of the vector from the `FocalPoint` of the camera to its

Position. (The camera is moved to infinity along the ray given by this “optical axis”, using an infinitesimal opening angle.)

The absolute camera position in 3-space as well as its opening angle are ignored.

## Examples

### Example 1

We look at a box with side length 2 using cameras at different positions. We double the distance between the camera and the center of the box from one scene to the next. At the same time, we use more and more powerful tele lenses by decreasing the camera’s opening angle by a factor of  $\frac{1}{2}$ , so that the box has approximately the same size.

- In S1, the camera is close to the box. The box is distorted heavily.
- In S2, the camera is farther away. The perspective distortions are smaller.
- In S3, the distance of the camera to the box center is about 5 times the diameter of the box. Only minor perspective distortions are visible.
- In S4, the distance of the camera is about 10 times the diameter of the box. The perspective distortions are almost gone:

```
b := plot::Box(-1..1, -1..1, -1..1, Filled = FALSE,
 LineColor = RGB::Black):
S1:= plot::Scene3d(b, plot::Camera([2, 1.8, 2.5], [0, 0, 0]),
S2:= plot::Scene3d(b, plot::Camera([4, 3.6, 5.0], [0, 0, 0]),
S3:= plot::Scene3d(b, plot::Camera([8, 7.2, 10.0], [0, 0, 0]),
S4:= plot::Scene3d(b, plot::Camera([16, 14.4, 20.0], [0, 0, 0]),
plot(S1, S2, S3, S4, Axes = None)
```

# OrthogonalProjection

---

We suppress the distortions completely by setting `OrthogonalProjection = TRUE`. Note the automatic scaling of the scene:

```
plot(S1, S2, S3, S4, Axes = None, OrthogonalProjection = TRUE)
```

```
delete b, S1, S2, S3, S4:
```

## Example 2

The following camera is too close to the scene to make all parts of the function graph visible:

```
f := plot::Function3d(sin(x^2 - y^2), x = -2..2, y = -2..2):
camera := plot::Camera([2, 2, 2], [0, 0, 0], PI/5):
plot(f, camera)
```

# OrthogonalProjection

---

With `OrthogonalProjection = TRUE`, the specified position and opening angle are ignored. The effect of `OrthogonalProjection` is the same as placing the camera far away and choosing a tiny opening angle such that the scene fills the drawing area optimally:

```
camera::OrthogonalProjection := TRUE:
plot(f,camera)
```

`delete f, camera:`

## MuPAD Functions

`CameraDirection` | `FocalPoint` | `Position` | `ViewingAngle`

# SpotAngle

---

**Purpose** Opening angle of the light cone of a spot light

**Value Summary** Mandatory Real-valued expression (interpreted in radians)

## Graphics Primitives

Objects	SpotAngle Default Values
plot::SpotLight	

## Description

SpotAngle sets the opening angle of the light cone of a spot light in radians, and defines the opening angle of the light cone emitted by spot lights of type plot::SpotLight.

The values for SpotAngle have to be given in radians. Reasonable values lie between 0 and  $\pi$ .

SpotAngle can be animated.

## Examples

### Example 1

When creating a spot light, the third argument is the SpotAngle:

```
spotlight := plot::SpotLight([0, 0, 1], [0, 0, 0], a*PI, 1,
 a = 0..0.4, LightColor = RGB::White):
spotlight::SpotAngle
```

$\pi a$

We illuminate the  $x$ - $y$  plane by the animated spot light and some ambient light. The spot light is visualized by a cone:

```
ambientlight := plot::AmbientLight(0.2):
s := plot::Surface([x, y, 0], x = -1..1, y = -1..1,
 Submesh = [2, 2], Color = RGB::White,
 FillColorType = Flat):
```

```
c := plot::Cone(0, [0, 0, 1],
 0.6*tan(a*PI/2), [0, 0, 1 - 0.6],
 a = 0..0.4, Color = RGB::Orange.[0.5]):
plot(s, c, spotlight, ambientlight,
 CameraDirection = [-9, -18, 12])
```

```
delete spotlight, ambientlight, s, c:
```

## See Also

## MuPAD Functions

CameraCoordinates | LightColor | LightIntensity | Position  
| Target

# Target, TargetX, TargetY, TargetZ

---

**Purpose** Target point of a light

**Value Summary**

Target	Library wrapper for “[TargetX, TargetY, TargetZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
TargetX, TargetY, TargetZ	Mandatory	MuPAD expression

**Graphics Primitives**

Objects	Default Values
plot::DistantLight, plot::SpotLight	

**Description**

The Target attribute refers to the point a spot light is aimed at. It also controls the direction of a distant light which is given by the vector Target - Position.

Target sets the position of the point lights of type plot::DistantLight and plot::SpotLight are aimed at. TargetX etc. refer to the single coordinates of this point.

The value of Target is a list or vector of coordinates. TargetX = x etc. refer to the single coordinates of this list.

These attributes can be animated.

By default, the positions and the targets of light objects are given in model coordinates that have nothing to do with the camera that is used to view the scene.

When using the attribute CameraCoordinates = TRUE, the light source is fixed to the camera. It moves automatically, when the camera is moved.

## Examples

### Example 1

When generating lights of type `plot::DistantLight` and `plot::SpotLight`, the second argument is the `Target`. In the following example, it is animated:

```
sunlight := plot::DistantLight([0, 0, 2],
 [cos(a), sin(a), 1],
 a = 0..2*PI):
spotlight := plot::SpotLight([0, 0, 1],
 [cos(a), sin(a), 1/2],
 PI/5, a = 0..2*PI):
sunlight::Target, spotlight::Target
```

$[\cos(a), \sin(a), 1], [\cos(a), \sin(a), \frac{1}{2}]$

We illuminate a paraboloid with sunlight. Its direction is animated by the `Target` attribute:

```
f := plot::Function3d(x^2 + y^2, x = -1..1, y = -1..1):
plot(f, sunlight, CameraDirection = [-1, -2, 6])
```

# Target, TargetX, TargetY, TargetZ

---

We use the animated spot light:

```
plot(f, spotlight, CameraDirection = [-1, -2, 6])
```

`delete sunlight, spotlight, f:`

## MuPAD Functions

`CameraCoordinates` | `SpotAngle` | `Position` | `LightIntensity`

# UpVector, UpVectorX, UpVectorY, UpVectorZ, KeepUpVector

**Purpose** Up direction of a camera

## Value Summary

UpVector	Library wrapper for “[UpVectorX, UpVectorY, UpVectorZ]” (3D)	List of 2 or 3 expressions, depending on the dimension
UpVectorX, UpVectorY, UpVectorZ	Optional	MuPAD expression
KeepUpVector	Inherited	FALSE, or TRUE

## Graphics Primitives

Objects	Default Values
plot::Camera	UpVector: [0.0, 0.0, 1.0] UpVectorX, UpVectorY: 0.0 UpVectorZ: 1.0 KeepUpVector: TRUE

## Description

UpVector = [x, y, z] sets the 3D vector that corresponds to the vertical direction of the 2D picture taken by the camera.

UpVectorX etc. denote the coordinates of the UpVector.

KeepUpVector = TRUE keeps the UpVector constant when the camera is moved. With KeepUpVector = FALSE, the UpVector is kept orthogonal to the optical axis when the camera is moved.

The picture taken by a camera is defined by the attributes Position (the 3D position of the camera) and FocalPoint (the 3D point the camera is pointed at). The vector from the position to the focal point is the optical axis of the camera.

As an additional degree of freedom, the camera may be rotated around the optical axis. This rotation is defined by specifying a 3D vector

# UpVector, UpVectorX, UpVectorY, UpVectorZ, KeepUpVector

---

UpVector. In the final 2D picture taken by the camera, this vector is parallel to the vertical axis, pointing upwards.

With the default value `UpVector = [0, 0, 1]` the z-axis in 3D points upwards in the 2D picture.

The UpVector of a camera must not be zero and must not be parallel to the optical axis.

The default values are `UpVector = [0, 0, 1]` and `KeepUpVector = TRUE`.

The restriction that the UpVector must not be parallel to the optical axis leads to discontinuities when the camera moves in such a way that this restriction is violated. In such a case, `KeepUpVector = FALSE` should be used. Cf. “Example 2” on page 23-1961.

## Examples

### Example 1

We view a cross of three arrows by a camera with the usual UpVector pointing into z-direction:

```
camera := plot::Camera([0.3, -4.0, 0.2], [0, 0, 0], PI/4,
 UpVector = [0, 0, 1]):
plot(plot::Arrow3d([-1, 0, 0], [1, 0, 0], Color = RGB::Red),
 plot::Arrow3d([0, -1, 0], [0, 1, 0], Color = RGB::Green),
 plot::Arrow3d([0, 0, -1], [0, 0, 1], Color = RGB::Blue),
 camera)
```

# UpVector, UpVectorX, UpVectorY, UpVectorZ, KeepUpVector

---

We redefine the UpVector of the camera to point into the direction  $[1, 0, 1]$ . Now, this 3D direction becomes the vertical direction of the 2D picture:

```
camera::UpVector := [1, 0, 1]:
plot(plot::Arrow3d([-1, 0, 0], [1, 0, 0], Color = RGB::Red),
 plot::Arrow3d([0, -1, 0], [0, 1, 0], Color = RGB::Green),
 plot::Arrow3d([0, 0, -1], [0, 0, 1], Color = RGB::Blue),
 camera)
```

# UpVector, UpVectorX, UpVectorY, UpVectorZ, KeepUpVector

delete camera:

## Example 2

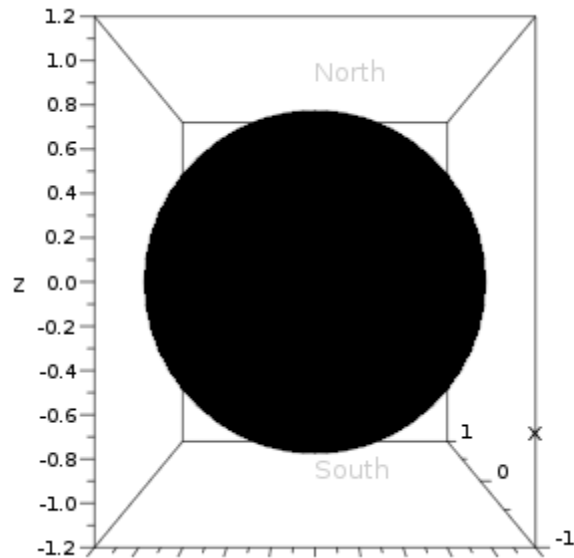

We use an animated camera to fly over the north pole of a planet using the default UpVector = [0, 0, 1]. With KeepUpVector = TRUE, we encounter a discontinuity when the camera is positioned exactly over the north pole pointing straight down. The UpVector is parallel to the optical axis at this point:

```
camera := plot::Camera([4*cos(a), 0, 4*sin(a)], [0, 0, 0], PI/4,
 a = 0..PI, Frames = 300,
 UpVector = [0, 0, 1],
 KeepUpVector = TRUE):
planet := plot::Surface([cos(u)*sin(v), sin(u)*sin(v), cos(v)],
 u = 0..2*PI, v = 0..PI,
 FillColorFunction = proc(u, v)
 begin
 [cos(u)*cos(v)^2, cos(u)*cos(v)^2, cos(u)]
```

# UpVector, UpVectorX, UpVectorY, UpVectorZ, KeepUpVector

---

```
end_proc):
font := ["sans-serif", 10, RGB::Grey80]:
text1 := plot::Text3d("North", [0, 0, 1.2], TextFont = font):
text2 := plot::Text3d("South", [0, 0, -1.2], TextFont = font):
plot(camera, planet, text1, text2, Scaling = Constrained);
```

With `KeepUpVector = FALSE`, no such discontinuity is encountered. However, when reaching the equator on the dark side of the planet, the `UpVector` has turned around: the upper side of the picture now is south, the lower side is north:

```
camera::KeepUpVector := FALSE:
plot(camera, planet, text1, text2, Scaling = Constrained);
```

# UpVector, UpVectorX, UpVectorY, UpVectorZ, KeepUpVector

---

```
delete camera, planet, font, text1, text2:
```

## MuPAD Functions

FocalPoint | Position

# ViewingAngle

---

**Purpose** Opening angle of the camera lense

**Value Summary** Mandatory MuPAD expression

## Graphics Primitives

Objects	ViewingAngle Default Values
plot::Camera	

## Description

ViewingAngle defines the viewing angle of a camera. It is also known as the “opening angle” of the camera’s lense and is determined by its focal length.

Small viewing angles correspond to a tele lense, large opening angles to a wide angle lense. Angles close to  $\pi$  correspond to an (extreme) fish eye lense.

The values for ViewingAngle have to be given in radians. The angles should be larger than  $\frac{1}{100}$  and smaller than  $\pi$ . Other values are replaced by some small positive angle or by an angle slightly less than  $\pi$ , respectively.

Note that when using a wide angle lense, the scene may fill only a part of the drawing area. With a tele lense, only parts of the scene may be visible.

When using a camera object with a given Position, you have to find out experimentally what viewing angle is suitable to make the scene fill a reasonable portion of the drawing area.

ViewingAngle does not have any effect when the attribute OrthogonalProjection = TRUE is set for the camera.

---

**Note** In fact, when a parallel projection without perspective distortion is desired, one should *not* position the camera far away from the scene and use an extreme tele lens (i.e, very small `ViewingAngle` values). This may lead to problems with the hidden line algorithm of the 3D renderer. Use `OrthogonalProjection = TRUE` instead.

---

`ViewingAngle` can be animated. Increasing or decreasing values of `ViewingAngle` correspond to “zooming out” or “zooming in”, respectively.

## Examples

### Example 1

When creating a camera object, the third argument is the `ViewingAngle`:

```
camera:= plot::Camera([5, 5, 5], [0, 0, 0], PI/4):
camera::ViewingAngle
```

$$\frac{\pi}{4}$$

We animate `ViewingAngle`. With the initial value of  $\frac{\pi}{3}$  the scene is fully visible (but rather small). Zooming in by decreasing the viewing angle, only parts of the scene are visible:

```
f := plot::Function3d(sin(x^3 - y^2), x = -2..2, y = -2..2,
 Submesh = [2, 2]):
camera:= plot::Camera([5, 5, 5], [0, 0, 0],
 (1 - a)*PI/3 + a*PI/10,
 a = 0..1, Frames = 200):
plot(f, camera)
```

# ViewingAngle

---

```
delete f, camera:
```

plot::Bars2d, plot::Boxplot, plot::Density, plot::Inequality, plot::Iteration,	FALSE

# AntiAliased

---

Objects	AntiAliased Default Values
---------	----------------------------

## Description

`plot::Lsys`, `plot::Raster`, `AntiAliased` controls whether lines and points are drawn antialiased or not. With `AntiAliased` enabled graphics usually look smoother.

## Examples

### Example 1

We draw a points in different sizes and point styles. The black points are drawn with `AntiAliased = FALSE`, the blue points are drawn with `AntiAliased = TRUE`:

```
pointStyles := [Squares, FilledSquares, Circles, FilledCircles,
 Crosses, XCrosses, Diamonds, FilledDiamonds, Stars]
pointSizes := [1.5, 3, 4.5, 6]:
plot(Axes = None,
 (plot::Point2d(i, 2*j, AntiAliased=TRUE, PointStyle=pointSt
 PointSize=pointSizes[j], Color=RGB::Blue),
 plot::Point2d(i, 2*j+1, AntiAliased=FALSE, PointStyle=pointSt
 PointSize=pointSizes[j], Color=RGB::Black)) $
 i = 1 .. nops(pointStyles) $ j = 1..nops(pointSizes))
```

With horizontal lines we see not much difference between `AntiAliased = FALSE` (black lines) and `AntiAliased = TRUE` (blue lines):

```

lineStyles := [Solid, Dashed, Dotted]:
lineWidth := [.25, .5, .75, 1, 1.25, 1.5]:
plot(Axes = None,
 (plot::Line2d([i, 2*j], [i+.8, 2*j], AntiAliased=TRUE, L
 LineWidth=lineWidth[j], Color=RGB::Blue),
 plot::Line2d([i, 2*j+1], [i+.8, 2*j+1], AntiAliased=FALSE, L
 LineWidth=lineWidth[j], Color=RGB::Black)) $
 i = 1 .. nops(lineStyles) $ j = 1..nops(lineWidth))

```

# AntiAliased

---

Diagonal lines are much smoother with `AntiAliased = TRUE`:

```
lineStyles := [Solid, Dashed, Dotted]:
lineWidth := [.25, .5, .75, 1, 1.25, 1.5]:
plot(Axes = None,
 (plot::Line2d([i, 2*j], [i+.8, 2*j+1], AntiAliased=TRUE, Li
 LineWidth=lineWidth[j], Color=RGB::Blue),
 plot::Line2d([i, 2*j+1], [i+.8, 2*j+2], AntiAliased=FALSE,
 LineWidth=lineWidth[j], Color=RGB::Black)) $
 i = 1 .. nops(lineStyles) $ j = 1..nops(lineWidth))
```

By default curves are plotted with `AntiAliased = TRUE` (blue curve) which is much nicer:

```
f := plot::Curve2d([Re, Im](zeta(I*y+1/2)), y=0..42,
 AdaptiveMesh=3):
f1 := plot::modify(f, AntiAliased=FALSE, Color=RGB::Black):
plot(f, plot::Translate2d([5, 0], f1),
 XAxisTitle = "Re(z)", YAxisTitle = "Im(z)")
```

# AntiAliased

**MuPAD  
Functions**

LineStyle | PointStyle

**Purpose** Scaling of arrows in a vector field

**Value Summary** Inherited Fixed, Logarithmic, or Proportional

## Graphics Primitives

Objects	ArrowLength Default Values
<code>plot::VectorField2d</code> , <code>plot::VectorField3d</code>	Proportional

## Description

ArrowLength determines how the lengths of the arrows in a vector field plot depend on the norms of the field at the evaluated points.

`plot::VectorField2d` plots a vector field by placing arrows at regular intervals, pointing in the directions of the field at these points.

ArrowLength determines whether the lengths of those arrows are constant (`ArrowLength =Fixed`), proportional to the norms of the field (`ArrowLength =Proportional`, the default), or proportional to the logarithm of these values increased by 1 (`ArrowLength =Logarithmic`).

## Examples

### Example 1

The vector field defined by  $f(x, y) = (x, y)^t$  takes on different absolute values at different points. By default, `plot::VectorField2d` plots arrows whose lengths are proportional to the norms of the field:

```
v := plot::VectorField2d(x, y, x=-3..3, y=-3..3):
plot(v)
```

# ArrowLength

---

If you only want to display the direction of the field, not its “strength”, use `ArrowLength =Fixed`:

```
v::ArrowLength := Fixed:
plot(v)
```

# AxesTitleFont, FooterFont, HeaderFont, LegendFont, TextFont, TicksLabelFont, TitleFont

---

**Purpose** Font of axes titles

**Value Summary** AxesTitleFont, FooterFont, HeaderFont, LegendFont, TextFont, TicksLabelFont, TitleFont  
 Inherited  
 Font definition

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	AxesTitleFont: [" sans-serif ", 10] TicksLabelFont: [" sans-serif ", 8]
plot::Canvas	FooterFont, HeaderFont: [" sans-serif ", 12]
plot::Scene2d, plot::Scene3d	FooterFont, HeaderFont: [" sans-serif ", 12] LegendFont: [" sans-serif ", 8]
plot::Integral, plot::Piechart2d, plot::Piechart3d, plot::Text2d, plot::Text3d	TextFont, TitleFont: [" sans-serif ", 11]

**Description** AxesTitleFont etc. determine the fonts to be used for axes titles etc.

A font is specified as follows:

```
XXXFont = [< family >, < size >, <<Bold>>, <<Italic>>, < color >>, < alignment >]
```

# AxesTitleFont, FooterFont, HeaderFont, LegendFont, TextFont, TicksLabelFont, TitleFont

---

The meaning of the parameters is as follows.

**family** Font family name: a string.

The available font families depend on the fonts that are installed on your machine. For example, typical font families available on Windows systems are "Times New Roman" (of type "serif"), "Arial" (of type "sans-serif"), or "Courier New" (of type "monospace").

To find out which fonts are available on your machine, open the menu "Format", submenu "Font" in your MuPAD notebook. The first column in the font dialog provides the names of the font families that you may specify. You may also specify one the three generic family names "serif", "sans-serif", or "monospace", and the system will automatically choose one of the available font families of the specified type for you.

**size** Size of the font in integral points: a positive integer.

**Bold** If specified, the font is bold.

**Italic** If specified, the font is italic.

**color** RGB color value: a list of 3 numerical values between 0 and 1

**alignment** Text alignment in case of new-lines: one of the flags Left, Center, or Right.

All font parameters are optional; some default values are chosen for entries that are not specified. For example, if you do not care about the footer font family for your plot, but you insist on a specific font size, you may specify an 18 pt font for the canvas footer by `FooterFont = [18]`.

## Examples

### Example 1

We specify the font for the canvas header:

```
plot(plot::Function2d(sin(x), x = 0 .. 2*PI),
 Header = "The sine function",
```

# AxesTitleFont, FooterFont, HeaderFont, LegendFont, TextFont, TicksLabelFont, TitleFont

---

```
HeaderFont = ["monospace", 14, Bold])
```

## The sine function

We specify a font size of 18 pt for the canvas footer:

```
plot(plot::Function2d(sin(x), x = 0 .. 2*PI),
 Footer = "The sine function", FooterFont = [18])
```

The sine function

### Example 2

With the “Symbol” font, it is possible to display Greek characters. The symbol  $\pi$  is referred to as the letter  $p$ :

```
plot(plot::Function2d(cos(x), x = -PI..PI),
 XTicksNumber = None,
 XTicksAt = [-PI/2 = "-p/2", PI = "p"],
 TicksLabelFont = ["Symbol", 20])
```

# AxesTitleFont, FooterFont, HeaderFont, LegendFont, TextFont, TicksLabelFont, TitleFont

---

Note, however, that this font is used for *all* tick labels:

```
plot(plot::Function2d(cos(x), x = -PI..PI),
 XTicksNumber = None,
 XTicksAt = [-PI/2 = "-p/2", PI = "p", 1.0 = "one"],
 TicksLabelFont = ["Symbol", 20])
```

# AxesTitleFont, FooterFont, HeaderFont, LegendFont, TextFont, TicksLabelFont, TitleFont

---

## Concepts

- “Fonts”

# BackgroundColor, BackgroundColor2

---

**Purpose** Background color

**Value Summary** BackgroundColor, Inherited Color  
BackgroundColor2

## Graphics Primitives

Objects	Default Values
plot::Canvas, plot::Scene2d	BackgroundColor: RGB::White
plot::Scene3d	BackgroundColor: RGB::White BackgroundColor2: RGB::Grey75

## Description

These attributes set background colors for scenes, scene margins, and the remaining space in a canvas.

BackgroundColor sets the background color of a scene or canvas, where “background” refers to any area not occupied by graphical elements, including the margin.

For a 3D-scene, if BackgroundStyle is not Flat, the actual scene background (not including the margin) is a blend from BackgroundColor to BackgroundColor2. See BackgroundStyle for details.

## Examples

### Example 1

In the following plot, we combine three scenes with backgrounds in red, blue, and green and set the background color of the canvas to yellow:

```
s1 := plot::Scene3d(plot::Sphere(1, Color = RGB::White),
 BackgroundColor = RGB::Red):
s2 := plot::modify(s1, BackgroundColor = RGB::Blue):
s3 := plot::modify(s1, BackgroundColor = RGB::Green):
plot(s1, s2, s3, BackgroundColor = RGB::Yellow):
```

# BackgroundColor, BackgroundColor2

---

## Example 2

Using `BackgroundColor2` and `BackgroundStyle`, you can set the background of 3D-scenes to use a color blend:

```
plotfunc3d(x^2-y^2,
 BackgroundStyle = LeftRight,
 BackgroundColor2 = RGB::Chartreuse)
```

# BackgroundColor, BackgroundColor2

---

But note that the margin of the scene is still painted in its BackgroundColor:

```
plotfunc3d(x^2-y^2,
 plot::Scene3d::BackgroundColor = RGB::Yellow,
 plot::Scene3d::BackgroundStyle = LeftRight,
 plot::Scene3d::BackgroundColor2 = RGB::LightBlue)
```

# BackgroundColor, BackgroundColor2

To avoid this margin, we set its width to zero:

```
plotfunc3d(x^2-y^2,
 plot::Scene3d::BackgroundColor = RGB::Yellow,
 plot::Scene3d::BackgroundStyle = LeftRight,
 plot::Scene3d::BackgroundColor2 = RGB::LightBlue,
 plot::Scene3d::Margin = 0)
```

# BackgroundColor, BackgroundColor2

---

### Example 3

The fact that `BackgroundColor` is an attribute of both canvas and scenes has the effect that giving it directly in a plot command will only affect the canvas, not the implicitly generated scenes of a plot:

```
plot(plot::Circle2d(1),
 BackgroundColor = RGB::Yellow)
```

# BackgroundColor, BackgroundColor2

---

```
plotfunc2d(sin(x), BackgroundColor = RGB::Black)
```

# BackgroundColor, BackgroundColor2

---

To set the background color of a scene, use one of the styles illustrated above: Either create a scene explicitly:

```
plot(plot::Scene2d(plot::Circle2d(1),
 BackgroundColor = RGB::Yellow))
```

# BackgroundColor, BackgroundColor2

---

Or, set the attribute explicitly for scenes:

```
plotfunc2d(sin(x),
 plot::Scene2d::BackgroundColor = RGB::Orange)
```

# BackgroundColor, BackgroundColor2

---

There is also a third option, not used in the examples above: You can set `BackgroundColor` as a hint in an object to be shown (but this does not work for `plotfunc2d` and `plotfunc3d`):

```
plot(plot::Text2d("Sample", [0, 0],
 TextFont = [RGB::White, 60],
 HorizontalAlignment = Center,
 BackgroundColor = RGB::Black))
```

### **See Also**

### **MuPAD Functions**

[BackgroundColor](#) | [BackgroundColor2](#) | [Margin](#)

# BackgroundStyle

---

**Purpose** Color blends in the background

**Value Summary** Inherited Flat, LeftRight, Pyramid, or TopBottom

## Graphics Primitives

Objects	BackgroundStyle Default Values
plot::Scene3d	Flat

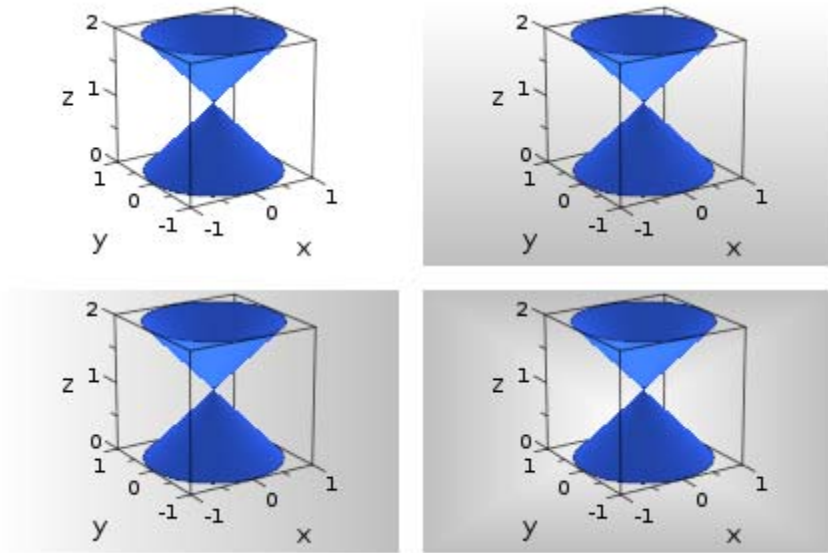

**Description** BackgroundStyle gives a color blend in the background of a 3D scene. The background of a 3D scene may be set to a single color (BackgroundStyle = Flat, using BackgroundColor) or to a blend from BackgroundColor to BackgroundColor2, in one of three possible directions: LeftRight and TopBottom are linear blends from left to right or from top to bottom, respectively, while Pyramid sets a linear blend from the center to the borders.

## Examples

### Example 1

We demonstrate all possible styles, using a simple plot and the default values for BackgroundColor and BackgroundColor2:

```
c1 := plot::Cone(1, [0, 0, 0], [0, 0, 1]):
c2 := plot::Cone(1, [0, 0, 2], [0, 0, 1]):
plot(plot::Scene3d(c1, c2, BackgroundStyle = Flat),
 plot::Scene3d(c1, c2, BackgroundStyle = TopBottom),
 plot::Scene3d(c1, c2, BackgroundStyle = LeftRight),
 plot::Scene3d(c1, c2, BackgroundStyle = Pyramid),
 Layout = Tabular)
```

`delete c1, c2:`

## See Also

### MuPAD Functions

`BackgroundColor` | `BackgroundColor2`

# BackgroundTransparent

---

**Purpose** Plot a scene on a transparent background

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	BackgroundTransparent Default Values
plot::Scene2d, plot::Scene3d	FALSE

## Description

Using `BackgroundTransparent`, you can have a scene “without a background.”

By default, each scene has an opaque background. In the case of overlapping scenes (which you can achieve by setting `Layout = Absolute` or `Layout = Relative` in the canvas and providing suitable values for `Bottom` and `Left` for the scenes), this may be undesirable. Using `BackgroundTransparent`, you can make the background of a scene transparent, so the canvas background and scenes behind it are visible.

With `BackgroundTransparent = TRUE`, other background settings (`BackgroundColor`, `BackgroundStyle`, `BackgroundColor2`) are ignored.

## Examples

### Example 1

We create a number of random points and two statistical plots of this sample:

```
gen := stats::normalRandom(0, 1):
data := [gen() $ i = 1..1000]:
s1 := plot::Scene2d(plot::PointList2d([[i, data[i]]
 $ i = 1..1000]),
 Left = 0, Bottom = 10,
 Width = 120, Height = 80):
s2 := plot::Scene2d(plot::Histogram2d(data, Cells=[20]),
```

# BackgroundTransparent

```
Left = 80, Bottom = 0,
Width = 50, Height = 40):
plot(s1, s2, Layout = Absolute, Width = 130, Height = 90)
```

The histogram plot obscures parts of the point list in a rectangle much larger than the bars of the histogram plot. Using `BackgroundTransparent`, we can set this rectangle to transparent:

```
s2::BackgroundTransparent := TRUE:
plot(s1, s2, Layout = Absolute, Width = 130, Height = 90)
```

# BackgroundTransparent

---

### MuPAD Functions

[BackgroundColor](#) | [BackgroundColor2](#) | [Bottom](#) | [Layout](#) | [Left](#)

**Purpose** Text orientation in space or towards observer

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	Billboarding Default Values
plot::Piechart3d, plot::Text3d	TRUE

**Description** With `Billboarding = TRUE`, text objects are always facing the observer. With `Billboarding = FALSE`, text objects retain their orientation relative to other objects.

Often, text objects in 3D are used to label certain places in a graphic (note that objects can contain a title, so text objects are usually only necessary for additional descriptions). In this case, it is desirable that they always face the observer to be readable and not rotate along with the rest of the scene. This is the default behavior. To get text objects that are actually part of the scene in the sense that rotating the scene also rotates the texts, set `Billboarding = FALSE`.

## Examples

### Example 1

In the following image, the prime numbers use `Billboarding = TRUE`, while other numbers do not:

```
plot(plot::Text3d(expr2text(i),
 [3*i, 0, 0],
 TextOrientation = [1, 0, 0, 0, 1, 0],
 Billboarding = isprime(i))
$ i = 1..15,
 TextFont = [20], Scaling = Constrained, Axes = None)
```

# Billboarding

---

1 2 3 4 5 6 7 8 9 10 11 12 13

Note that text objects with `Billboarding = TRUE` ignore `TextOrientation`.

## MuPAD Functions

Title

**Purpose** Color of frame/border around canvas and scenes

**Value Summary**      BorderColor,      Inherited      Color  
                         BorderWidth

## Graphics Primitives

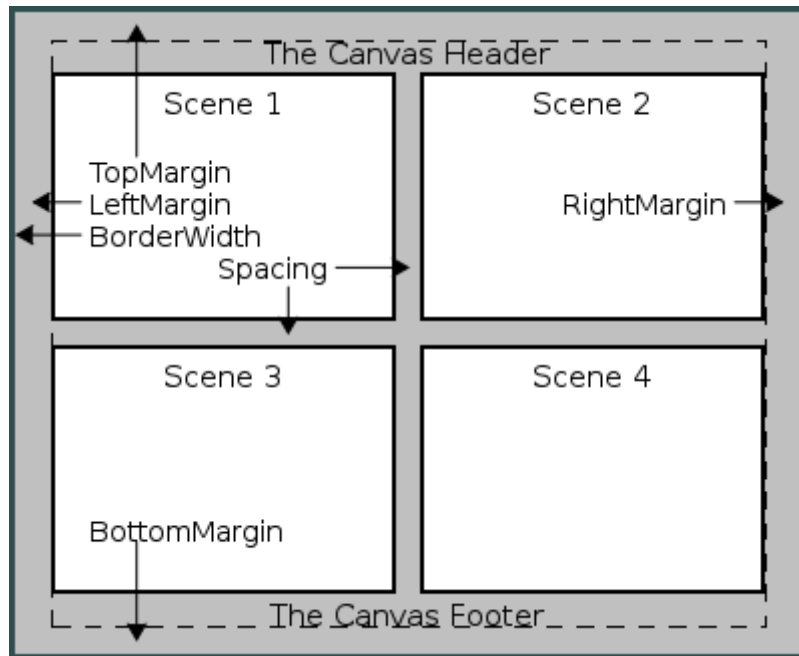

Objects	Default Values
plot::Canvas, plot::Scene2d, plot::Scene3d	BorderColor: RGB::Grey50 BorderWidth: 0

**Description** The canvas as well as the scenes in a canvas can be framed by a rectangular border. The width of the border is set by `BorderWidth`, its color is set by `BorderColor`.

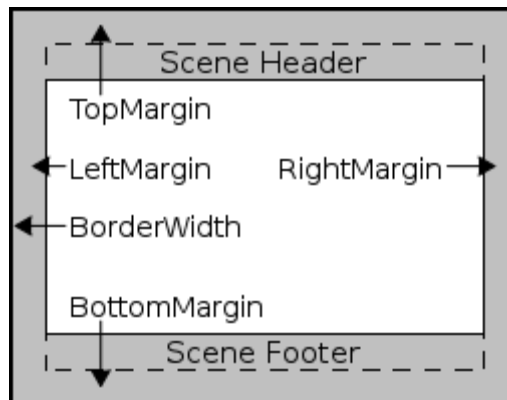

With the attributes `BorderWidth` and `BorderColor`, a canvas or individual scenes can be given a border, similar to an image frame. The border is “switched off” with the default value `BorderWidth = 0`. Set the border width to some positive value such as `BorderWidth = 0.5*unit::mm` to make the border visible.

The following picture illustrates the layout of the canvas:

# BorderColor, BorderWidth

The following picture illustrates the layout of a scene:

The size of a canvas, set by the attributes `Width` and `Height`, includes the width of the border set by `BorderWidth`. The same holds for the scenes.

With `BackgroundTransparent = TRUE`, transparent scenes (without a background) can be created. The borders do *not* become transparent!

The scene borders do not react to `Layout = Relative`. One always has to specify the border width as absolute physical lengths such as `BorderWidth = 0.5*unit::mm`.

Scenes do *not* inherit borders from the enclosing canvas. You can set the borders for all scenes simultaneously by specifying them in `plot::setDefault` as

```
plot::Scene2d::BorderWidth, plot::Scene2d::BorderColor
```

or

```
plot::Scene3d::BorderWidth, plot::Scene3d::BorderColor,
```

respectively. Cf. “Example 2” on page 23-2002.

## Examples

### Example 1

Two scenes are displayed side by side. The borders of the canvas and the two scenes are “switched on” by specifying positive values for `BorderWidth`:

```
S1 := plot::Scene2d(plot::Function2d(sin(x), x = 0 .. 2*PI),
 Header = "The sine function",
 BorderWidth = 0.5*unit::mm):
S2 := plot::Scene2d(plot::Function2d(cos(x), x = 0 .. 2*PI),
 Header = "The cosine function",
 BorderWidth = 0.5*unit::mm):
plot(S1, S2, Header = "Trigonometric functions",
 Width = 120*unit::mm, Height = 50*unit::mm,
 BorderWidth = 1.0*unit::mm, BorderColor = RGB::Black,
 Layout = Horizontal):
```

# BorderColor, BorderWidth

```
delete S1, S2:
```

## Example 2

We use `plot::setDefault` to define new default values for the layout and style parameters `BorderWidth`, `BorderColor`, `Margin`, and `BackgroundColor`:

```
plot::setDefault(
 plot::Canvas::BorderWidth = 0.5*unit::mm,
 plot::Canvas::BorderColor = RGB::Black,
 plot::Canvas::Margin = 1.5*unit::mm,
 plot::Canvas::BackgroundColor = RGB::SlateGrey,
 plot::Scene2d::BorderWidth = 0.5*unit::mm,
 plot::Scene2d::BorderColor = RGB::Black,
 plot::Scene2d::Margin = 2*unit::mm,
 plot::Scene2d::BackgroundColor = RGB::Grey
):
```

The following canvas contains two scenes. This plot uses the new defaults:

```
plot(plot::Scene2d(plot::Rectangle(-1..1, -1..1,
 Filled = TRUE, FillColor = RGB::Red,
 Header = "Scene 1"))),
```

# BorderColor, BorderWidth

```
plot::Scene2d(plot::Rectangle(-1..1, -1..1,
 Filled = TRUE, FillColor = RGB::Blue,
 Header = "Scene 2")),
Layout = Horizontal, Axes = None,
Header = "Canvas Header"):
```

### MuPAD Functions

BackgroundColor | BackgroundColor2 | BackgroundTransparent  
| BackgroundStyle | Bottom | Left | Margin

# BoxCenters, BoxWidths

---

**Purpose** Position of boxes in a box plot

**Value Summary** BoxCenters, Optional List of arithmetical expressions  
BoxWidths

## Graphics Primitives

Objects	Default Values
plot::Boxplot	BoxCenters: [1] BoxWidths: [0.8]

## Description

BoxCenters and BoxWidths govern horizontal center positions and widths of boxes in statistical box plots of Type plot::Boxplot.

A plot of type plot::Boxplot serves for visualizing and comparing statistical data samples.

A data sample defines the vertical coordinates of the corresponding box. The position along the horizontal axis as well as the horizontal width, however, is arbitrary and may be manipulated by the attributes BoxCenters and BoxWidths.

By default, the box of the  $i$ -th data sample is positioned at the horizontal value  $x = i$ . With the default width of 0.8, the  $i$ -th box extends from  $x = i - 0.4$  to  $x = i + 0.4$ .

The value of the attribute BoxCenters must be a list of  $x$ -values for the horizontal centers of the boxes.

If the length of this list is smaller than the number of data samples in the box plot, the center values are incremented by 1 for each surplus box.

If the length of the BoxCenters list is larger than the number of data samples, the surplus center values are ignored.

Setting BoxCenters = [ $x_1$ ], the first box is centered at  $x = x_1$ , while the standard distance between the boxes is kept. Thus, BoxCenters = [ $x_1$ ] allows to shift the entire box plot along the horizontal axis.

The value of the attribute `BoxWidths` must be a list of positive real values.

If the length of this list is smaller than the number of data samples in the box plot, the default width 0.8 is used for the surplus boxes.

If the length of the `BoxWidth` list is larger than the number of data samples, the surplus width values are ignored.

If the attribute `DrawMode = Horizontal` is set in the `plot::Boxplot` object, the boxes are drawn from left to right instead from bottom to top.

In this case, the attributes `BoxCenters` and `BoxWidths` refer to the vertical coordinates of the boxes.

## Examples

### Example 1

We create a box plot visualizing 5 data samples:

```
data1 := [stats::uniformRandom(2, 4)() $ k = 1..100]:
data2 := [stats::normalRandom(3, 0.3)() $ k = 1..100]:
data3 := [stats::normalRandom(3, 1)() $ k = 1..100]:
data4 := [stats::normalRandom(3, 1)() $ k = 1..100]:
data5 := [stats::normalRandom(3, 1)() $ k = 1..100]:
plot(plot::Boxplot(data1, data2, data3, data4, data5,
 Notched = TRUE)):
```

# BoxCenters, BoxWidths

---

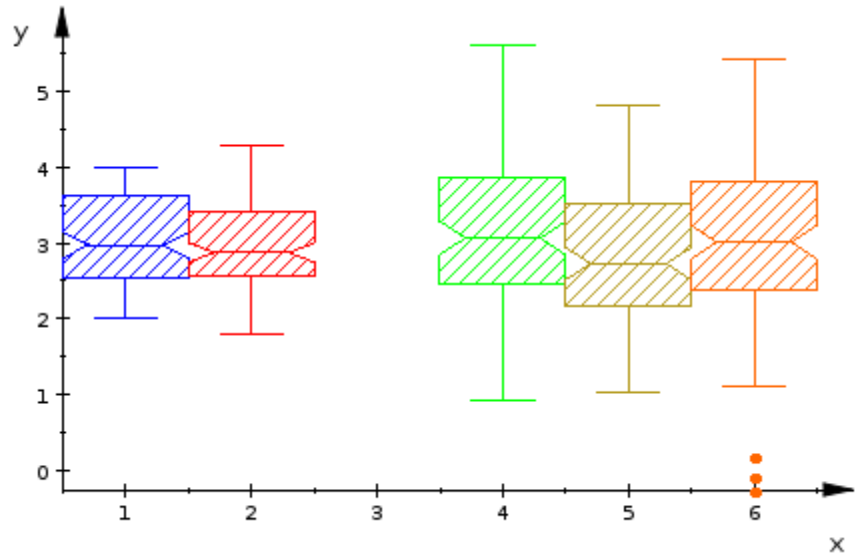

We specify the horizontal centers and the widths of the boxes such that the first two and the last three boxes touch each other:

```
plot(plot::Boxplot(data1, data2, data3, data4, data5,
 Notched = TRUE,
 BoxCenters = [1, 2, 4, 5, 6],
 BoxWidths = [1, 1, 1, 1, 1])):
```

# BoxCenters, BoxWidths

We place two of the data boxes on top of each other for direct comparison:

```
plot(plot::Boxplot(data1, data4, Notched = TRUE,
 BoxCenters = [1, 1], BoxWidths = [2, 2]))
```

# BoxCenters, BoxWidths

---

```
delete data1, data2, data3, data4, data5:
```

## See Also

## MuPAD Functions

[DrawMode](#) | [Notched](#) | [NotchWidth](#)

**Purpose** Orientation of boxes and bars

**Value Summary** Optional Horizontal or Vertical

## Graphics Primitives

Objects	DrawMode Default Values
plot::Bars2d, plot::Boxplot, plot::Histogram2d	Vertical

## Description

DrawMode = Vertical versus DrawMode = Horizontal determines the orientation of boxes in a box plot and bars in bar plots and histogram plots.

A plot of type plot::Boxplot serves for visualizing and comparing statistical data samples. The plot reduces the data to few simple descriptive parameters.

One coordinate direction provides information on the statistical data (25% quantile, median, 75% quantile etc.). The other coordinate direction just serves for placing several boxes associated with different data samples side by side for comparison.

With DrawMode = Vertical, the vertical direction provides the information on the statistical data.

With DrawMode = Horizontal, the boxes are turned by 90 degrees. Now, the horizontal direction provides the information on the statistical data.

Corresponding statements hold for the bars in a 2D bar plot of type plot::Bars2d and 2D histograms of type plot::Histogram2d.

## Examples

### Example 1

We create a box plot:

```
data1 := [2, 6, 4, 3, 1, 7, 9, 5, 3]:
data2 := [2, 4, 8, 8, 7, 6, 8, 7, 3, 1, 10]:
```

# DrawMode

```
data3 := [stats::normalRandom(6, 2)() $ k = 1 .. 100]:
plot(plot::Boxplot(data1, data2, data3, Notched = TRUE)):
```

The boxes are rendered horizontally:

```
plot(plot::Boxplot(data1, data2, data3, Notched = TRUE,
 DrawMode = Horizontal)):
```

`delete data1, data2, data3:`

**See Also**

**MuPAD  
Functions**

`BoxCenters` | `BoxWidths` | `Notched` | `NotchWidth`

# Gap, XGap, YGap

**Purpose** Gaps between the bars of a bar chart

**Value Summary**

Gap	[[XGap, YGap]]	See below
XGap, YGap	Optional	MuPAD expression

## Graphics Primitives

Objects	Default Values
plot::Bars3d	Gap: [0, 0] XGap, YGap: 0

## Description

Gap, XGap, YGap sets gaps between the bars of a bar chart.

In plot::Bars3d, the attribute Gap = [ $g_x$ ,  $g_y$ ] or, equivalently, XGap =  $g_x$ , YGap =  $g_y$  allows to introduce gaps between adjacent bars.

The values  $g_x$ ,  $g_y$  may be real numerical values between 0 and 1 or expressions of the animation parameter. These values set the fraction of the space reserved for a bar that is not filled by the bar.

With  $g_x = 0$ ,  $g_y = 0$ , there are no gaps. With  $g_x = 0.5$ ,  $g_y = 0.5$ , the gaps between adjacent bars are of the same size as the bars. With  $g_x = 1$ ,  $g_y = 1$ , there bars become lines.

Values of  $g_x$ ,  $g_y$  larger than 1 are treated like 1, negative values like 0.

The Gap attribute has an effect only for BarStyle = Boxes.

## Examples

### Example 1

We display the same data with different Gap values:

```
A := matrix::random(5, 5, frandom) :
plot(plot::Scene3d(plot::Bars3d(A, Gap = [0, 0])),
 plot::Scene3d(plot::Bars3d(A, Gap = [0.4, 0.4])),
 plot::Scene3d(plot::Bars3d(A, Gap = [0.7, 0.7])),
 Width = 150*unit::mm, Height = 50*unit::mm,
 Layout = Horizontal):
```

delete A:

# Notched, NotchWidth

---

**Purpose** Notched boxes in box plots

**Value Summary** Notched, NotchWidth Optional TRUE or FALSE

## Graphics Primitives

Objects	Default Values
<code>plot::Boxplot</code>	Notched: FALSE NotchWidth: 0.2

## Description

With `Notched = TRUE`, the boxes in a statistical box plot of type `plot::Boxplot` are notched. The notches provide further information on the statistical data.

The attribute `NotchWidth` determines the horizontal width of the notches.

A plot of type `plot::Boxplot` serves for visualizing and comparing statistical data samples. The plot reduces the data to few simple descriptive parameters.

One graphical parameter is the height of notches that are displayed in the sides of the boxes when using `Notched = TRUE`. A typical notched box looks like this:

# Notched, NotchWidth

The height of the notches is 3.14 times the height of the central box divided by the square root of the number of data elements in the corresponding data sample.

Notched box plots are useful for determining whether two random samples were drawn from the same population. Similar notches of boxes indicate that the data visualized by the boxes have the same distribution.

This, however, is not a *rigorous* criterion that the data samples are indeed identically distributed.

The horizontal width of the notches bears no statistical significance and is just a layout parameter. Setting `NotchWidth = r`, the absolute

# Notched, NotchWidth

horizontal notch width of a box is  $r$  times the width of the box.

Reasonable values for  $r$  lie between 0 and  $\frac{1}{2}$ .

The widths of the boxes can be set via the attribute `BoxWidths`.

## Examples

### Example 1

We create a notched box plot of several random samples:

```
r := stats::normalRandom(0, 1):
data1 := [r() $ k = 1..100]:
data2 := [r() $ k = 1..200]:
data3 := [r() $ k = 1..300]:
plot(plot::Boxplot(data1, data2, data3, Notched = TRUE)):
```

We change the `NotchWidth`:

```
plot(plot::Boxplot(data1, data2, data3, Notched = TRUE,
 NotchWidth = 0.4)):
```

```
delete r, data1, data2, data3:
```

## MuPAD Functions

[BoxCenters](#) | [BoxWidths](#) | [DrawMode](#)

# Projectors

---

**Purpose** Project an ODE solution to graphical points

**Value Summary** Mandatory List of arithmetical expressions

## Graphics Primitives

Objects	Projectors Default Values
<code>plot::Ode2d, plot::Ode3d</code>	

## Description

Projectors defines “generators of plot data” that project solution points  $(t, Y(t))$  of an ODE to graphical points  $[x, y]$  in 2D or  $[x, y, z]$  in 3D, respectively.

Internally, `plot::Ode2d` and `plot::Ode3d` generate a sequence of numerical solution points  $(t_0, Y(t_0)), (t_1, Y(t_1))$  etc. of an ODE. Each of these solution points is mapped to a graphical point via the “projectors” defined by Projectors.

Each projector  $G_i$  in `Projectors = [[G1], [G2], ...]` is a list

$[G_i] = [(t, Y) \rightarrow [x(t, Y), y(t, Y), \langle z(t, Y) \rangle], \langle \text{Style} = \text{style} \rangle, \langle \text{Color} = \text{color} \rangle]$ .

The procedures  $(t, Y) \rightarrow [x(t, Y), y(t, Y), \langle z(t, Y) \rangle]$  map the solution points  $(t_i, Y_i)$  of the ODE to points  $[x(t_i, Y_i), y(t_i, Y_i)]$  in 2D (for `plot::Ode2d`) or  $[x(t_i, Y_i), y(t_i, Y_i), z(t_i, Y_i)]$  in 3D (for `plot::Ode3d`). These points are drawn in the picture, interpolated by linear or cubic spline interpolation according to the attribute `Style = style` in the color set by the attribute `Color = color`.

The style parameter may be one of the flags `Points` (only the points are displayed), `Lines` (only interpolating line segments are displayed), `Splines` (only the interpolating cubic spline curve is displayed), `[Lines, Points]` (interpolating line segments together with the interpolation points are displayed), or `[Splines, Points]` (the interpolating cubic spline curve together with the interpolation points are displayed).

The default style is `Style = [Splines, Points]`.

Each of the projectors  $G_1, G_2$  etc. (denoted by  $G$  in the following) is a mapping  $G: (t, Y) \rightarrow [x(t, Y), y(t, Y)]$  in 2D or  $G: (t, Y) \rightarrow [x(t, Y), y(t, Y), z(t, Y)]$  in 3D. It must accept a numerical argument  $t$  and a vector  $Y$  (a list or a one-dimensional array) and must return a list of numerical coordinate values  $[x, y]$  (in `plot::Ode2d`) or  $[x, y, z]$  (in `plot::Ode3d`), respectively. Defining appropriate projectors, any information on the solution curve of the ODE can be displayed graphically.

Here are some examples:

`G := (t, Y) -> [t, Y[1]]` creates a 2D plot of the first component of the solution vector along the  $y$ -axis, plotted against the time variable  $t$  along the  $x$ -axis

`G := (t, Y) -> [Y[1], Y[2]]` creates a 2D phase plot, plotting the first component of the solution along the  $x$ -axis and the second component along the  $y$ -axis. The result is a solution curve in phase space (parametrized by the time  $t$ ).

`G := (t, Y) -> [Y[1], Y[2], Y[3]]` creates a 3D phase plot of the first three components of the solution curve.

If no projectors are specified in a call to `plot::Ode2d`, the default projectors `Generators = [[G1], [G2], ...]` are used, where

`[Gi] = [(t, Y) -> [t, Y[i]], Style = [Splines, Points]]`.

This plots the  $i$ -th component of the solution vector along the  $y$ -axis against the “time”  $t$  plotted along the  $x$ -axis.

In `plot::Ode3d`, the default projectors are

`[Gi] = [(t, Y) -> [t, Y[2*i - 1], Y[2*i]], Style = [Splines, Points]]`.

This plots two of the components of the solution vector along the  $y$ - and  $z$ -axis against the “time”  $t$  plotted along the  $x$ -axis.

# Projectors

---

## Examples

### Example 1

We consider the 2nd order ODE  
 $y'' = -y + \sin(3y)$ ,  $y(0) = 1$ ,  $y'(0) = 0$ . As a dynamical system  
for  $Y = (Y_1, Y_2) = (y, y')$ , the ODE to be solved is

$$\frac{d}{dt} Y = \frac{d}{dt} \begin{pmatrix} Y_1 \\ Y_2 \end{pmatrix} = \begin{pmatrix} Y_2 \\ -Y_1 + \sin(3Y_1) \end{pmatrix}$$

The first projector  $G_1$  plots the solution in red as a phase curve in the  $(x, y)$ -plane.

The second projector  $G_2$  plots the kinetic energy  $\frac{Y_2^2}{2} = \frac{y'^2}{2}$  in green along the  $z$ -axis.

The third projector  $G_3$  plots the potential energy

$$Y_1^2 + \frac{\cos(3Y_1)}{3} = \frac{y^2}{2} + \frac{\cos(3y)}{3} \text{ in blue along the } z\text{-axis.}$$

The fourth projector  $G_4$  plots the total energy in black along the  $z$ -axis:

```
f := (t, Y) -> [Y[2], - Y[1] + sin(3*Y[1])]:
Y0 := [0, 1]:
G1 := (t, Y) -> [Y[1], Y[2], 0]:
G2 := (t, Y) -> [Y[1], Y[2], Y[2]^2/2]:
G3 := (t, Y) -> [Y[1], Y[2], Y[1]^2/2 + cos(3*Y[1])/3]:
G4 := (t, Y) -> [Y[1], Y[2], Y[1]^2/2 + cos(3*Y[1])/3 + Y[2]^2/2]:
plot(plot::Ode3d(
 f, [i/10 $ i = 0..100], Y0,
 [G1, Style = Splines, Color = RGB::Red],
 [G2, Style = Lines, Color = RGB::Green],
 [G3, Color = RGB::Blue],
 [G4, Style = [Lines, Points], Color = RGB::Black]))
```

`delete f, Y0, G1, G2, G3, G4:`

# Scaling, YXRatio, ZXRatio

<b>Purpose</b>	Scaling ratios		
<b>Value Summary</b>	Scaling	Inherited	Automatic, Constrained, or Unconstrained
	YXRatio, ZXRatio	Inherited	Positive real number Real number

## Graphics Primitives

Objects	Default Values
plot::CoordinateSystem2d, plot::CoordinateSystem3d	Scaling: Unconstrained
plot::Scene3d	YXRatio: 1 ZXRatio: 2/3

## Description

With `Scaling = Constrained`, the graphics output is scaled like the model coordinates, i.e., circles appear as circles, spheres as spheres.

With `Scaling = Unconstrained`, the graphics output is scaled independently in each coordinate direction such that the graphics fits optimally into the viewing area. Circles may appear as ellipses, spheres as ellipsoids.

For `Scaling = Unconstrained`, the scaling ratios of the different coordinate directions in a 3D plot can be set via the attributes `YXRatio` and `ZXRatio`.

If the graphics consists of geometrical objects such as circles, pie charts, spheres etc., the setting `Scaling = Constrained` is appropriate. This prevents circles from being deformed to ellipses in the graphical output.

For the visualization of non-geometrical data (usually, in function plots etc.), a scaling constrained to model coordinates is usually not appropriate. Think of the graph of  $y = e^x$  for  $x \in [0, 10]$ , where

the  $y$  values extend over the range  $y \in [e^0, e^{10}]$ , which is roughly  $[1, 22026]$ . With `Scaling = Constrained`, the graphical output would consist of a narrow vertical strip with the side ratio  $y : x = 22025 : 10$ . Here, `Scaling = Unconstrained` is appropriate.

The default value is `Scaling = Unconstrained`. However, many “geometrical” objects in the MuPAD plot library override this default setting via the “hint mechanism” (see section Primitives Requesting Special Scene Attributes: “Hints” in this document). Whenever such an object is plotted in a scene, the whole scene uses `Scaling = Constrained`. A complete list of these “geometrical objects” such as circles, spheres, cones etc. is given further up on this help page.

With `Scaling = Automatic`, the graphics uses `Scaling = Constrained` for plots in which the coordinate ranges to be displayed have a ratio close to  $1 : 1$  in 2D or  $1 : 1 : 1$  in 3D. Otherwise, `Scaling = Unconstrained` is used.

The attributes `YXRatio = r1` and `ZXRatio = r2` only have an effect in 3D with `Scaling = Unconstrained`. The graphical scene is scaled to a box with side ratios  $z : y : x = r_2 : r_1 : 1$ . On the screen, the bounding box of the scene looks like a box with these side ratios.

## Examples

### Example 1

We plot a scene containing a function graph and some circles highlighting the extrema. Because the circle sends the “hint” `Scaling = Constrained`, this scaling is used for the whole scene. Consequently, the circles appear as circles:

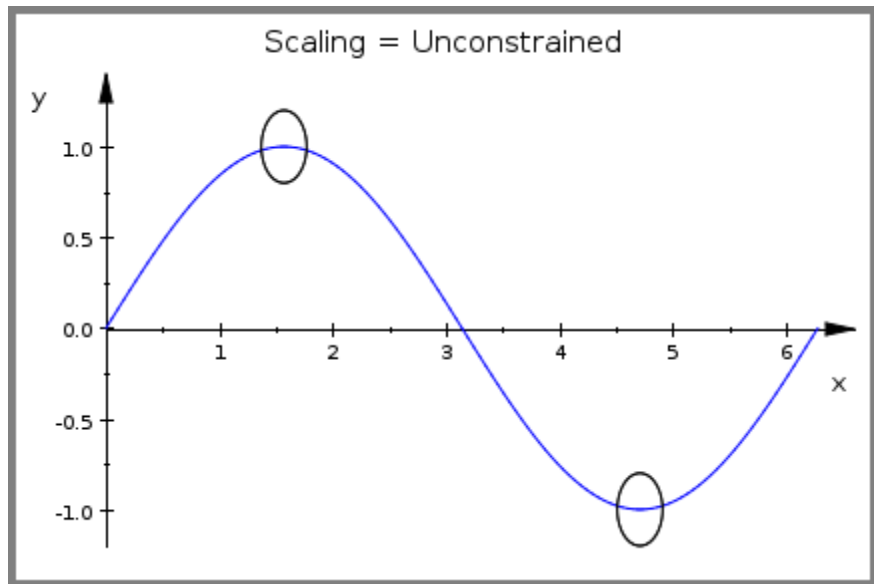

```
plot(plot::Function2d(sin(x), x = 0 .. 2*PI),
 plot::Circle2d(0.2, [PI/2, 1], Color = RGB::Black),
 plot::Circle2d(0.2, [3*PI/2, -1], Color = RGB::Black),
 BorderWidth = 1.0*unit::mm,
 Header = "Scaling = Constrained")
```

# Scaling, YXRatio, ZXRatio

With `Scaling = UnConstrained`, we get a better fit of the plot in the canvas. However, the circles are deformed to ellipses:

```
plot(plot::Function2d(sin(x), x = 0 .. 2*PI),
 plot::Circle2d(0.2, [PI/2, 1], Color = RGB::Black),
 plot::Circle2d(0.2, [3*PI/2, -1], Color = RGB::Black),
 Scaling = Unconstrained, BorderWidth = 1.0*unit::mm,
 Header = "Scaling = Unconstrained")
```

## Example 2

A sphere of type `plot::Sphere` sends the "hint" `Scaling = Constrained`.  
With this scaling, `YXRatio`, `ZXRatio` have no effect:

```
s := plot::Sphere(1, [0, 0, 0]):
plot(s, BorderWidth = 0.5*unit::mm,
 Header = "Scaling = Constrained",
 YXRatio = 3, ZXRatio = 10)
```

# Scaling, YXRatio, ZXRatio

---

We use `Scaling = Unconstrained`. With the default values `YXRatio = 1`, `ZXRatio = 2/3`, the objects in a 3D scene are displayed like a box with side ratios  $X : Y : Z = 3 : 3 : 2$ :

```
plot(s, BorderWidth = 0.5*unit::mm,
 Scaling = Unconstrained, Header = "X:Y:Z = 3:3:2")
```

# Scaling, YXRatio, ZXRatio

We request different scaling ratios:

```
plot(s, BorderWidth = 0.5*unit::mm, Header = "X:Y:Z = 5:5:1",
 Scaling = Unconstrained, YXRatio = 1, ZXRatio = 1/5,
 BorderWidth = 0.5*unit::mm)
```

## Scaling, YXRatio, ZXRatio

---

```
plot(s, BorderWidth = 0.5*unit::mm, Header = "X:Y:Z = 7:3:1",
 Scaling = Unconstrained, YXRatio = 3/7, ZXRatio = 1/7,
 BorderWidth = 0.5*unit::mm)
```

# Scaling, YXRatio, ZXRatio

delete s:

# VerticalAsymptotesVisible, VerticalAsymptotesStyle, VerticalAsymptotesColor, VerticalAsymptotesWidth

**Purpose** Vertical asymptotes indicating poles

**Value Summary**

VerticalAsymptotesVisible	Inherited	FALSE, or TRUE
VerticalAsymptotesStyle	Inherited	Dashed, Dotted, or Solid
VerticalAsymptotesColor	Inherited	Color
VerticalAsymptotesWidth		

## Graphics Primitives

Objects	Default Values
plot::Function2d	VerticalAsymptotesVisible: TRUE VerticalAsymptotesStyle: Dashed VerticalAsymptotesColor: RGB::Grey50 VerticalAsymptotesWidth: 0.2

**Description** These options control the appearance of vertical asymptotes in 2D function plots.

plot::Function2d and plotfunc2d are able to indicate poles by drawing vertical asymptotes. These asymptotes can be switched off with VerticalAsymptotesVisible = FALSE. Other than that, the attributes VerticalAsymptotesStyle, VerticalAsymptotesColor, and VerticalAsymptotesWidth influence their appearance, in the same way LineStyle, LineColor, and LineWidth do for other lines.

## Examples

### Example 1

By default, vertical asymptotes are drawn as dashed, gray lines:

```
plotfunc2d(tan(x))
```

# VerticalAsymptotesVisible, VerticalAsymptotesStyle, VerticalAsymptotesColor, VerticalAsymptotesWidth

The attributes mentioned above can be used to change these settings:

```
plotfunc2d(tan(x),
 VerticalAsymptotesColor = RGB::Blue,
 VerticalAsymptotesWidth = 1.0*unit::mm,
 VerticalAsymptotesStyle = Dotted)
```

# VerticalAsymptotesVisible, VerticalAsymptotesStyle, VerticalAsymptotesColor, VerticalAsymptotesWidth

---

## Example 2

Note that vertical asymptotes obey the setting of `Visible` of their function object: No asymptotes are drawn for an invisible object.

```
t := plot::Function2d(tan(x), x = -2*PI..2*PI, Visible = FALSE):
s := plot::Function2d(sin(x), x = -2*PI..2*PI):
plot(s, t)
```

# VerticalAsymptotesVisible, VerticalAsymptotesStyle, VerticalAsymptotesColor, VerticalAsymptotesWidth

---

To have `t` show its asymptotes, we must set `Visible` to `TRUE`. If we only want to see the asymptotes, we can set `LinesVisible` to `FALSE`:

```
t::Visible := TRUE:
t::LinesVisible := FALSE:
plot(s, t)
```

# VerticalAsymptotesVisible, VerticalAsymptotesStyle, VerticalAsymptotesColor, VerticalAsymptotesWidth

---

## Description

LineColor sets the color of line objects such as 2D function graphs, curves in 2D and 3D, parameter lines on surfaces etc.

LineColor2 is a secondary color used for color blends.

LineColor determines the RGB color of line objects. The RGB library provides many pre-defined colors such as RGB::Red etc. See the section Colors of this document for more information on colors.

For pure line objects such as lines, curves, arrows, 2D function graphs etc., the line color can also be set by the attribute Color.

For surface objects such as 3D function graphs, surfaces etc., however, the attribute Color sets the FillColor. If you wish to change the color of the parameter lines on a surface, you have to use LineColor.

The RGB color set by LineColor cannot be animated. However, setting LineColorType = Functional, you can define a LineColorFunction that overrides the color set by LineColor. The line color function accepts an animation parameter, thus allowing to implement animated coloring of lines. See the help page of LineColorFunction for further details.

When the attribute LineColorType is set to one of the values Dichromatic or Rainbow, many line objects react to a secondary color set by the attribute LineColor2.

# LineColor, LineColor2

---

A gradient between the colors defined by `LineColor` and `LineColor2` is created.

The color of the coordinate axes is set by the attribute `AxesLineColor`.

## Examples

### Example 1

We draw arrows of different colors:

```
plot(plot::Arrow2d([0, 0], [1, 2], LineColor = RGB::Red),
 plot::Arrow2d([0, 0], [1, 1], LineColor = RGB::Green),
 plot::Arrow2d([0, 0], [2, 1], LineColor = RGB::Blue)):
```

### Example 2

We draw a parabola with a gradient between green and blue:

```
plot(plot::Function2d(x^2, x = 1..10,
 LineColorType = Dichromatic,
 LineColor = RGB::Green,
```

```
LineColor2 = RGB::Blue)):
```

### Example 3

As with any attribute, the line color can be read and changed using the `::`-notation:

```
p := plot::Line2d([1, 2], [4, 5]):
p::LineColor := RGB::Blue
```

```
[0.0, 0.0, 1.0]
```

```
p::LineColor
```

```
[0.0, 0.0, 1.0]
```

# LineColor, LineColor2

---

delete p:

## Example 4

For surface objects such as 3D function graphs, LineColor sets the color of the parameter lines on the surface. Here, a semi-transparent RGBa color is chosen that gives only a faint indication of these lines:

```
plot(plot::Function3d(x^2 + y^2, x = -1..1, y = -1 ..1,
 LineColor = RGB::Green.[0.25])):
```

## Description

LineColorDirection determines the direction in which the color transitions for LineColorType = Dichromatic etc. take place.

When setting LineColorType to some other value than Flat or Functional, MuPAD produces a “height-coloring.” By default, this color

# LineColorDirection, LineColorDirectionX, LineColorDirectionY, LineColorDirectionZ

method actually uses the height of a point. Using `LineColorDirection`, the axis along which the color method should be applied can be changed.

## Examples

### Example 1

By default, MuPAD uses height coloring along the  $y$  axis for 2D objects:

```
f := plot::Function2d(sin(x), x=-PI..PI,
 LineWidth = 1, LineColorType = Rainbow):
plot(f)
```

By changing `LineColorDirection`, this direction can be set to any angle. Note that `LineColorDirection` is an inherited attribute and may therefore be set at “top level” in the plot call:

```
plot(f, LineColorDirection = [1, 1])
```

# LineColorDirection, LineColorDirectionX, LineColorDirectionY, LineColorDirectionZ

---

# LineColorType

## Description

Objects	LineColorType Default Values
<code>plot::VectorField2d,</code> <code>plot::VectorField3d,</code> <code>plot::WaterFall</code> and <code>Functional</code> , <code>height</code> , <code>rotate</code> , <code>plot::ZColor2D</code> or <code>3D</code> , respectively)	line coloring used. With the plotting functions, the coloring schemes depend on the height, <code>rotate</code> , <code>plot::ZColor2D</code> or <code>3D</code> , respectively) of points on the line, relative to the extension of the viewing box.
	By default, lines are drawn in the color set by the attribute <code>LineColor</code> . This is caused by the setting <code>LineColorType = Flat</code> . The other possible values for <code>LineColorType</code> mean:
	<ul style="list-style-type: none"><li>• <code>Dichromatic</code> The color of a point on a line depends on its height, with the lowest point using <code>LineColor2</code>, the highest one using <code>LineColor</code>, and all other points using a linear interpolation in RGB color space.</li></ul>
	<ul style="list-style-type: none"><li>• <code>Flat</code> The line is drawn with <code>LineColor</code>. No blend is used.</li></ul>
	<ul style="list-style-type: none"><li>• <code>Monochrome</code> The line is drawn with a blend from <code>LineColor</code> to a dimmed version of <code>LineColor</code>.</li></ul>
	<ul style="list-style-type: none"><li>• <code>Rainbow</code> This setting is technically similar to <code>Dichromatic</code>, but the effect is vastly different, since interpolation takes place in HSV color space. This creates a “rainbow effect”, which mostly conforms with a physical rainbow for suitable choices of colors.</li></ul>
	<ul style="list-style-type: none"><li>• <code>Functional</code> Both <code>LineColor</code> and <code>LineColor2</code> are ignored; the color scheme is derived from <code>LineColorFunction</code>. See <code>?LineColorFunction</code> for details (which depend on the object type). If no color function is given, the object will be rendered with <code>LineColorType = Flat</code>.</li></ul>

## Examples

### Example 1

By default, lines are drawn in one flat color:

```
plotfunc2d(sin(x))
```

```
plot(plot::Polygon2d([[-1,-1], [1,-1], [1,1], [-1,1]],
Closed = TRUE, Filled = FALSE))
```

# LineColorType

---

## Example 2

Using `LineColorType = Dichromatic`, `Monochrome`, or `Rainbow` causes a height-dependent color effect:

```
plotfunc2d(sin(x), LineColorType = Rainbow)
```

Note that height coloring depends on the height of the whole scene, not only on that of individual objects:

```
plot(
 plot::Function2d(sin(x) + 0.2, LineColorType = Dichromatic),
 plot::Function2d(sin(x) + 0.0, LineColorType = Monochrome),
 plot::Function2d(sin(x) - 0.2, LineColorType = Rainbow),
 LineColor = RGB::Red, LineColor2 = RGB::Blue
)
```

# LineColorType

---

# LinesVisible, ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible

Objects	Default Values
plot::Polygon2d, plot::Polygon3d, plot::Prism, plot::Pyramid, plot::QQplot, plot::Rectangle, plot::Rootlocus, plot::Scatterplot, plot::Sum, plot::Tetrahedron, plot::Turtle, plot::Waterman	
plot::Density, plot::Inequality, plot::Raster, plot::Sequence	LinesVisible: FALSE
plot::Function3d	LinesVisible, XLinesVisible, YLinesVisible: TRUE
plot::Cylindrical, plot::Matrixplot, plot::Spherical, plot::Surface, plot::Sweep, plot::Tube, plot::XRotate, plot::ZRotate	ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible: TRUE

## Description

LinesVisible = TRUE versus LinesVisible = FALSE governs the visibility of line objects.

ULinesVisible, VLinesVisible governs the visibility of coordinate lines on parametrized surfaces in 3D.

XLinesVisible, YLinesVisible governs the visibility of coordinate lines on 3D function graphs and matrix plots.

For most object types, LinesVisible determines whether lines are drawn. This includes the lines making up 2D function plots, curves, polygons, etc. as well as the circumference of (filled) circles, the edges of 2D rectangles and 3D boxes etc.

The exception are surface objects that exhibit parameter lines in two directions, such as 3D function plots, parameterized surfaces, tube

# LinesVisible, ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible

---

plots etc. Depending on whether they react to XMesh, YMesh or to UMesh, VMesh, the parameter lines on the surfaces can be made visible or invisible with the attributes XLinesVisible, YLinesVisible or ULinesVisible, VLinesVisible, respectively.

Note that setting LinesVisible = FALSE for a 2D function plot without setting PointsVisible = TRUE will render the function invisible. (In case of singular functions, the vertical asymptotes may remain visible, though).

The same holds true for plots involving filled areas: switching off the lines and the filling makes such objects invisible.

LinesVisible etc. do not have an effect on coordinate axes and coordinate grid lines. Use the attributes AxesVisible and GridVisible to control the visibility of axes and coordinate grid.

## Examples

### Example 1

By default, the lines of a box are visible:

```
plot(plot::Box(1..4, 2..5, 3..6), Axes = None)
```

# LinesVisible, ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible

---

We set `LinesVisible = FALSE` to switch them off:

```
plot(plot::Box(1..4, 2..5, 3..6, LinesVisible = FALSE),
 Axes = None)
```

# LinesVisible, ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible

---

## Example 2

By default, parameter lines are drawn on a parametrized surface:

```
plot(plot::Surface([u*cos(v), u*sin(v), u^2*sin(5*v)],
 u = 0..2, v = 0..2*PI, VSubmesh = 3)):
```

# LinesVisible, ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible

---

You can switch these lines off interactively, or, as we do here, by setting `ULinesVisible` and `VLinesVisible` to `FALSE` in the plot command:

```
plot(plot::Surface([u*cos(v), u*sin(v), u^2*sin(5*v)],
 u = 0..2, v = 0..2*PI, VSubmesh = 3,
 ULinesVisible = FALSE,
 VLinesVisible = FALSE)):
```

# LinesVisible, ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible

---

When the surface is created with an adaptive mesh, we can make the irregular adaptive mesh visible by setting `MeshVisible = TRUE`:

```
plot(plot::Surface([u*cos(v), u*sin(v), u^2*sin(5*v)],
 u = 0..2, v = 0..2*PI,
 UMesh = 5, VMesh = 10,
 ULinesVisible = FALSE,
 VLinesVisible = FALSE,
 AdaptiveMesh = 3,
 MeshVisible = TRUE)):
```

# LinesVisible, ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible

---

### Example 3

We plot a dodecahedron with and without the border lines of its faces:

```
plot(plot::Scene3d(plot::Dodecahedron(LinesVisible = TRUE)),
 plot::Scene3d(plot::Dodecahedron(LinesVisible = FALSE)),
 layout = Horizontal, Axes = None):
```

# LinesVisible, ULinesVisible, VLinesVisible, XLinesVisible, YLinesVisible

---

## See Also

Objects	LineWidth Default Values
plot::Ode2d, plot::Ode3d, plot::Parallelogram2d, plot::Parallelogram3d, plot::Piechart2d, plot::Piechart3d, plot::Polar, plot::Polygon2d, plot::Polygon3d, plot::Prism, plot::Pyramid, plot::QQplot, plot::Raster, plot::Rectangle, plot::Rootlocus, plot::Scatterplot, plot::Sequence, plot::Spherical, plot::Sum, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::Turtle, plot::VectorField2d, plot::XRotate, plot::ZRotate	
plot::VectorField3d	0.1
plot::Waterman	0.25
plot::Streamlines2d	0.35*unit::mm

## Description

LineWidth sets the width of line objects such as 2D function graphs, curves in 2D and 3D, arrows, parameter lines on surfaces etc.

The value should be specified as an absolute physical length including a length unit such as `LineWidth = 1.5*unit::mm`. Numbers without a physical unit give the size in mm.

Note that the graphics cannot always react to small changes of the line width because of the discretization into pixels.

# LineWidth

---

One cannot make lines invisible by setting their width to 0. Use `LinesVisible = FALSE` instead.

`LineWidth` does not have an effect on the line width of axes and coordinate grid lines. Use the attributes `AxesLineWidth` and `GridLineWidth` to manipulate axes and coordinate grid, respectively.

## Examples

### Example 1

We draw a house with thick walls:

```
plot(plot::Polygon2d(
 [[0, 0], [0, 3], [2, 5], [4, 3], [0, 3],
 [4, 0], [0, 0], [4, 3], [4, 0]],
 LineWidth = 4*unit::mm, Color = RGB::Grey),
 Axes = None):
```

The building instructions are added by arrows. The drawing order is indicated by the titles of the arrows and their increasing line width:

```
plot(plot::Polygon2d(
 [[0, 0], [0, 3], [2, 5], [4, 3], [0, 3],
 [4, 0], [0, 0], [4, 3], [4, 0]],
 LineWidth = 4*unit::mm, Color = RGB::Grey),
plot::Arrow2d([0, 0], [0, 3], LineWidth = 0.3*unit::mm,
 Title = "1", TitlePosition = [0.2, 1.4]),
plot::Arrow2d([0, 3], [2, 5], LineWidth = 0.5*unit::mm,
 Title = "2", TitlePosition = [0.5, 3.9]),
plot::Arrow2d([2, 5], [4, 3], LineWidth = 0.7*unit::mm,
 Title = "3", TitlePosition = [3.4, 3.9]),
plot::Arrow2d([4, 3], [0, 3], LineWidth = 0.9*unit::mm,
 Title = "4", TitlePosition = [1.9, 3.2]),
plot::Arrow2d([0, 3], [4, 0], LineWidth = 1.1*unit::mm,
 Title = "5", TitlePosition = [1.0, 2.5]),
plot::Arrow2d([4, 0], [0, 0], LineWidth = 1.3*unit::mm,
 Title = "6", TitlePosition = [1.9, 0.2]),
plot::Arrow2d([0, 0], [4, 3], LineWidth = 1.5*unit::mm,
 Title = "7", TitlePosition = [0.7, 0.9]),
plot::Arrow2d([4, 3], [4, 0], LineWidth = 1.7*unit::mm,
 Title = "8", TitlePosition = [3.7, 1.4]),
Axes = None,
TipLength = 5*unit::mm
):
```

# LineWidth

---

### MuPAD Functions

[AxesLineWidth](#) | [GridLineWidth](#) | [LineColor](#) | [LineColorType](#) | [LineStyle](#) | [LinesVisible](#)

**Purpose** Visibility of irregular mesh lines in 3D

**Value Summary** Inherited FALSE, or TRUE

**Graphics Primitives**

Objects	MeshVisible Default Values
plot::Cylindrical, plot::Function3d, plot::Implicit3d, plot::Spherical, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::XRotate, plot::ZRotate	FALSE

**Description** MeshVisible = TRUE versus MeshVisible = FALSE controls the visibility of the irregular mesh defining surfaces that are either computed by an adaptive algorithm or are given explicitly by a triangulation.

3D function plots and parametrized surfaces are usually defined over a regular mesh. When setting AdaptiveMesh = n with n > 0, an irregular adaptive mesh is created that refines the graphical object automatically in critical regions.

While visibility of the regular mesh is controlled by the attributes XLinesVisible, YLinesVisible or ULinesVisible, VLinesVisible, respectively, the visibility of the adaptively refined mesh is set MeshVisible.

Also special surfaces created from a given triangulation such as plot::SurfaceSet and plot::SurfaceSTL allow to make the triangulation visible by setting MeshVisible = TRUE.

The irregular mesh lines switched on by MeshVisible = TRUE react to the attributes LineColor, LineStyle, and LineWidth.

# MeshVisible

---

## Examples

### Example 1

We create a 3D function plot:

```
plot(plot::Function3d(sin(x*y), x = -3..3, y = -3..3))
```

By default, only the regular mesh is visible, even if adaptive evaluation is used:

```
plot(plot::Function3d(sin(x*y), x = -3..3, y = -3..3,
 AdaptiveMesh = 2))
```

The irregular mesh is made visible when using `MeshVisible = TRUE`:

```
plot(plot::Function3d(sin(x*y), x = -3..3, y = -3..3,
 AdaptiveMesh = 2, MeshVisible = TRUE))
```

# MeshVisible

---

A 3D plot of an implicit surface does not have regular mesh lines. We plot such a surface with and without the irregular mesh:

```
plot(plot::Implicit3d(z^4 + z^2 - x^2 + y^3,
 x = -1..1, y = -1..1, z = -1..1,
 MeshVisible = TRUE))
```

```
plot(plot::Implicit3d(z^4 + z^2 - x^2 + y^3,
 x = -1..1, y = -1..1, z = -1..1,
 MeshVisible = FALSE))
```

# MeshVisible

---

## See Also

### MuPAD Functions

[AdaptiveMesh](#) | [LineColor](#) | [LineStyle](#) | [LineWidth](#)

# XContours, YContours, ZContours

**Purpose** Contour lines at constant x values

**Value Summary** XContours, YContours, ZContours      Optional      List of arithmetical expressions

## Graphics Primitives

Objects	Default Values
plot::Implicit3d	XContours, YContours, ZContours: [Automatic, 15]
plot::Cylindrical, plot::Function3d, plot::Spherical, plot::Surface, plot::XRotate, plot::ZRotate	XContours, YContours, ZContours: []

## Description

XContours, YContours, and ZContours cause contour lines on surface objects at constant  $x$ ,  $y$ , or  $z$ -values, respectively.

By setting these attributes, many surface objects (such as implicit surfaces, function objects etc.) can be instructed to display contour lines.

By setting `ZContours = [z1, z2, ...]`, contour lines can be requested at specific places. This is demonstrated in “Example 1” on page 23-2075.

`ZContours = [Automatic, n]` causes  $n$  contour lines to be evenly spaced along the range of  $z$  values of the object. Cf. “Example 2” on page 23-2077.

## Examples

### Example 1

A function plot by default uses height coloring and mesh lines to improve the visual display. With mesh lines disabled, height coloring is often still sufficient:

```
plotfunc3d(sin(x+cos(0.3*y))*cos(y),
```

# XContours, YContours, ZContours

---

```
XLinesVisible=FALSE, YLinesVisible=FALSE,
CameraDirection=[0,0.01,1])
```

To get a better depth impression, it would help in this example to add contour lines:

```
plotfunc3d(sin(x+cos(0.3*y))*cos(y),
ZContours=[$ -1..1 step 0.25],
XLinesVisible=FALSE, YLinesVisible=FALSE,
CameraDirection=[0,0.01,1])
```

## Example 2

In the previous example, we set  $z$  values for the contour lines explicitly. There is an easier way of specifying equidistant lines, though, by giving the special value `Automatic`, followed by the number of lines to use. For example, implicit surfaces by default use 15 lines in each direction of space:

```
plot(plot::Implicit3d(abs(x)^3+abs(y)^3+abs(z)^3 - 1,
 x = -1..1, y=-1..1, z=-1..1),
 Axes = None, Scaling = Constrained)
```

# XContours, YContours, ZContours

---

To change the number of lines, we use the syntax outlined above:

```
plot(plot::Implicit3d(abs(x)^3+abs(y)^3+abs(z)^3 - 1,
 x = -1..1, y=-1..1, z=-1..1,
 XContours = [Automatic, 4],
 YContours = [Automatic, 11],
 ZContours = [Automatic, 21]),
 Axes = None, Scaling = Constrained)
```

Note that two of the lines are at the extremal values and therefore usually not visible.

### Example 3

Contour lines are drawn using the same settings for `LineWidth` and `LineColor` as parameter lines are. In the following example, we use a modified copy of a function object that *only* displays contour lines, but with settings different from the function object proper.

```
f := plot::Function3d(x^2 - 2*x*y - y^2, x = -2..2, y = -2..2):
plot(f, plot::modify(f, ZContours = [Automatic, 15],
 LineWidth = 1,
 LineColor = RGB::Gray30.[0.8],
 XLinesVisible = FALSE,
 YLinesVisible = FALSE,
 Filled = FALSE))
```

# XContours, YContours, ZContours

---

By using a transformation that maps space into a plane, we can use this technique (by setting some more options) to display height-colored contour lines below a function plot:

```
f := plot::Function3d(8*sin(x-cos(y))+(x^2+x*y),
 x = -3..3, y = -3..3, Submesh=[2,2]):
plot(f, plot::Transform3d([0, 0, -9], [1, 0, 0, 0, 1, 0, 0, 0, 0],
 plot::modify(f, ZContours = [Automatic, 15],
 LineWidth = 0.5,
 LineColorType = Dichromatic,
 LineColor = RGB::Red,
 LineColor2 = RGB::CornflowerBlue,
 XLinesVisible = FALSE,
 YLinesVisible = FALSE,
 Filled = FALSE)))
```

## See Also

## MuPAD Functions

`LineColor` | `LinesVisible` | `LineWidth`

# PointColor

---

**Purpose** Color of points

**Value Summary** Inherited Color

## Graphics Primitives

Objects	PointColor Default Values
plot::Matrixplot, plot::Point2d, plot::Point3d, plot::PointList2d, plot::PointList3d, plot::SparseMatrixplot, plot::Sum	RGB::MidnightBlue
plot::Listplot, plot::QQplot, plot::Scatterplot	RGB::Black

## Description

PointColor determines the color of points. The RGB library provides many pre-defined colors such as RGB::Red etc. See section Colors of this document for more information on colors.

Many graphical objects such as curves, surfaces etc. are approximated by a numerical mesh. With PointsVisible = TRUE, the points of this mesh become visible. These points do *not* react to PointColor.

PointColor cannot be animated.

For points of type plot::Point2d and plot::Point3d, the point color can also be set by the attribute Color.

## Examples

### Example 1

We plot a cluster of random points with random sizes and random colors:

```
r := frandom:
plot(plot::Point2d([r(),r()], PointSize = 5*r()*unit::mm,
 PointColor = [r(), r(), r()]
```

```
$ i = 1 .. 200):
```

```
delete r:
```

## Example 2

We can access the PointColor attribute from a point and change it:

```
p := plot::Point2d(1, 2):
p::PointColor := RGB::Black:
p::PointColor
```

```
[0.0, 0.0, 0.0]
```

```
delete p:
```

# PointColor

---

## See Also

### **MuPAD Functions**

`PointColor2` | `PointColorType` | `PointSize` | `PointStyle` |  
`PointsVisible`

**Purpose** Secondary point color for color blends

**Value Summary** Optional Color

## Graphics Primitives

Objects	PointColor2 Default Values
plot::SparseMatrixplot	RGB::Red

## Description

PointColor2 sets the secondary point color in objects of type plot::SparseMatrixplot.

Objects of type plot::SparseMatrixplot color their points according to the attribute PointColorType = Flat or PointColorType = Dichromatic, respectively.

With PointColorType = Flat, all points in a plot::SparseMatrixplot object are displayed in the color given by PointColor.

With PointColorType = Dichromatic, the points are colored differently using a color blend from the color PointColor to the color PointColor2. The actual color of a point indicates the size of the matrix entry visualized by plot::SparseMatrixplot.

PointColor corresponds to small matrix entries, PointColor2 corresponds to large matrix entries.

## Examples

### Example 1

We create a 30 50 matrix with 500 random entries.

```
smp := plot::SparseMatrixplot(
 matrix::random(30, 50, 500, frandom)):
```

We use the color type Dichromatic and request a dark green for large matrix entries and a light green for small matrix entries:

# PointColor2

---

```
smp::PointColorType := Dichromatic:
smp::PointColor := RGB::LightGreen:
smp::PointColor2 := RGB::DarkGreen:
smp::PointStyle := FilledDiamonds:
smp::PointSize := 2.5*unit::mm:
plot(smp):
```

The secondary color is changed to a dark red:

```
smp::PointColor2 := RGB::DarkRed:
plot(smp):
```

`delete smp:`

## See Also

## MuPAD Functions

[PointColor](#) | [PointColorType](#) | [PointSize](#) | [PointStyle](#)

# PointColorType

---

**Purpose** Point coloring types

**Value Summary** Optional Dichromatic, or Flat

## Graphics Primitives

Objects	PointColorType Default Values
plot::SparseMatrixplot	Flat

## Description

PointColorType controls the type of point coloring used in objects of type plot::SparseMatrixplot.

With PointColorType = Flat, all points in a plot::SparseMatrixplot object are displayed in the color given by PointColor.

With PointColorType = Dichromatic, the points are colored differently using a color blend from the color PointColor to the color PointColor2. The actual color of a point indicates the size of the matrix entry visualized by plot::SparseMatrixplot.

## Examples

### Example 1

We create a 30 50 matrix with 500 random entries. With the default setting of PointColorType = Flat, all nonzero entries are displayed in the color given by PointColor:

```
smp := plot::SparseMatrixplot(
 matrix::random(30, 50, 500, frandom)):
plot(smp):
```

We change the color type to Dichromatic and request a dark green for large matrix entries and a light green for small matrix entries:

```
smp::PointColorType := Dichromatic:
smp::PointColor := RGB::LightGreen:
smp::PointColor2 := RGB::DarkGreen:
smp::PointStyle := FilledDiamonds:
smp::PointSize := 2.5*unit::mm:
plot(smp):
```

# PointColorType

---

`delete smp:`

plot::Bars2d, plot::Bars3d, plot::Conformal, plot::Curve2d, plot::Curve3d, plot::Cylindrical, plot::Dodecahedron, plot::Function2d, plot::Function3d, plot::Hexahedron, plot::Histogram2d, plot::Icosahedron, plot::Integral, plot::Listplot, plot::Matrixplot, plot::Octahedron, plot::Ode2d, plot::Ode3d, plot::Point2d, plot::Point3d, plot::PointList2d, plot::PointList3d, plot::Polar, plot::Polygon2d, plot::Polygon3d, plot::Prism, plot::Pyramid, plot::QQplot, plot::Scatterplot, plot::Spherical, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron,	1.5

# PointSize

Objects	PointSize Default Values
---------	--------------------------

## Description

<p>plot::Turtle, plot::VectorField3d, plot::Watermark, plot::Size, plot::Unitize, plot::RootLocus, plot::SpansMatrixPlot, plot::Sequence</p>	<p>size of points. The value should be specified as an absolute physical length including a length unit such as mm. The value 1.0*unit::mm gives the size in mm.</p> <p>1.0</p> <p>2</p>
----------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Depending on your hardware, there is a maximal size of the graphical points that can be rendered in 3D. If the PointSize is too large, the 3D renderer uses the maximal size that is supported.

Many graphical objects such as curves, surfaces etc. are approximated by a numerical mesh. With PointsVisible = TRUE, the points of this mesh become visible. These points react to PointSize.

PointSize cannot be animated.

## Examples

### Example 1

We plot a cluster of points with random sizes within the unit square:

```
r := fromdom:
plot(plot::Point2d(r()),r(), PointSize = 2*r()*unit::mm)
 $ i = 1 .. 200)
```

`delete r:`

## Example 2

Due to pixelation, there is only a discrete number of `PointSize` values that the renderers can display faithfully. Further, note that the large points may protrude over the edges of the viewing box without being clipped:

```
plot(plot::Point2d([i, 5], PointSize = i*0.1*unit::mm,
 Color = RGB::Red)
 $ i = 1 .. 30,
 plot::Point2d([3*i, 15], PointSize = i*unit::mm,
 Color = RGB::Green)
 $ i = 1 .. 10,
 plot::Point2d([9*i, 30], PointSize = i*unit::cm,
 Color = RGB::Blue)
 $ i in [0.3, 0.5, 0.8, 1.3, 2, 3],
 ViewingBox = [0 .. 30, 0 .. 35], Axes = Boxed)
```

# PointSize

Here are the same points in 3D. Note the threshold for `PointSize` beyond which the graphical points do not grow:

```
plot(plot::Point3d([i, 5, 0], PointSize = i*0.1*unit::mm,
 Color = RGB::Red)
 $ i = 1 .. 30,
 plot::Point3d([3*i, 15, 0], PointSize = i*unit::mm,
 Color = RGB::Green)
 $ i = 1 .. 10,
 plot::Point3d([9*i, 30, 0], PointSize = i*unit::cm,
 Color = RGB::Blue)
 $ i in [0.3, 0.5, 0.8, 1.3, 2, 3],
 ViewingBox = [0 .. 30, 0 .. 35, -1 .. 1],
 Axes = Boxed, CameraDirection = [0, -10, 1000],
 YXRatio = 2/3)
```

### Example 3

We can access the `PointSize` attribute from a point and change it:

```
p := plot::Point2d(1, 2):
p::PointSize := 4*unit::inch:
p::PointSize
```

508 mm  
5

```
delete p:
```

<b>Examples</b>	<p>plot::SparseMatrixplot</p> <p><b>Example 1</b></p>	Diamonds

We plot 2D points in all available styles:

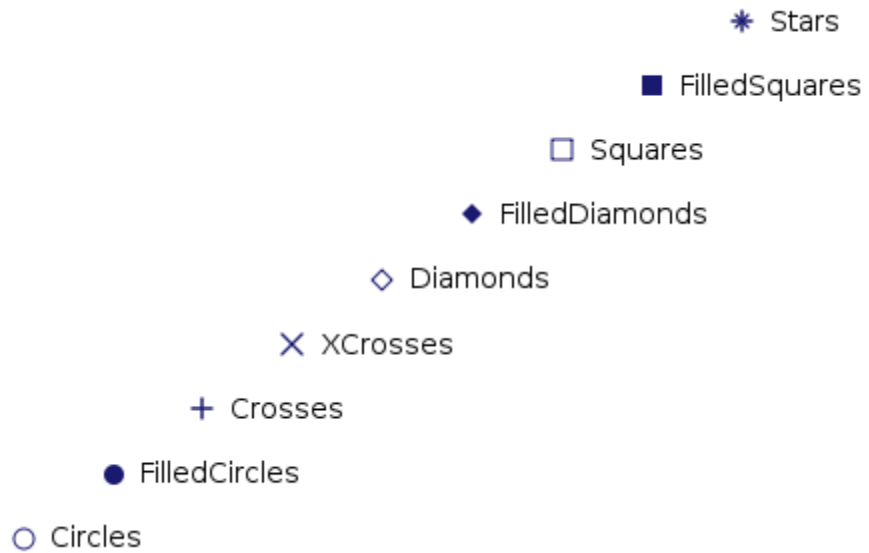

```

styles := [Circles, FilledCircles,
 Crosses, XCrosses,
 Diamonds, FilledDiamonds,
 Squares, FilledSquares,
 Stars]:
points := null():
for i from 1 to nops(styles) do
 points := points,
 plot::Point2d([i, i], PointStyle = styles[i],
 Title = expr2text(styles[i]),
 TitlePosition = [i + 0.3, i - 0.15]):
end_for:
plot(points, PointSize = 3*unit::mm, Axes = None,
 TitleAlignment = Left):

```

# PointStyle

---

```
delete styles, points, i:
```

## Example 2

In 3D, the renderer only supports the point styles `FilledCircles` and `FilledSquares`:

```
plot(plot::Point3d([-1, -1, 0], PointStyle = FilledCircles,
 Title = "FilledCircles",
 TitlePosition = [-1, -0.8, 0]),
 plot::Point3d([1, 1, 0], PointStyle = FilledSquares,
 Title = "FilledSquares",
 TitlePosition = [1, 1.2, 0]),
 PointSize = 3*unit::mm,
 ViewingBox = [-2..2, -2..2, 0..1],
 CameraDirection = [0, -1, 1000]):
```

### Example 3

We can access the `PointStyle` attribute from a point and change it:

```
p := plot::Point2d(1, 2):
p::PointStyle := Diamonds:
p::PointStyle
```

Diamonds

```
delete p:
```

plot::Listplot, plot::Matrixplot, plot::Ode2d, plot::Ode3d, plot::QQplot,	TRUE

## Objects

## PointsVisible Default Values

## Description

`plot::Scatterplot`,  
`plot::Sequence`, `TRUE/FALSE` enables/disables the plotting of mesh  
`plot::SparseMatrix`,  
`plot::Sixplot`,  
`plot::VectorField3d`  
 The mesh points react to the attributes `PointSize` and `PointStyle`.

However, they do *not* react to the attribute `PointColor`. Typically, mesh points are painted in the same color used for the line objects defined by the mesh points.

`PointsVisible` cannot be animated.

## Examples

### Example 1

We plot the sine function on a rather coarse mesh using the `PointsVisible` default value `FALSE`:

```
f := plot::Function2d(sin(x), x = -PI .. PI, Mesh = 20):
plot(f):
```

# PointsVisible

---

We use `PointsVisible = TRUE` to make the mesh points visible:

```
f::PointsVisible := TRUE:
plot(f, PointSize = 2*unit::mm)
```

We enable adaptive plotting:

```
f::AdaptiveMesh := 2:
plot(f, PointSize = 2*unit::mm)
```

`delete f:`

# BarCenters, BarWidths

---

**Purpose** Position of bars

**Value Summary** BarCenters, BarWidths Optional List of arithmetical expressions

## Graphics Primitives

Objects	Default Values
<code>plot::Bars2d</code>	<code>BarWidths: [[1.0]]</code>

## Description

`BarCenters` and `BarWidths` govern horizontal center positions and widths of the bars in 2D bar plots of Type `plot::Bars2d`.

A plot of type `plot::Bars2d` serves for visualizing and comparing discrete data samples by a 2D bar plot.

The data values define the vertical coordinates of the bars. The position along the horizontal axis and the horizontal width of the bars are controlled by the attributes `BarCenters` and `BarWidths`.

The value of the attribute `BarCenters` may be a list  $[x_1, x_2, \dots]$  of numerical values or expressions of the animation parameter. These values define the horizontal coordinates of the bar centers.

If several data samples are to be displayed simultaneously, the value of `BarCenters` may be a list of lists  $[[x_{11}, x_{12}, \dots], [x_{21}, x_{22}, \dots], \dots]$ , where  $x_{ij}$  is the center position of the bar indicating the  $j$ -th data point in the  $i$ -th sample.

If the length of a list in the `BarCenters` attribute is smaller than the number of data in the corresponding sample, the center values are chosen automatically for the surplus data items.

If the length of the `BarCenters` list is larger than the number of corresponding data items, the surplus center values are ignored.

Setting `BarCenters = [x_1]`, the first bar is centered at  $x = x_1$ , while the standard distance between the bars is kept. Thus, `BarCenters = [x_1]` allows to shift the entire bar plot along the horizontal axis.

The value of the attribute `BarWidths` may be a numerical value or an expression of the animation parameter. This sets the horizontal width of *all* bars.

Alternatively, it may be a list of values  $[w_1, w_2, \dots]$  allowing to define different widths of the bars. If several data samples are specified, each data sample uses the same list of `BarWidths` values.

Alternatively, the value of `BarWidths` may be a list of lists  $[[w_{11}, w_{12}, \dots], [w_{21}, w_{22}, \dots], \dots]$ , where  $w_{ij}$  is the horizontal width of the bar indicating the  $j$ -th data point in the  $i$ -th sample.

If the length of a list in the `BarWidths` attribute is smaller than the number of data in the corresponding sample, the width values are chosen automatically for the surplus data items.

If the length of the `BarWidths` list is larger than the number of corresponding data items, the surplus width values are ignored.

The `BarWidths` attribute only has an effect in conjunction with the (default) `BarStyle = Boxes`.

If the attribute `DrawMode = Horizontal` is set in the `plot::Bars2d` object, the bars are drawn from left to right instead from bottom to top.

In this case, the attributes `BarCenters` and `BarWidths` refer to the vertical coordinates of the bars.

## Examples

### Example 1

We display some discrete values as a bar plot:

```
data := [binomial(10, j) $ j = 0..10]:
plot(plot::Bars2d(data, BarCenters = [j $ j = 0..10])):
```

# BarCenters, BarWidths

---

We reduce the widths of the bars:

```
plot(plot::Bars2d(data, BarCenters = [j $ j = 0..10],
 BarWidths = 0.6)):
```

delete data:

## Example 2

For large values of  $n$  and small values of  $p$ , the binomial distribution `stats::binomialPF(n, p)` is approximated by the Poisson distribution `stats::poissonPF(n*p)`. We demonstrate this fact by plotting the probability values of these distributions in one bar plot:

```
n := 100: p:= 0.1:
data1 := [stats::binomialPF(n, p)(j) $ j = 0..20]:
data2 := [stats::poissonPF(n*p)(j) $ j = 0..20]:
plot(plot::Bars2d([data1, data2],
 BarCenters = [[j $ j = 0..20], [j + 0.4 $ j = 0..20]]
 BarWidths = 0.4)):
```

# BarCenters, BarWidths

---

The approximation is better for larger values of  $n$ . We reduce  $p$  accordingly to have the same value of  $np$  as in the previous plot:

```
n := 500: p:= 0.02:
data1 := [stats::binomialPF(n, p)(j) $ j = 0..20]:
data2 := [stats::poissonPF(n*p)(j) $ j = 0..20]:
plot(plot::Bars2d([data1, data2],
 BarCenters = [[j $ j = 0..20], [j + 0.4 $ j = 0..20]],
 BarWidths = 0.4)):
```

```
delete n, p, data1, data2:
```

## MuPAD Functions

DrawMode | BarStyle

# BarStyle, Shadows

---

**Purpose** Display style of bar plots

**Value Summary**

BarStyle	Optional	Boxes, Lines, LinesPoints, or Points
Shadows	Optional	TRUE or FALSE

## Graphics Primitives

Objects	Default Values
plot::Bars3d	BarStyle: Boxes
plot::Bars2d	BarStyle: Boxes Shadows: FALSE

## Description

BarStyle selects between bars drawn as boxes, as lines, just points, or lines with points. For box diagrams, Shadows can be used to have simple “shadows” drawn.

Bar plots can use different types of bars. The options are shown in the examples.

## Examples

### Example 1

With only few data, the option Boxes is often the most useful one:

```
plot(plot::Bars2d([[1,2,3],[2,5,4],[1,0.5,-1]],
 BarStyle = Boxes))
```

It can be combined with `Shadows = TRUE` and possibly `LinesVisible = FALSE` for a more pleasant display:

```
plot(plot::Bars2d([[1,2,3],[2,5,4],[1,0.5,-1]],
 BarStyle = Boxes, Shadows = TRUE,
 LinesVisible = FALSE))
```

# BarStyle, Shadows

---

Shadows are not displayed for the other bar styles:

```
plot(plot::Bars2d([[1,2,3],[2,5,4],[1,0.5,-1]],
 BarStyle = Lines, Shadows = TRUE))
```

## Example 2

When more data is to be displayed, a bar plot may be less adequate:

```
b := plot::Bars2d([[1/i^k$i=1..20] $ k = 1..4]):
plot(b)
```

# BarStyle, Shadows

---

We demonstrate the alternatives without any further comment:

```
b::BarStyle := Lines:
plot(b)
```

```
b::BarStyle := Points:
plot(b)
```

# BarStyle, Shadows

---

```
b::BarStyle := LinesPoints:
plot(b)
```

# Color

---

## Description

Color refers to the “main color” of an object.

Depending on the object type, Color refers to the line color (e.g., `plot::Function2d`), the fill color (`plot::Surface`), the point color (`plot::Point2d`), the light color (`plot::PointLight`), or the one-and-only entry in `Colors` (`plot::Histogram2d`).

In general, the main color of an object is the first one available in the list

- 1 The first entry of `Colors`, if `Colors` contains exactly one entry.
- 2 `FillColor`
- 3 `LineColor`
- 4 `PointColor`
- 5 `LightColor`

The following object types deviate from this general rule and choose the line color as main color: `plot::Arc2d`, `plot::Arc3d`, `plot::Circle2d`, `plot::Circle3d`, `plot::Ellipse2d`, `plot::Ellipse3d`, `plot::Ode2d`, `plot::Ode3d`, `plot::Parallelogram2d`, `plot::Polygon2d`, `plot::Polygon3d`, and `plot::Rectangle`. `plot::Sequence` uses `PointColor` as the main color.

---

**Note** Color is a *library attribute* and does not appear in the inspector.

---

## Examples

### Example 1

Color is useful for unified input of different object types:

```
plot(plot::Function3d(sin(x-y/2), Color = RGB::Green),
 plot::Point3d([0, 0, 0], Color = RGB::Red),
 plot::Curve3d([x, 0, sin(x)], x = -6..6,
 LineWidth = 2*unit::mm,
 Color = RGB::Blue),
```

Scaling = Constrained)

## Description

Colors sets a list of colors to use for object parts.

Plot objects like `plot::Piechart3d` or `plot::MuPADCube` that use more than one color use Colors to have a configurable list of colors to use.

The length of the list in `Colors` need not be fixed, it just must not be empty. If the list contains more colors than needed, the remaining colors are simply not used; if the list contains fewer colors than needed, it will be used cyclically, i.e., as if it were repeated as often as necessary. Cf. “Example 2” on page 23-2124.

## Examples

### Example 1

Most of the statistical plots use `Colors` for the colors of their groups:

```
plot(plot::Bars2d([[frandom() $i=1..2] $ i = 1..3]))
```

```
plot(plot::Bars2d([[frandom() $i=1..2] $ i = 1..3],
Colors = [RGB::Orange, RGB::Yellow, RGB::Magenta]))
```

# Colors

---

## Example 2

If more colors are required than given in Colors, the given list is used cyclically:

```
plot(plot::Piechart2d([1, 1, 1, 1], Colors = [RGB::White, RGB::Blue
```

plot::Arc3d, plot::Ellipse3d, plot::Parallelogram3d	FillColor: RGB::LightBlue FillColor2: RGB::CornflowerBlue
plot::Waterman	FillColor: RGB::SafetyOrange FillColor2: RGB::CornflowerBlue
plot::Integral	FillColor: RGB::PaleBlue

## Description

FillColor determines the color used to fill all types of areas and surfaces. FillColor2 is used for color blends. FillColors is used for objects that need more than one color.

2D objects that have a notion of “area” and 3D objects that have a surface support FillColor to determine the primary color to show objects in. If FillColorType is set to Dichromatic, FillColor2 sets the second color to blend to.

Functions and primitives displaying more than one object, such as plot::Bars2d, use FillColors for a list of colors used cyclically.

## Examples

### Example 1

By default, plot::Hatch objects are hatched in RGB ::Red, the same color used by default for plot::Function2d:

```
f := plot::Function2d(cos(2*x)+cos(x), x=-PI..PI):
h := plot::Hatch(f):
plot(h, f)
```

## FillColor, FillColor2

---

To change the color of the hatch, simply set the "FillColor"-slot to some other value:

```
h::FillColor := RGB::Grey:
plot(h, f)
```

## Example 2

The default setting for a surface is to have a height-dependent coloring with a linear blend from `FillColor` to `FillColor2`:

```
s := plot::Surface([cos(2*u+v), sin(u+2*v), sin(u+v)],
 u = 0..2*PI, v = 0..2*PI,
 ULinesVisible = FALSE,
 VLinesVisible = FALSE):
plot(s)
```

# FillColor, FillColor2

---

These colors can be manipulated in the usual way. As an example, we set the transition to a monochrome transition from opaque to transparent:

```
s::FillColor := RGB::Green:
s::FillColor2 := s::FillColor . [0.0]:
plot(s)
```

### Example 3

Using a utility function `randrange` that returns random ranges in  $[0, 1]$ , we can plot random rectangles with random colors:

```
randrange := () -> _range(op(sort([frandom(), frandom()]))) :
plot(plot::Rectangle(randrange(), randrange(),
 LinesVisible = FALSE,
 Filled = TRUE, FillPattern = Solid,
 FillColor = [frandom(), frandom(), frandom()])
$k=1..20,
AxesVisible = FALSE)
```

# FillColor, FillColor2

---

## Description

plot::Tube, plot::Waterman, plot::Cylinder, plot::Cone, plot::Sphere, plot::Ellipsoid, plot::Paraboloid, plot::Torus, plot::Listplot	FillColorDirection: [0, 0]
--------------------------------------------------------------------------------------------------------------------------------------	----------------------------

FillColorDirection, plot::Rotate the direction in which the color transitions for FillColorType = Dichromatic etc. take place. When setting FillColorType to some other value than Flat or Functional, MuPAD produces a “height-coloring.” By default, this color method actually uses the height of a point. Using FillColorDirection, the axis along which the color method should be applied can be changed.

## Examples

### Example 1

By default, MuPAD uses height coloring along the  $z$  axis for 3D objects:

```
s := plot::Spherical([sin(r), thet/(r+1)+1, thet*r],
 r=0..1, thet=0..3*PI, Submesh=[2,2]):
plot(s)
```

# FillColorDirection, FillColorDirectionX, FillColorDirectionY, FillColorDirectionZ

---

By changing `FillColorDirection`, the color can be rotated on the object:

```
plot(s, FillColorDirection = [0, 1, 0])
```

## MuPAD Functions

[FillColor](#) | [FillColor2](#) | [FillColorType](#) | [LineColorDirection](#)

# FillColorTrue, FillColorFalse, FillColorUnknown

---

**Purpose** Color for “true” areas (inequality plot)

**Value Summary** FillColorFalse, Optional Color  
FillColorTrue,  
FillColorUnknown

## Graphics Primitives

Objects	Default Values
plot::Inequality	FillColorTrue: RGB::Green FillColorFalse: RGB::Red FillColorUnknown: RGB::Black

## Description

FillColorTrue, FillColorFalse, and FillColorUnknown define the three colors use by plot::Inequality for the areas where the inequalities are fulfilled (true), violated (false) or the granularity is too small to decide (unknown).

plot::Inequality divides the plot area into rectangles that are colored according to these three attributes. Rectangles over which the inequalities are true get the color set by FillColorTrue; rectangles over which at least one inequality is violated (i.e., false over the whole rectangle) use FillColorFalse. If neither of these two apply and the rectangle is already too small for subdivision (the settings for XMesh and YMesh control this), it will be painted in FillColorUnknown.

## Examples

### Example 1

We show the same inequality plot with different settings of these three attributes:

```
ineq := plot::Inequality([sin(x)^2>y, y>x^5], x=-1..1, y=-1..1):
plot(ineq)
```

# FillColorTrue, FillColorFalse, FillColorUnknown

---

```
ineq::FillColorTrue := RGB::Green:
ineq::FillColorFalse := RGB::Red:
ineq::FillColorUnknown := RGB::Blue:
plot(ineq)
```

# FillColorTrue, FillColorFalse, FillColorUnknown

---

**Purpose** Surface filling types

**Value Summary** Inherited Dichromatic, Flat, Functional, Monochrome, or Rainbow

## Graphics Primitives

Objects	FillColorType Default Values
plot::Cylindrical, plot::Density, plot::Dodecahedron, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit3d, plot::Matrixplot, plot::Octahedron, plot::Prism, plot::Pyramid, plot::Spherical, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Sweep, plot::Tetrahedron, plot::Tube, plot::XRotate, plot::ZRotate	Dichromatic
plot::Arc3d, plot::Ellipse3d, plot::Parallelogram3d, plot::Waterman	Flat

**Description** FillColorType selects the type of surface fill color used.

With the exception of Flat and Functional, the coloring schemes depend on the height, i.e., the  $z$  value of points on the surface, in relation to the height of the whole coordinate system. (Everything on

# FillColorType

---

this page relating to surfaces holds for objects of type `plot::Density`, too, with the values plotted replacing height information.)

By default, surfaces are drawn with a linear blend from `FillColor` to `FillColor2`. This behavior may be changed with `FillColorType`, using one of the following options:

- **Dichromatic**

The default just described.

- **Flat**

The surface is filled with `FillColor`. No blend is used.

- **Monochrome**

The surface is filled with a blend from `FillColor` to a dimmed version of `FillColor`.

- **Rainbow**

This setting is technically similar to `Dichromatic`, but the effect is vastly different, since interpolation takes place in HSV color space. This creates a rainbow effect, similar to a physical rainbow for suitable choices of colors.

- **Functional**

Both `FillColor` and `FillColor2` are ignored; the color scheme is derived from `FillColorFunction`. See `FillColorFunction` for details (which depend on the object type). If no color function is given, the object will be rendered with `FillColorType = Flat`.

In this context, “a blend from *A* to *B*” means that color *A* is used at the top of the coordinate system (the part with the lowest *z* coordinate), color *B* is used at the bottom and in between each or the red, green, blues, and alpha channel are interpolated linearly.

## Examples

### Example 1

By default, function plots use `FillColorType = Dichromatic` with a color range from blue to red (as in a temperature scale):

```
plotfunc3d(sin(x)*sin(y))
```

Using `FillColorType`, we color the graph completely in red:

```
plotfunc3d(sin(x)*sin(y), FillColorType = Flat)
```

# FillColorType

---

Note, however, that the coloring is a visual aid, e.g., when looking from above:

```
plotfunc3d(sin(x)*sin(y),
 CameraDirection = [0, 0, 1])
```

```
plotfunc3d(sin(x)*sin(y), FillColorType = Flat,
 CameraDirection = [0, 0, 1])
```

# FillColorType

---

## Example 2

In MuPAD, rainbow coloring does react to `FillColor` and `FillColor2`. The following plot uses different color settings to show this effect:

```
plot(plot::Function3d(sin(y), x = 0..10, y = -PI..PI,
 FillColor = RGB::BlueLight,
 FillColor2 = RGB::Blue),
 plot::Function3d(sin(y), x = 0..10, y = PI..3*PI,
 FillColor = RGB::Green,
 FillColor2 = RGB::Red),
 FillColorType = Rainbow,
 XLinesVisible = FALSE, YLinesVisible = FALSE)
```

What is happening here technically is that MuPAD performs a linear interpolation in HSV color space, i.e., the *longest* path round the following color circle is followed, with saturation and value (roughly speaking, whiteness and blackness) interpolated linearly:

# FillColorType

---

The opacity of colors is treated the same way in both the Rainbow and Dichromatic settings of `FillColorType`, by linear interpolation:

```
plot((f:=plot::Function3d(sin(y), x = 0..10, y = -PI..PI,
 FillColorType = Rainbow, FillColor2 = RGB::VioletDark.[0.2],
 XLinesVisible = FALSE, YLinesVisible = FALSE)))
```

### Example 3

Setting a `FillColorFunction` for an object automatically sets `FillColorType` to `Functional`:

```
colorfunc := (x, y) -> [abs(x)/PI, 0, abs(y)/PI]:
f := plot::Function3d(sin(x)*cos(y), x = -PI..PI, y = -PI..PI,
 FillColorFunction = colorfunc):
f::FillColorType
```

`Functional`

```
plot(f)
```

# FillColorType

---

`delete colorfunc, f:`

# Filled

	Objects	Filled Default Values
<b>Description</b>	<code>plot::Circle3d</code> , <code>plot::Circle2d</code> , <code>plot::Ellipse2d</code> , <code>plot::Ellipse3d</code> , <code>plot::Parallelogram2d</code> , <code>plot::Polygon2d</code> , <code>plot::Polygon3d</code> , <code>plot::Rectangle</code> , <code>plot::Sum</code>	Whether areas and surfaces are filled or transparent. With <code>Filled = FALSE</code> , areas and surfaces are not filled. This means that, e.g. a surface plot is reduced to a wire frame model.
<b>Examples</b>	<b>Example 1</b>	

The following parametrization of a sphere uses a mesh similar to the graticule (longitudes and latitudes) of geography:

```
globe := plot::Surface([sin(u)*cos(v), cos(u)*cos(v), sin(v)],
 u = 0..2*PI, v = 0..2*PI,
 Mesh = [12, 12], Submesh = [3, 3]):
plot(globe, Scaling = Constrained)
```

To get a wire frame model, we set `Filled = FALSE`:

```
plot(globe, Filled = FALSE, LineColor = RGB::Black,
 Scaling = Constrained)
```

## Value Summary

FillPattern	Inherited	CrossedLines, DiagonalLines, FDiagonalLines, HorizontalLines, Solid, VerticalLines, or XCrossedLines
FillPatterns	Optional	Solid, HorizontalLines, VerticalLines, DiagonalLines, FDiagonalLines, CrossedLines, or XCrossedLines

## Graphics Primitives

Objects	Default Values
plot::Arc2d, plot::Boxplot, plot::Circle2d, plot::Ellipse2d, plot::Hatch, plot::Parallelogram2d, plot::Polygon2d, plot::Rectangle	FillPattern: DiagonalLines
plot::Bars2d, plot::Histogram2d, plot::Inequality, plot::Integral, plot::Piechart2d, plot::Sum	FillPattern, FillPatterns: Solid

## Description

FillPattern determines the style of area filling used: lines, grids, or a solid fill.

FillPatterns is used for objects with more than one type of area to fill.

Areas can be filled in various ways. You can have horizontal, vertical, or diagonal lines (HorizontalLines, VerticalLines, DiagonalLines, FDiagonalLines), a horizontal/vertical grid (CrossedLines), a diagonal grid (XCrossedLines), or a solid fill (Solid).

For types like `plot::Bars2d`, `FillPatterns` is a list of fill patterns used cyclically, in this case for the groups of data plotted.

## Examples

### Example 1

The fill patterns look like this:

```
plot(
 plot::Rectangle(0..1, 0..1, FillPattern = Solid),
 plot::Rectangle(1..2, 0..1, FillPattern = DiagonalLines),
 plot::Rectangle(2..3, 0..1, FillPattern = FDiagonalLines),
 plot::Rectangle(3..4, 0..1, FillPattern = HorizontalLines),
 plot::Rectangle(4..5, 0..1, FillPattern = VerticalLines),
 plot::Rectangle(5..6, 0..1, FillPattern = CrossedLines),
 plot::Rectangle(6..7, 0..1, FillPattern = XCrossedLines),
 Filled = TRUE, AxesInFront = TRUE
)
```

# FillPattern, FillPatterns

Except for Solid, the fill patterns let objects below be seen:

```
plot(
 plot::Function2d(sin(x*PI/14), x = 0..7, Color = RGB::Black),
 plot::Function2d(cos(x*PI/14), x = 0..7, Color = RGB::Blue),
 plot::Rectangle(0..1, 0..1, FillPattern = Solid),
 plot::Rectangle(1..2, 0..1, FillPattern = DiagonalLines),
 plot::Rectangle(2..3, 0..1, FillPattern = FDiagonalLines),
 plot::Rectangle(3..4, 0..1, FillPattern = HorizontalLines),
 plot::Rectangle(4..5, 0..1, FillPattern = VerticalLines),
 plot::Rectangle(5..6, 0..1, FillPattern = CrossedLines),
 plot::Rectangle(6..7, 0..1, FillPattern = XCrossedLines),
 Filled = TRUE, AxesInFront = TRUE
)
```

# FillStyle

---

**Purpose** Definition of inside/outside

**Value Summary** Inherited EvenOdd, or Winding

## Graphics Primitives

Objects	FillStyle Default Values
<code>plot::Polygon2d</code>	EvenOdd

**Description** For self-intersecting closed curves, `FillStyle` determines how holes are detected/defined.

Closed curves have an inside and an outside. With self-intersecting curves, the inside may have holes which are considered outside and not filled. To explain the difference between `EvenOdd` and `Winding`, we use the following two polygons which differ only in the order the inner points are visited:

If plotted with `FillStyle = EvenOdd`, there is no difference between the two:

# FillStyle

---

This is because for `FillStyle = EvenOdd`, a point is considered “inside” if a ray starting from the point and extending to infinity has an *odd* number of intersections with the polygon:

# FillStyle

---

With `FillStyle = Winding`, however, the triangles look different from one another:

For `FillStyle = Winding`, the *winding number* of a point must be nonzero for this point to be “inside”. The winding number is the number of times the polygon line actually “runs around” the point. It can be determined by sequentially looking at all the edges, summing up the angles under which neighboring edges are seen (take care of the sign of the angle!) and dividing by  $2\pi$ . In our example, a point in the square in the upper triangle has a winding number of 2, while one in the square in the lower triangle has a winding number of 0:

# FillStyle

FillStyle = Winding is similar to a complete filling of the polygon area, but it is stable under small displacements of the polygon points:

# FillStyle

---

**MuPAD  
Functions**

Filled

**Purpose** Grouping options in 2D bar plots

**Value Summary** Optional MultipleBars, or SingleBars

## Graphics Primitives

Objects	GroupStyle Default Values
plot::Bars2d	MultipleBars

## Description

GroupStyle determines whether a bar plot visualizes the data of different groups by separate bars or by single bars that are split into colored regions.

2D bar plots can group the bars in various ways. With the default setting `GroupStyle = MultipleBars`, data that are split into several groups are displayed by separate bars for each value in each group. With `GroupStyle = SingleBars`, corresponding data items in different groups are stacked up to one single bar. It is split into differently colored parts that correspond to the different groups.

With `SingleBars`, all data must be nonnegative.

`SingleBars` has no effect if the data of only one group are given. If you wish to visualize the data in a single bar, you have to turn each data item into a separate group. Cf. “Example 2” on page 23-2169.

## Examples

### Example 1

The attribute `GroupStyle` can have the values `MultipleBars` or `SingleBars`:

```
group1 := [1.0, 1.2, 0.9, 1.0]:
group2 := [2.2, 1.9, 1.7, 2.1]:
data:= [group1, group2]:
plot(plot::Bars2d(data, GroupStyle = MultipleBars))
```

# GroupStyle

---

With `SingleBars`, corresponding data items in the different groups are collected in a single bar:

```
plot(plot::Bars2d(data, GroupStyle = SingleBars))
```

The following data are the australian market shares (in percent) of major car producers in the years 2004 and 2005:

```
// 2004 2005
Toyota:= [21.1, 20.2]:
Holden_GM:= [18.7, 17.9]:
Ford:= [14.0, 13.0]:
Mazda:= [5.8, 6.7]:
Mitsubishi:= [5.9, 6.4]:
Others:= [34.5, 35.8]:
data:= [Toyota, Holden_GM, Ford, Mazda, Mitsubishi, Others]:
```

We visualize the change of the market shares by bar plots using different group styles:

```
plot(plot::Bars2d(data, GroupStyle = MultipleBars))
```

# GroupStyle

---

```
plot(plot::Bars2d(data, GroupStyle = SingleBars))
```

```
delete group1, group2, data, Toyota, Holden_GM,
 Ford, Mazda, Mitsubishi, Others:
```

## Example 2

The option `SingleBars` has no effect when the data of only one group are given:

```
group:= [1, 0.5, 2, PI/3, 2.7]:
plot(plot::Bars2d(group, GroupStyle = SingleBars))
```

# GroupStyle

---

Each value is turned into a separate group:

```
groups:= [[x] $ x in group]
```

```
[1], [0.5], [2], [$\frac{\pi}{3}$], [2.7]
```

Now, SingleBars has an effect:

```
plot(plot::Bars2d(groups, GroupStyle = SingleBars,
 BarCenters = [0.4], BarWidths = [0.3]),
 ViewingBox = [0..1, Automatic])
```

`delete group, groups:`

# InterpolationStyle

---

**Purpose** Interpolation via linear or cubic splines

**Value Summary** Optional Cubic, or Linear

## Graphics Primitives

Objects	InterpolationStyle Default Values
plot::Listplot, plot::Matrixplot	Linear

## Description

InterpolationStyle determines whether discrete data are interpolated linearly or via cubic splines.

With the default setting `InterpolationStyle = Linear`, the curve connecting the data points in a plot of type `plot::Listplot` consists of line segments. Similarly, the surface generated from the matrix data in `plot::Matrixplot` consists of linear segments (triangles).

These plot objects do not react to the attribute `Submesh` when using linear interpolation.

With `InterpolationStyle = Cubic`, the curve connecting the data points in a plot of type `plot::Listplot` is the graph of the cubic spline function interpolating the data points. Similarly, the surface generated by `plot::Matrixplot` is the graph of the cubic spline function interpolating the matrix data.

The spline functions can be rendered smoothly by setting appropriate values for the attribute `Submesh`.

For large amounts of data, rendering with cubic spline interpolation may be much more costly than linear interpolation.

## Examples

### Example 1

We sample the function  $f(x) = \frac{1}{(x+1)^2}$  at various points and store the data in a list. The data are displayed via `plot::Listplot` with different interpolation styles:

```
L := [1 - (i/2)^2 $ i = -2..2]:
plot(plot::Listplot(L, x = -1..1, InterpolationStyle = Cubic,
 Color = RGB::Red),
 plot::Listplot(L, x = -1..1, InterpolationStyle = Linear,
 Color = RGB::Blue)):
```

```
delete L:
```

# InterpolationStyle

---

## Example 2

We sample the function  $f(x, y) = 1 - x^2 - y^2$  at various points and store the data in a matrix. The matrix data are displayed as a matrix plot with different interpolation styles:

```
A := matrix([[1 - (i/2)^2 - (j/2)^2 $ j = 0..2] $ i = 0..2]):
plot(plot::Matrixplot(A, x = 0..2, y = 0..2,
 InterpolationStyle = Cubic),
 plot::Matrixplot(A, x = 4..6, y = 0..2,
 InterpolationStyle = Linear),
 CameraDirection = [10, 15, 9]):
```

```
delete A:
```

### **MuPAD Functions**

Submesh

# Shading

---

**Purpose** Smooth color blend of surfaces

**Value Summary** Inherited Flat, or Smooth

## Graphics Primitives

Objects	Shading Default Values
plot::Cone, plot::Dodecahedron, plot::Ellipsoid, plot::Function3d, plot::Hexahedron, plot::Icosahedron, plot::Implicit3d, plot::Matrixplot, plot::Octahedron, plot::Prism, plot::Pyramid, plot::Sphere, plot::Surface, plot::SurfaceSet, plot::SurfaceSTL, plot::Tetrahedron, plot::Tube, plot::Waterman, plot::XRotate, plot::ZRotate	Smooth

**Description** Using Shading, a smooth color blend of triangulated surfaces can be (de-)activated.

Most surfaces in 3D are triangulated for display. The triangles are then drawn using Gouraud-shading to achieve a smooth visual effect. Using `Shading = Flat`, you can instruct the viewer to display the plain triangles.

## Examples **Example 1**

Reducing the mesh density of a surface usually has more effect on its outer rim than on the display of the middle:

```
plot(plot::Spherical([1, u, v], u=0..PI, v=0..2*PI,
 UMesh=5, VMesh=5))
```

Setting `Shading = Flat`, you can see the triangles from which the sphere is constructed:

```
plot(plot::Spherical([1, u, v], u=0..PI, v=0..2*PI,
 UMesh=5, VMesh=5),
 Shading = Flat)
```

# Shading

---

### MuPAD Functions

[Lighting](#) | [UMesh](#) | [VMesh](#) | [USubmesh](#) | [VSubmesh](#)

**Purpose** Use predefined normals?

**Value Summary** Optional TRUE or FALSE

**Graphics Primitives**

Objects	UseNormals Default Values
plot::SurfaceSet, plot::SurfaceSTL	TRUE

**Description** UseNormals controls whether predefined normals of triangulation data are used when plotting a surface.

With UseNormals = FALSE, the predefined normals given in the triangulation data (MeshList) of a plot::SurfaceSet or in an STL file imported by a plot::SurfaceSTL are ignored when plotting this surface. This may reduce the data volume of the graphical object and the computing time as well. However, it usually leads to a somewhat less brilliant image.

**Examples Example 1**

By default, the normals defined in STL files are used when plotting the corresponding MuPAD object. For comparison, an STL graphics is plotted with and without using the normals provided by the STL file:

```
plot(plot::Scene3d(plot::SurfaceSTL("skin.stl")),
 plot::Scene3d(plot::SurfaceSTL("skin.stl",
 UseNormals = FALSE)),
 Width = 120*unit::mm, Height = 140*unit::mm,
 Layout = Vertical, BackgroundStyle = Pyramid,
 Axes = None):
```

# UseNormals

---

### **MuPAD Functions**

[MeshList](#) | [MeshListNormals](#) | [Filled](#)

# TipAngle

---

**Purpose** Opening angle of arrow heads

**Value Summary** Inherited Positive real number

## Graphics Primitives

Objects	TipAngle Default Values
plot::Arrow2d, plot::Arrow3d, plot::Streamlines2d	$(2 * \text{PI}) / 15$
plot::VectorField2d	0.6283185307

## Description

TipAngle determines the opening angle of arrow heads in radians.

TipAngle determines the opening angle of the tips of arrows of type plot::Arrow2d and plot::Arrow3d. Also the arrow tips in a vector field of type plot::VectorField2d are controlled by TipAngle. The opening angle must be specified in radians. Values for TipAngle between 0 and  $\pi$  are reasonable.

The tip angle is the geometric angle of the arrow heads as visible in the graphical output. It is invariant under scaling and zooming.

The values of TipAngle cannot be animated.

The attribute TipStyle sets the presentation style of arrow tips. TipLength sets the physical tip length.

## Examples

### Example 1

We create an arrow whose arrow tip has an angle of 20 degrees. This corresponds to  $\frac{\pi}{9}$  radians:

```
plot(plot::Arrow2d([0, 0], [1, 1], TipAngle = PI/9,
 TipLength = 10*unit::mm)):
```

We create several arrows with different tip angles. The angle is increased by 10 degrees from one arrow to the next:

```
plot(plot::Arrow2d([0, 0], [cos(a*2*PI/18), sin(a*2*PI/18)],
 TipAngle = a*PI/18) $ a = 0 .. 17,
 Scaling = Constrained):
```

# TipAngle

---

Here are corresponding arrows in 3D:

```
plot(plot::Arrow3d([0, 0, 0],
 [cos(a*2*PI/18), sin(a*2*PI/18), 0],
 TipAngle = a*PI/18) $ a = 0 .. 17,
 Scaling = Constrained,
 CameraDirection = [0, -10, 1000]):
```

We use `Tubular = TRUE`:

```
plot(plot::Arrow3d([0, 0, 0],
 [cos(a*2*PI/18), sin(a*2*PI/18), 0],
 TipAngle = a*PI/18) $ a = 0 .. 17,
 Tubular = TRUE, Scaling = Constrained,
 CameraDirection = [0, -10, 1000]):
```

# TipAngle

---

## See Also

## MuPAD Functions

[TipLength](#) | [TipStyle](#) | [TubeDiameter](#) | [Tubular](#)

**Purpose** Length of arrow heads

**Value Summary** Inherited Non-negative output size

## Graphics Primitives

Objects	TipLength Default Values
plot::Arrow2d, plot::Arrow3d	4
plot::VectorField2d	1.5
plot::Streamlines2d	0

## Description

TipLength determines the physical length of arrow heads

TipLength determines the length of the tips of arrows of type plot::Arrow2d and plot::Arrow3d. Also the arrow tips in a vector field of type plot::VectorField2d are controlled by TipLength. The value should be specified as an absolute physical length including a length unit such as TipLength = 2.5\*unit::mm. Numbers without a physical unit give the size in mm.

The tip length is the physical length of the arrow heads as visible in the graphical output. It is invariant under scaling and zooming.

The values of TipLength cannot be animated.

The attribute TipStyle sets the presentation style of arrow tips. TipAngle sets the opening angle of the tips.

## Examples

### Example 1

We create an arrow whose tip has physical length of 10 mm:

```
plot(plot::Arrow2d([0, 0], [1, 1], TipAngle = PI/9,
 TipLength = 10*unit::mm)):
```

# TipLength

---

We create several arrows with different tip lengths. The length is increased by 0.7 mm from one arrow to the next:

```
plot(plot::Arrow2d([0, 0], [cos(a*2*PI/18), sin(a*2*PI/18)],
 TipLength = a*unit::mm) $ a = 0 .. 17,
 plot::Circle2d(1, [0, 0]),
 Scaling = Constrained):
```

Here are corresponding arrows in 3D:

```
plot(plot::Arrow3d([0, 0, 0],
 [cos(a*2*PI/18), sin(a*2*PI/18), 0],
 TipLength = a*unit::mm) $ a = 0 .. 17,
 plot::Circle3d(1, [0, 0, 0], [0, 0, 1]),
 Scaling = Constrained,
 CameraDirection = [0, -10, 1000]):
```

# TipLength

---

We use `Tubular = TRUE`:

```
plot(plot::Arrow3d([0, 0, 0],
 [cos(a*2*PI/18), sin(a*2*PI/18), 0],
 TipLength = a*unit::mm) $ a = 0 .. 17,
 plot::Circle3d(1, [0, 0, 0], [0, 0, 1]),
 Tubular = TRUE, Scaling = Constrained,
 CameraDirection = [0, -10, 1000]):
```

# TipStyle

---

**Purpose** Presentation style of arrow heads

**Value Summary** Inherited Closed, Filled, or Open

## Graphics Primitives

Objects	TipStyle Default Values
plot::Arrow2d, plot::Arrow3d, plot::Streamlines2d	Filled
plot::VectorField2d	Open

## Description

TipStyle governs the appearance of arrow heads.

TipStyle determines how the tips of arrows of type plot::Arrow2d and plot::Arrow3d look. Also the arrow tips in a vector field of type plot::VectorField2d are controlled by TipStyle.

With TipStyle = Open, the tips are given by two lines.

With TipStyle = Closed, the tips are given by a triangle.

With TipStyle = Filled, the tips are given by a filled triangle.

TipStyle cannot be animated.

The opening angle and the physical length of the arrow tips are set by the attributes TipAngle and TipLength, respectively.

## Examples

### Example 1

We draw arrows with different tip styles:

```
plot(plot::Arrow2d([0, 0], [1, 0],
 TipStyle = Open),
 plot::Arrow2d([0, 0], [cos(2*PI/3), sin(2*PI/3)],
 TipStyle = Closed),
 plot::Arrow2d([0, 0], [cos(4*PI/3), sin(4*PI/3)],
 TipStyle = Filled),
```

```

Axes = None, ViewingBox = [-1..1, -1..1],
TipLength = 8*unit::mm, TipAngle = PI/5,
Scaling = Constrained):

```

Here are corresponding arrows in 3D:

```

plot(plot::Arrow3d([0, 0, 0], [1, 0, 0],
 TipStyle = Open),
 plot::Arrow3d([0, 0, 0], [cos(2*PI/3), sin(2*PI/3), 0],
 TipStyle = Closed),
 plot::Arrow3d([0, 0, 0], [cos(4*PI/3), sin(4*PI/3), 0],
 TipStyle = Filled),
 ViewingBox = [-1..1, -1..1, -1..1],
 TipLength = 8*unit::mm, TipAngle = PI/5,
 Scaling = Constrained, CameraDirection = [2, -10, 15]):

```

# TipStyle

---

We use `Tubular = TRUE`:

```
plot(plot::Arrow3d([0, 0, 0], [1, 0, 0],
 TipStyle = Open),
 plot::Arrow3d([0, 0, 0], [cos(2*PI/3), sin(2*PI/3), 0],
 TipStyle = Closed),
 plot::Arrow3d([0, 0, 0], [cos(4*PI/3), sin(4*PI/3), 0],
 TipStyle = Filled),
 TipLength = 8*unit::mm, TipAngle = PI/5,
 Tubular = TRUE, ViewingBox = [-1..1, -1..1, -1..1],
 Scaling = Constrained, CameraDirection = [2, -10, 15]):
```

### MuPAD Functions

[TipAngle](#) | [TipLength](#) | [TubeDiameter](#) | [Tubular](#)

# TubeDiameter

---

**Purpose** Diameter of tubular arrows and lines. , and coordinate axes

**Value Summary** Inherited Positive output size

## Graphics Primitives

Objects	TubeDiameter Default Values
plot::Arrow3d, plot::Line3d	1.0

## Description

TubeDiameter governs the size of tubular arrows and lines in 3D.

Arrows of type `plot::Arrow3d` as well as lines of type `plot::Line3d` can be rendered as 3D tubes by setting the attribute `Tubular = TRUE`.

The attribute `TubeDiameter` determines the diameter of tubular arrows and lines. Its value should be specified as an absolute physical length including a length unit such as `TubeDiameter = 2.5*unit::mm`.

Numbers without a physical unit give the size in mm.

Tubular arrows have a tip that is rendered as a little cone. The size of these cones is adjusted when the diameter of the arrow shaft changes.

The attribute `TubeDiameter` is not available in 2D.

## Examples

### Example 1

We draw some tubular arrows with different tube diameters:

```
plot(plot::Arrow3d([0, 0, 0], [1, 3, 5], Color = RGB::Red,
 TubeDiameter = 2.0*unit::mm),
 plot::Arrow3d([0, 0, 0], [5, 3, 1], Color = RGB::Green,
 TubeDiameter = 3.0*unit::mm),
 plot::Arrow3d([0, 0, 0], [5, 1, 3], Color = RGB::Blue,
 TubeDiameter = 4.0*unit::mm),
 Tubular = TRUE, TipLength = 18*unit::mm, Axes = Origin):
```

## See Also

## MuPAD Functions

# Tubular

---

**Purpose** Display 3D arrows and lines as tubes?

**Value Summary** Inherited FALSE, or TRUE

## Graphics Primitives

Objects	Tubular Default Values
plot::Arrow3d, plot::Line3d	FALSE

## Description

With `Tubular = TRUE`, arrows of type `plot::Arrow3d` and lines of type `plot::Line3d` are rendered as tubes (cylinders). The diameter is set by the attribute `TubeDiameter`.

Tubular arrows have a tip that is rendered as a little cone. The tip is determined by the attributes `TipLength` and `TipAngle`.

With `Tubular = FALSE`, arrows and lines are displayed as simple lines.

The attribute `Tubular` is not available in 2D.

## Examples

### Example 1

We draw a tubular arrow together with an arrow displayed as a line:

```
plot(plot::Arrow3d([0, 0, 0], [1/2, 3, 5], Tubular = TRUE,
 TubeDiameter = 2*unit::mm,
 Color = RGB::Red),
 plot::Arrow3d([0, 0, 0], [3, 5, 1], Tubular = FALSE,
 Color = RGB::Blue),
 TipLength = 12*unit::mm, Axes = Origin):
```

# polylib – Manipulating Polynomials

---

polylib::coeffRing  
polylib::cyclotomic  
polylib::decompose  
polylib::discrim  
polylib::divisors  
polylib::Dpoly  
polylib::elemSym  
polylib::makerat  
polylib::minpoly  
polylib::Poly  
polylib::primitiveElement  
polylib::primpart  
polylib::randpoly  
polylib::realroots  
polylib::representByElemSym  
polylib::resultant  
polylib::sortMonomials  
polylib::splitfield  
polylib::sqrfree  
polylib::subresultant  
polylib::support

# polylib::coeffRing

---

**Purpose** Coefficient ring of a polynomial

**Syntax** `polylib::coeffRing(P)`  
`polylib::coeffRing(p)`

**Description** `polylib::coeffRing(p)` returns the coefficient ring of `p`.  
`polylib::coeffRing(p)` allows to query in a uniform way the coefficient ring of the polynomial `p` or the polynomial domain `P`.

`P` can be any polynomial domain (`Dom::UnivariatePolynomialx`, `Dom::DistributedPolynomial[x,y]`, ...).

`P` can also be of the form `polylib::Poly([x,y],K)`. If `K` is `Expr` or `IntMod(n)`, then the corresponding domains `Dom::ExpressionField()` or `Dom::IntegerMod(p)` is returned. See `poly` for the details about `Expr` and `IntMod(n)`.

`p` can be a kernel polynomial (`DOM_POLY`), or an element of one of the above domains

## Examples **Example 1**

We define a polynomial ring over the ring of integers modulo 4, and query for its coefficient ring:

```
P := Dom::UnivariatePolynomial(x, Dom::IntegerMod(4)):
polylib::coeffRing(P)
```

```
Dom::IntegerMod(4)
```

The coefficient ring of the elements of this domain can be queried the same way:

```
polylib::coeffRing(P(x))
```

```
Dom::IntegerMod(4)
```

```
polylib::coeffRing(Dom::Matrix(Dom::IntegerMod(3)))
```

```
Dom::IntegerMod(3)
```

### Example 2

When no coefficient ring is specified, `poly` currently constructs kernel polynomials over the fake domain `Expr` instead of the mathematically equivalent field `Dom::ExpressionField()` of arbitrary expression (this happens to be more efficient with the current kernels):

```
extop(poly(x))
```

```
x, [x], Expr
```

```
polylib::coeffRing(poly(x))
```

```
Dom::ExpressionField()
```

This makes it possible to plug the result right away as coefficient ring of some other domain:

```
Dom::UnivariatePolynomial(x, polylib::coeffRing(poly(x)))
```

```
Dom::UnivariatePolynomial(x, Dom::ExpressionField(), LexOrder)
```

### Parameters

**P**

A polynomial domain

# polylib::coeffRing

<b>MuPAD Functions</b>	<code>numlib::phi</code>

# polylib::decompose

---

**Purpose** Functional decomposition of a polynomial

**Syntax** `polylib::decompose(p)`  
`polylib::decompose(p, x)`

**Description** `polylib::decompose(p, x)` returns a sequence of polynomials  $q_1, \dots, q_n$  such that  $p(x) = q_1(\dots q_n(x)\dots)$ .

The second argument may be left out if the polynomial is univariate, as in “Example 1” on page 24-6.

If a polynomial has several decompositions, it is not specified which of them is returned.

## Examples **Example 1**

In the simplest case, an univariate polynomial is decomposed with respect to its only variable:

```
polylib::decompose(x^4+x^2+1)
```

```
 $x^2 + x + 1, x^2$
```

## **Example 2**

If there are several variables, a main variable must be specified:

```
polylib::decompose(y*x^4+y,y);
```

```
 $y x^4 + y$
```

## **Parameters** **p**

Polynomial or polynomial expression

**x**

One of the indeterminates of the polynomial  $p$

## Return Values

If a decomposition is possible, `polylib::decompose` returns it as an expression sequence, each element being of the same type as the input. If no decomposition is possible, the input is returned.

## Overloaded By

$p$

## References

A description of the algorithm behind `polylib::decompose` can be found in *Barton and Zippel*, Polynomial decomposition algorithms, Journal of Symbolic Computation, 1 (1985), pp. 159–168.

## MuPAD Functions

`factor`

# polylib::discrim

---

**Purpose** Discriminant of a polynomial

**Syntax** `polylib::discrim(p, x)`

**Description** `polylib::discrim(p, x)` returns the discriminant of the polynomial `p` with respect to the variable `x`.

The function `normal` is applied to the discriminant before returning it.

## Examples **Example 1**

We compute the discriminant of the general quadratic equation:

```
polylib::discrim(a*x^2 + b*x + c, x);
```

$$b^2 - 4ac$$

**Parameters** **x**  
Indeterminante

**p**  
Polynomial or polynomial expression

**Return Values** `polylib::discrim` returns an element of the coefficient ring of `p`. If the coefficient ring is `Expr` or `IntMod(n)`, an expression is returned.

**Overloaded By** `p`

**Algorithms**

The discriminant of  $p$  with respect to the variable  $x$  is defined as:

$$\frac{(-1)^{\frac{d(d-1)}{2}} \operatorname{res}_x(p, p')}{c},$$

where  $d$  is the degree and  $c$  is the leading coefficient of  $p$ .

Functions**

`polylib::resultant`

# polylib::divisors

---

**Purpose** Divisors of a polynomial, polynomial expression, or Factored element

**Syntax** `polylib::divisors(p)`  
`polylib::divisors(f)`  
`polylib::divisors(e)`

**Description** `polylib::divisors(p)` computes the set of all monic divisors of the polynomial or polynomial expression `p`.  
`polylib::divisors(f)` returns all monic divisors of a pre-factored polynomial. Cf. “Example 3” on page 24-10.  
`polylib::divisors` works on polynomials of category `Cat::Polynomial` as well. Cf. “Example 4” on page 24-11.

## Examples

### Example 1

If the argument is a polynomial, a set of polynomials is returned:

```
polylib::divisors(poly(x^2 - 2*x + 1))
```

```
{poly(1, [x]), poly(x - 1, [x]), poly(x^2 - 2 x + 1, [x])}
```

### Example 2

If the argument is a polynomial expression, a set of polynomial expressions is returned:

```
polylib::divisors(x^2 - 1)
```

```
{1, x^2 - 1, x - 1, x + 1}
```

### Example 3

If the argument is of type `Factored` (a `factor` return value) a set of polynomials is returned:

```
p := factor(poly(x^2 - 1));
polylib::divisors(p)
```

```
poly(x - 1, [x]) poly(x + 1, [x])
```

```
{poly(1, [x]), poly(x - 1, [x]), poly(x + 1, [x]), poly(x^2 - 1, [x])}
```

The polynomials in the resulting set have the same type as the polynomials in the Factored element:

```
p := factor(x^2 - 1);
polylib::divisors(p)
```

```
(x - 1)(x + 1)
```

```
{1, x^2 - 1, x - 1, x + 1}
```

#### Example 4

polylib::divisors works on polynomials from category Cat::Polynomial as well:

```
P := Dom::Polynomial(Dom::IntegerMod(7)):
polylib::divisors(P(x^3 + 2*x^2 + 1))
```

```
{1 mod 7, (1 mod 7) x^3 + (2 mod 7) x^2 + (1 mod 7)}
```

#### Parameters

**p**

A polynomial or polynomial expression

**f**

# polylib::divisors

---

Factored (return value of factor)

**e**

Element of a domain of category `Cat::Polynomial`

## Return Values

`polylib::divisors` returns a set of polynomials. The polynomials are from the same type as the polynomials in the argument.

## See Also

## MuPAD Categories

`Cat::Polynomial`

## MuPAD Functions

`factor` | `irreducible` | `numlib::divisors` | `polylib::sqrfree`

<b>Purpose</b>	Differential operator for polynomials
<b>Syntax</b>	<pre>polylib::Dpoly(f) polylib::Dpoly(indexlist, f)</pre>
<b>Description</b>	<p>If <math>f</math> is a polynomial in the indeterminates <math>x_1</math> through <math>x_n</math>, <code>polylib::Dpoly([i1, ..., ik], f)</code> computes the <math>k</math>-th partial derivative</p> $\frac{\partial}{\partial x_{i_1}} \frac{\partial}{\partial \dots} \frac{\partial}{\partial x_{i_k}} f.$ <p><code>polylib::Dpoly(f)</code> returns the derivative of <math>f</math> with respect to its only variable for an univariate polynomial <math>f</math>.</p> <p>If some element of <code>indexlist</code> is greater than the number of indeterminates of <math>f</math>, the zero polynomial is returned.</p> <p><code>polylib::Dpoly([], p)</code> returns <math>p</math>.</p> <p>If the coefficients of the polynomial are elements of a domain <math>d</math>, then this domain must have the method "intmult" (<code>d::intmult(e,i)</code>) that must calculate the integer multiple of a domain element <math>e</math> and a positive integer <math>i</math>.</p>

**Examples****Example 1**

We differentiate a univariate polynomial with respect to its only indeterminate. In this case, we may leave out the first argument.

```
polylib::Dpoly(poly(2*x^2 + x + 1));
```

```
poly(4 x + 1, [x])
```

**Example 2**

Now we differentiate a bivariate polynomial, and must specify the indeterminate in this case.

```
polylib::Dpoly([1], poly(x^2*y + 3*x + y, [x, y]));
```

# polylib::Dpoly

---

```
poly(2 x y + 3, [x, y])
```

## Example 3

It is also possible to compute second or higher partial derivatives.

```
polylib::Dpoly([1, 2], poly(x^2*y + 3*x + y, [x, y]));
```

```
poly(2 x, [x, y])
```

## Parameters

**f**

Polynomial

**indexlist**

List of positive integers

## Return Values

`polylib::Dpoly` returns a polynomial in the same indeterminates and over the same coefficient ring as the input.

## Overloaded By

f

## See Also

## MuPAD Functions

D | diff

**Purpose** Elementary symmetric polynomials

**Syntax** `polylib::elemSym(l, k)`

**Description** `polylib::elemSym([x1, ..., xn], k)` returns the k-th elementary symmetric polynomial in the given variables x1 through xn.

A given list `l` is a valid first argument only if its elements can be used as indeterminates of a polynomial .

## Examples

### Example 1

The first elementary symmetric polynomial is just the sum of its variables:

```
polylib::elemSym([x,y,z], 1);
```

```
poly(x + y + z, [x, y, z])
```

### Example 2

Indeterminates may also be e.g. trigonometric functions:

```
polylib::elemSym([sin(u),cos(u), exp(u)], 2);
```

```
poly(sin(u) cos(u) + sin(u) eu + cos(u) eu, [sin(u), cos(u), eu])
```

## Parameters

**l**

List of indeterminates

**k**

Positive integer

## Return Values

Result is a polynomial over the coefficient ring Expr. If k is greater than the number of operands of `l`, undefined is returned.

# polylib::elemSym

---

## MuPAD Functions

`polylib::representByElemSym`

<b>Purpose</b>	Convert expression into rational function over a suitable field
<b>Syntax</b>	<pre>polylib::makerat(a, &lt;maxd&gt;) polylib::makerat(l, &lt;maxd&gt;)</pre>
<b>Description</b>	<p><code>polylib::makerat(a)</code> returns two polynomials <math>f</math> and <math>g</math> over the rationals and a list of substitutions such that applying the substitutions to the rational function <math>\frac{f}{g}</math> gives <math>a</math>.</p> <p><code>polylib::makerat(l)</code> does the same for every element of the list <math>l</math> and returns lists of resulting <math>f</math>'s and <math>g</math>'s.</p> <p><code>polylib::makerat(a, maxd)</code> replaces <math>d</math>-th roots of integers by elements of some algebraic extension field over the rationals if <math>d \leq \text{maxd}</math>, and returns polynomials <math>f</math> and <math>g</math> over that extension field.</p> <p><code>polylib::makerat(a)</code> replaces all irrational subexpressions (except identifiers) in <math>a</math> by newly created identifiers, thereby producing a rational function over the rationals. It returns the numerator and denominator of that rational function as polynomials over Expr, and the substitutions to be made to get back the numerator and denominator of the original input <math>a</math>.</p> <p><code>polylib::makerat(l)</code> replaces all irrational subexpressions in all elements of <math>l</math> by newly created identifiers.</p> <p>Every subexpression is replaced by the same identifier every time it occurs.</p> <p>All indeterminates of the input and all of the new identifiers become indeterminates of the result, unless a second argument <code>maxd</code> is given.</p> <p>The imaginary unit <math>I</math> is handled in a special way: it is replaced by the element <code>`#I`</code> of the algebraic extension field with minimal polynomial <code>`\#I`^2 + 1</code>. If <math>I</math> occurs in the input, the result consists of polynomials over that extension field.</p> <p>If a second argument <code>maxd</code> is given, <math>d</math>-th roots of rationals are replaced by elements of a suitable field extension of the rationals if <math>d \leq \text{maxd}</math>. In the same way, nested fractional powers of rationals are replaced</p>

unless the denominator of some exponent exceeds `maxd`. In this case, the returned result consists of polynomials over a tower of extension fields over the rationals.

## Examples

### Example 1

In the simplest case (integer polynomial), the numerator equals the input, the denominator equals 1, and no substitutions are necessary:

```
polylib::makerat(x^2+3)
```

```
poly(x2 + 3, [x]), poly(1, [x]), []
```

### Example 2

Transcendental expressions are replaced by new identifiers. The result indicates on which variables the generated identifiers depend:

```
polylib::makerat(sin(u)/x)
```

```
poly(X5, [X5, x]), poly(x, [X5, x]), [X5 = sin(u)]
```

### Example 3

Floating point numbers are considered transcendental:

```
polylib::makerat(0.27*x)
```

```
poly(X9 x, [X9, x]), poly(1, [X9, x]), [X9 = 0.27]
```

### Example 4

By default, radicals are treated like transcendental subexpressions:

```
polylib::makerat(sqrt(2)/x)
```

```
poly(X12, [X12, x]), poly(x, [X12, x]), [X12 = $\sqrt{2}$]
```

### Example 5

If a sufficiently large second argument is given, radicals are replaced by elements of algebraic extensions:

```
polylib::makerat(sqrt(2)/x, 2)
```

```
poly(X16, [x], Dom::AlgebraicExtension(Dom::Rational, X162 - 2 = 0, X16)),
```

```
poly(x, [x], Dom::AlgebraicExtension(Dom::Rational, X162 - 2 = 0, X16)), [X16 = $\sqrt{2}$]
```

### Parameters

**a**

Polynomial over Expr or arithmetical expression

**l**

List or set of polynomials over Expr or arithmetical expressions

**maxd**

Positive integer

### Return Values

polylib::makerat returns an expression sequence consisting of three operands:

- The first operand represents the numerator (or the list/set of numerators, respectively). It is a single polynomial if the call was polylib::makerat(a), otherwise it is a set or list of polynomials (the same type as the input). The polynomial(s) may have more indeterminates than the input. The coefficient ring is either Expr or a Dom::AlgebraicExtension.

## polylib::makerat

---

- The second operand represents the denominator (or the list/set of denominators, respectively). It is of the same type as the first operand.
- The third operand is a list of equations.

### See Also

#### **MuPAD Functions**

rationalize

**Purpose** Approximate minimal polynomial

**Syntax** `polylib::minpoly(a, n, x)`

**Description** `polylib::minpoly(a, n, x)` computes a univariate polynomial  $f$  in the variable  $x$  of degree  $n$  with integer coefficients such that  $a$  equals a root of  $f$  up to the precision given by `DIGITS`, and such that the sum of squares of its coefficients is minimal among all polynomials with this property.

**Environment Interactions** `polylib::minpoly` is sensitive to the environment variable `DIGITS`.

## Examples **Example 1**

We compute a polynomial of degree 4 that has a root close to `PI` (up to 6 decimal digits) and small integer coefficients:

```
DIGITS:=6: polylib::minpoly(PI, 4, x); delete DIGITS:
```

```
poly(x4 - 5 x3 + 5 x2 + 9 x - 20, [x])
```

If the root has to be even closer to `PI`, bigger coefficients are needed:

```
DIGITS:=20: polylib::minpoly(PI, 4, x); delete DIGITS
```

```
poly(- 108 x4 - 1717 x3 + 6952 x2 - 258 x - 4045, [x])
```

## Parameters

**a**

Arithmetical expression that can be converted to a floating point number

**n**

# polylib::minpoly

---

Positive integer

**x**

Identifier

## Return Values

`polylib::minpoly` returns a polynomial in `x`. Its coefficient ring is `Expr`, all of its coefficients are integers.

## Algorithms

The problem reduces to finding a shortest integer vector in the lattice  $\{e_i + a^i e_{n+1} \mid 0 \leq i \leq n\}$ , where  $e_i$  denotes the vector with  $e_i[j] = \delta_{i,j}$  (Kronecker symbol). This problem is solved using the algorithm of Lenstra/Lenstra/Lovasz.

"one"	the constant polynomial one
"indets"	list of unknowns
"coeffRing"	the coefficient ring R

## See Also

## MuPAD Domains

`Dom::DistributedPolynomial`

## Purpose

Primitive element for tower of field extensions

## Syntax

```
polylib::primitiveElement(F, G)
```

## Description

For given field extensions  $F = K(a)$  and  $G = F(\beta)$ , `polylib::primitiveElement(F, G)` returns a list consisting of a simple algebraic extension of  $K$  that is  $K$ -isomorphic to  $G$ , a symbol for a primitive element of that extension, and the images of  $a$  and  $\beta$  under some fixed  $K$ -isomorphism.

It is presumed that the extension is separable. Otherwise, it may happen that the algorithm does not terminate.

## Examples

### Example 1

Since the rational numbers are perfect, extensions of them can always be handled:

```
F := Dom::AlgebraicExtension(Dom::Rational, sqrt2^2 - 2):
G := Dom::AlgebraicExtension(F, sqrt3^2 - 3):
```

Now  $G = Q(\sqrt{2}, \sqrt{3})$ , and we use `polylib::primitiveElement` to find a primitive element for  $G$ :

```
polylib::primitiveElement(F, G)
```

```
[Dom::AlgebraicExtension(Dom::Rational, -10 X1^2 + X1^4 + 1 = 0, X1), X1, $\frac{X1^3}{2} - \frac{9X1}{2}$, $\frac{11X1}{2}$]
```

This means that a primitive element  $X_1$  of the extension is determined by its minimal polynomial  $X_1^4 - 10X_1^2 + 1$ . The last two operands of the list are field elements whose squares are 2 and 3, respectively.

### Example 2

The function works also for subdomains of `Dom::AlgebraicExtension`, e.g., Galois fields.

# polylib::primitiveElement

---

```
F := Dom::GaloisField(7, 2):
G := Dom::GaloisField(F, 2):
polylib::primitiveElement(F, G)
```

```
[Dom::AlgebraicExtension(Dom::IntegerMod(7), 3 X5 - X52 + 2 X53 + X54 - 1 = 0, X5),
X5, - 3 X53 + 3 X52 - 3 X5 - 2, X5]
```

## Parameters

**F**

A field created by Dom::AlgebraicExtension

**G**

A field created by Dom::AlgebraicExtension with ground field F

## Return Values

List consisting of four operands:

- a field H of type Dom::AlgebraicExtension over the same ground field as F;
- an identifier that equals the entry H::variable;
- an object of type H that satisfies the minimal polynomial for  $\alpha$ ;
- an object of type H that satisfies the minimal polynomial for  $\beta$ .

## Algorithms

The chosen primitive element is  $\alpha + s\beta$ , where  $s$  is a positive integer.

## See Also

### MuPAD Domains

Dom::AlgebraicExtension

### MuPAD Functions

polylib::splitfield

**Purpose** Primitive part of a polynomial

**Syntax** `polylib::primpart(f)`  
`polylib::primpart(q)`  
`polylib::primpart({xpr}, <{inds}>)`

**Description** `polylib::primpart(f)` returns the primitive part of the polynomial `f`.  
If the input is a polynomial, the greatest common divisor of its coefficients is removed. The function `gcd` must be able to calculate this `gcd`.  
If the first argument is an expression, it is converted into a polynomial in the indeterminates specified by the second argument, or in all of its indeterminates if no second argument is given. `polylib::primpart` returns FAIL if the expression cannot be converted into a polynomial.  
For a rational number, its sign is returned.

## Examples **Example 1**

In the following example, a bivariate polynomial is given. Its coefficients are the integers 3, 6, and 9; the primitive part is obtained by dividing the polynomial by their `gcd`.

```
polylib::primpart(poly(6*x^3*y + 3*x*y + 9*y, [x, y]));
```

```
poly(2 x3 y + x y + 3 y, [x, y])
```

However, consider the same polynomial viewed as a univariate polynomial in `x`. Its coefficients are polynomials in `y` in this case, and their `gcd 3*y` is divided off.

```
polylib::primpart(poly(6*x^3*y + 3*x*y + 9*y, [x]));
```

```
poly(2 x3 + x + 3, [x])
```

# polylib::primpart

---

## Example 2

polylib::primpart divides the coefficients by their gcd, but does not normalize the result. This must be done explicitly:

```
polylib::primpart(4*x*y + 6*x^3 + 6*x*y^2 + 9*x^3*y, [x])
```

$$\frac{x^3 (9 y + 6)}{3 y + 2} + \frac{x (6 y^2 + 4 y)}{3 y + 2}$$

```
normal(polylib::primpart(4*x*y + 6*x^3 + 6*x*y^2 + 9*x^3*y, [x]))
```

$$3 x^3 + 2 y x$$

## Parameters

**f**

Polynomial

**q**

Rational number

**xpr**

Expression

**inds**

List of identifiers

## Return Values

polylib::primpart returns an object of the same type as the input, or FAIL.

## Overloaded By

f

## Algorithms

The primitive part of a polynomial  $f$  is a polynomial  $g$  whose coefficients are relatively prime such that  $f = rg$  for some element  $r$  of the coefficient ring.

## See Also

## MuPAD Functions

`content` | `factor` | `gcd` | `icontent` | `irreducible`

# polylib::randpoly

---

**Purpose** Create a random polynomial

**Syntax** `polylib::randpoly()`  
`polylib::randpoly(<list>, <ring>, <Degree = n>, <Terms = k>, <Coeffs = f>, <Monic>)`

**Description** `polylib::randpoly()` returns a univariate random polynomial with integer coefficients; the global identifier `x` is used as the indeterminate.

`polylib::randpoly(list)` returns a random polynomial in all indeterminates given in `list`.

`polylib::randpoly(list, ring)` returns a random polynomial in the indeterminates given in `list` over the coefficient ring `ring`.

See `poly` for a detailed description of possible indeterminates and coefficient rings.

The polynomial is created by randomly choosing as many exponents as specified through the option `Terms` and then choosing random coefficients. It may of course happen that for some coefficient 0 is chosen, therefore the actual number of terms in the result can be smaller than the value of the option `Terms`.

If the option `Coeffs=f` is given, the random coefficients are generated by calling `f()`. Otherwise, if `ring` is `Expr`, the coefficients will be random integers in the range - 999, ..., 999. If `ring` is a user-defined domain, it must have a method "random" to create the coefficients if no function is given.

If the option `Monic` is given, the resulting polynomial has exactly the specified degree and the leading coefficient is 1.

If the requested number of terms exceeds the maximal possible number of terms for the specified degree and number of variables, a warning is emitted and a dense polynomial is created.

**Environment Interactions** Unless a generator is specified through the option `Coeffs`, `polylib::randpoly` uses `random` to create the exponents and coefficients. Therefore it is sensitive to the environment variable `SEED`.

**Examples****Example 1**

We generate a univariate random polynomial in the indeterminate  $z$ , and use the default values for the other options. Therefore the polynomial has integer coefficients, is of degree 5, and has 6 terms.

```
polylib::randpoly([z])
```

$$\text{poly}(-535 z^5 + 916 z^4 + 663 z^3 - 764 z^2 - 741 z - 65, [z])$$
**Example 2**

We create a bivariate random polynomial over the finite field with 7 elements. This works because `Dom::IntegerMod` has a "random" slot that generates random elements:

```
polylib::randpoly([x,y], Dom::IntegerMod(7), Degree=3, Terms=4);
```

$$\text{poly}(2 x^3 y^3 + x^3 y + 4 x y, [x, y], \text{Dom}::\text{IntegerMod}(7))$$
**Parameters****list**

List of indeterminates

**ring**

Coefficient ring

**Options****Degree**

Option, specified as `Degree = k`

The maximum degree the result can have in each variable.  $k$  must be a nonnegative integer. Default is 6.

**Terms**

Option, specified as `Terms = t`

# polylib::randpoly

---

Makes `polylib::randpoly` generate the sum of `t` random terms. `t` must be a positive integer or `infinity`. If `t` equals `infinity`, `polylib::randpoly` returns a dense polynomial. Default is 5.

## **Coeffs**

Option, specified as `Coeffs = f`

Create the coefficients of the result by calling `f()`.

## **Monic**

The created polynomial is monic, i.e., the leading coefficient is 1.

## **Return Values**

Polynomial in the given indeterminates over the given ring. If no list of indeterminates is given, `[x]` is used. If no ring is given, `Expr` is used.

## **See Also**

## **MuPAD Functions**

`poly` | `random`

<b>Purpose</b>	Isolate all real roots of a real univariate polynomial
<b>Syntax</b>	<pre>polylib::realroots(p) polylib::realroots(p, eps)</pre>
<b>Description</b>	<p><code>polylib::realroots(p)</code> returns intervals isolating the real roots of the real univariate polynomial <code>p</code>.</p> <p><code>polylib::realroots(p, eps)</code> returns refined intervals approximating the real roots of <code>p</code> to the relative precision given by <code>eps</code>.</p> <p>All coefficients of <code>p</code> must be real and numerical, i.e., either integers, rationals or floating-point numbers. Numerical symbolic objects such as <code>sqrt(2)</code>, <code>exp(10*PI)</code> etc. are accepted, if they can be converted to real floating-point numbers via <code>float</code>. The same holds for the precision goal <code>eps</code>.</p> <p>The isolating intervals are ordered such that their centers are increasing, i.e., <math>a_i + b_i &lt; a_{i+1} + b_{i+1}</math>.</p> <p>The number <code>nops(realroots(p))</code> of intervals is the number of real roots of <code>p</code>. Multiple roots are counted only once. Cf. “Example 3” on page 24-36.</p> <p>Isolating intervals may be quite large. The optional argument <code>eps</code> may be used to refine the intervals such that they approximate the real roots to a relative precision <code>eps</code>. With this argument the returned intervals satisfy <math>b_i - a_i \leq \frac{\text{eps}  a_i + b_i }{2}</math>, i.e., each center <math>\frac{(a_i + b_i)}{2}</math> approximates a root with a relative precision <code>eps/2</code>.</p>

---

**Note** Some care should be taken when trying to obtain highly accurate approximations of the roots via small values of `eps`. Internally, bisectioning with exact rational arithmetic is used to locate the roots to the precision `eps`. This process may take much more time than determining the isolating intervals without using the second argument `eps` in `polylib::realroots`. It may be faster to use moderate values of `eps` to obtain first approximations of the roots via `polylib::realroots`. These approximations may then be improved by a fast numerical solver such as `numeric::fsolve` with an appropriately high value of `DIGITS`. Cf. “Example 6” on page 24-38. However, note that `polylib::realroots` will always succeed in locating the roots to the desired precision eventually. Numerical solvers may fail or return a root not belonging to the interval which was used for the initial approximation.

---

---

**Note** Unexpected results may be obtained when the polynomial contains irrational coefficients. Internally, any such coefficient  $c$  is converted to a floating-point number. This float is then replaced by an approximating rational number  $r$  satisfying  $|r - c| \leq \frac{1}{\text{DIGITS}} |c|$ . Finally, `polylib::realroots` returns rigorous bounds for the real roots of the rationalized polynomial. Despite the fact that all coefficients are approximated correctly to `DIGITS` decimal places this may change the roots drastically. In particular, multiple roots or clusters of poorly separated simple roots are very sensitive to small perturbations in the coefficients of the polynomial. See “Example 4” on page 24-36 and “Example 5” on page 24-37.

---

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, if there are non-integer or non-rational coefficients in the polynomial. Any such coefficient is replaced by a rational number approximating the coefficient to `DIGITS` significant decimal places.

**Examples****Example 1**

We use a polynomial expression as input to `polylib::realroots`:

```
p := (x - 1/3)*(x - 1)*(x - 4/3)*(x - 2)*(x - 17):
```

```
polylib::realroots(p)
```

```
[[0, 1], [1, 1], [1, 2], [2, 2], [16, 32]]
```

The roots 1 and 2 are found exactly: the corresponding intervals have length 0. The other isolating intervals are quite large. We refine the intervals such that they approximate the roots to 12 decimal places. Note that this is independent of the current value of `DIGITS`, because no floating-point arithmetic is used:

```
polylib::realroots(p, 10^(-12))
```

```
[[[1466015503701, 733007751851], [1, 1], [1466015503701, 733007751851], [2, 2],
```

```
[4398046511104, 2199023255552], [1099511627776, 549755813888], [17, 17]]
```

We convert these exact bounds for the real roots to floating point approximations. Note that with the default value of `DIGITS=10` we ignore 2 of the 12 correct digits the rational bounds could potentially give:

```
map(%, map, float)
```

```
[[0.3333333333, 0.3333333333], [1.0, 1.0], [1.3333333333, 1.3333333333], [2.0, 2.0], [17.0, 17.0]]
```

```
delete p:
```

## Example 2

Orthogonal polynomials of degree  $n$  have  $n$  simple real roots. We consider the Legendre polynomial of degree 5, available in the library `orthpoly` for orthogonal polynomials:

```
polylib::realroots(orthpoly::legendre(5, x), 10^(-DIGITS)):
map(%, float@op, 1)

[- 0.906179846, - 0.5384693101, 0.0, 0.5384693101, 0.9061798459]
```

## Example 3

We consider a polynomial with a multiple root:

```
p := poly((x - 1/3)^3*(x - 1), [x])

poly($x^4 - 2x^3 + \frac{4x^2}{3} - \frac{10x}{27} + \frac{1}{27}$, [x])
```

Note that only one isolating interval  $[0, 1]$  is returned for the triple root  $\frac{1}{3}$ :

```
polylib::realroots(p)

[[0, 1], [1, 1]]
```

```
delete p:
```

## Example 4

We consider a polynomial with non-rational roots:

```
p := (x - 3)^2*(x - PI)^2:
```

Converting the result of `polylib::realroots` to floating-point numbers one sees that the exact roots 3, 3, PI, PI are approximated only to 3 decimal places:

```
map(polylib::realroots(p, 10^(-10)), map, float)
```

```
[[2.998807805, 2.998807805], [3.001213582, 3.001213582], [3.140323518, 3.140323518],
 [3.142840401, 3.142840401]]
```

This is caused by the internal rationalization of the coefficients of `p`.

The intervals returned by `polylib::realroots(p, 10^(-10))` correctly locate the 4 exact roots of this rationalized polynomial to a precision of 10 digits. However, because all 4 roots are close, the small perturbations of the coefficients introduced by rationalization have a drastic effect on the location of the roots. In particular, rationalization splits the two original double roots into 4 simple roots.

```
delete p:
```

## Example 5

We consider a further example involving non-exact coefficients. First we approximate the roots of a polynomial with exact coefficients:

```
p1 := (x - 1/3)^3*(x - 4/3):
```

```
map(polylib::realroots(p1, 10^(-10)), map, float)
```

```
[[0.3333333333, 0.3333333333], [1.3333333333, 1.3333333333]]
```

Now we introduce roundoff errors by replacing one entry by a floating-point approximation:

```
p2 := (x - 1.0/3)^3*(x - 4/3):
```

```
map(polylib::realroots(p2, 10^(-10)), map, float)

[[0.3332481323, 0.3332481323], [1.3333333333, 1.3333333333]]
```

In this example rationalization caused the triple root  $1/3$  to split into one real root and two complex conjugate roots.

```
delete p1, p2:
```

## Example 6

We want to approximate roots to a precision of 1000 digits:

```
p := x^5 - 129/20*x^4 + 69/5*x^3 - 14*x^2 + 12*x - 8:
```

We recommend not to obtain the result directly by `polylib::realroots(p, 10^(-1000))`, because the internal bisectioning process for refining crude isolating intervals converges only linearly. Instead, we compute first approximations of the roots to a precision of 10 digits:

```
approx := map(polylib::realroots(p, 10^(-10)), float@op, 1)

[1.489177599, 1.752191733, 3.255184556]
```

These values are used as starting points for a numerical root finder. The internal Newton search in `numeric::fsolve` converges quadratically and yields the high precision results much faster than `polylib::realroots`:

```
DIGITS := 1000:
```

```
roots := map(approx, x0 -> numeric::fsolve([p = 0], [x = x0]))

[[x = 1.489177598846870281338916114673844643894...],
```

```
[x = 1.752191733304413195335101727880090131407...],
[x = 3.255184555797733438479691333705558491124...]]
```

delete approx, DIGITS, roots, x0:

## Parameters

**p**

A univariate polynomial: either an expression or a polyomial of domain type DOM\_POLY.

**eps**

A (small) positive real number determining the size of the returned intervals.

## Return Values

List of lists  $[[a_1, b_1], [a_2, b_2], \dots]$  with rational numbers  $a_i \leq b_i$  is returned. Lists with  $a_i = b_i$  represent exact rational roots. Lists with  $a_i < b_i$  represent open intervals containing exactly one real root. If the polynomial has no real roots, then the empty list  $[\ ]$  is returned.

numeric::realroots

# polylib::representByElemSym

---

**Purpose** Represent symmetric by elementary symmetric polynomials

**Syntax** `polylib::representByElemSym(f, l)`

**Description** `polylib::representByElemSym(f, [x1, ..., xn])` returns a polynomial  $g$  in the identifiers  $x_1$  through  $x_n$  such that replacing each  $x_i$  by the  $i$ -th elementary symmetric polynomial gives  $f$ .

The list  $l$  must have as many operands as  $f$  has indeterminates.

The result is FAIL if the input is not symmetric.

## Examples

### Example 1

The symmetric polynomial  $x^2 + y^2$  can be written as  $(x + y)^2 - 2(xy)$ :

```
polylib::representByElemSym(poly(x^2+y^2), [u,v]);
```

```
poly(u^2 - 2 v, [u, v])
```

### Example 2

`polylib::representByElemSym` works over domains also:

```
f:=poly(x^2+y^2, Dom::IntegerMod(7));
polylib::representByElemSym(f, [u,v])
```

```
poly(u^2 + 5 v, [u, v], Dom::IntegerMod(7))
```

**Parameters** **f**

Symmetric polynomial

**l**

List of indeterminates

**Return Values**

Result is a polynomial having the same coefficient ring as  $f$ .

**Algorithms**

It is a well-known theorem that every symmetric polynomial can be written in this way.

**See Also****MuPAD Functions**

`polylib::elemSym`

# polylib::resultant

---

## Purpose

Resultant of two polynomials

## Syntax

```
polylib::resultant(f, g, <x>)
polylib::resultant(fexpr, gexpr, <inds>, <x>)
```

## Description

`polylib::resultant(f, g)` returns the resultant of `f` and `g` with respect to their first variable.

`polylib::resultant(f, g, x)` returns the resultant of `f` and `g` with respect to the variable `x`.

`polylib::resultant(fexpr, gexpr, inds, x)` returns the resultant of `fexpr` and `gexpr` with respect to the variable `x`; `fexpr` and `gexpr` are viewed as polynomials in the indeterminates `inds`.

Both input polynomials must have exactly the same second and third operand, i.e. their variables and coefficient rings must be identical.

If the arguments are expressions then these are converted into polynomials using `poly`. `polylib::resultant` returns `FAIL` if the expressions cannot be converted.

If the argument `inds` is missing, the input expressions are converted into polynomials in all indeterminates occurring in at least one of them. They are *not* independently converted, hence the conversion cannot result in two polynomials with different variables causing an error. See “Example 1” on page 24-42.

If the coefficient ring is a domain, it must have a “`_divide`” method.

If the coefficient ring is `Expr`, `polylib::resultant` returns an expression if called with two univariate polynomials. See “Example 2” on page 24-43.

For polynomials over `IntMod(n)`, the computation may stop with an error if `n` is not prime.

## Examples

### Example 1

If the input consists of expressions, the sets of indeterminates occurring in the expressions need not coincide:

```
polylib::resultant(a*x + c, c*x + d, x);
```

$$ad - c^2$$

## Example 2

If the coefficient ring of two univariate input polynomials is Expr, the result is an expression:

```
polylib::resultant(poly(x^2 -1), poly(x + 1));
```

0

## Parameters

**f, g**

Polynomials

**fexpr, gexpr**

Expressions

**x**

Indeterminate

**inds**

List of indeterminates

## Return Values

If the input consists of polynomials in at least two variables, `polylib::resultant` returns a polynomial in one variable less than the input.

## Overloaded By

p, q

# polylib::resultant

---

## Algorithms

The resultant of two polynomials is defined to be the determinant of their Sylvester matrix. A call to `polylib::resultant` is more efficient than consecutive calls to `linalg::sylvester` and `linalg::det`.

## See Also

## MuPAD Functions

`polylib::discrim` | `linalg::det` | `linalg::sylvester`

## Purpose

Sorting monomials with respect to a term ordering

## Syntax

```
polylib::sortMonomials(f)
polylib::sortMonomials(f, vars)
polylib::sortMonomials(f, ord)
polylib::sortMonomials(f, vars, ord)
```

## Description

`polylib::sortMonomials(f, ord)` returns a list of all monomials constituting the polynomial `f`, sorted in descending order with respect to `ord`.

A monomial ordering may be: one of the identifiers `LexOrder`, `DegreeOrder`, `DegInvLexOrder`; or an object of type `Dom::MonomOrdering` or convertible to that type; or any object returning a number when called as `ord(m1,m2)` for two degree vectors `m1` and `m2`. A degree vector is a list of integers, as returned by `degreevec`.

If no order is given, the lexicographical order is used.

If no list of variables is given, all indeterminates of `f` are used.

Given two degree vectors, `m1` is considered to be greater than `m2` if and only if `ord(m1,m2)` is positive.

## Examples

### Example 1

The monomials of the polynomial below are compared using a monomial ordering from `Dom::MonomOrdering`.

```
polylib::sortMonomials(poly(x^2+x*y^3+2, [x,y]), DegRevLex(2))
```

```
[poly(x y^3, [x, y]), poly(x^2, [x, y]), poly(2, [x, y])]
```

## Parameters

**f**

Polynomial or polynomial expression

# polylib::sortMonomials

---

**vars**

Nonempty list of identifiers

**ord**

Monomial ordering

**Return Values**

List of polynomials or expressions of the same type as `f`.

**Overloaded By**

`f`

**See Also****MuPAD Domains**

`Dom::MonomOrdering`

**MuPAD Functions**

`lmonomial` | `nthmonomial`

**Purpose** Splitting field of a polynomial

**Syntax** `polylib::splitfield(p)`

**Description** Given a polynomial  $p$  over a field  $K$  in one indeterminate  $X$ , `polylib::splitfield(p)` returns a simple field extension  $F$  of  $K$  and some elements  $a_1, \dots, a_n$  of  $F$ , such that  $\prod_{i=1}^n (X - \alpha_i)$  is an associate of  $p$ , and such that  $F$  is the smallest extension of  $K$  containing all of the  $a_i$ .  
If the input is a polynomial expression, as in “Example 1” on page 24-47, it is treated as a polynomial over the rationals.

The polynomial  $p$  need not be irreducible.

The name for the primitive element of the field extension is generated using `genident` and is therefore different in every call of `polylib::splitfield`, even if the same polynomial is passed.

MuPAD must be able to factor polynomials over the coefficient field of  $p$ .

The coefficient field must be perfect. Otherwise, it may happen that `polylib::splitfield` does not terminate.

## Examples **Example 1**

We adjoin  $\sqrt{-1}$  to the rationals:

```
polylib::splitfield(x^2+1)
```

```
[Dom::AlgebraicExtension(Dom::Rational, X1^2 + 1 = 0, X1), [X1, 1, -X1, 1]]
```

## **Example 2**

A call to `polylib::splitfield` becomes more interesting for polynomials of degree at least 3:

```
polylib::splitfield(x^3-2)
```

# polylib::splitfield

```
[Dom::AlgebraicExtension(Dom::Rational, X3^6 + 108 = 0, X3), [X3/2 - X3^4/36, 1, X3^4/18, 1, -X3^4/36 - X3/2
```

## Example 3

In this example, we work over the field of univariate rational functions (the quotient field of the univariate polynomials) over the rationals:

```
R:=Dom::DistributedPolynomial([x], Dom::Rational):
F:=Dom::Fraction(R):
f:=poly(y^3-x,[y],F):
polylib::splitfield(f)
```

```
[Dom::AlgebraicExtension(Dom::Fraction(Dom::DistributedPolynomial([x], Dom::Rational, Let
+ 27 x^2 = 0, X5), [X5/2 - X5^4/18 x, 1, X5^4/9 x, 1, -X5/2 - X5^4/18 x, 1]]]
```

## Parameters

**p**

Univariate polynomial over a field or univariate polynomial expression

## Return Values

`polylib::splitfield` returns a list of two operands: the first one is the splitting field of the polynomial, i.e. a `Dom::AlgebraicExtension` of the coefficient ring; the second one is a list of all roots of the polynomial in the splitting field, each root followed by its multiplicity.

## See Also

## MuPAD Functions

`factor` | `evalp`

**Purpose** Square-free factorization of polynomials

**Syntax** `polylib::sqrfree(f, <recollect>)`

**Description** `polylib::sqrfree(f)` returns the square-free factorization of  $f$ , that is, a factorization of  $f$  in the form  $f = up_1^{e_1} \dots p_r^{e_r}$  with primitive and pairwise different square-free divisors  $p_i$ .

`polylib::sqrfree(f)` returns the square-free factorization of the polynomial  $f$ , that is, a factorization of  $f$  in the form  $f = uf_1^{e_1} \dots f_r^{e_r}$  with primitive and pairwise different square-free divisors  $f_i$  (i.e.,  $\gcd(f_i, f_j) = 1$  for  $i \neq j$ ).

$u$  is a unit of the coefficient ring of  $f$ , and  $e_i$  are positive integers.

The result of `polylib::sqrfree` is an object of the domain type `Factored`. Let `g := polylib::sqrfree(f)` be such an object. It is represented internally as the list `[u, f1, e1, ..., fr, er]` of odd length  $2r + 1$ .

You may extract the unit  $u$  and the terms  $f_i^{e_i}$  by the ordinary index operator `[ ]`, i.e., `g[1] = u`, `g[2] = f1^e1`, `g[2] = f2^e2`, ....

The calls `Factored::factors(g)` and `Factored::exponents(g)` return a list of the factors  $f_i$  and the exponents  $e_i$  ( $1 \leq i \leq r$ ), respectively. The call `convert(g, DOM_LIST)` gives the internal representation of a factored object, i.e., the list `[u, f1, e1, ..., fr, er]`.

Note that the result of `polylib::sqrfree` is printed as an expression and behaves like that. As an example, the result of `polylib::sqrfree(x^2+2*x+1)` is the object printed as  $(x+1)^2$  which is of type `"_power"`.

Please read the help page of `Factored` for details.

The call `polylib::sqrfree(f, FALSE)` returns a square-free factorization of  $f$ , where the exponents  $e_i$  need not be pairwise different.

`polylib::sqrfree` can handle univariate and multivariate polynomials over `Expr`, residue class rings `IntMod(p)` with prime modulus  $p$ ,

# polylib::sqrfree

---

domains representing a unique factorization domain of characteristic zero, and finite fields.

If the argument of `polylib::sqrfree` is an expression, its numerator and denominator are converted into polynomials in all occurring indeterminates.

These polynomials are regarded as polynomials over some extension of the rational numbers (i.e., over `Expr`, see `poly`). The choice of that extension follows the same rules as in the case of the function `factor`.

Factors of the denominator of an expression are indicated by negative multiplicities.

## Examples

### Example 1

The factors in a squarefree factorization are pairwise relatively prime, but they need not be irreducible:

```
polylib::sqrfree(
 2 - 2*x - 6*x^4 + 6*x^5 + 6*x^8 - 6*x^9 -2*x^12 + 2*x^13
)
```

$$2 (x^3 + x^2 + x + 1)^3 (x - 1)^4$$

### Example 2

Even if a factorization into irreducibles has been found, irreducible factors with the same multiplicity are collected again:

```
polylib::sqrfree(x^6 + x^4*y*6 + x^2*y^2*9)
```

$$(x (x^2 + 3 y))^2$$

You can avoid this by giving a second argument:

```
polylib::sqrfree(x^6 + x^4*y*6 + x^2*y^2*9, FALSE)
```

$$x^2 (x^2 + 3 y)^2$$

### Example 3

polylib::sqrfree works also for polynomials:

```
polylib::sqrfree(poly(2 + 5*x + 4*x^2 + x^3))
```

$$\text{poly}(x + 2, [x]) \text{poly}(x + 1, [x])^2$$

### Parameters

**f**

A polynomial or an arithmetical expression

**recollect**

TRUE or FALSE

### Return Values

Factored object, i.e., an object of the domain type Factored.

### See Also

### MuPAD Functions

content | factor | Factored | irreducible |  
polylib::primpart

# polylib::subresultant

---

**Purpose** Subresultants of two polynomials

**Syntax** `polylib::subresultant(f, g, <x>, <i>)`  
`polylib::subresultant(fexpr, gexpr, <x>, <i>)`

**Description** `polylib::subresultant(f, g)` returns the table of subresultants of polynomials `f` and `g` with respect to their first variable.

`polylib::subresultant(f, g, i)` returns the `i`th subresultant of polynomials `f` and `g` with respect to their first variable.

`polylib::subresultant(f, g, x)` returns the table of subresultants of polynomials `f` and `g` with respect to the variable `x`.

`polylib::subresultant(f, g, x, i)` returns the `i`th subresultant of polynomials `f` and `g` with respect to the variable `x`.

`polylib::subresultant(fexpr, gexpr, x)` returns the table of subresultants of polynomial expressions `fexpr` and `gexpr` with respect to the variable `x`.

`polylib::subresultant(fexpr, gexpr, x, i)` returns the `i`th subresultant of polynomial expressions `fexpr` and `gexpr` with respect to the variable `x`.

`polylib::subresultant` returns a particular subresultant or a table of all subresultants.

The variables and coefficient rings of both input polynomials must be identical.

The 0th subresultant is the resultant of two polynomials. See “Example 1” on page 24-53

If you do not specify the variable when computing the subresultants of two polynomials, `polylib::subresultant` returns subresultants of the polynomials with respect to their first variable. See “Example 2” on page 24-54.

If you call `polylib::subresultant` for polynomial expressions, you must specify the variable with respect to which you want to compute subresultants. MuPAD uses the `poly` function to convert polynomial

expressions to polynomials with the specified variable. The system also converts computed subresultants back to polynomial expressions.

If `poly` cannot convert expressions to polynomials, `polylib::subresultant` returns FAIL.

If the degree of the polynomial `f` is less than the degree of the polynomial `g`, the `polylib::subresultant` function interchanges `f` and `g`.

If the coefficient ring is a domain, it must have a `_divide` method.

## Examples

### Example 1

If you do not specify which subresultant to return, `polylib::subresultant` returns the table of all subresultants:

```
f := poly(3*x^4 + 3*x^3 + 4):
g := poly(x^4 + x^3 + x^2 + x + 1):
polylib::subresultant(f, g)
```

```
0 | poly(205, [x])
1 | poly(9 x - 39, [x])
2 | poly(9 x + 9 x^2 - 3, [x])
3 | poly(3 x + 3 x^2 - 1, [x])
4 | poly(3 x^3 + 3 x^4 + 4, [x])
```

You can specify the number of the subresultant that you want to compute. For example, compute the 0th subresultant of the polynomials `f` and `g`:

```
polylib::subresultant(f, g, 0)
```

# polylib::subresultant

---

```
poly(205, [x])
```

The 0th subresultant is also the resultant of the polynomials:

```
polylib::resultant(f, g)
```

```
205
```

## Example 2

`polylib::subresultant` handles multivariate polynomials and polynomial expressions. When you compute subresultants of multivariate polynomials or polynomial expressions, you can specify the variable with respect to which you want to compute subresultants:

```
f := poly(3*x^4*y + 4*z^2):
g := poly(x^4 + x^3*y^3*z^3):
polylib::subresultant(f, g, z)
```

```
0 | poly(27 x18 y9 + 64 x8, [x, y])
1 | poly(16 x4 - 12 x7 y4 z, [x, y])
2 | poly(3 x4 y + 4 z2, [x, y])
3 | poly(x4 + x3 y3 z3, [x, y])
```

For multivariate polynomials, specifying the variable is not necessary. If you do not specify the variable when computing the subresultants of two polynomials, `polylib::subresultant` returns subresultants of the polynomials with respect to their first variable:

```
f := poly(3*x^4*y + 4*z^2):
```

```
g := poly(x^4 + x^3*y^3*z^3):
polylib::subresultant(f, g)
```

```
0 poly(192 y13 z18 + 256 z8, [y, z])
1 poly(48 y7 z10 + 48 x y4 z7, [y, z])
2 poly(12 y7 z8 + 12 x y4 z5, [y, z])
3 poly(-4 z2 + 3 x3 y4 z3, [y, z])
4 poly(3 x4 y + 4 z2, [y, z])
```

If you call `polylib::subresultant` for polynomial expressions, you must specify the variable with respect to which you want to compute subresultants:

```
f := 3*x^4*y + 4*z^2:
g := x^4 + x^3*y^3*z^3:
polylib::subresultant(f, g)
```

```
Error: A variable is missing. [polylib::subresultant]
```

```
polylib::subresultant(f, g, x)
```

# polylib::subresultant

---

$$\begin{array}{l|l} 0 & 192 y^{13} z^{18} + 256 z^8 \\ 1 & 48 y^7 z^{10} + 48 x y^4 z^7 \\ 2 & 12 y^7 z^8 + 12 x y^4 z^5 \\ 3 & -4 z^2 + 3 x^3 y^4 z^3 \\ 4 & 3 x^4 y + 4 z^2 \end{array}$$

## Parameters

**f, g**

Polynomials over Expr (the ring of arbitrary MuPAD expressions)

**fexpr, gexpr**

Polynomial expressions

**x**

An indeterminate

**i**

A nonnegative integer

## Return Values

Subresultant of two polynomials (or polynomial expressions) or a table of subresultants.

## Overloaded By

p, q

## See Also

## MuPAD Functions

polylib::resultant | polylib::discrim | linalg::det | linalg::syvester

**Purpose** Support of a polynomial

**Syntax** `polylib::support(p)`

**Description** `polylib::support(p)` returns the support of `p`, that is, the list of indices with non zero coefficient in `p`.

**Examples** **Example 1**

The support of a multivariate polynomial is the list of the degree vectors of its terms:

```
polylib::support(poly(x*y*z + x + 1, [x, y, z]))
```

```
[[1, 1, 1], [1, 0, 0], [0, 0, 0]]
```

For a univariate polynomial, the support is the list of the degrees of its terms. In the following polynomial `x` appears with degrees 3, 1, and 0:

```
polylib::support(Dom::UnivariatePolynomial(x)(x^3*y*z + x + 1))
```

```
[3, 1, 0]
```

**Parameters** **p**  
A polynomial.

**Return Values** List of elements of the support.

# Pref::abbreviateOutput

---

**Purpose** Controls the use of abbreviations in outputs

**Syntax** Pref::abbreviateOutput(TRUE)  
Pref::abbreviateOutput(FALSE)  
Pref::abbreviateOutput(NIL)  
Pref::abbreviateOutput()

**Description** When displaying results, MuPAD by default finds common subexpressions and replaces them with abbreviations. See “Example 1” on page 25-2.

If you want to see the results without abbreviations, use the Pref::abbreviateOutput(FALSE) command. See “Example 2” on page 25-3.

The Pref::abbreviateOutput() command shows whether abbreviations are enabled or disabled. See “Example 3” on page 25-4.

To restore the default setting, use the Pref::abbreviateOutput(NIL) command. See “Example 4” on page 25-5.

The output of the Pref::abbreviateOutput command itself displays the previous setting. You can save this previous setting and switch to a new setting in a single call of Pref::abbreviateOutput. See “Example 5” on page 25-5.

## Examples **Example 1**

By default, you can see the abbreviations in long outputs:

```
solve(a*x^3 + b*x + c, x, MaxDegree = 3, IgnoreSpecialCases)
```

$$\left\{ \begin{aligned}
 & \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3} - \frac{b}{3a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}}, \frac{b}{6a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}} \\
 & - \frac{\left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}}{2} - \frac{\sqrt{3} \left( \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3} + \frac{b}{3a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}} \right) i}{2}, \\
 & \frac{b}{6a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}} - \frac{\left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}}{2} \\
 & + \left. \frac{\sqrt{3} \left( \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3} + \frac{b}{3a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}} \right) i}{2} \right\}
 \end{aligned} \right.$$

### Example 2

Setting `Pref::abbreviateOutput(FALSE)`, you can disable the abbreviations in outputs:

```
Pref::abbreviateOutput(FALSE):
solve(a*x^3 + b*x + c, x, MaxDegree = 3, IgnoreSpecialCases)
```

## Pref::abbreviateOutput

$$\left\{ \begin{array}{l} \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3} - \frac{b}{3a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}}, \frac{b}{6a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}} \\ - \frac{\left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}}{2} - \frac{\sqrt{3} \left( \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3} + \frac{b}{3a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}} \right) i}{2}, \\ \frac{b}{6a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}} - \frac{\left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}}{2} \\ + \frac{\sqrt{3} \left( \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3} + \frac{b}{3a \left( \sqrt{\frac{b^3}{27a^3} + \frac{c^2}{4a^2} - \frac{c}{2a}} \right)^{1/3}} \right) i}{2} \end{array} \right\}$$

### Example 3

You can check the current setting:

```
Pref::abbreviateOutput()
```

```
FALSE
```

## Example 4

You can restore the default setting:

```
Pref::abbreviateOutput(NIL):
Pref::abbreviateOutput()
```

TRUE

## Example 5

You can save the current setting and switch it to a new one in one function call:

```
old := Pref::abbreviateOutput(FALSE):
solve(x^3 + x + 1 = 0, x, MaxDegree = 3)
```

$$\left\{ \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3} - \frac{1}{3 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}}, \frac{1}{6 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}} - \frac{\left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}}{2} \right.$$

$$- \frac{\sqrt{3} \left( \frac{1}{3 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}} + \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3} \right) i}{2}, \frac{1}{6 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}} - \frac{\left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}}{2}$$

$$\left. + \frac{\sqrt{3} \left( \frac{1}{3 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}} + \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3} \right) i}{2} \right\}$$

You can restore the saved setting:

# Pref::abbreviateOutput

```
Pref::abbreviateOutput(old):
solve(x^3 + x + 1 = 0, x, MaxDegree = 3)
```

$$\left\{ \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3} - \frac{1}{3 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}}, \frac{1}{6 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}} - \frac{\left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}}{2} \right. \\ \left. - \frac{\sqrt{3} \left( \frac{1}{3 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}} + \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3} \right) i}{2}, \frac{1}{6 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}} - \frac{\left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}}{2} \right. \\ \left. + \frac{\sqrt{3} \left( \frac{1}{3 \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3}} + \left( \frac{\sqrt{31}\sqrt{108}}{108} - \frac{1}{2} \right)^{1/3} \right) i}{2} \right\}$$

## Return Values

Previously set value TRUE or FALSE

## MuPAD Functions

`output::subexpr` | `output::asciiAbbreviate`

## Related Examples

- “Abbreviations”

<b>Purpose</b>	Controls the output of aliased expressions
<b>Syntax</b>	<pre>Pref::alias(TRUE) Pref::alias(FALSE) Pref::alias(NIL) Pref::alias()</pre>
<b>Description</b>	<p>An alias is an abbreviation for a MuPAD expression. If <code>Pref::alias</code> is enabled, the alias abbreviations will be used for output.</p> <p><code>Pref::alias()</code> returns the current value.</p> <p><code>Pref::alias(TRUE)</code> switches the usage of alias abbreviations in outputs on. This is the default setting.</p> <p><code>Pref::alias(FALSE)</code> switches the usage of aliases in outputs off.</p> <p><code>Pref::alias(NIL)</code> restores the default value which is <code>TRUE</code>.</p> <p><code>Pref::alias</code> has no effect on <code>print</code> and <code>fprint</code>.</p>
<b>Environment Interactions</b>	<code>Pref::alias</code> changes the output of aliased expressions.
<b>Examples</b>	<p><b>Example 1</b></p> <p>If an aliased expression occurs in output, it is replaced by the alias abbreviation:</p> <pre>alias(X = a + b): X, a + b</pre> <p><i>X, X</i></p> <p>This only works if the syntactical structure of expression matches the aliased expression:</p> <pre>2*X</pre>

# Pref::alias

---

$2a + 2b$

prog::exptree shows that  $2*X$  does not contain  $a + b$  any more:

prog::exptree(X): prog::exptree(2\*X):

```
_plus
|
+-- a
|
`-- b
```

```
_plus
|
+-- _mult
| |
| +-- a
| |
| `-- 2
|
`-- _mult
 |
 +-- b
 |
 `-- 2
```

The same holds for  $X+c$ :

$X + c$ ; prog::exptree(X + c):

```
a + b + c
```

```
_plus
|
+-- a
|
+-- b
|
-- c
```

With `Pref::alias(FALSE)` the back translation of aliases in the output is disabled:

```
Pref::alias(FALSE):
X
```

```
a + b
```

`Pref::alias` has no effect on `print` and `fprint` outputs:

```
Pref::alias(TRUE):
print(X):
```

```
a + b
```

## Return Values

Previously set value

# Pref::alias

---

## See Also

## MuPAD Functions

`alias` | `expr2text` | `fprint` | `print`

## Purpose

Set a limit for automatic expansions

## Syntax

```
Pref::autoExpansionLimit(n)
Pref::autoExpansionLimit(NIL)
Pref::autoExpansionLimit()
```

## Description

`Pref::autoExpansionLimit(n)` sets a limit for the size of the arguments up to which the functions `bernoulli`, `Ei`, `euler`, `fact`, `fact2`, `gamma`, `harmonic`, `igamma`, `psi`, and `zeta` produce explicit results. Cf. “Example 1” on page 25-11.

It also sets a limit for the exponent up to which real and imaginary parts of powers are computed explicitly. Cf. “Example 2” on page 25-12.

Use `expand` for larger arguments if explicit results are desired. Cf. “Example 1” on page 25-11.

The call `Pref::autoExpansionLimit()` returns the current value of the limit without changing it.

The call `Pref::autoExpansionLimit(NIL)` resets the limit to its default value 1000.

## Examples

### Example 1

The functions `bernoulli`, `euler`, `gamma`, `zeta` etc. automatically produce explicit results if the arguments are not too large:

```
bernoulli(22), euler(24), gamma(26), zeta(28)
```

```
 $\frac{854513}{138}$, 15514534163557086905, 15511210043330985984000000, $\frac{678556029}{564653660170076}$
```

These functions return symbolic answers when the argument is larger than the limit set by `Pref::autoExpansionLimit`:

```
Pref::autoExpansionLimit()
```

# Pref::autoExpansionLimit

---

1000

bernoulli(1002), euler(2002), gamma(3001), zeta(4001)

bernoulli(1002), euler(2002),  $\Gamma(3001)$ ,  $\zeta(4001)$

We reduce this limit:

Pref::autoExpansionLimit(20):

bernoulli(22), euler(24), gamma(26), zeta(28)

bernoulli(22), euler(24),  $\Gamma(26)$ ,  $\zeta(28)$

We can use expand to obtain explicit results:

expand(bernoulli(22)), expand(euler(24)), expand(gamma(26)), expand

$\frac{854513}{138}$ , 15514534163557086905, 15511210043330985984000000,  $\frac{6785560294 \pi^2}{56465366017007627}$

We restore the default value:

Pref::autoExpansionLimit(NIL):

## Example 2

If binomial expansion is needed, the closed formula for the real part of an expression can become quite large:

Re((a+sqrt(2)\*I)^6) assuming a in R\_

$$\begin{aligned} & \sqrt{2} (\sqrt{2} (\sqrt{2} (2 \sqrt{2} a^2 + \sqrt{2} (a^2 - 2)) + a (4 a - a (a^2 - 2)))) - a (a (2 \sqrt{2} a^2 + \sqrt{2} (a^2 - 2)) - \sqrt{2} \\ & - a (\sqrt{2} (a (2 \sqrt{2} a^2 + \sqrt{2} (a^2 - 2)) - \sqrt{2} (4 a - a (a^2 - 2)))) \\ & + a (\sqrt{2} (2 \sqrt{2} a^2 + \sqrt{2} (a^2 - 2)) + a (4 a - a (a^2 - 2)))) \end{aligned}$$

Thus, for exponents beyond `Pref::autoExpansionLimit()`, no expansion is carried out:

```
Re((a+sqrt(2)*I)^123456) assuming a in R_
```

$$\Re((a + \sqrt{2} i)^{123456})$$

## Parameters

**n**

The limit: a positive numerical real value

## Return Values

Previously defined limit.

# Pref::autoPlot

---

**Purpose** Automatically plot graphical objects

**Syntax** Pref::autoPlot(TRUE)  
Pref::autoPlot(FALSE)  
Pref::autoPlot(NIL)  
Pref::autoPlot()

**Description** Pref::autoPlot(TRUE) makes graphical objects be plotted instead of typeset.

By default, graphical objects such as `plot::Function3d` are output just like any other MuPAD object, i.e., as a rendered representation of the input. After setting `Pref::autoPlot(TRUE)`, graphical objects and sequences of such objects are automatically rendered instead, as if the user had written `plot(...)`.

This setting only works when typesetting is enabled.

**Return Values** Previously set value

**See Also**

**MuPAD Functions** `plot`

**Purpose** Informations during evaluation

**Syntax** Pref::callBack(<func>)

**Description** The function func defined by Pref::callBack(func) will be called permanently, when the MuPAD kernel works. Therewith informations can be displayed to inform the user.

A call of Pref::callBack without arguments returns the current value. The argument NIL resets the default value, which is NIL.

## Examples **Example 1**

The following combination of Pref::postInput (initialization) and time count with Pref::callBack shows the seconds during evaluating.

```
Pref::postInput(proc() begin START:= time(); TIME:= START end_proc)
Pref::callBack(proc()
 begin
 if time() - TIME > 1000 then // 1 sec
 TIME:= TIME+1000;
 print(floor((time() - START)/1000))
 end_if
 end_proc):
NOW:= time():
while time() - NOW <= 10000 do 1 end_while:
```

# Pref::dbgAutoDisplay

---

**Purpose** Enables the autodisplay mode of the debugger

**Syntax** Pref::dbgAutoDisplay(TRUE)  
Pref::dbgAutoDisplay(FALSE)  
Pref::dbgAutoDisplay(NIL)  
Pref::dbgAutoDisplay()

**Description** Pref::dbgAutoDisplay(TRUE) switches on the autodisplay mode of the debugger.

Pref::dbgAutoDisplay() returns the current value.

Pref::dbgAutoDisplay(NIL) or Pref::dbgAutoDisplay(TRUE) switch on the autodisplay mode. After every halt of the terminal debugger or up/down movements in the stack the expressions `args()`, `last(1) (%)` and the formal parameters and local variables of the currently visible procedure are added to the list of display variables.

Pref::dbgAutoDisplay(FALSE) switches the autodisplay mode off.

In the MuPAD debugger the automatically inserted expressions and variables are visible in the Watch window.

**Environment Interactions** Changes the behaviour of the debugger.

**Examples** **Example 1**

If the autodisplay feature is disabled, the terminal debugger only prints short messages:

```
>> Pref::dbgAutoDisplay(FALSE):
>> debug(int(f(x), x))
#0 in int($1=x, $2=x) at lib/STDLIB/int.mu:26
29 in lib/STDLIB/int.mu
mdx>
```

If the autodisplay feature is activated, we see the values of `args()`, `%`, the formal parameters `f` and `x` and the value of the local variable `integral`:

```
>> Pref::dbgAutoDisplay(TRUE):
>> debug(int(f(x), x))
#1 in int($1=f(x), $2=x)
29 in lib/STDLIB/int.mu
args() = f(x), x
% =
f = f(x)
x = x
integral = NIL
mdx>
```

## Return Values

Previously set value

## See Also

## MuPAD Functions

`debug` | `Pref::dbgAutoList`

# Pref::dbgAutoList

---

**Purpose** Enables the autolist mode of the terminal debugger

**Syntax** Pref::dbgAutoList(TRUE)  
Pref::dbgAutoList(FALSE)  
Pref::dbgAutoList(NIL)  
Pref::dbgAutoList()

**Description** Pref::dbgAutoList() returns the current value.  
Pref::dbgAutoList(TRUE) switches on the autolist mode. After every halt of the terminal debugger or up/down movements in the stack a short listing will be printed.  
Pref::dbgAutoList(NIL) or Pref::dbgAutoList(FALSE) will reset the default value, which is FALSE.  
In the terminal debugger the autolist mode can be toggled with the debugger command 't'.

**Environment Interactions** Changes the behaviour of the terminal debugger.

## **Examples** **Example 1**

If the autolist feature is disabled, the terminal debugger only prints short messages:

```
>> debug(int(x, x))
#0 in int($1=x, $2=x) at lib/STDLIB/int.mu:26
26 in lib/STDLIB/int.mu
mdx>
```

If the autolist feature is activated, a short excerpt of the debugged function is printed whenever the debugger halts:

```
>> Pref::dbgAutoList(TRUE):
#0 in int($1=x, $2=x) at lib/STDLIB/int.mu:26
```

```
26 in lib/STDLIB/int.mu

21 ++*/
22
23 int:= funcenv(
24 proc(f, x=null())
25 begin
26 -> if args(0)=0 then error("No argument given") end;
27
28 if testargs() and has([args()],FAIL) then
29 error("illegal argument(s)")
30 end_if;
31

mdx>
>> Pref::dbgAutoList(FALSE):
```

## Return Values

debug | Pref::dbgAutoDisplay

# Pref::floatFormat

---

**Purpose** Representation of floating-point numbers

**Syntax** Pref::floatFormat(mode)  
Pref::floatFormat(NIL)  
Pref::floatFormat()

**Description** Pref::floatFormat controls the output format of floating-point numbers.

The representation mode can be one of the characters "e", "f", "g", "h", or "x". These are the standard C-command printf switches. Their meaning is:

- "e":  
exponential representation (floating-point representation, "scientific format").
- "f":  
decimal representation without exponents.
- "g":  
a mix between "e" and "f". Numbers  $x$  satisfying  $\frac{1}{10^{\text{DIGITS}}} \leq |x| \leq 10^{\text{DIGITS}}$  are displayed without exponents. All other numbers are displayed in floating-point representation.
- "h" or "x":  
hexadecimal representation, except for `expr2text` and typesetting, which fall back to "g".

The default value is "g".

Pref::floatFormat() returns the current mode without changing it. The call Pref::floatFormat(NIL) resets to the default value "g".

## Examples

### Example 1

The exponential representation of a floating-point number consists of its sign, its mantissa and its exponent:

```
Pref::floatFormat("e"):
12345.67890, -0.00012345
```

```
12345.6789, - 0.00012345
```

Without exponents, the size of a number is indicated by trailing or leading zeroes:

```
Pref::floatFormat("f"):
7.0*10^21, 7.0/10^21
```

```
7.0 1021, 7.0 10-21
```

The mixed representation:

```
Pref::floatFormat("g"):
1e-10, 9.99e-11
```

```
0.0000000001, 9.99 10-11
```

```
2.0^36, 2.0^37
```

```
68719476744.0, 1.374389535 1011
```

Hexadecimal display is ignored in typeset output and `expr2text`:

```
Pref::floatFormat("h"):
```

# Pref::floatFormat

---

```
12345.67890, 0.00012345;
expr2text(12345.67890, 0.00012345)
```

```
12345.6789, 0.00012345
```

```
"12345.6789, 0.00012345"
```

Hexadecimal display is used in the ASCII print output:

```
print(Plain, 12345.67890, 0.00012345)
```

```
3.039adcc63f141208@3, 8.1725b672ee34260@-4
```

The representation is reset to the default mode:

```
Pref::floatFormat(NIL):
```

## Parameters

### **mode**

One of the character strings "e", "f", "g", "h", or "x"

## Return Values

Previously defined representation mode

## See Also

## MuPAD Functions

DIGITS | Pref::trailingZeroes | Pref::outputDigits | print

**Purpose** Specify parameters for Fourier and inverse Fourier transforms

**Syntax** Pref::fourierParameters(c, s)  
Pref::fourierParameters([c, s])  
Pref::fourierParameters(NIL)  
Pref::fourierParameters()

**Description** Pref::fourierParameters(c, s), or the equivalent call Pref::fourierParameters([c, s]), specifies parameters used by the fourier and ifourier functions when computing Fourier and inverse Fourier transforms. See “Example 1” on page 25-26.

The Fourier transform of the expression  $f = f(t)$  with respect to the variable  $t$  at the point  $w$  is defined as follows:

$$F(w) = c \int_{-\infty}^{\infty} f(t) e^{i s w t} dt$$

The inverse Fourier transform of the expression  $F = F(w)$  with respect to the variable  $w$  at the point  $t$  is defined as follows:

$$f(t) = \frac{|s|}{2 \pi c} \int_{-\infty}^{\infty} F(w) e^{-i s w t} dw$$

$c$  and  $s$  are the parameters of the Fourier transform controlled by Pref::fourierParameters.

By default,  $c = 1$  and  $s = -1$ . Other common choices for the parameter

$c$  are  $\frac{1}{2\pi}$  or  $\frac{1}{\sqrt{2\pi}}$ . Other common choices for the parameter  $s$  are 1,  $-2\pi$ , or  $\sqrt{2\pi}$ .

# Pref::fourierParameters

---

`Pref::fourierParameters()` returns the current values of the Fourier parameters without changing them.

`Pref::fourierParameters(NIL)` restores the default settings  $c = 1$ ,  $s = -1$ .

`Pref::fourierParameters` also controls the parameters used by the `fourier::addpattern` and `ifourier::addpattern` functions. See “Example 2” on page 25-27.

## Environment Interactions

Changing Fourier parameters using `Pref::fourierParameters` can affect results returned by `fourier` and `ifourier` in the current MuPAD session.

## Examples

### Example 1

Compute the Fourier transform of this expression using the default values  $c = 1$ ,  $s = -1$  of the Fourier parameters:

```
assume(Re(a) > 0):
fourier(t*exp(-a*t^2), t, w)
```

$$-\frac{\sqrt{\pi} w e^{-\frac{w^2}{4a}} i}{2 a^{3/2}}$$

Use `Pref::fourierParameters` to change the values of the Fourier parameters to  $c = 1$ ,  $s = 1$ . Then compute the Fourier transform of the same expression again:

```
Pref::fourierParameters(1, 1):
fourier(t*exp(-a*t^2), t, w)
```

$$\frac{\sqrt{\pi} w e^{-\frac{w^2}{4a}}}{2 a^{3/2}} i$$

Change the values of the Fourier parameters to  $\frac{1}{2\pi}$  and 1. Compute the Fourier transform using these values:

```
Pref::fourierParameters(1/(2*PI), 1):
fourier(t*exp(-a*t^2), t, w)
```

$$\frac{w e^{-\frac{w^2}{4a}}}{4 \sqrt{\pi} a^{3/2}} i$$

For further computations, restore the default values of the Fourier transform parameters:

```
Pref::fourierParameters(NIL):
```

## Example 2

Use the default values of the Fourier transform parameters:

```
Pref::fourierParameters()
```

```
[1, -1]
```

Add this new Fourier transform pattern for the function foo:

```
fourier::addpattern(foo(t), t, w, bar(w)):
fourier(foo(t), t, w)
```

# Pref::fourierParameters

---

$\bar{w}$

The Fourier pair ( $f$ ,  $\bar{w}$ ) is assumed to be valid for the current values of the Fourier parameters. When changing these parameters, you change the definition of the Fourier transform. Therefore, after changing Fourier parameters, the transform of  $f(t)$  is not  $\bar{w}$  anymore. The `fourier` function computes the result which is valid for the new parameters:

```
Pref::fourierParameters(c, s):
fourier(f(t), t, w)
```

$c \bar{w}$

Now restore the Fourier transform parameters to their default values 1 and -1:

```
Pref::fourierParameters(NIL):
```

## Parameters

**c**

Arithmetical expression

**s**

Arithmetical expression

## Return Values

List containing the previously set values of **c** and **s**

## See Also

# Pref::keepOrder

---

**Purpose** Order of terms in sum outputs

**Syntax** Pref::keepOrder(<Always>)  
Pref::keepOrder(<DomainsOnly>)  
Pref::keepOrder(<System>)  
Pref::keepOrder(NIL)  
Pref::keepOrder()

**Description** Pref::keepOrder influences the output order of terms in sums.

Usually, the output system uses its own ordering of the terms in a sum to optimize the appearance of the output. This order may be different from the internal ordering of the sum. The output system prefers to re-order the terms such that the first term is positive.

Sometimes it is desirable to see the terms of a sum in the internal order. This can be achieved with Pref::keepOrder(Always).

By default, the term order of polynomials and domain elements is left unchanged.

Pref::keepOrder(NIL) restores the default state, which is DomainsOnly.

Pref::keepOrder() returns the currently set value.

## Examples

### Example 1

Here we create a domain element  $e$ , an expression  $f$ , and a polynomial  $p$  containing sums. With the default setting `DomainsOnly`, only the output of the expression  $f$  is not in the internal order:

```
d := newDomain("d"): d::print := x -> extop(x):
e := new(d, b - a): f := b - a: p := poly(1 - x):
e, f, p
```

```
- a + b, b - a, poly(- x + 1, [x])
```

With the setting `Always`, `e`, `f`, and `p` are all printed in the internal order:

```
Pref::keepOrder(Always):
e, f, p
```

```
- a + b, - a + b, poly(- x + 1, [x])
```

With the setting `System`, the output order differs from the internal ordering for `e`, `f`, and `p`:

```
Pref::keepOrder(System):
e, f, p
```

```
b - a, b - a, poly(1 - x, [x])
```

`Pref::keepOrder(NIL)` restores the default state; `Pref::keepOrder()` returns the current setting:

```
Pref::keepOrder(NIL): Pref::keepOrder()
```

```
DomainsOnly
```

## Options

### Always

The output always corresponds to the internal order.

### DomainsOnly

In polynomials and domain elements, the ordering of terms corresponds to the internal order. Other sums may be re-ordered by the output system.

This is the default setting of `Pref::keepOrder`.

### System

# Pref::keepOrder

---

The output order of terms in sums is determined by the output system and does not necessarily correspond to the internal order.

## Return Values

Previously defined value: Always, DomainsOnly, or System.

## See Also

## MuPAD Domains

DOM\_POLY | Dom::MultivariatePolynomial | Dom::Polynomial | Dom::UnivariatePolynomial

## MuPAD Functions

print

**Purpose** Version number of the presently used kernel

**Syntax** `Pref::kernel()`  
`Pref::kernel(<BitsInLong>)`  
`Pref::kernel(<BuildNr>)`

**Description** The version numbers of the kernel and the library may differ. `Pref::kernel` refers to the kernel, whereas the call `version()` returns the version number of the installed MuPAD library.

**Examples** **Example 1**

Here the version numbers of kernel and library differ:

```
Pref::kernel() = version()
```

```
[5, 11, 0] = [5, 11, 0]
```

**Example 2**

A 32-bit architecture:

```
Pref::kernel(BitsInLong)
```

```
32
```

**Example 3**

At the time of this writing, kernels build number was 42703:

```
Pref::kernel(BuildNr)
```

```
42703
```

# Pref::kernel

---

## Options

### BitsInLong

`Pref::kernel(BitsInLong)` returns the number of bits of a long integer number. On a 64-bit architecture it returns 64, otherwise 32.

### BuildNr

The kernel has an additional build number which enables the developers to identify the exact sources for this kernel.

## Return Values

Version number: a list of three nonnegative integers or a number.

## See Also

## MuPAD Functions

`buildnumber` | `version`

## Purpose

Set a memory limit for the session

## Syntax

```
Pref::maxMem(kbytes)
Pref::maxMem(NIL)
Pref::maxMem()
```

## Description

`Pref::maxMem(kbytes)` with `kbytes` greater than 0 sets a limit for the physically allocated memory of the current MuPAD session. A computation exceeding this memory limit raises an error.

The physically allocated memory is the second of the values returned by `bytes()`.

---

**Note** The memory limit is “soft” because the memory is checked only occasionally. Usually, more memory is actually used before the excess is detected. Cf. “Example 1” on page 25-35.

---

The call `Pref::maxMem()` returns the current value of the memory limit without changing it.

The call `Pref::maxMem(NIL)` switches off the memory watch dog.

## Examples

### Example 1

No computation should increase the memory usage of the current MuPAD session to more than a total of 10 megabytes:

```
Pref::maxMem(10 * unit::MByte):
```

The following loop creates larger and larger matrices until the memory limit is exceeded. Note that the current physical memory allocation returned by `bytes()[2]` is measured in bytes:

```
for n from 100 to 150 step 5 do
 A := linalg::vandermonde([x.j $ j=1..n]);
 print(n, ceil(bytes()[2]/1024)*unit::kByte);
```

# Pref::maxMem

---

```
end_for:
```

```
100, 7311 kByte
```

```
105, 9311 kByte
```

```
110, 9648 kByte
```

```
115, 10113 kByte
```

```
Error: Out of
memory [watchdog-memory]; Evaluating: linalg::vandermonde
```

```
Error: Out of memory. [watchdog-memory]
Evaluating: linalg::vandermonde
```

Note that the memory limit was exceeded when computing the 115 115 Vandermonde matrix. However, because the memory consumption is measured only occasionally, this matrix was generated successfully without an error. Only in the next step, the memory watchdog recognizes excessive memory usage and aborts the computation of the 120 120 Vandermonde matrix.

```
Pref::maxMem(NIL) :
delete A:
```

## Parameters

### kbytes

The memory limit in kBytes: a nonnegative integer or an expression using `unit::Byte`, `unit::kByte`, `unit::MByte`, or `unit::GByte`.

## **Return Values**

Previously defined memory limit: 0 or an expression involving `unit::MByte`.

## **See Also**

## **MuPAD Functions**

`bytes` | `MAXDEPTH` | `Pref::maxTime`

# Pref::maxTime

---

**Purpose** Time limit for computations

**Syntax** Pref::maxTime(seconds)  
Pref::maxTime(NIL)  
Pref::maxTime()

**Description** Pref::maxTime(seconds) with seconds greater than 0 sets a time limit for all following MuPAD instructions. Each computation not finished within the given time raises an error.

The call Pref::maxTime() returns the current value of the time limit without changing it.

The call Pref::maxTime(NIL) switches off the timer watch dog.

## Examples **Example 1**

No computation should take more than 10 seconds:

```
Pref::maxTime(10 * unit::sec):
```

Note that time returns the CPU time in milliseconds. The following while loop is designed to run longer than 10 seconds:

```
TIME:= time():
while time() - TIME < 20000 do null() end_while
```

```
Error: Execution time is exceeded. [watchdog-time]
```

```
Pref::maxTime(NIL): delete TIME:
```

## Parameters **seconds**

The time limit in seconds: a nonnegative integer or an expression involving time units.

## **Return Values**

Previously defined time limit: 0 or an expression involving `unit::sec`.

## **See Also**

## **MuPAD Functions**

`Pref::maxMem` | `rttime` | `time` | `traperror`

# Pref::output

---

**Purpose** Modify the screen output of objects

**Syntax** Pref::output(f)  
Pref::output(NIL)

**Description** Pref::output allows to modify the screen output of objects returned by the MuPAD kernel.

When the MuPAD kernel returns a result  $x$ , say, of a computation, the function  $f$  is called before the result is printed to the screen. Instead of  $x$ , the return value  $f(x)$  is used as screen output of the computation.

Make sure that a user-defined output function  $f$  processes *arbitrary MuPAD objects*.

The call Pref::output(NIL) resets the output function to the identity map: the screen output coincides with the object returned by the computation. NIL is the default value of the output function.

## Examples

### Example 1

All numbers of type Type::Numeric shall be displayed as floating point numbers. Since the kernel may return sequences of objects, the output function may be called with an unknown numbers of parameters. It uses map to apply its functionality to all of its arguments. Whenever a numerical object of type Type::Numeric is encountered, it is replaced by a floating-point approximation:

```
f := proc(x)
begin
 if args(0) > 1 then
 return(map(args(), f))
 end_if;
 if testtype(x, Type::Numeric) then
 return(float(x))
 else return(x)
 end_if;
end_proc;
```

```
Pref::output(f):
```

```
4/9; sin(3); 4/9, sin(3), 1/2 + 17*I
```

```
0.444444444444
```

```
sin(3)
```

```
0.444444444444, sin(3), 0.5 + 17.0 i
```

We restore the standard mode:

```
Pref::output(NIL): delete f:
```

## Example 2

The procedure `generate::TeX` is applied to the result of a computation. The corresponding TeX code (a string) is displayed:

```
Pref::output(generate::TeX):
sqrt(x^2 - 1/x)
```

```
"\sqrt{x^2 - \frac{1}{x}}"
```

We restore the standard mode:

```
Pref::output(NIL):
```

## Parameters **f**

The “output function”: a procedure

# **Pref::output**

---

## **Return Values**

Previously defined “output function”, or NIL.

## **See Also**

## **MuPAD Functions**

`Pref::postOutput` | `Pref::postInput` | `Pref::keepOrder`

## Purpose

Set the number of digits in floating-point outputs

## Syntax

```
Pref::outputDigits(n)
Pref::outputDigits(<UseDigits>)
Pref::outputDigits(<InternalPrecision>)
Pref::outputDigits()
```

## Description

`Pref::outputDigits(n)` sets the number of digits in outputs of floating-point numbers to an integer  $n$ . This command does not set the precision for calculations. See “Example 1” on page 25-43.

`Pref::outputDigits(InternalPrecision)` sets the number of digits in floating-point outputs to settings MuPAD used when creating these floating-point numbers. If you use `Pref::outputDigits(InternalPrecision)`, the lengths of floating-point numbers in the same output region can differ because the numbers were created with different precision. See “Example 2” on page 25-44.

`Pref::outputDigits(UseDigits)` restores the setting to the number of digits previously set by `DIGITS`. The default value for `DIGITS` is 10. Suppose, you use internal precision for displaying numbers or explicitly specify a number of digits in outputs. If you want to switch back to the number of digits specified by `DIGITS`, use `Pref::outputDigits(UseDigits)`. See “Example 3” on page 25-45.

`Pref::outputDigits()` returns the current setting for the number of digits in outputs of floating-point numbers. This command does not change the setting.

## Examples

### Example 1

Display the floating-point approximation of  $\frac{1}{3}$  using 40 digits without changing the precision for calculations. The default number of digits that MuPAD uses for calculations with floating-point numbers is 10. MuPAD can increase the precision of calculations by several digits (guard digits). Round-off errors cause the last digits in the following result to be incorrect:

# Pref::outputDigits

---

## Parameters

**n**

An integer

## Return Values

Previously set value

## See Also

## MuPAD Functions

DIGITS | float | Pref::floatFormat

## Purpose

Actions after input

## Syntax

```
Pref::postInput(f)
Pref::postInput(NIL)
Pref::postInput()
```

## Description

`Pref::postInput` allows to set user actions directly after input.

After entering any MuPAD command  $x$ , say, and sending this command to the kernel,  $f(x)$  is called before the kernel starts to process the input. This happens for any input until the post-input is switched off via the call `Pref::postInput(NIL)`.

The function  $f$  implicitly uses the option `hold`, i.e.,  $f$  sees the input command as entered and parsed without any evaluation.

$f$  cannot change the input command that is sent to the kernel for evaluation. However,  $f$  can store the input in some global variable for later processing, or some other actions can be performed.

`Pref::postInput()` returns the current value of the post-input function or `NIL`, respectively.

`Pref::postInput`, possibly in conjunction with `Pref::postOutput`, is useful for initializing variables to compute status information such as the execution time for the command that is to be executed. See “Example 2” on page 25-49.

## Examples

### Example 1

The post-input function sees the input as entered, i.e., before evaluation by the kernel:

```
Pref::postInput(proc() begin
 print(Unquoted, "input" = args())
end):
```

```
1 + 2
```

# Pref::postInput

---

```
input = 1 + 2
```

```
3
```

```
1 + 2, x = sin(0.1)
```

```
input = (1 + 2, x = sin(0.1))
```

```
3, x = 0.09983341665
```

```
x := 1234; y := 5678
```

```
input = (x := 1234)
```

```
1234
```

```
input = (y := 5678)
```

```
5678
```

Post-input is switched off. This command calls the post-input function for the very last time:

```
Pref::postInput(NIL):
```

```
input = Pref::postInput(NIL)
```

```
delete x, y:
```

## Example 2

For any command, the run time is to be computed and displayed. The function declared in `Pref::postInput` sets a global timer value `TIME` after each input. After the output of the result, the function declared in `Pref::postOutput` compares the current time and the starting time `TIME`.

```
Pref::postInput(() -> (TIME:= time())):
Pref::postOutput(() -> "Time: ".expr2text((time() - TIME)*msec))
```

```
int(cos(x)*exp(sin(x)), x)
```

```
esin(x)
```

```
Time: 40 msec
```

```
esin(x)
```

```
Time: 40 msec
```

```
Pref::postInput(NIL): Pref::postOutput(NIL):
delete TIME:
```

# Pref::postInput

---

## Example 3

As another example of using `Pref::postInput` for storing information to influence the output, we combine it with `Pref::output` to include (a rendered version of) the input and the result:

```
Pref::postInput(() -> (LASTINPUT := args())):
Pref::output(() -> val(LASTINPUT) = args()):
```

This makes MuPAD write “input = result” to the screen, while leaving the history (accessible by `%`) intact:

```
int(x, x);
sum((-1)^i/(2*i+1), i=0..infinity);
sin(%)
```

$$\int x \, dx = \frac{x^2}{2}$$

$$\sum_{i=0}^{\infty} \frac{(-1)^i}{2i+1} = \frac{\pi}{4}$$

$$\sin(\%) = \frac{\sqrt{2}}{2}$$

## Parameters **f**

The function to be executed after input: a procedure. The default value of this function is `NIL` (no post-input).

## Return Values

Previously set post-input function.

## See Also

### MuPAD Functions

Pref::postOutput

# Pref::postOutput

---

**Purpose**            Actions after output

**Syntax**            Pref::postOutput(f)  
                     Pref::postOutput(NIL)  
                     Pref::postOutput()

**Description**      After the result  $x$ , say, of a MuPAD command is printed on the screen,  $f(x)$  is called and executed before the next prompt for user input appears. This happens for any output until the post-output is switched off via `Pref::postOutput(NIL)`.

After the usual output of the result  $x$  of a MuPAD command, the return value of  $f(x)$  is printed on the screen with `PRETTYPRINT = FALSE`. However,  $f(x)$  does not return any value to the MuPAD session. It cannot be accessed via `last`.

`Pref::postOutput()` returns the current value of the post-output function or `NIL`, respectively.

`Pref::postOutput`, possibly in conjunction with `Pref::postInput`, can be used to produce status information after each output. One may think of timer informations, memory usage, result types etc.

## Examples

### Example 1

Here, `Pref::postOutput` is used to enumerate the output line and display the type of the result. It uses the global variable `LineNumber` which must be initialized before any output is produced. The definition of the post-output operation as well as the initialization of the global variable can be done in the file “`userinit.mu`” which is read automatically during start-up.

```
Pref::postOutput(
 proc()
 begin
 LineNumber:= LineNumber + 1;
 "Out[" . expr2text(LineNumber). "]: "
 "type = ".expr2text(op(map([args()], domtype)));
```

```

end_proc):
LineNumber:= 0:

int(x^5*exp(-x), x)

```

$$-e^{-x} (x^5 + 5x^4 + 20x^3 + 60x^2 + 120x + 120)$$

```
Out[1]: type = DOM_EXPR
```

```

int(x^5*exp(-x), x = 0..infinity),
numeric::int(x^5*exp(-x), x = 0..infinity)

```

```
120, 120.0
```

```
Out[2]: type = DOM_INT, DOM_FLOAT
```

The following print command returns the void object `null()` to the MuPAD session. The output of `null()` is suppressed:

```
print("print returns the void object")
```

```
"print returns the void object"
```

The following command is terminated by a semicolon to suppress the output. Consequently, no post-output is created, either.

```
x := sin(2):
```

Post-output is switched off:

# Pref::postOutput

---

```
Pref::postOutput(NIL): delete LineNumber, x:
```

## Example 2

For any command, the run time is to be computed and displayed. The function declared in `Pref::postInput` sets a global timer value `TIME` after each input. After the output of the result, the function declared in `Pref::postOutput` compares the current time and the starting time `TIME`. The current `TEXTWIDTH` is used to prepend some suitable whitespace via `stringlib::format` to flush right the timer information:

```
Pref::postInput(() -> (TIME:= time())):
Pref::postOutput(
 proc() begin
 stringlib::format("Time: ".expr2text(time() - TIME)." msec",
 TEXTWIDTH-1, Right)
 end_proc):

int(x^10*exp(-x), x)
```

```
-e-x (x10 + 10 x9 + 90 x8 + 720 x7 + 5040 x6 + 30240 x5 + 151200 x4 + 604800 x3 + 1814400 x2 + 3628800)
```

Time: 84.005 msec

```
Pref::postInput(NIL): Pref::postOutput(NIL):
delete T, TIME:
```

## Example 3

The following post-output lists all identifiers with properties in the result of the last MuPAD command. It extracts the indeterminates via `indets` and uses `property::hasprop` to query whether they have properties:

```
Pref::postOutput(
 proc()
 begin
 select(indets({args()}), property::hasprop);
 "identifiers with properties: " . expr2text(op(%))
 end_proc):
```

```
assume(0 < a < b): a + b + c
```

```
a + b + c
```

```
identifiers with properties: a, b
```

```
Pref::postOutput(NIL): delete a, b:
```

## Parameters

**f**

The function to be executed after output: a procedure. The default value of this function is NIL (no post-output).

## Return Values

Previously set post-output function.

## See Also

## MuPAD Functions

Pref::postInput

# Pref::report

---

**Purpose** Informations during evaluation

**Syntax** `Pref::report(level)`

**Description** `Pref::report` controls the frequency of report messages of the MuPAD kernel during evaluation.

A kernel function displays frequently the three informations *memory used*, *memory reserved* and *evaluation time in seconds*.

The level 0 disables printing information. If level is 1, about every hour a message will be printed. With 9 as argument the most reports will be printed. The frequency depends on the machine's speed.

A call of `Pref::report` without arguments returns the current value. The argument NIL resets the default value 0.

## Examples

### Example 1

Frequently information:

```
Pref::report(9):
limit((1+1/n)^n,n=infinity)

[used=1612k,
reserved=1738k, seconds=1] [used=2716k, reserved=2856k, seconds=2]
exp(1)
```

Reset to no information:

```
Pref::report(0):
```

**Parameters** **level**

An integer between 0 and 9, or NIL

**Return Values** Last defined level

**See Also**

**MuPAD  
Functions**

`Pref::callBack`

# Pref::trailingZeroes

---

**Purpose** Trailing zeroes when printing floating-point numbers

**Syntax** Pref::trailingZeroes(value)  
Pref::trailingZeroes()

**Description** Pref::trailingZeroes determines, whether trailing zeroes will be appended, when floating-point numbers are printed.

If enabled (with argument TRUE), after the significant numbers of a floating-point number (behind the point) zeroes will be appended until the number of digits reaches the value of DIGITS.

A call of Pref::trailingZeroes without arguments will return the current value. The argument NIL will reset the default value, which is FALSE.

## Examples **Example 1**

By default, trailing zeroes will not be displayed:

```
DIGITS:= 10:
1.4
```

```
1.4
```

Display of trailing zeroes will be enabled:

```
Pref::trailingZeroes(TRUE):
1.4
```

```
1.40000000
```

The default mode is restored:

```
Pref::trailingZeroes(NIL):
```

## Parameters

**value**

TRUE, FALSE or NIL

## Return Values

Last defined value.

## See Also

## MuPAD Functions

DIGITS | Pref::floatFormat | print

# Pref::typeCheck

---

**Purpose** Type checking of formal parameters

**Syntax** Pref::typeCheck(Always | Interactive | None)  
Pref::typeCheck(NIL)  
Pref::typeCheck()

**Description** Pref::typeCheck determines the kind of type checking of procedure parameters.

The definition of a MuPAD procedure may contain formal parameters. There is a syntax to attach a type specification to these parameters. If and when type checking is enabled, the types of actual parameters are checked against the type specifications and an error is raised if a parameter does not meet the specification.

Type specifications are used as the second parameter of `testtype`. The most important ones are “Domain Types” and objects of the domain Type. With Type, user defined types can be easily added to the system to extend the type checking mechanism.

The arguments of `Pref::typeCheck` can be:

- **None**  
No parameters are checked.
- **Interactive**  
Parameters entered interactively are checked. This is the default.
- **Always**  
All formal parameters are checked.

The default value `Interactive` means: When the user is calling a procedure `f`, its parameters will be checked, but none of the procedures called by the user called procedure `f` performs type checking.

A call of `Pref::typeCheck` without arguments returns the current value. The argument `NIL` resets the default value, which is `Interactive`.

## Examples

### Example 1

We define a procedure `f` expecting an identifier and an integer:

```
f:= proc(a : DOM_IDENT, b : DOM_INT)
begin
 evalassign(a, b, 1)
end_proc:
f(a, 2)
```

2

Now `a` has the value 2, but an identifier is expected:

```
f(a, 2)
```

```
Error: The type of argument number 1 must be 'DOM_IDENT'. The ob
Evaluating: f
```

```
delete a:
```

## Options

### Always

Parameter types are checked for every call.

### Interactive

Parameter types are checked for interactive calls, not for “inner” calls during the computation.

### None

No parameter type checks are performed by the MuPAD kernel. Explicit checks inside procedures still use the usual `testargs` mechanism.

# Pref::typeCheck

---

## Return Values

Previously defined value

## Algorithms

The syntax to test parameters directly (without a test in the procedure body) is the formal parameter followed by a colon and then the type object: `proc(a : DOM_IDENT, b : Type::Integer)`. This means: `a` must be of the type `DOM_IDENT` and `b` must be of the type `Type::Integer`.

Note that you cannot use automatic type checking for arguments that are used for overloading inside the procedure.

The objects of the `Type` library are usually more general than the MuPAD kernel types.

### MuPAD Functions

`args` | `domtype` | `hastype` | `proc` | `testargs` | `testtype` | `type`

<b>Purpose</b>	Additional options when starting MuPAD
<b>Syntax</b>	<code>Pref::userOptions()</code>
<b>Description</b>	<p><code>Pref::userOptions()</code> returns additional options, given by the user when calling MuPAD.</p> <p>When starting the MuPAD kernel with the flag "-U" the user can define options that can be used in the MuPAD session.</p>

## Examples

### Example 1

If you start MuPAD with the command `mupad -U "Hello World"`, `Pref::userOptions` returns the string "Hello World":

```
Pref::userOptions()
```

```
"Hello World"
```

### Example 2

To define several user options one can use a separator between the strings. MuPAD is called with `mupad -U "myhome, /home/user/myhome,2"`:

```
Pref::userOptions()
```

```
"myhome, /home/user/myhome,2"
```

The following call splits the string into the three parts (to demonstrate, the string is written explicitly):

```
s := "myhome, /home/user/myhome,2":
opts := []:
ind := 0:
while (ind := stringlib::contains(s, ",", Index)) <> FALSE do
 opts := opts . [s[1 .. ind-1]];
 s := s[ind+1 .. length(s)]:
```

# Pref::userOptions

---

```
end_while:
opts := opts . [s]

["myhome", "/home/user/myhome", "2"]

delete s, opts, ind:
```

## Return Values

User defined options as strings

**Purpose** Shows reading of files

**Syntax** Pref::verboseRead(value)  
Pref::verboseRead()

**Description** With Pref::verboseRead the reading of library packages and files can be shown.

The arguments of Pref::verboseRead represent:

- 0:  
no messages when reading files (default).
- 1:  
message if a library packages will be read.
- 2:  
messages if a package or any library function will be read.
- NIL:  
restore the default value 0.

A call of Pref::verboseRead without arguments returns the current value.

## Examples

### Example 1

Show the reading of library packages:

```
reset():
Pref::verboseRead(1):
sin(x)

loading package 'Type' [mupad/share/lib/lib.tar#lib/
0.8414709848
```

Show reading of all library files:

# Pref::verboseRead

---

```
reset():
Pref::verboseRead(2):
sin(1.0)

reading file mupad/share/lib/lib.tar#lib/SPECFUNC/sin.mu
reading file mupad/share/lib/lib.tar#lib/SPECFUNC/sinh.mu reading
file mupad/share/lib/lib.tar#lib/STDLIB/infinity.mu loading package
'Type' [mupad/share/lib/lib.tar#lib/] reading file mupad/share/lib/
0.8414709848
```

The default mode is restored:

```
Pref::verboseRead(NIL):
```

## Parameters

### value

0, 1, 2, or NIL

## Return Values

Last defined value

## See Also

## MuPAD Functions

read | fread | prog::trace | loadproc

## Purpose

Warnings about wrong usage of lexical scope

## Syntax

```
Pref::warnDeadProcEnv(TRUE)
Pref::warnDeadProcEnv(FALSE)
Pref::warnDeadProcEnv(NIL)
Pref::warnDeadProcEnv()
```

## Description

`Pref::warnDeadProcEnv()` returns the current setting.

`Pref::warnDeadProcEnv(TRUE)` switches on warnings about unreachable procedure environments.

`Pref::warnDeadProcEnv(FALSE)` switches warning messages off.

`Pref::warnDeadProcEnv(NIL)` will reset the default value, which is `FALSE`.

If a procedure is executed a *procedure environment* is created for this procedure. It contains the current values of formal parameters and local variables. On exit of the procedure this procedure environment is normally not needed any more and destroyed.

If a procedure returns a local procedure as its result, this local *procedure escapes its scope*. Usually this is no problem. Only if the escaping procedure contains references to formal parameters or local variables of the outer procedure these *variables escape their scope*. These variables can not be dereferenced since they reference values of a procedure environment of the outer procedure which does not exist any more.

Use option *escape* in the outer procedure in order to keep its procedure environment untouched.

## Environment Interactions

Allows or suppresses warning messages.

## Examples

### Example 1

Here we write procedure `p` which returns a local procedure. The returned procedure adds the value of its argument `y` to the value of the argument `x` of the first procedure. The following naive implementation

# Pref::warnDeadProcEnv

---

produces a strange output and, when the resulting procedure is called, a warning message and an error:

```
Pref::warnDeadProcEnv(FALSE):
p := proc(x) begin y -> x + y end:
f := p(1); f(2)
```

```
y → DOM_VAR(1, 2) + y
```

```
Warning:
Uninitialized variable 'unknown' used. Evaluating: f

Error: Illegal operand. [_plus] Evaluating:
f
```

If `Pref::warnDeadProcEnv` is set to `TRUE` MuPAD will print a warning message when the local procedure escapes its scope:

```
Pref::warnDeadProcEnv(TRUE):
p := proc(x) begin y -> x + y end:
f := p(1)
```

```
Warning:
Found dead closure of procedure 'p'.
```

```
y → DOM_VAR(1, 2) + y
```

Use option *escape* in the outer procedure to prevent this warning. The returned procedure `f` will then work as expected:

```
p := proc(x) option escape; begin y -> x + y end:
f := p(1); f(2)
```

$y \rightarrow x + y$

3

## Return Values

Previously set value

prog::untrace
prog::wait
```

# prog::check

---

## **Purpose**

Checking objects

## **Syntax**

```
prog::check(object, <infolevel>, options)
```

## **Description**

The call `prog::check(object)` checks the MuPAD object `object`. `object` may be a procedure, a function environment, or a domain. One may also give a list of such objects.

If `All` is given as first parameter, all defined procedures, function environments and domains are checked (see `anames`).

`infolevel` determines the amount of information given while checking. The following values are useful:

- 1  
summarizing number of warnings per checked object, if at least one warning occurs (default)
- 2  
as 1, but a short message is printed even if no warning was produced
- 3  
summary of warnings per checked object
- 5  
displays each checked object, followed by individual warnings, followed by a summary and the number of warnings, if any.
- 10 ... 15  
additional outputs (for debugging/information)

`options` can be any of the described options.

With option `All`, all are checked. Without options, the set `{Domain, Global, Interface, Level, Local, Protect, Save}` is used.

---

**Note** The arguments of hold expressions are not checked.

---

## Examples

### Example 1

The following function contains a number of mistakes, some of which were actually legal in previous versions of MuPAD.

Lines 1 and 2 contains declarations of local variables. In line 4 an undeclared (global) variable `g` is used. Line 7 applies `level` to a local variable (the call simply returns the value of `X` in MuPAD 2.0). Line 10 contains an assignment to a formal parameter. This parameter will be overwritten and its old value lost:

```
f:= proc(X, Y) // 1 Local
 local a, b; // 2 Local
 begin // 3
 g:= proc(X) // 4 Global
 option hold; // 5
 begin // 6
 a:= level(X, 2); // 7 Level
 a:= a + X // 8
 end_proc; // 9
 Y:= g(Y); // 10 Assign, Global
 end_proc:
prog::check(f, 3)
```

Critical usage of 'level' on local variable ' [f]

Function 'level' applied to variables: {X} in [f, proc in 'f']

Global idents: {g} in [f]

Unused local variables: {b} in [f]

# prog::check

---

Warnings: 3 [f]

Only search for global variables, but give more messages:

```
prog::check(f, 5, Global)
```

```
Checking f (DOM_PROC)
```

```
Global variable 'g' in [f]
```

```
Global variable 'g' in [f]
```

```
Global idents: {g} in [f]
```

Warnings: 1 [f]

Now check everything:

```
prog::check(f, 5, All)
```

```
Checking f (DOM_PROC)
```

```
Global variable 'g' in [f]
```

```
Critical usage of 'level' on local variable ' [f]
```

Function 'level' applied to variables: {X} in [f, proc in 'f']

Procedure environment of [f] used by [f, proc in 'f']

Assignment to formal parameter 'Y' in [f].

Global variable 'g' in [f]

Global idents: {g} in [f]

Unused local variables: {b} in [f]

Unused formal parameters: {X} in [f]

Assignments to formal parameters: {Y} in [f]

Warnings: 8 [f]

Global variables declared with the option “save” are allowed:

```
f:= proc(X) // 1 Local
 save g; // 2 Save
 begin // 3
 g:= X
 end_proc:
prog::check(f, 2, Global, Save)
```

Warnings: 0 [f]

## Parameters

### **object**

Procedure, function environment or domain to check, the identifier `All`, or a list of objects

### **infolevel**

Positive integer that determines the completeness of messages

## Options

### **All**

Enables all known options

### **Global**

Report unknown global identifiers

### **Local**

Report unused local variables

These are variables that were declared by `local`, but never used in the procedure.

### **Localf**

Report unused local variables *and* unused formal parameters

The same as `Local`, but the same check is additionally performed for formal parameters of a procedure. Those are the argument names as given in the definition of the procedure.

### **Assign**

Report assignments to formal parameters of procedures

Because a formal parameter will be overwritten, those assignments *could* indicate a programming error (however, not imperative).

### **Level**

The application of `level` to local variables is reported. Starting with MuPAD 2.0, local variables are simply replaced by their values on evaluation and calling `level` on them does not have any effect.

## **Domain**

Report undefined entries of domains (uses the slot "undefinedEntries")

## **Interface**

Information about undefined entries of a domain interface are printed, i.e., entries in the domain interface, that are not defined as entries of the domain.

## **Environment**

Information about assignments to environment variables of MuPAD are printed. These assignments could change the global behavior of MuPAD if the change is not undone (preferably using `save`, to catch error conditions).

## **Protect**

Information about assignments to protected variables of MuPAD are printed.

## **Save**

A message about a global identifier is suppressed, when the checked object is a procedure and the identifier is saved with option "save".

## **Special**

Information about some special cases are printed. Currently, the only implemented special case is assignments to `HISTORY`.

## **Escape**

`prog::check` prints warnings about procedures which may require the option `escape`.

# prog::check

---

## **Return Values**

prog::check returns the void object null(). Output messages are printed on the screen.

## **See Also**

## **MuPAD Functions**

debug | prog::init | prog::isGlobal | prog::trace | prog::getname

**Purpose** Convert an expression into a nested list

**Syntax** prog::exprlist(ex)

**Description** prog::exprlist returns a list that contains all operands of the expression ex. Each operand of type DOM\_EXPR is converted into a list, too.

The return value of prog::exprlist can be used directly as argument for adt::Tree resp. output::tree.

**Examples** **Example 1**

The example shows the nested list for the expression  $a + b \cdot 2 - d \cdot (a + c)$ :

```
prog::exprlist(a + b*2 - d*(a + c))
```

```
[_plus, a, [_mult, b, 2], [_mult, d, [_plus, a, c], -1]]
```

The return value can be used to create and display a tree:

```
expose(adt::Tree(prog::exprlist(a + b*2 - d*(a + c))))
```

```

_plus
|
+-- a
|
+-- _mult
| |
| +-- b
| |
| -- 2
|
-- _mult

```

# prog::exprlist

---

```
|
+-- d
|
+-- _plus
|
| +-- a
| |
| | +-- c
| | |
| | | +-- -1
```

**Parameters**    **ex**  
Expression to convert

**Return Values**    List

**See Also**

**MuPAD Functions**    prog::exprtree | adt::Tree | output::tree

**Purpose** Visualize an expression as tree

**Syntax** prog::exprtree(ex, <Quiet>)

**Description** prog::exprtree(ex) visualizes any MuPAD expression ex as tree.  
 Every expression in MuPAD is internally a tree. The operations are the nodes, and the operands are the leafs.

**Examples** **Example 1**

The example shows the structure of the expression  $a + b^2 - d(a + c)$ :

`prog::exprtree(a + b*2 - d*(a + c))`

# prog::exptree

---

`Tree1`

`Tree1`

`Tree1` is the return value of type `adt::Tree`. This object can be exposed or taken for other operations.

The option `Quiet` suppresses the output, only the tree is returned:

```
prog::exptree(a + b*2 - d*(a + c), Quiet)
```

`Tree2`

## Parameters

**ex**

Expression to visualize

## Options

**Quiet**

With this option no output will be printed on screen. The return value of type `adt::Tree` represents the tree structure of `ex`.

## Return Values

Object of type `adt::Tree`

## See Also

## MuPAD Functions

`adt::Tree`

**Purpose**

Find operands of objects

**Syntax**

prog::find(obj, piece, <Depth = d>, <Type>)

**Description**

prog::find(obj, piece) returns the position of the object piece in the MuPAD object obj as list. The list represents a “path” to the given object. With this list and the functions op and subsop, the object can directly be accessed.

A path to an object piece is a list that contains integers i1, ..., in.

The meaning is that piece is the in-th operand of the (in - 1)-st operand etc. of the i1-st operand of the given object obj.

Stated differently, op(ex, [i1, ..., in]) = opr.

If the searched object is containing several times, a sequence of lists is returned.

An empty list [ ] as path determines the object obj itself.

**Examples**

**Example 1**

The identifier a is the first operand of the expression:

```
prog::find(a + b + c, a)
```

```
[1]
```

The number 1 occurs several times:

```
prog::find(f(1, 1, 1), 1)
```

```
[1], [2], [3]
```

## Example 2

The identifier `a` is the first operand of the second operand of the first operand of the expression:

```
prog::find(b*(a - 1) + b*(x - 1), a)
```

```
[1, 2, 1]
```

The result of `prog::find` can be used to access the element with `op` or replace it with `subsop`:

```
op(b*(a - 1) + b*(x - 1), [1, 2, 1]);
subsop(b*(a - 1) + b*(x - 1), [1, 2, 1] = A)
```

```
a
```

```
b (A - 1) + b (x - 1)
```

## Example 3

How many calls of `return` does `sin` contain?

```
nops([prog::find(sin, return)])
```

```
50
```

`sin` contains many `return` calls! However, `sin` is a function environment and the slots are examined, too. To examine only the main procedure, take the first operand of the function environment:

```
nops(prog::find(op(sin, 1), return))
```

23

**Example 4**

prog::find can also find all objects of a given type:

```
nops(prog::find(sin, DOM_PROC, Type))
```

61

To find only the top level procedures, option Depth can be used:

```
nops(prog::find(sin, DOM_PROC, Type, Depth = 1))
```

14

**Example 5**

prog::find works with tables and other containers, too:

```
T := table(1 = sin(x), 2 = cos(x), 3 = tan(x),
 4 = tan(y), 5 = sin(y), 6 = cos(y)):
prog::find(T, sin)
```

```
[1, 2, 0], [5, 2, 0]
```

```
prog::find(T, "cos", Type)
```

```
[2, 2], [6, 2]
```

**Example 6**

In this example we show how to manipulate an existing function by substitution. We use subsop for the substitution and prog::find to get

the path for the substitution. Here we replace the ^-function by the function `mypower` which additionally counts the number of its calls:

```
f := x -> `+(x^j $ j = 1 .. random(10)()):
mypower := (b, e) -> (count := count + 1; b^e):
map([prog::find(f, `^`)],
 X -> (f := subsop(f, X = mypower))):
```

After calling the function `f` ten times in a loop, we see the resulting number of calls of `^` in `count`:

```
count := 0:
for i from 1 to 10 do f(i); end:
count
```

48

## Parameters

### **obj**

Any MuPAD object

### **piece**

Any MuPAD object

## Options

### **Depth**

Option, specified as `Depth = d`

This option allows examining operands of the given object, that are domains, procedures and function environments, only with recursion depth `d`.

Option `Depth` can be used to find procedures, but not locally defined procedures inside the procedures that were found in the first step.

### **Type**

When the option `Type` is given, `prog::find` does not search positions `p` in `obj` such that `op(obj, p) = piece`, but rather those with `testtype(op(obj, p), piece) = TRUE`. Cf. “Example 4” on page 26-15.

## Return Values

List of numbers that determine the position of the given object inside of the given expression, or a sequence of lists, if the expression contains the object several times

## Algorithms

`prog::find` can be used to examine and manipulate complex MuPAD objects with `subsop`.

## See Also

## MuPAD Functions

`op` | `subsop` | `has` | `prog::exprtree`

# prog::getname

---

**Purpose** Name of an object

**Syntax** prog::getname(object)

**Description** prog::getname(object) returns the name of the MuPAD object object.

The return value is a string, irrespective of the type of the input.

Names can be extracted from procedures, identifiers, function environments, domains and their methods (and strings, of course). If no name can be extracted from an object, the string "(noname)" is returned.

For all other MuPAD objects the result of expr2text(object) is returned as name.

## Examples

### Example 1

My own name:

```
prog::getname(prog::getname)
```

```
"prog::getname"
```

The name of a Domain:

```
prog::getname(Dom::ExpressionField())
```

```
"Dom::ExpressionField()"
```

The "name" of an arbitrary MuPAD object:

```
prog::getname(1)
```

```
"1"
```

```
prog::getname(a + 2*b)
```

```
"a + 2*b"
```

## Parameters

**object**

Any MuPAD object

## Return Values

Name as string

## See Also

## MuPAD Functions

op | print | expr2text | text2expr | info

# prog::getOptions

---

**Purpose** Get and verify options within a procedure

**Syntax** `prog::getOptions(n, arguments, allOptions, <ErrorOnUnexpected>, <optionTypes>)`

**Description** `prog::getOptions` called within a procedure collects and verifies all options from the list of arguments of the calling procedure.

When you write your own procedure, `prog::getOptions` lets you embed the collection and verification of all options of the procedure. When a user calls your procedure, `prog::getOptions` scans all the arguments and provides a data structure that contains all option values. See “Example 1” on page 26-21.

The `prog::getOptions` function returns a list that contains a table of all valid options along with their values and a list of unexpected arguments. For expected options, `prog::getOptions` returns the following values:

If an option can have only TRUE or FALSE values, a user of your procedure can provide the option name, instead of providing an option-value pair. If a user provides an option without specifying its value, `prog::getOptions` returns the Boolean value TRUE for that option. See “Example 2” on page 26-22.

`prog::getOptions` returns a list with two components: a table of expected options and a list of unexpected arguments. You can access the components of that list separately by using the index operator (see `_index`). See “Example 3” on page 26-23.

By default, the `prog::getOptions` function does not error when it finds an unexpected argument. To switch to issuing errors on unexpected arguments, use the parameter `ErrorOnUnexpected`. See “Example 4” on page 26-23.

The procedure that includes `prog::getOptions` must accept the arguments in the following order: first nonoptional parameters, and then all options. The `prog::getOptions` function lets you specify the number `n` of the argument from which the function starts verifying options. The `prog::getOptions` function assumes that the first `n - 1`

arguments are parameters and, therefore, does not verify them. See “Example 5” on page 26-23.

The parameter `optionTypes` lets you specify acceptable types for the option values. You can specify acceptable types for some or all of the expected options provided in the `allOptions` table. See “Example 6” on page 26-25.

The first three parameters of `prog::getOptions` (`n`, `arguments`, and `allOptions`) are required. `ErrorOnUnexpected` and `optionTypes` are optional. You must provide the parameters of `prog::getOptions` using the order shown in the Calls section of this page. Therefore, if you want to use the fifth parameter `optionTypes`, you also must explicitly use the fourth parameter `ErrorOnUnexpected`.

The second parameter of the `prog::getOptions` function, `arguments`, is a list of all arguments of your procedure. `prog::getOptions` scans the arguments provided in that list. Although `prog::getOptions` accepts any list as a second argument, the calling procedure always must provide a list of all its arguments (both parameters and options) to avoid potential errors. The syntax `[ args() ]` provides a list of all arguments of the calling procedure. See “Example 7” on page 26-26.

## Examples

### Example 1

To embed the option collection and verification step into your procedure, call `prog::getOptions` function within that procedure. To test the behaviour of `prog::getOptions`, create a function `f` that calls `prog::getOptions` to scan and verify the arguments of `f`. For example, create the function `f` that accepts only one option `All`:

```
f := () -> prog::getOptions(1, [args()], table(All = TRUE)):
```

`prog::getOptions` returns a list. The first entry of the list is a table containing all expected options and their values. The second entry is a list of unexpected arguments. For example the function call `f()` does not contain any unexpected arguments:

```
f();
```

# prog::getOptions

---

$\left[ \overline{\text{All}} \mid \text{TRUE} \cdot [] \right]$

The function call `f(Unexpected)` contains the unexpected argument `Unexpected`:

```
f(Unexpected);
```

$\left[ \overline{\text{All}} \mid \text{TRUE} \cdot [\text{Unexpected}] \right]$

## Example 2

When users call the procedure that includes `prog::getOptions`, they can specify new values for any of the valid options of that procedure. In this case, `prog::getOptions` returns the new values. If a user uses the option without specifying its value, `prog::getOptions` returns the Boolean value `TRUE` for that option. If a user does not explicitly use an expected option, `prog::getOptions` returns the default value of that option provided in the `allOptions` table. For example, in the function call `f(Proc = op, Warning)`, the `prog::getOptions` function returns the following values:

- If a user provides a value for the option, `prog::getOptions` returns that value.
- If a user does not use the option in a procedure call, `prog::getOptions` returns the default value for that option.

```
f := () -> prog::getOptions(1, [args()], table(All = FALSE, Proc =
f(Proc = op, Warning)
```

$\overline{\text{All}}$	$\text{FALSE}$
$\text{Proc}$	$\text{op}$
$\text{Warning}$	$\text{TRUE}$

## Example 3

To access the table of expected options and the list of unexpected arguments separately, use the index operator (see `_index`):

```
f := () -> prog::getOptions(1, [args()], table(All = TRUE))[1]:
g := () -> prog::getOptions(1, [args()], table(All = TRUE))[2]:
ExpectedOptions = f(Unexpected);
UnexpectedOptions = g(Unexpected)
```

```
ExpectedOptions = All|TRUE
```

```
UnexpectedOptions = [Unexpected]
```

## Example 4

When a user supplies unexpected arguments to your procedure, `prog::getOptions` can collect these arguments and return them as a list. Also, `prog::getOptions` can stop and issue an error when it finds the first unexpected argument. To issue an error instead of listing unexpected arguments, use `TRUE` as the fourth parameter of `prog::getOptions`:

```
f := () -> prog::getOptions(1, [args()], table(All = TRUE), TRUE,
f(Unexpected))
```

```
Error: The argument number 1 is invalid.
Evaluating: f
```

## Example 5

The `prog::getOptions` function does not distinguish parameters from options automatically. If some arguments of a procedure are parameters, exclude them from option verification. Otherwise, the `prog::getOptions` function lists those parameters as unexpected

## prog::getOptions

---

arguments. For example, `prog::getOptions` lists 1 and 2 as unexpected arguments of the function call `f(1, 2, All)`:

```
f := () -> prog::getOptions(1, [args()], table(All = TRUE))[2]:
UnexpectedOptions = f(1, 2, All);
```

```
UnexpectedOptions = [1, 2]
```

If you set the `prog::getOptions` function to error on unexpected arguments, it will error on the parameters too:

```
f := () -> prog::getOptions(1, [args()], table(All = TRUE), TRUE):
f(1, 2, All);
```

```
Error: The argument number 1 is invalid.
Evaluating: f
```

To exclude first  $n$  parameters of a function from option verification, provide the number  $n + 1$  as a first argument of `prog::getOptions`. In a function call, specify all  $n$  parameters before you specify options. For example, to avoid checking the first two arguments in the function call `f(1, 2, All)`, use the following syntax:

```
f := () -> prog::getOptions(3, [args()], table(All = TRUE))[2]:
UnexpectedOptions = f(1, 2, All);
```

```
UnexpectedOptions = []
```

When you use `prog::getOptions`, you must provide all nonoptional parameters first, and then provide the options. The following syntax does not work because `prog::getOptions` assumes that the first two

arguments in the function call `f(1, All, 2)` are parameters, and the number 2 is an option:

```
f := () -> prog::getOptions(3, [args()], table(All = TRUE), TRUE)
f(1, All, 2);
```

```
Error: The argument number 3 is invalid.
Evaluating: f
```

## Example 6

To specify acceptable types of the option values, use a table that contains acceptable options as indices and their expected types as entries. For example, specify that the `All` option must be of the type `DOM_BOOL`, and the `Proc` option must be of the type `Type::Function`:

```
f:= () -> prog::getOptions(1, [args()], table(All = TRUE, Proc =
 table(All = DOM_BOOL, Proc = Type::Fu
```

Now, options can have only values of the correct types:

```
f(All = FALSE, Proc = id)
```

All	FALSE
Proc	id

If you try to use a value of the wrong type, the function issues an error:

```
f(All = FALSE, Proc = 0)
```

```
Error: The type of argument number 2 is incorrect.
Evaluating: f
```

# prog::getOptions

---

Also, you can define and use a procedure for performing the type check. For arguments of the valid type, the procedure must return TRUE or an expression that can be evaluated to TRUE by the bool function:

```
f := () -> prog::getOptions(2, [args()], table(File=""), TRUE,
 table(File = (X -> contains({DOM_STRING,
 type(X)})))[
f(FALSE, File = 0), f(TRUE, File = "test.log")
```

```
File|0' File|"test.log"
```

## Example 7

Using arguments to separate options from parameters is not recommended because it can lead to errors. Always use the first parameter of prog::getOptions to specify how many parameters you have. Although prog::getOptions accepts any list as a second argument, the best practice is to use only args(). The following example demonstrates that using arguments to separate options from parameters can result in the wrong error message. Although this error message correctly indicates that one of the options has a value of the wrong type, the index of the argument is wrong:

```
f := () -> prog::getOptions(1, [args(2..args(0))], table(Option1 =
 TRUE, table(Option1 = DOM_BOOL)):
f(x, Option1 = 1, Option2)
```

```
Error: The type of argument number 1 is incorrect.
Evaluating: f
```

To get the correct error message for this example, use the first parameter of prog::getOptions to exclude x from option verification:

```
f := () -> prog::getOptions(2, [args()], table(Option1 = TRUE),
```

```
f(x, Option1 = 1, Option2) TRUE, table(Option1 = DOM_BOOL)):
```

```
Error: The type of argument number 2 is incorrect.
Evaluating: f
```

## Parameters

**n**

A positive integer that specifies the number of the first option in the list of arguments. When calling the procedure, a user must provide all nonoptional parameters before the options.

### arguments

A list of all arguments of the procedure. Use `args()` to access all arguments.

### allOptions

A table that contains all acceptable options as indices and their default values as entries: `table(Option = defaultValue)`

### ErrorOnUnexpected

A Boolean constant TRUE or FALSE. If the value is TRUE, `prog::getOptions` issues an error when it finds an unexpected argument. If the value is FALSE, `prog::getOptions` collects all unexpected arguments and returns them as a list. By default, `ErrorOnUnexpected = FALSE`.

### optionTypes

A table that contains acceptable options as indices and their expected types as entries: `table(Option = optionType)`. Here `optionType` must be a valid second argument of the `testtype` function or a procedure that returns TRUE (or an expression that can be evaluated to TRUE by the `bool` function) for arguments of the valid type. If you want to specify `optionTypes`, you also must explicitly specify `ErrorOnUnexpected`.

# prog::getOptions

---

## **Return Values**

List that contains a table and a list. The table contains all valid options of the calling procedure and their values. For expected options that are not specified in the procedure, the values are their default values. The list contains all unexpected arguments in the procedure.

## **See Also**

## **MuPAD Functions**

testtype

**Purpose** Loading objects

**Syntax** prog::init(object)

**Description** prog::init(object) initializes the MuPAD object object.

Almost all MuPAD objects (domains, procedures etc.) are loaded into memory at their first use. This mechanism saves a lot of memory and time while starting MuPAD. Most of the MuPAD objects are not needed in a given session and would only fill up the system.

This strategy is transparent with respect to the usage of MuPAD objects. On slower computers, you may notice a delay on the first use of a function or domain.

Using Pref::verboseRead, you can make MuPAD print information on files loaded automatically.

**Examples** **Example 1**

Initializing all objects from any additional MuPAD library increases the memory requirements. For example, you can initialize the object from the linalg library:

```
bytes()
522304, 815604, 2147483647
```

```
prog::init(linalg):
```

Check the memory usage again:

```
bytes()
15990660, 16507016, 2147483647
```

# prog::init

---

## Example 2

Using `Pref::verboseRead`, we obtain information on what is loaded by the system:

```
reset():
Pref::verboseRead(2):
prog::init(prog::trace)

loading package
'prog' [lib/] reading file lib/PROG/checkini.mu reading file lib/PR
```

## Parameters

### object

MuPAD object to initialize or option `All`

## Options

### All

Initializing all MuPAD objects

With this option (instead of some MuPAD object), all MuPAD objects will be initialized.

## Return Values

`prog::init` returns the void object `null()`.

## See Also

## MuPAD Functions

`loadproc` | `Pref::verboseRead` | `prog::check`

**Purpose** Information about reserved identifiers

**Syntax** `prog::isGlobal(ident)`

**Description** `prog::isGlobal(ident)` checks whether the identifier `ident` is “used by the system”. Here, “used by the system” means that `ident` is an environment variable (e.g., `PRETTYPRINT`), a system-wide constant (e.g., `PI` or `undefined`), an option (for some function call, e.g., `All`), or a system function (such as `sin`).

The most of those identifiers are protected (see `protect`).

## Examples **Example 1**

Assume you would like to use some identifiers as options for a new function you wrote. In this example, we will check the elements of the list `[All, Beta, Circle, D, eval, First]` for suitability. (Note that `eval` would not be a good choice, even if it was not a system function, because options should start with a capital letter.)

We define a test function which is mapped to the list and returns `FAIL`, if the tested object is not an identifier, `TRUE`, if the identifier is used by the system and `FALSE` otherwise:

```
LIST:= [All, Beta, Circle, D, eval, First]:
map(LIST, X -> if domtype(X) <> DOM_IDENT then
 X = FAIL
 else
 X = prog::isGlobal(X)
 end_if)
```

`[All = TRUE, Beta = FALSE, Circle = FALSE, D = FAIL, eval = FAIL, First = TRUE]`

The identifiers `All` and `First` can be used as options because they have already been protected by the system (actually, they are already used as options, which makes them a good choice), the identifiers `Beta` and `Circle` are free and one must only take care that they have no value if

# prog::isGlobal

---

they will be used as options—they should be protected first. `D` and `eval` have values and cannot be used as options.

## Parameters

**ident**

Identifier to check

## Return Values

`prog::isGlobal` return TRUE, if the given identifier is used by the system, otherwise FALSE.

## See Also

## MuPAD Functions

`prog::check` | `anames` | `type` | `domtype`

**Purpose** Hardware independent time unit

**Syntax** `prog::ntime()`

**Description** `prog::ntime()` returns a time unit that represents roughly the speed of the current machine *for typical library programs*.

`prog::ntime` can be used to perform timing tests of typical MuPAD library programs on different machines.

`prog::ntime` uses a mix of different operations to calculate the time factor.

One call to `prog::ntime` takes about 1.5 seconds.

A real timing value must be divided by the value of `prog::ntime`, to get a machine independent timing value.

**Examples**      **Example 1**

On this machine, a timing must be divided by the value of `prog::ntime`, then the timing is comparable with the timing of the same code on another machine, also divided by the value of `prog::ntime` on the other machine:

```
prog::ntime()
```

```
0.7052155095
```

**Return Values** Floating point number

**See Also**

**MuPAD Functions**      `time` | `prog::testinit`

# prog::profile

---

**Purpose** Display timing data of nested function calls

**Syntax** `prog::profile(stmt)`

**Description** `prog::profile(stmt)` evaluates the MuPAD statement `stmt` and displays timing data of all nested function calls, additionally a graph with the calling structure.

`prog::profile` measures and displays the time usage of *library functions*. Kernel functions are not measured. For every function called during the evaluation of `stmt`, `prog::profile` prints the time spent in this function and the number of calls.

`prog::profile` can be helpful in finding time critical functions and unnecessary nested function calls.

`stmt` could be reading a whole test file, too.

A trick to observe also kernel functions is to call `prog::trace` with the kernel function as argument. `prog::trace` takes a library wrapper procedure around the kernel function, that has the same name and can be found in the output of `prog::profile`, when the kernel function is used during the evaluation of `stmt`. The time use of the wrapper function is nearly zero.

The first part of the output is a table with the timing values for each procedure, the second part is a graph, that presents information about the dependences between all measured functions, when `stmt` is evaluated.

The table contains several columns that are described below.

Each row shows all data of one function (called “the function”), that was measured by `prog::profile`. There is one special entry: The first entry is called `procedure entry point`. It shows the sum of all functions and represents the evaluation of `stmt`.

- "percent usage of all"

the time spent in the function with respect to the whole time used for the evaluation of `stmt` (in percent)

- "time self per single call"  
the value "time self" divided by the sum of all calls of the function (in milli seconds)
- "time self"  
the whole time spent *in the body* of the function, i.e., the sum of all calls, without the time, used by all other measured functions called by the function (in milli seconds)
- "time children per single call"  
the value "time children" divided by the sum of all calls of the function (in milli seconds)
- "time children"  
the sum of *all time* (self and children) spent in all functions that are called by the function directly
- "calls/normal exit"  
number of all calls of the function that leave the function without errors
- "calls/remember exit"  
number of all calls of the function that return a remembered value by the kernel remember mechanism (and does not call the function body)
- "calls/errors"  
number of all calls of the function that leave the function with an error
- ["[index] function name"]  
the index of the function (assigned by prog::profile) and the name of the function

An index is assigned to each function, in descending order of time usage, to identify and find the function in the call graph that is described now.

The second part of the output of `prog::profile` is a dependence graph. It shows each function, their parents (functions that call the function directly), and their children (functions that are called from the function directly), together with timing information and the number of calls.

Each part of the graph that is separated by horizontal lines of minus chars, belongs to one function. It contains several columns:

- "index"  
the index, assigned unique to the function
- "%time"  
the percentage of the function on the whole run time
- "self"  
the sum of all times used by the function (in milli seconds)
- "children"  
the sum of all times used by the children of the function (in milli seconds)
- "called"  
the number of all calls of the function
- ["[index] name"]  
the index and the name of the function

There are two kinds of entries: the function that belongs to the part has its index in the first column of the part, and in this column, only their name is printed.

All other functions (parents and children of the function) are only printed in this column with their index and name together, with small indentation for highlighting the function that belongs to the part.

The parents are located above the function itself, all children are written below the line with the function, the part belongs to.

For a more detailed explanation of the lines in a graph part see the first example.

## Examples

### Example 1

We define three functions f, g and h. prog::profile displays the time spent in each function and the number of calls to it:

```
f := proc()
 local t;
 begin
 t := time();
 while time() < 10 + t do nothing end_while
 end_proc:
g := proc()
 local t;
 begin
 f();
 t := time();
 while time() < 10 + t do nothing end_while;
 f()
 end_proc:
h := proc() begin g(), f(), g() end_proc:
```

```
prog::profile(h()):
```

percent usage of all single call	children per single call	percent usage of all single call	[index]	func. name	calls/errors	calls/remember	calls/normal	exit	time self	per	time chil
100.0	70.0	70.0	.	.	1	.	.	[0]	proc.	entry	pt
71.4	10.0	50.0	.	.	5	.	.	[1]	f	28.6	10.
20.0	20.0	40.0	2	.	[2]	g	.	.	.	.	70.

# prog::profile

```

70.0 1 . . [3] h -----
index %time self children called [index] name -----
[0] 100.0 70 0 1 proc. entry point
 0 70 1 [3] h -----
 40 0 4 [2] g
 10 0 1 [3] h [1] 71.4
 50 0 5 f -----
 20 40 2 [3] h [2]
28.6 20 40 2 g
40 0 4 [1] f -----
[3] 0.0 0 70 1 h
 10 0 1 [1] f
20 40 2 [2] g -----
Time sum: 70 ms

```

(The output is shortened slightly, because the page is too small.)

The lines of the table above are described following:

```

percent usage of all | time self per
single call | | time self | | time
children per single call | | calls/normal exit | | time childre
| | | | | calls/remember exit | | | |
| | | | | calls/errors | | | |
| | | [index] funct. name -----
100.0 70.0 70.0 . . 1 . . [0] proc. entry pt.

```

The whole function call takes 100 percent of the time (certainly), 70.0 milli seconds and is called once (the evaluation of stmt), without an error.

```

71.4 10.0 50.0 . . 5 . .
[1] f

```

Function `f` takes 71.4 percent of all evaluation time in its body. It uses 10.0 milli seconds per call on the average (in this case exactly), their children (if existing) uses no time measurable (because it has no children), and it is called 5 times and returns without errors. `f` has the index 1.

```
28.6 10.0 20.0 20.0 40.0 2 . .
[2] g
```

Function `g` takes 28.6 percent of the whole time that are 20.0 milli seconds, and 10.0 milli seconds on the average per call. Their children uses 20.0 milli seconds pre call on the average and 40.0 total, and `g` is called twice and returns without errors. `g` gets the index 2.

```
. . . 70.0 70.0 1 . .
[3] h
```

Function `h` uses nearly no evaluation time, their children uses 70.0 milli seconds on the average and 70.0 total, and `h` is called once and finished without errors. `h` gets the index 3.

The parts of the graph above are described following:

```
index %time self children called
[index] name -----
[0] 100.0 70 0 1 proc entry point
 0 70 1 [3] h -----
```

The whole function call takes 100 percent of the evaluation time (by definition), that are 70.0 milli seconds, and it is called once.

It calls once the function `h` with index [3] (as argument of `prog::profile`), and `h` uses 70.0 milli seconds of the time that are spent in the children of `h`, not in the body.

```
index %time self children called
[index] name -----
 40 0 4 [2] g
```

# prog::profile

---

```
 10 0 1 [3] h [1] 71.4
 50 0 5 f -----
```

Function `f` spends 71.4 percent of the whole evaluation time. It uses 50.0 milli seconds, their children uses no time measurable, and it is called 5 times.

`f` has two parents and no children.

`f` is called by its parent `g` 4 times and by `h` once.

`f` spends 40 milli seconds by itself (in its body), when it is called from `g` (the first line in the part of `f`), and `f` spends 10 milli seconds in its body, when it is called from `h` (the second line).

```
index %time self children called
[index] name -----
 28.6 20 40 2 [3] h [2]
40 0 4 [1] f -----
```

Function `g` takes 28.6 percent of the whole time, 20 milli seconds in its body, and their children take 40 milli seconds. `g` is called twice.

`g` is called from `h` twice, and spends 20 ms in its body and 40 ms in its children.

`g` calls the function `f` four times, and `f` spend 40 ms in its body, when it is called from `g`.

```
index %time self children called
[index] name -----
 0.0 0 70 1 h
 10 0 1 [1] f
20 40 2 [2] g -----
```

Function `h` takes nearly no evaluation time, their children spends 70.0 milli seconds, and `h` is called once.

`h` calls the functions `f` and `g` directly, `f` once and `g` twice.

f uses 10 ms in its body, when it is called from h, and g uses 20 ms in its body and 40 ms in its children.

## Parameters

**stmt**

A MuPAD statement

## Return Values

Result of `stmt`

## Algorithms

The timings displayed by `prog::profile` are generated by the kernel.

The evaluation of `stmt` inside `prog::profile` takes partly substantially longer than evaluating `stmt` directly. This extra time does not influence the validity of the timings, i.e., if `prog::profile` reports `f` taking three times as long as `g`, then this is also the case when evaluating `stmt` directly.

## MuPAD Functions

`prog::trace` | `time`

# prog::remember

---

<b>Purpose</b>	Extended remember mechanism for procedures
<b>Syntax</b>	<code>prog::remember(f, &lt;depends&gt;, &lt;PreventRecursion, &lt;predef&gt;&gt;)</code>
<b>Description</b>	<p><code>prog::remember(f)</code> returns a modified copy of the procedure <code>f</code> that stores previously computed results and additional information in a remember table. When you call <code>f</code> with arguments that you already used in previous calls, <code>f</code> finds the results in its remember table and returns them immediately.</p> <p>If you assign <code>f</code> to an identifier or a domain slot, you also must assign the copy returned by <code>prog::remember</code> to the same identifier or slot, for example, <code>f := prog::remember(f)</code>.</p> <p><code>f :=prog::remember(f)</code> remembers results without context information, such as properties or the value of <code>DIGITS</code>. The first time you call <code>f</code> with any new combination of input parameters, the remember table of <code>f</code> stores <code>`input` -&gt; `f(input)`</code>. After that, when you call <code>f</code> with the same input parameters, it takes the result <code>f(input)</code> from the remember table instead of recomputing it. See “Example 1” on page 26-44.</p> <p><code>f := prog::remember(f, depends)</code> remembers results and additional context information. The dependency function <code>depends</code> lets you specify the context information to store along with computed results in the remember table and verify in each function call. See “Example 2” on page 26-44.</p> <p>Typically, it is useful to store and verify properties of the input and the values of <code>DIGITS</code> and <code>ORDER</code>. To access properties of the input, use <code>property::depends</code>. This dependency function verifies all three values:</p> <pre>( ) -&gt; [property::depends(args()), DIGITS, ORDER]</pre> <p>Another common problem is that an overloading function does not register when its overloading slot changes in some other function or domain. This dependency function that uses <code>slotAssignCounter</code> lets you avoid this problem:</p>

```
() -> [property::depends, slotAssignCounter("foo")]
```

To combine all three tasks, use this dependency function:

```
() -> [property::depends(args()),
 DIGITS, ORDER, slotAssignCounter("foo")]
```

The first time you call `f` with any new combination of input parameters, the remember table of `f` stores `[input, depends(input)] -> f(input)`. After that, when you call `f` with the same input parameters, it checks whether `depends(input)` returns the same value as before. If it does, then `f` takes the result `f(input)` from the remember table. Otherwise, it computes `f(input)` and adds the new values `[input, depends(input)] -> f(input)` to the remember table. The only exception to this rule is results computed with different values of `MAXEFFORT`. If in previous calls `f(input)` was computed with lower `MAXEFFORT`, then the new call with higher `MAXEFFORT` is evaluated and remembered results are replaced with the new ones.

If the dependency function is constant or returns the value that does not depend on the input, then the remember mechanism disregards context information.

You can call the modified procedure with the `Remember` option as the first argument, and one of these special options as the second argument:

- `Clear` clears the remember table of the procedure.
- `ClearPrevent` clears the remember table that prevents infinite recursions inside the procedure. For details about preventing infinite recursions, see the description of the `PreventRecursion` option.
- `Print` returns the remember table of the procedure.

For example, the call `f(Remember, Clear)` clears the remember table of `f`. Also see “Example 3” on page 26-46.

# prog::remember

---

## Examples

### Example 1

Create this function:

```
f := X -> if X > 1 then f(X - 1)*f(X - 2) - f(X - 2) else 1 end_if:
```

Calling this function is time-consuming because the function calls itself recursively and evaluates every call:

```
f(20), time(f(20))
```

```
0, 3260.204
```

Using the remember mechanism eliminates these reevaluations. To enable the remember mechanism, use `prog::remember`:

```
f := prog::remember(f):
```

```
f(200), time(f(200))
```

```
0, 0.0
```

### Example 2

Create the procedure `pos` that checks if its parameter is positive:

```
pos := proc(x)
 begin
 is(x > 0)
 end_proc:
```

Enable the remember mechanism for `pos`:

```
pos := prog::remember(pos):
```

`pos` returns UNKNOWN for variable `a`:

```
pos(a)
```

```
UNKNOWN
```

Now use `assume` to specify that variable `a` is positive:

```
assume(a > 0):
```

When you call `pos` for variable `a`, it finds the value of `pos(a)` in the remember table. In this case, the remember table does not store the context information, and therefore does not check for the new assumptions on variable `a`. It returns the remembered result, which is incorrect because of the new assumption:

```
pos(a)
```

```
UNKNOWN
```

Calling `pos` for `a^3` returns the correct result because `pos(a^3)` is not in the remember table yet:

```
pos(a^3)
```

```
TRUE
```

Assume that `a` is negative:

```
assume(a < 0):
```

Now both calls return incorrect values because the results are taken from the remember tables:

```
pos(a), pos(a^3)
```

## prog::remember

---

UNKNOWN, TRUE

To make the remember mechanism aware of the changes in assumptions, use `prog::remember` with the second argument `property::depends` as the dependency function:

```
unassume(a) :
pos := proc(x)
 begin
 is(x > 0)
 end_proc :
pos := prog::remember(pos, property::depends) :
pos(a)
```

UNKNOWN

Now `pos` reacts properly to the new assumption:

```
assume(a > 0) :
pos(a)
```

TRUE

`pos` also returns the correct result after you clear the assumption:

```
unassume(a) :
pos(a)
```

UNKNOWN

### Example 3

Create the procedure `pos` and enable the remember mechanism for it:

```
pos := proc(x)
 begin
 is(x > 0)
 end_proc:
pos := prog::remember(pos, getprop):
```

Call `pos` for these parameters:

```
pos(a):
assume(b > a, _and):
pos(b):
```

After you call the procedure at least once, it creates the remember table. To see the remember table of a procedure, use the special option `Print`. The value  $10^6$  in the second column is the value of `MAXEFFORT` used during computations.

```
pos(Remember, Print)
```

$[\text{pos}(a), [\mathbb{C}, 0]]$	$[\text{UNKNOWN}, 1000000.0]$
$[\text{pos}(b), [(a, \infty), 0]]$	$[\text{UNKNOWN}, 1000000.0]$

To clear the remember table of a procedure and thus force the function to reevaluate all results, use the special option `Clear`:

```
pos(Remember, Clear):
pos(b)
```

UNKNOWN

#### Example 4

Create the procedure `deps` that collects all operands of the properties of a given expression, including the identifiers of assumed properties:

## prog::remember

---

```
deps := proc(x)
 begin
 if domtype(x) <> DOM_IDENT then
 op(map(indets(x), deps))
 else
 x, deps(getprop(x))
 end_if
 end_proc:
```

Set the following assumption. Note that now `deps` contains potentially infinite recursions because the property of `x` refers to `y`, and the property of `y` refers back to `x`:

```
assume(x > y):
```

```
deps(x)
```

Error: Recursive definition [See ?MAXDEPTH]

To prevent infinite recursions, use `prog::remember` with the `PreventRecursion` option:

```
deps := prog::remember(deps, PreventRecursion):
deps(x)
```

*x, y, x*

To simplify the return value of `deps`, rewrite the function so that it returns a set of all identifiers:

```
deps := proc(x)
 begin
 if domtype(x) <> DOM_IDENT then
 _union(op(map(indets(x), deps)))
 else
 {x} union deps(getprop(x))
 end_if
 end_proc:
```

```

 end_if
 end_proc:
deps := prog::remember(deps, PreventRecursion):

deps(x)

{x, y} ∪ x

```

Now `deps` expects the return value to be a set. By default, when recursion is detected, the procedure returns the value of its input (which is not a set in this example). When preventing recursion in a procedure where the type of the input differs from the type of the return value, specify the value `predef` that the procedure returns when recursion is detected:

```

deps := proc(x)
 begin
 if domtype(x) <> DOM_IDENT then
 _union(op(map(indets(x), deps)))
 else
 {x} union deps(getprop(x))
 end_if
 end_proc:
deps := prog::remember(deps, PreventRecursion, () -> {args()}):

```

Here `predef` returns a set with the input as an operand:

```

deps(x)

{x, y}

```

## Parameters

**f**

A procedure or function environment

**depends**

A procedure or expression

**predef**

A procedure or expression

**Options****PreventRecursion**

With this option, the procedure returned by `prog::remember` uses remembered information to prevent infinite recursion inside the procedure.

`f := prog::remember(f, PreventRecursion, predef )` stores the input parameters only during the function call. This approach lets you avoid reevaluating the same function call when the function calls itself recursively. Instead, it returns the input (by default) or the result of the call `predef(input)` (if you specify `predef`). If returning the input is not an appropriate result for the function call (for example, if the return value of `f` and the input are of different types), then you must specify the value `predef`. See “Example 4” on page 26-47.

At the end of the function call, all remembered values are discarded. If you call the function with the same input parameters again, the function call is evaluated with the same costs as before.

You can prevent recursion inside the function call and simultaneously use the remember mechanism outside the function call by using this syntax: `f := prog::remember(f, depends, PreventRecursion, predef )`. If you want to use the remember mechanism with the context information, specify the dependency function `depends` as usual. If you want to use the remember mechanism without the context information and prevent recursions inside a procedure, specify `depends` as a constant (or any function whose return value does not depend on the input). Note that if you omit the `depends` function and just use the syntax `f := prog::remember(f, PreventRecursion,`

`predef` ), then the remember mechanism does not work outside the function call. In this case, you only prevent recursions.

## Return Values

Modified procedure or function environment

## MuPAD Functions

`proc` | `property::depends` | `slotAssignCounter`

## Concepts

- “Remember Mechanism”

# prog::sort

---

**Purpose** Sort objects by an index function

**Syntax** `prog::sort(list, func, <Reverse>, <p1, p2, >)`

**Description** `prog::sort(list, func)` applies the function `func` to any object of the list `list` and returns a list with the given objects sorted by the order of the indices calculated by `func`.

`func` is applied only once to any object in `list`.

If optional arguments are present, then the indices are computed from the objects `x` of `list` by `f(x, p1, p2, ...)`.

An alternative call to `prog::sort` is the call `sort(list, (X, Y) -> func(X) <= func(Y))`.

## Examples

### Example 1

Sort a list of expressions by their length:

```
prog::sort([2*x, x - 4, sin(x), x + y + z], length)
```

```
[sin(x), 2 x, x + y + z, x - 4]
```

Sort a list of lists by the number of operands, with descending order:

```
prog::sort([[1,2,3],[4,2],[0 $ 10],[]], nops, Reverse)
```

```
[[0, 0, 0, 0, 0, 0, 0, 0, 0, 0], [1, 2, 3], [4, 2], []]
```

## Parameters

**list**

A list of MuPAD objects

**func**

A function that must return a numerical value, when applied to any object of the list

**Reverse**

An option

**p1, p2, ...**

Any MuPAD objects accepted by `func` as additional parameters

**Options**

**Reverse**

`prog::sort` compares the calculated indices in reverse order.

**Return Values**

List with the same objects as the given list

**See Also**

**MuPAD Functions**

`sort` | `sysorder` | `stringlib::order`

## Purpose

Report on test coverage (passed program lines)

## Syntax

```
prog::tcov(Reset)
prog::tcov(<stmt>, Write = fname)
prog::tcov(Append = fname)
prog::tcov(<stmt>, Info, <Summary>, <Lines>,
<Hidden>, <Unused>, <All>)
prog::tcov(<stmt>, Annotate, <Path = pname>,
<Comment = comment>)
prog::tcov(<stmt>, Export = fname, <Annotate>, <Path =
pname>, <Comment = comment>, <Graphical>)
```

## Description

`prog::tcov` inspects the data on the statements executed in library code. MuPAD collects these data if you start the MuPAD engine with the option `-t`. To set different options for starting the MuPAD engine, use the **Arguments** field in the Engine dialog.

You can use `prog::tcov` in two different modes:

- With a given first argument `stmt`, `prog::tcov` resets all `tcov` information, evaluates the statement, and shows all debug node passes for this statement during the evaluation. `prog::tcov(stmt)` clears all information about the debug node passes of current session.
- Without the first argument `stmt`, `prog::tcov` shows the debug node pass information collected by the MuPAD engine during the whole session.

You can display the logged debug node passes on the screen or export the data to an HTML file. You also can save the data about the debug node passes to a file, which enables you to read or recover a whole session state later.

`prog::tcov` can produce annotated source files containing the information collected by `prog::tcov` and the MuPAD source code.

## Environment Interactions

prog::tcov can produce screen outputs.

If you use the Annotate option, prog::tcov creates new files. For some operating systems creating new files might require special permissions.

## Examples

### Example 1

To use prog::tcov, start the kernel in tcov mode with option -t.

The outputs in the following examples are cropped in this documentation.

The following example shows a short procedure created and called inside prog::tcov. The line numbers correspond to the ones in the Debugger:

```
f:= // 1
proc(a, b) // 2
begin // 3
 if a > b then // 4
 return(a) // 5
 else // 6
 return(f(b, a)) // 7
 end_if // 8
end_proc: // 9
```

prog::tcov returns all the lines passed during the evaluation of f:

```
prog::tcov(f(2, 1), Info, Lines)
```

```
File: /tmp/debug0.5932 Use index: 50%
Nodes: 2/4 (0 hidden) Passes: 2 Line 4,0:
1 pass Line 5,0: 1 pass
```

```
prog::tcov(f(1, 2), Info, Lines)
```

```
File: /tmp/debug0.5932 Use index: 75% Nodes:
3/4 (0 hidden) Passes: 4 Line 4,0: 2 passes
Line 5,0: 1 pass Line 7,0:
pass
```

## Example 2

The following example shows the logging of passes during a session. Before running this example, define the function `f` from “Example 1” on page 26-55.

If you start the kernel with the option `-v`, the `expose` command shows the debug nodes with pass information.

`prog::tcov(Reset)` resets all `tcov` information:

```
prog::tcov(Reset):
prog::tcov(Info)
```

```
SUMMARY Files
 : 1 in 1 libraries Nodes : 0/4 (0 hidden) Use index : 0%
 Passes : 0 (~ 0.00 passes per all nodes)
```

If you call the function `f` twice, the number of passes doubles:

```
f(1, 2): f(1, 4): prog::tcov(Info)
```

```
File: /tmp/debug0.5932 Use index: 75%
Nodes: 3/4 (0 hidden) Passes: 8 Line 4,0:
4 passes Line 5,0: 2 passes Line
7,0: 2 passes
```

To see the passes, expose the function `f`:

```
expose(f)
```

```
proc(a, b) name f; begin // /tmp/debug0.5932:4,0 [4 passes]
 if b < a then // /tmp/debug0.5932:5,0 [2 passes];
 return(a) else // /tmp/debug0.5932:7,0 [2 passes];
 return(f(b, a)) end_if; // /tmp/debug0.5932:9,0 [0 passes]
end_proc
```

You can write the tcov data to a data file:

```
prog::tcov(Write = "tcov_example.dat"):
```

To delete the information about the previous passes, use the `Reset` option:

```
prog::tcov(Reset):
prog::tcov(Info)
```

```
SUMMARY Files
: 1 in 1 libraries Nodes : 0/4 (0 hidden) Use index :
Passes : 0 (~ 0.00 passes per all nodes)
```

To retrieve the former state, use the `Append` option:

```
prog::tcov(Append = "tcov_example.dat"):
prog::tcov(Info, Summary)
```

```
SUMMARY
Files : 1 in 1 libraries Nodes : 3/4 (0 hidden) Us
index : 75% Passes : 8 (~ 2.00 passes per all nodes)
```

Also, you can use the `Append` option to add the passes:

```
prog::tcov(Append = "tcov_example.dat"):
prog::tcov(Info, Summary)
```

```
SUMMARY
Files : 1 in 1 libraries Nodes : 3/4 (0 hidden) Us
index : 75% Passes : 16 (~ 4.00 passes per all nodes)
```

### Example 3

The following example presents incomplete pieces of code. Note that you cannot execute this example without additional code lines.

Suppose, you have a source file with the following function:

```
1: f := proc(a, b)
2: begin
3: if a > b then
4: return(a)
5: elif a = b then return(0)
6: else
7: f(b, a)
8: end_if
9: end_proc:
```

Before executing this source file, read the commands. After reading commands, all the objects defined in the source file are available in the notebook. Calling the function `f` several times and creating the annotated source file, you get:

```
f(2, 1): // passing the lines 3 and 4
f(1, 1): // passing the lines 3 and 5 twice, because line 5 has two
f(1, 2): // passing the lines 3, 5 and 7 and the recursively 3 and
 // because the statement in line 7 has no return
prog::tcov(Annotate)
```

The annotated source file uses the same path as the source file and looks like this:

```
// Generated by prog::tcov session

1: f := proc(a, b)
2: begin
3:4 if a > b then
4:2 return(a)
5:2 elif a = b then return(
5:1 0)
6: else
7:1 f(b, a)
8: end_if
```

```
9:1 end_proc:
```

Note that the line 5 contains two debug nodes and appears in two lines. The line splits where the second debug node starts.

For better readability of the annotated source files, use the HTML export.

## Parameters

### **stmt**

Any MuPAD statement or MuPAD expression

### **fname**

A file name given as a string

### **pname**

A directory name given as a string

### **comment**

Any string

## Options

### **Reset**

Reset the number of passes at each debug node to 0.

### **Write**

Option, specified as `Write = fname`

This option allows you to write the information about all debug node passes of the current session to the file `fname`. You can use this file for external analysis (see the Algorithms section) or to recover or merge the information collected by `prog::tcov` (see the Append option).

### **Append**

Option, specified as `Append = fname`

Append all information about debug node passes from the file `fname` to the current session.

This option allows you to merge the data generated during several sessions.

## **Info**

Display the information about debug node passes.

## **Summary**

Display only a short summary.

## **Lines**

Display each pass through a debug node.

## **Unused**

Display all code lines with debug nodes, including unpassed ones.

## **Hidden**

This option allows you to display the hidden debug nodes. A hidden debug node is a node in a procedure with the noDebug option.

## **All**

Display unpassed and hidden debug nodes.

## **Export**

Option, specified as `Export = fname`

This option allows you to display the debug node passes information in summary for all read source files and for all individual source files.

The information is ordered according to the names of the directories containing the source files. Directory names can be folded.

You can see the list of all the files of a library below each library name.

Each file name presents a link that points to the annotated source file.

You can select graphical indices. Each point leads to the related line in the annotated source file.

**Annotate**

This option allows you to rewrite each executed MuPAD source file `filename.mu` as `filename.tcov` with an annotation at the beginning of each line. The annotation contains the line number of a debug node and the number of passes of this line, followed by the source code.

In text mode the line containing several debug nodes splits so that each line contains one debug node (see “Example 3” on page 26-57).

The new files have the extension `.tcov` instead of `.mu`. See also option `Path`.

If this option is used together with `Export`, `prog::tcov` creates the annotated source files as HTML files with the extension `.tcov.html`. The line colors depend on the passes.

**Path**

Option, specified as `Path = pname`

This option allows you to specify a path `pname` to the annotated source files and the exported status file. If you do not specify the path, `prog::tcov` creates the files in the same directory where the source files are.

**Comment**

Option, specified as `Comment = comment`

This option allows you to write the string `comment` on the first line of each annotated source file (see the option `Annotate`) or in the header of an exported HTML file (see the option `Export`).

**Graphical**

Show a graphical index for each source file in an HTML export file.

## Return Values

`prog::tcov` returns the void object `null()` of type `DOM_NULL`.

## Algorithms

To be able to use the `prog::tcov` function, start the MuPAD engine with option `-t`. Use the *Arguments* field in the Engine dialog to set this option.

If you start the kernel using both options `-v` and `-t`, the function `expose` shows information about the debug node and passes (see “Example 2” on page 26-56).

The functionality of `prog::tcov` depends on the internal debugger. For details, see the help page for the `debug` command.

Some special considerations:

- If the MuPAD library is read from a tar archive (file `lib.tar`), `prog::tcov` excludes from inspection all the files from this archive. The output of `prog::tcov` also includes the call of `prog::tcov` itself and some other MuPAD utility function passes.
- `prog::tcov` counts only the lines containing a “debug node”.

When called with the option `Write` or the option `Append`, `prog::tcov` creates a data file using the following format: `"filename":fileindex:.` For each read MuPAD source file, “filename” is the name of the source file and `fileindex` is a numerical index. For temporary files, the index is negative:

- `-1:-1:`

The colon separates the first and the second parts:

- `fileindex:line:column:hidden:passes:unused:`

For each debug node, `fileindex` corresponds to the first part, `line` and `column` determine the start of the debug node in the source file, `hidden` is 1 for hidden nodes, otherwise 0, `passes` is the number of passes, `unused` is an empty and currently unused string.

# prog::test

---

## Purpose

Automatic comparing of calculation results

## Syntax

```
prog::test(stmt, res | TrapError = errnr, <Timeout
= sec>, <message>, options)
prog::test(stmt)
```

## Description

`prog::test` works in two different modes: interactive and inside of test files.

In interactive mode a single call of `prog::test` can be used to compare two MuPAD statements.

The call `prog::test(stmt, res)` evaluates both arguments `stmt` and `res`. When the evaluation leads to exactly the same MuPAD object and no Enhancement was requested, nothing is printed and `prog::test` returns the void object `null()`.

If the results are different, the test fails and a message is printed.

The additional arguments are described in the following part for using `prog::test` in test files.

Another mode is using `prog::test` inside of test files. A test file must start with `prog::testinit`. This function initializes the test file. Then you can write several tests using `prog::test`. The last statement in a test file must be `prog::testexit()`. You also can specify the name of the tested procedure by using `print(Unquoted, "testname")` after `prog::testinit`. This name does not affect the tested procedure itself. It only appears in the test reports generated by your test script.

The tests can be arbitrary MuPAD statements and `prog::test` statements. However, most of the functionality should be executed as argument of `prog::test`. Only initialization of variables should be performed outside of `prog::test` statements in a test file, because `prog::test` traps every error (with the function `traperror`) and prints a specific error message.

---

**Note** If an error occurs outside of `prog::test`, reading of the test file is interrupted.

---

If no error occurs (as should be the default case), the results are compared and a message is printed, if they are different.

Timing information can be collected and compared that consider only the evaluation time of the first argument `stmt` of `prog::test` (see `prog::testinit`).

If a test fails, for example, the two first arguments of `prog::test` lead to different MuPAD objects, or if an enhancement request was given, `prog::test` prints a message. This message lists the following pieces of information:

- 1** The first line starts with the `Error in test` string and contains the name and a sequence number of the individual test.
- 2** The next three lines contain the input, the expected result, and the result actually observed.
- 3** For each of the options `Priority`, `Enhancement`, `Message`, `Developers`, and `BugId`, if the option has been set, a corresponding line will be printed. Note that `Message` can be set by simply providing a message string.

This information is followed by an empty blank line.

If only one argument is given, the argument is evaluated and compared with `TRUE`, i.e., `prog::test(ex)` is equivalent to `prog::test(ex, TRUE)`.

When a test is initialized with `prog::testinit` and ended by `prog::testexit`, a short message is printed with the following format:

```
Info: 20 test, 1 error, runtime factor 1.7 (expected 2.0)
```

The message contains the number of all tests performed (20), the number of errors (1), and two time factors: The first time factor is the based on the actual time of the test and the second time factor is the expected value given by `prog::testinit`.

## Examples

### Example 1

`prog::test` can be called interactively:

```
prog::test(1 + 1, 2):
prog::test(is(2 > 1)):
prog::test(sin(PI), 0, "check sin"):
```

These tests checked all right. In the next tests wrong results are tested against, to demonstrate the messages given by `prog::test`:

```
prog::test(1 + 2, 2):
```

```
Error in test 4
```

```
Input: 1 + 2
```

```
Expected: 2
```

```
Got: 3
```

```
Near line: 1
```

```
prog::test(is(x > 1)):
```

```
Error in test 5
```

```
Input: is(1 < x)
```

```
Expected: TRUE
```

```
Got: UNKNOWN
```

```
Near line: 1
prog::test(sin(PI), PI, "check sin"):
Error in test 6
Input: sin(PI)
Expected: PI
Got: 0
Message: check sin

Near line: 1
```

## Example 2

A test file must contain calls to `prog::testinit` and `prog::testexit`. In the following file, we test a function defined in the same file, which is rather uncommon, obviously.

```
// test file "test.tst"
test:= (a, b) -> a^2 + 2*b^2 - a*b:
prog::testinit("test", 0.1):
print(Unquoted, "testname"):
prog::test(test(1, 4), 29, Message = "my first example"):
prog::test(test(3, -2), 24, "the second example"):
prog::test(error("test"), TrapError = 1028):
prog::testexit():
```

The first statement is only a comment. The second line contains an initialization of a test procedure called `test`. Then the test is initialized with `prog::testinit`.

After that three tests are performed: The first test is right, the second expected result is wrong, and the third test produces an error, but the expected result is this error, the error number returned by `traperror` is 1028 (user call of error).

The whole test takes nearly no time:

```
read("test.tst")
Info: memory limit is 256 MB
Error in test 2
Input: test(3, -2)
Expected: 24
Got: 23
Message: the second example
Near line: 4
Info: time used outside of 'prog::test' takes 100%
Info: 3 tests, 1 error, runtime factor 0.0 (expected 0.1)
Info: CPU time: 1.1 s
Info: Memory allocation 9026800 bytes [prog::testexit]
```

### Example 3

Most of the options accepted by `prog::test` are more or less directly placed in the output:

```
prog::test(1+1, 1, Baseline, Message(2)="well ...",
 Priority=Low, BugId="123-456")
Baseline Error in test 1
Input: 1 + 1
```

```
Expected: 1
Got: 2
Priority: Low
Message: well ...
BugId: 123-456
Near line: 2
```

#### Example 4

To test that a certain call does not take longer than a specified number of seconds, use the option `Timeout`:

```
prog::test(prog::wait(5.0), null(), Timeout = 2)
```

#### Example 5

In most cases, the actual and the expected result are simply compared for equality. Sometimes, however, this is not desirable, especially for floating-point results:

```
prog::test(float(PI), 3.1415926535897932385)
```

```
Error in test 2
Input: float(PI)
Expected: 3.141592654
Got: 3.141592654
Near line: 1
```

The problem here is that there are many floating-point values which are not identical, yet are displayed as such (unless you increase `DIGITS` far

enough to see the difference). Using the option `Method`, you can provide a function to compare the values:

```
prog::test(float(PI), 3.1415926535897932385, Method = `~=`)
```

## Example 6

When implementing symbolic algorithms, there are often multiple correct and acceptable answers. In some cases, getting any of a certain set of solutions is fine. In these cases, using `Method = _in` is a reasonable way of writing tests (`_in` is the functional form of the `in` operator):

```
prog::test(int(ln(ln(a*x)^(1/2))), x),
 {
 x*ln(ln(a*x)^(1/2)) - Li(a*x)/(2*a),
 x*ln(ln(a*x))/2 - Li(a*x)/(2*a)
 },
 Method = _in,
 Timeout = 20)
```

Sometimes, however, while multiple results are acceptable, you are actually targeting for one particular output. For these cases, you can use `Enhancement` to set the golden goal:

```
prog::test((x^2+2*x+1)/(x+1),
 (x^2+2*x+1)/(x+1),
 Enhancement = x+1)
```

Enhancement request: 5

Input:  $(x^2 + 2x + 1)/(x + 1)$

Got:  $(x^2 + 2x + 1)/(x + 1)$

Requested:  $x + 1$

Near line: 3

If the enhancement request ever is fulfilled, the output changes:

```
prog::test(normal((x^2+2*x+1)/(x+1)),
 (x^2+2*x+1)/(x+1),
 Enhancement = x+1)
```

Enhancement done: 6

Input: normal((x^2 + 2\*x + 1)/(x + 1))

Got: x + 1

Requested: x + 1

Near line: 3

Note that a test with an enhancement request is, first and foremost, still an ordinary test and behaves as such:

```
prog::test((x^2+x+1)/(x+1),
 (x^2+2*x+1)/(x+1),
 Enhancement = x+1)
```

Error in test 7

Input: (x^2 + x + 1)/(x + 1)

Expected: (x^2 + 2\*x + 1)/(x + 1)

Got: (x^2 + x + 1)/(x + 1)

Near line: 3

### Example 7

Certain calls are expected to give warnings to the user:

```
numeric::quadrature(sin(1/x), x=0..1)
```

Warning: Precision goal is not achieved after 10000 function calls.

0.5040669411

Placing such calls into an unadorned call to `prog::test` causes the test to fail, because by default, `prog::test` expects the calls not to emit any warnings:

```
prog::test(
 bool(numeric::quadrature(sin(1/x), x=0..1) < 1),
 TRUE)
```

Error in test 8

Input: `bool(numeric::quadrature(sin(1/x), x = 0..1) < 1)`

Expected: TRUE

Got: TRUE

Expected warnings: []

Got warnings: [message("symbolic:numeric:PrecisionGoalNotReached")]

Near line: 3

Used Time: 0.615 (0.946\*prog::ntime())

To check for this warning, add `ExpectedWarnings` with the list shown above:

```
prog::test(
 bool(numeric::quadrature(sin(1/x), x=0..1) < 1), TRUE,
 ExpectedWarnings = ["Precision goal is not achieved after 10000"])
```

" function calls. Increase 'MaxCalls' and try again for a more

It is possible to abbreviate the expected warnings (and make tests robust against changes in places where they are expected) by using regular expression matching for the expected warnings (see `strmatch` for details on pattern matching):

```
prog::test(
 bool(numeric::quadrature(sin(1/x), x=0..1) < 1), TRUE,
 ExpectedWarnings = ["Precision goal is not achieved .* for a m
```

## Parameters

### **stmt**

A MuPAD statement to test

### **res**

A MuPAD expression or statement that determines the expected result.

### **message**

A message (a string) that is displayed if the test fails – see option `Message` below

## Options

### **TrapError**

Option, specified as `TrapError = errnr`

Expect the test to throw an error. `errnr` must be the integer expected from the call `traperror(stmt)` or a list of an integer and a string, as returned by `getlasterror()`.

### **Method**

Option, specified as `Method = comp`

A method used to compare the actual and the expected result. Will be called with both expressions and must return `TRUE` or `FALSE`.

### **Timeout**

Option, specified as `Timeout = sec`

# prog::test

---

A timeout for the evaluation of the tests. Both the actual and the expected result are evaluated with this time limit. If the computation takes too long, `prog::test` behaves as if the command had resulted in a timeout error (error number 1320).

## Message

Option, specified as `Message = message` or `Message(res1) = message`

Append a message (a string) to the output of `prog::test`. If `res1` is given, the message is given if the result of evaluating `stmt` is `res1`.

## Baseline

Mark this test as failing in some sort of “baseline,” to differentiate new bugs (stemming from new code developments, regression failures) from bugs already present in some specific earlier version. This affects the output of `prog::test`.

## Enhancement

Option, specified as `Enhancement = res1`

Request some other output than the one currently tested for. Semantically, a call of the form `prog::test(inp, out, Enhancement = out2)` means “check that the call `inp` results in the same thing as the call `out`, but note that we’d actually prefer to see `out2`.”

## ExpectedWarnings

Option, specified as `ExpectedWarnings = list`

Gives a list of warnings the call should emit, as strings. Not emitting these warnings, or additional ones, is considered an error.

## High, Low, Medium, Priority

Option, specified as `Priority = Low | Medium | High`

Denote the importance of this test. This will usually be a very subjective question and affects the output of `prog::test` only, to allow tools parsing the output displaying the problems of higher priority more prominently.

**Developers**

Option, specified as `Developers = devnames`

A string included in the output of `prog::test`, denoting the developers deemed responsible for the code tested. This is intended for post-processing tools.

**BugId**

Option, specified as `BugId = bugid`

Again, for the output of `prog::test`, include a reference to some bug tracking system. `bugid` can be any MuPAD object.

**Return Values**

`prog::test` returns the void object `null()`.

**See Also****MuPAD Functions**

`prog::testexit` | `prog::testinit` | `traperror`

# prog::testexit

---

**Purpose** Closing tests

**Syntax** prog::testexit()

**Description** prog::testexit closes automatic tests from test files and prints a short statistic about the test (see prog::test).  
prog::testexit closes the last opened protocol file.

---

**Note** prog::testexit must be called before beginning of a new test with prog::testinit.

---

**Return Values** prog::testexit returns the void object null() and closes the last opened protocol file.

**See Also**

**MuPAD Functions** prog::test | prog::testinit

**Purpose**

Initialize tests

**Syntax**

```
prog::testinit()
prog::testinit(string)
prog::testinit(expected_time, <All>)
prog::testinit(string, expected_time, <All>)
prog::testinit(arch = expected_time, , <All>)
prog::testinit(string, arch = expected_time, , <All>)
```

**Description**

The function `prog::testinit` initializes automatic tests (see `prog::test`).

The second argument `expected_time` determines the time, that the test should need.

---

**Note** This time is not the real time, but a time factor that is given by `prog::testexit` at the end of a complete test.

---

This time factor is computed to be independent of the real speed of the used machine.

In general (without option `All`) the base for the time factor is the sum of all times for the evaluation of the first arguments of each call of `prog::test`.

The time factor can be useful to detect differences of the run time of tests, e.g., when the system or programs were changed.

For tests which run time depends on the architecture of the computer, the expected test time factor can be given apart for each test system as equation `arch = time_factor`.

The string `arch` must be one of the results returned by the function `sysname`. `time_factor` is the time factor given by `prog::testexit` at the end of the complete test on the reference system.

# prog::testinit

---

## Examples

### Example 1

Initialize a test that should need a run time factor of 2.0:

```
prog::testinit("test1", 2.0):
```

Initialize a test that should need a run time factor of 2.8, where the time is measured between prog::testinit and prog::testexit:

```
prog::testinit("test2", 2.8, All):
```

Initialize a test that should need a run time factor of 12.0 on Linux and 15.5 on Windows:

```
prog::testinit("test3", "glnxa64" = 12.0, "win32" = 15.5):
```

## Parameters

### string

String: a test name

### expected\_time

Expected test time factor (see below) in seconds as floating point number

### arch

The computer architecture name as string (see sysname)

## Options

### All

The base for the time factor is the whole time between the command prog::testinit and prog::testexit.

## Return Values

prog::testinit returns the void object null().

**MuPAD  
Functions**

`prog::test` | `prog::testexit`

# prog::trace

---

**Purpose**            Observe functions

**Syntax**            prog::trace(obj, <Recursive = FALSE>)  
                      prog::trace({obj<sub>1</sub>, obj<sub>2</sub>, }, <Recursive = FALSE>)  
                      prog::trace(options)

**Description**        prog::trace(obj) manipulates the MuPAD object obj to observe entering and exiting this object.

---

**Note** prog::trace has a new syntax and a new set of options. The old syntax has been removed.

---

prog::trace lets you observe functions, domains, domain methods, and function environments. Use the prog::trace function for debugging. See “Example 1” on page 23-83.

prog::trace lets you specify a set of functions, domains, methods, or function environments that you want to observe. See “Example 2” on page 26-82.

prog::trace lets you observe the relations between calls to the traced objects.

To trace the object obj, use the function call prog::trace(obj). After that call, every time the function call enters or exits the object obj, MuPAD prints a message and returns the arguments and the return value of that call. See “Example 3” on page 26-83.

prog::trace lets you observe a domain or a function environment. When you call the prog::trace function for a domain, the function observes all methods of the domain. When you call prog::trace for a function environment, it observes all slots of the function environment. To trace only particular methods (slots), provide a set of these methods (slots). See the slot help page for more details. See “Example 8” on page 26-89.

To prevent tracing of all slots of a function environment, set the value of the `Recursive` option to `FALSE`. See “Example 7” on page 26-88.

The function `prog::untrace(obj)` terminates tracing of an object `obj`. Here `obj` is a function, a set of functions, a domain, a domain method, or a function environment. The function `prog::traced` detects whether the system currently traces a particular object.

## Examples

### Example 1

Define a function `f`, and observe this function:

```
f := x -> if x > 0 then x else -f(-x) end:
prog::trace(f):
f(-2)
```

```
enter f(-2)
 enter f(2)
 computed 2
 computed -2
```

-2

Change the function, and reassign the new function to `f`. Although you use the same function name (`f`), MuPAD does not trace the new function:

```
f := x -> if x > 0 then x else f(-x) end:
f(-2)
```

2

To trace the new function, call `prog::trace` again. Now, the trace mechanism observes the updated function:

```
prog::trace(f):
f(-2)
```

```
enter f(-2)
 enter f(2)
 computed 2
 computed 2
```

```
2
```

For further computations, stop observation of the function:

```
prog::untrace(f)
```

## Example 2

If you want to trace more than one function, use a set to specify these functions in one function call:

```
prog::trace({sin, cos, exp}):
sin(5*PI/2);
cos(5*PI);
exp(5)
```

```
enter sin((5*PI)/2)
 enter sin(PI/2)
 remembered 1
 computed 1
```

```
1
```

```
enter cos(5*PI)
```

```

 enter cos(PI)
 remembered -1
 computed -1

```

- 1

```

 enter exp(5)
 computed exp(5)

```

$e^5$

To stop observation of all functions, use `prog::untrace` without arguments:

```
prog::untrace()
```

### Example 3

Define a short function that calls itself recursively, and observe the calls:

```

fib:= proc(n)
 begin
 if n < 2 then
 n
 else
 fib(n - 1) + fib(n - 2)
 end_if
 end_proc:
prog::trace(fib):
fib(3)

enter fib(3)

```

## prog::trace

---

```
enter fib(2)
 enter fib(1)
 computed 1
 enter fib(0)
 computed 0
 computed 1
enter fib(1)
 computed 1
computed 2
```

2

To limit the number of the nested function calls displayed by `prog::trace`, use the `Depth` option. To specify the value of `Depth`, use a separate `prog::trace` function call:

```
prog::trace(fib):
prog::trace(Depth = 2);
fib(12)
```

```
enter fib(12)
 enter fib(11)
 computed 89
 enter fib(10)
 computed 55
 computed 144
```

144

The `Depth` option is independent of the `fib` procedure. Now, if you use `prog::trace` to trace any other procedure, `prog::trace` displays the nested calls to that procedure using `Depth = 2`. Remove this global option for further computations:

```
prog::untrace(fib):
prog::trace(Depth = 0)
```

#### Example 4

To display memory usage, use the Mem option:

```
prog::trace(Mem):
prog::trace(sin):
sin(3/2*PI)

enter
remember::sin((3*PI)/2) [mem: 3267052] enter remember::sin(PI/
[mem: 4033596] remembered 1 [mem: 4033436] computed -1 [mem: 4
-1
```

The Mem option is independent of the traced procedure. Now, if you use prog::trace to trace any other procedure, prog::trace displays memory usage in every step of that procedure. Remove this global option for further computations::

```
prog::untrace(sin):
prog::trace(Mem = FALSE)
```

#### Example 5

The NoArgs option suppresses the output of arguments of traced objects:

```
prog::trace(linalg):
prog::trace(NoArgs);
linalg::eigenvalues(matrix([[1, 0, 0],
 [0, -1, 2],
 [0, 1, 1]]))

enter linalg::eigenvalues
 enter linalg::checkForFloats
 return
 enter linalg::charpoly
 enter linalg::charpolyBerkowitz
```

```
 return
 return
return
```

```
{1, $\sqrt{3}$, $-\sqrt{3}$ }
```

The NoArgs option is independent of the traced procedure. Now, if you use `prog::trace` to trace any other procedure, `prog::trace` hides arguments in every step of that procedure. Remove this global option for further computations:

```
prog::untrace(linalg):
prog::trace(NoArgs = FALSE)
```

## Example 6

If you use the Parent option, `prog::trace` shows the name of the procedure that calls the traced object:

```
prog::trace(cos):
prog::trace(Parent):
f := x -> cos(2*x):
g := (x, y) -> f(x) + f(y):
g(3/2*PI, -3/2*PI)

enter cos(3*PI) (called from f)
 enter cos(PI) (called from cos)
 remembered -1
computed -1
enter cos(-3*PI) (called from f)
 enter cos(3*PI) (called from cos)
 remembered -1
computed -1
```

- 2

```
prog::trace(f):
prog::trace(g):
g(-PI, PI)
```

```
enter g(-PI, PI)
 enter f(-PI) (called from g)
 enter cos(-2*PI) (called from f)
 enter cos(2*PI) (called from cos)
 enter cos(0) (called from cos)
 remembered 1
 computed 1
 computed 1
 computed 1
 enter f(PI) (called from g)
 enter cos(2*PI) (called from f)
 remembered 1
 computed 1
 computed 2
```

2

The Parent option is independent of the traced procedures. Now, if you use `prog::trace` to trace any other object, `prog::trace` shows relations between calls to the traced objects. Remove this global option for further computations:

```
prog::untrace(cos):
prog::trace(Parent = FALSE)
```

## Example 7

By default, the `prog::trace` function traces all slots of a function environment. For example, trace the `besselJ` function and observe the following function call:

```
prog::trace(besselJ);
besselJ(1, 2.3)

enter besselJ(1, 2.3)
 enter besselJ::float(1, 2.3)
 computed 0.5398725326
 computed 0.5398725326
```

0.5398725326

To omit tracing of all slots, set the value of the `Recursive` option to `FALSE`:

```
prog::untrace(besselJ);
prog::trace(besselJ, Recursive=FALSE);
besselJ(1, 4.5)

enter besselJ(1, 4.5)
computed -0.2310604319
```

- 0.2310604319

For further computations, stop observation of the `besselJ` function:

```
prog::untrace(besselJ)
```

### Example 8

You can trace domains and domain methods. For example, create the following small domain:

```
T := newDomain("T"):
T::new := proc(h, m = 0) name T; begin new(T, h*60 + m) end:
T::intern := x -> [op(x) div 60, op(x) mod 60]:
T::print := x -> expr2text(T::intern(x)[1]).":".
 substring(expr2text(100 + T::intern(x)[2]), 2,
T::_plus := () -> new(T, _plus(map(args(), op))):
T::expr := op:
T::_mult := () -> new(T, _mult(map(args(), expr))):
prog::trace(T):
T(1, 30) + T(0, 45)*T(1, 05)
```

```
enter T(1, 30)
computed 1:30
enter T(0, 45)
computed 0:45
enter T(1, 5)
computed 1:05
enter T::_mult(0:45, 1:05)
computed 48:45
enter T::_plus(1:30, 48:45)
computed 50:15
```

50:15

MuPAD does not trace the process of displaying traced outputs. Therefore, the `T::intern` and `T::print` methods do not appear in the traced outputs.

Now, trace the arithmetic methods only. When specifying the methods to trace, use their slot names, such as `slot(T, "_plus")` or `T::_plus`:

```
prog::untrace():
prog::trace({T::_plus, T::_mult}):
T(1, 30) + T(0, 45)*T(1, 05)
```

```
enter T::_mult(0:45, 1:05)
computed 48:45
enter T::_plus(1:30, 48:45)
computed 50:15
```

```
50:15
```

```
prog::untrace():
```

## Parameters

### obj

A MuPAD function, a domain, a method, or a function environment to observe. Specify methods by their slot names (strings).

### {obj<sub>1</sub>, obj<sub>2</sub>, ...}

A set of MuPAD functions, domains, methods, or function environments to observe.

## Options

### Depth

Option, specified as `Depth = level`

Display nested function calls only up to the recursion depth `level`. Here `level` is a positive integer. After you set this option, all new and regenerated outputs for traced objects show the nested function calls only up to the specified recursion depth. See “Example 3” on page 26-83.

### Mem

Show the current memory usage. After you set this option, all new and regenerated outputs for traced objects show the information about the current memory usage. See “Example 4” on page 26-85.

**NoArgs**

Do not show the arguments of calls to traced objects and the returned values. Without this option, all outputs for traced objects show the arguments and returned values for each call of a traced object. See “Example 5” on page 26-85.

**Parent**

Show the name of the procedure that calls the traced object. After you set this option, all new and regenerated outputs for traced objects show the names of the procedures that call the traced objects. See “Example 6” on page 26-86.

**Recursive**

Option, specified as `Recursive = FALSE`

Do not trace all slots of a function environment or domain. By default, `Recursive = TRUE`. See “Example 7” on page 26-88.

**Return Values**

`prog::trace` returns the void object `null()`.

**See Also****MuPAD Functions**

`prog::untrace` | `prog::traced` | `debug` | `prog::profile`

# prog::traced

---

**Purpose** Find traced functions

**Syntax** `prog::traced(<obj>)`

**Description** `prog::traced()` lists all traced functions.  
`prog::traced(obj)` detects, whether the function `obj` is traced. If `obj` is a library or a function environment, then all methods will be checked. If no argument is given, all traced functions will be displayed.  
`prog::traced` determines whether a copy exists and whether the function has been manipulated the way `prog::trace` does.

## Examples **Example 1**

The `sin` function is traced:

```
prog::trace(sin):
prog::traced(sin)
```

TRUE

The `cos` function is not traced:

```
prog::traced(cos)
```

FALSE

**Parameters** `obj`

A MuPAD function, a function environment or a library

**Return Values** `prog::traced` returns the void object `null()`.

**See Also**

**MuPAD  
Functions**

`prog::trace` | `prog::untrace`

# prog::untrace

---

**Purpose** Terminates observation of functions

**Syntax** prog::untrace(obj)  
prog::untrace()

**Description** prog::untrace(obj) terminates the observation of the MuPAD function obj performed by prog::trace.  
obj can be a domain or a function environment, too. Then all methods of the domain or function environment will be restored.  
If no argument is given, all observed objects will be restored from observation.

**Examples**      **Example 1**

The observation of a function will be terminated:

```
prog::trace(sin):
sin(2)
```

```
enter sin(2)
computed sin(2)
```

```
sin(2)
```

```
prog::untrace(sin):
sin(2)
```

```
sin(2)
```

**Parameters**      **obj**

The MuPAD function that is observed, or a domain or a function environment

**Return Values**

prog::untrace returns the void object null().

**See Also****MuPAD Functions**

prog::trace | debug | prog::profile

# prog::wait

---

**Purpose** Wait for a while

**Syntax** prog::wait(m)  
prog::wait(s)

**Description** prog::wait(m) waits for m milli seconds.  
prog::wait(s) waits for s seconds.  
prog::wait uses the function rtime for time measurement.

## Examples

### Example 1

Wait for 3 seconds:

```
prog::wait(3000)
```

Wait for 3 seconds again:

```
prog::wait(3.0)
```

The next example shows the difference between the system time and the CPU time used by MuPAD:

```
time(prog::wait(2.5))
```

```
2040
```

In 2.5 seconds realtime the MuPAD process runs nearly two seconds.

### Example 2

Use traperror to limit the evaluation time:

```
traperror(prog::wait(100.0), 5): lasterror()
```

```
Error: Execution time is exceeded.
```

Evaluating: `prog::wait`

## Parameters

**m**

Milli seconds to wait as positive integer

**s**

Seconds to wait as positive floating-point number

## Return Values

`prog::wait` returns the empty object `null()`.

## See Also

## MuPAD Functions

`runtime` | `time` | `traperror`

**prog::wait**

---

# property – Properties and Assumptions

---

property::depends  
property::hasprop  
property::showprops

# property::depends

---

**Purpose** Dependence table with all properties of an expression

**Syntax** `property::depends(ex, )`

**Description** `property::depends(...)` returns a table which contains all information about the properties of the whole input. This table can be used to determine any change of the properties of an expression.

The returned table is mainly used inside the MuPAD library, to ensure the validity of remembered results of the remember mechanism.

A MuPAD expression can have different properties at different times, without changing its value.

---

**Note** The kernel remember mechanism cannot determine the change of the properties and returns wrong results, when the result depends on the properties of the input.

---

In this case the extended remember mechanism provided by `prog::remember` should be used together with `property::depends`.

## Examples

### Example 1

A compare of the dependence table at different times detects changes of the properties of an expression.

The first call to the defined function `has_changed` initializes the table `DEPENDS` that keeps the dependence information:

```
DEPENDS := table():
has_changed :=
 proc(ex)
 begin
 if not contains(DEPENDS, ex)
 or property::depends(ex) <> DEPENDS[ex] then
 DEPENDS[ex] := property::depends(ex);
```

```
 TRUE
 else
 FALSE
 end_if
 end_proc:
 has_changed(sin(x*PI)):
```

The properties has not changed:

```
has_changed(sin(x*PI))
```

FALSE

Every change is detected:

```
assume(x, Type::Integer):
has_changed(sin(x*PI))
```

TRUE

```
assume(x, Type::PosInt):
has_changed(sin(x*PI))
```

TRUE

```
assume(x >= 0):
has_changed(sin(x*PI))
```

TRUE

```
unassume(x):
has_changed(sin(x*PI))
```

# property::depends

---

TRUE

delete DEPENDS, has\_changed:

## Example 2

The next example shows the problems with the kernel remember mechanism:

```
pos := proc(x)
 option remember;
 begin
 is(x > 0)
 end:
pos(x)
```

UNKNOWN

The result UNKNOWN was stored for the input x and is returned, although the properties of x are changed:

```
assume(x > 0): pos(x);
assume(x < 0): pos(x)
```

UNKNOWN

UNKNOWN

This problem can only be solved by the extended remember mechanism together with property::depends (x still is less than zero):

```
pos := proc(x)
 begin
```

```
 is(x > 0)
 end:
pos := prog::remember(pos, property::depends):
pos(x)
```

FALSE

After changing the properties of the input, the defined function recomputes the result:

```
assume(x > 0): pos(x);
unassume(x): pos(x)
```

TRUE

UNKNOWN

## Parameters

**ex**

Any MuPAD expression

## Return Values

Table that can be compared with another dependence table

## See Also

## MuPAD Functions

[assume](#) | [getprop](#) | [is](#) | [prog::remember](#)

# property::hasprop

---

**Purpose** Does an object have properties?

**Syntax** `property::hasprop(object)`  
`property::hasprop()`

**Description** `property::hasprop(object)` tests, whether the object has properties and returns TRUE if the object or any subexpression has a property, otherwise FALSE.

Compared with `getprop`, `property::hasprop` is a fast function and can be used to determine, whether an object has properties without using the slower functions `getprop` or `is`.

---

**Note** In some cases, the function `is` can derive some aspects without any defined property (see “Example 2” on page 27-7)!

---

## Examples

### Example 1

Does the expression  $2*(x+1)$  have any properties?

```
property::hasprop(2*(x + 1))
```

```
FALSE
```

```
assume(x > 0):
property::hasprop(2*(x + 1))
```

```
TRUE
```

```
getprop(2*(x + 1))
```

```
(2, ∞)
```

```
delete x:
```

## Example 2

property::hasprop returns FALSE, but is can determine an answer unequal to UNKNOWN:

```
property::hasprop(0 < x/(x + y) + y/(x + y))
```

```
FALSE
```

```
is(exp(x) = 0)
```

```
FALSE
```

## Parameters

**object**

Any MuPAD object

## Return Values

TRUE or FALSE

## See Also

## MuPAD Functions

assume | getprop | is | indets | unassume

# property::showprops

---

<b>Purpose</b>	What assumptions are made?
<b>Syntax</b>	<code>property::showprops(object)</code>
<b>Description</b>	<code>property::showprops(object)</code> shows all assumptions set for identifiers in <code>object</code> . If no assumptions were set, the empty list is returned.
<b>Examples</b>	<b>Example 1</b>  <pre>assume(x &gt; 0); property::showprops(x);</pre> <pre>[0 &lt; x]</pre> <pre>assumeAlso(x &lt; 1); property::showprops(x);</pre> <pre>[x &lt; 1, 0 &lt; x]</pre> <pre>delete x;</pre>
<b>Parameters</b>	<b>object</b> Any MuPAD object
<b>Return Values</b>	List containing all assumptions.

solvelib::Union
solvelib::VectorImageSet
```

# solvelib::BasicSet

---

**Purpose** Basic infinite sets

**Syntax** **Domain Creation**  
solvelib::BasicSet(Dom::Integer)  
solvelib::BasicSet(Dom::Rational)  
solvelib::BasicSet(Dom::Real)  
solvelib::BasicSet(Dom::Complex)

**Description** The domain solvelib::BasicSet comprises the four sets of integers, reals, rationals, and complex numbers, respectively.

The four basic sets are assigned to the identifiers Z\_, Q\_, R\_, and C\_ during system initialization.

The set of positive integers, too, is assigned to the identifier N\_ during system initialization. It is not represented by a basic set but by the intersection of Z\_ and the interval Dom::Interval([1, infinity).

**Superdomain** Dom::BaseDomain

**Axioms** Ax::canonicalRep

**Categories** Cat::Set

**Examples** **Example 1**

The domain of basic sets know about the basic arithmetical and set-theoretic functions:

```
J:=Dom::Interval(3/2, 21/4):
Z_ intersect J

{2, 3, 4, 5}
```

## Methods

### Mathematical Methods

**contains** - Test whether some object is a member

`contains(a, S)`

Equivalently, `is(a in S)` may be used.

### Conversion Methods

**convert** - Convert a domain into a basic set

`convert(d)`

**set2prop** - Convert a set to a property

`set2prop(S)`

# **solveLib::cartesianPower**

---

**Purpose** Cartesian power of a set

**Syntax** **Domain Creation**  
`solveLib::cartesianPower()`  
`solveLib::cartesianPower(S, n)`

**Description** `solveLib::cartesianPower` is the domain of all cartesian powers of subsets of the complex numbers.

`solveLib::cartesianPower(S, n)` returns the set of all n-tuples of elements of S.

`solveLib::cartesianPower(S, n)` returns the n-fold cartesian product of S with itself, that is, the set of all vectors of length n whose components are elements of S.

S must represent a subset of the complex numbers; see `solve` for an overview of the different kinds of sets in MuPAD.

The set of one-tuples of elements of S consists of vectors and therefore differs from the set S in the same way as matrices of type `matrix` with one row and one column are different from numbers.

**Superdomain** `Dom::BaseDomain`

**Categories** `Cat::Set`

**Examples** **Example 1**

A cartesian power of a finite set of numbers is a finite set of vectors:

```
A:= solveLib::cartesianPower({1, 2, I}, 3)
```

$$\left\{ \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 2 \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix}, \begin{pmatrix} 2 \\ 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 2 \\ 1 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 2 \end{pmatrix}, \begin{pmatrix} 2 \\ 2 \\ 2 \end{pmatrix}, \begin{pmatrix} i \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ i \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \\ i \end{pmatrix}, \begin{pmatrix} 2 \\ 2 \\ i \end{pmatrix}, \begin{pmatrix} i \\ 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix}, \begin{pmatrix} i \\ 2 \\ 2 \end{pmatrix}, \begin{pmatrix} 2 \\ 2 \\ i \end{pmatrix}, \begin{pmatrix} i \\ i \\ 1 \end{pmatrix}, \begin{pmatrix} i \\ 1 \\ i \end{pmatrix}, \begin{pmatrix} 1 \\ i \\ i \end{pmatrix}, \begin{pmatrix} i \\ i \\ 2 \end{pmatrix}, \begin{pmatrix} 2 \\ i \\ i \end{pmatrix}, \begin{pmatrix} i \\ i \\ i \end{pmatrix} \right\}$$

We can select those vectors with all components real as follows:

```
A intersect solvelib::cartesianPower(R_, 3)
```

$$\left\{ \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 2 \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \\ 2 \end{pmatrix}, \begin{pmatrix} 2 \\ 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 2 \\ 1 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 2 \end{pmatrix}, \begin{pmatrix} 2 \\ 2 \\ 2 \end{pmatrix} \right\}$$

### Example 2

Cartesian powers of the set of complex numbers may occur as the result of a call to solve if every n-tuple of complex numbers is a solution of the given system:

```
solve([x+y = x+y], [x, y], VectorFormat)
```

$$\mathbb{C}^2$$

### Parameters

**s**

Set

**n**

Positive integer

### Methods

Access Methods

**base - Set s**

# solvelib::cartesianPower

---

base(A)

**dimension - Exponent n**

dimension(A)

**Technical Methods**

**print - Print a cartesian power**

print(A)

**Purpose**

Cartesian product of sets

**Syntax**

```
solveLib::cartesianProduct(S,)
```

**Description**

`solveLib::cartesianProduct(S, ...)` returns the cartesian product of its arguments.

The arguments may be sets of any type, consisting of complex numbers; the result is a set that consists of vectors, or a symbolic call to `solveLib::cartesianProduct`. See `solve` for an overview of the different kinds of sets in MuPAD.

**Examples****Example 1**

For finite sets, the result is similar to that of `combinat::cartesianProduct` but consists of vectors and not of lists:

```
S:= solveLib::cartesianProduct({1, 2}, {3, 4})
```

```
{(1/3), (2/3), (1/4), (2/4)}
```

```
solveLib::splitVectorSet(S)
```

```
[[{1, 2}, {3, 4}]]
```

```
delete S:
```

**Example 2**

For infinite sets, results of various types are possible, e.g., `solveLib::VectorImageSet` or `solveLib::cartesianPower`:

```
solveLib::cartesianProduct(R_, R_)
```

# solveLib::cartesianProduct

---

$$\mathbb{R}^2$$

`solveLib::cartesianProduct(PI*Z_, Z_)`

$$\left\{ \begin{pmatrix} \pi k \\ l \end{pmatrix} \mid k \in \mathbb{Z}, l \in \mathbb{Z} \right\}$$

**Parameters**     **s**

Set of complex numbers

**Return Values**     Set

**See Also**

**MuPAD Functions**     `combinat::cartesianProduct` | `solve` |  
`solveLib::cartesianPower` | `solveLib::splitVectorSet`

**Purpose**

Possible sortings of a list depending on parameters

**Syntax**

```
solvelib::conditionalSort(l)
```

**Description**

`solvelib::conditionalSort(l)` sorts the list `l` in ascending order. Unlike for `sort`, only the usual order on the real numbers and not the internal order (see `sysorder`) is used. `solvelib::conditionalSort` does a case analysis if list elements contain indeterminates.

`solvelib::conditionalSort` invokes the inequality solver to get simple conditions in the case analysis. The ability of `solvelib::conditionalSort` to recognize sortings as impossible is thus limited by the ability of the inequality solver to recognize an inequality as unsolvable. See “Example 3” on page 28-16.

Only expressions representing real numbers can be sorted. It is an error if non-real numbers occur in the list; it is implicitly assumed that all parameters take on only such values that cause all list elements to be real.

Sorting is unstable, i.e. equal elements may be placed in any order in the resulting list; these cases may be listed separately in the case analysis.

The usual simplifications for piecewise defined objects are applied, e.g., equalities that can be derived from a condition are applied (by substitution) to the list.

**Environment Interactions**

`solvelib::conditionalSort` takes into account the assumptions on all occurring identifiers.

**Examples****Example 1**

In the simplest case, sorting a two-element list `[a,b]` just amounts to solving the inequation  $a \leq b$  w.r.t. all occurring parameters.

```
solvelib::conditionalSort([x,x^2])
```

# solveLib::conditionalSort

---

$$\begin{cases} [x, x^2] & \text{if } 0 < x(x-1) \\ [x^2, x] & \text{if } x(x-1) \leq 0 \end{cases}$$

## Example 2

If, by implicit or explicit assumptions on the parameters, no different sortings can occur, the result is just a list.

According to the implicit assumption that all list elements are real,  $x$  must be nonnegative.

```
solveLib::conditionalSort([sqrt(x), -3])
```

```
[-3, sqrt(x)]
```

## Example 3

Sometimes cases are not recognized as impossible.

```
assume(x>5): solveLib::conditionalSort([x, gamma(x)])
```

$$\begin{cases} [x, \Gamma(x)] & \text{if } x < \Gamma(x) \\ [\Gamma(x), x] & \text{if } \Gamma(x) \leq x \end{cases}$$

## Parameters

**I**

List of arithmetical expressions

## Return Values

List if the sorting is the same for all possible parameter values; or an object of type `piecewise` if some case analysis is necessary.

## Algorithms

The complexity of sorting a list of  $n$  elements is up to  $n!$ .

## See Also

## MuPAD Functions

`sort` | `piecewise`

# solvelib::getElement

---

**Purpose** Get one element of a set

**Syntax** `solvelib::getElement(S, <Random>)`

**Description** `solvelib::getElement(S)` returns an element of S.

S can be a set of any type; see `solve` for an overview of all sets.

`solvelib::getElement` returns the value FAIL if:

- S is the empty set
- the solver cannot find any element of the set due to the solver's limitations
- the solver cannot compute the first element of a set. You can use the `Random` option to check a random element of a set instead of the first element
- the answer depends on a case analysis on some parameter

With the option `Random`, the probability to get any particular element of a set is:

- Roughly equal for the elements of a finite set
- Proportional to the multiplicities for the elements of a finite multiset of type `Dom::Multiset`
- Unspecified for the elements of an infinite set. Practically, the same result does not occur twice for infinite sets.

## Examples

### Example 1

If S is a finite set, the solver returns just one of the elements:

```
solvelib::getElement({2, 7, a})
```

2

## Example 2

For image sets, the solver replaces every parameter by a constant:

```
S:=Dom::ImageSet(k*PI, k, solvelib::BasicSet(Dom::Integer))
```

```
{π k | k ∈ ℤ}
```

```
solvelib::getElement(S)
```

```
0
```

## Example 3

If the set is empty, the solver cannot find any element:

```
solvelib::getElement({})
```

```
FAIL
```

`solvelib::getElement` might fail to find an element of a set although that set is not empty.

```
solvelib::getElement(solve(exp(x) + cos(x) = x^2,x))
```

```
FAIL
```

## Example 4

Without the option `Random`, `solvelib::getElement` always produces the same result for a set:

```
solvelib::getElement({$1..5}) $i=1..5
```

# solvelib::getElement

---

```
1, 1, 1, 1, 1
```

With the option `Random`, the returned element varies randomly from call to call:

```
solvelib::getElement({$1..5}, Random) $i=1..15
```

```
2, 1, 3, 4, 2, 4, 1, 4, 2, 5, 1, 4, 3, 1, 5
```

The distribution of the returned values is close to the uniform distribution. For multisets, the multiplicity of elements is taken into account:

```
solvelib::getElement(Dom::Multiset(1$4, 2$2), Random) $i=1..18
```

```
1, 1, 1, 1, 2, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1, 2, 1, 1
```

## Example 5

For the following set parametrized by integers, the solver fails to find an element. This is because the solver tries only the first parameter-value pair  $k = 0$  for which the result is undefined. After that the solver does not try any other parameter-value pairs:

```
solvelib::getElement(1/Z_)
```

```
FAIL
```

For the sets with the undefined first element, you can get the result calling the solver with the option `Random`:

```
solvelib::getElement(1/Z_, Random)
```

$\frac{1}{902}$

## Parameters

**S**

Any set

## Options

**Random**

Returns a random element of a set. Without this option, `solveLib::getElement(S)` always returns the same element.

## Return Values

`solveLib::getElement` returns a MuPAD object representing an element of `S`, or `FAIL` if no element could be determined.

## Overloaded By

`S`

## See Also

## MuPAD Functions

`solve`

# solvelib::isEmpty

---

**Purpose** Predicate expressing the emptiness of a set

**Syntax** `solvelib::isEmpty(S)`

**Description** `solvelib::isEmpty(S)` returns a boolean expression that is equivalent to the statement that `S` is the empty set.

Since functions operating on boolean expressions like `assume`, `is`, or `solve` cannot handle equations involving sets, it is not possible to pass the expression `S={}` to them. `solvelib::isEmpty(S)` helps to get around this problem, as it tries to express the emptiness of `S` in an equivalent way that can be handled by the aforementioned functions. If no suitable equivalent expression is found, the unevaluated call to `solvelib::isEmpty` is returned.

`S` may be a set of any type; see `solve` for an enumeration of the various types of sets.

The `solvelib::isEmpty` function always returns Boolean expressions, even if the function cannot resolve an expression. See “Example 4” on page 28-23.

## Examples

### Example 1

The emptiness of a `DOM_SET` can be decided immediately:

```
solvelib::isEmpty({a, b}), solvelib::isEmpty({})
```

```
FALSE, TRUE
```

### Example 2

The intersection of a finite set with any other set is empty if and only if none of the elements of the finite set is in the other set:

```
solvelib::isEmpty({a, b} intersect Z_)
```

$$a \in \mathbb{Z} \wedge b \in \mathbb{Z}$$

### Example 3

The output of solve can be entered directly into solveLib::isEmpty:

```
solveLib::isEmpty(solve(a*x=b, x))
```

$$a = 0 \wedge b \neq 0$$

### Example 4

Sometimes, no simpler equivalent expression can be found:

```
result := solveLib::isEmpty(solve(x^2 = sin(x), x))
```

$$\text{solveLib::isEmpty}(\text{solve}(x^2 - \sin(x) = 0, x))$$

The returned expression is a Boolean expression:

```
testtype(result, Type::Boolean)
```

TRUE

<b>Parameters</b>	<b>s</b> Any set
<b>Return Values</b>	Boolean expression
<b>Overloaded By</b>	s

# **solveLib::isEmpty**

---

## **See Also**

## **MuPAD Functions**

`solve` | `assume` | `is`

<b>Purpose</b>	Test whether a set is finite
<b>Syntax</b>	<code>solveLib::isFinite(S)</code>
<b>Description</b>	<code>solveLib::isFinite(S)</code> returns TRUE, FALSE, or UNKNOWN depending on whether S is finite, infinite, or the question could not be settled.  S may be a set of any type; see <code>solve</code> for an enumeration of the various types of sets.
<b>Examples</b>	<p><b>Example 1</b></p> <p>A DOM_SET is always finite:</p> <pre>solveLib::isFinite({2,5})</pre> <p>TRUE</p> <p><b>Example 2</b></p> <p>The set of integers is infinite.</p> <pre>solveLib::isFinite(Z_)</pre> <p>FALSE</p>
<b>Parameters</b>	<b>s</b> Any set
<b>Return Values</b>	Boolean value
<b>Overloaded By</b>	S

# **solveLib::isFinite**

---

## **See Also**

## **MuPAD Functions**

`solve`

**Purpose** Solve polynomial Diophantine equations

**Syntax** solveLib::pdioe(a, b, c)  
 solveLib::pdioe(aexpr, bexpr, cexpr, x)

**Description** solveLib::pdioe(a, b, c) returns polynomials u and v that satisfy the equation  $au + bv = c$ .

solveLib::pdioe(aexpr, bexpr, cexpr, x) does the same after converting the arguments into univariate polynomials a, b, c in the variable x.

The coefficient ring of the polynomials a, b, and c must be either Expr, or IntMod(p) for some prime p, or a domain belonging to the category Cat::Field.

**Examples** **Example 1**

If expressions are passed as arguments, a fourth argument must be provided:

```
solveLib::pdioe(x, 13*x + 22*x^2 + 18*x^3 + 7*x^4 + x^5 + 3, x^2
```

$$- \frac{x^4}{3} - \frac{7x^3}{3} - 6x^2 - \frac{19x}{3} - \frac{13}{3}, \frac{1}{3}$$

**Example 2**

x is not a multiple of the gcd of x + 1 and x<sup>2</sup> - 1. Hence the equation  $u(x + 1) + v(x^2 - 1) = x$  has no solution for u and v:

```
solveLib::pdioe(x + 1, x^2 - 1, x, x)
```

FAIL

# solveLib::pdioe

---

## Example 3

If the arguments are polynomials, the fourth argument may be omitted:

```
solveLib::pdioe(poly(a + 1, [a]), poly(a^2 + 1, [a]), poly(a - 1, [a]),
poly(a, [a]), poly(- 1, [a]))
```

## Parameters

**x**

Identifier or indexed identifier

**a, b, c**

Univariate polynomials

**aexpr, bexpr, cexpr**

Polynomial expressions

## Return Values

If the equation is solvable, `solveLib::pdioe` returns an expression sequence consisting of two operands of the same type as the input (expressions or polynomials). If the equation has no solution, `solveLib::pdioe` returns FAIL.

## See Also

## MuPAD Functions

`solve`

**Purpose** Preimage of a set under a mapping

**Syntax** `solveLib::preImage(a, x, S)`

**Description** `solveLib::preImage(a, x, S)` returns the set of all numbers  $y$  such that substituting  $y$  for  $x$  in  $a$  gives an element of  $S$ .

$S$  can be a set of any type (finite or infinite).

## Examples **Example 1**

In case of a finite set  $S$ , the preimage of  $S$  is just the union of all sets `solve(a=s, x)`, where  $s$  ranges over the elements of  $S$ .

```
solveLib::preImage(x^2+2, x, {11, 15});
```

```
{-3, 3, sqrt(13), -sqrt(13)}
```

Note that computing this set may take a long time for large finite sets:

```
time(solveLib::preImage(x, x,
 Z_ intersect Dom::Interval(0, 1000000)))
```

```
14657
```

## **Example 2**

For intervals, the preimage is usually an interval or a union of intervals.

```
solveLib::preImage(x^2+2, x, Dom::Interval(3..7));
```

```
(1, sqrt(5)) U (-sqrt(5), -1)
```

# solveLib::preImage

---

## Parameters

**a**

Arithmetic expression

**x**

Identifier

**s**

Set

## Return Values

Set

## See Also

## MuPAD Functions

`solve`

**Purpose**

Factor a set of vectors into a cartesian product

**Syntax**

```
solveLib::splitVectorSet(S)
```

**Description**

`solveLib::splitVectorSet(S)` returns a list  $S_1, \dots, S_n$  of sets of complex numbers such that  $S$  is the cartesian product of the  $S_i$ , or FAIL if such factorization could not be found.

The set  $S$  may be finite or infinite, of any type.

**Examples****Example 1**

We split a finite set of vectors into its factors:

```
solveLib::splitVectorSet({[1, 2], [1, 3], [0, 2], [0, 3]})

[[0, 1], [2, 3]]
```

The following set cannot be written as a cartesian product:

```
solveLib::splitVectorSet({[1, 2], [0, 2], [0, 3]})

FAIL
```

**Example 2**

Infinite sets can also be handled:

```
S := Dom::ImageSet([k*PI, l*PI+2], [k, l], [Z_, Z_])
```

$$\left\{ \left( \begin{array}{c} \pi k \\ \pi l + 2 \end{array} \right) \mid k \in \mathbb{Z}, l \in \mathbb{Z} \right\}$$

```
solveLib::splitVectorSet(S)
```

# solveLib::splitVectorSet

---

$[\{\pi k \mid k \in \mathbb{Z}\}, \{\pi k + 2 \mid k \in \mathbb{Z}\}]$

delete S:

**Parameters**    **s**

Set of vectors

**Return  
Values**

List of type DOM\_LIST, or FAIL

**See Also**

**MuPAD  
Functions**

solve

**Purpose** Union of a system of sets

**Syntax** `solvelib::Union(set, param, paramset)`  
`solvelib::Union(set, paramlist, vectorset)`

**Description** `solvelib::Union (set, paramlist, vectorset)` returns the set of all objects that can be obtained by replacing, in some element of `set`, the list of free parameters `paramlist` by an element of `vectorset`.

`set` may be a set of any type; it need not depend on the parameter `param`, and it may also contain other free parameters.

`paramset` may be a set of any type and may depend on some free parameters. See “Example 1” on page 28-33.

If `paramset` is empty, the result is the empty set. Overloading has no effect in this case.

`vectorset` may be a set of any type, consisting of vectors whose dimension equals the number of variables in `paramlist`.

**Examples** **Example 1**

We compute the set of all numbers that are equal to  $k + 1$  or  $k + 3$  for  $k = 2$ ,  $k = 4$ , or  $k = l$ , where  $l$  is a free parameter.

```
solvelib::Union({k+1, k+3}, k, {2,4,l});
```

```
{3, 5, 7, l + 1, l + 3}
```

**Example 2**

In the same way, we can let a pair of parameters range over a set of pairs:

```
solvelib::Union(Dom::ImageSet(PI*k + exp(x) + y, k, Z_), [x, y], [1, 4])
```

# solveLib::Union

---

$$\{e + \pi k + 4 \mid k \in \mathbb{Z}\} \cup \{e^3 + \pi k + 2 \mid k \in \mathbb{Z}\}$$

## Parameters

**set**

Set of any type

**param**

Identifier

**paramset**

Set of any type

**paramlist**

List of identifiers

**vectorset**

Set of vectors

## Return Values

`solveLib::Union` returns a set of any type; see `solve` for an overview of the different types of sets. It may also return the unevaluated call if the union could not be computed.

## Overloaded By

set

## See Also

## MuPAD Functions

solve

<b>Purpose</b>	Domain of set of vectors that are images of sets under mappings
<b>Syntax</b>	<p><b>Domain Creation</b>  <code>solvelib::VectorImageSet()</code></p> <p><b>Element Creation</b>  <code>solvelib::VectorImageSet(v, x, S)</code>  <code>Dom::ImageSet(v, [x1, ], [S1, ])</code></p>
<b>Description</b>	<p><b>Domain Creation</b></p> <p><code>solvelib::VectorImageSet</code> is the domain of all sets of vectors of complex numbers that can be written as the set of all values taken on by some mapping, i.e., sets of the form <math>\{[f_1(X_1, \dots, X_n), \dots, f_m(X_1, \dots, X_n)] \mid X_i \in S_i\}</math> for some complex-valued functions <math>f_j</math> and some sets <math>S_1, \dots, S_n</math> of complex numbers.</p> <p>Sets of this type are used by <code>solve</code> to express solutions of systems of equations like <math>\{[k \pi, z] \mid k \in \mathbb{Z}, z \in \mathbb{C}\}</math>.</p> <p><b>Element Creation</b></p> <p><code>solvelib::VectorImageSet(v, x, S)</code> represents the set of all vectors that can be obtained by substituting some element of <code>S</code> for <code>x</code> in the vector <code>v</code>.</p> <p><code>solvelib::VectorImageSet(v, [x1, ...], [S1, ...])</code> represents the set of all values that can be obtained by substituting, for each <math>i</math>, the identifier <math>x_i</math> by some element of <math>S_i</math> in the vector <code>v</code>.</p> <p>The user never needs to call <code>solvelib::VectorImageSet</code> directly. Instead, <code>Dom::ImageSet</code> should be used; it will automatically create a vector image set if its first argument is a list or matrix. The entries and methods of the domain <code>solvelib::VectorImageSet</code> are the same as those of <code>Dom::ImageSet</code>, and may be found on that help page.</p>
<b>Superdomain</b>	<code>Dom::ImageSet</code>
<b>Categories</b>	<code>Cat::Set</code>

# solvelib::VectorImageSet

---

## Examples

### Example 1

We create a set of two-dimensional vectors:

```
S := Dom::ImageSet([k*PI, k*I*PI], k, Z_)
```

$$\left\{ \begin{pmatrix} \pi k \\ \pi k i \end{pmatrix} \mid k \in \mathbb{Z} \right\}$$

Since this is a set of vectors, a `solvelib::VectorImageSet` is created automatically:

```
type(S)
```

```
DomImageSet
```

Set-theoretic operations (union, intersection, set difference) may be applied to S:

```
S intersect {[0, 0], [1, 1]}, S minus S
```

```
{[0, 0]}, ∅
```

```
delete S:
```

## Parameters

**v**

List or matrix

**x**

Identifier or indexed identifier

**S**

Set of any type

**Purpose** Cumulative distribution function of the beta distribution

**Syntax** `stats::betaCDF(a, b)`

**Description** `stats::betaCDF(a, b)` returns a procedure representing the cumulative distribution function

$$X \rightarrow \begin{cases} 0 & \text{if } x \leq 0 \\ \frac{1}{\beta(a, b)} \int_0^x t^{a-1} (1-t)^{b-1} dt & \text{if } 0 < x \wedge x < 1 \\ 1 & \text{if } x \geq 1 \end{cases}$$

of the beta distribution with shape parameters  $a > 0$ ,  $b > 0$ .

The procedure `f := stats::betaCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

- If `x` can be converted to a real floating-point number and `a` and `b` can be converted to positive floating-point numbers, then the return value `f(x)` is a floating-point number.
- For numerical values  $x \leq 0$  and  $x \geq 1$ , the floating-point numbers `0.0`, respectively `1.0`, are returned even if `a` and `b` are symbolic quantities.
- The call `f(-infinity)` returns `0.0`; the call `f(infinity)` return `1.0`.
- In all other cases, `f(x)` returns the symbolic call `stats::betaCDF(a, b)(x)`.

Numerical values of `a` and `b` are only accepted if they are positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

# stats::betaCDF

---

## Examples

### Example 1

We evaluate the cumulative distribution function with  $a = 5$  and  $b = 7$  at various points:

```
f := stats::betaCDF(5, 7):
f(-infinity), f(-PI), f(1/sqrt(10)), f(0.75), f(1), f(infinity)

0.0, 0.0, 0.247351489, 0.9924387932, 1.0, 1.0
```

Nonpositive numerical values of  $a$  or  $b$  lead to an error:

```
stats::betaCDF(-5, 7)(0.75)
```

```
Error: The first shape parameter must be positive. [stats::betaCDF]
```

```
Error:
the first shape parameter must be positive [stats::betaCDF]
```

```
delete f:
```

### Example 2

For symbolic arguments, symbolic calls of `stats::betaCDF` are returned, unless  $x \leq 0$  or  $x \geq 1$  can be decided:

```
f := stats::betaCDF(a, b):
f(-2), f(0), f(1/3), f(0.4), f(1), f(PI), f(x)

0.0, 0.0, stats::betaCDF(a, b)(1/3), stats::betaCDF(a, b)(0.4), 1.0, 1.0, stats::betaCDF(a, b)(x)
```

When positive real numbers are assigned to  $a$  and  $b$ , the call  $f(x)$  returns a floating-point number if  $x$  is numerical:

```
a := 2: b := PI:
f(-2), f(1/3), f(0.4), f(PI)
```

```
0.0, 0.4272662874, 0.5465772418, 1.0
```

```
delete f, a, b:
```

**Parameters****a, b**

The shape parameters of the beta distribution: arithmetical expressions representing positive real values.

**Return Values**

procedure.

**See Also****MuPAD Functions**

[stats::betaPDF](#) | [stats::betaQuantile](#) | [stats::betaRandom](#)

# stats::betaPDF

---

**Purpose** Probability density function of the beta distribution

**Syntax** stats::betaPDF(a, b)

**Description** stats::betaPDF(a, b) returns a procedure representing the probability density function

$$X \rightarrow \begin{cases} \frac{x^{a-1} (1-x)^{b-1}}{\beta(a, b)} & \text{if } X > 0 \wedge X < 1 \\ 0 & \text{if } X \leq 0 \vee X \geq 1 \end{cases}$$

of the beta distribution with shape parameters  $a > 0$  and  $b > 0$

The procedure `f := stats::betaPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

- If `x` is a real floating-point number and `a` and `b` can be converted to positive floating-point numbers, then `f(x)` returns a floating-point number.
- If  $0 < x < 1$  can be decided, the expression  $x^{a-1} \cdot (1-x)^{b-1} / \beta(a, b)$  is returned. If  $x \leq 0$  or  $x \geq 1$  can be decided, then 0, respectively 0.0, is returned.
- The calls `f(-infinity)` and `f(infinity)` return 0.
- In all other cases, `f(x)` returns the symbolic call `stats::betaPDF(a, b)(x)`.

Numerical values of `a` and `b` are only accepted if they are positive.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. The procedure returned by `stats::betaPDF` reacts to properties of its argument.

**Examples****Example 1**

We evaluate the probability density function with  $a = 3$  and  $b = 4$  at various points:

```
f := stats::betaPDF(3, 4):
f(-infinity), f(-1), f(1/2), f(0.7), f(infinity)
```

```
0, 0, $\frac{15}{8}$, 0.7938, 0
```

```
delete f:
```

**Example 2**

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $0 < x < 1$  holds. A symbolic function call is returned:

```
f := stats::betaPDF(a, b): f(x)
```

```
stats::betaPDF(a, b)(x)
```

With suitable properties, an explicit expression is returned:

```
assume(0 < x < 1): f(x)
```

$$\frac{x^{a-1} (1-x)^{b-1}}{\beta(a, b)}$$

```
assume(x > 1): f(x)
```

```
0
```

# stats::betaPDF

---

`unassume(x): delete f:`

**Parameters**      **$\alpha$ ,  $\beta$**

The shape parameters of the beta distribution: arithmetical expressions representing positive real values.

**Return Values**     procedure.

**See Also**

**MuPAD Functions**     `stats::betaCDF` | `stats::betaQuantile` | `stats::betaRandom`

**Purpose** Quantile function of the beta distribution

**Syntax** `stats::betaQuantile(a, b)`

**Description** `stats::betaQuantile(a, b)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::betaCDF(a, b)`. For  $0 \leq x \leq 1$ , the solution of  $\text{stats::betaCDF}(a, b)(y) = x$  is given by  $y = \text{stats::betaQuantile}(a, b)(x)$ .

The procedure `f := stats::betaQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, or a symbolic expression:

- If `a` and `b` can be converted to positive floating-point numbers and `x` is a real number between 0 and 1, then the return value `f(x)` is a floating-point number between 0.0 and 1.0 approximating the real solution `y` of  $\text{stats::betaCDF}(a, b)(y) = x$ .
- `f(0)`, `f(0.0)`, `f(1)`, and `f(1.0)` produce 0, 0.0, 1, and 1.0, respectively, for all values of `a` and `b`.
- In all other cases, `f(x)` returns the symbolic call `stats::betaQuantile(a, b)(x)`.

Numerical values of `a` and `b` are only accepted if they are positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

**Examples** **Example 1**

We evaluate the quantile function with  $a = \pi$  and  $b = 11$  at the point

$$x = \frac{9}{10}$$

```
f := stats::betaQuantile(PI, 11): f(9/10)
```

```
0.368643722
```

# stats::betaQuantile

---

The value  $f(x)$  satisfies  $\text{stats::betaCDF}(\text{PI}, 11)(f(x)) = x$ :

```
stats::betaCDF(PI, 11)(f(0.98765))
```

```
0.98765
```

```
delete f:
```

## Example 2

For symbolic arguments, symbolic calls are returned:

```
f := stats::betaQuantile(a, b): f(x), f(0.9)
```

```
stats::betaQuantile(a, b)(x), stats::betaQuantile(a, b)(0.9)
```

If  $a, b$  evaluate to real numbers and  $x$  to a real number between 0 and 1, then the call  $f(x)$  produces a float:

```
a := 17: b := 6: f(0.9)
```

```
0.8499783131
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f, a, b:
```

**Parameters**    **a, b**

The shape parameters of the beta distribution: arithmetical expressions representing positive real values.

## **Return Values**

procedure.

## **See Also**

## **MuPAD Functions**

[stats::betaCDF](#) | [stats::betaPDF](#) | [stats::betaRandom](#)

# stats::betaRandom

---

**Purpose** Generate a random number generator for beta deviates

**Syntax** stats::betaRandom(a, b, <Seed = n>)

**Description** stats::betaRandom(a, b) returns a procedure that produces beta deviates (random numbers) with shape parameters  $a > 0$ ,  $b > 0$ .

The procedure  $f := \text{stats::betaRandom}(a, b)$  can be called in the form  $f()$ . The return value of  $f()$  is either a floating-point number or a symbolic expression:

- If  $a$  and  $b$  can be converted to positive floating-point numbers, then  $f()$  returns a random floating-point number between 0.0 and 1.0.
- In all other cases,  $f()$  return the symbolic call  $\text{stats::betaRandom}(a, b)()$ .

Numerical values of  $a$  and  $b$  are only accepted if they are positive.

The values  $X = f()$  are distributed randomly according to the beta distribution with parameters  $a$  and  $b$ . For any  $0 \leq x \leq 1$ , the probability that  $X \leq x$  is given by

$$\frac{1}{\beta(a, b)} \int_0^x t^{a-1} (1-t)^{b-1} dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::betaRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::betaRandom(a, b): f() $ k = 1..K;
```

rather than by

```
stats::betaRandom(a, b)() $ k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::betaRandom(a, b, Seed = n)() $ k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate beta deviates with parameters  $a = 2$  and  $b = \frac{3}{4}$ :

```
f := stats::betaRandom(2, 3/4): f() $ k = 1..4
```

```
0.9454511844, 0.8615078721, 0.121495159, 0.379420364
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::betaRandom(a, b): f()
```

# stats::betaRandom

---

```
stats::betaRandom(a, b)()
```

When `a` and `b` evaluate to positive real numbers, the generator starts to produce random numbers:

```
a := 1: b := 2: f() $ k = 1..4
```

```
0.1700845647, 0.1490672548, 0.6022714953, 0.2217977725
```

```
delete f, a, b:
```

### Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::betaRandom(1, 3, Seed = 1): f() $ k = 1..4
```

```
0.07584461034, 0.6146360615, 0.2188856232, 0.1020817554
```

```
g := stats::betaRandom(1, 3, Seed = 1): g() $ k = 1..4
```

```
0.07584461034, 0.6146360615, 0.2188856232, 0.1020817554
```

```
f() = g(), f() = g()
```

```
0.3303369551 = 0.3303369551, 0.1975445744 = 0.1975445744
```

```
delete f, g:
```

**Parameters**    **a, b**

The shape parameters of the beta distribution: arithmetical expressions representing positive real values.

## Options

### Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the shape parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of the beta deviates uses gamma deviates `x`, `y` to produce a beta deviate  $x/(x + y)$ . For more information see: D. Knuth, *Seminumerical Algorithms* (1998), Vol. 2, p. 134.

## See Also

## MuPAD Functions

`stats::betaCDF` | `stats::betaPDF` | `stats::betaQuantile`

# stats::binomialCDF

---

**Purpose** The (discrete) cumulative distribution function of the binomial distribution

**Syntax** stats::binomialCDF(n, p)

**Description** stats::binomialCDF(n, p) returns a procedure representing the (discrete) cumulative distribution function

$$x \rightarrow \begin{cases} 0 & \text{if } x < 0 \\ \sum_{i=0}^{\lfloor x \rfloor} \binom{n}{i} p^i (1-p)^{n-i} & \text{if } x \geq 0 \wedge x < 1 \\ 1 & \text{if } x \geq 1 \end{cases}$$

of the binomial distribution with “trial parameter”  $n$  and “probability parameter”  $p$ .

The procedure  $f := \text{stats::binomialCDF}(n, p)$  can be called in the form  $f(x)$  with an arithmetical expression  $x$ . The return value of  $f(x)$  is either a floating-point number, an exact numerical value, or a symbolic expression:

- If  $x$  is a numerical real value and  $n$  is a positive integer, then an explicit value is returned. If  $p$  is a numerical value satisfying  $0 \leq p \wedge p \leq 1$ , this is a numerical value. Otherwise, it is a symbolic expression in  $p$ .
- If  $x$  is a numerical value with  $x < 0$ , then 0, respectively 0.0, is returned for any value of  $n$  and  $p$ .
- For symbolic values of  $n$ , explicit results are returned if  $x$  is a numerical value with  $x < 2$ .
- For symbolic values of  $n$ , explicit results are returned if  $n - x$  is a numerical value with  $n - x \leq 2$ .
- If  $n - x$  is a numerical value with  $n - x \leq 0$ , then 1, respectively 1.0, is returned for any value of  $n$  and  $p$ .

- In all other cases,  $f(x)$  returns the symbolic call `binomialCDF(n, p)(x)`.

Numerical values for  $n$  are only accepted if they are positive integers.

Numerical values for  $p$  are only accepted if they satisfy  $0 \leq p \leq 1$ .

If  $x$  is a real floating-point number, the result is a floating number provided  $n$  and  $p$  are numerical values. If  $x$  is an exact numerical value, the result is an exact number.

---

**Note** Note that for large  $n$ , floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number  $x$  to the procedure generated by `stats::binomialCDF!`

---

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the distribution function with  $n = 20$  and  $p = \frac{3}{4}$  at various points:

```
f := stats::binomialCDF(5, 3/4):
f(-1), f(2), f(PI), f(5), f(6)
```

```
0, 53/512, 47/128, 1, 1
```

```
f(-1.2), f(2.0), f(float(PI)), f(5.5)
```

```
0.0, 0.103515625, 0.3671875, 1.0
```

# stats::binomialCDF

---

```
delete f:
```

## Example 2

We use symbolic arguments:

```
f := stats::binomialCDF(n, p): f(x), f(8), f(8.0)
```

```
stats::binomialCDF(n, p)(x), stats::binomialCDF(n, p)(8), stats::binomialCDF(n, p)(8.0)
```

When numerical values are assigned to  $n$  and  $p$ , the function  $f$  starts to produce explicit results if the argument is numerical:

```
n := 3: p := 1/3:
f(2), f(2.5), f(PI +1), f(4.0)
```

```
 $\frac{26}{27}$, 0.962962963, 1, 1.0
```

```
delete f, n, p:
```

## Example 3

If  $n$  and  $x$  are numerical, symbolic expressions are returned for symbolic values of  $p$ :

```
f := stats::binomialCDF(3, p):
f(-1), f(0), f(3/2), f(1 + sqrt(3)), f(2.999), f(3)
```

```
0, -(p-1)3, 3 p (p-1)2 - (p-1)3, 1 - p3, 1.0 - 1.0 p3, 1
```

```
delete f:
```

## Parameters

**n**

The “trial parameter”: an arithmetical expression representing a positive integer

**p**

The “probability parameter”: an arithmetical expression representing a real number  $0 \leq p \leq 1$ .

## Return Values

procedure.

## See Also

## MuPAD Functions

`stats::binomialPF` | `stats::binomialQuantile` |  
`stats::binomialRandom`

# stats::binomialPF

---

**Purpose** Probability function of the binomial distribution

**Syntax** stats::binomialPF(n, p)

**Description** stats::binomialPF(n, p) returns a procedure representing the probability function

$$x \rightarrow \binom{n}{x} p^x (1-p)^{n-x}$$

for  $x=0, 1, \dots, n$  of the binomial distribution with “trial parameter”  $n$  and “probability parameter”  $p$ .

The procedure `f := stats::binomialPF(n, p)` can be called in the form `f(x)` with arithmetical expressions  $x$ . The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

- If  $x$  is a non-integer numerical value,  $f(x)$  returns 0 or 0.0, respectively.
- If  $x$  is an integer or the floating point equivalent of an integer and  $n$  is a positive integer, then an explicit value is returned. If  $p$  is a numerical value satisfying  $0 \leq p \leq 1$ , this is a numerical value. Otherwise, it is a symbolic expression in  $p$ .

For symbolic values of  $n$ , explicit results are returned if  $x$  is a numerical value with  $x < 2$ .

- For symbolic values of  $n$ , explicit results are returned if  $n - x$  is a numerical value with  $n - x < 2$ .
- In all other cases, `f(x)` returns the symbolic call `stats::binomialPF(n,p)(x)`.

Numerical values for  $n$  are only accepted if they are positive integers.

Numerical values for  $p$  are only accepted if they satisfy  $0 \leq p \leq 1$ .

If  $x$  is a floating-point number, the result is a floating number provided  $n$  and  $p$  are numerical values. If  $x$  is an exact value, the result is an exact number.

Note that for large  $n$ , floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number  $x$  to the procedure created by `stats::binomialPF`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We compute the probability function with  $n = 3$  and  $p = \frac{3}{4}$  at various points:

```
f := stats::binomialPF(3, 3/4):
f(-1/2), f(0), f(1/2), f(1), f(7/4), f(2), f(3), f(4)
```

```
0, 1/64, 0, 9/64, 0, 27/64, 27/64, 0
```

```
f(-0.2), f(0.0), f(0.7), f(1.0), f(2.0), f(2.7), f(3.0), f(4.0)
```

```
0.0, 0.015625, 0.0, 0.140625, 0.421875, 0.0, 0.421875, 0.0
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::binomialPF(n, p): f(x), f(8), f(8.0)
```

# stats::binomialPF

---

```
stats::binomialPF(n, p)(x), stats::binomialPF(n, p)(8), stats::binomialPF(n, p)(8.0)
```

When real numbers are assigned to  $n$  and  $p$ , the function  $f$  starts to produce explicit results if the argument is numerical:

```
n := 3: p := 1/3:
f(0), f(1), f(2.0), f(3.5), f(4)
```

```
 $\frac{8}{27}, \frac{4}{9}, 0.2222222222, 0.0, 0$
```

```
delete f, n, p, x:
```

### Example 3

If  $n$  and  $x$  are numerical, symbolic expressions are returned for symbolic values of  $p$ :

```
f := stats::binomialPF(3, p):
f(-1), f(0), f(3/2), f(2), f(3)
```

```
 $0, -(p-1)^3, 0, -3p^2(p-1), p^3$
```

```
delete f:
```

## Parameters

**n**

The “trial parameter”: an arithmetical expression representing a positive integer

**p**

The “probability parameter”: an arithmetical expression representing a real number  $0 \leq p \leq 1$ .

## Return Values

procedure.

## MuPAD Functions

`stats::binomialCDF` | `stats::binomialQuantile` |  
`stats::binomialRandom`

# stats::binomialQuantile

---

**Purpose** Quantile function of the binomial distribution

**Syntax** `stats::binomialQuantile(n, p)`

**Description** `stats::binomialQuantile(n, p)` returns a procedure representing the quantile function (discrete inverse) of the cumulative distribution function `stats::binomialCDF(n, p)`. For  $0 \leq x \leq 1$ , the quantile value  $k = \text{stats::binomialQuantile}(n, p)(x)$  satisfies

$$\text{stats::binomialCDF}(n, p)(k - 1) < x \wedge x \leq \text{stats::binomialCDF}(n, p)(k)$$

The procedure `f := stats::binomialQuantile(n, p)` can be called in the form `f(x)` with arithmetical expressions  $x$ . The return value of `f(x)` is either a natural number between 0 and  $n$ , or a symbolic expression:

- If  $n$  is a positive integer,  $p$  a real number satisfying  $0 \leq p \leq 1$ , and  $x$  a real number satisfying  $0 \leq x \leq 1$ , then `f(x)` returns an integer between 0 and  $n$ .
- If  $p = 0$ , then `f(x)` returns 0 for any values of  $n$  and  $x$ .
- If  $p = 1$ , then `f(x)` returns  $n$  for any values of  $n$  and  $x$ .
- For  $p \neq 1$ , the call `f(0)` returns 0 for any value of  $n$ .
- For  $p \neq 0$ , the call `f(1)` returns  $n$  for any value of  $n$ .
- In all other cases, `f(x)` returns the symbolic call `stats::binomialQuantile(n, p)(x)`.

Numerical values for  $n$  are only accepted if they are positive integers.

Numerical values for  $p$  are only accepted if they satisfy  $0 \leq p \leq 1$ .

If floating-point arguments are passed to the quantile function `f`, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors. In particular, round-off may be significant for arguments  $x$  close to 1. Cf. “Example 3” on page 29-28.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with  $n = 30$  and  $p = \frac{1}{3}$  at some points:

```
f := stats::binomialQuantile(30, 1/3):
f(0), f((2/3)^30), f(PI/10), f(0.5), f(1 - 1/10^10)
```

```
0, 0, 9, 10, 27
```

The quantile value  $f(x)$  satisfies

$$\text{stats::binomialCDF}(n, p)(f(x) - 1) < x \wedge x \leq \text{stats::binomialCDF}(n, p)(f(x))$$

```
x := 0.7: f(x)
```

```
11
```

```
stats::binomialCDF(30, 1/3)(float(f(x) - 1)), x,
stats::binomialCDF(30, 1/3)(float(f(x)))
```

```
0.5847595988, 0.7, 0.7238643653
```

```
delete f, x:
```

### Example 2

We use symbolic arguments:

```
f := stats::binomialQuantile(n, p): f(x), f(9/10)
```

# stats::binomialQuantile

---

```
stats::binomialQuantile(n, p)(x), stats::binomialQuantile(n, p)($\frac{9}{10}$)
```

When  $n$  and  $p$  evaluate to suitable numbers, the function  $f$  starts to produce quantile values:

```
n := 80: p := 1/10:
f(1/2), f(999/1000), f(1 - 1/10^10), f(1 - 1/10^80)
```

```
8, 17, 29, 79
```

```
delete f, n, p:
```

### Example 3

If floating-point arguments are passed to the quantile function, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors:

```
f := stats::binomialQuantile(1000, 1/30):
f(1 - 1/10^16) <> f(float(1 - 1/10^16))
```

```
89 ≠ 88
```

```
delete f:
```

## Parameters

**n**

The “trial parameter”: an arithmetical expression representing a positive integer

**p**

The “probability parameter”: an arithmetical expression representing a real number  $0 \leq p \leq 1$ .

## Return Values

procedure.

## MuPAD Functions

[stats::binomialCDF](#) | [stats::binomialPF](#) |  
[stats::binomialRandom](#)

# stats::binomialRandom

---

**Purpose** Generate a random number generator for binomial deviates

**Syntax** stats::binomialRandom(*n*, *p*, <Seed = *s*>)

**Description** stats::binomialRandom(*n*, *p*) returns a procedure that produces binomial-deviates (random numbers) with trial parameter *n* and probability parameter *p*.

The procedure  $f := \text{stats::binomialRandom}(n, p)$  can be called in the form  $f()$ . The return value of  $f()$  is an integer between 0 and  $n$  or a symbolic expression:

- If  $n$  is a positive integer and  $p$  is a real value satisfying  $0 \leq p \leq 1$ , then  $f()$  returns an integer between 0 and  $n$ .
- If  $p = 0$  or  $p = 0.0$ , then  $f()$  returns 0 for any value of  $n$ .
- If  $p = 1$  or  $p = 1.0$ , then  $f()$  returns  $n$  for any value of  $n$ .

In all other cases,  $f()$  return the symbolic call  $\text{stats::binomialRandom}(n, p)()$ .

Numerical values for  $n$  are only accepted if they are positive integers.

Numerical values for  $p$  are only accepted if they satisfy  $0 \leq p \leq 1$ .

The values  $X = f()$  are distributed randomly according to the binomial distribution with trial parameter  $n$  and probability parameter  $p$ . For any  $x \in [0, 1]$ , the probability of  $X \leq x$  is given by

$$\sum_{i=0}^{\lfloor x \rfloor} \binom{n}{i} p^i (1-p)^{n-i}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** With this option, the parameters  $n$  and  $p$  must evaluate to suitable numerical values at the time, when the generator is created.

---

---

**Note** In contrast to the function `random`, the generators produced by `stats::binomialRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::binomialRandom(n, p): f() $k = 1..K;
```

rather than by

```
stats::binomialRandom(n, p)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::binomialRandom(n, p, Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We generate binomial deviates with parameters  $n = 80$  and  $p = \frac{1}{7}$ :

```
f := stats::binomialRandom(80, 1/7): f() $ k = 1..10
```

# stats::binomialRandom

---

```
9, 9, 16, 11, 8, 5, 11, 13, 14, 12
```

```
delete f:
```

## Example 2

With symbolic parameters, no random numbers can be produced:

```
f := stats::binomialRandom(n, p): f()
```

```
stats::binomialRandom(n, p())
```

When  $n$  and  $p$  evaluate to suitable numbers, the generator starts to produce random numbers:

```
n := 200: p := 1/PI: f() $ k= 1..10
```

```
79, 69, 69, 64, 77, 70, 80, 66, 62, 69
```

```
delete f, n, p:
```

## Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::binomialRandom(70, 7/8, Seed = 1): f() $ k = 1..10
```

```
63, 65, 60, 65, 60, 57, 58, 63, 57, 61
```

```
g := stats::binomialRandom(70, 7/8, Seed = 1): g() $ k = 1..10
```

```
63, 65, 60, 65, 60, 57, 58, 63, 57, 61
```

```
f() = g(), f() = g()
```

```
61 = 61, 63 = 63
```

```
delete f, g:
```

## Parameters

**n**

The “trial parameter”: an arithmetical expression representing a positive integer

**p**

The “probability parameter”: an arithmetical expression representing a real number  $0 \leq p \leq 1$ .

## Options

**Seed**

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `n` and `p` must be numerical values at the time when the random generator is generated.

## Return Values

procedure.

# stats::binomialRandom

---

## See Also

## MuPAD Functions

stats::binomialCDF | stats::binomialPF |  
stats::binomialQuantile

**Purpose**

Apply functions to a sample

**Syntax**

```
stats::calc(s, c, f1, f2, ...)
stats::calc(s, [c1, c2, ...], f1, f2, ...)
```

**Description**

`stats::calc` applies functions to columns of the sample `s`.

In a call such as `stats::calc(s, c, f1)` the function `f1` is applied to the elements of the column `c` of `s`. This generates a new column which is appended to `s`. If present, the next function `f2` is applied to the new sample etc. Thus, a call of `stats::calc` with  $m$  functions appends  $m$  new columns to `s`.

Each function must accept exactly one parameter.

In a call such as `stats::calc(s, [c1, c2, ...], f1)` the  $i$ -th element of the new column is given by `f1(si, c1, si, c2, ...)`.

Each function must accept as many parameters as specified by the second argument of `stats::calc`.

**Examples****Example 1**

We create a sample of three rows and three columns:

```
stats::sample([[1, a1, b1], [2, a2, b2], [3, a3, b3]])
```

```
1 a1 b1
2 a2 b2
3 a3 b3
```

We add and multiply the elements of the columns 2 and 3 by applying the system functions `_plus` and `_mult`:

```
stats::calc(%, [2, 3], _plus, _mult)
```

## stats::calc

---

```
1 a1 b1 a1 + b1 a1*b1
2 a2 b2 a2 + b2 a2*b2
3 a3 b3 a3 + b3 a3*b3
```

The following call maps each element of the second column of the original sample to its fourth power:

```
stats::calc(%2, 2, x -> x^4)
```

```
1 a1 b1 a1^4
2 a2 b2 a2^4
3 a3 b3 a3^4
```

The following call computes the mean values of the rows of the last sample:

```
stats::calc(%, [1, 2, 3, 4],
 (x1, x2, x3, x4) -> (x1 + x2 + x3 + x4)/4)
```

```
1 a1 b1 a1^4 a1^4/4 + a1/4 + b1/4 + 1/4
2 a2 b2 a2^4 a2^4/4 + a2/4 + b2/4 + 1/2
3 a3 b3 a3^4 a3^4/4 + a3/4 + b3/4 + 3/4
```

The same is achieved by the following call:

```
stats::calc(%2, [1, 2, 3, 4], stats::mean)
```

```
1 a1 b1 a1^4 a1^4/4 + a1/4 + b1/4 + 1/4
2 a2 b2 a2^4 a2^4/4 + a2/4 + b2/4 + 1/2
3 a3 b3 a3^4 a3^4/4 + a3/4 + b3/4 + 3/4
```

**Parameters****s**A sample of domain type `stats::sample`**c, c<sub>1</sub>, c<sub>2</sub>, ...**

Positive integers representing column indices of the sample

**f<sub>1</sub>, f<sub>2</sub>, ...**

Procedures

**Return  
Values**Sample of domain type `stats::sample`.**See Also****MuPAD  
Functions**`stats::tabulate`

# stats::cauchyCDF

---

**Purpose** Cumulative distribution function of the Cauchy distribution

**Syntax** `stats::cauchyCDF(a, b)`

**Description** `stats::cauchyCDF(a, b)` returns a procedure representing the cumulative distribution function

$$x \rightarrow \frac{1}{\pi} \arctan\left(\frac{x - a}{b}\right) + \frac{1}{2}$$

of the Cauchy distribution with median  $a$  and scale parameter  $b > 0$ .

The procedure `f := stats::cauchyCDF(a, b)` can be called in the form `f(x)` with arithmetical expressions  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

- If  $x$  is a floating-point number and  $a$  and  $b$  can be converted to suitable floating-point numbers, then `f(x)` returns a floating-point number.
- In all other cases, the symbolic expression  $\arctan((x - a)/b)/\text{PI} + 1/2$  is returned.

Numerical values of  $a$  and  $b$  are only accepted if they are real and  $b$  is positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

**Examples** **Example 1**

We evaluate the cumulative distribution function with  $a = 2$  and  $b = \frac{3}{4}$  at various points:

```
f := stats::cauchyCDF(2, 3/4):
f(-infinity), f(-10), f(0.8), f(2), f(10.0^4), f(infinity)
```

$$0, \frac{1}{2} - \frac{\arctan(16)}{\pi}, 0.1778076845, \frac{1}{2}, 0.999976122, 1$$

delete f, x:

## Example 2

We use symbolic arguments:

```
f := stats::cauchyCDF(a, b):
f(x), f(sqrt(2)), f(0.9)
```

$$\frac{1}{2} - \frac{\arctan\left(\frac{a-x}{b}\right)}{\pi}, \frac{1}{2} - \frac{\arctan\left(\frac{a-\sqrt{2}}{b}\right)}{\pi}, \frac{1}{2} - \frac{\arctan\left(\frac{a-0.9}{b}\right)}{\pi}$$

When numbers are assigned to  $a$  and  $b$ , the function  $f$  starts to produce corresponding numerical values:

```
a := PI:
b := 1/8:
f(sqrt(2)), f(0.9)
```

$$\frac{\arctan(8\sqrt{2} - 8\pi)}{\pi} + \frac{1}{2}, 0.01773184344$$

## Parameters

**a**

The median: an arithmetical expression representing a real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

# stats::cauchyCDF

---

## Return Values

procedure.

## MuPAD Functions

stats::cauchyPDF | stats::cauchyQuantile |  
stats::cauchyRandom

**Purpose**

Probability density function of the Cauchy distribution

**Syntax**

`stats::cauchyPDF(a, b)`

**Description**

`stats::cauchyPDF(a, b)` returns a procedure representing the probability density function

$$x \rightarrow \frac{b}{\pi} \frac{1}{(x - a)^2 + b^2}$$

of the Cauchy distribution with median  $a$  and scale parameter  $b > 0$ .

The procedure `f := stats::cauchyPDF(a, b)` can be called in the form `f(x)` with arithmetical expressions  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

- If  $x$  is a floating-point number and  $a$  and  $b$  can be converted to suitable floating-point numbers, then `f(x)` returns a floating-point number.
- In all other cases, the symbolic expression `b/PI * 1/((x-a)^2 + b^2)` is returned.

Numerical values of  $a$  and  $b$  are only accepted if they are real and  $b$  is positive.

**Environment Interactions**

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

**Examples****Example 1**

We calculate the Cauchy density with  $a = 2$  and  $b = \frac{3}{4}$  at various points:

```
f := stats::cauchyPDF(2, 3/4):
f(-infinity), f(9/10), f(0.9), f(2), f(infinity)
```

# stats::cauchyPDF

---

$$0, \frac{300}{709 \pi}, 0.1346868348, \frac{4}{3 \pi}, 0$$

delete f:

## Example 2

We use symbolic arguments:

```
f := stats::cauchyPDF(a, b):
f(x), f(2), f(2.0)
```

$$\frac{b}{\pi (b^2 + (a - x)^2)}, \frac{b}{\pi ((a - 2)^2 + b^2)}, \frac{b}{\pi (b^2 + (a - 2.0)^2)}$$

When  $a$  and  $b$  evaluate to numbers, the function  $f$  starts to produce numerical values:

```
a := PI:
b := 1/8:
f(2), f(2.0)
```

$$\frac{1}{8 \pi \left( (\pi - 2)^2 + \frac{1}{64} \right)}, 0.03016906448$$

delete f, a, b:

## Parameters

**a**

The median: an arithmetical expression representing a real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## MuPAD Functions

stats::cauchyCDF | stats::cauchyQuantile |  
stats::cauchyRandom

# stats::cauchyQuantile

---

**Purpose** Quantile function of the Cauchy distribution

**Syntax** stats::cauchyQuantile(a, b)

**Description** stats::cauchyQuantile(a, b) returns a procedure representing the quantile function (inverse) of the cumulative distribution function stats::cauchyCDF(a, b): for  $0 \leq x \leq 1$ , the solution of  $\text{stats::cauchyCDF}(a, b)(y) = x$  is given by  $y = \text{stats::cauchyQuantile}(a, b)(x)$ .

The procedure  $f := \text{stats::cauchyQuantile}(a, b)$  can be called in the form  $f(x)$  with arithmetical expressions  $x$ . The return value of  $f(x)$  is either a floating-point number,  $\pm\infty$  or a symbolic expression:

If  $x$  is a floating-point number between 0 and 1 and  $a$  and  $b$  can be converted to suitable floating-point numbers, then  $f(x)$  returns a floating-point number approximating the real solution  $y$  of  $\text{stats::cauchyCDF}(a, b)(y) = x$ .

For any value of  $a$  and  $b$ , the calls  $f(0)$  and  $f(0.0)$  produce  $-\infty$ . The calls  $f(1)$  and  $f(1.0)$  produce *infinity*.

In all other cases, the symbolic expression  $a + b \cdot \tan(\text{PI} \cdot (x - 1/2))$  is returned.

Numerical values of  $a$  and  $b$  are only accepted, if they are real and  $b$  is positive.

**Environment Interactions** The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

**Examples** **Example 1**

We evaluate the quantile function with  $a = 2$  and  $b = \frac{3}{4}$  at various points:

```
f := stats::cauchyQuantile(2, 3/4):
f(0), f(4/5), f(0.8), f(1)
```

$$-\infty, \frac{3\sqrt{5}\sqrt{2\sqrt{5}+5}}{20} + 2, 3.03228644, \infty$$

delete f:

## Example 2

We use symbolic arguments:

```
f := stats::cauchyQuantile(a, b):
f(0), f(x), f(1/sqrt(2)), f(0.9), f(1)
```

$$-\infty, a + b \tan\left(\pi\left(x - \frac{1}{2}\right)\right), a + b \tan\left(\pi\left(\frac{\sqrt{2}}{2} - \frac{1}{2}\right)\right), a + b \tan(0.4\pi), \infty$$

When numbers are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values when called with arguments between 0 and 1:

```
a := PI: b := 1/8:
f(0), f(1/sqrt(2)), f(0.9), f(1)
```

$$-\infty, \pi + \frac{\tan\left(\pi\left(\frac{\sqrt{2}}{2} - \frac{1}{2}\right)\right)}{8}, 3.526303096, \infty$$

## Parameters

**a**

The median: an arithmetical expression representing a real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

# stats::cauchyQuantile

---

## MuPAD Functions

[stats::cauchyPDF](#) | [stats::cauchyCDF](#) | [stats::cauchyRandom](#)

**Purpose**

Generate a random number generator for Cauchy deviates

**Syntax**

`stats::cauchyRandom(a, b, <Seed = n>)`

**Description**

`stats::cauchyRandom(a, b)` returns a procedure that produces Cauchy deviates (random numbers) with median  $a$  and scale parameter  $b > 0$ .

The procedure `f := stats::cauchyRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If  $a$  can be converted to a real floating point number and  $b$  to a positive real floating point number, then `f()` returns a real floating point number.

In all other cases, `f()` returns the symbolic call `stats::cauchyRandom(a, b)()`.

Numerical values of  $a$  and  $b$  are only accepted, if they are real and  $b$  is positive.

The values  $X = f()$  are distributed randomly according to the the Cauchy distribution with parameters  $a$  and  $b$ . For any real  $x$ , the probability that  $X \leq x$  is given by

$$\frac{1}{\pi} \arctan\left(\frac{x - a}{b}\right) + \frac{1}{2}$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::cauchyRandom` do not react to the environment variable `SEED`.

---

# stats::cauchyRandom

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::cauchyRandom(a, b): f() $ k = 1..K;
```

rather than by

```
stats::cauchyRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::cauchyRandom(a, b, Seed = n)() $ k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate Cauchy deviates with parameters  $a = 2$  and  $b = \frac{3}{4}$ :

```
f := stats::cauchyRandom(2, 3/4): f() $ k = 1..4
```

```
1.340284406, 3.277664042, 0.5634392829, 48.01912393
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::cauchyRandom(a, b): f()
```

```
stats::cauchyRandom(a, b)()
```

When  $a$  and  $b$  evaluate to suitable real numbers, the generator starts to produce random numbers:

```
a := -PI: b := 1/2: f() $ k = 1..4
```

```
-3.592915903, -3.928568815, -3.217434162, -2.82696038
```

```
delete f, a, b:
```

### Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:

```
f := stats::cauchyRandom(PI, 3, Seed = 1): f() $ k = 1..4
```

```
3.786179405, 7.050017894, -4.775376375, -1.791650747
```

```
g := stats::cauchyRandom(PI, 3, Seed = 1): g() $ k = 1..4
```

```
3.786179405, 7.050017894, -4.775376375, -1.791650747
```

```
f() = g(), f() = g()
```

```
8.362838563 = 8.362838563, -302.9342996 = -302.9342996

delete f, g:
```

## Parameters

**a**

The median: an arithmetical expression representing a real value

# stats::cauchyRandom

---

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Options

**Seed**

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to suitable floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of the Cauchy deviates uses the quantile function of the Cauchy distribution applied to uniformly distributed random numbers between 0 and 1.

## See Also

## MuPAD Functions

`stats::cauchyCDF` | `stats::cauchyPDF` | `stats::cauchyQuantile`

**Purpose** Cumulative distribution function of the chi-square distribution

**Syntax** stats::chisquareCDF(m)

**Description** stats::chisquareCDF(m) returns a procedure representing the cumulative distribution function

$$x \rightarrow \begin{cases} \int_0^x \frac{t^{\frac{m}{2}-1} e^{-\frac{t}{2}}}{2^{m/2} \Gamma(\frac{m}{2})} dt & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases}$$

of the chi-square distribution with mean  $m > 0$ .

The procedure `f := stats::chisquareCDF(m)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x > 0$  can be decided, then

`f(x)` returns the value  $1 - \frac{\Gamma(\frac{m}{2}, \frac{x}{2})}{\Gamma(\frac{m}{2})}$ .

If `x` is a floating-point number and `m` can be converted to a positive floating-point number, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If `x` is a symbolic expression with the property  $x \leq 0$  or  $x \geq 0$ , the corresponding values are returned.

`f(x)` returns the symbolic call `stats::chisquareCDF(m)(x)` if neither  $x \leq 0$  nor  $x > 0$  can be decided.

Numerical values for `m` are only accepted if they are real and positive.

Note that, for large `m`, exact results may be costly to compute. If floating-point values are desired, it is recommended to pass

# stats::chisquareCDF

---

floating-point arguments  $x$  to  $f$  rather than to compute exact results  $f(x)$  and convert them via `float`. Cf. “Example 4” on page 29-54.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the cumulative distribution function with mean  $m = 2$  at various points:

```
f := stats::chisquareCDF(2):
f(-infinity), f(-3), f(1/2), f(0.5), f(PI), f(infinity)
```

```
0, 0, 1 - e-1/4, 0.2211992169, 1 - e-π/2, 1
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \geq 0$  holds. A symbolic function call is returned:

```
f := stats::chisquareCDF(m):
f(x)
```

```
stats::chisquareCDF(m)(x)
```

With suitable properties, it can be decided whether  $x \geq 0$  holds. An explicit expression is returned:

```
assume(0 <= x):
f(x)
```

$$1 - \frac{\Gamma(\frac{m}{2}, \frac{x}{2})}{\Gamma(\frac{m}{2})}$$

For integer values of m, the special function igamma can be expressed in terms of more elementary functions:

m := 6:  
f(x)

$$1 - \frac{e^{-\frac{x}{2}} \left( \frac{x^2}{4} + x + 2 \right)}{2}$$

m := 5:  
f(x)

$$1 - \frac{4 \left( \frac{3 \sqrt{\pi} \operatorname{erfc}\left(\sqrt{\frac{x}{2}}\right)}{4} + e^{-\frac{x}{2}} \left( \frac{3 \sqrt{\frac{x}{2}}}{2} + \left(\frac{x}{2}\right)^{3/2} \right) \right)}{3 \sqrt{\pi}}$$

unassume(x): delete f, m:

### Example 3

We use a symbolic mean m:

f := stats::chisquareCDF(m):  
f(3), f(3.0)

$$1 - \frac{\Gamma(\frac{m}{2}, \frac{3}{2})}{\Gamma(\frac{m}{2})}, 1.0 - \frac{1.0 \Gamma(0.5 m, 1.5)}{\Gamma(0.5 m)}$$

# stats::chisquareCDF

---

When a numerical value is assigned to `m`, the function `f` starts to produce numerical values:

```
m := PI:
f(3), f(3.0)
```

$$1 - \frac{\Gamma(\frac{\pi}{2}, \frac{3}{2})}{\Gamma(\frac{\pi}{2})}, 0.5840678031$$

```
delete f, m:
```

## Example 4

We consider a chi-square distribution with large mean  $m = 1000$ :

```
f := stats::chisquareCDF(1000):
```

For floating-point approximations, one should not compute an exact result and convert it via `float`. For large mean  $m$ , it is faster to pass a floating-point argument to `f`. The following call takes some time, because an exact computation of the huge integer  $\text{gamma}(m/2) = \text{gamma}(500) = 499!$  is involved:

```
float(f(1023))
```

```
0.7003071959
```

The following call is much faster:

```
f(float(1023))
```

```
0.7003071959
```

`delete f:`

## Parameters

**m**

The mean: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

`gamma` | `igamma` | `stats::chisquarePDF` | `stats::chisquareQuantile` | `stats::chisquareRandom`

# stats::chisquarePDF

---

**Purpose** Probability density function of the chi-square distribution

**Syntax** stats::chisquarePDF(m)

**Description** stats::chisquarePDF(m) returns a procedure representing the probability density function

$$X \rightarrow \begin{cases} \frac{x^{\frac{m}{2}-1} e^{-\frac{x}{2}}}{2^{m/2} \Gamma(\frac{m}{2})} & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases}$$

of the chi-square distribution with mean  $m > 0$ .

The procedure `f := stats::chisquarePDF(m)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x > 0$  can be decided, then

$$f(x) \text{ returns the value } \frac{x^{\frac{m}{2}-1} e^{-\frac{x}{2}}}{2^{m/2} \Gamma(\frac{m}{2})}.$$

If `x` is a floating-point number and `m` can be converted to a positive floating-point number, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If `x` is a symbolic expression with the property  $x \leq 0$  or  $x \geq 0$ , the corresponding values are returned.

`f(x)` returns the symbolic call `stats::chisquarePDF(m)(x)` if neither  $x \leq 0$  nor  $x > 0$  can be decided,

Numerical values of `m` are only accepted if they are positive.

Note that, for large  $m$ , exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments  $x$  to `f` rather than to compute exact results `f(x)` and convert them via `float`. Cf. “Example 4” on page 29-58.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the probability density function with  $m = 2$  at various points:

```
f := stats::chisquarePDF(2):
f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)
```

```
0, 0, $\frac{e^{-\frac{1}{4}}}{2}$, 0.3894003915, $\frac{e^{-\frac{\pi}{2}}}{2}$, 0
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \geq 0$  holds. A symbolic function call is returned:

```
f := stats::chisquarePDF(m): f(x)
```

```
stats::chisquarePDF(m)(x)
```

With suitable properties, it can be decided whether  $x \geq 0$  holds. An explicit expression is returned:

```
assume(0 <= x): f(x)
```

# stats::chisquarePDF

---

$$\frac{x^{\frac{m}{2}-1} e^{-\frac{x}{2}}}{2^{\frac{m}{2}} \Gamma(\frac{m}{2})}$$

`unassume(x): delete f:`

## Example 3

We use symbolic a symbolic mean  $m$ :

```
f := stats::chisquarePDF(m): f(x)
```

```
stats::chisquarePDF(m)(x)
```

When a numerical value is assigned to  $m$ , the function  $f$  starts to produce numerical values:

```
m := PI: f(3), f(3.0)
```

$$\frac{3^{\frac{\pi}{2}-1} e^{-\frac{3}{2}}}{2^{\pi/2} \Gamma(\frac{\pi}{2})}, 0.1578981008$$

`delete f, m:`

## Example 4

We consider a chi-square distribution with large mean  $m = 1000$ :

```
f := stats::chisquarePDF(1000):
```

For floating-point approximations, one should not compute an exact result and convert it via `float`. For large mean  $m$ , it is faster to pass a floating-point argument to  $f$ . The following call takes some

time, because an exact computation of the huge integer  $\text{gamma}(m/2) = \text{gamma}(500) = 499!$  is involved:

```
float(f(1023))
```

```
0.00765380452
```

The following call is much faster:

```
f(float(1023))
```

```
0.00765380452
```

```
delete f:
```

## Parameters

**m**

The mean: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

[gamma](#) | [stats::chisquareCDF](#) | [stats::chisquareQuantile](#) | [stats::chisquareRandom](#)

# stats::chisquareQuantile

---

**Purpose** Quantile function of the chi-square distribution

**Syntax** stats::chisquareQuantile(m)

**Description** stats::chisquareQuantile(m) returns a procedure representing the quantile function (inverse) of the cumulative distribution function stats::chisquareCDF(m). For  $0 \leq x \leq 1$ , the solution of  $\text{stats::chisquareCDF}(m)(y) = x$  is given by  $y = \text{stats::chisquareQuantile}(m)(x)$ .

The procedure  $f := \text{stats::chisquareQuantile}(m)$  can be called in the form  $f(x)$  with an arithmetical expression  $x$ . The return value of  $f(x)$  is either a floating-point number, *infinity*, or a symbolic expression:

If  $x$  is a real number between 0 and 1 and  $m$  can be converted to a positive floating-point number, then  $f(x)$  returns a positive floating-point number approximating the solution  $y$  of  $\text{stats::chisquareCDF}(m)(y) = x$ .

The calls  $f(0)$  and  $f(0.0)$  produce 0.0 for all values of  $m$ .

The calls  $f(1)$  and  $f(1.0)$  produce *infinity* for all values of  $m$ .

In all other cases,  $f(x)$  returns the symbolic call  $\text{stats::chisquareQuantile}(m)(x)$ .

Numerical values of  $m$  are only accepted if they are real and positive.

**Environment Interactions** The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

**Examples** **Example 1**

We evaluate the quantile function with  $m = \pi$  at various points:

```
f := stats::chisquareQuantile(PI):
f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)
```

```
0.0, 0.6469867417, 2.505845123, 50.00263604, ∞
```

The value  $f(x)$  satisfies  $\text{stats::chisquareCDF}(\text{PI})(f(x)) = x$ :

Der Wert  $f(x)$  erfüllt  $\text{stats::chisquareCDF}(\text{PI})(f(x)) = x$ :

```
stats::chisquareCDF(PI)(f(0.987654))
```

```
0.987654
```

```
delete f:
```

## Example 2

We use symbolic arguments:

```
f := stats::chisquareQuantile(m): f(x), f(9/10)
```

```
stats::chisquareQuantile(m)(x), stats::chisquareQuantile(m)($\frac{9}{10}$)
```

When a positive real value is assigned to  $m$ , the function  $f$  starts to produce floating-point values:

```
m := PI + 1: f(0.999), f(1 - sqrt(2)/10^5)
```

```
18.76468483, 28.07485542
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(2)
```

```
Error: An argument x with $0 \leq x \leq 1$ is expected. [f]
```

```
delete f, m:
```

# stats::chisquareQuantile

---

## Parameters

**m**

The mean: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::chisquareCDF | stats::chisquarePDF |  
stats::chisquareRandom

**Purpose** Generate a random number generator for chi-square deviates

**Syntax** stats::chisquareRandom(m, <Seed = n>)

**Description** stats::chisquareRandom(m) returns a procedure that produces chi-square deviates (random numbers) with mean  $m > 0$ .

The procedure  $f := \text{stats::chisquareRandom}(m)$  can be called in the form  $f()$ . The return value of  $f()$  is either a floating-point number or a symbolic expression:

If  $m$  can be converted to a positive floating point number, then  $f()$  returns a nonnegative floating point number.

In all other cases,  $\text{stats::chisquareRandom}(m)()$  is returned symbolically.

A numerical value of  $m$  is only accepted if it is positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the chi-square distribution with mean  $m$ . For any  $x \geq 0$ , the probability that  $X \leq x$  is given by

$$\frac{1}{\Gamma\left(\frac{m}{2}\right) 2^{m/2}} \int_0^x t^{\frac{m}{2}-1} e^{-\frac{t}{2}} dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::chisquareRandom` do not react to the environment variable `SEED`.

---

# stats::chisquareRandom

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::chisquareRandom(m): f() $k = 1..K;
```

rather than by

```
stats::chisquareRandom(m)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::chisquareRandom(m, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate chi-square deviates with mean  $m = 12$ :

```
f := stats::chisquareRandom(12): f() $ k = 1..4
```

```
17.54103319, 13.4630887, 17.34866815, 4.820644436
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::chisquareRandom(m): f()
```

```
stats::chisquareRandom(m())
```

When  $m$  evaluates to a positive real number, the generator starts to produce random numbers:

```
m := PI: f() $ k = 1..4
```

```
1.557180623, 0.3840766601, 0.5560473903, 3.185747198
```

```
delete f, m:
```

### Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:

```
f := stats::chisquareRandom(70, Seed = 1): f() $ k = 1..4
```

```
55.24812677, 78.10283482, 68.16283459, 80.01866787
```

```
g := stats::chisquareRandom(70, Seed = 1): g() $ k = 1..4
```

```
55.24812677, 78.10283482, 68.16283459, 80.01866787
```

```
f() = g(), f() = g()
```

```
94.28358259 = 94.28358259, 57.54456 = 57.54456
```

```
delete f, g:
```

# stats::chisquareRandom

---

## Parameters

**m**

The mean: an arithmetical expression representing a positive real value

## Options

**Seed**

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the mean `m` must be convertible to a positive floating-point number at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of the chi-square deviates uses a gamma deviate `x` with shape parameters  $m/2$  and  $2$ . For more information see: D. Knuth, *Seminumerical Algorithms* (1998), Vol. 2, p. 135.

## See Also

## MuPAD Functions

`stats::chisquareCDF` | `stats::chisquarePDF` |  
`stats::chisquareQuantile`

**Purpose**

Select and rearrange columns of a sample

**Syntax**

```
stats::col(s, c1, <c2, >)
stats::col(s, c1 .. c2, <c3 .. c4, >)
```

**Description**

`stats::col(s, ...)` creates a new sample from selected columns of the sample `s`.

`stats::col` is useful for selecting columns of interest or for rearranging columns.

The columns of `s` specified by the remaining arguments of `stats::col` are used to build a new sample. The new sample contains the columns of `s` in the order specified by the call to `stats::col`. Columns can be duplicated by specifying the column index more than once.

**Examples****Example 1**

The following sample contains columns for “gender”, “age”, “height”, the “number of yellow socks” and “eye color” of a person:

```
stats::sample([["m", 26, 180, 3, "blue"],
 ["f", 22, 160, 0, "brown"],
 ["f", 48, 155, 2, "green"],
 ["m", 30, 172, 1, "brown"]])
```

```
"m" 26 180 3 "blue"
"f" 22 160 0 "brown"
"f" 48 155 2 "green"
"m" 30 172 1 "brown"
```

Since nobody is really interested in the yellow socks, we create a new sample without that column:

```
stats::col(%, 1..3, 5)
```

## stats::col

---

```
"m" 26 180 "blue"
"f" 22 160 "brown"
"f" 48 155 "green"
"m" 30 172 "brown"
```

We can use `stats::col` to rearrange the sample. As an illustrating example, we duplicate the first column:

```
stats::col(%, 1, 3, 2, 1, 4)
```

```
"m" 180 26 "m" "blue"
"f" 160 22 "f" "brown"
"f" 155 48 "f" "green"
"m" 172 30 "m" "brown"
```

### Parameters

**s**

A sample of domain type `stats::sample`.

**c<sub>1</sub>, c<sub>2</sub>, ...**

Positive integers representing column indices of the sample `s`. A range `c1 .. c2` represents all columns from `c1` through `c2`.

### Return Values

Sample of domain type `stats::sample`.

### See Also

### MuPAD Functions

`stats::concatCol` | `stats::concatRow` | `stats::row`

**Purpose**

Concatenate samples column-wise

**Syntax**

```
stats::concatCol(s1, s2, <s3, >)
```

**Description**

`stats::concatCol(s1, s2, )` creates a new sample consisting of the columns of the samples `s1`, `s2` etc.

If the samples `s1`, `s2` etc. have different numbers of rows, then the number of rows in the resulting sample is given by the “shortest” sample with the minimal number of rows. Elements below this row in “longer” samples are ignored.

**Examples****Example 1**

We create two samples:

```
s1 := stats::sample([[a1, a2], [b1, b2]]);
s2 := stats::sample([[a3, a4], [b3, b4]])
```

```
a1 a2
b1 b2
```

```
a3 a4
b3 b4
```

Concatenation of the columns yields:

```
stats::concatCol(s1, s2)
```

```
a1 a2 a3 a4
b1 b2 b3 b4
```

# stats::concatCol

---

```
delete s1, s2:
```

## Example 2

The following sample contains columns for “gender”, “age” and “height” of a person:

```
stats::sample([["m", 26, 180], ["f", 22, 160],
 ["f", 48, 155], ["m", 30, 172]])
```

```
"m" 26 180
"f" 22 160
"f" 48 155
"m" 30 172
```

We append a further column “nationality”, specified by a list:

```
stats::concatCol(%, ["German", "French", "Italian",
 "British", "German"])
```

```
"m" 26 180 "German"
"f" 22 160 "French"
"f" 48 155 "Italian"
"m" 30 172 "British"
```

## Parameters

$s_1, s_2, \dots$

Samples of domain type `stats::sample`. Alternatively, lists may be entered, which are treated as columns of a sample.

## Return Values

Sample of domain type `stats::sample`.

## See Also

## MuPAD Functions

`stats::col` | `stats::concatRow` | `stats::row`

# stats::concatRow

---

**Purpose** Concatenate samples row-wise

**Syntax** `stats::concatRow(s1, s2, <s3, >)`

**Description** `stats::concatRow(s1, s2, )` creates a new sample consisting of the rows of the samples s<sub>1</sub>, s<sub>2</sub> etc.

All samples must have the same number of columns.

## Examples

### Example 1

We create a small sample:

```
stats::sample([[123, g], [442, f]])
```

```
123 g
442 f
```

A list is concatenated to the sample as a row:

```
stats::concatRow(%, [x, y])
```

```
123 g
442 f
 x y
```

### Example 2

The following samples contain columns for “gender” and “age”:

```
s1 := stats::sample(["f", 36], ["m", 25]);
s2 := stats::sample(["m", 26], ["f", 22])
```

```
"f" 36
"m" 25
```

```
"m" 26
"f" 22
```

We build a larger sample:

```
stats::concatRow(s1, s2)
```

```
"f" 36
"m" 25
"m" 26
"f" 22
```

```
delete s1, s2:
```

## Parameters

$s_1, s_2, \dots$

Samples of domain type `stats::sample`. Alternatively, lists may be entered, which are treated as rows of a sample.

## Return Values

Sample of domain type `stats::sample`.

## See Also

## MuPAD Functions

`stats::col` | `stats::concatCol` | `stats::row`

# stats::correlation

---

**Purpose** Correlation between data samples

**Syntax**

```
stats::correlation([x1, x2,], [y1, y2,],
<BravaisPearson | Fechner>)
stats::correlation([[x1, y1], [x2, y2],],
<BravaisPearson | Fechner>)
stats::correlation(s, <c1, c2>, <BravaisPearson | Fechner>)
stats::correlation(s, <[c1, c2]>, <BravaisPearson
| Fechner>)
stats::correlation(s1, <c1>, s2, <c2>, <BravaisPearson
| Fechner>)
```

**Description** stats::correlation([x<sub>1</sub>, x<sub>2</sub>, ], [y<sub>1</sub>, y<sub>2</sub>, ]) returns the linear (Bravais-Pearson) correlation coefficient

$$\frac{\sum_i (x_i(y_i - \bar{y}) - \bar{x}(y_i - \bar{y}))}{\sqrt{(\sum_i (x_i - \bar{x})^2) (\sum_i (y_i - \bar{y})^2)}}$$

where  $\bar{x}$  and  $\bar{y}$  are the means of the data  $x_i$  and  $y_i$ .

stats::correlation([x<sub>1</sub>, x<sub>2</sub>, ], [y<sub>1</sub>, y<sub>2</sub>, ], Fechner) returns the Fechner correlation  $\frac{2}{n} \left( \sum_{i=1}^n v_i \right) - 1$ , where  $n$  is the sample size. The number  $v_i$  is 1, if  $x_i - \bar{x}$  and  $y_i - \bar{y}$  have the same sign or are both 0. It is  $\frac{1}{2}$  if either  $x_i - \bar{x}$  or  $y_i - \bar{y}$  is 0. Otherwise,  $v_i = 0$ .

Both the Bravais-Pearson correlation as well as the Fechner correlation are numbers between - 1 and 1.

The Bravais-Pearson correlation is close to 1 if the data pairs  $x_i, y_i$  are approximately related by a 'positive' linear relation (i.e.,  $y_i \approx ax_i + b$  with some positive coefficient  $a$ ). It is close to - 1 if there is a 'negative' linear relation (with some negative coefficient  $a$ ).

Correlation coefficients close to 0 correspond to non-linear relations or to unrelated data, respectively.

If the input data are floating-point numbers, the sums defining the Bravais-Pearson correlation are computed in a numerically stable way. If a floating-point result is desired, it is recommended to make sure that all input data are floats.

The Fechner correlation is always returned as a rational number.

The column indices  $c_1$ ,  $c_2$  are optional if the data are given by a `stats::sample` object `s` containing only two non-string data columns. If the data are provided by two samples  $s_1$ ,  $s_2$ , the column indices are optional for samples containing only one non-string data column.

---

**Note** The Fechner correlation should not be computed for symbolic data. This may lead to unexpected results, if the sign of symbolic parameters cannot be determined.

---

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We compute the correlation of samples passed as lists:

```
X := [7, 33/7, 3, 5, 2]: Y := [3, 5, 1, 7, 2]:
stats::correlation(X, Y)
```

$$\frac{147 \sqrt{26506}}{53012}$$

Alternatively, the data may be passed as a list of data pairs:

```
stats::correlation([[7, 3], [33/7, 5], [3, 1], [5, 7], [2, 2]])
```

## stats::correlation

---

$$\frac{147 \sqrt{26506}}{53012}$$

If all data are floating-point numbers, the result is a float:

```
stats::correlation(float(X), float(Y))
```

0.4514558056

The Fechner correlation of the data is always returned as a rational number:

```
stats::correlation(X, Y, Fechner),
stats::correlation(float(X), float(Y), Fechner)
```

$$\frac{3}{5}, \frac{3}{5}$$

The following exact result indicates an exact linear between the data pairs:

```
stats::correlation([0, 1, 2, 3], [7, 5, 3, 1])
```

-1

Indeed, there is the 'negative' linear relation  $y = 7 - 2x$  between the data pairs.

```
delete X, Y:
```

### Example 2

We create a sample of type `stats::sample`:

```
s := stats::sample([[1.0, 2.4, 3.0],
 [7.0, 4.8, 4.0],
 [3.3, 3.0, 5.0]])
```

```
1.0 2.4 3.0
7.0 4.8 4.0
3.3 3.0 5.0
```

We compute the correlation between the data of the first and the third column in several equivalent ways:

```
stats::correlation(s, 1, 3),
stats::correlation(s, [1, 3]),
stats::correlation(s, 1, s, 3)
```

```
0.3799015783, 0.3799015783, 0.3799015783
```

```
stats::correlation(s, 1, 3, Fechner),
stats::correlation(s, [1, 3], Fechner),
stats::correlation(s, 1, s, 3, Fechner)
```

```
0, 0, 0
```

```
delete s:
```

### Example 3

With symbolic data, the Bravais-Pearson correlation is returned as a symbolic expression:

```
stats::correlation([x1, x2], [y1, y2])
```

# stats::correlation

---

$$\frac{x_1 y_1 + x_2 y_2 - 2 \left(\frac{x_1}{2} + \frac{x_2}{2}\right) \left(\frac{y_1}{2} + \frac{y_2}{2}\right)}{\sqrt{\left(x_1^2 - 2 \left(\frac{x_1}{2} + \frac{x_2}{2}\right)^2 + x_2^2\right) \left(y_1^2 - 2 \left(\frac{y_1}{2} + \frac{y_2}{2}\right)^2 + y_2^2\right)}}$$

simplify(%)

$$\frac{(x_1 - x_2) (y_1 - y_2)}{\sqrt{(x_1 - x_2)^2 (y_1 - y_2)^2}}$$

## Parameters

**$x_1, y_1, x_2, y_2, \dots$**

The statistical data: arithmetical expressions. The number of data  $x_i$  must coincide with the number of data  $y_i$ .

**$s, s_1, s_2$**

Samples of type stats::sample

**$c_1, c_2$**

Column indices: positive integers. Column  $c_1$  of  $s$  or  $s_1$ , respectively, provides the data  $x_i$ . Column  $c_2$  of  $s$  or  $s_2$ , respectively, provides the data  $y_i$ .

**mode**

Either BravaisPearson or Fechner. The default is the linear (Bravais-Pearson) correlation.

## Options

**BravaisPearson, Fechner**

Linear (Bravais-Pearson) or Fechner's correlation coefficient. Bravais-Pearson coefficient is the default, but may in some cases where the data is not normally distributed be less useful than Fechner's correlation.

## Return Values

The Bravais-Pearson correlation is returned as an arithmetical expression. FAIL is returned if the variance of one of the data samples vanishes (the Bravais-Pearson correlation does not exist).

The Fechner correlation is returned as a rational number.

FAIL is returned if the data samples are empty.

### MuPAD Functions

`stats::correlationMatrix` | `stats::covariance` | `stats::stdev`

### MuPAD Graphical Primitives

`plot::Scatterplot`

# stats::correlationMatrix

---

**Purpose** Compute the correlation matrix associated with a covariance matrix

**Syntax** `stats::correlationMatrix(cov)`

**Description** `stats::correlationMatrix(cov)` returns to correlation matrix `cor` of the variance-covariance matrix `cov`. It is given by:

$$\text{cor}_{i,j} = \frac{\text{COV}_{i,j}}{\sqrt{\text{COV}_{i,i}} \sqrt{\text{COV}_{j,j}}}$$

A covariance matrix  $C$  should be positive (semi-)definite and hence satisfies  $|C_{ij}|^2 \leq C_{ii}C_{jj}$  for all indices  $i, j$ . Consequently, the absolute values of the entries of the corresponding correlation matrix do not exceed 1.

With the option `CovarianceMatrix`, the routine `stats::reg` returns the variance-covariance matrix of the fit parameters in a regression analysis. The corresponding correlation matrix of the fit parameters is computed conveniently by applying `stats::correlationMatrix` to this matrix. Cf. “Example 2” on page 29-81.

## Examples

### Example 1

We generate a positive definite matrix that may serve as a covariance matrix:

```
A := matrix([[4, -3, 2], [-1, 2, 1], [0, 1, 1]]):
cov := A*linalg::transpose(A)
```

$$\begin{pmatrix} 29 & -8 & -1 \\ -8 & 6 & 3 \\ -1 & 3 & 2 \end{pmatrix}$$

The corresponding correlation matrix is:

```
stats::correlationMatrix(cov)
```

$$\begin{pmatrix} 1 & -\frac{4\sqrt{6}\sqrt{29}}{87} & -\frac{\sqrt{2}\sqrt{29}}{58} \\ -\frac{4\sqrt{6}\sqrt{29}}{87} & 1 & \frac{\sqrt{2}\sqrt{6}}{4} \\ -\frac{\sqrt{2}\sqrt{29}}{58} & \frac{\sqrt{2}\sqrt{6}}{4} & 1 \end{pmatrix}$$

If the input matrix consists of floating-point data, the result is a matrix of floats:

```
stats::correlationMatrix(float(cov))
```

$$\begin{pmatrix} 1.0 & -0.6064784349 & -0.1313064329 \\ -0.6064784349 & 1.0 & 0.8660254038 \\ -0.1313064329 & 0.8660254038 & 1.0 \end{pmatrix}$$

```
delete A, cov:
```

## Example 2

We consider a covariance matrix arising in a non-linear regression problem. The model function  $y = a + b\cos(x - c)$  is to be fit to the following randomized data:

```
r := stats::uniformRandom(-0.1, 0.1):
xdata := [i $i = 1..100]:
ydata := [1 + 2*cos(x - 3) + r() $ x in xdata]:
```

By construction, the variance of the  $y$  values is the variance of the uniformly distributed random data on the interval  $[-0.1, 0.1]$  generated by the random generator  $r$ . This variance is  $\sigma^2 = \frac{1}{300}$ . We use `stats::reg` to obtain estimates of the fit parameters  $a, b, c$  of the model.

# stats::correlationMatrix

---

Appropriate weights for the regression are given by  $\frac{1}{\sigma^2} = 300$ . The option `CovarianceMatrix` makes `stats::reg` include the covariance matrix `cov` of the fit parameters in its return list:

```
weights := [300 $ i = 1..100]:
DIGITS:= 4:
[abc, chisquare, cov] :=
 stats::reg(xdata, ydata, weights, a + b*cos(x - c),
 [x], [a, b, c], StartingValues = [1, 2, 3],
 CovarianceMatrix)
```

```
[1.004, 1.998, 3.0], 107.4, $\begin{pmatrix} 0.00003334 & -0.0000003414 & -0.00000006749 \\ -0.0000003414 & 0.00006697 & 0.0000001379 \\ -0.00000006749 & 0.0000001379 & 0.00001663 \end{pmatrix}$
```

The correlation matrix of the parameters  $a$ ,  $b$ ,  $c$  is obtained via `stats::correlationMatrix` applied to the covariance matrix `cov` returned by `stats::reg`:

```
stats::correlationMatrix(cov)
```

```
 $\begin{pmatrix} 1.0 & -0.007226 & -0.002866 \\ -0.007226 & 1.0 & 0.004132 \\ -0.002866 & 0.004132 & 1.0 \end{pmatrix}$
```

```
delete r, xdata, ydata, weights, DIGITS, abc, chisquare, cov:
```

## Parameters

**cov**

The covariance matrix: a square matrix of category `Cat::Matrix`, or an array.

## Return Values

Matrix of the same dimension and type as the input matrix cov. FAIL is returned if at least one of the diagonal elements of the input matrix cov is zero.

## See Also

## MuPAD Functions

stats::correlation | stats::covariance | stats::reg | stats::stdev

# stats::covariance

---

**Purpose** Covariance of data samples

**Syntax**

```
stats::covariance([x1, x2,], [y1, y2,],
<Sample | Population>)
stats::covariance([[x1, y1], [x2, y2],],
<Sample | Population>)
stats::covariance(s, <c1, c2>, <Sample | Population>)
stats::covariance(s, <[c1, c2]>, <Sample | Population>)
stats::covariance(s1, <c1>, s2, <c2>, <Sample | Population>)
```

**Description** stats::covariance([x<sub>1</sub>, x<sub>2</sub>, ..., x<sub>n</sub>], [y<sub>1</sub>, y<sub>2</sub>, ..., y<sub>n</sub>]) returns the covariance

$$\frac{1}{n-1} \left( \sum_{i=1}^n (x_i - \bar{X})(y_i - \bar{Y}) \right) = \frac{1}{n-1} \left( \sum_{i=1}^n x_i y_i \right) - \frac{n}{n-1} \bar{X} \bar{Y}$$

where  $\bar{X}$  and  $\bar{Y}$  are the arithmetic means of the data  $x_i$  and  $y_i$ , respectively.

stats::covariance([x<sub>1</sub>, x<sub>2</sub>, ..., x<sub>n</sub>], [y<sub>1</sub>, y<sub>2</sub>, ..., y<sub>n</sub>], Population) returns

$$\frac{1}{n} \left( \sum_{i=1}^n (x_i - \bar{X})(y_i - \bar{Y}) \right) = \frac{1}{n} \left( \sum_{i=1}^n x_i y_i \right) - \bar{X} \bar{Y}$$

If the input data are floating-point numbers, the sums defining the covariance are computed in a numerically stable way. If a floating point result is desired, it is recommended to make sure that all input data are floats.

For exact input data, exact symbolic expressions are returned.

The column indices  $c_1$ ,  $c_2$  are optional if the data are given by a stats::sample object s containing only two non-string data columns.

If the data are provided by two samples  $s_1$ ,  $s_2$ , the column indices are optional for samples containing only one non-string data column.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We compute the covariance of samples passed as lists:

```
X := [2, 33/7, 21/9, PI]: Y := [3, 5, 1, 7]:
stats::covariance(X, Y)
```

$$\pi - \frac{10}{7}$$

Alternatively, the data may be passed as a list of data pairs:

```
stats::covariance([[2, 3], [33/7, 5], [21/9, 1], [PI, 7]])
```

$$\pi - \frac{10}{7}$$

If all data are floating-point numbers, the result is a float:

```
stats::covariance(float(X), float(Y))
```

```
1.713021225
```

```
delete X, Y:
```

### Example 2

We create a sample of type `stats::sample`:

## stats::covariance

---

```
s := stats::sample([[1.0, 2.4, 3.0],
 [7.0, 4.8, 4.0],
 [3.3, 3.0, 5.0]])
```

```
1.0 2.4 3.0
7.0 4.8 4.0
3.3 3.0 5.0
```

We compute the covariance of the first column and the third column in several equivalent ways:

```
stats::covariance(s, 1, 3),
stats::covariance(s, [1, 3]),
stats::covariance(s, 1, s, 3)
```

```
1.15, 1.15, 1.15
```

```
delete s:
```

### Example 3

The covariance of symbolic data is returned as a symbolic expression:

```
stats::covariance([x1, x2], [y1, y2])
```

$$x1 y1 + x2 y2 - 2 \left( \frac{x1}{2} + \frac{x2}{2} \right) \left( \frac{y1}{2} + \frac{y2}{2} \right)$$

```
expand(%)
```

$$\frac{x1 y1}{2} - \frac{x1 y2}{2} - \frac{x2 y1}{2} + \frac{x2 y2}{2}$$

**Parameters**

$x_1, y_1, x_2, y_2, \dots$

The statistical data: arithmetical expressions. The number of data  $x_i$  must coincide with the number of data  $y_i$ .

$s, s_1, s_2$

Samples of type stats::sample

$c_1, c_2$

Column indices: positive integers. Column  $c_1$  of  $s$  or  $s_1$ , respectively, provides the data  $x_i$ . Column  $c_2$  of  $s$  or  $s_2$ , respectively, provides the data  $y_i$ .

**Options**

**Sample**

The data are regarded as a “sample”, not as a full population. This is the default.

**Population**

The data are regarded as the whole population, not as a sample.

**Return Values**

arithmetical expression.

**See Also**

**MuPAD Functions**

stats::correlation | stats::correlationMatrix | stats::stdev

# stats::cutoff

---

**Purpose** Discard outliers

**Syntax**  
`stats::cutoff([x1, x2, ...],  $\mathcal{A}$ )`  
`stats::cutoff([[x11, x12, ...], [x21, x22, ...], ...],  $\mathcal{A}$ , i)`  
`stats::cutoff(s,  $\mathcal{A}$ , i)`

**Description** `stats::cutoff([x1, x2, ...],  $\mathcal{A}$ )` returns those elements of  $[x_1, x_2, \dots]$  larger than the  $\alpha$  quantile and smaller than the  $1 - \alpha$  quantile of this list.  
`stats::cutoff([[x11, x12, ...], [x21, x22, ...], ...],  $\mathcal{A}$ , i)` and `stats::cutoff(stats::sample([[x11, x12, ...], [x21, x22, ...], ...]),  $\mathcal{A}$ , i)` perform the operations described above on the  $i$ -th entries of the input rows.

Measurement data often contains “outliers,” sample points rather far outside the range containing the majority of the points. While expected both from theory and experience, these outliers, for small or medium-sized samples, tend to distort statistical data such as the mean value.

One of the standard methods dealing with this problem for (real) continuous scales is discarding the outliers. `stats::cutoff` discards all data points below or above a given quantile.

## Examples

### Example 1

We create a normally distributed sample, slightly contaminated:

```
r := stats::normalRandom(0, 1, Seed=2):
data := [r() $ i = 1..300, 100*r() $ i = 1..2]:
```

The two extra points distort the data significantly:

```
plot(plot::Histogram2d(data, Cells=20))
```

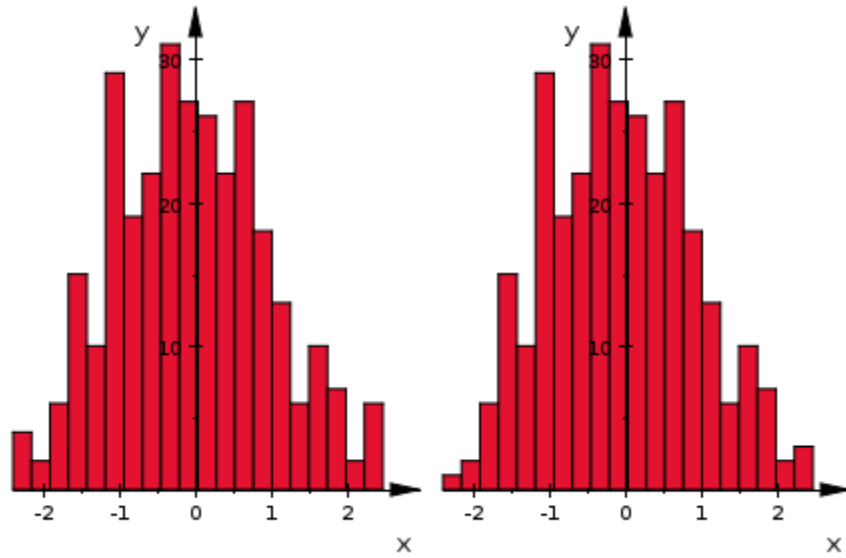

Using either `stats::winsorize` or `stats::cutoff` removes this noise and the image shows more detail:

```
plot(plot::Scene2d(plot::Histogram2d
 (stats::winsorize(data, 1/100), Cells=20)),
 plot::Scene2d(plot::Histogram2d
 (stats::cutoff(data, 1/100), Cells=20)))
```

# stats::cutoff

---

With larger values of  $a$ , the difference between the two is easier to see:

```
plot(plot::Scene2d(plot::Histogram2d
 (stats::winsorize(data, 1/20), Cells=20)),
 plot::Scene2d(plot::Histogram2d
 (stats::cutoff(data, 1/20), Cells=20)))
```

Both `stats::winsorize` and `stats::cutoff` reduce the standard deviation of the sample. This effect is considerably stronger for `stats::cutoff`, though. Keeping in mind that the standard deviation of our random number generator is 1, we compute that of the data in its various forms:

```
stats::stdev(data),
stats::stdev(stats::winsorize(data, 1/20)),
stats::stdev(stats::cutoff(data, 1/20))
```

9.133931298, 0.9276576788, 0.8142529511

## Parameters

$x_1, x_2, x_{11}, \dots$

The statistical data: arithmetical expressions. The data to filter on must be real-valued.

**s**

# stats::cutoff

---

Sample of type `stats::sample`

Cutoff parameter: a real-valued expression  $0 \leq \alpha \leq \frac{1}{2}$ .

**i**

Column index: positive integer. The nested list or the sample is filtered on its *i*-th column.

## Return Values

The input data with outliers being removed.

## See Also

## MuPAD Functions

`stats::winsorize` | `stats::sample`

## Concepts

- “Handle Outliers”

## Purpose

Clamp (winsorize) extremal values

## Syntax

```
stats::winsorize([x1, x2, ...], α)
stats::winsorize([[x11, x12, ...], [x21, x22, ...], ...], α , i)
stats::winsorize(s, α , i)
```

## Description

`stats::winsorize([x1, x2, ...],  $\alpha$ )` returns a copy of  $[x_1, x_2, \dots]$  in which all entries smaller than the  $\alpha$  quantile have been replaced by this value and likewise for all entries larger than the  $1 - \alpha$  quantile.

`stats::winsorize([[x11, x12, ...], [x21, x22, ...], ...],  $\alpha$ , i)` and `stats::winsorize(stats::sample([[x11, x12, ...], [x21, x22, ...], ...]),  $\alpha$ , i)` perform the operations described above on the  $i$ -th entries of the input rows.

Measurement data often contains “outliers,” sample points rather far outside the range containing the majority of the points. While expected both from theory and experience, these outliers, for small or medium-sized samples, tend to distort statistical data such as the mean value.

One of the standard methods dealing with this problem for (real) continuous scales is clamping the outliers. `stats::winsorize` sets all data points below or above a given quantile to these quantiles. (This operation is named after its inventor, Charles P. Winsor.)

## Examples

### Example 1

We create a normally distributed sample, slightly contaminated:

```
r := stats::normalRandom(0, 1, Seed=2):
data := [r() $ i = 1..300, 100*r() $ i = 1..2]:
```

The two extra points distort the data significantly:

```
plot(plot::Histogram2d(data, Cells=20))
```

## stats::winsorize

---

Using either `stats::winsorize` or `stats::cutoff` removes this noise and the image shows more detail:

```
plot(plot::Scene2d(plot::Histogram2d
 (stats::winsorize(data, 1/100), Cells=20)),
 plot::Scene2d(plot::Histogram2d
 (stats::cutoff(data, 1/100), Cells=20)))
```

With larger values of  $a$ , the difference between the two is easier to see:

```
plot(plot::Scene2d(plot::Histogram2d
 (stats::winsorize(data, 1/20), Cells=20)),
 plot::Scene2d(plot::Histogram2d
 (stats::cutoff(data, 1/20), Cells=20)))
```

# stats::winsorize

Both `stats::winsorize` and `stats::cutoff` reduce the standard deviation of the sample. This effect is considerably stronger for `stats::cutoff`, though. Keeping in mind that the standard deviation of our random number generator is 1, we compute that of the data in its various forms:

```
stats::stdev(data),
stats::stdev(stats::winsorize(data, 1/20)),
stats::stdev(stats::cutoff(data, 1/20))
```

9.133931298, 0.9276576788, 0.8142529511

## Parameters

$x_1, x_2, x_{11}, \dots$

The statistical data: arithmetical expressions. The data to filter on must be real-valued.

**s**

Sample of type `stats::sample`

Cut-off parameter: a real-valued expression  $0 \leq \alpha \leq \frac{1}{2}$ .

**i**

Column index: positive integer. The nested list or the sample is winsorized on its *i*-th column.

### **Return Values**

The input data with outliers being replaced by the values of quantiles.

### **See Also**

### **MuPAD Functions**

`stats::cutoff` | `stats::sample`

### **Concepts**

- “Handle Outliers”

**Purpose** Classical chi-square goodness-of-fit test

**Syntax**

```
stats::csGOFT(x1, x2, ..., [[a1, b1], [a2, b2], ...],
CDF = f | PDF = f | PF = f)
stats::csGOFT([x1, x2, ...], [[a1, b1], [a2, b2], ...],
CDF = f | PDF = f | PF = f)
stats::csGOFT(s, <c>, [[a1, b1], [a2, b2], ...], CDF
= f | PDF = f | PF = f)
```

**Description** stats::csGOFT(data, cells, CDF = f) applies the classical chi-square goodness-of-fit test for the null hypothesis: “the data are f-distributed”.

The chi-square goodness-of-fit test divides the real line into  $k$  intervals  $C_i = (a_i, b_i]$  (‘the cells’). It computes the number of data  $x_j$  falling into the cells  $c_i$  and compares these ‘empirical cell frequencies’ with the ‘expected cell frequencies’  $np_i$ , where  $n$  is the sample size and  $p_i = Pr(a_i < x \leq b_i)$  are the ‘cell probabilities’ of a random variable with the hypothesized distribution specified by  $X = f$ .

All data  $x_1, x_2$  etc. must be convertible to real floating-point numbers. The data do not have to be sorted on input: stats::csGOFT automatically converts the data to floats and sorts them internally.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

Finite cell boundaries  $a_i, b_i$  must be convertible to real floating-point numbers satisfying  $a_1 < b_1 \leq a_2 < b_2 \leq a_3 < \dots$ . They define *semiopen* intervals  $C_i = (a_i, b_i]$ .

When the hypothesized distribution  $f$  is specified as a cumulative distribution function (CDF = f), the left boundary of the first cell and the right boundary of the last cell are ignored. They are replaced by  $-\infty$  and *infinity*, respectively, i.e., the cell partitioning

$$(-\infty, b_1], (a_2, b_2], \dots, (a_{k-1}, b_{k-1}], (a_k, \infty)$$

is used internally.

The cells must be disjoint. Their union must cover the support area of the distribution, i.e., the 'cell probabilities'  $p_i = Pr(a_i < x \leq b_i)$  must add up to 1 for a random variable  $x$  with the hypothesized distribution given by  $f$ . For continuous distributions, adjacent cells with  $b_1 = a_2$ ,  $b_2 = a_3$ , ... are appropriate.

You may use  $a_1 = -\infty$  and  $b_k = \infty$  for distributions supported on the entire real line.

---

**Note** The cells must be chosen such that no cell probability  $p_i$  vanishes!

---

See the 'Background' section of this help page for recommendations on the cell partitioning. In particular, the use of equiprobable cells (with constant  $p_i$ ) is recommended. For convenience, a utility function `stats::equiprobableCells` is provided to generate such cells. See "Example 1" on page 29-101, "Example 3" on page 29-105, and "Example 4" on page 29-108.

The distribution the data are tested for is specified by the equation  $X = f$ , where  $X$  is one of the flags CDF, PDF or PF.

For efficiency, it is recommended to specify a cumulative distribution function (CDF =  $f$ ).

The function  $f$  can be a procedure provided by the MuPAD `stats` library. Specifications such as `CDF = stats::normalCDF(m, v)` or `CDF = stats::poissonCDF(m)` with suitable numerical values of  $m$ ,  $v$  are possible and recommended.

Distributions that are not provided by the `stats`-package can be implemented easily by the user. A user defined procedure  $f$  can implement any distribution function. In the CDF case, `stats::csGOFT`

calls `f` with the boundary values  $a_i, b_i$  of the cells to compute the cell probabilities via  $p_i = f(b_i) - f(a_i)$  (automatically setting  $f(a_1) = 0$  and  $f(b_k) = 1$ ).

The function `f` must return a numerical real value between 0 and 1. See “Example 5” on page 29-110 and “Example 6” on page 29-111.

Alternatively, the function `f` can be specified by a univariate arithmetical expression  $g(x)$  depending on a symbolic variable `x`. It is interpreted as the function  $f: X \rightarrow g(X)$ . Cf. “Example 6” on page 29-111.

See the ‘Background’ section of this help page for further information on the specification of the distribution via `CDF = f`, `PDF = f` or `PF = f`.

The call `stats::csGOFT(data, cells, X = f)` returns the list [`PValue = p`, `StatValue = s`, `MinimalExpectedCellFrequency = m`]:

- `s` is the observed value of the chi-square statistic

$$s = \sum_{i=1}^k \frac{(y_i - n p_i)^2}{n p_i}$$

where  $n$  is the sample size,  $k$  is the number of cells,  $y_i$  is the observed cell frequency of the data (i.e.,  $y_i$  is the number of data  $x_j$  falling into the cell  $c_i$ ), and  $p_i$  is the cell probability corresponding to the hypothesized distribution  $f$ .

- `p` is the observed significance level of the chi-square statistic with  $k - 1$  degrees of freedom, i.e.,  $p = 1 - \text{stats::chisquareCDF}(k - 1)(s)$
- $m = \min(n p_i, i = 1..k)$  is the minimum of the expected cell frequencies  $n p_i$ . This information is provided by the test to make sure that the boundary conditions for a “reasonable” cell partitioning are met (see the “Background” section of this help page).

The most relevant information returned by `stats::csGOFT` is the observed significance level `PValue = p`. It has to be interpreted in the following way: Under the null hypothesis, the chi-square statistic

$$S = \sum_{i=1}^k \frac{(y_i - n p_i)^2}{n p_i}$$

is approximately chi-square distributed (for large samples):

$$\Pr(S \leq s) = \text{stats::chisquareCDF}(k - 1)(s)$$

Under the null hypothesis, the probability  $p = \Pr(S > s)$  should not be small, where  $s$  is the value of the statistic attained by the sample.

Specifically,  $p = \Pr(S > s) \geq \alpha$  should hold for a given significance level  $0 < \alpha < 1$ . If this condition is violated, the hypothesis may be rejected at level  $\alpha$ .

Thus, if the `PValue` (observed significance level)  $p = \Pr(S > s)$  satisfies  $p < \alpha$ , the sample leading to the observed value  $s$  of the statistic  $S$  represents an unlikely event, and the null hypothesis may be rejected at level  $\alpha$ .

On the other hand, values of  $p$  close to 1 should raise suspicion about the randomness of the data: they indicate a fit that is *too good*.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We consider random data that should be normally distributed with mean 15 and variance 2:

```
f := stats::normalRandom(15, 2, Seed = 0):
```

```
data := [f() $ i = 1..1000]:
```

According to the recommendations in the ‘Background’ section of this help page, the number of cells should be approximately  $2 n^{2/5} \approx 31.7$ , where  $n = 1000$  is the sample size.

We wish to use 32 cells that are equiprobable with respect to the hypothesized normal distribution. We estimate the mean  $m$  and the variance  $v$  of the data:

```
[m, v] := [stats::mean(data), stats::variance(data, Sample)]
```

```
[14.94011963, 2.014256118]
```

The utility function `stats::equiprobableCells` is used to compute an equiprobable cell partitioning via the quantile function of the normal distribution with the empirical parameters:

```
cells := stats::equiprobableCells(32, stats::normalQuantile(m, v)):
stats::csGOFT(data, cells, CDF = stats::normalCDF(m, v))
```

```
[PValue = 0.6359912784, StatValue = 27.712, MinimalExpectedCellFrequency = 31.25]
```

The observed significance level **0.635...** attained by the sample is not small. Hence, one should not reject the hypothesis that the sample is normally distributed with mean **14.94...** and variance **2.014...**

In the following, we impurify the sample by appending some uniformly distributed numbers. A new equiprobable cell partitioning appropriate for the new data is computed:

```
r := stats::uniformRandom(10, 20, Seed = 0):
data := append(data, r() $ 40):
[m, v] := [stats::mean(data), stats::variance(data, Sample)]:
```

```
k := round(2*nops(data)^(2/5)):
cells := stats::equiprobableCells(k, stats::normalQuantile(m, v))
stats::csGOFT(data, cells, CDF = stats::normalCDF(m, v))
```

[PValue = 0.007653320709, StatValue = 53.29230769, MinimalExpectedCellFrequency =

The impure data may be rejected as a normally distributed sample at levels as small as 0.0076....

```
delete f, data, m, v, k, cells, r:
```

## Example 2

We create a sample of random data that should be binomially distributed with trial parameter 70 and probability parameter  $\frac{1}{2}$ :

```
r := stats::binomialRandom(70, 1/2, Seed = 123):
data := [r() $ k = 1..1000]:
```

With the expectation value of 35 and the standard deviation of  $\frac{\sqrt{70}}{2} \approx 4.18$  of this distribution, we expect most of the data to have values between 30 and 40. Thus, a cell partitioning consisting of 12 cells corresponding to the intervals

(0, 30], (30, 31], (31, 32], ..., (39, 40], (40, 70]

should be appropriate. Note that all cells are interpreted as the intervals  $(a_i, b_i]$ , i.e., the left boundary is not included in the interval. Strictly speaking, the value 0 is not covered by these cells. However, with a CDF specification, stats::csGOFT ignores the leftmost boundary and replaces it by -infinity. Thus, the union of the cells does cover all integers 0, ..., 70 that can be attained by the hypothesized binomial distribution with 'trial parameter' 70:

## stats::csGOFT

---

```
cells := [[0, 30], [i, i + 1] $ i = 30..39, [40, 70]]
```

```
[[0, 30], [30, 31], [31, 32], [32, 33], [33, 34], [34, 35], [35, 36], [36, 37], [37, 38], [38, 39], [39, 40], [40, 70]]
```

We apply the  $\chi^2$  test with various specifications of the binomial distribution. They all produce the same result. However, the first call using a CDF specification is the most efficient (fastest) call:

```
stats::csGOFT(data, cells, CDF = stats::binomialCDF(70, 1/2));
```

```
[PValue = 0.4810610726, StatValue = 10.55729362, MinimalExpectedCellFrequency = 46.88]
```

```
stats::csGOFT(data, cells, PF = stats::binomialPF(70, 1/2));
```

```
[PValue = 0.4810610726, StatValue = 10.55729362, MinimalExpectedCellFrequency = 46.88]
```

```
f := binomial(70, x)*(1/2)^x*(1/2)^(70 - x):
stats::csGOFT(data, cells, PF = f)
```

```
[PValue = 0.4810610726, StatValue = 10.55729362, MinimalExpectedCellFrequency = 46.88]
```

The observed significance level **0.481...** indicates that the data pass the test well.

Next, we do the sample by appending the value 35 forty times:

```
data := data . [35 $ 40]:
stats::csGOFT(data, cells, CDF = stats::binomialCDF(70, 1/2));
```

```
[PValue = 0.0098099163, StatValue = 24.78215227, MinimalExpectedCellFrequency = 48.75]
```

Now, the data may be rejected as a binomial sample with the specified parameters at levels as small as 0.0098...

```
delete r, data, cells, f:
```

### Example 3

We test data that purport to be a sample of beta distributed numbers with scale parameters 3 and 2. Since beta deviates attain values between 0 and 1, we choose an equidistant cell partitioning of the interval [0, 1] consisting of 10 cells. Various equivalent calls to stats::csGOFT are demonstrated:

```
r := stats::betaRandom(3, 2, Seed = 1):
data := [r() $ i = 1..100]:
cells := [(i - 1)/10, i/10] $ i = 1..10]:
stats::csGOFT(data, cells, CDF = stats::betaCDF(3, 2));
stats::csGOFT(data, cells, CDF = (x -> stats::betaCDF(3, 2)(x)))
```

[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.

[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.

Alternatively, the beta distribution may be passed by a PDF specification. This, however, is less efficient than the CDF specification used before:

```
stats::csGOFT(data, cells, PDF = stats::betaPDF(3, 2));
stats::csGOFT(data, cells, PDF = (x -> stats::betaPDF(3, 2)(x)))
```

[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.

[PValue = 0.7329969624, StatValue = 6.068961653, MinimalExpectedCellFrequency = 0.

The observed significance level 0.732... is not small. Hence, this test does not indicate that the data should be rejected as a beta distributed sample with the specified parameters. Note, however, that the minimal expected cell frequency given by the third element of the returned list is rather small. This indicates that the cell partitioning is not very fortunate. We investigate the expected cell frequencies by computing  $np_i = n(f(b_i) - f(a_i))$ , where  $f$  is the cumulative distribution function of the beta distribution and  $n$  is the sample size:

```
f := stats::betaCDF(3, 2):
map(cells, cell -> 100*(f(cell[2]) - f(cell[1])))

[0.37, 2.35, 5.65, 9.55, 13.33, 16.27, 17.65, 16.75, 12.85, 5.23]
```

These values show that the first two or three cells should be joined to a single cell. We modify the cell partitioning by joining the first three and the last two cells:

```
cells := [[0, 3/10], [(i - 1)/10, i/10] $ i = 4..8, [8/10, 1]]

[[[0, 3/10], [3/10, 2/5], [2/5, 1/2], [1/2, 3/5], [3/5, 7/10], [7/10, 4/5], [4/5, 1]]]
```

For this cell partitioning, the expected frequencies in a random sample of size 100 are sufficiently large for all cells:

```
map(cells, cell -> 100*(f(cell[2]) - f(cell[1])))

[8.37, 9.55, 13.33, 16.27, 17.65, 16.75, 18.08]
```

We apply another  $\chi^2$  test with this improved partitioning:

```
stats::csGOFT(data, cells, CDF = f)
```

[PValue = 0.9023533657, StatValue = 2.180685972, MinimalExpectedCellFrequency = 8.

Again, with the observed significance level 0.902..., the test does not give any hint that the data are not beta distributed with the specified parameters.

Now, we test whether the data can be regarded as being normally distributed. First, we estimate the parameters (mean and variance) required for the normal distribution:

```
[m, v] := [stats::mean(data), stats::variance(data, Sample)]
[0.6101560142, 0.03595065085]
```

The cell partitioning used before was a partitioning of the interval [0, 1], because beta deviates attain values in this interval. Now we construct a partitioning of 7 equiprobable cells using the quantile function of the normal distribution:

```
k := 7:
cells := stats::equiprobableCells(7, stats::normalQuantile(m, v))
[[-∞, 0.4077376304], [0.4077376304, 0.5028484001], [0.5028484001, 0.5760244864],
 [0.5760244864, 0.6442875419], [0.6442875419, 0.7174636283], [0.7174636283, 0.8125743979],
 [0.8125743979, ∞]]
```

Indeed, these cells are equiprobable:

```
f := stats::normalCDF(m, v):
map(cells, cell -> f(cell[2]) - f(cell[1]))
```

```
[0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429, 0.1428571429]
```

We test for normality with the estimated mean and variance:

```
stats::csGOFT(data, cells, CDF = f)
```

```
[PValue = 0.7118124259, StatValue = 3.74, MinimalExpectedCellFrequency = 14.28571429]
```

With the observed significance level of 0.711..., the data should not be rejected as a normally distributed sample. We note that the nonparametric Shapiro-Wilk test implemented in `stats::swGOFT` does detect nonnormality of the sample:

```
stats::swGOFT(data)
```

```
[PValue = 0.04753801335, StatValue = 0.97429647]
```

With the observed significance level of 0.0475..., normality can be rejected at levels as low as 0.0475....

```
delete r, data, cells, f, m, v, k, boundaries:
```

## Example 4

We demonstrate the use of samples of type `stats::sample`. We create a sample consisting of one string column and two non-string columns:

```
s := stats::sample(
 [["1996", 1242, 156], ["1997", 1353, 162], ["1998", 1142, 168],
 ["1999", 1201, 182], ["2001", 1201, 190], ["2001", 1201, 190],
 ["2001", 1201, 205], ["2001", 1201, 210], ["2001", 1201, 220],
 ["2001", 1201, 213], ["2001", 1201, 236], ["2001", 1201, 260],
 ["2001", 1201, 198], ["2001", 1201, 236], ["2001", 1201, 245],
```

```
["2001", 1201, 188], ["2001", 1201, 177], ["2001", 1201, 233]
["2001", 1201, 270])
```

```
"1996" 1242 156
"1997" 1353 162
"1998" 1142 168
"1999" 1201 182
"2001" 1201 190
"2001" 1201 190
"2001" 1201 205
"2001" 1201 210
"2001" 1201 220
"2001" 1201 213
"2001" 1201 236
"2001" 1201 260
"2001" 1201 198
"2001" 1201 236
"2001" 1201 245
"2001" 1201 188
"2001" 1201 177
"2001" 1201 233
"2001" 1201 270
```

We consider the data in the third column. The mean and the variance of these data are computed:

```
[m, v] := float([stats::mean(s, 3),
 stats::variance(s, 3, Sample)])
```

```
[207.3157895, 1082.672515]
```

We check whether the data of the third column are normally distributed with the empirical mean and variance computed above. We compute an

appropriate cell partitioning in the same way as explained in “Example 1” on page 29-101:

```
samplesize := s::dom::size(s):
k := round(2*samplesize^(2/5)):
cells := stats::equiprobableCells(k, stats::normalQuantile(m, v)):
stats::csGOFT(s, 3, cells, CDF = stats::normalCDF(m, v))
```

[PValue = 0.9100131461, StatValue = 1.526315789, MinimalExpectedCellFrequency = 3.166]

Thus, the data pass the test.

```
delete s, m, v, samplesize, k, cells:
```

## Example 5

We demonstrate how user-defined distribution functions can be used. A die is rolled 60 times. The following frequencies of the scores 1, 2, ..., 6 are observed:

	score	1	2	3			
	4	5	6		-----+-----+-----+-----+-----+-----		
	frequency	7	16	8	17	3	9

We test the null hypothesis that the dice is fair. Under this hypothesis, the variable  $X$  given by the score of a single roll attains the values 1 through 6 with constant probability  $\frac{1}{6}$ . Presently, the stats-package does not provide a discrete uniform distribution, so we implement a corresponding cumulative discrete distribution function  $f$ :

```
f := proc(x)
begin
 if x < 0 then
 0
 elif x <= 6 then
 trunc(x)/6
```

```

else 1
end_if;
end_proc:

```

We create the data representing the 60 rolls:

```
data := [1 $ 7, 2 $ 16, 3 $ 8, 4 $ 17, 5 $ 3, 6 $ 9]:
```

We choose a collection of cells, each of which contains exactly one of the integers 1, ..., 6:

Wir wählen sodann eine Zellzerlegung, so dass jede Zelle genau eine der ganzen Zahlen 1, ..., 6 enthält:

```
cells := [[i - 1/2, i + 1/2] $ i = 1..6]
```

```
[[[1/2, 3/2], [3/2, 5/2], [5/2, 7/2], [7/2, 9/2], [9/2, 11/2], [11/2, 13/2]]]
```

```
stats::csGOFT(data, cells, CDF = f)
```

```
[PValue = 0.01125197903, StatValue = 14.8, MinimalExpectedCellFrequency = 10.0]
```

At a significance level as small as 0.011..., the null hypothesis ‘the dice is fair’ should be rejected.

```
delete f, data, cells:
```

### Example 6

We give a further demonstration of user-defined distribution functions. The following procedure represents the cumulative distribution function

$f: X \rightarrow \Pr(X \leq x) = x^2$  of a variable  $X$  supported on the interval  $[0, 1]$ . It will be called with values from the cell boundaries and must return numerical values between 0 and 1:

```
f := proc(x)
 begin
 if x <= 0 then return(0)
 elif x <= 1 then return(x^2)
 else return(1)
 end_if
 end_proc:
```

We test the hypothesis that the following data are  $f$ -distributed. The cells form an equidistant partitioning of the interval  $[0, 1]$ :

```
data := [sqrt(frandon()) $ i = 1..10^3]:
k := 10:
cells := [(i - 1)/k, i/k] $ i = 1..k]:
stats::csGOFT(data, cells, CDF = f)
```

[PValue = 0.5637573509, StatValue = 7.708606165, MinimalExpectedCellFrequency = 10.0]

The test does not disqualify the sample as being  $f$ -distributed. Indeed, for a uniform deviate  $Y$  on the interval  $[0, 1]$  (as produced by `frandon`), the cumulative distribution function of  $\sqrt{Y}$  is indeed given by  $f$ .

We note that the previous function yields the correct CDF values for all real arguments. The chosen cell partitioning indicates that only values from the interval  $(0, 1]$  are considered. Since `stats::csGOFT` just evaluates the CDF on the cell boundaries to compute the cell probability of the cell  $(a, b]$  by  $f(b) - f(a)$ , it suffices to restrict  $f$  to the interval  $(0, 1]$ . Hence, for the chosen cells, the symbolic expression `f = x^2` can also be used to specify the distribution:

```
stats::csGOFT(data, cells, CDF = x^2)
```

[PValue = 0.5637573509, StatValue = 7.708606165, MinimalExpectedCellFrequency = 10.0]

delete f, data, k, cells:

## Parameters

**$x_1, x_2, \dots$**

The statistical data: real numerical values

**s**

A sample of domain type stats::sample

**c**

An integer representing a column index of the sample s. This column provides the data  $x_1, x_2$  etc. There is no need to specify a column c if the sample has only one column.

**$a_1, b_1, a_2, b_2, \dots$**

Cell boundaries: real numbers satisfying  $a_1 < b_1 \leq a_2 < b_2 \leq a_3 < \dots$ . Also  $\pm \infty$  is admitted as a cell boundary. At least 3 cells have to be specified.

**f**

A procedure representing the hypothesized distribution: either a cumulative distribution function (CDF = f), a probability density function (PDF = f), or a (discrete) probability function (PF = f). Typically, f is one of the distribution functions of the stats package such as stats::normalCDF(m, v) etc. Instead of a procedure, also an arithmetical expression in some indeterminate x may be specified which will be interpreted as a function of x.

## Options

**CDF, PDF, PF**

This determines how the procedure f is interpreted by stats::csGOFT.

## Return Values

a list of three equations

[PValue = p, StatValue = s, MinimalExpectedCellFrequency = m]

with floating-point values  $p$ ,  $s$ ,  $m$ . See the “Details” section below for the interpretation of these values.

## Algorithms

In R.B. D’Agostino and M.A. Stephens, “Goodness-Of-Fit Techniques”, Marcel Dekker, 1986, p. 70-71, one finds the following recommendations for choosing the cell partitioning:

- The number of cells used should be approximately  $2 n^{2/5}$ , where  $n$  is the sample size.
- The cells should have equal probabilities  $p_i$  under the hypothesized distribution.
- With equiprobable cells, the average of the expected cell frequencies  $np_i$  should be at least 1 when testing at the significance level  $\alpha = 0.05$ . For  $\alpha = 0.01$ , the average expected cell frequency should be at least 2. When cells are not approximately equiprobable, the average expected cell frequency for the significance levels above should be doubled. For example, the average expected cell frequency at the significance level  $\alpha = 0.01$  should be at least 4.

The distribution function  $f$  passed to `stats::csGOFT` via  $X = f$  is only used to compute the cell probabilities  $p_i = Pr(a_i < x \leq b_i)$  of the cells  $C_i = (a_i, b_i]$ .

A cumulative distribution function  $f$  specified by `CDF = f` is used to compute the cell probabilities via  $p_i = f(b_i) - f(a_i)$ .

A probability density function  $f$  specified via `PDF = f` is used to compute the cell probabilities via numerical integration:

$p_i = \text{numeric::int}(f(x), x = a_i..b_i)$ . This is rather expensive!

A discrete probability function specified via `PF = f` is used to compute

the cell probabilities via the summation  $p_i = \sum_{x=[a_i]+1}^{b_i} f(x)$ .

---

**Note** Thus, with the specification  $\text{PF} = \mathbf{f}$ , the distribution is implicitly supposed to be supported on the integers in the cells  $c_i = (a_i, b_i]$ . Do not use  $\text{PF} = \mathbf{f}$  if the discrete probability function is not supported on the integers! Use  $\text{CDF} = \mathbf{f}$  with an appropriate (discrete) cumulative distribution function instead!

---

With the specification  $\text{PF} = \mathbf{f}$ , the value  $-\infty$  is not admitted for the left boundary  $a_1$  of the first cell  $c_1 = \text{Intval}([a_1], [b_1])$ .

`stats::empiricalCDF([x1, x2, ])`  
`stats::empiricalCDF(s, c)`

**Description** `stats::empiricalCDF(x1, x2, , xn)` returns a procedure representing the empirical (discrete) cumulative distribution function  $X \rightarrow \frac{1}{n} |\{i \mid X_i \leq x\}|$  (the relative frequency of data elements  $x_i$  less than or equal to  $x$ ).

All data  $x_1, x_2, \dots$  must be convertible to real floating-point numbers.

The procedure `f := stats::empiricalCDF(x1, x2, )` can be called in the form `f(x)` with an arithmetical expression  $x$ .

If  $x$  is a numerical value, `f(x)` returns a rational number from the interval  $[0, 1]$ .

The call `f(-infinity)` produces 0; the call `f(infinity)` produces 1.

Otherwise, if  $x$  is a symbolic expression that cannot be converted to a real floating-point number, `f(x)` returns the symbolic call `stats::empiricalCDF([x1, x2, ])(x)` with the data  $x_1, x_2, \dots$  in ascending order.

For a sample of size  $n$ , the call `f := stats::empiricalCDF(x1, x2, )` needs a run time of  $O(n \ln(n))$  due to internal sorting of the data. Each call to `f` needs a run time of  $O(\ln(n))$ . If several evaluations of the distribution function are needed, a calling sequence such as

```
f := stats::empiricalCDF(x1, x2,); f(a1); f(a2); dots
```

is more efficient than

```
stats::empiricalCDF(x1, x2,)(a1);
```

```
stats::empiricalCDF(x1, x2,)(a2);
```

```
dots.
```

`stats::empiricalCDF` is generalized by `stats::finiteCDF`, which allows to specify different probabilities for the elements of the sample. The call `stats::empiricalCDF([x1, ..., xn])` corresponds to `stats::finiteCDF([x1, dots, xn], [1/n, dots, 1/n])`.

Further, `stats::finiteCDF` does not only allow numerical values  $x_1, x_2, \dots$ , but arbitrary MuPAD objects.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. Note, however, that this function is implemented with option `remember`. After the first call it does not react to changes of `DIGITS` unless the input parameters are changed.

## Examples

### Example 1

We evaluate the empirical distribution function of the data  $-1, 0, 2.3, \pi, 8$  at various points:

```
f := stats::empiricalCDF(-1, 0, 2.3, PI, 8):
f(-infinity), f(-3), f(2.4), f(PI), f(10), f(infinity)
```

```
0, 0, $\frac{3}{5}$, $\frac{4}{5}$, 1, 1
```

Alternatively, the data may be passed as a list:

```
f := stats::empiricalCDF([-1, 0, 2.3, PI, 8]):
f(-infinity), f(-3), f(2.4), f(PI), f(10), f(infinity)
```

```
0, 0, $\frac{3}{5}$, $\frac{4}{5}$, 1, 1
```

```
delete f:
```

# stats::empiricalCDF

---

## Example 2

We use a symbolic argument. In the symbolic return value, the input data appear as a sorted list:

```
stats::empiricalCDF(PI, -3, 25, PI, 4/3)(x)
```

```
stats::empiricalCDF([-3, $\frac{4}{3}$, π , π , 25])(x)
```

## Example 3

We create a sample consisting of one string column and two non-string columns:

```
s := stats::sample(
 [{"1996", 1242, PI - 1/2}, {"1997", 1353, PI + 0.3},
 {"1998", 1142, PI + 0.5}, {"1999", 1201, PI - 1},
 {"2001", 1201, PI}])
```

```
"1996" 1242 PI - 1/2
"1997" 1353 PI + 0.3
"1998" 1142 PI + 0.5
"1999" 1201 PI - 1
"2001" 1201 PI
```

We compute values of the empirical distributions of the data in the second and third column, respectively:

```
f2 := stats::empiricalCDF(s, 2): f2(1000), f2(1200), f2(1201)
```

```
0, $\frac{1}{5}$, $\frac{3}{5}$
```

```
f3 := stats::empiricalCDF(s, 3): f3(0.7), f3(3), f3(PI), f3(4)
```

0,  $\frac{2}{5}$ ,  $\frac{3}{5}$ , 1

delete s, f2, f3:

## Parameters

$x_1, x_2, \dots$

The statistical data: real numerical values

**s**

A sample of domain type stats::sample

**c**

A column index of the sample **s**: a positive integer. This column provides the data  $x_1, x_2$  etc. There is no need to specify a column number **c** if the sample has only one non-string column.

## Return Values

procedure.

## MuPAD Functions

stats::empiricalPF | stats::empiricalQuantile |  
stats::empiricalRandom | stats::finiteCDF | stats::finitePF  
| stats::finiteQuantile | stats::finiteRandom

# stats::empiricalPF

---

**Purpose** Probability function of a finite data sample

**Syntax**  
`stats::empiricalPF(x1, x2, ...)`  
`stats::empiricalPF([x1, x2, ...])`  
`stats::empiricalPF(n, <c>)`  
`stats::empiricalPF(n, <[c]>)`

**Description** `stats::empiricalPF([x1, x2, ..., xn])` returns a procedure representing the probability function

$$x \rightarrow \begin{cases} \frac{1}{n} & \text{if } x = x_i \\ 0 & \text{otherwise} \end{cases}$$

of the sample given by the data  $x_1, x_2, \dots$ .

The procedure `f := stats::empiricalPF([x1, x2, ...])` can be called in the form `f(x)` with an arithmetical expression `x` or sets of lists of such expressions.

If `x` is a numerical expression that is contained in the data  $x_1, x_2, \dots$ , then the corresponding probability value  $\frac{1}{n}$  is returned ( $n$  is the size of the sample).

If `x` is a numerical expression that is not contained in the data  $x_1, x_2, \dots$ , then 0 is returned.

If `x` is a symbolic expression that cannot be converted to a real floating-point number, `f(x)` returns the symbolic call `stats::empiricalPF([x1, x2, ...])(x)` with the data  $x_1, x_2, \dots$  in ascending order.

If `x` is a set, the sum of the probability values of its elements is returned.

If `x` is a list, it is treated like a set (i.e., duplicate entries in `x` are eliminated). The sum of the probability values of the elements in `x` is returned.

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values. Cf. “Example 4” on page 29-123.

`stats::empiricalPF` is generalized by `stats::finitePF`, which allows to specify different probabilities for the elements of the sample. The call `stats::empiricalPF([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalPF([x_1, , x_n])`.

Further, `stats::finitePF` does not only allow numerical values  $x_1$ ,  $x_2$ , , but arbitrary MuPAD objects.

## Examples

### Example 1

We demonstrate the basic usage of this function:

```
f := stats::empiricalPF(1, 3, PI, 4.0):
f(0), f(1), f(1.0), f(3), f(PI), f(float(PI)), f(4), f(4.0)
```

$$0, \frac{1}{4}, 0, \frac{1}{4}, \frac{1}{4}, 0, 0, \frac{1}{4}$$

Alternatively, the data may be passed as a list:

```
f := stats::empiricalPF(1, 3, PI, 4.0):
f(0), f(1), f(1.0), f(3), f(PI), f(float(PI)), f(4), f(4.0)
```

$$0, \frac{1}{4}, 0, \frac{1}{4}, \frac{1}{4}, 0, 0, \frac{1}{4}$$

A symbolic value of the argument in `f` leads to a symbolic return value:

```
f(x)
```

$$\text{stats::empiricalPF}([1, 3, \pi, 4.0])(x)$$

# stats::empiricalPF

---

Symbolic data are not accepted:

```
stats::empiricalPF(1, 3, x, 4.0):
```

```
Error: Some data cannot be converted to floating-point numbers. [st
```

```
delete f:
```

## Example 2

We create a sample of type `stats::sample` consisting of one string column and two non-string columns:

```
s := stats::sample(
 [["1996", 1242, 2/5],
 ["1997", 1353, 0.1],
 ["1998", 1142, 0.2],
 ["1999", 1201, 0.2],
 ["2001", 1201, 0.1]])
```

```
"1996" 1242 2/5
"1997" 1353 0.1
"1998" 1142 0.2
"1999" 1201 0.2
"2001" 1201 0.1
```

We use the data in the first and third column:

```
f := stats::empiricalPF(s, 2):
f(1242), f(1353), f(1200), f(1201)
```

```
 $\frac{1}{5}, \frac{1}{5}, 0, \frac{2}{5}$
```

```
delete s, f:
```

### Example 3

We consider a fair die:

```
f:= stats::empiricalPF([1, 2, 3, 4, 5, 6]):
```

What is the probability that tossing the die produces a score more than or equal to 4?

```
f({4, 5, 6})
```

$$\frac{1}{2}$$

```
delete f:
```

### Example 4

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values:

```
f:= stats::empiricalPF([1, 2, 1, 1, 2]):
f(1), f(2)
```

$$\frac{3}{5}, \frac{2}{5}$$

```
delete f:
```

## Parameters

$x_1, x_2, \dots$

The statistical data: real numerical values

**s**

A sample of domain type stats::sample

# stats::empiricalPF

---

**c**

A column index of the sample  $s$ : a positive integer. This column provides the data  $x_1, x_2$  etc. There is no need to specify a column number  $c$  if the sample has only one non-string column.

## Return Values

procedure.

## MuPAD Functions

stats::empiricalCDF | stats::empiricalQuantile |  
stats::empiricalRandom | stats::finiteCDF | stats::finitePF  
| stats::finiteQuantile | stats::finiteRandom

## Purpose

Quantile function of the empirical distribution

## Syntax

```
stats::empiricalQuantile(x1, x2, ...)
stats::empiricalQuantile([x1, x2, ...])
stats::empiricalQuantile(s, c)
```

## Description

`stats::empiricalQuantile(x1, x2, ...)` returns a procedure representing the quantile function of the data  $x_1, x_2$  etc. It is the (discrete) inverse of the empirical cumulative distribution function `stats::empiricalCDF(x1, x2, ...)`. For  $0 \leq x \leq 1$ , the  $x$ -quantile  $y = \text{stats::empiricalQuantile}(x_1, x_2, \dots)(x)$  is the smallest of the data elements  $x_1, x_2, \dots$  satisfying

$$\text{stats::empiricalCDF}(x_1, x_2, \dots)(y) \geq x$$

All data  $x_1, x_2, \dots$  must be convertible to real floating-point numbers. The data do not have to be sorted on input.

The procedure `f := stats::empiricalQuantile(x1, x2, ...)` can be called in the form `f(x)` or `f(x, Averaged)` with an arithmetical expression  $x$ .

If  $x$  is a real number satisfying  $0 \leq x \leq 1$ , then `f(x)` returns one of the data elements; `f(x, Averaged)` uses interpolation of adjacent data elements:

The  $x$ -quantile of  $n$  sorted values  $x_1 \leq \dots \leq x_n$  is computed as follows.

- `f(x)` returns  $x_k$  with  $k = \text{ceil}(n*x)$ .
- `f(x, Averaged)` returns  $x_k$  with  $k = \text{ceil}(n*x)$  if  $n*x$  is not an integer. Otherwise, it returns  $\frac{(x_k + x_{k+1})}{2}$ .

If  $x$  is a symbolic expression that cannot be converted to a real floating-point number, `f(x, <Averaged>)` returns the symbolic call

## stats::empiricalQuantile

---

`stats::empiricalQuantile([x1, x2, ...])(x, <Averaged>)` with the data `x1, x2, ...` in ascending order.

Numerical values of  $x$  are only accepted if  $0 \leq x \leq 1$ .

$y = \text{stats::empiricalQuantile}(x_1, x_2, \dots)(x)$  satisfies

$$\text{stats::empiricalCDF}(x_1, x_2, \dots)(z) < x \leq \text{stats::empiricalCDF}(x_1, x_2, \dots)(y)$$

for all data elements  $z$  in the sample satisfying  $z < y$ .

For a sample of size  $n$ , the call `f := stats::empiricalQuantile(x1, x2, ...)` needs a run time of  $O(n \ln(n))$  due to internal sorting of the data. The costs of a call to `f` are essentially dependent of  $n$ . If several evaluations of the quantile function are needed, a calling sequence such as

```
f := stats::empiricalQuantile(x1, x2, ...); f(a1); f(a2); dots
```

is more efficient than

```
stats::empiricalQuantile(x1, x2, ...)(a1);
```

```
stats::empiricalQuantile(x1, x2, ...)(a2);
```

```
dots.
```

The  $\frac{1}{2}$ -quantile is called “median”. The function `stats::median` implements this special quantile.

`stats::empiricalQuantile` is generalized by `stats::finiteQuantile`, which allows to specify different probabilities for the elements of the sample. The call `stats::empiricalQuantile([x1, ..., xn])` corresponds to `stats::finiteQuantile([x1, ..., xn], [1/n, ..., 1/n])`.

Further, `stats::finiteQuantile` does not only allow numerical values `x1, x2, ...`, but arbitrary MuPAD objects.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. Note, however, that this function is implemented with option remember. After the first call it does not react to changes of DIGITS unless the input parameters are changed.

## Examples

### Example 1

We compute various quantiles of the data -1, 0, 0, 2.3, PI, PI, 8:

```
f := stats::empiricalQuantile(-1, 0, 0, 2.3, PI, PI, 8):
f(0), f(0.1), f(3/10), f(0.5), f(1/sqrt(2)), f(99/100), f(1)

-1, -1, 0, 2.3, π , 8, 8
```

Alternatively, the data may be passed as a list:

```
f := stats::empiricalQuantile([-1, 0, 2.3, PI, 8]):
f(0), f(0.1), f(3/10), f(0.5), f(1/sqrt(2)), f(99/100), f(1)

-1, -1, 0, 2.3, π , 8, 8
```

```
delete f:
```

### Example 2

We use a symbolic argument. In the symbolic return value, the input data appear as a sorted list:

```
f := stats::empiricalQuantile(3, 25, PI, 4/3): f(x)

stats::empiricalQuantile($\left[\frac{4}{3}, 3, \pi, 25\right]$)(x)
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

# stats::empiricalQuantile

---

```
f(0.5)
```

```
3
```

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f:
```

## Example 3

We create a sample of type `stats::sample` consisting of one string column and two non-string columns:

```
s := stats::sample(
 [{"1996", 1242, PI - 1/2}, {"1997", 1353, PI + 0.3},
 {"1998", 1142, PI + 0.5}, {"1999", 1201, PI - 1/3},
 {"2001", 1201, PI + 0.5}])
```

```
"1996" 1242 PI - 1/2
"1997" 1353 PI + 0.3
"1998" 1142 PI + 0.5
"1999" 1201 PI - 1/3
"2001" 1201 PI + 0.5
```

We compute quantile values of the data in the second and third column, respectively:

```
f2 := stats::empiricalQuantile(s, 2):
f2(0.1), f2(1/4), f2(0.7), f2(99/100)
```

```
1142, 1201, 1242, 1353
```

```
f3 := stats::empiricalQuantile(s, 3):
f3(0.1), f3(1/4), f3(0.7), f3(99/100)
```

```
 $\pi - \frac{1}{2}$, $\pi - \frac{1}{3}$, $\pi + 0.5$, $\pi + 0.5$
```

```
delete s, f2, f3:
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: real numerical values

**s**

A sample of domain type stats::sample

**c**

A column index of the sample s: a positive integer. This column provides the data  $x_1, x_2$  etc. There is no need to specify a column number c if the sample has only one non-string column.

## Return Values

procedure.

## MuPAD Functions

```
stats::empiricalCDF | stats::empiricalPF |
stats::empiricalRandom | stats::finiteCDF | stats::finitePF
| stats::finiteQuantile | stats::finiteRandom |
stats::median
```

# stats::empiricalRandom

---

**Purpose** Generate a random generator for uniformly distributed elements of a data sample

**Syntax**

```
stats::empiricalRandom(x1, x2, ..., <Seed = n>)
stats::empiricalRandom([x1, x2, ...], <Seed = n>)
stats::empiricalRandom(n, <c>, <Seed = n>)
stats::empiricalRandom(n, <[c]>, <Seed = n>)
```

**Description** stats::empiricalRandom([x<sub>1</sub>, x<sub>2</sub>, ..., x<sub>n</sub>]) returns a procedure that picks out random elements from the data x<sub>1</sub>, x<sub>2</sub> etc.

All data x<sub>1</sub>, x<sub>2</sub>, ... must be convertible to real floating-point numbers.

The procedure `f := stats::empiricalRandom([x1, x2, ...])` can be called in the form `f()`. The call `f()` returns one of the data elements x<sub>1</sub>, x<sub>2</sub>, ...

The values produced by `f()` are distributed randomly. Each element of the sample is chosen with the same probability.

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::empiricalRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random elements via

```
f := stats::empiricalRandom([x1, x2, ...]):
```

```
f() $k = 1..K;
```

rather than by

```
stats::empiricalRandom([x1, x2, dots])() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::empiricalRandom([x_1, x_2, dots], Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

`stats::empiricalRandom` is generalized by `stats::finiteRandom`, which allows to specify different probabilities for the elements of the sample. The call `stats::empiricalRandom([x1, ..., xn])` corresponds to `stats::finiteRandom([x1, dots, xn], [1/n, dots, 1/n])`.

Further, `stats::finiteRandom` does not only allow numerical values  $x_1, x_2, \dots$ , but arbitrary MuPAD objects.

## Examples

### Example 1

We pick out random elements of some data:

```
f := stats::empiricalRandom(1, 7, 4, PI, Seed = 234):
f(), f(), f(), f(), f(), f(), f(), f(), f()
```

1, 1,  $\pi$ , 7, 7,  $\pi$ ,  $\pi$ , 7, 7

Alternatively, the data may be passed as a list:

```
f := stats::empiricalRandom([1, 7, 4, PI], Seed = 234):
f(), f(), f(), f(), f(), f(), f(), f(), f()
```

1, 1,  $\pi$ , 7, 7,  $\pi$ ,  $\pi$ , 7, 7

Symbolic data are not accepted:

```
stats::empiricalRandom(1, 7, 4, x):
```

# stats::empiricalRandom

---

```
Error: Some data cannot be converted to floating-point numbers. [st
```

```
delete f:
```

## Example 2

We create a sample of type `stats::sample` consisting of one string column and two non-string columns:

```
s := stats::sample(
 ["1996", 1242, 2/5],
 ["1997", 1353, 0.1],
 ["1998", 1142, 0.2],
 ["1999", 1201, 0.2],
 ["2001", 1201, 0.1])
```

```
"1996" 1242 2/5
"1997" 1353 0.1
"1998" 1142 0.2
"1999" 1201 0.2
"2001" 1201 0.1
```

We pick random values using the data in the second and third column, respectively:

```
f := stats::empiricalRandom(s, 2, Seed = 12345):
f(), f(), f(), f(), f(), f(), f()
```

```
1353, 1142, 1142, 1201, 1142, 1142, 1353
```

```
f := stats::empiricalRandom(s, 3, Seed = 12345):
f(), f(), f(), f(), f(), f(), f()
```

$\frac{2}{5}, 0.1, 0.1, 0.1, 0.1, 0.1, \frac{2}{5}$

delete s, f:

### Example 3

We toss a fair die:

```
f:= stats::empiricalRandom([1, 2, 3, 4, 5, 6], Seed = 12345):
f(), f(), f(), f(), f(), f(), f(), f(), f(), f()
```

5, 1, 2, 3, 1, 1, 6, 3, 1, 2

We toss the die 6000 times and count the frequencies of the scores 1 through 6:

```
t := [f() $ k = 1..6000]:
i = nops(select(t, _equal, i)) $ i = 1..6
```

1 = 982, 2 = 1006, 3 = 911, 4 = 1037, 5 = 1021, 6 = 1043

The routine stats::finiteRandom allows to model a loaded die:

```
f:= stats::finiteRandom(
 [[1, 0.1],
 [2, 0.1],
 [3, 0.1],
 [4, 0.1],
 [5, 0.1],
 [6, 0.5]],
 Seed = 12345):
t := [f() $ k = 1..6000]:
i = nops(select(t, _equal, i)) $ i = 1..6
```

# stats::empiricalRandom

---

```
1 = 572, 2 = 611, 3 = 614, 4 = 548, 5 = 554, 6 = 3101
```

```
delete f, t:
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: real numerical values

**s**

A sample of domain type `stats::sample`

**c**

A column index of the sample `s`: a positive integer. This column provides the data  $x_1, x_2$  etc. There is no need to specify a column number `c` if the sample has only one non-string column.

## Options

**Seed**

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random values. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of values.

## Return Values

procedure.

`stats::finiteRandom` | `stats::median`

# stats::equiprobableCells

---

**Purpose** Divide the real line into equiprobable intervals

**Syntax** stats::equiprobableCells(k, q, <NoWarning>)

**Description** stats::equiprobableCells is a utility function for the classical chi-square test implemented by stats::csGOFT. The call stats::equiprobableCells(k, q) creates a list of intervals (“cells”) that are equiprobable with respect to the statistical distribution corresponding to the quantile function q.

The chi-square goodness-of-fit test needs a cell partitioning of the real line to compare the empirical frequencies of data falling into the cells with the expected frequencies corresponding to a hypothesized statistical distribution. It is recommended to use equiprobable cells in this test. stats::equiprobableCells is a utility function to compute such a partitioning.

The cell boundaries  $b_i$  of the returned cell partitioning  $[[b_0, b_1], \dots, [b_{k-1}, b_k]]$  are computed via  $b_i = \text{float}\left(q\left(\text{float}\left(\frac{i}{k}\right)\right)\right)$ . Mathematically, each cell  $[b_{i-1}, b_i]$  corresponds to a semi-open interval  $(b_{i-1}, b_i]$ .

If q is the quantile function of a *continuous* statistical distribution, all cells have the same cell probability  $\Pr(b_{i-1} < X \leq b_i) = \frac{1}{k}$ .

The function q can be a quantile procedure provided by the MuPAD stats-library.

Quantile functions not provided by the stats-package can be implemented easily by the user. A user defined quantile procedure q can correspond to any statistical distribution. Quantile functions must accept one numerical floating-point parameter x satisfying  $0.0 \leq x \leq 1.0$ . The call q(x) must produce a real value. In particular, the return values  $q(0.0) = -\text{infinity}$  and  $q(1.0) = \text{infinity}$  are allowed.

Quantile functions must be monotonically increasing.

stats::equiprobableCells issues warnings if the computed quantile

values  $b_i = \text{float}(\mathcal{Q}(\text{float}(\frac{i}{k})))$  are not real or  $\pm\infty$ , or if these values do not increase monotonically.

`stats::equiprobableCells` also accepts quantile functions of *discrete* distributions such as `stats::empiricalQuantile(data)` or `stats::binomialQuantile(n, p)`.

---

**Note** Note, however, that in general, there are no equiprobable cell partitionings for discrete distributions. Consequently, equiprobability of the cells returned by `stats::equiprobableCells` is not guaranteed if  $q$  is not a continuous function.

---

In particular, it may happen for large  $k$ , that  $\mathcal{Q}(\frac{i-1}{k})$  coincides with  $\mathcal{Q}(\frac{i}{k})$ , i.e., the corresponding cell is empty. This will always happen, when  $k$  exceeds the number of possible discrete values the random variable can attain.

In such a case, a warning is issued. Passing such a cell partitioning to `stats::csgoft` raises an error.

Further to the examples on this help page, see also the examples on the help page of `stats::csgoft`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We divide the real line into 4 intervals that are equiprobable with respect to the standard normal distribution:

```
k:= 4: q := stats::normalQuantile(0, 1):
cells := stats::equiprobableCells(k, q)
```

## stats::equiprobableCells

---

```
[[-∞, -0.6744897502], [-0.6744897502, 0.0], [0.0, 0.6744897502], [0.6744897502, ∞]]
```

We check equiprobability by applying the function `stats::normalCDF(0, 1)` to the cell boundaries:

```
cdf := stats::normalCDF(0, 1):
p := map(cells, map, cdf)
```

```
[[0, 0.25], [0.25, 0.5], [0.5, 0.75], [0.75, 1]]
```

The cell probabilities are given by the differences of the CDF function applied to the cell boundaries:

```
(p[i][2] - p[i][1]) $ i = 1..k
```

```
0.25, 0.25, 0.25, 0.25
```

We use these cells for a chi-square test for normality of some random data:

```
r := stats::normalRandom(0, 1, Seed = 0):
data := [r() $ i = 1..1000]:
stats::csGOFT(data, cells, CDF = cdf)
```

```
[PValue = 0.8398775533, StatValue = 0.84, MinimalExpectedCellFrequency = 250.0]
```

With the observed significance level **0.839...**, the data pass this test well. We experiment with other equiprobable cell partitionings:

```
for k in [20, 30, 40, 50] do
 cells := stats::equiprobableCells(k, q);
 print(stats::csGOFT(data, cells, CDF = cdf));
end
```

```
end_for:
```

```
[PValue = 0.1798122173, StatValue = 24.44, MinimalExpectedCellFrequency = 50.0]
```

```
[PValue = 0.713000696, StatValue = 24.32, MinimalExpectedCellFrequency = 33.333333]
```

```
[PValue = 0.7039429342, StatValue = 33.84, MinimalExpectedCellFrequency = 25.0]
```

```
[PValue = 0.932574698, StatValue = 35.1, MinimalExpectedCellFrequency = 20.0]
```

```
delete k, cells, p, cdf, r, data:
```

## Example 2

We create a sample of 1000 random integers between 0 and 100:

```
SEED := 10^2: r := random(0 .. 100):
data := [r() $ i = 1..1000]:
```

We construct an ‘equiprobable’ cell partitioning of 10 cells using the (discrete) empirical distribution of the data. I.e., each of the following cells should contain approximately the same number of data from the random sample:

```
k := 10:
quantile := stats::empiricalQuantile(data):
cells := stats::equiprobableCells(k, quantile)
```

```
[[0.0, 9.0], [9.0, 19.0], [19.0, 31.0], [31.0, 38.0], [38.0, 49.0], [49.0, 59.0], [59.0, 69.0], [69.0, 78.0], [78.0, 91.0], [91.0, 100.0]]
```

## stats::equiprobableCells

---

For discrete distributions, ‘equiprobability’ can only be achieved approximately. We compute the cell probabilities with respect to the empirical cumulative distribution function (CDF), by subtracting the CDF value of the left boundary from the CDF value of the right boundary:

```
cdf := stats::empiricalCDF(data):
map(cells, cell -> cdf(cell[2]) - cdf(cell[1]))

[12, 99, 14, 89, 51, 103, 103, 23, 21, 93]
 [125, 1000, 125, 1000, 500, 1000, 1000, 250, 200, 1000]
```

The actual empirical frequency of the data in each cell is the cell probability times the sample size (1000):

```
map(cells, cell -> 1000*(cdf(cell[2]) - cdf(cell[1])))

[96, 99, 112, 89, 102, 103, 103, 92, 105, 93]
```

When computing the probability of the cell  $[b[i-1], b[i]]$  via  $cdf(b_i) - cdf(b_{i-1})$ , the cell is regarded as the semiopen interval  $(b_{i-1}, b_i]$  mathematically. For this reason, the data points 0 contained in the sample are not counted, and the cell frequencies do not quite add up to the sample size:

```
_plus(op(%))

994
```

For the `Symbol::chi^2` test, this does not matter because it replaces the left boundary of the first cell by `-infinity`, anyway. With an observed significance level of `0.161...`, the data pass the test for a uniform distribution at levels as high as `0.161...`:

```
stats::csGOFT(data, cells, CDF = stats::uniformCDF(0, 100))
```

```
[PValue = 0.1619543558, StatValue = 13.01443112, MinimalExpectedCellFrequency = 70]
```

We test whether the data fit a normal distribution with the empirical mean and variance:

```
[m, v] := [stats::mean(data), stats::variance(data)];
stats::csGOFT(data, cells, CDF = stats::normalCDF(m, v))
```

```
[$\frac{9863}{200}$, $\frac{1221413}{1480}$]
```

```
[PValue = 0.00000000207226197, StatValue = 59.0175707, MinimalExpectedCellFrequency = 70]
```

With the observed significance level 0.00000000207..., the hypothesis of a normal distribution clearly has to be rejected.

```
delete r, data, k, quantile, cells, cdf, m, v:
```

### Example 3

We consider a binomial distribution with ‘trial parameter’  $n = 100$  and ‘probability parameter’  $p = \frac{1}{2}$ . It is the distribution of the number of successes in  $n = 100$  independent Bernoulli experiments, each with success probability  $p = \frac{1}{2}$ . This random variable can attain the discrete values 0, 1, ..., 100. We create a cell partitioning of 4 cells:

```
n := 100: p := 1/2:
quantile := stats::binomialQuantile(n, p):
cells := stats::equiprobableCells(4, quantile)
```

```
[[0.0, 47.0], [47.0, 50.0], [50.0, 53.0], [53.0, 100.0]]
```

## stats::equiprobableCells

---

Because of discreteness, an exact equiprobable cell partitioning does not exist. We compute the expected cell frequencies in the same way as in the previous example:

```
cdf := stats::binomialCDF(n, p):
map(cells, cell -> n*(cdf(cell[2]) - cdf(cell[1])))
```

```
[30.86497068, 23.11449119, 21.81461745, 24.20592068]
```

We create a random sample and apply the Symbol::chi<sup>2</sup> test:

```
r := stats::binomialRandom(n, p, Seed = 123):
data := [r() $ i = 1..100]:
stats::csGOFT(data, cells, CDF = cdf)
```

```
[PValue = 0.3394635837, StatValue = 3.359377148, MinimalExpectedCellFrequency = 21.81]
```

The observed significance level **0.339...** is not small, i.e., the data pass the test well.

The ‘trial parameter’  $n = 100$  is large enough for the binomial distribution to be approximated by a normal distribution with mean  $np$  and variance  $np(1 - p)$ . The data pass the test for a normal distribution, too:

```
cdf := stats::normalCDF(n*p, n*p*(1 - p)):
stats::csGOFT(data, cells, CDF = cdf)
```

```
[PValue = 0.1547938521, StatValue = 5.243756673, MinimalExpectedCellFrequency = 22.57]
```

We repeat the test with another cell partitioning:

```
quantile := stats::normalQuantile(n*p, n*p*(1 - p)):
cells := stats::equiprobableCells(4, quantile)
```

```
[[-∞, 46.62755125], [46.62755125, 50.0], [50.0, 53.37244875], [53.37244875, ∞]]
```

```
stats::csGOFT(data, cells, CDF = cdf)
```

```
[PValue = 0.1422716505, StatValue = 5.44, MinimalExpectedCellFrequency = 25.0]
```

```
delete k, quantile, cells, cdf, r, data:
```

## Example 4

We demonstrate user-defined quantile functions. We consider the following distribution of a random variable  $X$  supported on the interval  $[0, 1]$ :

$$\Pr(X \leq x) = \begin{cases} 0 & \text{if } x < 0 \\ x^2 & \text{if } 0 \leq x \leq 1 \\ 1 & \text{if } x > 1 \end{cases}$$

The quantile function  $q$  is given by  $q(x) = \sqrt{x}$  for  $0 \leq x \leq 1$ :

```
quantile := x -> sqrt(x):
```

We test the hypothesis that the following data are distributed as defined above.

```
cells := stats::equiprobableCells(6, quantile)
```

```
[[0.0, 0.4082482905], [0.4082482905, 0.5773502692], [0.5773502692, 0.7071067812],
 [0.7071067812, 0.8164965809], [0.8164965809, 0.9128709292], [0.9128709292, 1.0]]
```

```
data := [sqrt(frandon()) $ i = 1..10^3]:
```

# stats::equiprobableCells

---

```
cdf := proc(x)
begin
 if x <= 0 then return(0)
 elif x <= 1 then return(x^2)
 else return(1)
 end_if
end_proc:
stats::csGOFT(data, cells, CDF = cdf)
```

[PValue = 0.2230310886, StatValue = 6.968, MinimalExpectedCellFrequency = 166.6666667]

The data pass the test well. In fact, for a uniform deviate  $Y$  on the interval  $[0, 1]$  (as produced by `frandom`), the cumulative distribution function of  $\sqrt{Y}$  is indeed given by *cdf*.

```
delete quantile, cells, data, cdf:
```

## Parameters

**k**

The number of cells: a positive integer

**q**

A procedure representing a quantile function of a statistical distribution. Typically, *q* is one of the quantile functions of the `stats`-package such as `stats::normalQuantile(m, v)`, `stats::empiricalQuantile(data)` etc. Alternatively, user defined procedures may be passed if the `stats`-package does not provide a suitable quantile function.

## Options

**NoWarning**

`stats::equiprobableCells` issues warnings if the computed cell partitioning is not suitable for `stats::csGOFT`. These warnings may be switched off with this option.

## Return Values

List of  $k$  “cells”

$$\left[ [b_0, b_1], [b_1, b_2], \dots, [b_{k-1}, b_k] \right]$$

with floating-point values  $b_i = q\left(\frac{i}{k}\right)$ ,  $i = 0, \dots, k$ . This ‘cell partitioning’ is suitable as input parameter for stats::csGOFT.

## MuPAD Functions

stats::csGOFT

# stats::erlangCDF

---

**Purpose** Cumulative distribution function of the Erlang distribution

**Syntax** stats::erlangCDF(a, b)

**Description** stats::erlangCDF(a, b) returns a procedure representing the cumulative distribution function

$$X \rightarrow \begin{cases} \frac{b^a}{\Gamma(a)} \int_0^x t^{a-1} e^{-t b} dt & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases}$$

of the Erlang distribution with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure `f := stats::erlangCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x \geq 0$  can be decided, then

`f(x)` returns the value  $1 - \frac{\Gamma(a, x b)}{\Gamma(a)}$ .

If  $x$  is a floating-point number and both  $a$  and  $b$  can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x \leq 0$  or  $x \geq 0$ , the corresponding values are returned.

The call `f(-infinity)` returns 0.

The call `f(infinity)` returns 1.

`f(x)` returns the symbolic call `stats::erlangCDF(a, b)(x)` if neither  $x \leq 0$  nor  $x \geq 0$  can be decided.

Numerical values for  $a$  and  $b$  are only accepted if they are real and positive.

Note that, for large  $a$ , exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments  $x$  to `f` rather than to compute exact results `f(x)` and convert them via `float`. Cf. “Example 4” on page 29-148.

Note that  $\text{stats::erlangCDF}(a, b) = \text{stats::gammaCDF}\left(a, \frac{1}{b}\right)$ .

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. The procedure generated by `stats::erlangCDF` reacts to properties of identifiers set via `assume`.

## Examples

### Example 1

We evaluate the cumulative probability function with  $a = 2$  and  $b = 1$  at various points:

```
f := stats::erlangCDF(2, 1):
f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)
```

```
0, 0, 0.09020401043, 1 - $\frac{5 e^{-\frac{2}{3}}}{3}$, 1 - e-π (π + 1), 1
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \geq 0$  holds. A symbolic function call is returned:

```
f := stats::erlangCDF(a, b): f(x)
```

```
stats::erlangCDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x \geq 0$  holds. An explicit expression is returned:

# stats::erlangCDF

---

```
assume(0 <= x): f(x)
```

$$1 - \frac{\Gamma(a, b x)}{\Gamma(a)}$$

```
unassume(x): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::erlangCDF(a, b): f(3), f(3.0)
```

$$1 - \frac{\Gamma(a, 3 b)}{\Gamma(a)}, 1.0 - \frac{1.0 \Gamma(a, 3.0 b)}{\Gamma(a)}$$

When numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 2: b := 4: f(3), f(3.0)
```

$$1 - 13 e^{-12}, 0.9999201252$$

```
delete f, a, b:
```

### Example 4

We consider an Erlang distribution with large shape parameter:

```
f := stats::erlangCDF(2000, 2):
```

For floating-point approximations, one should not compute an exact result and convert it via `float`. For large shape parameter, it is faster to pass a floating-point argument to `f`. The following call takes some time,

because an exact computation of the huge integer  $\Gamma(2000) = 1999!$  is involved:

```
float(f(1010))
```

```
0.6747900654
```

The following call is much faster:

```
f(float(1010))
```

```
0.6747900654
```

```
delete f:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

[gamma](#) | [igamma](#) | [stats::erlangPDF](#) | [stats::erlangQuantile](#) | [stats::erlangRandom](#) | [stats::gammaCDF](#) | [stats::gammaPDF](#) | [stats::gammaQuantile](#) | [stats::gammaRandom](#)

# stats::erlangPDF

---

**Purpose** Probability density function of the Erlang distribution

**Syntax** stats::erlangPDF(a, b)

**Description** stats::erlangPDF(a, b) returns a procedure representing the probability density function

$$X \rightarrow \begin{cases} \frac{b^a}{\Gamma(a)} X^{a-1} e^{-Xb} & \text{if } X > 0 \\ 0 & \text{if } X \leq 0 \end{cases}$$

of the Erlang distribution with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure `f := stats::erlangPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x > 0$  can be decided, then

`f(x)` returns the value  $\frac{x^{a-1} b^a}{\Gamma(a) \exp b x}$ .

If  $x$  is a floating-point number and both  $a$  and  $b$  can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x \leq 0$  or  $x > 0$ , the corresponding values are returned.

`f(-infinity)` and `f(infinity)` return 0.

`f(x)` returns the symbolic call `stats::erlangPDF(a, b)(x)` if neither  $x \leq 0$  nor  $x > 0$  can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

Note that, for large  $a$ , exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments `x` to `f` rather than to compute exact results `f(x)` and convert them via `float`. Cf. “Example 4” on page 29-152.

Note that  $\text{stats::erlangPDF}(a, b) = \text{stats::gammaPDF}\left(a, \frac{1}{b}\right)$ .

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. The procedure generated by `stats::erlangPDF` reacts to properties of identifiers set via `assume`.

## Examples

### Example 1

We evaluate the probability density function with  $a = 2$  and  $b = 1$  at various points:

```
f := stats::erlangPDF(2, 1):
f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)
```

```
0, 0, $\frac{e^{-\frac{1}{2}}}{2}$, 0.3032653299, $\pi e^{-\pi}$, 0
```

```
delete f:
```

### Example 2

If `x` is a symbolic object without properties, then it cannot be decided whether  $x > 0$  holds. A symbolic function call is returned:

```
f := stats::erlangPDF(a, b): f(x)
```

```
stats::erlangPDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x > 0$  holds. An explicit expression is returned:

```
assume(0 < x): f(x)
```

$$\frac{b^a x^{a-1} e^{-bx}}{\Gamma(a)}$$

```
unassume(x): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::erlangPDF(a, b): f(x), f(3)
```

$$\text{stats::erlangPDF}(a, b)(x), \frac{3^{a-1} b^a e^{-3b}}{\Gamma(a)}$$

When numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 2: b := 1: f(3), f(3.0)
```

$$3 e^{-3}, 0.1493612051$$

```
delete f, a, b:
```

### Example 4

We consider an Erlang distribution with large shape parameter:

```
f := stats::erlangPDF(2000, 1):
```

For floating-point approximations, one should not compute an exact result and convert it via `float`. For large shape parameter, it is faster to pass a floating-point argument to `f`. The following call takes some time, because an exact computation of the huge integer  $\Gamma(2000) = 1999!$  is involved:

```
float(f(2010))
```

```
0.008657442277
```

The following call is much faster:

```
f(float(2010))
```

```
0.008657442277
```

```
delete f:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

# stats::erlangPDF

## MuPAD Functions

`gamma` | `stats::erlangCDF` | `stats::erlangQuantile` |  
`stats::erlangRandom` | `stats::gammaCDF` | `stats::gammaPDF` |  
`stats::gammaQuantile` | `stats::gammaRandom`

**Purpose** Quantile function of the Erlang distribution

**Syntax** stats::erlangQuantile(a, b)

**Description** stats::erlangQuantile(a, b) returns a procedure representing the quantile function (inverse) of the cumulative distribution function stats::erlangCDF(a, b). For  $0 \leq x \leq 1$ , the solution of stats::erlangCDF(a, b)(y) = x is given by

$$y = \text{stats::erlangQuantile}(a, b)(x)$$

The procedure `f := stats::erlangQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, *infinity*, or a symbolic expression:

If `x` is a real number between 0 and 1 and `a` and `b` can be converted to positive floating-point numbers, then `f(x)` returns a positive floating-point number approximating the solution `y` of stats::erlangCDF(a, b)(y) = x.

The calls `f(0)` and `f(0.0)` produce 0.0 for all values of `a` and `b`.

The calls `f(1)` and `f(1.0)` produce *infinity* for all values of `a` and `b`.

In all other cases, `f(x)` returns the symbolic call stats::erlangQuantile(a, b)(x).

Numerical values of `x` are only accepted if  $0 \leq x \leq 1$ .

Numerical values of `a` and `b` are only accepted if they are real and positive.

Note that

$$\text{stats::erlangQuantile}(a, b) = \text{stats::gammaQuantile}\left(a, \frac{1}{b}\right).$$

**Environment Interactions** The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

# stats::erlangQuantile

---

## Examples

### Example 1

We evaluate the quantile function with  $a = \pi$  and  $b = 11$  at various points:

```
f := stats::erlangQuantile(PI, 1/11):
f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)
```

```
0.0, 13.08489993, 30.96813726, 324.7230043, ∞
```

The value  $f(x)$  satisfies  $\text{stats::erlangCDF}(\pi, 1/11)(f(x)) = x$ :

```
stats::erlangCDF(PI, 1/11)(f(0.987654))
```

```
0.987654
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::erlangQuantile(a, b): f(x), f(9/10)
```

```
stats::erlangQuantile(a, b)(x), stats::erlangQuantile(a, b)($\frac{9}{10}$)
```

When positive real values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce floating-point values:

```
a := 17: b := 1/6: f(0.999), f(1 - sqrt(2)/10^5)
```

```
195.7416524, 240.0294477
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

```
100.0071221
```

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f, a, b:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## MuPAD Functions

stats::erlangCDF | stats::erlangPDF | stats::erlangRandom |  
stats::gammaCDF | stats::gammaPDF | stats::gammaQuantile |  
stats::gammaRandom

# stats::erlangRandom

---

**Purpose** Generate a random number generator for Erlang deviates

**Syntax** stats::erlangRandom(a, b, <Seed = n>)

**Description** stats::erlangRandom(a, b) returns a procedure that produces Erlang deviates (random numbers) with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure  $f := \text{stats::erlangRandom}(a, b)$  can be called in the form  $f()$ . The return value of  $f()$  is either a floating-point number or a symbolic expression:

If  $a$  and  $b$  can be converted to positive floating-point numbers, then  $f()$  returns a nonnegative floating-point number.

In all other cases,  $\text{stats::erlangRandom}(a, b)()$  is returned symbolically.

Numerical values of  $a$  and  $b$  are only accepted if they are real and positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the Erlang distribution with parameters  $a$  and  $b$ . For any  $0 \leq x$ , the probability that  $X \leq x$  is given by

$$\frac{b^a}{\Gamma(a)} \int_0^x t^{a-1} e^{-t b} dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::erlangRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::erlangRandom(a, b): f() $k = 1..K;
```

rather than by

```
stats::erlangRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::erlangRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Note that `stats::erlangRandom(a, b) = stats::gammaRandom(a, 1/b)`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We generate Erlang deviates with parameters  $a = 2$  and  $b = \frac{3}{4}$ :

```
f := stats::erlangRandom(2, 3/4): f() $ k = 1..4
```

```
3.958784095, 3.891811185, 6.046842446, 3.142485711
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::erlangRandom(a, b): f()
```

# stats::erlangRandom

---

```
stats::erlangRandom(a, b)()
```

When positive real numbers are assigned to `a` and `b`, the function `f` starts to produce random floating point numbers:

```
a := PI: b := 1/8: f() $ k = 1..4
```

```
19.74371462, 12.37357049, 13.40137346, 29.97534861
```

```
delete f, a, b:
```

### Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:

```
f := stats::erlangRandom(PI, 3, Seed = 1): f() $ k = 1..4
```

```
0.125771079, 1.179788536, 0.7213738523, 1.268143263
```

```
g := stats::erlangRandom(PI, 3, Seed = 1): g() $ k = 1..4
```

```
0.125771079, 1.179788536, 0.7213738523, 1.268143263
```

```
f() = g(), f() = g()
```

```
1.926015116 = 1.926015116, 1.1178812 = 1.1178812
```

```
delete f, g:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Options

**Seed**

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## MuPAD Functions

`stats::erlangCDF` | `stats::erlangPDF` | `stats::erlangQuantile`  
| `stats::gammaCDF` | `stats::gammaPDF` | `stats::gammaQuantile`  
| `stats::gammaRandom`

# stats::exponentialCDF

---

**Purpose** Cumulative distribution function of the exponential distribution

**Syntax** `stats::exponentialCDF(a, b)`

**Description** `stats::exponentialCDF(a, b)` returns a procedure representing the cumulative distribution function

$$x \rightarrow \begin{cases} 1 - e^{-b(x-a)} & \text{if } x > a \\ 0 & \text{if } x \leq a \end{cases}$$

of the exponential distribution with real location parameter  $a$  and scale parameter  $b > 0$ .

The procedure `f := stats::exponentialCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq a$  can be decided, then `f(x)` returns 0. If  $x > a$  can be decided, then `f(x)` returns the value  $1 - e^{-b(x-a)}$ .

If  $x$  is a floating-point number and both  $a$  and  $b$  can be converted to floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x \leq a$  or  $x > a$ , the corresponding values are returned.

`f(x)` returns the symbolic call `stats::exponentialCDF(a, b)(x)` if neither  $x \leq a$  nor  $x > a$  can be decided.

Numerical values for  $a$  and  $b$  are only accepted if they are real and  $b$  is positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the cumulative distribution function with  $a = 0$  and  $b = 1$  at various points:

```
f := stats::exponentialCDF(0, 1):
f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)
```

```
0, 0, 1 - e-1/2, 0.3934693403, 1 - e-π, 1
```

```
delete f:
```

### Example 2

If  $a$  or  $x$  are symbolic objects without properties, then it cannot be decided whether  $x \geq a$  holds. A symbolic function call is returned:

```
f := stats::exponentialCDF(a, b): f(x)
```

```
stats::exponentialCDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x \geq a$  holds. An explicit expression is returned:

```
assume(a <= x): f(x)
```

```
1 - eb(a-x)
```

Note that `assume(a <= x)` attached properties both to  $a$  and  $x$ . When cleaning up, the properties have to be removed separately for  $a$  and  $x$  via `unassume`:

```
unassume(a): unassume(x): delete f:
```

# stats::exponentialCDF

---

## Example 3

We use symbolic arguments:

```
f := stats::exponentialCDF(a, b): f(x)
```

```
stats::exponentialCDF(a, b)(x)
```

When numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 0: b := 2: f(3), f(3.0)
```

```
1 - e-6, 0.9975212478
```

```
delete f, a, b:
```

## Parameters

**a**

The location parameter: an arithmetical expression representing a real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## MuPAD Functions

[exp](#) | [stats::exponentialPDF](#) | [stats::exponentialQuantile](#) | [stats::exponentialRandom](#)

<b>Purpose</b>	Probability density function of the exponential distribution
<b>Syntax</b>	<code>stats::exponentialPDF(a, b)</code>
<b>Description</b>	<code>stats::exponentialPDF(a, b)</code> returns a procedure representing the probability density function

$$x \rightarrow \begin{cases} b e^{-b(x-a)} & \text{if } x \geq a \\ 0 & \text{if } x < a \end{cases}$$

of the exponential distribution with real location parameter  $a$  and scale parameter  $b > 0$ .

The procedure `f := stats::exponentialPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x < a$  can be decided, then `f(x)` returns 0. If  $x \geq a$  can be decided, then `f(x)` returns the value  $b e^{b(a-x)}$ .

If  $x$  is a floating-point number and both  $a$  and  $b$  can be converted to floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x < a$  or  $x \geq a$ , the corresponding values are returned.

`f(x)` returns the symbolic call `stats::exponentialPDF(a, b)(x)` if neither  $x < a$  nor  $x \geq a$  can be decided.

Numerical values for  $a$  and  $b$  are only accepted if they are real and  $b$  is positive.

<b>Environment Interactions</b>	The function is sensitive to the environment variable <code>DIGITS</code> which determines the numerical working precision.

# stats::exponentialPDF

---

## Examples

### Example 1

We evaluate the probability density function with  $a = 0$  and  $b = 1$  at various points:

```
f := stats::exponentialPDF(0, 1):
f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)
```

```
0, 0, $e^{-\frac{1}{2}}$, 0.6065306597, $e^{-\pi}$, 0
```

```
delete f:
```

### Example 2

If  $a$  or  $x$  are symbolic objects without properties, then it cannot be decided whether  $x \geq a$  holds. A symbolic function call is returned:

```
f := stats::exponentialPDF(a, b): f(x)
```

```
stats::exponentialPDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x \geq a$  holds. An explicit expression is returned:

```
assume(a <= x): f(x)
```

```
 $b e^{b(a-x)}$
```

Note that `assume(a <= x)` attached properties both to  $a$  and  $x$ . When cleaning up, the properties have to be removed separately for  $a$  and  $x$  via `unassume`:

```
unassume(a): unassume(x): delete f:
```

## Example 3

We use symbolic arguments:

```
f := stats::exponentialPDF(a, b): f(x)
```

```
stats::exponentialPDF(a, b)(x)
```

When numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 0: b := 2: f(3), f(3.0)
```

```
2 e-6, 0.004957504353
```

```
delete f, a, b:
```

## Parameters

**a**

The location parameter: an arithmetical expression representing a real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## MuPAD Functions

stats::exponentialCDF | stats::exponentialQuantile |  
stats::exponentialRandom

# stats::exponentialQuantile

---

**Purpose** Quantile function of the exponential distribution

**Syntax** `stats::exponentialQuantile(a, b)`

**Description** `stats::exponentialQuantile(a, b)` returns a procedure representing the quantile function (inverse)

$$x \rightarrow a - \frac{\ln(1 - x)}{b}$$

of the cumulative distribution function `stats::exponentialCDF(a, b)`. For  $0 \leq x \leq 1$ , the solution of `stats::exponentialCDF(a, b)(y) = x` is given by

$$y = \text{stats::exponentialQuantile}(a, b)(x)$$

The procedure `f := stats::exponentialQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, `infinity`, or a symbolic expression:

If `x` is a real floating-point number between 0 and 1 and `a` and `b` can be converted to suitable real floating-point numbers, then `f(x)` returns a floating-point number.

The calls `f(1)` and `f(1.0)` produce *infinity*.

In all other cases, `f(x)` returns the symbolic expression  $a - \ln(1 - x) / b$ .

Numerical values of `x` are only accepted if  $0 \leq x \leq 1$ .

Numerical values of `a` and `b` are only accepted if they are real and `b` is positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with  $a = 2$  and  $b = 3$  at various points:

```
f := stats::exponentialQuantile(2, 3):
f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)
```

$$2, 2 - \frac{\ln(\frac{9}{10})}{3}, 2.23104906, \frac{\ln(10000000000)}{3} + 2, \infty$$

The value  $f(x)$  satisfies  $\text{stats::exponentialCDF}(2, 3)(f(x)) = x$ :

```
stats::exponentialCDF(2, 3)(f(0.987654))
```

```
0.987654
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::exponentialQuantile(a, b): f(x), f(1/3), f(0.4)
```

$$a - \frac{\ln(1 - x)}{b}, a - \frac{\ln(\frac{2}{3})}{b}, a + \frac{0.5108256238}{b}$$

When suitable numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 7: b := 1/8: f(0.999), f(999/1000)
```

```
62.26204223, 8 ln(1000) + 7
```

# stats::exponentialQuantile

---

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

```
12.54517744
```

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f, a, b:
```

## Parameters

**a**

The location parameter: an arithmetical expression representing a real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::exponentialCDF | stats::exponentialPDF |  
stats::exponentialRandom

## Purpose

Generate a random number generator for exponential deviates

## Syntax

`stats::exponentialRandom(a, b, <Seed = n>)`

## Description

`stats::exponentialRandom(a, b)` returns a procedure that produces exponential deviates (random numbers) with real location parameter  $a$  and scale parameter  $b > 0$ .

The procedure `f := stats::exponentialRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If  $a$  can be converted to a real floating point number and  $b$  to a positive floating-point number, then `f()` returns nonnegative floating-point number.

In all other cases, `stats::exponentialRandom(a, b)()` is returned symbolically.

Numerical values of  $a$  and  $b$  are only accepted if they are real and  $b$  is positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the exponential distribution with parameters  $a$  and  $b$ . For real  $x \geq a$ , the probability that  $X \leq x$  is given by

$$1 - \frac{1}{e^{\frac{b}{-a+x}}}$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

# stats::exponentialRandom

---

---

**Note** In contrast to the function `random`, the generators produced by `stats::exponentialRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::exponentialRandom(a, b): f() $k = 1..K;
```

rather than by

```
stats::exponentialRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::exponentialRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We generate exponential deviates with parameters  $a = 2$  and  $b = \frac{3}{4}$ :

```
f := stats::exponentialRandom(2, 3/4): f() $ k = 1..4
```

```
3.744010213, 2.246774327, 4.501726533, 2.006934293
```

```
delete f:
```

## Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::exponentialRandom(a, b): f()
```

```
stats::exponentialRandom(a, b)()
```

When  $a$  and  $b$  evaluate to suitable real numbers,  $f$  starts to produce random floating-point numbers:

```
a := PI: b := 1/8: f() $ k = 1..4
```

```
13.72746104, 16.8526844, 9.492707582, 6.241235276
```

```
delete f, a, b:
```

## Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:

```
f := stats::exponentialRandom(PI, 1/2, Seed = 1): f() $ k = 1..4
```

```
4.275085081, 3.608946643, 7.462091361, 6.63997707
```

```
g := stats::exponentialRandom(PI, 1/2, Seed = 1): g() $ k = 1..4
```

```
4.275085081, 3.608946643, 7.462091361, 6.63997707
```

```
f() = g(), f() = g()
```

# stats::exponentialRandom

---

```
3.504644667 = 3.504644667, 14.68155806 = 14.68155806
```

```
delete f, g:
```

## Parameters

**a**

The location parameter: an arithmetical expression representing a real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Options

**Seed**

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to suitable floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of the exponential deviates uses the quantile function of the exponential distribution applied to uniformly distributed random numbers between 0 and 1.

## See Also

### MuPAD Functions

`stats::exponentialCDF` | `stats::exponentialPDF` |  
`stats::exponentialQuantile`

# stats::fCDF

---

**Purpose** Cumulative distribution function of Fisher's f-distribution (fratio distribution)

**Syntax** stats::fCDF(a, b)

**Description** stats::fCDF(a, b) returns a procedure representing the cumulative distribution function

$$X \rightarrow \begin{cases} \frac{\left(\frac{a}{b}\right)^{a/2}}{\beta\left(\frac{a}{2}, \frac{b}{2}\right)} \int_0^x \frac{t^{\frac{a}{2}-1}}{\left(\frac{a}{b}t + 1\right)^{\frac{a}{2} + \frac{b}{2}}} dt & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases}$$

of Fisher's f-distribution with shape parameters  $a > 0$ ,  $b > 0$ .

The procedure `f:=stats::fCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `x` can be converted to a real floating point number and the shape parameters can be converted to positive floating-point numbers, then `f(x)` returns a floating point number between 0.0 and 1.0.

For all values of `a` and `b`, the call `f(x)` returns 0.0 if `x` is a nonpositive numerical value or a symbolic expression with the property `x ≤ 0`.

The call `f(- infinity )` returns 0.0.

The call `f( infinity )` returns 1.0.

In all other cases, `f(x)` returns the symbolic call `stats::fCDF(a, b)(x)`.

Numerical values for `a` and `b` are only accepted if they are real and positive.

**Environment Interactions**

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. It reacts to properties of identifiers set via `assume`.

**Examples****Example 1**

We evaluate the cumulative distribution function with  $a = 2$  and  $b = 1$  at various points:

```
f := stats::fCDF(2, 1):
f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)
```

```
0.0, 0.0, 0.2928932188, 0.3453463293, 0.629456397, 1.0
```

```
delete f:
```

**Example 2**

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \leq 0$  holds. A symbolic function call is returned:

```
f := stats::fCDF(a, b): f(x)
```

```
stats::fCDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x \leq 0$  holds. The value 0.0 is returned:

```
assume(x <= 0): f(x)
```

```
0.0
```

MuPAD does not provide a special function to represent the cumulative distribution function for positive arguments. A symbolic call is returned:

# stats::fCDF

---

```
assume(x > 0): f(x)
```

```
stats::fCDF(a, b)(x)
```

```
unassume(x): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::fCDF(a, b): f(x), f(2)
```

```
stats::fCDF(a, b)(x), stats::fCDF(a, b)(2)
```

When numerical values are assigned to `a` and `b`, the function `f` starts to produce floating-point numbers for numerical arguments:

```
a := 2: b := 1: f(2)
```

```
0.5527864045
```

```
delete f, a, b:
```

### Parameters

**a, b**

The shape parameters: arithmetical expressions representing positive real values

### Return Values

procedure.

**See Also**

**MuPAD  
Functions**

`stats::fPDF` | `stats::fQuantile` | `stats::fRandom`

**Purpose** Probability density function of Fisher's f-distribution (fratio distribution)

**Syntax** stats::fPDF(a, b)

**Description** stats::fPDF(a, b) returns a procedure representing the probability density function

$$X \rightarrow \begin{cases} \frac{\left(\frac{a}{b}\right)^{a/2} x^{\frac{a}{2}-1}}{\beta\left(\frac{a}{2}, \frac{b}{2}\right)} & \text{if } X > 0 \\ \left(\frac{a x}{b} + 1\right)^{\frac{a}{2} + \frac{b}{2}} & \\ 0 & \text{if } X \leq 0 \end{cases}$$

of Fisher's f-distribution with shape parameters  $a > 0$ ,  $b > 0$ .

The procedure `f:=stats::fPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x > 0$  can be decided, then `f(x)` returns the value

$$\frac{\left(\frac{a}{b}\right)^{a/2} X^{\frac{a}{2}-1}}{\beta\left(\frac{a}{2}, \frac{b}{2}\right) \left(\frac{a x}{b} + 1\right)^{\frac{a}{2} + \frac{b}{2}}}$$

If  $x$  is a floating-point number and both  $a$  and  $b$  can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x \leq 0$  or  $x \geq 0$ , the corresponding values are returned.

`f(-infinity)` and `f(infinity)` return 0.

`f(x)` returns the symbolic call `stats::fPDF(a, b)(x)` if neither  $x \leq 0$  nor  $x > 0$  can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. It reacts to properties of identifiers set via `assume`.

## Examples

### Example 1

We evaluate the probability density function with  $a = 2$  and  $b = 4$  at various points:

```
f := stats::fPDF(2, 4):
f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)
```

```
0, 0, 64/125, 0.512, 1/(pi/2 + 1)^3, 0
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \geq 0$  holds. A symbolic function call is returned:

```
f := stats::fPDF(a, b): f(x)
```

```
stats::fPDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x \geq 0$  holds. An explicit expression is returned:

```
assume(0 <= x): f(x)
```

$$\frac{x^{\frac{a}{2}-1} \left(\frac{a}{b}\right)^{a/2}}{\left(\frac{ax}{b} + 1\right)^{\frac{a}{2} + \frac{b}{2}} \beta\left(\frac{a}{2}, \frac{b}{2}\right)}$$

```
unassume(x): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::fPDF(a, b): f(x)
```

```
stats::fPDF(a, b)(x)
```

When numerical values are assigned to a and b, the function f starts to produce numerical values:

```
a := 2: b := 1: f(3), f(3.0)
```

```
 $\frac{\sqrt{7}}{49}, 0.05399492472$
```

```
delete f, a, b:
```

## Parameters **a, b**

The shape parameters: arithmetical expressions representing positive real values

**Return Values**

procedure.

`stats::fCDF` | `stats::fQuantile` | `stats::fRandom`

# stats::fQuantile

---

<b>Purpose</b>	Quantile function of Fisher's f-distribution (fratio distribution)
<b>Syntax</b>	<code>stats::fQuantile(a, b)</code>
<b>Description</b>	<p><code>stats::fQuantile(a, b)</code> returns a procedure representing the quantile function (inverse) of the cumulative distribution function <code>stats::fCDF(a, b)</code>. For <math>0 \leq x \leq 1</math>, the solution of <code>stats::fCDF(a, b)(y) = x</code> is given by <code>y = stats::fQuantile(a, b)(x)</code>.</p> <p>The procedure <code>f:=stats::fQuantile(a, b)</code> can be called in the form <code>f(x)</code> with arithmetical expressions <code>x</code>. The return value of <code>f(x)</code> is either a floating-point number, <i>infinity</i>, or a symbolic expression:</p> <p>If <code>x</code> is a real number between 0 and 1 and <code>a</code> and <code>b</code> can be converted to positive floating-point numbers, then <code>f(x)</code> returns a positive floating-point number approximating the solution <code>y</code> of <code>stats::fCDF(a, b)(y) = x</code>.</p> <p>The calls <code>f(0)</code> and <code>f(0.0)</code> produce 0.0 for all values of <code>a</code> and <code>b</code>.</p> <p>The calls <code>f(1)</code> and <code>f(1.0)</code> produce <i>infinity</i> for all values of <code>a</code> and <code>b</code>.</p> <p>In all other cases, <code>f(x)</code> returns the symbolic call <code>stats::fQuantile(a, b)(x)</code>.</p> <p>Numerical values of <code>x</code> are only accepted if <math>0 \leq x \leq 1</math>.</p> <p>Numerical values of <code>a</code> and <code>b</code> are only accepted if they are real and positive.</p>
<b>Environment Interactions</b>	The function is sensitive to the environment variable <code>DIGITS</code> which determines the numerical working precision. The procedure generated by <code>stats::fQuantile</code> is sensitive to properties of identifiers, which can be set via <code>assume</code> .
<b>Examples</b>	<b>Example 1</b> We evaluate the quantile function with $a = \pi$ and $b = 11$ at various points:

```
f := stats::fQuantile(PI, 11):
f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)

0.0, 0.2017865341, 0.8492236618, 280.937214, ∞
```

The value  $f(x)$  satisfies  $stats::fCDF(\pi, 11)(f(x)) = x$ :

```
stats::fCDF(PI, 11)(f(0.987654321))

0.987654321
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::fQuantile(a, b): f(x), f(9/10)

stats::fQuantile(a, b)(x), stats::fQuantile(a, b)($\frac{9}{10}$)
```

When positive real values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce floating-point values:

```
a := 17: b := 6: f(0.999), f(1 - sqrt(2)/10^5)

17.35343418, 75.00107347
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

# stats::fQuantile

---

```
1.077968248
```

```
f(2)
```

```
Error: An argument x with $0 \leq x \leq 1$ is expected. [f]
```

```
delete f, a, b:
```

## Parameters

**a, b**

The shape parameters: arithmetical expressions representing positive real values

## Return Values

procedure.

## See Also

## MuPAD Functions

[stats::fCDF](#) | [stats::fPDF](#) | [stats::fRandom](#)

**Purpose**

Generate a random number generator for Fisher's f-deviates (fratio deviates)

**Syntax**

stats::fRandom(a, b, <Seed = n>)

**Description**

stats::fRandom(a, b) returns a procedure that produces f-deviates (random numbers) with shape parameters  $a > 0$ ,  $b > 0$ .

The procedure `f:=stats::fRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` and `b` can be converted to positive floating-point numbers, then `f()` returns a positive floating-point number.

In all other cases, `stats::fRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the f-distribution with shape parameters  $a$  and  $b$ . For  $0 \leq x$ , the probability that  $X \leq x$  is given by

$$\frac{\left(\frac{a}{b}\right)^{a/2}}{\beta\left(\frac{a}{2}, \frac{b}{2}\right)} \int_0^x \frac{t^{\frac{a}{2}-1}}{\left(\frac{a}{b}t + 1\right)^{\frac{a}{2} + \frac{b}{2}}} dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

**Note** In contrast to the function `random`, the generators produced by `stats::fRandom` do not react to the environment variable `SEED`.

# stats::fRandom

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::fRandom(a, b): f() $k = 1..K;
```

rather than by

```
stats::fRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::fRandom(a, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate  $f$ -deviates with shape parameters  $a = 2$  and  $b = \frac{3}{4}$ :

```
f := stats::fRandom(2, 3/4): f() $ k = 1..4
```

```
0.06381499229, 4.951243823, 4.433412266, 2.189546079
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::fRandom(a, b): f()
```

```
stats::fRandom(a, b)()
```

When the shape parameters evaluate to positive real numbers, `f` starts to produce random floating-point numbers:

```
a := PI: b := 8: f()
```

```
1.641736211
```

```
delete f, a, b:
```

### Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:

```
f := stats::fRandom(4, 5, Seed = 1): f() $ k = 1..4
```

```
0.002660717454, 1.586532187, 0.6498965358, 0.8953358537
```

```
g := stats::fRandom(4, 5, Seed = 1): g() $ k = 1..4
```

```
0.002660717454, 1.586532187, 0.6498965358, 0.8953358537
```

```
f() = g(), f() = g()
```

```
1.672785971 = 1.672785971, 0.5207718594 = 0.5207718594
```

```
delete f, g:
```

### Parameters

**a, b**

# stats::fRandom

---

The shape parameters: arithmetical expressions representing positive real values

## Options

### Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the shape parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm uses independent gamma deviates `X` and `Y` to produce an `f`-deviate  $\frac{b}{a} \frac{X}{Y}$ . For more information see: D. Knuth, *Seminumerical Algorithms* (1998), Vol. 2, p. 135.

## See Also

## MuPAD Functions

`stats::fCDF` | `stats::fPDF` | `stats::fQuantile`

**Purpose**

Cumulative distribution function of a finite sample space

**Syntax**

```
stats::finiteCDF([x1, x2, ...], [p1, p2, ...])
stats::finiteCDF([x1, p1], [x2, p2], ...)
stats::finiteCDF(s, <c1, c2>)
stats::finiteCDF(s, <[c1, c2]>)
```

**Description**

stats::finiteCDF([x<sub>1</sub>, x<sub>2</sub>, ..., x<sub>n</sub>], [p<sub>1</sub>, p<sub>2</sub>, ..., p<sub>n</sub>]) returns a procedure representing the cumulative distribution function

$x \rightarrow \sum_{i=1}^k p_i$  of the finite sample space consisting of the data elements  $x_1, \dots, x_n$  with the probabilities  $p_1, \dots, p_n$ . Here,  $k = |\{j \mid x_j \leq x\}|$ , i.e.,  $x_k$  is the largest element of the data sample less or equal to  $x$  (the data elements are assumed to be ordered:  $x_1 < x_2 < x_3$  etc.)

The procedure `f := stats::finiteCDF([x1, x2, ...], [p1, p2, ...])` can be called in the form `f(x)` with an arithmetical expression  $x$ .

If  $x$  is a numerical value and the data elements  $x_1, x_2, \dots$  are all numerical, then `f(x)` returns an arithmetical expression (the sum of the probabilities of all data elements smaller or equal to  $x$ ).

The call `f(-infinity)` produces 0; the call `f(infinity)` produces 1.

Otherwise, if  $x$  is a symbolic expression that cannot be converted to a real floating-point number or if the data  $x_1, x_2, \dots$  contain elements that cannot be converted to real floating-point numbers, then `f(x)` returns the symbolic call `stats::finiteCDF([x1, x2, ...], [p1, p2, ...])(x)` with the data  $x_1, x_2, \dots$  in ascending order.

If all probability values  $p_1, p_2, \dots$  are numerical, they must add up to 1. Otherwise, an error is raised.

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values. Cf. “Example 5” on page 29-195.

The data elements  $x_1, x_2, \dots$  are assumed to be in ascending order:  $x_1 < x_2 < \dots$ . If all data elements are numerical, they are re-ordered

# stats::finiteCDF

---

automatically, if they are not ascending. If the data contain symbolic elements that cannot be converted to floating-point numbers, the ordering is assumed implicitly.

`stats::finiteCDF` generalizes `stats::empiricalCDF`, which assumes equiprobable data. For numerical data  $x_1, x_2, \dots, x_n$ , the call `stats::finiteCDF([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalCDF([x_1, , x_n])`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. Note, however, that this function is implemented with option `remember`. After the first call it does not react to changes of `DIGITS` unless the input parameters are changed.

## Examples

### Example 1

We evaluate the finite distribution function of some numerical data at various points:

```
f := stats::finiteCDF([1, 0, 2.3, PI], [p1, p0, 0.2, 0.3]):
f(-infinity), f(0.1), f(2.3), f(PI), f(10), f(infinity)
```

```
0, p0, p0 + p1 + 0.2, p0 + p1 + 0.5, p0 + p1 + 0.5, 1
```

Alternatively, the data may be passed as a list:

```
f := stats::finiteCDF([[1, p1], [0, p0], [2.3, 0.2], [PI, 0.3]]):
f(-infinity), f(0.1), f(2.3), f(PI), f(10), f(infinity)
```

```
0, p0, p0 + p1 + 0.2, p0 + p1 + 0.5, p0 + p1 + 0.5, 1
```

```
delete f:
```

**Example 2**

We use symbolic arguments. In the symbolic return value, the input data appear as a sorted list:

```
stats::finiteCDF([3, 4, PI], [0.2, 0.5, 0.3])(x)
```

```
stats::finiteCDF([3, π , 4], [0.2, 0.3, 0.5])(x)
```

If the data contain symbolic elements, the return value is again a symbolic call:

```
stats::finiteCDF([3, x, PI], [0.2, 0.5, 0.3])(0.7)
```

```
stats::finiteCDF([3, x, π], [0.2, 0.5, 0.3])(0.7)
```

**Example 3**

We create a sample consisting of one string column and two non-string columns:

```
s := stats::sample(
 [["1996", 1242, 2/5],
 ["1997", 1353, 0.1],
 ["1998", 1142, 0.2],
 ["1999", 1201, 0.2],
 ["2001", 1201, 0.1]])
```

```
"1996" 1242 2/5
"1997" 1353 0.1
"1998" 1142 0.2
"1999" 1201 0.2
"2001" 1201 0.1
```

## stats::finiteCDF

---

We compute values of the finite distributions of the data in the second and third column:

```
f := stats::finiteCDF(s, 2, 3):
f(1000), f(1200), f(1201)
```

```
0, 0.2, 0.5
```

```
delete s, f:
```

### Example 4

If numerical probability values are given, they must add up to 1:

```
f := stats::finiteCDF([Head, TAIL], [0.45, 0.54]):
```

```
Error: The probabilities do not add up to one. [stats::finiteCDF]
```

Symbolic probability values are not checked for consistency:

```
f := stats::finiteCDF([Head, TAIL], [0.45, p]):
f(x)
```

```
stats::finiteCDF([Head, TAIL], [0.45, p])(x)
```

However, when the probabilities are set to numerical values, they are checked:

```
p:= 0.7: f(x)
```

```
Error: The probabilities do not add up to one. [f]
```

```
delete f, p:
```

### Example 5

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values:

```
f:= stats::finiteCDF([x1, x2, x1, x2], [0.1, 0.2, 0.3, 0.4]):
f(3)
```

```
stats::finiteCDF([x1, x2], [0.4, 0.6])(3)
```

```
x1 := 1: x2 := 3: f(2)
```

```
0.4
```

```
delete f, x1, x2:
```

## Parameters

$x_1, x_2, \dots$

The statistical data: arbitrary MuPAD objects

$p_1, p_2, \dots$

Probability values: arithmetical expressions

$s$

A sample of domain type `stats::sample`

$c_1, c_2$

Column indices of the sample  $s$ : positive integers. Column  $c_1$  provides the data  $x_1, x_2$  etc. Column  $c_2$  provides the data  $p_1, p_2$  etc. There is no need to specify column numbers if the sample has only two columns.

# stats::finiteCDF

## MuPAD Functions

stats::empiricalCDF | stats::empiricalPF |  
stats::empiricalQuantile | stats::empiricalRandom  
| stats::finitePF | stats::finiteQuantile |  
stats::finiteRandom

**Purpose** Probability function of a finite sample space

**Syntax**

```
stats::finitePF([x1, x2,], [p1, p2,])
stats::finitePF([[x1, p1], [x2, p2],])
stats::finitePF(n, <c1, c2>)
stats::finitePF(n, <[c1, c2]>)
```

**Description** stats::finitePF([x<sub>1</sub>, x<sub>2</sub>, , x<sub>n</sub>], [p<sub>1</sub>, p<sub>2</sub>, , p<sub>n</sub>]) returns a procedure representing the probability function

$$x \rightarrow \begin{cases} p_i & \text{if } x = x_i \\ 0 & \text{otherwise} \end{cases}$$

of the sample space given by the data x<sub>1</sub>, x<sub>2</sub>, , with the probabilities p<sub>1</sub>, p<sub>2</sub>, .

The procedure `f := stats::finitePF([x1, x2, ], [p1, p2, ])` can be called in the form `f(x)` with an arithmetical expression `x` or sets of lists of such expressions.

If `x` is an expression that is contained in the data x<sub>1</sub>, x<sub>2</sub>, , then the corresponding probability value is returned.

If `x` is an expression that is not contained in the data x<sub>1</sub>, x<sub>2</sub>, , then 0 is returned.

If `x` is a set, the sum of the probability values of its elements is returned.

If `x` is a list, it is treated like a set (i.e., duplicate entries in `x` are eliminated). The sum of the probability values of the elements in `x` is returned.

If all probability values p<sub>1</sub>, p<sub>2</sub>, are numerical, they must add up to 1. Otherwise, an error is raised. Cf. “Example 4” on page 29-199.

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values. Cf. “Example 5” on page 29-200.

`stats::finitePF` generalizes `stats::empiricalPF`, which assumes equiprobable data. For numerical data  $x_1, x_2, \dots$ , the call `stats::finitePF([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalPF([x_1, ..., x_n])`.

## Examples

### Example 1

We demonstrate the basic usage of this function:

```
f := stats::finitePF([1, x, y, PI], [1/4, px, py, 0.25]):
f(0), f(1), f(1.0), f(x), f(y), f(PI), f(float(PI)), f(10)
```

```
0, $\frac{1}{4}$, 0, px, py, 0.25, 0, 0
```

Alternatively, the data may be passed as a list:

```
f := stats::finitePF([[1, 1/4], [x, px], [y, py], [PI, 0.25]]):
f(0), f(1), f(1.0), f(x), f(y), f(PI), f(float(PI)), f(10)
```

```
0, $\frac{1}{4}$, 0, px, py, 0.25, 0, 0
```

```
delete f:
```

### Example 2

We create a sample of type `stats::sample` consisting of one string column and two non-string columns:

```
s := stats::sample(
 ["1996", 1242, 2/5],
 ["1997", 1353, 0.1],
 ["1998", 1142, 0.2],
 ["1999", 1201, 0.2],
 ["2001", 1201, 0.1])
```

```
"1996" 1242 2/5
"1997" 1353 0.1
"1998" 1142 0.2
"1999" 1201 0.2
"2001" 1201 0.1
```

We use the data in the first and third column:

```
f := stats::finitePF(s, 1, 3):
f("1995"), f("1998"), f("2000"), f("2001")

0, 0.2, 0, 0.1
```

```
delete s, f:
```

### Example 3

We consider a loaded die:

```
f:= stats::finitePF([1, 2, 3, 4, 5, 6],
 [0.1, 0.1, 0.1, 0.2, 0.2, 0.3]):
```

What is the probability that tossing the die produces a score more than or equal to 4?

```
f({4, 5, 6})
```

```
0.7
```

```
delete f:
```

### Example 4

The probability values must add up to 1:

# stats::finitePF

---

```
stats::finitePF([Head, TAIL], [0.45, 0.54]):
```

```
Error: The probabilities do not add up to one. [stats::finitePF]
```

## Example 5

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values:

```
f:= stats::finitePF([x1, x2, x1, x2], [0.1, 0.2, 0.3, 0.4]):
f(x1), f(x2)
```

```
0.4, 0.6
```

```
delete f:
```

## Parameters

$x_1, x_2, \dots$

The statistical data: arbitrary MuPAD objects

$p_1, p_2, \dots$

Probability values: arithmetical expressions

$s$

A sample of domain type `stats::sample`

$c_1, c_2$

Column indices of the sample  $s$ : positive integers. Column  $c_1$  provides the data  $x_1, x_2$  etc. Column  $c_2$  provides the data  $p_1, p_2$  etc. There is no need to specify column numbers if the sample has only two columns.

## Return Values

procedure.

`stats::empiricalQuantile` | `stats::empiricalRandom`  
| `stats::finiteCDF` | `stats::finiteQuantile` |  
`stats::finiteRandom`

# stats::finiteQuantile

---

**Purpose** Quantile function of a finite sample space

**Syntax**  
`stats::finiteQuantile([x1, x2, ...], [p1, p2, ...])`  
`stats::finiteQuantile([[x1, p1], [x2, p2], ...])`  
`stats::finiteQuantile(s, <c1, c2>)`  
`stats::finiteQuantile(s, <[c1, c2]>)`

**Description** `stats::finiteQuantile([x1, x2, ..., xn], [p1, p2, ..., pn])` returns a procedure representing the quantile function of the data  $x_1, x_2$  etc. with the probabilities  $p_1, p_2$  etc. It is the (discrete) inverse of the cumulative distribution function `stats::finiteCDF([x1, x2, ...], [p1, p2, ...])`. For  $0 \leq x \leq 1$ , the  $x$ -quantile  $y = \text{stats::finiteQuantile}([x_1, x_2, \dots], [p_1, p_2, \dots])(x)$  is the smallest of the data elements  $x_1, x_2, \dots$  satisfying

$$\text{stats::finiteCDF}([x_1, x_2, \dots], [p_1, p_2, \dots])(y) \geq x$$

(The data elements are assumed to be ordered:  $x_1 < x_2 < x_3$  etc.)

The procedure `f := stats::finiteQuantile([x1, x2, ...], [p1, p2, ...])` can be called in the form `f(x)` with an arithmetical expression  $x$ .

If  $x$  is a real number satisfying  $0 \leq x \leq 1$  and all probability values  $p_1, p_2, \dots$  are numerical, then `f(x)` returns one of the data elements  $x_1, x_2, \dots$ .

Otherwise, if  $x$  is a symbolic expression that cannot be converted to a real floating-point number or if the probabilities  $p_1, p_2, \dots$  contain elements that cannot be converted to real floating-point numbers, then `f(x)` returns the symbolic call `stats::finiteQuantile([x1, x2, ...], [p1, p2, ...])(x)` with the data  $x_1, x_2, \dots$  in ascending order.

Numerical values of  $x$  are only accepted if  $0 \leq x \leq 1$ .

If all probability values  $p_1, p_2, \dots$  are numerical, they must add up to 1. Otherwise, an error is raised.

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values. Cf. “Example 5” on page 29-206.

$y = \text{stats::finiteQuantile}([x_1, x_2, \dots], [p_1, p_2, \dots])(x)$  satisfies

$$\text{stats::finiteCDF}([x_1, x_2, \dots], [p_1, p_2, \dots])(x_i) < x \leq \text{stats::finiteCDF}([x_1, x_2, \dots], [p_1, p_2, \dots])(x_{i+1})$$

for all data elements  $x_i$  in the sample satisfying  $x_i < y$ .

The data elements  $x_1, x_2, \dots$  are assumed to be in ascending order:  $x_1 < x_2 < \dots$ . If all data elements are numerical, they are re-ordered automatically, if they are not ascending. If the data contain symbolic elements that cannot be converted to floating-point numbers, the ordering is assumed implicitly.

`stats::finiteQuantile` generalizes `stats::empiricalQuantile`, which assumes equiprobable data. For numerical data  $x_1, x_2, \dots, x_n$ , the call `stats::finiteQuantile([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalQuantile([x_1, dots, x_n])`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. Note, however, that this function is implemented with `option remember`. After the first call it does not react to changes of `DIGITS` unless the input parameters are changed.

## Examples

### Example 1

We compute various quantiles of some numerical data:

```
f := stats::finiteQuantile([1, x, y, PI], [1/4, 3/8, 1/4, 1/8]):
f(0), f(0.1), f(3/10), f(0.5), f(1/sqrt(2)), f(99/100), f(1)
```

```
1, 1, x, x, y, pi, pi
```

# stats::finiteQuantile

---

Alternatively, the data may be passed as a list:

```
f := stats::finiteQuantile([[1, 1/4], [x, 3/8], [y, 1/4], [PI, 1/8]]
f(0), f(0.1), f(3/10), f(0.5), f(1/sqrt(2)), f(99/100), f(1)
```

```
1, 1, x, x, y, pi, pi
```

```
delete f:
```

## Example 2

We use symbolic arguments. In the symbolic return value, the input data appear as a sorted list:

```
f:= stats::finiteQuantile([3, 4, PI], [0.2, 0.5, 0.3]):
f(x)
```

```
stats::finiteQuantile([3, pi, 4], [0.2, 0.3, 0.5])(x)
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

```
pi
```

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f:
```

## Example 3

We create a sample of type `stats::sample` consisting of one string column and two non-string columns:

```
s := stats::sample(
 [{"1996", 1242, 2/5},
 {"1997", 1353, 0.1},
 {"1998", 1142, 0.2},
 {"1999", 1201, 0.2},
 {"2001", 1201, 0.1}])
```

```
"1996" 1242 2/5
"1997" 1353 0.1
"1998" 1142 0.2
"1999" 1201 0.2
"2001" 1201 0.1
```

We compute quantile values of the data in the second and third column:

```
f := stats::finiteQuantile(s, 2, 3):
f(0.1), f(1/4), f(0.7), f(99/100)
```

```
1142, 1201, 1242, 1353
```

```
delete s, f:
```

## Example 4

If numerical probability values are given, they must add up to 1:

```
f := stats::finiteQuantile([Head, TAIL], [0.45, 0.54]):
```

```
Error: The probabilities do not add up to one. [stats::finiteQua
```

# stats::finiteQuantile

---

Symbolic probability values are not checked for consistency:

```
f := stats::finiteQuantile([Head, TAIL], [0.45, p]):
f(x)
```

```
stats::finiteQuantile([Head, TAIL], [0.45, p])(x)
```

However, when the probabilities are set to numerical values, they are checked:

```
p := 0.7: f(x)
```

```
Error: The probabilities do not add up to one. [f]
```

```
delete f, p:
```

## Example 5

Duplicate data elements are automatically combined to a single data element, adding up the corresponding probability values:

```
f := stats::finiteQuantile([x1, x2, x1, x2], [p1, p2, 0.3, 0.4]):
f(0.5)
```

```
stats::finiteQuantile([x1, x2], [p1 + 0.3, p2 + 0.4])(0.5)
```

```
p1 := 0.1: p2 := 0.2: f(0.5)
```

```
x2
```

delete f, p1, p2:

## Parameters

$x_1, x_2, \dots$

The statistical data: arbitrary MuPAD objects

$p_1, p_2, \dots$

Probability values: arithmetical expressions

$s$

A sample of domain type `stats::sample`

$c_1, c_2$

Column indices of the sample  $s$ : positive integers. Column  $c_1$  provides the data  $x_1, x_2$  etc. Column  $c_2$  provides the data  $p_1, p_2$  etc. There is no need to specify column numbers if the sample has only two columns.

## Return Values

procedure.

## MuPAD Functions

`stats::empiricalCDF` | `stats::empiricalPF` |  
`stats::empiricalQuantile` | `stats::empiricalRandom` |  
`stats::finiteCDF` | `stats::finitePF` | `stats::finiteRandom` |  
`stats::median`

# stats::finiteRandom

---

**Purpose** Generate a random generator for elements of a finite sample space

**Syntax**

```
stats::finiteRandom([x1, x2, ...], [p1, p2, ...], <Seed = n>)
stats::finiteRandom([x1, p1], [x2, p2], ...], <Seed = n>)
stats::finiteRandom(n, <c1, c2>, <Seed = n>)
stats::finiteRandom(n, <[c1, c2]>, <Seed = n>)
```

**Description** stats::finiteRandom([x<sub>1</sub>, x<sub>2</sub>, ..., x<sub>n</sub>], [p<sub>1</sub>, p<sub>2</sub>, ..., p<sub>n</sub>]) returns a procedure that picks out random elements from the data x<sub>1</sub>, x<sub>2</sub> etc. The chances of picking out elements are given by the probabilities p<sub>1</sub>, p<sub>2</sub> etc.

The procedure `f := stats::finiteRandom([x1, x2, ...], [p1, p2, ...])` can be called in the form `f()`. The call `f()` returns one of the data elements x<sub>1</sub>, x<sub>2</sub>, ...

The values  $X = f()$  are distributed randomly according to the discrete distribution function of the sample space, i.e., the probability of  $X \leq x$  is given by `stats::finiteCDF([x1, x2, ...], [p1, p2, ...])(x)`.

All probability values p<sub>1</sub>, p<sub>2</sub>, ... must be convertible to floating-point numbers. They must add up to 1.

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::finiteRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::finiteRandom([x1, x2, ...], [p1, p2, ...]):
```

```
f() $k = 1..K;
```

rather than by

```
stats::finiteRandom([x_1, x_2, dots], [p_1, p_2, dots])()
$k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::finiteRandom([x_1, x_2, dots], [p_1, p_2, dots],
Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

`stats::finiteRandom` generalizes `stats::empiricalRandom`, which assumes equiprobable data. For numerical data  $x_1, x_2, \dots, x_n$ , the call `stats::finiteRandom([x_1, dots, x_n], [1/n, dots, 1/n])` corresponds to `stats::empiricalRandom([x_1, ..., x_n])`.

## Examples

### Example 1

We pick out random elements of some data:

```
f := stats::finiteRandom([1, x, y, PI], [1/4, 3/8, 1/4, 1/8], Seed = 123)
f(), f(), f(), f(), f(), f(), f(), f(), f()
```

```
1, 1, x, y, y, x, x, y, π
```

Alternatively, the data may be passed as a list:

```
f := stats::finiteRandom([[1, 1/4], [x, 3/8], [y, 1/4], [PI, 1/8]], Seed = 123)
f(), f(), f(), f(), f(), f(), f(), f(), f()
```

```
1, 1, x, y, y, x, x, y, π
```

```
delete f:
```

# stats::finiteRandom

---

## Example 2

We create a sample of type `stats::sample` consisting of one string column and two non-string columns:

```
s := stats::sample(
 [{"1996", 1242, 2/5},
 {"1997", 1353, 0.1},
 {"1998", 1142, 0.2},
 {"1999", 1201, 0.2},
 {"2001", 1201, 0.1}])
```

```
"1996" 1242 2/5
"1997" 1353 0.1
"1998" 1142 0.2
"1999" 1201 0.2
"2001" 1201 0.1
```

We pick random values using the data in the first and third column:

```
f := stats::finiteRandom(s, 1, 3, Seed = 123):
f(), f(), f(), f(), f(), f(), f()

"1996", "1998", "1997", "1996", "1998", "1996", "1996"
```

```
delete s, f:
```

## Example 3

We toss a loaded coin:

```
f:= stats::finiteRandom([Head, Tail], [0.4, 0.6], Seed = 123):
f(), f(), f(), f(), f(), f(), f(), f(), f(), f()
```

```
Head, Tail, Tail, Head, Tail, Head, Head, Tail, Head, Tail
```

We toss the coin 10000 times and count the number of Heads and Tails:

```
t := [f() $ k = 1..10^4]:
NumberOfHeads = nops(select(t, _equal, Head)),
NumberOfTails = nops(select(t, _equal, Tail))
```

```
NumberOfHeads = 3975, NumberOfTails = 6025
```

```
delete f, t:
```

## Example 4

The probability values must add up to 1:

```
stats::finiteRandom([Head, TAIL], [0.45, 0.54]):
```

```
Error: The probabilities do not add up to one. [stats::finiteRandom]
```

## Parameters

$x_1, x_2, \dots$

The statistical data: arbitrary MuPAD objects

$p_1, p_2, \dots$

Probability values: real numerical values

$s$

A sample of domain type `stats::sample`

$c_1, c_2$

Column indices of the sample  $s$ : positive integers. Column  $c_1$  provides the data  $x_1, x_2$  etc. Column  $c_2$  provides the data  $p_1, p_2$  etc.

# stats::finiteRandom

---

There is no need to specify column numbers if the sample has only two columns.

## Options

### Seed

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random values. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of values.

## Return Values

procedure.

## Algorithms

The random values are chosen by applying the quantile function to uniformly distributed random numbers between 0 and 1.

| `stats::median`

## Purpose

Tally numerical data into classes and count frequencies

## Syntax

```
stats::frequency(data, <ClassesClosed = Left | Right>)
stats::frequency(data, n, <ClassesClosed = Left | Right>)
stats::frequency(data, [n], <ClassesClosed = Left | Right>)
stats::frequency(data, [a1 .. b1, a2 .. b2,],
<ClassesClosed = Left | Right>)
stats::frequency(data, [[a1, b1], [a2, b2],],
<ClassesClosed = Left | Right>)
stats::frequency(data, Classes = n, <ClassesClosed
= Left | Right>)
stats::frequency(data, Classes = [n], <ClassesClosed
= Left | Right>)
stats::frequency(data, Classes = [a1 .. b1, a2 .. b2,
], <ClassesClosed = Left | Right>)
stats::frequency(data, Classes = [[a1, b1], [a2, b2],
], <ClassesClosed = Left | Right>)
stats::frequency(data, Cells = n, <CellsClosed
= Left | Right>)
stats::frequency(data, Cells = [n], <CellsClosed
= Left | Right>)
stats::frequency(data, Cells = [a1 .. b1, a2 .. b2,
], <CellsClosed = Left | Right>)
stats::frequency(data, Cells = [[a1, b1], [a2, b2],
], <CellsClosed = Left | Right>)
```

## Description

`stats::frequency(data, [[a1, b1], [a2, b2], ])` tallies numerical data into different classes given by semiopen intervals  $(a_i, b_i]$ . It counts how many data elements fall into each class.

All data elements must be real numerical values. Exact numerical values such as  $\pi$ ,  $\sqrt{3}$  etc. are allowed if they can be converted to real floating-point numbers via `float`. An error is raised if symbolic data are found that cannot be converted to real floating point numbers.

## stats::frequency

---

---

**Note** Note that `stats::frequency` is fast if all data elements are integers, rational numbers, or floating point numbers. Exact numerical values such as  $\pi$ ,  $\sqrt{3}$  etc. are processed, but have a noticeable impact on the efficiency of `stats::frequency`.

---

Data given by an array, a table etc. are internally treated like a list containing all operands of the data container. In particular, all rows and columns of arrays, matrices and `stats::sample` objects are taken into account. A `stats::sample` object must not contain any text entries.

For the specification of the classes, `stats::frequency` accepts either a single positive integer (or, equivalently, a list of one positive integer), or a list of classes given as ranges or lists of two elements.

A single integer  $n$  in the specification `Classes= n` or `Classes= [n]` is interpreted as “subdivide the range from  $\min(data)$  to  $\max(data)$  into  $n$  classes of equal size”. The left border of the first class is set to  $-\infty$ .

The classes may be specified directly as in `Classes = [[a1, b1], [a2, b2], ...]` or `Classes=[a_1..b_1, a_2..b_2, dots]`.

---

**Note** With the default setting `ClassesClosed = Right`, the  $i$ -th class is the *semi-open* interval  $(a_i, b_i]$ , i.e., a datum  $x$  is tallied into the  $i$ -th class if  $a_i < x \leq b_i$  is satisfied.

With `ClassesClosed = Left`, the  $i$ -th class is the semi-open interval  $[a_i, b_i)$ , i.e., a datum  $x$  is tallied into the  $i$ -th class if  $a_i \leq x < b_i$  is satisfied.

---

The class boundaries must be numerical real values satisfying  $a_1 \leq b_1 \leq a_2 \leq b_2 \leq a_3 \leq \dots$ . In most applications,  $b_1 = a_2$ ,  $b_2 = a_3$  etc. is appropriate.

Exact values such as  $\pi$ ,  $\sqrt{3}$  etc. are accepted and processed.

The classes need not cover the entire data range. Data are ignored if they do not fall into one of the specified classes.

If giving classes directly, the leftmost border may be  $-\infty$  and the rightmost border may be *infinity*.

## Examples

### Example 1

We split the following data into 10 classes of equal size (default). The first class covers the values from  $-\infty$  to 2:

```
data := [0, 1, 2, PI, 4, 5, 6, 7, 7.1, 20]:
T := stats::frequency(data)
```

1	[[ $-\infty$ , 2], 3, [0, 1, 2]]
2	[[2, 4], 2, [ $\pi$ , 4]]
3	[[4, 6], 2, [5, 6]]
4	[[6, 8], 2, [7, 7.1]]
5	[[8, 10], 0, []]
6	[[10, 12], 0, []]
7	[[12, 14], 0, []]
8	[[14, 16], 0, []]
9	[[16, 18], 0, []]
10	[[18, 20], 1, [20]]

We split the information on the classes into 3 separate tables:

```
TheClasses = map(T, op, 1)
```

## stats::frequency

---

```
1 | [- ∞, 2]
2 | [2, 4]
3 | [4, 6]
4 | [6, 8]
TheClasses = 5 | [8, 10]
6 | [10, 12]
7 | [12, 14]
8 | [14, 16]
9 | [16, 18]
10 | [18, 20]
```

```
TheFrequencies = map(T, op, 2)
```

```
1 | 3
2 | 2
3 | 2
4 | 2
TheFrequencies = 5 | 0
6 | 0
7 | 0
8 | 0
9 | 0
10 | 1
```

```
TheValues = map(T, op, 3)
```

```

 1 | [0, 1, 2]
 2 | [π, 4]
 3 | [5, 6]
 4 | [7, 7.1]
TheValues = 5 | []
 6 | []
 7 | []
 8 | []
 9 | []
 10 | [20]

```

The classes are specified explicitly:

```

classes:= [[0, 5], [5, 10], [10, 20]]:
stats::frequency(data, classes)

```

```

 1 | [[0, 5], 5, [1, 2, π, 4, 5]]
 2 | [[5, 10], 3, [6, 7, 7.1]]
 3 | [[10, 20], 1, [20]]

```

Note that the value 0 is not tallied into any of the classes (the first class represents the semi-open interval  $(0, 5]$ )! In order to include all values, we use  $\pm\infty$  as class boundaries:

```

classes:= [[-infinity, 5], [5, 10], [10, infinity]]:
stats::frequency(data, classes)

```

# stats::frequency

---

```
1 | [[-∞, 5], 6, [0, 1, 2, π, 4, 5]]
2 | [[5, 10], 3, [6, 7, 7.1]]
3 | [[10, ∞], 1, [20]]
```

delete data, T, classes:

## Example 2

We demonstrate the difference between the options `ClassesClosed = Left` and `ClassesClosed = Right`. In the first case, the value 1 is tallied into the second class:

```
stats::frequency([0, 1, 2], Classes = [-infinity..1, 1..infinity],
```

```
1 | [[-∞, 1], 1, [0]]
2 | [[1, ∞], 2, [1, 2]]
```

With `ClassesClosed = Right`, the value 1 is tallied into the first class:

```
stats::frequency([0, 1, 2], Classes = [-infinity..1, 1..infinity],
```

```
1 | [[-∞, 1], 2, [0, 1]]
2 | [[1, ∞], 1, [2]]
```

The default setting is `ClassesClosed = Right`:

```
stats::frequency([0, 1, 2], Classes = [-infinity..1, 1..infinity])
```

```
1 | [[-∞, 1], 2, [0, 1]]
2 | [[1, ∞], 1, [2]]
```

### Example 3

We create a sample of 1000 normally distributed data points:

```
X := stats::normalRandom(0, 10):
data := [X() $ i = 1..1000]:
```

These data are tallied into 5 different classes of equal width:

```
T := stats::frequency(data, 5):
```

We determine the number of data values in each class:

```
for i from 1 to 5 do
 print(Class = T[i][1], NumberOfElements = T[i][2]);
end_for:
```

```
Class = [- ∞, - 5.982260368], NumberOfElements = 23
```

```
Class = [- 5.982260368, - 1.635193057], NumberOfElements = 300
```

```
Class = [- 1.635193057, 2.711874254], NumberOfElements = 485
```

```
Class = [2.711874254, 7.058941565], NumberOfElements = 182
```

```
Class = [7.058941565, 11.40600888], NumberOfElements = 10
```

We determine the outliers of the data sample by collecting the values smaller than - 9 and the values larger than 10:

```
classes := [[-infinity, -9], [10, infinity]]:
T := stats::frequency(data, classes);
```

# stats::frequency

---

```
1 | [[[-∞, -9], 2, [-10.32932768, -9.707360153]]
2 | [[10, ∞], 1, [11.40600888]]
```

delete X, data, T, i, classes:

## Parameters

### data

The statistical data: a list, a set, a table, an array, a matrix, or an object of type `stats::sample` containing numerical real data values

### n

The number of classes (cells): a positive integer. If not specified,  $n = 10$  is used.

### $a_1, b_1, a_2, \dots$

The class boundaries: real numerical values satisfying

$$a_1 \leq b_1 \leq a_2 \leq b_2 \leq \dots$$

Also  $\pm\infty$  are allowed as class boundaries.

## Return Values

table is returned with integer indices from 1 through the number of classes. The  $i$ -th entry of the table  $T = \text{stats::frequency}(\text{data}, \dots)$  is the list  $T[i] = [[a_i, b_i], n_i, [v_1, v_2, \dots]]$ , where  $[a_i, b_i]$  is the  $i$ -th class,  $n_i$  is the number of data falling in this class, and  $[v_1, v_2, \dots]$  is the sorted list of all data in this class (i.e.,  $a_i < v_j \leq b_i$  for all  $j$  from 1 through  $n_i$ ).

## See Also

### MuPAD Functions

`stats::mean` | `stats::stdev`

**MuPAD  
Graphical  
Primitives**

plot::Histogram2d

# stats::gammaCDF

---

**Purpose** Cumulative distribution function of the gamma distribution

**Syntax** stats::gammaCDF(a, b)

**Description** stats::gammaCDF(a, b) returns a procedure representing the cumulative distribution function

$$X \rightarrow \begin{cases} \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases}$$

of the gamma distribution with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure `f:=stats::gammaCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x \geq 0$  can be decided, then

`f(x)` returns the value  $1 - \frac{\Gamma(a, \frac{x}{b})}{\Gamma(a)}$ .

If  $x$  is a floating-point number and both  $a$  and  $b$  can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x \leq 0$  or  $x \geq 0$ , the corresponding values are returned.

The call `f(-infinity)` returns 0.

The call `f(infinity)` returns 1.

`f(x)` returns the symbolic call `stats::gammaCDF(a, b)(x)` if neither  $x \leq 0$  nor  $x \geq 0$  can be decided.

Numerical values for  $a$  and  $b$  are only accepted if they are real and positive.

Note that, for large  $a$ , exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments  $x$  to  $f$  rather than to compute exact results  $f(x)$  and convert them via `float`. Cf. “Example 4” on page 29-224.

Note that  $\text{stats::gammaCDF}(a, b) = \text{stats::erlangCDF}\left(a, \frac{1}{b}\right)$ .

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. The procedure generated by `stats::gammaCDF` reacts to properties of identifiers set via `assume`.

## Examples

### Example 1

We evaluate the cumulative distribution function with  $a = 2$  and  $b = 1$  at various points:

```
f := stats::gammaCDF(2, 1):
f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)
```

```
0, 0, 0.09020401043, 1 - $\frac{5 e^{-\frac{2}{3}}}{3}$, 1 - $e^{-\pi}$ ($\pi + 1$), 1
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \geq 0$  holds. A symbolic function call is returned:

```
f := stats::gammaCDF(a, b): f(x)
```

```
stats::gammaCDF(a, b)(x)
```

# stats::gammaCDF

---

With suitable properties, it can be decided whether  $x \geq 0$  holds. An explicit expression is returned:

```
assume(0 <= x): f(x)
```

$$1 - \frac{\Gamma(a, \frac{x}{b})}{\Gamma(a)}$$

```
unassume(x): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::gammaCDF(a, b): f(x)
```

```
stats::gammaCDF(a, b)(x)
```

When numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 2: b := 4: f(3), f(3.0)
```

$$1 - \frac{7 e^{-\frac{3}{4}}}{4}, 0.1733585327$$

```
delete f, a, b:
```

### Example 4

We consider a gamma distribution with large shape parameter:

```
f := stats::gammaCDF(2000, 2):
```

For floating-point approximations, one should not compute an exact result and convert it via `float`. For large shape parameter, it is faster to pass a floating-point argument to `f`. The following call takes some time, because an exact computation of the huge integer  $\Gamma(2000) = 1999!$  is involved:

```
float(f(4010))
```

```
0.5474266776
```

The following call is much faster:

```
f(float(4010))
```

```
0.5474266776
```

```
delete f:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

# stats::gammaCDF

---

## See Also

## MuPAD Functions

gamma | igamma | stats::erlangCDF | stats::erlangPDF  
| stats::erlangQuantile | stats::erlangRandom |  
stats::gammaPDF | stats::gammaQuantile | stats::gammaRandom

**Purpose**

Probability density function of the gamma distribution

**Syntax**

stats::gammaPDF(a, b)

**Description**

stats::gammaPDF(a, b) returns a procedure representing the probability density function

$$X \rightarrow \begin{cases} \frac{1}{b^a \Gamma(a)} X^{a-1} e^{-X/b} & \text{if } X > 0 \\ 0 & \text{if } X \leq 0 \end{cases}$$

of the gamma distribution with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure `f:=stats::gammaPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x > 0$  can be decided, then

$$f(x) \text{ returns the value } \frac{x^{a-1}}{b^a \Gamma(a)} \exp\left(-\frac{x}{b}\right).$$

If `x` is a floating-point number and both `a` and `b` can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If `x` is a symbolic expression with the property  $x \leq 0$  or  $x \geq 0$ , the corresponding values are returned.

`f(-infinity)` and `f(infinity)` return 0.

`f(x)` returns the symbolic call `stats::gammaPDF(a, b)(x)` if neither  $x \leq 0$  nor  $x > 0$  can be decided.

Numerical values for  $a$  and  $b$  are only accepted if they are real and positive.

Note that, for large  $a$ , exact results may be costly to compute. If floating-point values are desired, it is recommended to pass floating-point arguments  $x$  to  $f$  rather than to compute exact results  $f(x)$  and convert them via `float`. Cf. “Example 4” on page 29-229.

Note that  $\text{stats::gammaPDF}(a, b) = \text{stats::erlangPDF}\left(a, \frac{1}{b}\right)$ .

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. The procedure generated by `stats::gammaPDF` reacts to properties of identifiers set via `assume`.

## Examples

### Example 1

We evaluate the probability density function with  $a = 2$  and  $b = 1$  at various points:

```
f := stats::gammaPDF(2, 1):
f(-infinity), f(-PI), f(1/2), f(0.5), f(PI), f(infinity)
```

```
0, 0, $\frac{e^{-\frac{1}{2}}}{2}$, 0.3032653299, $\pi e^{-\pi}$, 0
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \geq 0$  holds. A symbolic function call is returned:

```
f := stats::gammaPDF(a, b): f(x)
```

```
stats::gammaPDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x \geq 0$  holds. An explicit expression is returned:

```
assume(0 < x): f(x)
```

$$\frac{x^{a-1} e^{-\frac{x}{b}}}{b^a \Gamma(a)}$$

```
unassume(x): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::gammaPDF(a, b): f(x), f(3)
```

$$\text{stats::gammaPDF}(a, b)(x), \frac{3^{a-1} e^{-\frac{3}{b}}}{b^a \Gamma(a)}$$

When numerical values are assigned to a and b, the function f starts to produce numerical results:

```
a := 2: b := 4: f(3), f(3.0)
```

$$\frac{3 e^{-\frac{3}{4}}}{16}, 0.08856872864$$

```
delete a, b, f:
```

### Example 4

We consider a gamma distribution with large shape parameter:

# stats::gammaPDF

---

```
f := stats::gammaPDF(2000, 2):
```

For floating-point approximations, one should not compute an exact result and convert it via `float`. For large shape parameter, it is faster to pass a floating-point argument to `f`. The following call takes some time, because an exact computation of the huge integer  $\Gamma(2000) = 1999!$  is involved:

```
float(f(4050))
```

```
0.00377271215
```

The following call is much faster:

```
f(float(4050))
```

```
0.00377271215
```

```
delete f:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

### MuPAD Functions

`gamma` | `igamma` | `stats::erlangCDF` | `stats::erlangPDF`  
| `stats::erlangQuantile` | `stats::erlangRandom` |  
`stats::gammaCDF` | `stats::gammaQuantile` | `stats::gammaRandom`

# stats::gammaQuantile

---

**Purpose** Quantile function of the gamma distribution

**Syntax** stats::gammaQuantile(a, b)

**Description** stats::gammaQuantile(a, b) returns a procedure representing the quantile function (inverse) of the cumulative distribution function stats::gammaCDF(a, b). For  $0 \leq x \leq 1$ , the solution of stats::gammaCDF(a, b)(y) = x is given by  $y = \text{stats::gammaQuantile}(a, b)(x)$ .

The procedure  $f := \text{stats::gammaQuantile}(a, b)$  can be called in the form  $f(x)$  with arithmetical expressions  $x$ . The return value of  $f(x)$  is either a floating-point number, *infinity*, or a symbolic expression:

If  $x$  is a real number between 0 and 1 and  $a$  and  $b$  can be converted to positive floating-point numbers, then  $f(x)$  returns a positive floating-point number approximating the solution  $y$  of stats::gammaCDF(a, b)(y) = x.

The calls  $f(0)$  and  $f(0.0)$  produce 0.0 for all values of  $a$  and  $b$ .

The calls  $f(1)$  and  $f(1.0)$  produce *infinity* for all values of  $m$ .

In all other cases,  $f(x)$  returns the symbolic call stats::gammaQuantile(a, b)(x).

Numerical values of  $x$  are only accepted if  $0 \leq x \leq 1$ .

Numerical values of  $a$  and  $b$  are only accepted if they are real and positive.

Note that

$$\text{stats::gammaQuantile}(a, b) = \text{stats::erlangQuantile}\left(a, \frac{1}{b}\right).$$

**Environment Interactions** The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with  $a = \pi$  and  $b = 11$  at various points:

```
f := stats::gammaQuantile(PI, 11):
f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)
```

```
0.0, 13.08489993, 30.96813726, 324.7230043, ∞
```

The value  $f(x)$  satisfies  $\text{stats::gammaCDF}(\pi, 11)(f(x)) = x$ :

```
stats::gammaCDF(PI, 11)(f(0.987654))
```

```
0.987654
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::gammaQuantile(a, b): f(x), f(9/10)
```

```
stats::gammaQuantile(a, b)(x), stats::gammaQuantile(a, b)($\frac{9}{10}$)
```

When positive real values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce floating-point values:

```
a := 17: b := 6: f(0.999), f(1 - sqrt(2)/10^5)
```

```
195.7416524, 240.0294477
```

# stats::gammaQuantile

---

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

```
100.0071221
```

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f, a, b:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::erlangCDF | stats::erlangPDF | stats::erlangQuantile  
| stats::erlangRandom | stats::gammaCDF | stats::gammaPDF |  
stats::gammaRandom

**Purpose**

Generate a random number generator for gamma deviates

**Syntax**

stats::gammaRandom(a, b, <Seed = n>)

**Description**

stats::gammaRandom(a, b) returns a procedure that produces gamma deviates (random numbers) with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure  $f := \text{stats::gammaRandom}(a, b)$  can be called in the form  $f()$ . The return value of  $f()$  is either a floating-point number or a symbolic expression:

If  $a$  and  $b$  can be converted to positive floating-point numbers, then  $f()$  returns a nonnegative floating-point number.

In all other cases,  $\text{stats::gammaRandom}(a, b)()$  is returned symbolically.

Numerical values of  $a$  and  $b$  are only accepted if they are real and positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the gamma distribution with parameters  $a$  and  $b$ . For any  $0 \leq x$ , the probability that  $X \leq x$  is given by

$$\frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-b t} dt$$

Without the option `Seed = n`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::gammaRandom` do not react to the environment variable `SEED`.

---

# stats::gammaRandom

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::gammaRandom(a, b): f() $k = 1..K;
```

rather than by

```
stats::gammaRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::gammaRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

Note that

$$\text{stats::gammaRandom}(a, b) = \text{stats::erlangRandom}\left(a, \frac{1}{b}\right).$$

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate gamma deviates with parameters  $a = 2$  and  $b = \frac{4}{3}$ :

```
f := stats::gammaRandom(2, 4/3): f() $ k = 1..4
```

```
3.958784095, 3.891811185, 6.046842446, 3.142485711
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::gammaRandom(a, b): f()
```

```
stats::gammaRandom(a, b)()
```

When  $a$  and  $b$  evaluate to positive real numbers, the result is evaluated to a real floating point number:

```
a := PI: b := 8: f() $ k = 1..4
```

```
19.74371462, 12.37357049, 13.40137346, 29.97534861
```

```
delete f, a, b:
```

### Example 3

We use the option `Seed = n` to reproduce a sequence of random numbers:

```
f := stats::gammaRandom(PI, 1/3, Seed = 10^3): f() $ k = 1..4
```

```
0.3631090007, 0.8803177461, 0.9712460319, 1.740056499
```

```
g := stats::gammaRandom(PI, 1/3, Seed = 10^3): g() $ k = 1..4
```

```
0.3631090007, 0.8803177461, 0.9712460319, 1.740056499
```

```
f() = g(), f() = g()
```

```
1.561212345 = 1.561212345, 0.4650866732 = 0.4650866732
```

```
delete f:
```

# stats::gammaRandom

---

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Options

**Seed**

Option, specified as `Seed = n`

Initializes the random generator with the integer seed `n`. `n` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `n` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of gamma deviates uses a rejection method applied to uniform random numbers. For more information see: D. Knuth, *Seminumerical Algorithms* (1998), Vol. 2, pp. 133.

| `stats::erlangRandom` | `stats::gammaCDF` | `stats::gammaPDF`  
| `stats::gammaQuantile`

# stats::geometricMean

---

**Purpose** Geometric mean of a data sample

**Syntax** `stats::geometricMean(x1, x2, ...)`  
`stats::geometricMean([x1, x2, ...], c)`  
`stats::geometricMean(s, <c>)`

**Description** `stats::geometricMean(x1, x2, ..., xn)` returns the geometric mean  $(X_1 X_2 \dots X_n)^{1/n}$  of the data  $x_i$ .

The column index `c` is optional, if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-241.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We calculate the geometric mean of three values:

```
stats::geometricMean(a, b, c)
```

$$(a b c)^{1/3}$$

Alternatively, the data may be passed as a list:

```
stats::geometricMean([2, 3, 5])
```

$$30^{1/3}$$

### Example 2

We create a sample:

```
stats::sample([[a1, b1, c1], [a2, b2, c2]])
```

```
a1 b1 c1
a2 b2 c2
```

The geometric mean of the second column is:

```
stats::geometricMean(%, 2)
```

$$\sqrt{b1 \ b2}$$

### Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]])
```

```
"1996" 1242
"1997" 1353
"1998" 1142
```

We compute the geometric mean of the second column. In this case this column does not have to be specified, since it is the only non-string column in the sample:

```
float(stats::geometricMean(%))
```

```
1242.68722
```

### Parameters

$x_1, x_2, \dots$

# stats::geometricMean

---

The statistical data: arithmetical expressions.

**s**

A sample of domain type `stats::sample`.

**c**

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc.

## Return Values

arithmetical expression.

## See Also

## MuPAD Functions

`stats::harmonicMean` | `stats::mean` | `stats::median` |  
`stats::modal` | `stats::quadraticMean` | `stats::stdev` |  
`stats::variance`

**Purpose** The (discrete) cumulative distribution function of the geometric distribution

**Syntax** stats::geometricCDF(p)

**Description** stats::geometricCDF(p) returns a procedure representing the (discrete) cumulative distribution function

$$x \rightarrow \begin{cases} 0 & \text{if } x < 1 \\ 1 - (1 - p)^{\lfloor x \rfloor} & \text{if } x \geq 1 \end{cases}$$

of the geometric distribution with 'probability parameter'  $p$ .

The procedure  $f := \text{stats::geometricCDF}(p)$  can be called in the form  $f(x)$  with an arithmetical expression  $x$ . The return value of  $f(x)$  is either a number or a symbolic expression:

If  $x < 1$  can be decided, then  $f(x)$  returns 0. If  $x \geq 1$  can be decided, then  $f(x)$  returns the value  $1 - (1 - p)^{\lfloor x \rfloor}$ .

If  $x$  is a floating-point number and  $p$  can be converted to a floating-point number, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function  $f$  reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x < 1$  or  $x \geq 1$ , the corresponding values are returned.

$f(x)$  returns the symbolic call  $\text{stats::geometricCDF}(p)(x)$  if neither  $x < 1$  nor  $x \geq 1$  can be decided.

If  $p = 0$  or  $p = 0.0$ , then  $f(x)$  returns 0 or 0.0, respectively, for any value of  $x$ .

Numerical values for  $p$  are only accepted if they satisfy  $0 \leq p \leq 1$ .

# stats::geometricCDF

---

If  $x$  is a real floating-point number,  $f(x)$  produces a floating number provided  $p$  is a numerical value. If  $x$  is an exact numerical value, no internal floating-point conversion of the parameter  $p$  is attempted.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We evaluate the distribution function with  $p = \frac{1}{3}$  at various points:

```
f := stats::geometricCDF(1/3):
f(-PI) = f(float(-PI)), f(1) = f(1.0), f(103/10) = f(10.3)
```

```
0 = 0.0, $\frac{1}{3} = 0.3333333333$, $\frac{58025}{59049} = 0.9826584701$
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \geq 1$  holds. A symbolic function call is returned:

```
f := stats::geometricCDF(p): f(x)
```

```
stats::geometricCDF(p)(x)
```

With suitable properties, it can be decided whether  $x \geq 1$  holds. An explicit expression is returned:

```
assume(1 <= x): f(x)
```

```
 $1 - (1 - p)^{\lfloor x \rfloor}$
```

```
unassume(x): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::geometricCDF(p): f(x)
```

```
stats::geometricCDF(p)(x)
```

If  $x$  is a numerical value, symbolic expressions in  $p$  are returned:

```
f(-1), f(1), f(5/2), f(PI)
```

```
0, p, 1 - (p - 1)2, (p - 1)3 + 1
```

When numerical values are assigned to  $p$ , the function  $f$  starts to produce numbers if the argument is numerical:

```
p := 1/3: f(-1), f(1), f(5/2), f(PI)
```

```
0, $\frac{1}{3}$, $\frac{5}{9}$, $\frac{19}{27}$
```

```
delete f, p:
```

### Parameters

**p**

The 'probability parameter': an arithmetical expression representing a real number  $0 \leq p \leq 1$ .

### Return Values

procedure.

# stats::geometricCDF

---

## Algorithms

The geometric distribution describes the number of Bernoulli trials with success probability  $p$  up to and including the first success.

## See Also

## MuPAD Functions

`stats::geometricPF` | `stats::geometricQuantile` |  
`stats::geometricRandom`

**Purpose** Probability function of the geometric distribution

**Syntax** `stats::geometricPF(p)`

**Description** `stats::geometricPF(p)` returns a procedure representing the probability function

$$x \rightarrow p (1 - p)^{x-1}$$

for  $x = 1, 2, 3, \dots$  of the geometric distribution with 'probability parameter'  $p$ .

The procedure `f:=stats::geometricPF(p)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a number or a symbolic expression:

If  $x$  is a non-integer numerical value, `f(x)` returns 0 or 0.0, respectively.

If  $x$  is a positive integer or the floating point equivalent of such an integer, then an explicit value is returned.

In all other cases, `f(x)` returns the symbolic call `stats::geometricPF(n,p)(x)`.

Numerical values for  $p$  are only accepted if they satisfy  $0 \leq p \leq 1$ .

If  $x$  is a floating-point number, the result is a floating-point number provided  $p$  can be converted to a floating-point number between 0.0 and 1.0. If  $x$  is an exact numerical value, no internal floating point conversion of the parameter  $p$  is attempted.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

**Examples** **Example 1**

We calculate the geometric probability with  $p = \frac{1}{8}$  at various points:

# stats::geometricPF

---

```
f := stats::geometricPF(1/8):
f(-1), f(0.5), f(1), f(3/2), f(3) = f(float(3))
```

```
0, 0.0, $\frac{1}{8}$, 0, $\frac{49}{512}$ = 0.095703125
```

```
delete f:
```

## Example 2

We use symbolic arguments:

```
f := stats::geometricPF(p): f(x)
```

```
stats::geometricPF(p)(x)
```

If  $x$  is a numerical value, symbolic expressions in  $p$  are returned:

```
f(17/2), f(8), f(9.0), f(9.2)
```

```
0, $-p(p-1)^7$, $p(1.0-1.0p)^{8.0}$, 0.0
```

When numerical values are assigned to  $p$ , the function  $f$  starts to produce numbers if the argument is numerical:

```
p := 1/3: f(17/2), f(8), f(9.0), f(9.2)
```

```
0, $\frac{128}{8561}$, 0.01300614744, 0.0
```

```
delete f, p:
```

**Parameters**    **p**

The ‘probability parameter’: an arithmetical expression representing a real number  $0 \leq p \leq 1$ .

## Return Values

procedure.

## See Also

## MuPAD Functions

`stats::geometricCDF` | `stats::geometricQuantile` |  
`stats::geometricRandom`

# stats::geometricQuantile

---

**Purpose** Quantile function of the geometric distribution

**Syntax** `stats::geometricQuantile(p)`

**Description** `stats::geometricQuantile(p)` returns a procedure representing the quantile function (discrete inverse) of the cumulative distribution function `stats::geometricCDF(p)`. For  $0 \leq x \leq 1$ ,  $k = \text{stats::geometricQuantile}(p)(x)$  is the smallest positive integer satisfying

$$\text{stats::geometricCDF}(p)(k) = 1 - (1 - p)^k \geq x$$

The procedure `f:=stats::geometricQuantile(p)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of the call `f(x)` is either a positive integer, *infinity*, or a symbolic expression:

If  $p$  is a real number satisfying  $0 < p \leq 1$  and  $x$  is a real number satisfying  $0 \leq x < 1$ , then `f(x)` returns a positive integer.

If  $p = 0$ , then `f(x)` returns *infinity* for any  $x$ .

If  $p = 1$ , then `f(x)` returns 1 for any  $x$ .

If  $p \neq 0$ , then `f(0)` and `f(0.0)` return 1.

If  $p \neq 1$ , then `f(1)` and `f(1.0)` return *infinity*.

In all other cases, `f(x)` returns the symbolic call `stats::geometricQuantile(p)(x)`.

Numerical values for  $p$  are only accepted if they satisfy  $0 \leq p \leq 1$ .

If floating-point arguments are passed to the quantile function `f`, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors. In particular, round-off may be significant for arguments  $x$  close to 1. Cf. “Example 3” on page 29-252.

Finite quantile values  $k = \text{stats::geometricQuantile}(p)(x)$  satisfy

$$\text{stats::geometricCDF}(p)(k - 1) < x \leq \text{stats::geometricCDF}(p)(k)$$

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with  $p = \frac{1}{\pi}$  at various points:

```
f := stats::geometricQuantile(1/PI):
f(0), f(1/20), f(PI/6), f(0.7), f(1-1/10^10), f(1)
```

```
1, 1, 2, 4, 61, ∞
```

The value  $f(x)$  satisfies

$$\text{stats::geometricCDF}(p)(f(x) - 1) < x \leq \text{stats::geometricCDF}(p)(f(x))$$

```
x := 0.98: k := f(x)
```

```
11
```

```
float(stats::geometricCDF(1/PI)(k - 1)), x,
float(stats::geometricCDF(1/PI)(k))
```

```
0.9783294488, 0.98, 0.9852273995
```

```
delete f, x, k:
```

# stats::geometricQuantile

---

## Example 2

We use symbolic arguments:

```
f := stats::geometricQuantile(p): f(x), f(9/10)
```

```
stats::geometricQuantile(p)(x), stats::geometricQuantile(p)($\frac{9}{10}$)
```

When  $p$  evaluates to a suitable real number, the function  $f$  starts to produce quantile values:

```
p := 1/sqrt(2):
f(1/2), f(999/1000), f(1 - 1/10^10), f(1 - 1/10^80)
```

```
1, 6, 19, 151
```

```
delete f, p:
```

## Example 3

If floating-point arguments are passed to the quantile function, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors:

```
f := stats::geometricQuantile(1/123):
f(1 - 1/10^19) <> f(float(1 - 1/10^19))
```

```
5360 ≠ ∞
```

```
delete f:
```

**Parameters**    **p**

The “probability parameter”: an arithmetical expression representing a real number  $0 \leq p \leq 1$ .

## Return Values

procedure.

## See Also

## MuPAD Functions

`stats::geometricCDF` | `stats::geometricPF` |  
`stats::geometricRandom`

# stats::geometricRandom

---

**Purpose** Generate a random number generator for geometric deviates

**Syntax** `stats::geometricRandom(p, <Seed = s>)`

**Description** `stats::geometricRandom(p)` returns a procedure that produces geometric deviates (random numbers) with 'probability parameter'  $p$ .

The procedure `f:=stats::geometricRandom(p)` can be called in the form `f()`. The return value of `f()` is a positive integer if  $p$  is a real number satisfying  $0 \leq p \leq 1$ .

Otherwise, `stats::geometricRandom(p)()` is returned symbolically.

Numerical values for  $p$  are only accepted if they satisfy  $0 \leq p \leq 1$ .

The values  $X = f()$  are distributed randomly according to the discrete distribution function of the geometric distribution with parameter  $p$ ,

i.e., for  $1 \leq x$ , the probability of  $X \leq x$  is given by  $1 - (1 - p)^{[x]}$ .

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** With this option, the parameter  $p$  must evaluate to a numerical value at the time, when the generator is created.

---

---

**Note** In contrast to the function `random`, the generators produced by `stats::geometricRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::geometricRandom(p): f() $k = 1..K;
```

rather than by

```
stats::geometricRandom(p)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::geometricRandom(p, Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate geometric deviates with  $p = \frac{1}{3}$ :

```
f := stats::geometricRandom(1/3): f() $ k = 1..10
```

```
4, 1, 5, 1, 4, 5, 2, 1, 3, 1
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::geometricRandom(p): f()
```

```
stats::geometricRandom(p)()
```

When  $p$  evaluates to a real number between 0 and 1, the generator starts to produce random numbers:

# stats::geometricRandom

---

```
p := 1/sqrt(70): f(), f(), f()
```

```
3, 6, 2
```

```
delete f, p:
```

### Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::geometricRandom(1/10, Seed = 1): f() $ k = 1..10
```

```
6, 3, 21, 17, 2, 55, 7, 16, 26, 11
```

```
g := stats::geometricRandom(1/10, Seed = 1): g() $ k = 1..10
```

```
6, 3, 21, 17, 2, 55, 7, 16, 26, 11
```

```
f() = g(), f() = g()
```

```
9 = 9, 8 = 8
```

```
delete f, g:
```

### Parameters

**p**

The “probability parameter”: an arithmetical expression representing a real number  $0 \leq p \leq 1$ .

### Options

**Seed**

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameter `p` must be convertible to a floating-point number between 0.0 and 1.0 at the time when the random generator is generated.

## Return Values

procedure.

## MuPAD Functions

`stats::geometricCDF` | `stats::geometricPF` |  
`stats::geometricQuantile`

# stats::harmonicMean

---

**Purpose** Harmonic mean of a data sample

**Syntax** `stats::harmonicMean(x1, x2, ...)`  
`stats::harmonicMean([x1, x2, ...])`  
`stats::harmonicMean(s, <c>)`

**Description** `stats::harmonicMean(x1, x2, ..., xn)` returns the harmonic mean

$\frac{1}{\left(\frac{1}{x_1} + \frac{1}{x_2} + \dots + \frac{1}{x_n}\right)}$  of the data  $x_i$ .

The column index  $c$  is optional, if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-259.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We calculate the harmonic mean of three values:

```
stats::harmonicMean(a, b, c)
```

$$\frac{3}{\frac{1}{a} + \frac{1}{b} + \frac{1}{c}}$$

Alternatively, data may be passed as a list:

```
stats::harmonicMean([2, 3, 5])
```

$$\frac{90}{31}$$

### Example 2

We create a sample:

```
stats::sample([[a1, b1, c1], [a2, b2, c2]])
```

```
a1 b1 c1
a2 b2 c2
```

The harmonic mean of the second column is:

```
stats::harmonicMean(%, 2)
```

$$\frac{2}{\frac{1}{b_1} + \frac{1}{b_2}}$$

### Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample(["1996", 1242], ["1997", 1353], ["1998", 1142])
```

```
"1996" 1242
"1997" 1353
"1998" 1142
```

We compute the harmonic mean of the second column. In this case this column does not have to be specified, since it is the only non-string column:

```
float(stats::harmonicMean(%))
```

```
1239.71654
```

# stats::harmonicMean

---

## Parameters

$x_1, x_2, \dots$

The statistical data: arithmetical expressions.

**s**

A sample of domain type `stats::sample`.

**c**

An integer representing a column index of the sample *s*. This column provides the data  $x_1, x_2$  etc.

## Return Values

arithmetical expression. FAIL is returned, if one of the data values is zero (the harmonic mean does not exist).

## See Also

## MuPAD Functions

`stats::geometricMean` | `stats::mean` | `stats::median` |  
`stats::modal` | `stats::quadraticMean` | `stats::stdev` |  
`stats::variance`

## Purpose

The Hodrick-Prescott filter

## Syntax

```
stats::hodrickPrescottFilter([x1, x2, ...], p)
stats::hodrickPrescottFilter(s, <c>, p)
```

## Description

`stats::hodrickPrescottFilter([x1, x2, ...], p)` returns a list of data from which cyclic variations of the time series given by the input data  $x_1, x_2$  etc. are eliminated using the Hodrick-Prescott filter process.

The Hodrick-Prescott filter scheme tries to split a time series consisting of the data  $x_1, x_2$  etc. into a “trend” that is approximately linear in time plus a “cyclic” contribution. The data returned by `stats::hodrickPrescottFilter` describe the trend. The cyclic part  $c$  may be computed by

```
x := [x1, x2, ...]:
y := stats::HodrickPrescottFilter(x, p):
c := zip(x, y, _subtract):
```

Thus,  $x_i = y_i + c_i$ .

Large values of the penalty parameter  $p$  lead to smooth straight trend curves. Cf. “Example 5” on page 29-267.

If the data are provided by a `stats::sample` object containing only one non-string column, the column index  $c$  is optional. Cf. “Example 3” on page 29-263.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We apply the Hodrick-Prescott filter to some data. The result shows an obvious trend towards increasing data values:

```
stats::hodrickPrescottFilter([1, 2, 3, 2, 3, 4, 3, 4, 5], 10)
```

# stats::hodrickPrescottFilter

---

```
[1.356447588, 1.819582682, 2.247073017, 2.621315566, 3.0, 3.378684434, 3.752926983,
4.643552412]
```

## Example 2

We create a sample:

```
s := stats::sample([[i + frandom() - 0.5, -i + frandom() - 0.5]
$ i = 1..10])
```

```
0.7703581656 -0.6689628213
1.653156516 -1.505187219
2.766272902 -3.319835772
3.952083055 -3.821218044
4.854984926 -4.818141187
6.221918655 -6.026170226
7.288981492 -7.288474164
8.355687175 -8.455102606
9.379160127 -8.580615152
10.23505742 -9.712454973
```

The Hodrick-Prescott filter process applied to the data in the first column yields:

```
p := 10:
stats::hodrickPrescottFilter(s, 1, p)
```

```
[0.7163345093, 1.721715792, 2.781120731, 3.880013706, 4.989011271, 6.150799324, 7.2
8.338504453, 9.338923372, 10.28719986]
```

```
stats::hodrickPrescottFilter(s, 2, p)
```

```
[- 0.6351055566, - 1.760720308, - 2.903263691, - 3.951897795, - 5.004070747, - 6.091897795, - 7.154501435, - 8.098185826, - 8.896213527, - 9.700312476]
```

```
delete s, p:
```

### Example 3

We create a sample consisting of one string column and one non-string column:

```
s := stats::sample([["1996", 1242],
 ["1997", 1353],
 ["1998", 1142],
 ["1999", 1255],
 ["2000", 1417],
 ["2001", 1312],
 ["2002", 1440],
 ["2003", 1422],
 ["2004", 1470]
])
```

```
"1996" 1242
"1997" 1353
"1998" 1142
"1999" 1255
"2000" 1417
"2001" 1312
"2002" 1440
"2003" 1422
"2004" 1470
```

We apply the Hodrick-Prescott filter to the second column. In this case, this column needs not be specified, since it is the only non-string column:

```
y := stats::hodrickPrescottFilter(s, 10)
```

# stats::hodrickPrescottFilter

---

```
[1239.848378, 1255.015604, 1270.397993, 1296.009146, 1329.022865, 1362.512038, 1398.347268, 1433.347951, 1468.498758]
```

We convert this list to a sample object:

```
y := stats::sample(y)
```

```
1239.848378
1255.015604
1270.397993
1296.009146
1329.022865
1362.512038
1398.347268
1433.347951
1468.498758
```

We create a new sample consisting of the filtered data:

```
stats::concatCol(stats::col(s, 1), y)
```

```
"1996" 1239.848378
"1997" 1255.015604
"1998" 1270.397993
"1999" 1296.009146
"2000" 1329.022865
"2001" 1362.512038
"2002" 1398.347268
"2003" 1433.347951
"2004" 1468.498758
```

```
delete s, y:
```

## Example 4

We model monthly data with a decaying trend of  $\frac{1}{1+0.01i}$ , where  $i$  is the index of the month. These trend data are obscured by cyclic contributions and random noise:

```
monthlyData:= i ->
 (1/(1 + 0.01*i) // the trend
 + 0.7*cos(i * 1.12*2*float(PI)) // cycle
 + 0.3*sin(i * 2.04*4*float(PI)) // cycle
 + 0.2*cos(i * 1.01*6*float(PI)) // cycle
 + 2.3*frandom() // random noise
):

```

We provide monthly data for 10 years, i.e., 120 months. The cyclic contributions and the noise are eliminated from the time series by the Hodrick-Prescott filter process:

```
n := 120:
x := [monthlyData(i) $ i = 1..n]:
trend := stats::hodrickPrescottFilter(x, 10^5):
cycle := zip(x, trend, _subtract):

```

We visualize the splitting of the time series (black) into the approximately linear trend contribution (red) plus the cyclic part (blue):

```
plot(
 plot::Listplot([[i, x[i]] $ i = 1..n], Color = RGB::Black),
 plot::Listplot([[i, trend[i]] $ i = 1..n], Color = RGB::Red),
 plot::Listplot([[i, cycle[i]] $ i = 1..n], Color = RGB::Blue)
)

```

## stats::hodrickPrescottFilter

---

We use a scatterplot to visualize a linear regression of the unfiltered data. The regression line is in good accordance with the trend line above:

```
plot(plot::Scatterplot([[i, x[i]] $ i = 1..n]))
```

```
delete monthlyData, n, x, trend, cycle:
```

## Example 5

We demonstrate the effect of the penalty parameter  $p$  by an animated plot:

```
delete p:
n := 100:
data := [1/(1 + 0.01*i) + frandom() $ i = 1..n]:
for i from 0 to 30 step 1/5 do
 trend := stats::hodrickPrescottFilter(data, 10^(0.2*i));
 L[i] := plot::Listplot([[i, trend[i]] $ i = 1..n],
 Color = RGB::Red, VisibleFromTo = i .. i + 0.2);
 T[i] := plot::Text2d(expr2text(p = 10^(0.2*i)), [70, 1.7],
 VisibleFromTo = i .. i + 0.2);
end_for:
plot(plot::Listplot([[i, data[i]] $ i = 1..n], Color=RGB::Black),
 L[i] $ i = 0..30 step 1/5, T[i] $ i = 0..30 step 1/5)
```

# stats::hodrickPrescottFilter

Large penalty parameters  $p$  result in trend curves that are close to a straight line. This is not always the desired information. The following animation features a time series with a parabolic trend curve obscured by random noise. Too large values of  $p$  produce a trend curve that just displays the mean of the data:

```
data := [8*frandom() + 5 - (i - 50)^2/100 $ i = 1..n]:
for i from 0 to 50 do
 trend := stats::hodrickPrescottFilter(data, 10^(0.2*i));
 L[i] := plot::Listplot([[i, trend[i]] $ i = 1..n],
 Color = RGB::Red,
 VisibleFromTo = i/5 .. (i + 1)/5);
 T[i] := plot::Text2d(expr2text(p = 10^(0.2*i)), [50, -5],
 VisibleFromTo = i/5 .. (i + 1)/5);
end_for:
plot(plot::Listplot([[i, data[i]] $ i= 1..n], Color=RGB::Black),
 L[i] $ i = 0..50, T[i] $ i = 0..50)
```

delete n, data, i, trend, L, T:

## Parameters

**x<sub>1</sub>, x<sub>2</sub>, ...**

The statistical data (time series): arithmetical expressions.

**s**

A sample of domain type stats::sample.

**c**

An integer representing a column index of the sample *s*. This column provides the data *x<sub>1</sub>*, *x<sub>2</sub>* etc.

**p**

The penalty parameter of the Hodrick-Prescott scheme: a real positive numerical value.

# stats::hodrickPrescottFilter

---

If the data  $x_1, x_2$  etc. represent monthly measurements, the literature recommends values of  $p$  between 1000 and 1400.

If the data represent quarterly measurements, values of  $p$  around 1600 are recommended.

If the data represent yearly measurements, values of  $p$  between 6 and 14 are recommended.

## Return Values

List of floating-point data.

## MuPAD Functions

`stats::linReg` | `stats::reg`

## MuPAD Graphical Primitives

`plot::Listplot` | `plot::Scatterplot`

**Purpose** The (discrete) cumulative probability function of the hypergeometric distribution

**Syntax** stats::hypergeometricCDF(N, X, n)

**Description** stats::hypergeometricCDF(N, X, n) returns a procedure representing the probability function

$$X \rightarrow \begin{cases} 0 & \text{if } x < \max(0, n + X - N) \\ \sum_{i=\max(0, n + X - N)}^{\lfloor x \rfloor} \frac{\binom{X}{i} \binom{N-X}{n-i}}{\binom{N}{n}} & \text{if } \max(0, n + X - N) \leq x \leq \min(n, X) \\ 1 & \text{if } x > \min(n, X) \end{cases}$$

of the hypergeometric distribution with “population size”  $N$ , “success population size”  $X$  and “sample size”  $n$ .

The procedure  $f := \text{stats::hypergeometricCDF}(N, X, n)$  can be called in the form  $f(x)$  with arithmetical expressions  $x$ . The return value of  $f(x)$  is either a floating-point number, an exact numerical value, or a symbolic expression:

If  $x$  is an integer, a rational or a floating point number, while  $N$  is a positive integer and both  $X$  and  $n$  are nonnegative integers, then an explicit numerical value is returned.

The function  $f$  reacts to properties of identifiers set via `assume`.

If any of the parameters is symbolic with properties as follows, then 0, 1 or a symbolic result is returned:

If  $x < \max(0, n + X - N)$ , then  $f(x) = 0$ .

If  $x \geq \min(n, X)$ , then  $f(x) = 1$ .

If  $X = N$ , then  $f(x) = 0$  for  $x < n$  and  $f(x) = 1$  for  $x \geq n$ .

# stats::hypergeometricCDF

---

If  $n = N$ , then  $f(x) = 0$  for  $x < X$  and  $f(x) = 1$  for  $x \geq X$ .

If  $X = N - 1$ , then  $f(x) = 0$  for  $x < n - 1$ ,  $f(x) = \frac{n}{N}$  for  $n - 1 \leq x < n$  and  $f(x) = 1$  for  $x \geq n$ .

If  $n = N - 1$ , then  $f(x) = 0$  for  $x < X - 1$ ,  $f(x) = \frac{X}{N}$  for  $X - 1 \leq x < X$  and  $f(x) = 1$  for  $x \geq X$ .

If  $X = 1$ , then  $f(x) = \frac{N-n}{N}$  for  $0 \leq x < 1$  and  $f(x) = 1$  for  $x \geq 1$ .

If  $n = 1$ , then  $f(x) = \frac{N-X}{N}$  for  $0 \leq x < 1$  and  $f(x) = 1$  for  $x \geq 1$ .

If  $X = 0$  or  $n = 0$ , then  $f(x) = 1$  for  $x \geq 0$ .

If  $x$  and all parameters but  $N$  are numerical and the assumption on  $N$  is `assume(N > X)`, then symbolic values are returned.

`f(x)` returns the symbolic call `stats::hypergeometricCDF(N, X, n)(x)` in all other cases.

Numerical values for  $N$  are only accepted if they are positive integers.

Numerical values for  $X$  are only accepted if they are nonnegative integers.

Numerical values for  $n$  are only accepted if they are nonnegative integers.

---

**Note** If  $x$  is a floating-point number, the result is a floating number provided  $N$ ,  $X$  and  $n$  are numerical values. If  $x$  is an exact value, the result is a rational number.

---

Note that for large numbers, floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number  $x$  to `stats::hypergeometricCDF`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We compute the distribution function with  $N = 20$ ,  $X = 4$  and  $n = 3$  at various points:

```
f := stats::hypergeometricCDF(20, 4, 3):
f(-1), f(0), f(1/2), f(1), f(2), f(PI), f(5)
```

```
0, 28/57, 28/57, 52/57, 284/285, 1, 1
```

```
f(-infinity), f(infinity)
```

```
0, 1
```

```
f(-0.2), f(0.0), f(0.7), f(1.0), f(float(PI)), f(4.0)
```

```
0.0, 0.4912280702, 0.4912280702, 0.9122807018, 1.0, 1.0
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::hypergeometricCDF(N, X, n): f(x), f(8), f(8.0)
```

```
stats::hypergeometricCDF(N, X, n)(x), stats::hypergeometricCDF(N, X, n)(8),
stats::hypergeometricCDF(N, X, n)(8.0)
```

When real numbers are assigned to  $N$ ,  $X$  and  $n$ , the function  $f$  starts to produce explicit results if the argument is numerical:

```
N := 15: X := 6: n := 5:
```

# stats::hypergeometricCDF

---

```
f(0), f(1), f(2.0), f(3.5), f(4)
```

```
 $\frac{6}{143}, \frac{42}{143}, 0.7132867133, 0.953046953, \frac{999}{1001}$
```

```
delete f, N, X, n:
```

## Example 3

If one or more parameters are symbolic, usually a symbolic call is returned. Some combinations of symbolic and numeric values for  $N$ ,  $X$ ,  $n$  and  $x$ , however, may yield symbolic or numeric results:

```
f := stats::hypergeometricCDF(N, X, n):
X := 1:
f(-1), f(0), f(1/2), f(0.5), f(3/2), f(2.0)
```

```
 $0, \frac{N-n}{N}, \frac{N-n}{N}, \frac{N-1.0n}{N}, 1, 1.0$
```

```
X := N - 1:
f(1), f(n-1), f(n)
```

```
stats::hypergeometricCDF(N, N - 1, n)(1), $\frac{n}{N}, 1$
```

```
delete X:
```

## Example 4

If  $x$  and all parameters but  $N$  are numerical and  $N$  is assumed to be greater than  $X$ , a symbolic expression is returned:

```
X := 6:
assume(N > X):
f := stats::hypergeometricCDF(N, X, 5):
```

$f(1), f(2), f(3)$

$$1 - \frac{15N + 20 \binom{N-6}{2} + 15 \binom{N-6}{3} - 84}{\binom{N}{5}}, 1 - \frac{15N + 20 \binom{N-6}{2} - 84}{\binom{N}{5}}, 1 - \frac{15N - 84}{\binom{N}{5}}$$

delete f, N, X:

## Parameters

**N**

The “population size”: an arithmetical expression representing a positive integer

**X**

The “success population size”: an arithmetical expression representing a nonnegative integer

**n**

The “sample size”: an arithmetical expression representing a nonnegative integer

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::hypergeometricPF | stats::hypergeometricQuantile | stats::hypergeometricRandom

# stats::hypergeometricPF

---

**Purpose** Probability function of the hypergeometric distribution

**Syntax** stats::hypergeometricPF(N, X, n)

**Description** stats::hypergeometricPF(N, X, n) returns a procedure representing the probability function

$$X \rightarrow \frac{\binom{X}{x} \binom{N-X}{n-x}}{\binom{N}{n}}$$

for  $x \in \mathbb{N} \cap [\max(0, n + X - N), \min(n, X)]$  of the hypergeometric distribution with “population size”  $N$ , “success population size”  $X$  and “sample size”  $n$ .

The procedure `f:=stats::hypergeometricPF(N, X, n)` can be called in the form `f(x)` with arithmetical expressions  $x$ . The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

If  $x$  is a noninteger numerical value, `f(x)` returns 0 or 0.0, respectively.

If  $x$  is an integer or the floating-point equivalent of an integer, while  $N$  is a positive integer and both  $X$  and  $n$  are nonnegative integers, then an explicit numerical value is returned.

The function `f` reacts to properties of identifiers set via `assume`.

If any of the parameters is symbolic with properties as follows, then 0, 1 or a symbolic result is returned:

If  $X = N$ , then  $f(x) = 1$  for  $x = n$  and  $f(x) = 0$  for  $x \neq n$ . If  $n = N$ , then  $f(x) = 1$  for  $x = X$  and  $f(x) = 0$  for  $x \neq X$ .

If  $X = N - 1$ , then  $f(X) = \frac{N-n}{N}$  for  $x = n$ ,  $f(X) = \frac{n}{N}$  for  $x = n - 1$  and  $f(x) = 0$  for  $x \neq n, n - 1$ .

If  $n = N - 1$ , then  $f(X) = \frac{N-X}{N}$  for  $x = X$ ,  $f(X) = \frac{X}{N}$  for  $x = X - 1$  and  $f(x) = 0$  for  $x \neq X, X - 1$ .

If  $X = 1$ , then  $f(X) = \frac{N-n}{N}$  for  $x = 0$ ,  $f(X) = \frac{n}{N}$  for  $x = 1$  and  $f(x) = 0$  for  $x \neq 0, 1$ .

If  $n = 1$ , then  $f(X) = \frac{N-X}{N}$  for  $x = 0$ ,  $f(X) = \frac{X}{N}$  for  $x = 1$  and  $f(x) = 0$  for  $x \neq 0, 1$ .

If  $X = 0$  or  $n = 0$ , then  $f(x) = 1$  for  $x = 0$  and  $f(x) = 0$  for  $x \neq 0$ .

If  $x$  and all parameters but  $N$  are numerical and the assumption on  $N$  is `assume(N > X)`, then symbolic values are returned.

$f(x)$  returns the symbolic call `stats::hypergeometricPF(N, X, n)(x)` in all other cases.

Numerical values for  $N$  are only accepted if they are positive integers.

Numerical values for  $X$  are only accepted if they are nonnegative integers.

Numerical values for  $n$  are only accepted if they are nonnegative integers.

---

**Note** If  $x$  is a floating-point number, the result is a floating number provided  $N$ ,  $X$  and  $n$  are numerical values. If  $x$  is an exact value, the result is a rational number.

---

Note that for large numbers, floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number  $x$  to `stats::hypergeometricPF`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

# stats::hypergeometricPF

---

## Examples

### Example 1

We compute the probability function with  $N = 20$ ,  $X = 4$  and  $n = 3$  at various points:

```
f := stats::hypergeometricPF(20, 4, 3):
f(-infinity), f(0), f(1/2), f(1), f(2), f(4), f(infinity)
```

```
0, $\frac{28}{57}$, 0, $\frac{8}{19}$, $\frac{8}{95}$, 0, 0
```

```
f(-0.2), f(0.0), f(0.7), f(1.0), f(2.0), f(2.7), f(3.0), f(4.0)
```

```
0.0, 0.4912280702, 0.0, 0.4210526316, 0.08421052632, 0.0, 0.00350877193, 0.0
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::hypergeometricPF(N, X, n): f(x), f(8), f(8.0)
```

```
stats::hypergeometricPF(N, X, n)(x), stats::hypergeometricPF(N, X, n)(8),
stats::hypergeometricPF(N, X, n)(8.0)
```

When real numbers are assigned to  $N$ ,  $X$  and  $n$ , the function  $f$  starts to produce explicit results if the argument is numerical:

```
N := 15: X := 6: n := 5:
f(0), f(1), f(2.0), f(3.5), f(4)
```

```
 $\frac{6}{143}$, $\frac{36}{143}$, 0.4195804196, 0.0, $\frac{45}{1001}$
```

```
delete f, N, X, n, x:
```

### Example 3

If one or more parameters are symbolic, usually a symbolic call is returned. Some combinations of symbolic and numeric values for  $N$ ,  $X$ ,  $n$  and  $x$ , however, may yield symbolic or numeric results:

```
f := stats::hypergeometricPF(N, X, n):
X := 1:
f(-1), f(0), f(1), f(3/2), f(2), f(3)
```

$$0, \frac{N-n}{N}, \frac{n}{N}, 0, 0, 0$$

```
X := N:
f(-1), f(n), f(n + 1)
```

$$0, 1, 0$$

```
delete f, X:
```

### Example 4

If  $x$  and all parameters but  $N$  are numerical and  $N$  is assumed to be greater than  $X$ , a symbolic expression is returned:

```
X := 6:
assume(N > X):
f := stats::hypergeometricPF(N, X, 5):
f(2), f(4), f(5.0)
```

$$\frac{15 \binom{N-6}{3}}{\binom{N}{5}}, \frac{15 N - 90}{\binom{N}{5}}, \frac{6.0}{\binom{N}{5.0}}$$

# stats::hypergeometricPF

---

delete f, N, X:

## Parameters

**N**

The “population size”: an arithmetical expression representing a positive integer

**X**

The “success population size”: an arithmetical expression representing a nonnegative integer

**n**

The “sample size”: an arithmetical expression representing a nonnegative integer

## Return Values

procedure.

## MuPAD Functions

stats::hypergeometricCDF | stats::hypergeometricQuantile | stats::hypergeometricRandom

**Purpose** Quantile function of the hypergeometric distribution

**Syntax** stats::hypergeometricQuantile(N, X, n)

**Description** stats::hypergeometricQuantile(N, X, n) returns a procedure representing the quantile function (discrete inverse) of the cumulative distribution function stats::hypergeometricCDF(N, X, n). For  $0 \leq x \leq 1$ ,  $k = \text{stats::hypergeometricQuantile}(N, X, n)(x)$  is the smallest nonnegative integer satisfying

$$\text{stats::hypergeometricCDF}(N, X, n)(k) = \sum_{i=0}^k \frac{\binom{X}{i} \binom{N-X}{n-i}}{\binom{N}{n}} \geq X$$

The procedure  $f := \text{stats::hypergeometricQuantile}(N, X, n)$  can be called in the form  $f(x)$  with arithmetical expressions  $x$ . The return value of  $f(x)$  is either a natural number between 0 and  $\min(X, n)$ , or a symbolic expression:

If  $x$  is a real number satisfying  $0 \leq x \leq 1$ , while  $N$  is a positive integer and both  $X$  and  $n$  are nonnegative integers, then an explicit numerical value is returned.

The function  $f$  reacts to properties of identifiers set via `assume`.

If any of the parameters is symbolic, then in some cases a symbolic result will be returned:

0 will be returned if either any of  $x$ ,  $n$  or  $X$  is zero or if  $n = 1$  and

$$X \leq \frac{N-X}{N} \text{ or if } X = 1 \text{ and } X \leq \frac{N-n}{N}.$$

1 will be returned if  $n = 1$  and  $X > \frac{N-X}{N}$  or if  $X = 1$  and  $X > \frac{N-n}{N}$ .

$n$  will be returned if  $X = N - 1$  and  $X > \frac{n}{N}$  or if  $X = N$  and  $x > 0$ .

$X$  will be returned if  $n = N - 1$  and  $X > \frac{X}{N}$  or if  $n = N$  and  $x > 0$ .

# stats::hypergeometricQuantile

---

$n - 1$  will be returned if  $X = N - 1$  and  $x = \frac{n}{N}$  provided that  $n$  is symbolic, whereas  $X - 1$  will be returned if  $n = N - 1$  and  $x = \frac{X}{N}$  provided that  $X$  is symbolic.

Finally  $\min(X, n)$  will be returned if  $x = 1$ .

The symbolic call `stats::hypergeometricQuantile(N, X, n)(x)` is returned by `f(x)` in all other cases.

Numerical values for  $N$  are only accepted if they are positive integers.

Numerical values for  $X$  are only accepted if they are nonnegative integers.

Numerical values for  $n$  are only accepted if they are nonnegative integers.

If  $x$  is a floating-point number, the result is a floating number provided  $N$ ,  $X$  and  $n$  are numerical values. If  $x$  is an exact value, the result is a rational number.

---

**Note** Note that if floating-point arguments are passed to the quantile function  $f$ , the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors. In particular, round-off may be significant for arguments  $x$  close to 1. Cf. “Example 4” on page 29-285.

---

The quantile value  $k = \text{stats::hypergeometricQuantile}(N, X, n)(x)$  satisfies

$$\text{cdf}(k - 1) < x \leq \text{cdf}(k)$$

where  $\text{cdf} = \text{stats::hypergeometricCDF}(N, X, n)$ .

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with  $N = 50$ ,  $X = 30$  and  $n = 10$  at some points:

```
f := stats::hypergeometricQuantile(50, 30, 10):
f(0), f((2/3)^30), f(PI/10), f(0.5), f(1 - 1/10^10)
```

```
0, 0, 5, 6.0, 10
```

With  $cdf = stats::hypergeometricCDF(N, X, n)$ , the quantile value  $f(x)$  satisfies the inequalities  $cdf(f(x) - 1) < x \leq cdf(f(x))$ :

```
x := 0.7: f(x)
```

```
7.0
```

```
stats::hypergeometricCDF(50, 30, 10)(float(f(x) - 1)), x,
stats::hypergeometricCDF(50, 30, 10)(float(f(x)))
```

```
0.6350317132, 0.7, 0.8609613426
```

```
delete f, x:
```

### Example 2

We use symbolic arguments:

```
f := stats::hypergeometricQuantile(N, X, n): f(x), f(9/10)
```

```
stats::hypergeometricQuantile(N, X, n)(x), stats::hypergeometricQuantile(N, X, n)($\frac{9}{10}$)
```

# stats::hypergeometricQuantile

---

When  $N$ ,  $X$  and  $n$  evaluate to suitable numbers, the function  $f$  starts to produce quantile values:

```
N := 500: X := 80: n := 18:
f(1/2), f(999/1000), f(1 - 1/10^10), f(1 - 1/10^80)
```

```
3, 8, 15, 18
```

```
delete f, N, X, n:
```

### Example 3

If one or more parameters are symbolic, usually a symbolic call is returned. Some combinations of symbolic and numeric values for  $N$ ,  $X$ ,  $n$  and  $x$ , however, may yield symbolic or numeric results:

```
f := stats::hypergeometricQuantile(N, X, n):
f(0), f(1)
```

```
0, min(X, n)
```

```
X := N - 1:
f(n/N), f(7/10)
```

```
n - 1, stats::hypergeometricQuantile(N, N - 1, n)($\frac{7}{10}$)
```

```
assume(x > n/N):
f(0.5), f(x)
```

```
stats::hypergeometricQuantile(N, N - 1, n)(0.5), n
```

```
delete f, X, x:
```

## Example 4

If floating-point arguments are passed to the quantile function, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors:

```
f := stats::hypergeometricQuantile(10000, 2000, 30):
f(1 - 1/10^18) <> f(float(1 - 1/10^18))
```

```
28 ≠ 27.0
```

```
delete f:
```

## Parameters

**N**

The “population size”: an arithmetical expression representing a positive integer

**X**

The “success population size”: an arithmetical expression representing a nonnegative integer

**n**

The “sample size”: an arithmetical expression representing a nonnegative integer

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::hypergeometricCDF | stats::hypergeometricPF |  
stats::hypergeometricRandom

# stats::hypergeometricRandom

---

**Purpose** Generate a random number generator for hypergeometric deviates

**Syntax** stats::hypergeometricRandom(N, X, n, <Seed = s>)

**Description** stats::hypergeometricRandom(N, X, n) returns a procedure that produces hypergeometric-deviates (random numbers) with population size N, success population size X and sample size n.

The procedure `f:=stats::hypergeometricRandom(N, X, n)` can be called in the form `f()`.

The return value of `f(x)` is either an integer between  $\max(0, X + n - N)$  and  $\min(X, n)$  or a symbolic expression:

If N is a positive integer and both X and n are nonnegative integers, then an explicit numerical value is returned.

If any of the parameters is symbolic, then in some cases numerical or symbolic result will be returned:

0 will be returned if either n or X is zero, n will be returned if  $N = X$  and X will be returned if  $N = n$ .

The symbolic call `stats::hypergeometricRandom(N, X, n)()` is returned in all other cases.

Numerical values for N are only accepted if they are positive integers.

Numerical values for X and n are only accepted if they are integers that satisfy  $0 \leq X, n \leq N$ .

The values  $R = f()$  are distributed randomly according to the hypergeometric distribution with population size N, success population size X and sample size n.

For any  $\max(0, X + n - N) \leq x \leq \min(X, n)$ , the probability of  $R \leq x$  is given by

$$\sum_{i=\max(0, n+X-N)}^{|x|} \frac{\binom{X}{i} \binom{N-X}{n-i}}{\binom{N}{n}}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** With this option, the parameters `N`, `X` and `n` must evaluate to suitable numerical values at the time, when the generator is created.

---

---

**Note** In contrast to the function `random`, the generators produced by `stats::hypergeometricRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::hypergeometricRandom(N, X, n): f() $k = 1..K;
```

rather than by

```
stats::hypergeometricRandom(N, X, n)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::hypergeometricRandom(N, X, n, Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

# stats::hypergeometricRandom

---

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate hypergeometric deviates with parameters  $N = 100$ ,  $X = 30$ , and  $n = 7$ :

```
f := stats::hypergeometricRandom(100, 30, 7): f() $ k = 1..10

2, 2, 6, 2, 2, 3, 0, 3, 4, 4
```

```
delete f:
```

### Example 2

With symbolic parameters, no random numbers can be produced:

```
f := stats::hypergeometricRandom(N, X, n): f()

stats::hypergeometricRandom(N, X, n)()
```

When  $N$ ,  $X$  and  $n$  evaluate to suitable numbers, the generator starts to produce random numbers:

```
N := 200: X := 80: n := 20: f() $ k= 1..10

6, 4, 12, 5, 10, 5, 11, 5, 9, 7
```

```
delete f, N, X, n:
```

### Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::hypergeometricRandom(500, 100, 50, Seed = 1): f() $ k =
```

```
6, 10, 4, 13, 8, 5, 12, 12, 11, 11
```

```
g := stats::hypergeometricRandom(500, 100, 50, Seed = 1): g() $
```

```
6, 10, 4, 13, 8, 5, 12, 12, 11, 11
```

```
f() = g(), f() = g()
```

```
5 = 5, 10 = 10
```

```
delete f, g:
```

## Parameters

**N**

The “population size”: an arithmetical expression representing a positive integer

**X**

The “success population size”: an arithmetical expression representing a nonnegative integer

**n**

The “sample size”: an arithmetical expression representing a nonnegative integer

## Options

**Seed**

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator

# stats::hypergeometricRandom

---

is initialized with the seed  $s$  which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters  $N$ ,  $X$  and  $n$  must be numerical values at the time when the random generator is generated.

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::hypergeometricCDF | stats::hypergeometricPF |  
stats::hypergeometricQuantile

**Purpose** The Kolmogorov-Smirnov goodness-of-fit test

**Syntax**

```
stats::ksGOF(x1, x2, , CDF = f)
stats::ksGOF([x1, x2,], CDF = f)
stats::ksGOF(s, <c>, CDF = f)
```

**Description** stats::ksGOF([x<sub>1</sub>, x<sub>2</sub>, ...], CDF = f) applies the Kolmogorov-Smirnov goodness-of-fit test for the null hypothesis: “x<sub>1</sub>, x<sub>2</sub>, ... is an f-distributed sample”.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

An error is raised if any of the data cannot be converted to a real floating-point number.

Let y<sub>1</sub>, ..., y<sub>n</sub> be the input data x<sub>1</sub>, ..., x<sub>n</sub> arranged in ascending order. stats::ksGOF returns the list

[PValue1 = p1, StatValue1 = K1, PValue2 = p2, StatValue2 = K2]

containing the following information:

**1** K1 is the Kolmogorov-Smirnov statistic

$$\sqrt{n} \max\left\{\frac{j}{n} - f(y_j) \mid 1 \leq j \leq n\right\}.$$

**2** p1 is the observed significance level  $e^{-2K1^2} \left(1 - \frac{2K1}{3\sqrt{n}} + \frac{2K1^2}{3n} - \frac{4K1^4}{9n}\right)$  of the statistic K1.

**3** K2 is the Kolmogorov-Smirnov statistic

$$\sqrt{n} \max\left\{f(y_j) - \frac{j-1}{n} \mid 1 \leq j \leq n\right\}.$$

**4**  $p_2$  is the observed significance level  $e^{-2K_2^2} \left( 1 - \frac{2K_2}{3\sqrt{n}} + \frac{2K_2^2}{3n} - \frac{4K_2^4}{9n} \right)$  of the statistic  $K_2$ .

For the Kolmogorov-Smirnov statistic  $K$  corresponding to  $K_1$  or  $K_2$ , respectively, the observed significance levels  $p_1$ ,  $p_2$  are computed by an asymptotic approximation of the exact probability

$$\Pr(K > k) = \frac{k}{n} \frac{1}{n - \frac{1}{2}} \left( \sum_{i=1}^{\lfloor \sqrt{n} k \rfloor} \binom{n}{i} \left( (i - \sqrt{n} k)^i (\sqrt{n} k + n - i)^{n-i-1} \right) \right)$$

For large  $n$ , these probabilities are approximated by

$$e^{-2k^2} \left( 1 - \frac{2k}{3\sqrt{n}} + \frac{2k^2}{3n} - \frac{4k^4}{9n} \right)$$

Thus, the observed significance levels returned by `stats::ksGOF` approximate the exact probabilities for large  $n$ . Roughly speaking, for  $n = 10$ , the 3 leading digits of  $p_1$ ,  $p_2$  correspond to the exact probabilities. For  $n = 100$ , the 4 leading digits of  $p_1$ ,  $p_2$  correspond to the exact probabilities. For  $n = 1000$ , the 6 leading digits of  $p_1$ ,  $p_2$  correspond to the exact probabilities.

The observed significance level `PValue1 = p1` returned by `stats::ksGOF` has to be interpreted in the following way:

Under the null hypothesis, the probability  $p_1 = \Pr(K > K_1)$  should not be small. Specifically,  $p_1 = \Pr(K > K_1) \geq \alpha$  should hold for a given significance level  $0 < \alpha < 1$ . If this condition is violated, the hypothesis may be rejected at level  $\alpha$ .

Thus, if the observed significance level  $p1 = Pr(K > K1)$  satisfies  $p1 < \alpha$ , the sample leading to the value  $K1$  of the statistic  $K$  represents an unlikely event and the null hypotheses may be rejected at level  $\alpha$ .

The corresponding interpretation holds for  $PValue2 = p2$ : if  $p2 = Pr(K > K2)$  satisfies  $p2 < \alpha$ , the null hypotheses may be rejected at level  $\alpha$ .

Note that *both* observed significance levels  $p1$ ,  $p2$  must be sufficiently large to make the data pass the test. The null hypothesis may be rejected at level  $\alpha$  if any of the two values is smaller than  $\alpha$ .

If  $p1$  and  $p2$  are both close to 1, this should raise suspicion about the randomness of the data: they indicate a fit that is *too good*.

Distributions that are not provided by the stats-package can be implemented easily by the user. A user defined procedure  $f$  can implement any cumulative distribution function; stats::ksGOF calls  $f(x)$  with real floating-point arguments from the data sample. The function  $f$  must return a numerical real value between 0 and 1. Cf. “Example 3” on page 29-295.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We create a sample of 1000 normally distributed random numbers:

```
r := stats::normalRandom(0, 1, Seed = 123):
data := [r() $ i = 1 .. 1000]:
```

We test whether these data are indeed normally distributed with mean 0 und variance 1. We pass the corresponding cumulative distribution function stats::normalCDF(0, 1) to stats::ksGOF:

```
stats::ksGOF(data, CDF = stats::normalCDF(0, 1))
```

```
[PValue1 = 0.722852785, StatValue1 = 0.397634617, PValue2 = 0.2073651285,
StatValue2 = 0.8816932145]
```

The result shows that the data can be accepted as a sample of normally distributed numbers: both observed significance levels 0.722... and 0.207... are not small.

Next, we inject some further data into the sample:

```
data := data . [frandom() $ i = 1..100]:
stats::ksGOFT(data, CDF = stats::normalCDF(0, 1))
```

```
[PValue1 = 0.7520868926, StatValue1 = 0.3724682725, PValue2 = 0.00006540335794,
StatValue2 = 2.188978212]
```

Now, the data should not be accepted as a sample of normal deviates with mean 0 and variance 1, because the second observed significance level  $PValue2 = 0.000065..$  is very small.

```
delete r, data:
```

## Example 2

We create a sample consisting of one string column and two non-string columns:

```
s := stats::sample(
 [{"1996", 1242, PI - 1/2}, {"1997", 1353, PI + 0.3},
 {"1998", 1142, PI + 0.5}, {"1999", 1201, PI - 1},
 {"2001", 1201, PI}])
```

```
"1996" 1242 PI - 1/2
"1997" 1353 PI + 0.3
"1998" 1142 PI + 0.5
```

```
"1999" 1201 PI - 1
"2001" 1201 PI
```

We consider the data in the third column. The mean and the variance of these data are computed:

```
[m, v] := [stats::mean(s, 3), stats::variance(s, 3)]
```

```
[π - 0.14, 0.373]
```

We check whether the data of the 3rd column are normally distributed with the mean and variance computed above:

```
stats::ksGOF(s, 3, CDF = stats::normalCDF(m, v))
```

```
[PValue1 = 0.7366062033, StatValue1 = 0.3294603834, PValue2 = 0.6216810571,
StatValue2 = 0.4263183582]
```

Both observed significance levels 0.736... and 0.621... returned by the test are not small. There is no reason to reject the null hypothesis that the data are normally distributed.

```
delete s, m, v:
```

### Example 3

We demonstrate how user-defined distribution functions can be used. The following function represents the cumulative distribution function  $Pr(X \leq x) = x^2$  of a variable  $X$  supported on the interval  $[0, 1]$ . It will be called with floating-point arguments  $x$  and must return numerical values between 0 and 1:

```
f := proc(x)
begin
```

```
 if x <= 0 then return(0)
 elif x < 1 then return(x^2)
 else return(1)
 end_if
end_proc:
```

We test the hypothesis that the following data are  $f$ -distributed:

```
data := [sqrt(frando()) $ k = 1..10^2]:
stats::ksGOFT(data, CDF = f)
```

```
[PValue1 = 0.366526126, StatValue1 = 0.692353403, PValue2 = 0.8844815733,
 StatValue2 = 0.2318684139]
```

At a given significance level of 0.1, say, the hypothesis should not be rejected: both observed significance levels  $p_1 = 0.366\dots$  and  $p_2 = 0.884\dots$  exceed 0.1.

```
delete f, data:
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: real numerical values

**f**

A procedure representing a cumulative distribution function. Typically, one of the distribution functions of the stats-package such as `stats::normalCDF(n, v)` etc.

**s**

A sample of domain type `stats::sample`

**c**

An integer representing a column index of the sample  $s$ . This column provides the data  $x_1, x_2$  etc. There is no need to specify a column number  $c$  if the sample has only one column.

**Return Values**

List with four equations [PValue1 =  $p_1$ , StatValue1 =  $K_1$ , PValue2 =  $p_2$ , StatValue2 =  $K_2$ ], with floating-point values  $p_1, K_1, p_2, K_2$ . See the “Details” section below for the interpretation of these values.

`stats::csGOFT` | `stats::sample` | `stats::swGOFT` | `stats::tTest`

# stats::kurtosis

---

**Purpose** Kurtosis (excess) of a data sample

**Syntax**  
`stats::kurtosis(x1, x2, ...)`  
`stats::kurtosis([x1, x2, ...], c)`  
`stats::kurtosis(s, <c>)`

**Description** `stats::kurtosis(x1, x2, ..., xn)` returns the kurtosis (the coefficient of excess)

$$\frac{\frac{1}{n} \left( \sum_{i=1}^n (X_i - \bar{X})^4 \right)}{\left( \frac{1}{n} \left( \sum_{i=1}^n (X_i - \bar{X})^2 \right) \right)^2} - 3$$

where  $\bar{X}$  is the mean of the data  $x_i$ .

The kurtosis measures whether a distribution is “flat” or “peaked”. For normally distributed data, the kurtosis is zero. If the distribution function of the data has a flatter top than the normal distribution, then the kurtosis is negative. The kurtosis is positive, if the distribution function has a high peak compared to the normal distribution.

The column index `c` is optional, if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-299.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We calculate the kurtosis of some values:

```
stats::kurtosis(0, 7, 7, 6, 6, 6, 5, 5, 4, 1)
```

$$- \frac{74146}{271441}$$

Alternatively, data may be passed as a list:

```
stats::kurtosis([2, 2, 4, 6, 8, 10, 10])
```

$$- \frac{85}{54}$$

## Example 2

We create a sample:

```
stats::sample([[a, 5, 8], [b, 3, 7], [c, d, 0]])
```

```
a 5 8
b 3 7
c d 0
```

The kurtosis of the second column is:

```
stats::kurtosis(%, 2)
```

$$\frac{3 \left(\frac{d}{3} - \frac{1}{3}\right)^4 + 3 \left(\frac{d}{3} - \frac{7}{3}\right)^4 + 3 \left(\frac{2d}{3} - \frac{8}{3}\right)^4}{\left(\left(\frac{d}{3} - \frac{1}{3}\right)^2 + \left(\frac{d}{3} - \frac{7}{3}\right)^2 + \left(\frac{2d}{3} - \frac{8}{3}\right)^2\right)^2} - 3$$

## Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample(["1996", 1242], ["1997", 1353], ["1998", 1142])
```

# stats::kurtosis

---

```
"1996" 1242
"1997" 1353
"1998" 1142
```

We compute the kurtosis of the second column. In this case this column does not have to be specified, since it is the only non-string column:

```
stats::kurtosis(%)
```

```
 $-\frac{3}{2}$
```

## Parameters

$x_1, x_2, \dots$

The statistical data: arithmetical expressions.

**s**

A sample of domain type `stats::sample`.

**c**

An integer representing a column index of the sample **s**. This column provides the data  $x_1, x_2$  etc.

## Return Values

Arithmetical expression. FAIL is returned, if the kurtosis does not exist.

## See Also

## MuPAD Functions

`stats::obliquity`

**Purpose**

Linear regression (least squares fit)

**Syntax**

```
stats::linReg([x1, x2,], [y1, y2,], <[w1, w2,
]>, <CovarianceMatrix>)
stats::linReg([[x1, y1, <w1>], [x2, y2, <w2>],],
 <CovarianceMatrix>)
stats::linReg(s, <cx, cy, <cw>>, <CovarianceMatrix>)
stats::linReg(s, <[cx, cy, <cw>]>, <CovarianceMatrix>)
```

**Description**

stats::linReg([x<sub>1</sub>, x<sub>2</sub>, ], [y<sub>1</sub>, y<sub>2</sub>, ], [w<sub>1</sub>, w<sub>2</sub>, ]) computes the least squares estimators *a*, *b* of a linear relation  $y_i = a + bx_i$  between the data pairs  $(x_i, y_i)$  by minimizing

$$\chi^2 = \sum_i w_i |y_i - a - b x_i|^2$$

A linear relation  $y_i = a + bx_i + e_i$  between the data pairs  $(x_i, y_i)$  is assumed.

The column indices cx, cy are optional if the data are given by a stats::sample object containing only two non-string columns. Cf. “Example 2” on page 29-303.

Multivariate linear regression and non-linear regression is provided by stats::reg.

External statistical data stored in an ASCII file can be imported into a MuPAD session via import::readdata. In particular, see Example 1 of the corresponding help page.

**Examples**

**Example 1**

We calculate the least square estimators of four pairs of values given in two lists. Note that there is a linear relation  $y = 1 + 2x$  between the entries of the lists. The minimized quadratic deviation is 0 indicating a perfect fit:

## stats::linReg

---

```
stats::linReg([0, 1, 2, 3], [1, 3, 5, 7])
```

```
[[1, 2], 0]
```

Alternatively, data may be specified by a list of pairs:

```
stats::linReg([[1, 1.0], [2, 1.2], [3, 1.3], [4, 1.5]])
```

```
[[0.85, 0.16], 0.002]
```

We assume that the variable  $y$  in the previous example is Poissonian, i.e. that the measurements  $(y_i) = (1.0, 1.2, 1.3, 1.5)$  have errors given by the standard deviation  $\sigma(y_i) = \sqrt{y_i}$ . We provide corresponding

weights  $w_i = \frac{1}{\sigma(y_i)^2} = \frac{1}{y_i}$  and estimate confidence intervals for the least squares estimators by using the option `CovarianceMatrix`:

```
stats::linReg([[1, 1.0, 1/1.0], [2, 1.2, 1/1.2],
 [3, 1.3, 1/1.3], [4, 1.5, 1/1.5]], CovarianceMatrix)
```

```
[[0.8491476359, 0.1601801222], 0.001608234159, (1.650048247 -0.5751045352)
 [-0.5751045352 0.2460598263]]
```

The square roots of the diagonal elements of the covariance matrix provide standard deviations for the estimated parameters:

```
sqrt(%[3][1,1]), sqrt(%[3][2,2])
```

```
1.284542038, 0.4960441778
```

Thus, we obtain the estimates  $a \pm \sigma(a) = 0.849 \pm 1.28$ ,  
 $b \pm \sigma(b) = 0.16 \pm 0.496$ .

### Example 2

We create a sample consisting of one string column and two non-string columns:

```
stats::sample(["1", 0, 0], ["2", 10, 15], ["3", 20, 30])
```

```
"1" 0 0
"2" 10 15
"3" 20 30
```

The least square estimators are calculated using the data columns 2 and 3. In this example there are only two non-string columns, so the column indices do not have to be specified:

```
stats::linReg(%)
```

```
[[0, 3/2], 0]
```

### Example 3

We create a sample consisting of three data columns:

```
stats::sample([1, 0, 0], [2, 10, 15], [3, 20, 30])
```

```
1 0 0
2 10 15
3 20 30
```

We compute the least square estimators for the data pairs given by the first and the second column:

```
stats::linReg(%, 1, 2)
```

```
[[-10, 10], 0]
```

## Example 4

We create a sample of three columns containing symbolic data:

```
stats::sample([[x, y, 0], [2, 4, 15], [3, 20, 30]])
```

```
x y 0
2 4 15
3 20 30
```

We compute the symbolic least square estimators for the data pairs given by the first and the second column. Here we specify these columns by a list of column indices:

```
map(stats::linReg(%, [1, 2], CovarianceMatrix), normal)
```

$$\left[ \begin{array}{c} -\frac{68x - 13y + 5xy - 24x^2 + 28}{2(x^2 - 5x + 7)}, -\frac{24x + 5y - 2xy - 84}{2(x^2 - 5x + 7)}, \frac{256x^2 - 32xy - 896x + y^2}{2(x^2 - 5x + 7)} \\ \left( \begin{array}{cc} \frac{x^2 + 13}{2(x^2 - 5x + 7)} & -\frac{x + 5}{2(x^2 - 5x + 7)} \\ -\frac{x + 5}{2(x^2 - 5x + 7)} & \frac{3}{2(x^2 - 5x + 7)} \end{array} \right) \end{array} \right]$$

### Example 5

We create data  $(x_i, y_i)$  with a randomized relation  $y_i = a + bx_i$ :

```
DIGITS := 5:
r := stats::normalRandom(0, 5):
X := [i $ i = 0..100]:
Y := [12 + 17*x + r() $ x in X]:
```

By construction, the variances  $\sigma(y_i)^2$  for the data  $y_i$  in the list Y is 5. We

use the weights  $W_i = \frac{1}{\sigma(y_i)^2} = \frac{1}{5}$  for all data:

```
W := [1/5 $ i = 0..100]:
[ab, chisquared, C] := stats::linReg(X, Y, W, CovarianceMatrix)
```

$$\left[ [12.065, 16.998], 87.997, \begin{pmatrix} \frac{335}{1717} & -\frac{5}{1717} \\ -\frac{5}{1717} & \frac{1}{1717} \end{pmatrix} \right]$$

The standard deviations of the estimators  $a, b$  are the square roots of the diagonal elements of C:

```
sqrt(float(C[1,1])), sqrt(float(C[2,2]))
```

```
0.44171, 0.0076316
```

Thus, the estimate for  $a$  is  $a \pm \sigma(a) \approx 11.93 \pm 0.44$ , the estimate for  $b$  is  $b \pm \sigma(b) \approx 17.003 \pm 0.0076$ .

```
delete r, X, Y, W, ab, chisquared, C:
```

## Parameters

**$x_1, x_2, \dots$**

Statistical data: arithmetical expressions

**$y_1, y_2, \dots$**

Statistical data: arithmetical expressions

**$w_1, w_2, \dots$**

Weights: arithmetical expressions. If no weights are provided,  $w_1 = w_2 = \dots = 1$  is used.

**$s$**

A sample of domain type `stats::sample`.

**$cx, cy, cw$**

Integers representing column indices of the sample  $s$ . Column  $cx$  provides the data  $x_1, x_2, \dots$ , column  $cy$  provides the data  $y_1, y_2, \dots$ . Column  $cw$ , if present, provides the weights  $w_1, w_2, \dots$ . If no index for the weights is provided,  $w_1 = w_2 = \dots = 1$  is used.

## Options

**CovarianceMatrix**

Changes the return value from `[[a, b], chisquared]` to `[[a, b], chisquared, C]`, where  $C$  is the covariance matrix

$$\begin{pmatrix} \sigma(a)^2 & \text{cov}(a, b) \\ \text{cov}(a, b) & \sigma(b)^2 \end{pmatrix}$$

Of the estimators  $a, b$ .

With this option, information on confidence intervals for the least squares estimators are provided. In particular, the return value includes the covariance matrix

$$\begin{pmatrix} \sigma(a)^2 & \text{cov}(a, b) \\ \text{cov}(a, b) & \sigma(b)^2 \end{pmatrix}$$

Of type `Dom::Matrix()`. Assuming that the data ( $y_i$ ) are randomly perturbed with stochastic variations  $\sigma(y_i)^2$ , the quadratic error to be minimized is

$$\chi^2 = \sum_i w_i |y_i - a - b x_i|^2$$

With

$$w_i = \frac{1}{\sigma(y_i)^2}$$

The covariance matrix of the least squares estimators is given by

$$\sigma(a)^2 = \frac{\sum_i w_i x_i^2}{(\sum_i w_i) (\sum_i w_i x_i^2) - (\sum_i w_i x_i)^2}$$

$$\sigma(b)^2 = \frac{\sum_i w_i}{(\sum_i w_i) (\sum_i w_i x_i^2) - (\sum_i w_i x_i)^2}$$

$$\text{cov}(a, b) = \frac{\sum_i w_i x_i}{(\sum_i w_i) (\sum_i w_i x_i^2) - (\sum_i w_i x_i)^2}$$

## Return Values

Without the option `CovarianceMatrix`, a list `[[a, b], chisquared]` is returned. The arithmetical expressions  $a$  and  $b$  are estimators of the the offset and the slope of the linear relation. The arithmetical expression `chisquared` is the quadratic deviation

$$\chi^2 = \sum_i w_i |y_i - a - b x_i|^2$$

where  $a$ ,  $b$  are the optimized estimators.

With the option `CovarianceMatrix`, a list `[[a, b], chisquared, C]` is returned. The matrix `C` is the covariance matrix of the optimized estimators  $a$  and  $b$ .

`FAIL` is returned if the estimators  $a$  and  $b$  do not exist.

### MuPAD Functions

stats::reg | stats::sample

### MuPAD Graphical Primitives

plot::Scatterplot

# stats::logisticCDF

---

**Purpose** Cumulative distribution function of the logistic distribution

**Syntax** stats::logisticCDF(m, s)

**Description** stats::logisticCDF(m, s) returns a procedure representing the cumulative distribution function

$$x \rightarrow \frac{1}{2} \left( 1 + \tanh \left( \frac{\pi (x - m)}{2 \sqrt{3} s} \right) \right)$$

of the logistic distribution with mean  $m$  and standard deviation  $s > 0$  as a procedure.

The procedure `f := stats::logisticCDF(m, s)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x$  is a floating-point number and  $m$  and  $s$  can be converted to floating-point numbers, then `f(x)` returns a floating-point number between 0.0 and 1.0.

The call `f(-infinity)` returns 0; the call `f(infinity)` returns 1.

In all other cases, the expression  $1/2*(1 + \tanh(\pi*(x - m)/(2*\sqrt{3}*s)))$  is returned symbolically.

Numerical values for  $m$  and  $s$  are only accepted if they are real and  $s$  is positive.

**Environment Interactions** The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

**Examples** **Example 1**

We evaluate the cumulative distribution function with  $m = 0$  and  $s = 1$  at various points:

```
f := stats::logisticCDF(0, 1):
f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)
```

$$0, \frac{1}{2} - \frac{\tanh\left(\frac{\pi\sqrt{3}}{2}\right)}{2}, 0.7123653231, \frac{\tanh\left(\frac{\pi\sqrt{3}}{9}\right)}{2} + \frac{1}{2}, \frac{\tanh\left(\frac{\sqrt{3}\pi^2}{6}\right)}{2} + \frac{1}{2}, 1$$

```
delete f:
```

## Example 2

We use symbolic arguments:

```
f := stats::logisticCDF(m, s): f(x)
```

$$\frac{1}{2} - \frac{\tanh\left(\frac{\pi\sqrt{3}(m-x)}{6s}\right)}{2}$$

When numerical values are assigned to  $m$  and  $s$ , the function  $f$  starts to produce numerical values:

```
m := 0: s := 1: f(3), f(3.0)
```

$$\frac{\tanh\left(\frac{\pi\sqrt{3}}{2}\right)}{2} + \frac{1}{2}, 0.995685277$$

## MuPAD Functions

`stats::logisticPDF` | `stats::logisticQuantile` |  
`stats::logisticRandom`

<b>Purpose</b>	Probability density function of the logistic distribution
<b>Syntax</b>	<code>stats::logisticPDF(m, s)</code>
<b>Description</b>	<code>stats::logisticPDF(m, s)</code> returns the probability density function

$$x \rightarrow \frac{\pi}{4 s \sqrt{3}} \operatorname{sech}\left(\frac{\pi (x - m)}{4 \sqrt{3} s}\right)^2$$

of the logistic distribution with mean  $m$  and standard deviation  $s > 0$ .

The procedure `f := stats::logisticPDF(m, s)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x$  is a floating-point number and  $m$  and  $s$  can be converted to floating-point numbers, then `f(x)` returns a positive floating-point number.

`f(infinity)` and `f(-infinity)` return 0.

In all other cases, the expression  $\frac{\pi}{4 s \sqrt{3}} \operatorname{sech}\left(\frac{\pi (x - m)}{4 \sqrt{3} s}\right)^2$  is returned symbolically.

Numerical values for  $m$  and  $s$  are only accepted if they are real and  $s$  is positive.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the probability density function with  $m = 0$  and  $s = 1$  at various points:

```
f := stats::logisticPDF(0, 1): f(1/2), f(0.5), f(x)
```

# stats::logisticPDF

---

$$\frac{\pi \sqrt{3}}{12 \cosh\left(\frac{\pi \sqrt{3}}{12}\right)^2}, 0.3716492483, \frac{\pi \sqrt{3}}{12 \cosh\left(\frac{\pi \sqrt{3} x}{6}\right)^2}$$

delete f:

## Example 2

We use symbolic arguments:

```
f := stats::logisticPDF(m, s): f(x), f(3)
```

$$\frac{\pi \sqrt{3}}{12 s \cosh\left(\frac{\pi \sqrt{3} (m-x)}{6 s}\right)^2}, \frac{\pi \sqrt{3}}{12 s \cosh\left(\frac{\pi \sqrt{3} (m-3)}{6 s}\right)^2}$$

When numerical values are assigned to  $m$  and  $s$ , the function  $f$  starts to produce numerical values:

```
m := 0: s := 1: f(3), f(3.0)
```

$$\frac{\pi \sqrt{3}}{12 \cosh\left(\frac{\pi \sqrt{3}}{2}\right)^2}, 0.007792274633$$

delete f, m, s:

## Parameters

**m**

The mean: an arithmetical expression representing a real value

**s**

The standard deviation: an arithmetical expression representing a positive real value

## Return Values

procedure.

## MuPAD Functions

stats::logisticCDF | stats::logisticQuantile |  
stats::logisticRandom

# stats::logisticQuantile

---

**Purpose** Quantile function of the logistic distribution

**Syntax** stats::logisticQuantile(*m*, *s*)

**Description** stats::logisticQuantile(*m*, *s*) returns a procedure representing the quantile function (inverse)

$$x \rightarrow m + \frac{\sqrt{3} s}{\pi} \ln\left(\frac{x}{1-x}\right)$$

of the cumulative distribution function stats::logisticCDF(*m*, *s*). For  $0 \leq x \leq 1$ , the solution of stats::logisticCDF(*m*, *s*)(*y*) = *x* is given by

$$y = \text{stats::logisticQuantile}(m, s)(x)$$

The procedure `f := stats::logisticQuantile(m, s)` can be called in the form `f(x)` with an arithmetical expression *x*. The return value of `f(x)` is either a floating-point number, `±infinity`, or a symbolic expression:

The call `f(x)` returns a real floating-point number if *x* is a floating-point number between 0.0 and 1.0, *m* can be converted to a real floating-point number, and *s* can be converted to a positive real floating-point number.

The calls `f(0)` and `f(0.0)` produce `-infinity`; the calls `f(1)` and `f(1.0)` produce `infinity`.

In all other cases, the symbolic expression  $m + \frac{\sqrt{3} s \ln(x/(1-x))}{\pi}$  is returned.

Numerical values of *x* are only accepted if  $0 \leq x \leq 1$ .

Numerical values of *m* and *s* are only accepted if they are real and *s* is positive.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with mean  $m = 0$  and standard deviation  $s = 1$  at various points:

```
f := stats::logisticQuantile(0, 1):
f(0), f(1/10), f(0.7), f(0.999999999), f(1)

-∞, - $\frac{\sqrt{3} \ln(9)}{\pi}$, 0.4671397935, 11.42533526, ∞
```

The value  $f(x)$  satisfies  $\text{stats::logisticCDF}(0, 1)(f(x)) = x$ :

```
stats::logisticCDF(0, 1)(f(0.987654321))

0.987654321
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::logisticQuantile(m, s): f(x), f(1/3), f(0.4)

 $m + \frac{\sqrt{3} s \ln\left(-\frac{x}{x-1}\right)}{\pi}$, $m - \frac{\sqrt{3} s \ln(2)}{\pi}$, $m - 0.2235446302 s$
```

When suitable numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

# stats::logisticQuantile

---

```
m := 0: s := 1: f(0.999), f(999/1000)
```

```
3.807893483, $\frac{\sqrt{3} \ln(999)}{\pi}$
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

```
0.0
```

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f, m, s:
```

## Parameters

**m**

The mean: an arithmetical expression representing a real value

**s**

The standard deviation: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::logisticCDF | stats::logisticPDF |  
stats::logisticRandom

**Purpose**

Generate a random number generator for logistic deviates

**Syntax**

`stats::logisticRandom(m, s, <Seed = s>)`

**Description**

`stats::logisticRandom(m, s)` returns a procedure that produces logistic deviates (random numbers) with mean  $m$  and standard deviation  $b > 0$ .

The procedure `f := stats::logisticRandom(m, s)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If  $m$  can be converted to a floating-point number and  $s$  can be converted to a positive floating point number, then `f(x)` returns a real floating point number.

Otherwise, `stats::logisticRandom(m, s)()` is returned symbolically.

Numerical values of  $m$  and  $s$  are only accepted if they are real and  $s$  is positive.

The values  $X = f()$  are distributed randomly according to the logistic distribution with mean  $m$  and standard deviation  $s$ . For any real  $x$ , the probability that  $X \leq x$  is given by

$$\frac{1 + \tanh\left(\frac{\pi (x-m)}{2 \sqrt{3} s}\right)}{2}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::logisticRandom` do not react to the environment variable `SEED`.

---

# stats::logisticRandom

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::logisticRandom(m, s): f() $k = 1..K;
```

rather than by

```
stats::logisticRandom(m, s)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::logisticRandom(m, s, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate logistic deviates with mean  $m = 0$  and standard deviation  $s = 1$ :

```
f := stats::logisticRandom(0, 1): f() $ k = 1..4
```

```
- 0.5473627217, 0.8782646344, - 0.9428030153, 2.897981396
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::logisticRandom(m, s): f()
```

```
stats::logisticRandom(m, s)()
```

When numbers are assigned to `m` and `s`, the function `f` starts to produce random floating point numbers:

```
m := PI: s := 1/8: f() $ k = 1..4
```

```
3.071738219, 3.037168533, 3.128342993, 3.193154296
```

```
delete f, m, s:
```

### Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::logisticRandom(PI, 3, Seed = 1): f() $ k = 1..4
```

```
3.590026186, 5.349173335, -0.228813398, 0.5644575096
```

```
g := stats::logisticRandom(PI, 3, Seed = 1): g() $ k = 1..4
```

```
3.590026186, 5.349173335, -0.228813398, 0.5644575096
```

```
f() = g(), f() = g()
```

```
5.811492258 = 5.811492258, -6.396713726 = -6.396713726
```

```
delete f, g:
```

## Parameters

**m**

The mean: an arithmetical expression representing a real value

# stats::logisticRandom

---

**s**

The standard deviation: an arithmetical expression representing a positive real value

## Options

### Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `m` and `s` must be convertible to floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of the logistic deviates uses the quantile function of the logistic distribution applied to uniformly distributed random numbers on the interval  $[0, 1)$ .

## See Also

## MuPAD Functions

`stats::logisticCDF` | `stats::logisticPDF` |  
`stats::logisticQuantile`

**Purpose** Cumulative distribution function of the log-normal distribution

**Syntax** `stats::lognormalCDF(m, v)`

**Description** `stats::lognormalCDF(m, v)` returns a procedure representing the cumulative distribution function

$$X \rightarrow \frac{1}{\sqrt{2\pi v}} \int_{-\infty}^x e^{-\frac{\ln(t-m)^2}{2v}} dt$$

of the log-normal distribution with location parameter  $m$  and shape parameter  $v$ .

A random variable  $X$  is log-normally distributed if  $\ln(X)$  is a normally distributed variable. The “location parameter”  $m$  of  $X$  is the mean of  $\ln(X)$  and the “shape parameter”  $v$  is the variance of  $\ln(X)$ .

The procedure `f := stats::lognormalCDF(m, v)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The value

$$\frac{1}{2} + \frac{\operatorname{erf}\left(\frac{\ln(x)-m}{\sqrt{2v}}\right)}{2}$$

is returned.

If  $x$  is a floating-point number and both  $m$  and  $v$  can be converted to floating-point numbers, this value is returned as a floating-point number. Otherwise, a symbolic expression is returned.

Numerical values for  $m$  and  $v$  are only accepted if they are real and  $v$  is positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

# stats::lognormalCDF

---

## Examples

### Example 1

We evaluate the CDF of a lognormal distribution for some arbitrary parameter values:

```
f := stats::lognormalCDF(1/2, 3/4):
f(0.1), f(10.3)
```

```
0.0006057758986, 0.9828096232
```

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::lognormalCDF(m, v):
f(3), f(x)
```

$$\frac{1}{2} - \frac{\operatorname{erf}\left(\frac{\sqrt{2}(m - \ln(3))}{2\sqrt{v}}\right)}{2}, \frac{1}{2} - \frac{\operatorname{erf}\left(\frac{\sqrt{2}(m - \ln(x))}{2\sqrt{v}}\right)}{2}$$

When numerical values are assigned to  $m$  and  $v$ , the function  $f$  starts to produce numerical values:

```
m := 4: v := PI:
f(3), f(3.0)
```

$$\frac{\operatorname{erf}\left(\frac{\sqrt{2}(\ln(3) - 4)}{2\sqrt{\pi}}\right)}{2} + \frac{1}{2}, 0.05082226366$$

```
delete f, m, v:
```

### Example 3

From the definition of “lognormal” above it is clear that the probability of  $X < 0$  is zero for  $X$  lognormally distributed:

```
plotfunc2d(stats::lognormalCDF(0,1))
```

The following plot shows the influence of the shape parameter on the shape of the lognormal distribution:

```
f03 := stats::lognormalCDF(0, 0.3):
f1 := stats::lognormalCDF(0, 1):
f3 := stats::lognormalCDF(0, 3):
f9 := stats::lognormalCDF(0, 9):
plotfunc2d(f03, f1, f3, f9, x = 0..10)
```

# stats::lognormalCDF

As for the normal distribution, a larger value of the shape parameter stretches the lognormal distribution, also changing its shape in the process:

```
plotfunc2d(stats::lognormalCDF(m, 1)$ m = 0..2 step .1,
 LegendVisible = FALSE)
```

## Parameters

**m**

The location parameter: an arithmetical expression representing a real value

**v**

The shape parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

`erf` | `stats::normalCDF` | `stats::lognormalPDF` |  
`stats::lognormalQuantile` | `stats::lognormalRandom`

# stats::lognormalPDF

---

**Purpose** Probability density function of the log-normal distribution

**Syntax** stats::lognormalPDF(m, v)

**Description** stats::lognormalPDF(m, v) returns a procedure representing the probability density function

$$X \rightarrow \frac{e^{-\frac{(\ln(x)-m)^2}{2v}}}{\sqrt{2\pi vx}}$$

of the lognormal distribution with location parameter  $m$  and shape parameter  $v$ .

A random variable  $X$  is log-normally distributed if  $\ln(X)$  is a normally distributed variable. The “location parameter”  $m$  of  $X$  is the mean of  $\ln(X)$  and the “shape parameter”  $v$  is the variance of  $\ln(X)$ .

The procedure `f := stats::lognormalPDF(m, v)` can be called in the

form `f(x)` with an arithmetical expression  $x$ . The value  $\frac{e^{-\frac{(\ln(x)-m)^2}{2v}}}{\sqrt{2\pi vx}}$  is returned.

If  $x$  is a floating-point number and both  $m$  and  $v$  can be converted to floating-point numbers, this value is returned as a floating-point number. Otherwise, a symbolic expression is returned.

Numerical values for  $m$  and  $v$  are only accepted if they are real and  $v$  is positive.

**Environment Interactions** The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We compute the probability density with location parameter  $m = 2$  and shape parameter  $v = 4$  at various points:

```
f := stats::lognormalPDF(2, 4):
f(-infinity), f(-3), f(2.0), f(PI), f(infinity)
```

$$0, 0, 0.08056298881, \frac{\sqrt{2} e^{-\frac{(\ln(\pi)-2)^2}{8}}}{4 \pi^{3/2}}, 0$$

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::lognormalPDF(m, v):
f(x), f(0.4)
```

$$\frac{\sqrt{2} e^{-\frac{(m-\ln(x))^2}{2v}}}{2\sqrt{\pi}\sqrt{v}x}, \frac{1.25\sqrt{2} e^{-\frac{(m+0.9162907319)^2}{2v}}}{\sqrt{\pi}\sqrt{v}}$$

When numerical values are assigned to  $m$  and  $v$ , the function  $f$  starts to produce numerical values:

```
m := PI: v := 2:
f(3), f(3.0)
```

# stats::lognormalPDF

---

$$\frac{e^{-\frac{(\pi - \ln(3))^2}{4}}}{6\sqrt{\pi}}, 0.03312170057$$

delete f, m, v:

## Example 3

The following plot shows the influence of the shape parameter on the log-normal distribution:

```
plotfunc2d(stats::lognormalPDF(1, 0.25)(x),
 stats::lognormalPDF(1, 0.5)(x),
 stats::lognormalPDF(1, 1)(x),
 stats::lognormalPDF(1, 2)(x),
 stats::lognormalPDF(1, 4)(x),
 stats::lognormalPDF(1, 8)(x),
 x = -0.5 .. 4, ViewingBoxYRange = 0 .. 1.1,
 LegendVisible = FALSE)
```

Due to its logarithmic influence, the location parameter changes the shape of the distribution, too:

```
plotfunc2d(stats::lognormalPDF(m, 0.5)(x) $ m = 0.5..2 step 0.5,
 x = -0.5 ..4, ViewingBoxYRange = 0 .. 0.5,
 LegendVisible = FALSE)
```

# stats::lognormalPDF

---

## Parameters

**m**

The location parameter: an arithmetical expression representing a real value

**v**

The shape parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

`exp` | `stats::normalPDF` | `stats::lognormalCDF` |  
`stats::lognormalQuantile` | `stats::lognormalRandom`

## Purpose

Quantile function of the log-normal distribution

## Syntax

```
stats::lognormalQuantile(m, v)
```

## Description

`stats::normalQuantile(m, v)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::lognormalCDF(m, v)` of the log-normal distribution with location parameter  $m$  and shape parameter  $v > 0$ : For  $0 \leq x \leq 1$ , the solution of `stats::lognormalCDF(m, v)(y) = x` is given by  $y = \text{stats::lognormalQuantile}(m, v)(x)$ .

The procedure `f := stats::lognormalQuantile(m, v)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number, 0, `infinity`, or a symbolic expression:

If  $x$  is a real number between 0 and 1 and both  $m$  and  $v$  can be converted to floating-point numbers, then `f(x)` returns a real floating-point number approximating the solution  $y$  of `stats::lognormalCDF(m, v)(y) = x`.

The call `f(0)` returns 0.

The calls `f(1)` and `f(1.0)` produce `infinity` for all values of  $m$  and  $v$ .

In all other cases, `f(x)` returns the symbolic call `stats::lognormalQuantile(m, v)(x)`.

Numerical values for  $m$  and  $v$  are only accepted if they are real and  $v$  is positive.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with location parameter  $m = \pi$  and shape parameter  $v = 11$  at various points:

```
f := stats::lognormalQuantile(PI, 11):
```

# stats::lognormalQuantile

---

```
f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)
```

```
0, 0.3299437681, 23.14069263, 33666650688.0, ∞
```

The value  $f(x)$  satisfies  $\text{stats::lognormalCDF}(\text{PI}, 11)(f(x)) = x$ :

```
stats::lognormalCDF(PI, 11)(f(0.987654))
```

```
0.987654
```

```
delete f:
```

## Example 2

We use symbolic arguments:

```
f := stats::lognormalQuantile(m, v):
f(x), f(9/10)
```

```
stats::lognormalQuantile(m, v)(x), stats::lognormalQuantile(m, v)($\frac{9}{10}$)
```

When numerical values are assigned to  $m$  and  $v$ , the function  $f$  starts to produce floating-point values:

```
m := 17: v := 6:
f(9/10), f(0.999)
```

```
557597210.5, 46816069055.0
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

```
24154952.75
```

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f, m, v:
```

## Parameters

**m**

The location parameter: an arithmetical expression representing a real value

**v**

The shape parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::lognormalCDF | stats::lognormalPDF |  
stats::lognormalRandom

# stats::lognormalRandom

---

**Purpose** Generate a random number generator for log-normal deviates

**Syntax** stats::lognormalRandom(*m*, *v*, <Seed = *s*>)

**Description** stats::normalRandom(*m*, *v*) returns a procedure that produces lognormal deviates (random numbers) with location parameter *m* and shape parameter *v* > 0.

A random variable *X* is log-normally distributed if  $\ln(X)$  is a normally distributed variable. The “location parameter” *m* of *X* is the mean of  $\ln(X)$  and the “shape parameter” *v* is the variance of  $\ln(X)$ .

The procedure  $f := \text{stats::lognormalRandom}(m, v)$  can be called in the form  $f()$ . The return value of  $f()$  is either a floating-point number or a symbolic expression:

If *m* and *v* can be converted to floating-point numbers,  $f()$  returns a real floating point number. Otherwise, the symbolic call  $\text{stats::lognormalRandom}(m, v)()$  is returned.

Numerical values of *m* and *v* are only accepted if they are real and *v* is positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the log-normal distribution with parameters *m* and *v*. For any real *x*, the probability that  $X \leq x$  is given by

$$\frac{1}{2} + \frac{\text{erf}\left(\frac{\ln(x)-m}{\sqrt{2v^3}}\right)}{2}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::normalRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via `f := stats::lognormalRandom(m, v): f() $k = 1..K` rather than by `stats::lognormalRandom(m, v)() $k = 1..K`. The latter call produces a sequence of generators each of which is called once. Also note that `stats::lognormalRandom(m, v, Seed = n)() $k = 1..K` does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We generate log-normal deviates with location parameter 2 and shape parameter  $\frac{3}{4}$ :

```
f := stats::normalRandom(2, 3/4):
f() $ k = 1..4
```

```
1.541231663, 1.506864857, 1.553005641, 1.055326957
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::lognormalRandom(m, v):
f()
```

# stats::lognormalRandom

---

```
stats::lognormalRandom(m, v())
```

When *m* and *v* evaluate to real numbers, `f` starts to produce random floating point numbers:

```
m := PI/10: v := 1/8:
f() $ k = 1..4
```

```
2.57120706, 1.714950915, 1.747513452, 1.543972889
```

```
delete f, m, v:
```

## Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::lognormalRandom(1, 3, Seed = 1):
f() $ k = 1..4
```

```

```

```
delete f, g:
```

## Parameters

**m**

The location parameter: an arithmetical expression representing a real value

**v**

The shape parameter: an arithmetical expression representing a positive real value

## Options

**Seed**

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `m` and `v` must be convertible to suitable floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implementation uses `stats::normalRandom`.

## MuPAD Functions

`stats::lognormalCDF` | `stats::lognormalPDF` |  
`stats::lognormalQuantile`

# stats::mean

---

**Purpose** Arithmetic mean of a data sample

**Syntax**  
`stats::mean(x1, x2, ...)`  
`stats::mean([x1, x2, ...])`  
`stats::mean(s, <c>)`

**Description** `stats::mean(x1, x2, ..., xn)` returns the arithmetic mean  $\frac{1}{n} \left( \sum_{i=1}^n x_i \right)$  of the data  $x_i$ .

The column index `c` is optional if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-341.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We calculate the arithmetic mean of three values:

```
stats::mean(a, b, c)
```

$$\frac{a}{3} + \frac{b}{3} + \frac{c}{3}$$

Alternatively, data may be passed as a list:

```
stats::mean([2, 3, 5])
```

$$\frac{10}{3}$$

### Example 2

We create a sample:

```
stats::sample([[a1, b1, c1], [a2, b2, c2]])
```

```
a1 b1 c1
a2 b2 c2
```

The arithmetic mean of the second column is:

```
stats::mean(%, 2)
```

$$\frac{b1}{2} + \frac{b2}{2}$$

### Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample(["1996", 1242], ["1997", 1353], ["1998", 1142])
```

```
"1996" 1242
"1997" 1353
"1998" 1142
```

We compute the arithmetic mean of the second column. In this case, this column does not have to be specified, since it is the only non-string column:

```
float(stats::mean(%))
```

```
1245.666667
```

## Parameters

$x_1, x_2, \dots$

## stats::mean

---

The statistical data: arithmetical expressions.

**s**

A sample of domain type `stats::sample`.

**c**

An integer representing a column index of the sample `s`. This column provides the data `x1`, `x2` etc.

### **Return Values**

Arithmetical expression.

### **See Also**

### **MuPAD Functions**

`stats::geometricMean` | `stats::harmonicMean` | `stats::median`  
| `stats::modal` | `stats::quadraticMean` | `stats::stdev` |  
`stats::variance`

**Purpose** Mean deviation of a data sample

**Syntax** `stats::meandev(x1, x2, ...)`  
`stats::meandev([x1, x2, ...])`  
`stats::meandev(s, <c>)`

**Description** `stats::meandev(x1, x2, ..., xn)` returns the mean deviation

$$\frac{1}{n} \left( \sum_{i=1}^n |x_i - \bar{x}| \right)$$

where  $\bar{x}$  is the mean of the data  $x_i$ .

If all data are floating-point numbers, a float is returned. For symbolic data, the mean is returned as a symbolic expression.

The column index `c` is optional if the data are given by a `stats::sample` object containing only one non-string column.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples **Example 1**

We calculate the mean deviation of some data:

```
stats::meandev(2, 33/7, PI)
```

$$\frac{104}{63} - \frac{2\pi}{9}$$

Alternatively, the data may be passed as a list:

```
data:=[2, 33/7, PI]: stats::meandev(data)
```

## stats::meandev

---

$$\frac{104}{63} - \frac{2\pi}{9}$$

If all data are floating-point numbers, the result is a float:

```
stats::meandev(float(data))
```

```
0.95266195
```

```
delete data:
```

### Example 2

We create a sample of type `stats::sample`:

```
s := stats::sample([[22, 4, 1], [9, 8/3, 1], [2.0, 3, x]])
```

```
22 4 1
 9 8/3 1
2.0 3 x
```

The mean deviations of the columns are computed:

```
stats::meandev(s, 1), stats::meandev(s, 2), stats::meandev(s, 3)
```

$$7.333333333, \frac{14}{27}, \frac{2 \left| \frac{x}{3} - \frac{1}{3} \right|}{3} + \frac{\left| \frac{2x}{3} - \frac{2}{3} \right|}{3}$$

```
delete s:
```

**Example 3**

With symbolic arguments, the mean deviation is returned as a symbolic expression:

```
stats::meandev(x1, x2, x3)
```

$$\frac{\left| \frac{x_1}{3} + \frac{x_2}{3} - \frac{2x_3}{3} \right|}{3} + \frac{\left| \frac{x_1}{3} - \frac{2x_2}{3} + \frac{x_3}{3} \right|}{3} + \frac{\left| \frac{x_2}{3} - \frac{2x_1}{3} + \frac{x_3}{3} \right|}{3}$$

**Parameters**

$x_1, x_2, \dots$

The statistical data: arithmetical expressions

**s**

A sample of domain type stats::sample

**c**

A column index of the sample **s**: a positive integer. This column provides the data  $x_1, x_2$  etc.

**Return Values**

arithmetical expression.

**See Also****MuPAD Functions**

stats::moment | stats::stdev | stats::variance

# stats::median

---

**Purpose** Median value of a data sample

**Syntax**  
`stats::median(x1, x2, ..., <Averaged>)`  
`stats::median([x1, x2, ...], <Averaged>)`  
`stats::median(s, <c>, <Averaged>)`

**Description** `stats::median(x1, x2, ...)` returns the median of the data  $x_i$ .

The median of  $n$  sorted values  $x_1 \leq \dots \leq x_n$  is  $X_{\lfloor \frac{n}{2} \rfloor}$

The averaged median of  $n$  sorted values  $x_1 \leq \dots \leq x_n$  is  $\frac{\left( X_{\lfloor \frac{n}{2} \rfloor} + X_{\lfloor \frac{n+1}{2} \rfloor} \right)}{2}$ .

For odd  $n$ , both the median and the averaged median coincide with the

element  $X_{\frac{(n+1)}{2}}$  of the sorted data list. For even  $n$ , the median is  $X_{\frac{n}{2}}$ ,

whilst the averaged median is  $\frac{\left( X_{\frac{n}{2}} + X_{\frac{(n+2)}{2}} \right)}{2}$ .

The median coincides with the  $\frac{1}{2}$ -quantile of the data: the calls `stats::median(data, <Averaged>)` and `stats::empiricalQuantile(data)(1/2, <Averaged>)` are equivalent. See the help page of `stats::empiricalQuantile` for details on the parameters specifying the data.

The column index  $c$  is optional if the data are given by a `stats::sample` object containing only one non-string column. Cf. "Example 3" on page 29-347.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We calculate the median of a sequence of five values:

```
stats::median(3, 8, 5, 9/2, 11)
```

5

Alternatively, data may be passed as a list:

```
stats::median([2, 7, 3, 9/2, 11, 12]),
stats::median([2, 7, 3, 9/2, 11, 12], Averaged)
```

$\frac{9}{2}, \frac{23}{4}$

## Example 2

We create a sample:

```
stats::sample([[4, 7, 5], [3, 6, 17], [8, 2, 2]])
```

```
4 7 5
3 6 17
8 2 2
```

The median of the second column is 6:

```
stats::median(%, 2)
```

6

## Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample(["1996", 1242], ["1997", 1353], ["1998", 1142])
```

# stats::median

---

```
"1996" 1242
"1997" 1353
"1998" 1142
```

The median of the second column is calculated. In this case, there is no need to specify the index of the column, since it is the only non-string data column in the sample:

```
stats::median(%)
```

```
1242
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: real numerical values.

**s**

A sample of domain type `stats::sample`

**c**

A column index of the sample `s`: a positive integer. This column provides the data `x1, x2` etc.

## Options

**Averaged**

Return the averaged median value

## Return Values

arithmetical expression. FAIL is returned if the data sample is empty.

## See Also

### MuPAD Functions

stats::empiricalQuantile | stats::geometricMean |  
stats::harmonicMean | stats::mean | stats::modal |  
stats::quadraticMean | stats::stdev | stats::variance

# stats::modal

---

**Purpose** Modal (most frequent) value(s) in a data sample

**Syntax** `stats::modal(x1, x2, ...)`  
`stats::modal([x1, x2, ...], c)`  
`stats::modal(s, <c>)`

**Description** `stats::modal(x1, x2, ...)` returns the most frequent value(s) of the data  $x_i$ .  
The column index `c` is optional, if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-351.  
External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples **Example 1**

We calculate the modal value of a data sequence:

```
stats::modal(2, a, b, c, b, 10, 12, 2, b)
```

```
[b], 3
```

Alternatively, data may be passed as a list:

```
stats::modal([a, a, a, b, c, b, 10, 12, 2, b])
```

```
[a, b], 3
```

## **Example 2**

We create a sample containing “age” and “gender”:

```
stats::sample([[32, "f"], [25, "m"], [40, "f"], [23, "f"]])
```

```
32 "f"
25 "m"
40 "f"
23 "f"
```

The modal value of the second column (the most frequent “gender”) is calculated:

```
stats::modal(%, 2)
```

```
["f"], 3
```

### Example 3

We create a sample consisting of only one column:

```
stats::sample([4, 6, 2, 6, 8, 3, 2, 1, 7, 9, 3, 6, 5, 1, 6, 8]):
```

The modal value of these data is calculated. In this case, the column does not have to be specified, since there is only one column:

```
stats::modal(%)
```

```
[6], 4
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: arithmetical expressions.

**s**

A sample of domain type `stats::sample`.

**c**

# stats::modal

---

An integer representing a column index of the sample  $s$ . This column provides the data  $x_1, x_2$  etc.

## Return Values

Sequence consisting of a list and an integer. The list contains the most frequent element(s) in the data, the integer specifies the number of occurrences. E.g., the result  $[x_5, x_{10}], 21$  means that  $x_5$  and  $x_{10}$  are the most frequent data items, each occurring 21 times.

## See Also

## MuPAD Functions

`stats::empiricalQuantile` | `stats::geometricMean` |  
`stats::harmonicMean` | `stats::mean` | `stats::median` |  
`stats::quadraticMean` | `stats::stdev` | `stats::variance`

**Purpose**

The K-th moment of a data sample

**Syntax**

```
stats::moment(k, X, x1, x2, ...)
stats::moment(k, X, [x1, x2, ...])
stats::moment(k, X, s, <C>)
```

**Description**

`stats::moment(k, X, [x1, x2, ..., xn])` returns the k-th moment

$$\frac{1}{n} \left( \sum_{i=1}^n (x_i - X)^k \right)$$

of the data  $x_i$  centered around  $X$ .

If  $k$  is an integer, rational or float, and all data  $X, x_1, x_2, \dots$  are floating-point numbers, then the moment is returned as a floating-point number. For symbolic data, a symbolic expression is returned.

The column index  $c$  is optional if the data are given by a `stats::sample` object containing only one non-string column.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

**Environment Interactions**

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

**Examples****Example 1**

We calculate the third moment of some data centered around 0:

```
stats::moment(3, 0, 2, 33/7, 21/9, PI)
```

$$\frac{\pi^3}{4} + \frac{290509}{9261}$$

## stats::moment

---

Alternatively, the data may be passed as a list:

```
data := [2, 33/7, 21/9, PI]: stats::moment(3, 0, data)
```

$$\frac{\pi^3}{4} + \frac{290509}{9281}$$

If all data are floating-point numbers, the result is a float:

```
data := float(data): stats::moment(3, 0, data)
```

```
39.12064378
```

We use `stats::moment` to compute the variance of the data:

```
m := stats::mean(data):
stats::moment(2, m, data) = stats::variance(data, Population)
```

```
1.098579542 = 1.098579542
```

```
delete data, m:
```

### Example 2

We create a sample of type `stats::sample`:

```
s := stats::sample([[22, 4, 1], [9, 8/3, 1], [0.1, 2, 3]])
```

```
22 4 1
9 8/3 1
0.1 2 3
```

The fourth moment around a symbolic center  $X$  is computed for all columns in the sample:

```
stats::moment(4, X, s, i) $ i = 1..3
```

$$\frac{(X-9)^4}{3} + \frac{(X-22)^4}{3} + \frac{(X-0.1)^4}{3}, \frac{(X-2)^4}{3} + \frac{(X-4)^4}{3} + \frac{(X-\frac{8}{3})^4}{3}, \frac{2(X-1)^4}{3} + \frac{(X-3)^4}{3}$$

```
delete s:
```

### Example 3

For symbolic arguments, the moment is returned as a symbolic expression:

```
stats::moment(k, X, [x1, x2, x3, x4])
```

$$\frac{(x1-X)^k}{4} + \frac{(x2-X)^k}{4} + \frac{(x3-X)^k}{4} + \frac{(x4-X)^k}{4}$$

## Parameters

**k**

An arithmetical expression

**X**

The center: an arithmetical expression

**x<sub>1</sub>, x<sub>2</sub>, ...**

The statistical data: arithmetical expressions

**s**

A sample of domain type stats::sample

**c**

## stats::moment

---

A column index of the sample `s`: a positive integer. This column provides the data  $x_1, x_2, \dots$

### **Return Values**

arithmetical expression.

### **See Also**

### **MuPAD Functions**

`stats::quadraticMean` | `stats::variance`

<b>Purpose</b>	Cumulative distribution function of the normal distribution
<b>Syntax</b>	<code>stats::normalCDF(m, v)</code>
<b>Description</b>	<code>stats::normalCDF(m, v)</code> returns a procedure representing the cumulative distribution function

$$x \rightarrow \frac{1}{\sqrt{2\pi v}} \int_{-\infty}^x e^{-\frac{(t-m)^2}{2v}} dt$$

of the normal distribution with mean  $m$  and variance  $v$ .

The procedure `f := stats::normalCDF(m, v)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The value  $1/2 + 1/2 * \operatorname{erf}((x - m)/\sqrt{2*v})$  is returned.

If  $x$  is a floating-point number and both  $m$  and  $v$  can be converted to floating-point numbers, this value is returned as a floating-point number. Otherwise, a symbolic expression is returned.

Numerical values for  $m$  and  $v$  are only accepted if they are real and  $v$  is positive.

<b>Environment Interactions</b>	The function is sensitive to the environment variable DIGITS which determines the numerical working precision.
---------------------------------	----------------------------------------------------------------------------------------------------------------

### Examples **Example 1**

We evaluate the cumulative distribution function with mean  $m = 2$  and variance  $v = \frac{3}{4}$  at various points:

```
f := stats::normalCDF(2, 3/4):
f(-infinity), f(-3), f(PI), f(infinity)
```

# stats::normalCDF

---

$$0, \frac{1}{2} - \frac{\operatorname{erf}\left(\frac{5\sqrt{2}\sqrt{3}}{3}\right)}{2}, \frac{\operatorname{erf}\left(\frac{\sqrt{2}\sqrt{3}(\pi-2)}{3}\right)}{2} + \frac{1}{2}, 1$$

`f(-100.0), f(-3.0), f(float(PI)), f(10.0), f(100.0)`

`1.833507721 10-3015, 0.000000003882018269, 0.9062812543, 1.0, 1.0`

`delete f:`

## Example 2

We use symbolic arguments:

`f := stats::normalCDF(m, v): f(3), f(x)`

$$\frac{1}{2} - \frac{\operatorname{erf}\left(\frac{\sqrt{2}(m-3)}{2\sqrt{v}}\right)}{2}, \frac{1}{2} - \frac{\operatorname{erf}\left(\frac{\sqrt{2}(m-x)}{2\sqrt{v}}\right)}{2}$$

When numerical values are assigned to  $m$  and  $v$ , the function  $f$  starts to produce numerical values:

`m := 4: v := PI: f(3), f(3.0)`

$$\frac{1}{2} - \frac{\operatorname{erf}\left(\frac{\sqrt{2}}{2\sqrt{\pi}}\right)}{2}, 0.286312558$$

`delete f, m, v:`

## Parameters **m**

The mean: an arithmetical expression representing a real value

**v**

The variance: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

`erf` | `stats::normalPDF` | `stats::normalQuantile` | `stats::normalRandom`

# stats::normalPDF

---

**Purpose** Probability density function of the normal distribution

**Syntax** stats::normalPDF(*m*, *v*)

**Description** stats::normalPDF(*m*, *v*) returns a procedure representing the probability density function

$$X \rightarrow \frac{e^{-\frac{1}{2v}(x-m)^2}}{\sqrt{2\pi v}}$$

of the normal distribution with mean *m* and variance *v*.

The procedure `f := stats::normalPDF(m, v)` can be called in the form `f(x)` with an arithmetical expression *x*. The value  $\exp(-(x - m)^2 / (2*v)) / \sqrt{2*PI*v}$  is returned.

If *x* is a floating-point number and both *m* and *v* can be converted to floating-point numbers, this value is returned as a floating-point number. Otherwise, a symbolic expression is returned.

Numerical values for *m* and *v* are only accepted if they are real and *v* is positive.

**Environment Interactions** The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

**Examples** **Example 1**

We compute the probability density with mean  $m = 2$  and variance  $v = 4$  at various points:

```
f := stats::normalPDF(2, 4):
f(-infinity), f(-3), f(2.0), f(PI), f(infinity)
```

$$0, \frac{\sqrt{2} e^{-\frac{25}{8}}}{4 \sqrt{\pi}}, 0.1994711402, \frac{\sqrt{2} e^{-\frac{(\pi-2)^2}{8}}}{4 \sqrt{\pi}}, 0$$

delete f:

### Example 2

We use symbolic arguments:

`f := stats::normalPDF(m, v): f(x), f(0.4)`

$$\frac{\sqrt{2} e^{-\frac{(m-x)^2}{2v}}}{2 \sqrt{\pi} \sqrt{v}}, \frac{\sqrt{2} e^{-\frac{(m-0.4)^2}{2v}}}{2 \sqrt{\pi} \sqrt{v}}$$

When numerical values are assigned to  $m$  and  $v$ , the function  $f$  starts to produce numerical values:

`m := PI: v := 2: f(3), f(3.0)`

$$\frac{e^{-\frac{(\pi-3)^2}{4}}}{2 \sqrt{\pi}}, 0.2806844362$$

delete f, m, v:

## Parameters

**m**

The mean: an arithmetical expression representing a real value

**v**

# stats::normalPDF

---

The variance: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

`exp` | `stats::normalCDF` | `stats::normalQuantile` |  
`stats::normalRandom`

**Purpose** Quantile function of the normal distribution

**Syntax** `stats::normalQuantile(m, v)`

**Description** `stats::normalQuantile(m, v)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::normalCDF(m, v)` of the normal distribution with mean  $m$  and variance  $v > 0$ : For  $0 \leq x \leq 1$ , the solution of  $stats::normalCDF(m, v)(y) = x$  is given by  $y = stats::normalQuantile(m, v)(x)$ .

The procedure `f := stats::normalQuantile(m, v)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number, `±infinity`, or a symbolic expression:

If  $x$  is a real number between 0 and 1 and both  $m$  and  $v$  can be converted to floating-point numbers, then `f(x)` returns a real floating-point number approximating the solution  $y$  of `stats::normalCDF(m, v)(y) = x`.

The calls `f(0)` and `f(0.0)` produce `-infinity` for all values of  $m$  and  $v$ . The calls `f(1)` and `f(1.0)` produce `infinity` for all values of  $m$  and  $v$ .

In all other cases, `f(x)` returns the symbolic call `stats::normalQuantile(m, v)(x)`.

Numerical values for  $m$  and  $v$  are only accepted if they are real and  $v$  is positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

**Examples** **Example 1**

We evaluate the quantile function with mean  $m = \pi$  and variance  $v = 11$  at various points:

```
f := stats::normalQuantile(PI, 11):
f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)
```

# stats::normalQuantile

---

```
- ∞, - 1.108833039, 3.141592654, 24.23977359, ∞
```

The value  $f(x)$  satisfies `stats::normalCDF(PI, 11)(f(x)) = x`:

```
stats::normalCDF(PI, 11)(f(0.987654))
```

```
0.987654
```

```
delete f:
```

## Example 2

We use symbolic arguments:

```
f := stats::normalQuantile(m, v): f(x), f(9/10)
```

```
stats::normalQuantile(m, v)(x), stats::normalQuantile(m, v)($\frac{9}{10}$)
```

When numerical values are assigned to  $m$  and  $v$ , the function  $f$  starts to produce floating-point values:

```
m := 17: v := 6: f(9/10), f(0.999)
```

```
20.13914741, 24.56949234
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

```
17.0
```

f(2)

Error: An argument x with  $0 \leq x \leq 1$  is expected. [f]

delete f, m, v:

## Parameters

**m**

The mean: an arithmetical expression representing a real value

**v**

The variance: an arithmetical expression representing a positive real value

## Return Values

procedure.

## MuPAD Functions

stats::normalCDF | stats::normalPDF | stats::normalRandom

# stats::normalRandom

---

**Purpose** Generate a random number generator for normal deviates

**Syntax** stats::normalRandom(*m*, *v*, <Seed = *s*>)

**Description** stats::normalRandom(*m*, *v*) returns a procedure that produces normal deviates (random numbers) with mean *m* and variance *v* > 0.

The procedure `f := stats::normalRandom(m, v)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If *m* and *v* can be converted to floating-point numbers, `f()` returns a real floating point number. Otherwise, the symbolic call `stats::normalRandom(m, v)()` is returned.

Numerical values of *m* and *v* are only accepted if they are real and *v* is positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the normal distribution with parameters *m* and *v*. For any real *x*, the probability that  $X \leq x$  is given by

$$\frac{1}{\sqrt{2\pi v}} \int_{-\infty}^x e^{-\frac{(t-m)^2}{2v}} dt$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::normalRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::normalRandom(m, v): f() $k = 1..K;
```

rather than by

```
stats::normalRandom(m, v)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::normalRandom(m, v, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate normal deviates with mean 2 and variance  $\frac{3}{4}$ :

```
f := stats::normalRandom(2, 3/4): f() $ k = 1..4
```

```
1.541231663, 1.506864857, 1.553005641, 1.055326957
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::normalRandom(m, v): f()
```

# stats::normalRandom

---

```
stats::normalRandom(m, v())
```

When *m* and *v* evaluate to real numbers, `f` starts to produce random floating point numbers:

```
m := PI: v := 1/8: f() $ k = 1..4
```

```
3.77180885, 3.366817847, 3.385627281, 3.261792281
```

```
delete f, m, v:
```

## Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::normalRandom(PI, 3, Seed = 1): f() $ k = 1..4
```

```
3.151659011, 1.573331837, 1.961614435, 4.084887424
```

```
g := stats::normalRandom(PI, 3, Seed = 1): g() $ k = 1..4
```

```
3.151659011, 1.573331837, 1.961614435, 4.084887424
```

```
f() = g(), f() = g()
```

```
3.20340985 = 3.20340985, 1.538612606 = 1.538612606
```

```
delete f, g:
```

## Parameters

**m**

The mean: an arithmetical expression representing a real value

**v**

The variance: an arithmetical expression representing a positive real value

## Options

**Seed**

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `m` and `v` must be convertible to suitable floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of the normal deviates uses the Box-Mueller method. For more information see: D. Knuth, *Seminumerical Algorithms* (1998), Vol. 2, pp. 122.

## MuPAD Functions

`stats::normalCDF` | `stats::normalPDF` | `stats::normalQuantile`

# stats::obliquity

---

**Purpose** Obliquity (skewness) of a data sample

**Syntax**  
`stats::obliquity(x1, x2, ...)`  
`stats::obliquity([x1, x2, ...], c)`  
`stats::obliquity(s, <c>)`

**Description** `stats::obliquity(x1, x2, ..., xn)` returns the obliquity (skewness)

$$\frac{\frac{1}{n} \left( \sum_{i=1}^n (X_i - \bar{X})^3 \right)}{\left( \frac{1}{n} \left( \sum_{i=1}^n (X_i - \bar{X})^2 \right) \right)^{3/2}}$$

where  $\bar{X}$  is the mean of the data  $x_i$ .

The obliquity is a measure for the symmetry of a distribution. It is zero, if the distribution of the data is symmetric around the mean. Positive values indicate that the distribution function has a “longer tail” to the right of the mean than to the left. Negative values indicate a “longer tail” to the left.

The column index `c` is optional, if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-371.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We calculate the obliquity of a data sequence:

```
float(stats::obliquity(0, 7, 7, 6, 6, 6, 5, 5, 4, 1))
```

```
- 1.041368312
```

Alternatively, data may be passed as a list:

```
stats::obliquity([2, 2, 4, 6, 8, 10, 10])
```

```
0
```

### Example 2

We create a sample:

```
stats::sample([[a, 5, 8], [b, 3, 7], [c, d, 0]])
```

```
a 5 8
b 3 7
c d 0
```

The obliquity of the second column is:

```
stats::obliquity(%, 2)
```

$$-\frac{\sqrt{3} \left( \left( \frac{d}{3} - \frac{1}{3} \right)^3 + \left( \frac{d}{3} - \frac{7}{3} \right)^3 - \left( \frac{2d}{3} - \frac{8}{3} \right)^3 \right)}{\left( \left( \frac{d}{3} - \frac{1}{3} \right)^2 + \left( \frac{d}{3} - \frac{7}{3} \right)^2 + \left( \frac{2d}{3} - \frac{8}{3} \right)^2 \right)^{3/2}}$$

### Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample([["1996", 1242], ["1997", 1353], ["1998", 1142]])
```

```
"1996" 1242
"1997" 1353
```

# stats::obliquity

---

```
"1998" 1142
```

We compute the obliquity of the second column. In this case this column does not have to be specified, since it is the only non-string column:

```
float(stats::obliquity(%))
```

```
0.06374333648
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: arithmetical expressions.

**$s$**

A sample of domain type `stats::sample`.

**$c$**

An integer representing a column index of the sample  $s$ . This column provides the data  $x_1, x_2$  etc.

## Return Values

Arithmetical expression. FAIL is returned, if the obliquity does not exist.

## See Also

## MuPAD Functions

`stats::kurtosis`

**Purpose**

The (discrete) cumulative distribution function of the Poisson distribution

**Syntax**

stats::poissonCDF(m)

**Description**

stats::poissonCDF(m) returns a procedure representing the (discrete) cumulative distribution function

$$X \rightarrow \begin{cases} 0 & \text{if } X < 0 \\ \sum_{i=0}^{\lfloor X \rfloor} \frac{m^i e^{-m}}{i!} & \text{if } X \geq 0 \end{cases}$$

of the Poisson distribution with mean  $m$ .

The procedure `f := stats::poissonCDF(m)` can be called in the form `f(x)` with arithmetical expressions  $x$ . The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

If  $x$  is a numerical real value, then an explicit value is returned. It is a floating-point number if  $x$  is a floating-point number and  $m$  can be converted to a positive real float. Otherwise, an exact expression is returned.

If  $x$  is a numerical value  $< 0$ , then 0, respectively 0.0, is returned for any value of  $m$ .

For symbolic values of  $x$ , `f(x)` returns the symbolic call `stats::poissonCDF(m)(x)`.

Numerical values for  $m$  are only accepted if they are nonnegative.

If  $x$  is a real floating-point number, the result is a floating number provided  $m$  is a nonnegative numerical value. If both  $x$  and  $m$  are exact numerical values, the result is an exact number.

# stats::poissonCDF

---

---

**Note** Note that for large  $m$ , floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number  $x$  to `stats::poissonCDF`!

---

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the distribution function with  $m = \frac{1}{2}$  at various points:

```
f := stats::poissonCDF(1/2):
f(-PI) = f(float(-PI)), f(0) = f(0.0), f(4) = f(4.0)
```

$$0 = 0.0, e^{-\frac{1}{2}} = 0.6065306597, \frac{211 e^{-\frac{1}{2}}}{128} = 0.9998278844$$

```
delete f:
```

### Example 2

We use symbolic arguments. If  $x$  is symbolic, a symbolic call is returned:

```
f := stats::poissonCDF(m): f(x)
```

```
stats::poissonCDF(m)(x)
```

If  $x$  is a numerical value, symbolic expressions in  $m$  are returned:

```
f(-1), f(0), f(5/2), f(PI)
```

$$0, e^{-m}, e^{-m} \left( \frac{m^2}{2} + m + 1 \right), e^{-m} \left( \frac{m^3}{6} + \frac{m^2}{2} + m + 1 \right)$$

When numerical values are assigned to  $m$ , the function  $f$  starts to produce explicit results if the argument is numerical:

```
m := 3: f(-1), f(0), f(5/2), f(PI)
```

$$0, e^{-3}, \frac{17 e^{-3}}{2}, 13 e^{-3}$$

```
delete f, m:
```

## Parameters

**m**

The mean: an arithmetical expression representing a nonnegative real number

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::poissonPF | stats::poissonQuantile |  
stats::poissonRandom

# stats::poissonPF

---

**Purpose** Probability function of the Poisson distribution

**Syntax** stats::poissonPF(m)

**Description** stats::poissonPF(m) returns a procedure representing the probability function

$$X \rightarrow \frac{m^x}{e^m X!}$$

of the Poisson distribution with mean  $m$ .

The procedure `f := stats::poissonPF(m)` can be called in the form `f(x)` with arithmetical expressions  $x$ . The return value of `f(x)` is either a floating-point number, an exact numerical value, or a symbolic expression:

If  $x$  is a non-integer numerical value, `f(x)` returns 0 or 0.0, respectively.

If  $x$  is an integer or the floating-point equivalent of an integer, then an explicit value is returned.

In all other cases, `f(x)` returns the symbolic call `stats::poissonPF(m, p)(x)`.

Numerical values for  $m$  are only accepted if they are nonnegative.

If  $x$  is a floating-point number, the result is a floating-point number provided  $m$  is a nonnegative numerical value. If both  $x$  and  $m$  are exact values then the result is an exact number.

Note that for large  $m$ , floating-point results are computed much faster than exact results. If floating-point approximations are desired, pass a floating-point number  $x$  to the procedure generated by `stats::poissonPF`.

**Environment Interactions** The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

**Examples****Example 1**

We calculate the Poisson probability with  $m = 8$  at various points:

```
f := stats::poissonPF(8):
f(-1), f(-1.0), f(0), f(1/2), f(1), f(3/2), f(3) = f(float(3))
```

$$0, 0.0, e^{-8}, 0, 8 e^{-8}, 0, \frac{256 e^{-8}}{3} = 0.02862614425$$

```
delete f:
```

**Example 2**

We use symbolic arguments:

```
f := stats::poissonPF(m): f(x)
```

$$\text{stats::poissonPF}(m)(x)$$

If  $x$  is a numerical value, symbolic expressions in  $m$  are returned:

```
f(8), f(17/2), f(9.0), f(9.2)
```

$$\frac{m^8 e^{-m}}{40320}, 0, 0.000002755731922 m^{9.0} e^{-1.0 m}, 0.0$$

When numerical values are assigned to  $m$ , the function  $f$  starts to produce numbers if the argument is numerical:

```
m := 3: f(8), f(17/2), f(9.0), f(9.2)
```

# stats::poissonPF

---

$$\frac{729 e^{-3}}{4480}, 0, 0.002700503932, 0.0$$

delete f, m:

## Parameters

**m**

The mean: an arithmetical expression representing a nonnegative real number

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::poissonCDF | stats::poissonQuantile |  
stats::poissonRandom

**Purpose** Quantile function of the Poisson distribution

**Syntax** stats::poissonQuantile(m)

**Description** stats::poissonQuantile(m) returns a procedure representing the quantile function (discrete inverse) of the cumulative distribution function stats::poissonCDF(m). For  $0 \leq x \leq 1$ ,  $k = \text{stats::poissonQuantile}(m)(x)$  is the smallest nonnegative integer satisfying

$$\text{stats::poissonCDF}(m)(k) = \sum_{i=0}^k \frac{m^i}{i!} e^{-m} \geq x$$

The procedure `f := stats::poissonQuantile(m)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of the call `f(x)` is either a nonnegative integer, infinity, or a symbolic expression:

If  $m$  is a nonnegative real number and  $x$  a real number satisfying  $0 \leq x < 1$ , then `f(x)` returns a nonnegative integer.

If  $m = 0$ , then `f(x)` returns 0 for any  $x$ .

If  $m \neq 0$ , then `f(1)` and `f(1.0)` return infinity.

In all other cases, `f(x)` returns the symbolic call `stats::poissonQuantile(m)(x)`.

Numerical values for `m` are only accepted if they are positive.

If floating-point arguments are passed to the quantile function `f`, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors. In particular, round-off may be significant for arguments  $x$  close to 1. Cf. “Example 3” on page 29-381.

Finite quantile values  $k = \text{stats::poissonQuantile}(m)(x)$  satisfy

# stats::poissonQuantile

---

$$\text{stats::poissonCDF}(m)(k - 1) < x \leq \text{stats::poissonCDF}(m)(k)$$

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with  $m = \pi$  at various points:

```
f := stats::poissonQuantile(PI):
f(0), f(1/20), f(0.3), f(PI/6), f(0.7), f(1-1/10^10), f(1)
```

```
0, 1, 2, 3, 4, 20, ∞
```

The value  $f(x)$  satisfies

$$\text{stats::poissonCDF}(\pi)(f(x) - 1) < x \leq \text{stats::poissonCDF}(\pi)(f(x))$$

```
x := 0.98: k := f(x)
```

```
7
```

```
float(stats::poissonCDF(PI)(k - 1)), x,
float(stats::poissonCDF(PI)(k))
```

```
0.9588410737, 0.98, 0.9847376421
```

```
delete f, x, k:
```

### Example 2

We use symbolic arguments:

```
f := stats::poissonQuantile(m): f(x), f(9/10)
```

```
stats::poissonQuantile(m)(x), stats::poissonQuantile(m)($\frac{9}{10}$)
```

When  $m$  evaluates to a positive real number, the function  $f$  starts to produce quantile values:

```
m := 17:
f(1/2), f(999/1000), f(1 - 1/10^10), f(1 - 1/10^80)
```

```
17, 31, 49, 144
```

```
delete f, m:
```

### Example 3

If floating-point arguments are passed to the quantile function, the result is computed with floating-point arithmetic. This is faster than using exact arithmetic, but the result is subject to internal round-off errors:

```
f := stats::poissonQuantile(123):
f(1 - 1/10^19) <> f(float(1 - 1/10^19))
```

```
236 ≠ ∞
```

```
delete f:
```

## Parameters

**m**

The mean: a arithmetical expression representing a nonnegative real number

# stats::poissonQuantile

---

## Return Values

procedure.

## See Also

## MuPAD Functions

[stats::poissonCDF](#) | [stats::poissonPF](#) | [stats::poissonRandom](#)

**Purpose**

Generate a random number generator for Poisson deviates

**Syntax**

`stats::poissonRandom(m, <Seed = s>)`

**Description**

`stats::poissonRandom(m)` returns a procedure that produces poisson-deviates (random numbers) with mean  $m$ .

The procedure `f := stats::poissonRandom(m)` can be called in the form `f()`. The return value of `f()` is a nonnegative integer if  $m$  is a nonnegative numerical value.

Otherwise, `stats::poissonRandom(m)()` is returned symbolically.

Numerical values for  $m$  are only accepted if they are nonnegative.

The values  $X = f()$  are distributed randomly according to the discrete distribution function of the Poisson distribution with mean  $m$ , i.e., for  $0 \leq x$ , the probability of  $X \leq x$  is given by

$$\sum_{i=0}^{\lfloor x \rfloor} \frac{m^i}{i!} e^{-m}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** With this option, the mean  $m$  must evaluate to a nonnegative numerical value at the time, when the generator is created.

---

---

**Note** In contrast to the function `random`, the generators produced by `stats::poissonRandom` do not react to the environment variable `SEED`.

---

# stats::poissonRandom

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::poissonRandom(m): f() $k = 1..K;
```

rather than by

```
stats::poissonRandom(m)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::poissonRandom(m, Seed = s)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate Poisson deviates with mean  $m = 80$ :

```
f := stats::poissonRandom(80): f() $ k = 1..10
```

```
69, 105, 77, 81, 71, 79, 86, 77, 87, 97
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::poissonRandom(m): f()
```

```
stats::poissonRandom(m())
```

When  $m$  evaluates to a positive real number, the generator starts to produce random numbers:

```
m := 80: f(), f(), f()
```

```
89, 76, 82
```

```
delete f, m:
```

### Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::poissonRandom(12, Seed = 1): f() $ k = 1..10
```

```
12, 15, 8, 9, 15, 4, 12, 9, 7, 10
```

```
g := stats::poissonRandom(12, Seed = 1): g() $ k = 1..10
```

```
12, 15, 8, 9, 15, 4, 12, 9, 7, 10
```

```
f() = g(), f() = g()
```

```
11 = 11, 11 = 11
```

```
delete f, g:
```

# stats::poissonRandom

---

## Parameters

**m**

The mean: an arithmetical expression representing a nonnegative real number

## Options

**Seed**

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the mean `m` must be convertible to a positive floating-point number at the time when the random generator is generated.

## Return Values

procedure.

## See Also

## MuPAD Functions

`stats::poissonCDF` | `stats::poissonPF` |  
`stats::poissonQuantile`

**Purpose** Quadratic mean of a data sample

**Syntax** `stats::quadraticMean(x1, x2, ...)`  
`stats::quadraticMean([x1, x2, ...], c)`  
`stats::quadraticMean(s, <c>)`

**Description** `stats::quadraticMean(x1, x2, ..., xn)` returns the quadratic mean

$$\sqrt{\frac{1}{n} \left( \sum_{i=1}^n x_i^2 \right)}$$

of the data  $x_i$ .

The column index `c` is optional, if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-388.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We calculate the quadratic mean of three values:

```
stats::quadraticMean(a, b, c)
```

$$\sqrt{\frac{a^2}{3} + \frac{b^2}{3} + \frac{c^2}{3}}$$

Alternatively, data may be passed as a list:

```
stats::quadraticMean([2, 3, 5])
```

# stats::quadraticMean

---

$$\frac{\sqrt{3} \sqrt{38}}{3}$$

## Example 2

We create a sample:

```
stats::sample([[a1, b1, c1], [a2, b2, c2]])
```

```
a1 b1 c1
a2 b2 c2
```

The quadratic mean of the second column is:

```
stats::quadraticMean(%, 2)
```

$$\sqrt{\frac{b1^2}{2} + \frac{b2^2}{2}}$$

## Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample(["1996", 1242], ["1997", 1353], ["1998", 1142])
```

```
"1996" 1242
"1997" 1353
"1998" 1142
```

We compute the quadratic mean of the second column. In this case this column does not have to be specified, since it is the only non-string column:

```
float(stats::quadraticMean(%))
```

```
1248.644198
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: arithmetical expressions.

**s**

A sample of domain type `stats::sample`.

**c**

An integer representing a column index of the sample s. This column provides the data  $x_1, x_2$  etc.

## Return Values

arithmetical expression.

## See Also

## MuPAD Functions

<StartingValues = [p1(0), ..., pn(0)]>, <CovarianceMatrix>)
```

## Description

Consider a “model function”  $f$  with  $n$  parameters  $p_1, \dots, p_n$  relating a dependent variable  $y$  and  $m$  independent variables  $x_1, \dots, x_m$ :  $y = f(x_1, \dots, x_m, p_1, \dots, p_n)$ . Given  $k$  different measurements  $x_{1j}, \dots, x_{kj}$  for the independent variables  $x_j$  and corresponding measurements  $y_1, \dots, y_k$  for the dependent variable  $y$ , one fits the parameters  $p_1, \dots, p_n$  by minimizing the “weighted quadratic deviation” (“chi-squared”)

$$\chi^2(p_1, \dots, p_n) = \sum_{i=1}^k w_i |y_i - f(x_{i1}, \dots, x_{im}, p_1, \dots, p_n)|^2$$

`stats::reg(..data.., f, [x.1, ... , x.m], [p.1, ... , p.n], [w.1, ... , w.n])` computes numerical approximations of the fit parameters  $p_1, \dots, p_n$ .

All data must be convertible to real or complex floating-point values via `float`.

The number of measurements  $k$  must not be less than the number  $n$  of parameters  $p_i$ .

The model function  $f$  may be non-linear in the independent variables  $x_i$  and the fit parameters  $p_i$ . E.g., a model function such as  $p_1 + p_2 * x_1^2$

+  $\exp(p_3 + p_4 \cdot x_2)$  with the independent variables  $x_1$ ,  $x_2$  and the fit parameters  $p_1$ ,  $p_2$ ,  $p_3$ ,  $p_4$  is accepted.

Note that the fitting of model functions with a non-linear dependence on the parameters  $p_i$  is much more costly than a linear regression, where the  $p_i$  enter linearly. The functional dependence of the model function on the variables  $x_i$  is of no relevance.

---

**Note** There are rare cases where the implemented algorithm converges to a local minimum rather than to a global minimum. In particular, this problem may arise when the model involves periodic functions. It is recommended to provide suitable starting values for the fit parameters in this case. Cf. “Example 4” on page 29-393.

---

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

We fit a linear function  $y = p_1 + p_2 x_1$  to four data pairs  $(x_{i1}, y_i)$  given by two lists:

```
stats::reg([0, 1, 2, 3], [1, 3, 5, 7],
 p1 + p2*x1, [x1], [p1, p2])
```

```
[[1.0, 2.0], 0.0]
```

The parameter values  $p_1 = 1.0$ ,  $p_2 = 2.0$  provide a perfect fit: up to numerical round-off, the quadratic deviation vanishes.

## Example 2

We fit an exponential function  $y = ae^{bx}$  to five data pairs  $(x_i, y_i)$ . Weights are used to decrease the influence of the “exceptional pair”  $(x, y) = (5.0, 6.5 \cdot 10^6)$  on the fit:

```
stats::reg([[1.1, 54, 1], [1.2, 73, 1], [1.3, 98, 1],
 [1.4, 133, 1], [5.0, 6.5*10^6, 10^(-4)]],
 a*exp(b*x), [x], [a, b])
```

```
[[1.992321622, 2.999602426], 0.2001899629]
```

## Example 3

We create a sample with four columns. The first column is a counter labeling the measurements. This column is of no further relevance here. The second and third column provide measured data of two variables  $x_1$  and  $x_2$ , respectively. The last column provides corresponding measurements of a dependent variable.

```
s := stats::sample([[1, 0, 0, 1.1], [2, 0, 1, 5.4],
 [3, 1, 1, 8.5], [4, 1, 2, 18.5],
 [5, 2, 1, 15.0], [6, 2, 2, 24.8]])
```

```
1 0 0 1.1
2 0 1 5.4
3 1 1 8.5
4 1 2 18.5
5 2 1 15.0
6 2 2 24.8
```

First, we try to model the data provided by the columns 2, 3, 4 by a function that is linear in the variables  $x_1, x_2$ . We specify the data columns by a list of column indices:

```
stats::reg(s, [2, 3, 4], p1 + p2*x1 + p3*x2,
 [x1, x2], [p1, p2, p3])
```

```
[[-0.9568181818, 4.688636364, 7.272727273], 15.23613636]
```

The quadratic deviation is rather large, indicating that a linear function is inappropriate to fit the data. Next, we extend the model and consider a polynomial fit function of degree 2. This is still a linear regression problem, because the fit parameters enter the model function linearly. We specify the data columns by a sequence of column indices:

```
stats::reg(s, 2, 3, 4,
 p1 + p2*x1 + p3*x2 + p4*x1^2 + p5*x2^2,
 [x1, x2], [p1, p2, p3, p4, p5])
```

```
[[1.1, 1.525, 1.5, 1.625, 2.8], 0.01]
```

Finally, we include a further term  $p6*x1*x2$  in the model, obtaining a perfect fit:

```
stats::reg(s, 2, 3, 4,
 p1 + p2*x1 + p3*x2 + p4*x1^2 + p5*x2^2 + p6*x1*x2,
 [x1, x2], [p1, p2, p3, p4, p5, p6])
```

```
[[1.1, 1.6, 1.35, 1.7, 2.95, -0.2], 1.796307589 10-27]
```

```
delete s:
```

#### Example 4

We create a sample of two columns:

```
s := stats::sample([[1, -1.44], [2, -0.82],
 [3, 0.97], [4, 1.37]])
```

```
1 -1.44
2 -0.82
3 0.97
4 1.37
```

The data are to be modeled by a function of the form  $y = p_1 \sin(p_2 x)$ , where the first column contains measurements of  $x$  and the second column contains corresponding data for  $y$ . Note that in this example there is no need to specify column indices, because the sample contains only two columns:

```
stats::reg(s, a*sin(b*x), [x], [a, b])
```

```
[[-1.499812823, 1.281963381], 0.00001255632629]
```

Fitting a periodic function may be problematic. We provide starting values for the fit parameters and obtain a quite different set of parameters approximating the data with the same quality:

```
stats::reg(s, a*sin(b*x), [x], [a, b], StartingValues = [2, 5])
```

```
[[1.499812823, 5.001221926], 0.00001255632629]
```

```
delete s:
```

## Example 5

The blood sugar level  $y$  (in mmol/L) of a diabetic is measured over a period of 10 days with 5 measurements per day at  $x_1 = 7$  (o'clock a.m.),  $x_1 = 12$  (noon),  $x_1 = 15$  (afternoon),  $x_1 = 19$  (before dinner), and  $x_1 = 23$  (bed time). These are the measurements:

```
Y:= //hour: 7 12 15 19 23
```

```

[[7.2, 5.5, 6.8, 5.4, 6.0], // day 1
 [6.3, 5.0, 5.5, 5.8, 4.9], // day 2
 [6.5, 6.3, 4.8, 4.5, 5.0], // day 3
 [4.3, 5.2, 4.3, 4.7, 4.0], // day 4
 [7.1, 7.2, 6.7, 7.2, 5.5], // day 5
 [5.8, 5.5, 4.9, 5.0, 6.2], // day 6
 [6.2, 4.8, 5.0, 5.2, 5.3], // day 7
 [4.8, 5.8, 5.7, 6.2, 5.0], // day 8
 [5.2, 3.8, 4.8, 5.8, 4.7], // day 9
 [5.8, 4.7, 5.0, 6.5, 6.3] // day 10
]:

```

We have a total of 50 measurements. Each measurement is a triple  $[x_1, x_2, y]$ , where  $x_1$  is the hour of the day,  $x_2$  is the day number, and  $y$  is the blood sugar level:

```

data:= ([[7, x2, Y[x2][1]],
 [12, x2, Y[x2][2]],
 [15, x2, Y[x2][3]],
 [19, x2, Y[x2][4]],
 [23, x2, Y[x2][5]]
) $ x2 = 1 .. 10]:

```

We model the blood sugar  $y$  as a function of the hour of the day  $x_1$  and the day number  $x_2$  (trying to detect a general tendency). We assume a periodic dependence on  $x_1$  with a period of 24 hours:

```

y := y0 + a*x2 + b*sin(2*PI/24*x1 + c):

```

A least squares fit of the given data leads to the following parameters  $y_0$ ,  $a$ ,  $b$ ,  $c$ :

```

[y0abc, residue]:= stats::reg(data, y, [x1, x2], [y0, a, b, c]):
[y0, a, b, c]:= y0abc

```

```

[5.809945498, -0.04618181818, 0.2055298076, 0.07751988162]

```

The average blood sugar level is  $y_0 = 5.8...$  with an improvement of  $a = -0.046...$  per day. The amplitude of the daily variation of  $y$  is  $b = 0.205...$ . We visualize the measurements  $Y$  by a `plot::Matrixplot`. The least squares fit of our model function  $y$  is added as a function graph:

```
plot(plot::Matrixplot(Y, x1 = 0..24, x2 = 1..10),
 plot::Function3d(y, x1 = 0..24, x2 = 1..10,
 Color = RGB::Green))
```

```
delete Y, data, y, y0abc, y0, a, b, c, residue:
```

## Example 6

We consider a decaying radioactive source, whose activity  $N$  (“counts”) is measured at intervals of 1 second. The physical model for the decay is

$N(t) = \frac{N_0}{1 + t/\tau}$ , where  $N(t)$  is the count rate at time  $t$ ,  $N_0$  is the base rate at time  $t = 0$  and  $\tau$  is the lifetime of the radioactive source. Instead of taking data from an actual physical experiment, we create artificial data with a base rate  $N_0 = 100$  and a lifetime  $\tau = 300$ :

```
T := [i $ i= 0 .. 100]:
N := [100*exp(-t/300) $ t in T]:
```

By construction, we obtain a perfect fit when estimating the parameters  $N_0$  and  $\tau$  of the model:

```
stats::reg(T, N, NO*exp(-t/tau), [t], [NO, tau]);
```

```
[[100.0, 300.0], 1.133987551 10-30]
```

We perturb the data:

```
N := [stats::poissonRandom(n)() $ n in N]:
```

Since the data  $n_i$  in  $N$  are Poissonian, their standard deviation is the square root of their mean:  $\sigma(n_i) \approx \sqrt{n_i}$ . Thus, suitable weights for a least squares estimation of the parameters are given by

$$W_i = \frac{1}{\sigma(n_i)^2} = \frac{1}{n_i}$$

```
W := [1/n $ n in N]:
```

With these weights, a least squares fit of the model parameters  $N_0$  and  $\tau$  is computed. The option `CovarianceMatrix` is used to get information on confidence intervals for the parameters:

```
[p, chisquared, C] :=
 stats::reg(T, N, W, NO*exp(-t/tau), [t], [NO, tau],
```

CovarianceMatrix)

```
[95.43096895, 309.3571484], 87.4642626, (3.998386217 -61.38541859)
[-61.38541859 1302.650416]
```

The square roots of the diagonal elements of the covariance matrix provides the statistical standard deviations of the fit parameters:

```
sqrt(float(C[1,1])), sqrt(float(C[2,2]))
```

```
1.999596513, 36.0922487
```

Thus, the estimate for the base rate  $N_0$  is  $N_0 \pm \sigma(N_0) \approx 95.4 \pm 2.0$ , the estimate for the lifetime  $\tau$  is  $\tau \pm \sigma(\tau) \approx 309.4 \pm 36.1$ . The correlation matrix of the fit parameters is obtained from the covariance matrix via `stats::correlationMatrix`:

```
stats::correlationMatrix(C)
```

```
(1.0 -0.8505677452)
[-0.8505677452 1.0]
```

```
delete T, N, W, p, chisquared, C:
```

## Parameters

$\mathbf{x}_1, \mathbf{y}_1, \dots, \mathbf{x}_k, \mathbf{y}_k$

Numerical sample data for the independent variables. The entry  $x_{i,j}$  represents the  $i$ -th measurement of the independent variable  $x_j$ .

$\mathbf{y}_1, \dots, \mathbf{y}_k$

Numerical sample data for the dependent variable. The entry  $y_i$  represents the  $i$ -th measurement of the dependent variable.

**w<sub>1</sub>, ..., w<sub>k</sub>**

Weight factors: positive real numerical values. The entry  $w_i$  is used as a weight for the data  $x_{i,1}, \dots, x_{i,m}, y_i$  of the  $i$ -th measurement. If no weights are provided, then  $w_i = 1$  is used.

**f**

The model function: an arithmetical expression representing a function of the independent variables  $x_1, \dots, x_m$  and the fit parameters  $p_1, \dots, p_n$ . The expression must not contain any symbolic objects apart from  $x_1, \dots, x_m, p_1, \dots, p_n$ .

**x<sub>1</sub>, ..., x<sub>m</sub>**

The independent variables: identifiers or indexed identifiers.

**p<sub>1</sub>, ..., p<sub>n</sub>**

The fit parameters: identifiers or indexed identifiers.

**p<sub>1</sub>(0), ..., p<sub>n</sub>(0)**

The user can assist the internal numerical search by providing numerical starting values  $p_i(0)$  for the fit parameters  $p_i$ . These should be reasonably close to the optimal fit values. The starting values  $p_i(0) = 1.0$  are used if no starting values are provided by the user.

**s**

A sample of domain type `stats::sample` containing the data  $x_{i,j}$  for the independent variables, the data  $y_i$  for the dependent variable and, optionally, the weights  $w_i$ .

**cy**

A positive integer representing a column index of the sample `s`. This column provides the measurements  $y_i$  for the dependent variable.

## **cw**

A positive integer representing a column index of the sample  $s$ . This column provides the weight factors  $w_i$ .

## **Options**

### **StartingValues**

Option, specified as `StartingValues = [p1(0), ..., pn(0)]`

Positive integers representing column indices of the sample  $s$ . Column  $p_j$  provides the measurements  $x_{i,j}$  for the independent variable  $x_j$ .

If the model function depends linearly on the fit parameters  $p_j$  (“linear regression”), then the optimized parameters are the solution of a linear system of equations. In this case there is no need to provide starting values for a numerical search. In fact, initial values provided by the user are ignored.

If the model function depends non-linearly on the fit parameters  $p_j$  (“non-linear regression”), then the optimized fitting parameters are the solution of a non-linear optimization problem. There is no guarantee that the internal search for a numerical solution will succeed. It is recommended to assist the internal solver by providing reasonably good estimates for the optimal fit parameters.

### **CovarianceMatrix**

Changes the return value from  $[[p_1, \dots, p_n], x^2]$  to  $[[p_1, \dots, p_n], x^2, C]$ , where  $C$  is the covariance matrix of the estimators  $p_i$  given by  $C_{i,i} = \sigma(p_i)^2$  and  $C_{i,j} = \text{cov}(p_i, p_j)$  for  $i \neq j$ .

With this option, information on confidence intervals for the least squares estimators  $p_i$  are provided. In particular, the return value includes the covariance matrix  $C$  of type `Dom::Matrix()`. This matrix provides the variances  $C_{ii} = \sigma(p_i)^2$  of the least squares estimators  $p_i$  and their covariances  $C_{ij} = \text{cov}(p_i, p_j)$ . The covariance matrix is defined via its inverse

$$\left(\frac{1}{C}\right)_{i,j} = \frac{\frac{\partial}{\partial p_j} \frac{\partial}{\partial p_i} \chi^2}{2},$$

Where

$$\chi^2(p_1, \dots, p_n) = \sum_{i=1}^k w_i |y_i - f(x_{i1}, \dots, x_{in}, p_1, \dots, p_n)|^2$$

The covariance matrix of the least squares estimators only has a statistical meaning if the stochastic variances  $\sigma(y_i)^2$  of the measurements  $y_i$  are known. These variances are to be included

in the computation by choosing the weights  $w_i = \frac{1}{\sigma(y_i)^2}$ . Cf. “Example 6” on page 29-396.

The function `stats::correlationMatrix` serves for converting the covariance matrix to the corresponding correlation matrix. See “Example 6” on page 29-396

## Return Values

Without the option `CovarianceMatrix`, a list  $[[p_1, \dots, p_n], \chi^2]$  is returned. It contains the optimized fit parameters  $p_i$  minimizing the quadratic deviation. The minimized value of this deviation is given by  $\chi^2$ , it indicates the quality of the fit.

With the option `CovarianceMatrix`, a list  $[[p_1, \dots, p_n], \chi^2, C]$  is returned. The  $n \times n$  matrix `C` is the covariance matrix of the fit parameters.

All returned data are floating-point values. `FAIL` is returned if a least square fit of the data is not possible with the given model function or if the internal numerical search failed.

## Algorithms

`stats::reg` uses a Marquardt-Levenberg gradient expansion algorithm.

Searching for the minimum of  $\chi^2(p_1, \dots, p_n)$ , the algorithm does not simply follow the negative gradient, but the diagonal terms of the

curvature matrix are increased by a factor that is optimized in each step of the search.

### MuPAD Functions

`stats::correlationMatrix` | `stats::linReg` | `stats::sample`

**Purpose**

Select and re-arrange rows of a sample

**Syntax**

```
stats::row(s, r1, <r2, >)
stats::row(s, r1 .. r2, <r3 .. r4, >)
```

**Description**

`stats::row(s, ..)` creates a new sample from selected rows of the sample `s`.

`stats::row` is useful for selecting rows of interest or for re-arranging rows.

The rows of `s` specified by the remaining arguments of `stats::row` are used to build a new sample. The new sample contains the rows of `s` in the order specified by the call to `stats::row`. Rows can be duplicated by specifying the row index more than once.

**Examples****Example 1**

The following sample represents the “population” of a small town:

```
stats::sample([["1990", 10564], ["1991", 10956],
 ["1992", 11007], ["1993", 11123],
 ["1994", 11400], ["1995", 11645]])
```

```
"1990" 10564
"1991" 10956
"1992" 11007
"1993" 11123
"1994" 11400
"1995" 11645
```

We are only interested in the years 1990, 1991, 1992 and 1995. We create a new sample containing the rows of interest:

```
stats::row(%, 1..3, 6)
```

## stats::row

---

```
"1990" 10564
"1991" 10956
"1992" 11007
"1995" 11645
```

We reorder the sample:

```
stats::row(%, 4, 3, 2, 1)
```

```
"1995" 11645
"1992" 11007
"1991" 10956
"1990" 10564
```

### Parameters

**s**

A sample of domain type `stats::sample`.

**$r_1, r_2, \dots$**

Positive integers representing row indices of the sample `s`. A range  $r_1..r_2$  represents all rows from  $r_1$  through  $r_2$ .

### Return Values

Sample of domain type `stats::sample`.

### See Also

### MuPAD Functions

`stats::col` | `stats::concatCol` | `stats::concatRow` | `stats::selectRow`

**Purpose**

Domain of statistical samples

**Syntax**

```
stats::sample([[a1, 1, a1, 2, ...], [a2, 1, a2, 2, ...], ...])
stats::sample([a1, 1, a2, 1, ...])
```

**Description**

*sample* represents a collection of statistical data, organized as a matrix. Usually, each row refers to an individual of the population described by the sample. Each column represents an attribute.

`stats::sample( [[a1, 1, ..., a1, n], ..., [am, 1, ..., am, n]] )` creates a sample with  $m$  rows and  $n$  columns,  $a_{i,j}$  being the entry in the  $i$ -th row,  $j$ -th column.

`stats::sample( [a1, 1, ..., am, 1] )` creates a sample with  $m$  rows and one column.

Each row  $[a_{i, 1}, \dots, a_{i, n}]$  must contain the same number of entries.

Elements of domain type `DOM_COMPLEX`, `DOM_EXPR`, `DOM_FLOAT`, `DOM_IDENT`, `DOM_INT`, or `DOM_RAT` are regarded as “data” and are stored in a sample as on input. All other types of input parameters are converted to strings (`DOM_STRING`).

If one element in a column is a string or is converted to a string, then all elements of that column are converted to strings.

This produces two kinds of columns: data columns and string columns.

**Superdomain**

`Dom::BaseDomain`

**Axioms**

`Ax::canonicalRep`

**Categories**

`Cat::Set`

**Examples**

**Example 1**

A sample is created from a list of rows:

```
stats::sample([[5, a], [b, 7.534], [7/4, c+d]])
```

# stats::sample

---

```
5 a
b 7.534
7/4 c + d
```

For a sample with only one column one can use a flat list instead of a list of rows:

```
stats::sample([5, 3, 8])
```

```
5
3
8
```

## Example 2

The following input creates a small sample with columns for “gender”, “age” and “height”, respectively:

```
stats::sample([["m", 26, 180], ["f", 22, 160],
 ["f", 48, 155], ["m", 30, 172]])
```

```
"m" 26 180
"f" 22 160
"f" 48 155
"m" 30 172
```

Note that all entries in a column are automatically converted to strings, if one entry of that column is a string:

```
stats::sample([[m, 26, 180], [f, 22, 160],
 ["f", 48, 155], [m, 30, 172]])
```

```
"m" 26 180
"f" 22 160
"f" 48 155
"m" 30 172
```

### Example 3

The functions `float`, `has`, `map`, `nops`, `op`, and `subsop` are overloaded to work on samples as on lists of lists:

```
s := stats::sample([[a, 1], [b, 2], [c, 3]])
```

```
a 1
b 2
c 3
```

```
float(s), has(s, a), map(s, list -> [list[1], list[2]^2]),
nops(s), subsop(s, 1 = [d, 4]), op(s, [1, 2])
```

```
a 1.0 a 1 d 4
b 2.0 , TRUE, b 4 , 3, b 2 , 1
c 3.0 c 9 c 3
```

Indexing works like on arrays:

```
s[1, 2] := x : s
```

```
a x
b 2
c 3
```

# stats::sample

---

delete s:

## Example 4

The dot operator may be used to concatenate samples and lists (regarded a samples with one row):

```
s := stats::sample([[1, a], [2, b]]): s.[X, Y].s
```

```
1 a
2 b
X Y
1 a
2 b
```

delete s:

## Parameters

$a_1, 1'$   $a_1, 2'$  ...

Arithmetical expressions or strings.

## Methods

Mathematical Methods

### equal - Test for equality

equal(s1, s2)

Conversion Methods

### convert - Convert a list to a sample

convert(x)

### convert\_to - Convert a sample to a list of lists

convert\_to(s, T)

### expr - Convert a sample to a list of lists of expressions

expr(s)

## Access Methods

### **size - Return the number of rows**

```
size(s)
```

### **col2list - Return a particular column as a list**

```
col2list(s, c,)
```

### **append - Append a row**

```
append(s, row)
```

### **\_concat - Create a sample from the rows of several samples**

```
_concat(s, s1,)
```

### **delCol - Delete one or more columns**

```
delCol(s, c)
```

### **delRow - Delete one or more rows**

```
delRow(s, r)
```

### **float - Map the float function to all entries**

```
float(s)
```

### **has - Test for the occurrence of elements**

```
has(s, e)
```

If *e* is a list or a set, then this method tests, whether at least one of its elements is among the entries of *s*.

### **\_index - Return a particular entry**

```
_index(s, i, j)
```

Indexed calls such as `s[i, j]` call this method.

### **set\_index - Assign a new value to an entry**

```
set_index(s, i, j, x)
```

This method is called by indexed assignments of the form `s[i, j] := x`.

**map - Map a function to the rows**

```
map(s, f)
```

**nops - Number of rows**

```
nops(s)
```

**op - Get the operands (rows)**

```
op(s, i)
```

```
op(s, [i, j])
```

**subsop - Replace a row**

```
subsop(s, i = newrow,)
```

**row2list - Return a particular row as a list**

```
row2list(s, r,)
```

**Technical Methods**

**print - Output**

```
print(s)
```

**fastprint - Fast output**

```
fastprint(s)
```

**Purpose** Convert a sample to a list of lists

**Syntax** `stats::sample2list(s)`

**Description** `stats::sample2list(s)` converts the sample `s` to a list of lists. The sub-lists of the list returned by `stats::sample2list(s)` are the rows of the sample `s`.

**Examples** **Example 1**

First we create a sample from a list of lists:

```
stats::sample([[123, s, 1/2], [442, s, -1/2], [322, p, -1/2]])
```

```
123 s 1/2
442 s -1/2
322 p -1/2
```

The input list may be recovered by `stats::sample2list`:

```
stats::sample2list(%)
```

```
[[[123, s, 1/2], [442, s, -1/2], [322, p, -1/2]]]
```

**Parameters** `s`

A sample of domain type `stats::sample`.

**Return Values** List of lists.

# stats::sample2list

---

## See Also

## MuPAD Functions

`stats::unzipCol` | `stats::zipCol`

## Purpose

Select rows of a sample

## Syntax

```
stats::selectRow(s, c, x, <Not>)
stats::selectRow(s, [c1, c2, ...], [x1, x2, ...], <Not>)
```

## Description

`stats::selectRow(s, ...)` selects rows of the sample `s` having specific entries in specific places.

`stats::selectRow(s, c, x)` returns a sample consisting of all rows in `s`, which contain the data element `x` at the position `c`.

`stats::selectRow(s, [c1, c2, ...], [x1, x2, ...])` returns a sample consisting of all rows in `s`, which contain the data element `x1` at the position `c1` and `x2` at the position `c2` etc. There must be as many positions `c1, c2, ...` as data elements `x1, x2, ...`

## Examples

### Example 1

We create a sample with two columns:

```
stats::sample([[a, 5], [c, 1], [a, 2], [b, 3]])
```

```
a 5
c 1
a 2
b 3
```

We select all rows with `a` as their first entry:

```
stats::selectRow(%, 1, a)
```

```
a 5
a 2
```

# stats::selectRow

---

## Example 2

We create a sample containing income and costs in the years 1997 and 1998:

```
stats::sample([[123, "costs", "97"], [442, "income", "98"],
 [11, "costs", "98"], [623, "income", "97"]])
```

```
123 "costs" "97"
442 "income" "98"
 11 "costs" "98"
623 "income" "97"
```

We select the row which has "income" in the second and "97" in the third column:

```
stats::selectRow(%, [2, 3], ["income", "97"])
```

```
623 "income" "97"
```

We select the remaining rows:

```
stats::selectRow(%2, [2, 3], ["income", "97"], Not)
```

```
123 "costs" "97"
442 "income" "98"
 11 "costs" "98"
```

## Parameters **s**

A sample of domain type `stats::sample`.

**$c$ ,  $c_1$ ,  $c_2$ , ...**

Integers representing column indices of the sample  $s$ .

**$x$ ,  $x_1$ ,  $x_2$ , ...**

Arithmetical expressions.

## Options

### Not

Causes `stats::selectRow` to select those rows which do *not* have the specified entries.

## Return Values

Sample of domain type `stats::sample`.

## See Also

## MuPAD Functions

`stats::row`

# stats::sortSample

---

**Purpose** Sort the rows of a sample

**Syntax**  
`stats::sortSample(s)`  
`stats::sortSample(s, c1, c2, ...)`  
`stats::sortSample(s, [c1, c2, ...])`

**Description** `stats::sortSample(s, ...)` sorts the rows of the sample `s`.

The sorting of rows only uses the entries of the specified columns. First, rows are sorted according to the elements of the first specified column. Those rows with identical elements in the first specified column are then ordered according to the elements in the second specified column etc.

If no columns are specified, then column 1 is used for sorting. In case of a tie, column 2 is used etc.

Numbers are sorted numerically, strings are sorted lexicographically. Identifiers are sorted according to the strategy used by the MuPAD `sort` command. Numbers come first, identifiers second.

## Examples

### Example 1

We create a sample with one column and sort it:

```
stats::sortSample(stats::sample([x, g2, 3, g1, 8/5, 2]))
```

```
8/5
2
3
g1
g2
x
```

### Example 2

We create a sample with two columns:

```
stats::sample([[b, 2], [a, 5], [a, 2], [c, 1], [b, 3]])
```

```
b 2
a 5
a 2
c 1
b 3
```

Note the different sorting priorities specified by the column indices:

```
stats::sortSample(%, 1), stats::sortSample(%, 2),
stats::sortSample(%, 1, 2), stats::sortSample(%, 2, 1)
```

```
a 2 c 1 a 2 c 1
a 5 a 2 a 5 a 2
b 3 , b 2 , b 2 , b 2
b 2 b 3 b 3 b 3
c 1 a 5 c 1 a 5
```

### Example 3

We create a sample containing income and costs in the years 1997 and 1998:

```
stats::sample([[123, "costs", "97"], [720, "income", "98"],
 [623, "income", "97"], [150, "costs", "98"]])
```

```
123 "costs" "97"
720 "income" "98"
623 "income" "97"
150 "costs" "98"
```

# stats::sortSample

---

We sort according to the year (third column):

```
stats::sortSample(%, 3)
```

```
623 "income" "97"
123 "costs" "97"
150 "costs" "98"
720 "income" "98"
```

We sort with priority on the year. Items of the same year are then sorted lexicographically (“costs” before “income”):

```
stats::sortSample(%2, 3, 2)
```

```
123 "costs" "97"
623 "income" "97"
150 "costs" "98"
720 "income" "98"
```

## Parameters

**s**

A sample of domain type `stats::sample`.

**c<sub>1</sub>, c<sub>2</sub>, ...**

Integers representing column indices of the sample `s`.

## Return Values

Sample of domain type `stats::sample`.

## See Also

## MuPAD Functions

`stats::selectRow`

# stats::stdev

---

**Purpose** Standard deviation of a data sample

**Syntax**  
`stats::stdev(x1, x2, ..., <Sample | Population>)`  
`stats::stdev([x1, x2, ..., ], <Sample | Population>)`  
`stats::stdev(s, <c>, <Sample | Population>)`

**Description** `stats::stdev(x1, x2, ..., xn)` returns the standard deviation

$$\sqrt{\frac{1}{n-1} \left( \sum_{i=1}^n (x_i - \bar{x})^2 \right)}$$

where  $\bar{x}$  is the arithmetic mean of the data  $x_i$ .

`stats::stdev(x1, x2, ..., xn, Population)` returns

$$\sqrt{\frac{1}{n} \left( \sum_{i=1}^n (x_i - \bar{x})^2 \right)}$$

The standard deviation is the square root of the variance.

The column index `c` is optional, if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-421.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Examples

### Example 1

We calculate the standard deviation of three values:

```
stats::stdev(2, 3, 5)
```

$$\frac{\sqrt{3} \sqrt{7}}{3}$$

Alternatively, the data may be passed as a list:

```
stats::stdev([2, 3, 5])
```

$$\frac{\sqrt{3} \sqrt{7}}{3}$$

## Example 2

We create a sample:

```
stats::sample([[a1, b1, c1], [a2, b2, c2]])
```

```
a1 b1 c1
a2 b2 c2
```

The standard deviation of the second column is:

```
expand(stats::stdev(%, 2))
```

$$\sqrt{2} \sqrt{\frac{b1^2}{4} - \frac{b1 b2}{2} + \frac{b2^2}{4}}$$

## Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample(["1996", 1242], ["1997", 1353], ["1998", 1142])
```

```
"1996" 1242
"1997" 1353
"1998" 1142
```

We compute the standard deviation of the second column. In this case this column does not have to be specified, since it is the only non-string column:

```
float(stats::stdev(%))

105.5477775
```

We repeat the computation with the option `Population`:

```
float(stats::stdev(%2, Population))

86.17939945
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: arithmetical expressions

**`s`**

A sample of domain type `stats::sample`

**`c`**

An integer representing a column index of the sample `s`. This column provides the data  $x_1, x_2$  etc.

## Options

**Population, Sample**

With `Sample`, the data are regarded as a “sample”, not as a full population. The default is `Sample`.

**Return  
Values**

Arithmetical expression.

**See Also****MuPAD  
Functions**

`stats::geometricMean` | `stats::harmonicMean` | `stats::mean`  
| `stats::median` | `stats::modal` | `stats::quadraticMean` |  
`stats::variance`

**Purpose** The Shapiro-Wilk goodness-of-fit test for normality

**Syntax**  
`stats::swGOFT(x1, x2, ...)`  
`stats::swGOFT([x1, x2, ...])`  
`stats::swGOFT(s, <c>)`

**Description** `stats::swGOFT([x1, x2, ...])` applies the Shapiro-Wilk goodness-of-fit test for the null hypothesis: “the data  $x_1, x_2, \dots$  are normally distributed (with unknown mean and variance)”. The sample size must not be larger than 5000 and not smaller than 3.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

An error is raised by `stats::swGOFT` if any of the data cannot be converted to a real floating-point number or if the sample size is too large or too small.

Let  $y_1, \dots, y_n$  be the input data  $x_1, \dots, x_n$  arranged in ascending order. `stats::swGOFT` returns the list [PValue = p, StatValue = w] containing the following information:

- w is the attained value of the Shapiro-Wilk statistic

$$W = \frac{\left(\sum_{i=1}^n a_i y_i\right)^2}{n S^2} = \frac{\left(\sum_{i=1}^{\lfloor \frac{n}{2} \rfloor} a_{n+1-i} (y_{n+1-i} - y_i)\right)^2}{n S^2}$$

Here, the  $a_i$  are the Shapiro-Wilk coefficients, and  $S^2$  is the statistical variance of the sample.

- p is the observed significance level of the Shapiro-Wilk statistic  $W$ .

The observed significance level `PValue = p` returned by `stats::swGOFT` has to be interpreted in the following way: If `p` is smaller than a given significance level  $\alpha \ll 1$ , the null hypothesis may be rejected at level  $\alpha$ . If `p` is larger than  $\alpha$ , the null hypothesis should not be rejected at level  $\alpha$ .

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We test a list of random data that purport to be a sample of normally distributed numbers:

```
f := stats::normalRandom(0, 1, Seed = 123):
data := [f() $ i = 1..400]:
stats::swGOFT(data)
```

```
[PValue = 0.4902802259, StatValue = 0.9963301659]
```

The observed significance level `0.49...` is not small. Consequently, one should not reject the null hypothesis that the data are normally distributed.

Next, we dote the data with some uniformly continuous deviates:

```
impuredata := data . [frandom() $ i = 1..101]:
stats::swGOFT(impuredata)
```

```
[PValue = 0.00001713272044, StatValue = 0.9833725964]
```

The dotted data may be rejected as a sample of normal deviates at significance levels as small as `0.000017....`

```
delete f, data, impuredata:
```

## Example 2

We create a sample consisting of one string column and two non-string columns:

```
s := stats::sample(
 [["1996", 1242, PI - 1/2],
 ["1997", 1353, PI + 0.3],
 ["1998", 1142, PI + 0.5],
 ["1999", 1201, PI - 1],
 ["2001", 1201, PI]
]
)
```

```
"1996" 1242 PI - 1/2
"1997" 1353 PI + 0.3
"1998" 1142 PI + 0.5
"1999" 1201 PI - 1
"2001" 1201 PI
```

We check whether the data of the third column are normally distributed:

```
stats::swGOFT(s, 3)
```

```
[PValue = 0.7314967372, StatValue = 0.9492034961]
```

The observed significance level returned by the test is not small: the test does not indicate that the data are not normally distributed.

```
delete s:
```

## Parameters

$x_1, x_2, \dots$

The statistical data: real numerical values

**s**

A sample of domain type `stats::sample`

**c**

An integer representing a column index of the sample `s`. This column provides the data  $x_1, x_2$  etc. There is no need to specify a column number `c` if the sample has only one column.

## Return Values

List of two equations [`PValue = p`, `StatValue = w`] with floating-point values `p` and `w`. See the 'Details' section below for the interpretation of these values.

## Algorithms

The implemented algorithm for the computation of the Shapiro-Wilk coefficients, the Shapiro-Wilk statistic and the observed significance level is based on: Patrick Royston, "Algorithm AS R94", Applied Statistics, Vol.44, No.4 (1995).

Following Royston, the Shapiro-Wilk coefficients  $a_i$  are computed by an approximation of

$$a = \frac{M}{V \left( \left( \frac{M^T}{V} \right) \left( \frac{M}{V} \right) \right)}$$

where  $M$  denotes the expected values of standard normal order statistic for a sample,  $V$  is the corresponding covariance matrix, and  $M^T$  is the transpose of  $M$ .

## MuPAD Functions

`stats::csGOFT` | `stats::ksGOFT` | `stats::tTest`

# stats::tabulate

---

**Purpose** Statistics of duplicate rows in a sample

**Syntax**

```
stats::tabulate(s)
stats::tabulate(s, c1, c2, , <f>)
stats::tabulate(s, c1 .. c2, c3 .. c4, , <f>)
stats::tabulate(s, [c1, f1], [c2, f2],)
stats::tabulate(s, [c1, c2, , f1], [c3, c4, , f2],)
```

**Description** `stats::tabulate(s)` eliminates duplicate rows in the sample `s` and appends a column containing the multiplicities.

`stats::tabulate( s, c1, c2, , f )` combines all rows that are identical except for entries in the specified columns `c1, c2` etc. The function `f` is applied to these columns, its result replaces the values in these columns.

`stats::tabulate( s, [c1, f1], [c2, f2], )` combines all rows that are identical except for entries in the columns `c1, c2` etc. The functions `f1, f2` etc. are applied to these columns, the results replace the values in these columns.

`stats::tabulate` regards rows as duplicates if they have identical entries in the columns that are *not* specified.

With `stats::tabulate( s, c1, c2, , f )` the function `f` is applied to the entries of the duplicate rows in the specified columns. Duplicates are eliminated and replaced by a single instance of the row, the result of `f` is inserted into the corresponding columns.

The function `f` must accept as many parameters as there are duplicates. Typical applications involve functions such as `stats::mean` which accept arbitrarily many arguments.

E.g., with `stats::mean` duplicate rows are replaced by a single row, in which the entries of the columns `c1, c2` etc. are replaced by the mean values of the corresponding entries of the duplicates.

If no function `f` is specified, then the default function `_plus` is used.

If column indices are specified more than once, extra columns with the result of the specified function are inserted into the sample.

Consecutive columns may be specified by ranges. E.g., the call `stats::tabulate(s, c[1]..c[2], dots, f)` is a short hand notation for `stats::tabulate(s, c1, c1 + 1, , c2, , f)`.

With `stats::tabulate(s, [c1, f1], [c2, f2], )` pairs of columns and corresponding procedures are specified. Again, rows are regarded as duplicates if they have identical entries in the columns that are *not* specified. Duplicates are eliminated and replaced by a single instance of the row, the result of  $f_1$  is inserted in column  $c_1$ , the result of  $f_2$  is inserted in column  $c_2$  etc.

If column indices are specified more than once, then extra columns with the result of the specified functions are inserted into the sample.

With `stats::tabulate(s, [c1, c2, , f1], )` it is possible to apply functions that act on several columns. The procedure  $f_1$  has to accept a sequence of lists (each representing a column). The specified columns are replaced by a single column containing the result of  $f_1$ . If column indices are specified more than once, then extra columns with the result of the specified function(s) are inserted into the sample. See “Example 2” on page 29-430 and “Example 3” on page 29-432.

## Examples

### Example 1

We create a sample:

```
s := stats::sample([[a, A, 1], [a, A, 1], [a, A, 2],
 [b, B, 5], [b, B, 10]])
```

```
a A 1
a A 1
a A 2
b B 5
b B 10
```

Duplicate rows of the sample are counted. There are four unique rows, one occurring twice:

# stats::tabulate

---

```
stats::tabulate(s)
```

```
a A 1 2
a A 2 1
b B 5 1
b B 10 1
```

In the following call, rows are regarded as duplicates if the entries in the first two columns coincide. We compute the mean value of the third entry of the duplicates:

```
stats::tabulate(s, 3, stats::mean)
```

```
a A 4/3
b B 15/2
```

We compute both the mean and the standard deviation of the data in the third column for the sub-samples labeled 'a A' and 'b B' by the first two columns:

```
stats::tabulate(s, [3, stats::mean], [3, stats::stdev])
```

```
a A 4/3 3^(1/2)/3
b B 15/2 (5*2^(1/2))/2
```

```
delete s:
```

## Example 2

We create a sample containing columns for “gender”, “age” and “size”:

```
s := stats::sample(["f", 25, 166], ["m", 30, 180],
```

```
["f", 54, 160], ["m", 40, 170],
["f", 34, 170], ["m", 20, 172]])
```

```
"f" 25 166
"m" 30 180
"f" 54 160
"m" 40 170
"f" 34 170
"m" 20 172
```

We use `stats::mean` on the second and third column to calculate the average “age” and “size” of each gender:

```
stats::tabulate(s, 2..3, float@stats::mean)
```

```
"f" 37.66666667 165.3333333
"m" 30.0 174.0
```

With the next call both the mean and the standard deviation of “age” and “size” for each gender are inserted into the sample.

```
stats::tabulate(s,
 [2, float@stats::mean], [2, float@stats::stdev],
 [3, float@stats::mean], [3, float@stats::stdev])
```

```
"f" 37.66666667 14.84362939 165.3333333 5.033222957
"m" 30.0 10.0 174.0 5.291502622
```

We compute the Bravais-Pearson correlation coefficient between “age” and “size” for each gender:

# stats::tabulate

---

```
stats::tabulate(s, [2, 3, float@stats::correlation])
```

```
"f" -0.7540135991
"m" -0.1889822365
```

delete s:

## Example 3

We create a sample:

```
s := stats::sample([[a, x1, 1, 2], [b, x2, 2, 4],
 [b, x1, 2, 4], [e, x2, 3, 5.5]])
```

```
a x1 1 2
b x2 2 4
b x1 2 4
e x2 3 5.5
```

We regard rows with the same entry in the second column as “of the same kind”. We tabulate the sample using different functions on the remaining columns:

```
stats::tabulate(s, [1, _plus], [3, _mult], [4, stats::mean])
```

```
a + b x1 2 3
b + e x2 6 4.75
```

One can apply customized procedures. In the following we define the procedure `plussmult`, which sums up the elements of two lists (representing columns) and then multiplies the sums.

```
plusmult := proc(x, y) begin _plus(op(x))*_plus(op(y)) end_proc:
```

This procedure is then used to combine the first and the third column. Simultaneously, the mean and the standard deviation of the fourth column is inserted into the sample.

```
stats::tabulate(s, [1, 3, plusmult], [4, stats::mean],
 [4, stats::stdev])
```

```
3*a + 3*b x1 3 2^(1/2)
5*b + 5*e x2 4.75 1.060660172
```

```
delete plusmult, s:
```

## Parameters

**s**

A sample of domain type stats::sample

**c<sub>1</sub>, c<sub>2</sub>, ...**

Integers representing column indices of the sample s

**f, f<sub>1</sub>, f<sub>2</sub>, ...**

Procedures

## Return Values

Sample of domain type stats::sample.

## See Also

## MuPAD Functions

stats::calc

**Purpose** Cumulative distribution function of Student's t-distribution

**Syntax** stats::tCDF(a)

**Description** stats::tCDF(a) returns a procedure representing the cumulative distribution function

$$X \rightarrow \frac{\Gamma\left(\frac{a+1}{2}\right)}{\Gamma\left(\frac{a}{2}\right) \sqrt{a} \pi} \int_{-\infty}^x \frac{1}{\left(1 + \frac{t^2}{a}\right)^{\frac{a+1}{2}}} dt$$

of Student's t-distribution with shape parameter ('degrees of freedom')  $a > 0$ .

The procedure `f := stats::tCDF(a)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `a` can be converted to a positive floating point number `x` is a real number, the return value `f(x)` is a floating-point number.

`f(infinity)` produces 0.0; `f(-infinity)` produces 1.0.

In all other cases, `f(x)` returns the symbolic call `stats::tCDF(a)(x)`.

The procedure `f := stats::tCDF(a)` can also be called in the form `f(x, Symbolic)` with arithmetical expressions `x`.

If `a` is a positive integer, explicit symbolic expressions in `x` are returned. Otherwise, the function behaves as if called without the option `Symbolic`. Cf. "Example 3" on page 29-436.

Numerical values of `a` are only accepted if they are positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

**Examples****Example 1**

We evaluate the cumulative distribution function with  $a = \frac{3}{4}$  at various points:

```
f := stats::tCDF(3/4):
f(-infinity), f(-4), f(0), f(1/2), f(0.75), f(PI), f(infinity)
```

```
0.0, 0.1085580939, 0.5, 0.6374082038, 0.689341961, 0.8707365121, 1.0
```

Nonpositive numerical values of the shape parameter lead to an error:

```
stats::tCDF(-1)(0.75)
```

```
Error: The shape parameter must be positive. [stats::tCDF]
```

```
delete f:
```

**Example 2**

We use symbolic arguments:

```
f := stats::tCDF(a): f(x), f(1/3), f(0.4)
```

```
stats::tCDF(a)(x), stats::tCDF(a)(1/3), stats::tCDF(a)(0.4)
```

When a positive real number is assigned to  $a$ , the call  $f(x)$  returns a floating-point number if  $x$  is numerical:

```
a := sqrt(10): f(PI)
```

```
0.9759846335
```

delete f, a:

### Example 3

We demonstrate the option `Symbolic`. Without this option, the CDF function only produces explicit results if both `a` and `x` are numerical values:

```
stats::tCDF(3)(x)
```

```
stats::tCDF(3)(x)
```

If the shape parameter is a positive integer, an explicit symbolic representation of the t-distribution exists for any `x`:

```
f := stats::tCDF(3): f(x, Symbolic)
```

$$\frac{\arctan\left(\frac{\sqrt{3}x}{3}\right)}{\pi} + \frac{\sqrt{3}x}{3\left(\frac{\pi x^2}{3} + \pi\right)} + \frac{1}{2}$$

No internal floating-point conversions occur even if all input parameters are exact numerical values:

```
f(sqrt(2), Symbolic) = f(sqrt(2))
```

$$\frac{\arctan\left(\frac{\sqrt{2}\sqrt{3}}{3}\right)}{\pi} + \frac{\sqrt{2}\sqrt{3}}{5\pi} + \frac{1}{2} = 0.8738922518$$

If the shape parameter is not a positive integer, the option `Symbolic` has no effect. The function `f` behaves as if called without this option:

```
f := stats::tCDF(PI):
```

```
f(sqrt(2), Symbolic) = f(sqrt(2))
```

```
0.8758345238 = 0.8758345238
```

```
f := stats::tCDF(PI):
f(x, Symbolic)
```

```
stats::tCDF(π)(x, Symbolic)
```

```
delete f:
```

**Parameters****a**

The shape parameter: an arithmetical expression representing a positive real value

**Return Values**

procedure.

**See Also****MuPAD Functions**

stats::tPDF | stats::tQuantile | stats::tRandom

**Purpose** Probability density function of Student's t-distribution

**Syntax** stats::tPDF(a)

**Description** stats::tPDF(a) returns a procedure representing the probability density function

$$X \rightarrow \frac{\Gamma\left(\frac{a+1}{2}\right)}{\Gamma\left(\frac{a}{2}\right) \sqrt{a \pi}} \left(\frac{x^2}{a} + 1\right)^{-\frac{a}{2} - \frac{1}{2}}$$

of Student's t-distribution with shape parameter ('degrees of freedom')  $a > 0$ .

The procedure `f := stats::tPDF(a)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `x` is a floating-point number and `a` can be converted to a floating-point number, then `f(x)` returns a floating-point number.

`f(infinity)` and `f(-infinity)` produce the result 0.0.

In all other cases, the expression  $\frac{\Gamma\left(\frac{a+1}{2}\right)}{\Gamma\left(\frac{a}{2}\right) \sqrt{a} \sqrt{\pi}}$  is returned.

If floating-point results are desired, call `f(x)` with a floating-point value `x`.

Numerical values for `a` are only accepted if they are real and positive.

**Examples****Example 1**

We evaluate the probability density function with  $a = \frac{3}{4}$  at various points:

```
f := stats::tPDF(3/4):
f(-infinity), f(-PI), f(1/2), f(0.5), f(3), f(infinity)
```

$$0.0, \frac{2\sqrt{3}\Gamma(\frac{7}{8})}{3\sqrt{\pi}\Gamma(\frac{3}{8})\left(\frac{4\pi^2}{3}+1\right)^{7/8}}, \frac{3^{3/8}4^{1/8}\Gamma(\frac{7}{8})}{2\sqrt{\pi}\Gamma(\frac{3}{8})}, 0.2328286673, \frac{2\sqrt{3}13^{1/8}\Gamma(\frac{7}{8})}{39\sqrt{\pi}\Gamma(\frac{3}{8})}, 0.0$$

```
delete f:
```

**Example 2**

We use symbolic arguments:

```
f := stats::tPDF(a): f(x), f(0.3)
```

$$\frac{\Gamma(\frac{a}{2} + \frac{1}{2})}{\sqrt{\pi}\sqrt{a}\Gamma(\frac{a}{2})\left(\frac{x^2}{a} + 1\right)^{\frac{a}{2} + \frac{1}{2}}}, \frac{0.5641895835\Gamma(\frac{a}{2} + \frac{1}{2})}{\sqrt{a}\Gamma(\frac{a}{2})\left(\frac{0.09}{a} + 1\right)^{\frac{a}{2} + \frac{1}{2}}}$$

When numerical values are assigned to  $a$ , the function  $f$  starts to produce floating-point values for floating-point arguments:

```
a := PI: f(0.3)
```

```
0.347916859
```

```
delete f, a:
```

# stats::tPDF

`stats::tCDF` | `stats::tQuantile` | `stats::tRandom`

<b>Purpose</b>	Quantile function of Student's t-distribution
<b>Syntax</b>	<code>stats::tQuantile(a)</code>
<b>Description</b>	<p><code>stats::tQuantile(a)</code> returns a procedure representing the quantile function (inverse) of the cumulative distribution function <code>stats::tCDF(a)</code>. For <math>0 \leq x \leq 1</math>, the solution of <math>stats::tCDF(a)(y) = x</math> is given by <math>y = stats::tQuantile(a)(x)</math>.</p> <p>The procedure <code>f := stats::tQuantile(a)</code> can be called in the form <code>f(x)</code> with an arithmetical expression <code>x</code>. The return value of <code>f(x)</code> is either a floating-point number, <code>±infinity</code>, or a symbolic expression:</p> <p>If <code>x</code> is a real number between 0 and 1 and the shape parameter <code>a</code> can be converted to a positive real floating-point number, then <code>f(x)</code> returns a real floating-point number approximating the solution <code>y</code> of <math>stats::tCDF(a)(y) = x</math>.</p> <p>The calls <code>f(1/2)</code> and <code>f(0.5)</code> produce <code>0.0</code> for all values of <code>a</code>.</p> <p>The calls <code>f(0)</code> and <code>f(0.0)</code> produce <code>-infinity</code> for all values of <code>a</code>.</p> <p>The calls <code>f(1)</code> and <code>f(1.0)</code> produce <code>infinity</code> for all values of <code>a</code>.</p> <p>In all other cases, <code>f(x)</code> returns the symbolic call <code>stats::tQuantile(a)(x)</code>.</p> <p>Numerical values of <code>x</code> are only accepted if <math>0 \leq x \leq 1</math>.</p> <p>Numerical values of the shape parameter <code>a</code> are only accepted if they are real and positive.</p>
<b>Environment Interactions</b>	The function is sensitive to the environment variable <code>DIGITS</code> which determines the numerical working precision.
<b>Examples</b>	<p><b>Example 1</b></p> <p>We evaluate the quantile function with <code>a = π</code> at various points:</p> <pre>f := stats::tQuantile(PI): f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)</pre>

# stats::tQuantile

---

```
- ∞, - 1.618021174, 0.0, 1639.390923, ∞
```

The value  $f(x)$  satisfies `stats::tCDF(PI)(f(x)) = x`:

```
stats::tCDF(PI)(f(0.987654))
```

```
0.987654
```

```
delete f:
```

## Example 2

We use symbolic arguments:

```
f := stats::tQuantile(a): f(x), f(9/10)
```

```
stats::tQuantile(a)(x), stats::tQuantile(a)($\frac{9}{10}$)
```

When a positive real value is assigned to the shape parameter  $a$ , the function  $f$  starts to produce floating-point values:

```
a := 17: f(0.999), f(1 - sqrt(2)/10^5)
```

```
3.64576738, 5.65913443
```

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

```
f(0.5)
```

```
0.0
```

```
f(2)
```

```
Error: An argument x with 0 <= x <= 1 is expected. [f]
```

```
delete f, a:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::tCDF | stats::tPDF | stats::tRandom

# stats::tRandom

---

**Purpose** Generate a random number generator for Student deviates (t-deviates)

**Syntax** stats::tRandom(a, <Seed = s>)

**Description** stats::tRandom(a) returns a procedure that produces t-deviates (random numbers) with shape parameter ('degrees of freedom') a>0.

The procedure `f := stats::tRandom(a)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If a can be converted to a positive floating point number, then `f()` returns a real floating point number.

In all other cases, `stats::tRandom(a)()` is returned symbolically.

Numerical values of a are only accepted if they are real and positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the t-distribution with shape parameter a. For any real x, the probability that  $X \leq x$  is given by

$$\frac{\Gamma\left(\frac{a+1}{2}\right)}{\Gamma\left(\frac{a}{2}\right) \sqrt{a} \pi} \int_{-\infty}^x \frac{1}{\left(1 + \frac{t^2}{a}\right)^{\frac{a+1}{2}}} dt$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::tRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

```
f := stats::tRandom(a): f() $k = 1..K;
```

rather than by

```
stats::tRandom(a)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::tRandom(a, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate t-deviates with shape parameter  $a = 23$ :

```
f := stats::tRandom(23): f() $ k = 1..4
```

```
-0.4417960021, 0.8951424894, 1.291568047, -0.8938637441
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::tRandom(a): f()
```

# stats::tRandom

---

```
stats::tRandom(a())
```

When the shape parameter `a` evaluates to a positive real number, `f` starts to produce random floating-point numbers:

```
a := sqrt(99): f() $ k = 1..4
```

```
0.2115095721, 0.3326980658, 0.6483250281, 4.341741815
```

```
delete f, a:
```

### Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::tRandom(PI, Seed = 1): f() $ k = 1..4
```

```
0.006866430292, -1.483500533, -0.6688788771, 0.4017860587
```

```
g := stats::tRandom(PI, Seed = 1): g() $ k = 1..4
```

```
0.006866430292, -1.483500533, -0.6688788771, 0.4017860587
```

```
f() = g(), f() = g()
```

```
0.03860593782 = 0.03860593782, -1.259521158 = -1.259521158
```

```
delete f, g:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

## Options

**Seed**

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `CurrentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the shape parameter `a` must be convertible to a positive floating-point number at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of the t-deviates uses a gamma deviate  $X$  with shape parameter  $a/2$  and a normal deviate  $Y$  to arrive at a t-deviate  $X/\sqrt{Y/a}$ . For more information see: D. Knuth, *Seminumerical Algorithms* (1998), Vol. 2, p. 135.

## MuPAD Functions

`stats::tCDF` | `stats::tPDF` | `stats::tQuantile`

# stats::tTest

---

**Purpose** T-test for a mean

**Syntax**  
`stats::tTest(x1, x2, , m, <Normal>)`  
`stats::tTest([x1, x2, ], m, <Normal>)`  
`stats::tTest(s, <c>, m, <Normal>)`

**Description** `stats::tTest( [x1, x2, ], m )` tests the null hypothesis: “the true mean of the data  $x_i$  is larger than  $m$ ”.

`stats::tTest` accepts numerical data as well as symbolic data.

If all data are real floating-point numbers, the returned values  $p$  and  $t$  are floating-point numbers.

If  $m$  is a floating-point number, the sample data are converted to floating-point numbers automatically.

For a sample  $x_1, x_2, \dots$  of size  $n$ , `stats::tTest` computes

$t = \sqrt{\frac{n}{v}} (X - m)$ , where

$$X = \frac{1}{n} \left( \sum_{i=1}^n X_i \right)$$

is the empirical mean of the data and

$$v = \frac{1}{n - 1} \left( \sum_{i=1}^n (X_i - X)^2 \right)$$

is the empirical variance.

`stats::tTest(data, m)` returns the list [PValue =  $p$ , StatValue =  $t$ ], where the observed significance level  $p$  is computed as  $p = \text{stats::tCDF}(n - 1)(t)$ .

`stats::tTest(data, m, Normal)` returns the list [`PValue = p`, `StatValue = t`], where the observed significance level  $p$  is computed as  $p = \text{stats::normalCDF}(0, 1)(t)$ . For large  $n$ , this is an approximation of  $\text{stats::tCDF}(n - 1)(t)$ .

Intuitively,  $p$  corresponds to the “probability” that the true mean of the data (the expectation value of the underlying distribution) is larger than  $m$ .

The most relevant information returned by `stats::tTest` is the observed significance level `PValue = p`. It has to be interpreted in the following way:

The t-test may be used as a one-tailed test of the null hypothesis: “the true mean of the data is larger than  $m$ ”. In this case, the null hypothesis may be rejected at level  $\alpha$  if the observed significance level  $p$  satisfies  $p < \alpha$ .

Alternatively, the t-test may also be used as a one-tailed test of the null hypothesis: “the true mean of the data is smaller than  $m$ ”. In this case, the null hypothesis may be rejected at level  $\alpha$  if the observed “significance level”  $p$  satisfies  $p > 1 - \alpha$ .

Alternatively, the t-test may also be used as a two-tailed test of the null hypothesis: “the true mean of the data is  $m$ ”. If the observed “significance level”  $p$  returned by `stats::tTest` satisfies either  $p < \frac{\alpha}{2}$  or  $p > 1 - \frac{\alpha}{2}$  for some given level  $0 < \alpha < 1$ , this null hypothesis may be rejected at level  $\alpha$ .

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

10 experiments produced the values 1, -2, 3, -4, 5, -6, 7, -8, 9, 10, which are assumed to be normally distributed with unknown mean and variance. The empirical mean of the sample data is 1.5. There is only a small probability  $p = 0.057\dots$  that the true mean is larger than 5.0:

```
data := [1, -2, 3, -4, 5, -6, 7, -8, 9, 10]:
stats::tTest(data, 5.0)
```

```
[PValue = 0.05758660092, StatValue = -1.743955077]
```

We compare this result with the observed significance level computed via a standard normal distribution:

```
stats::tTest(data, 5.0, Normal)
```

```
[PValue = 0.04058346175, StatValue = -1.743955077]
```

The approximation of the observed significance level  $p$  by the standard normal distribution is rather poor because of the small sample size. Next, we consider a larger sample. The true mean of the random data should be 10:

```
r := stats::normalRandom(10, 12, Seed = 0):
data := [r() $ i = 1..100]:
stats::tTest(data, 10);
```

```
[PValue = 0.2129644942, StatValue = -0.7994751641]
```

```
stats::tTest(data, 10, Normal)
```

[PValue = 0.212007471, StatValue = - 0.7994751641]

With the observed significance level of  $p = 0.212\dots$ , the data are not disqualified as having the true mean 10. For samples of this size, the normal distribution approximates the t-distribution well.

delete data, r:

## Parameters

**$x_1, x_2, \dots$**

The statistical data: arithmetical expressions

**m**

The estimate for the true mean of the data: an arithmetical expression

**s**

A sample of domain type `stats::sample`.

**c**

An integer representing a column index of the sample `s`. This column provides the data  $x_1, x_2$  etc. There is no need to specify a column number `c` if the sample has only one non-string column.

## Options

**Normal**

Compute the observed significance level by a standard normal distribution instead of a t-distribution.

## Return Values

a list of two equations [PValue = p, StatValue = t] with numerical values p and t. See the 'Details' section below for the interpretation of these values.

If the variance of the data vanishes, FAIL is returned.

## Algorithms

If the data are normally distributed with expectation value ('true mean')

$\mu$ , the variable  $T = \sqrt{\frac{n}{V}} (X - \mu)$  is t-distributed with  $n - 1$  degrees of freedom. The probability of the event that  $T$  attains values not larger than  $t$  is  $Pr(T \leq t) = \text{stats::tCDF}(n - 1)(t)$ .

### MuPAD Functions

stats::csGOFT | stats::ksGOFT | stats::mean |  
stats::normalCDF | stats::stdev | stats::swGOFT |  
stats::tCDF

**Purpose** Cumulative distribution function of the uniform distribution

**Syntax** stats::uniformCDF(a, b)

**Description** stats::uniformCDF(a, b) returns a procedure representing the cumulative distribution function

$$x \rightarrow \frac{x - a}{b - a}$$

of the uniform distribution on the interval  $[a, b]$ .

The procedure `f := stats::uniformCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x < a$  can be decided, then `f(x)` returns 0. If  $x > b$  can be decided, then `f(x)` returns the value 1. If  $a \leq x$  and  $x \leq b$  can be decided, then `f(x)` returns the value  $(x - a) / (b - a)$ .

If  $x$  is a real floating-point number and both  $a$  and  $b$  can be converted to real floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x \leq a$ , or  $x \geq b$ , or  $a \leq x$  and  $x \leq b$ , then the corresponding values are returned.

`f(x)` returns the symbolic call `stats::uniformCDF(a, b)(x)` if it cannot be decided whether  $x$  lies in the interval  $[a, b]$ .

Numerical values for  $a$  and  $b$  are only accepted if they are real and  $a \leq b$ .

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

# stats::uniformCDF

---

## Examples

### Example 1

We evaluate the cumulative distribution function on the interval  $[-3, 2\pi]$  at various points:

```
f := stats::uniformCDF(-3, 2*PI):
f(-infinity), f(-3), f(0.5), f(2/3), f(3.0), f(PI), f(infinity)
```

```
0, 0, 0.3770257605, $\frac{11}{3(2\pi+3)}$, 0.6463298751, $\frac{\pi+3}{2\pi+3}$, 1
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $a \leq x \leq b$  holds. A symbolic function call is returned:

```
f := stats::uniformCDF(a, b): f(x)
```

```
stats::uniformCDF(a, b)(x)
```

With suitable properties, it can be decided whether  $a \leq x \leq b$  holds. An explicit expression is returned:

```
assume(x < a): f(x)
```

```
0
```

Note that `assume(x < a)` attached properties both to  $a$  and  $x$ . With the next call, we overwrite the property attached to  $x$ . However, the property attached to  $a$  has to be 'unassumed' as well to avoid inconsistent assumptions  $x < a$  and  $x > b$ :

```
unassume(a): assume(x > b): f(x)
```

$$1$$

```
assume(a <= x <= b): f(x)
```

$$\frac{a - x}{a - b}$$

```
assume(b > a): f(a + (b - a)/3)
```

$$\frac{1}{3}$$

```
unassume(x): unassume(a): unassume(b): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::uniformCDF(a, b): f(3), f(3.0)
```

```
stats::uniformCDF(a, b)(3), stats::uniformCDF(a, b)(3.0)
```

When numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 0: b := PI: f(3), f(3.0)
```

```
 $\frac{3}{\pi}$, 0.9549296586
```

# stats::uniformCDF

---

delete f, a, b:

**Parameters**    **a, b**

arithmetical expressions representing real values;  $a \leq b$  is assumed.

**Return Values**    procedure.

**See Also**

**MuPAD Functions**    stats::uniformPDF | stats::uniformQuantile | stats::uniformRandom

**Purpose**

Probability density function of the uniform distribution

**Syntax**

`stats::uniformPDF(a, b)`

**Description**

`stats::uniformPDF(a, b)` returns a procedure representing the probability density function

$$x \rightarrow \frac{1}{b - a}$$

of the uniform distribution on the interval  $[a, b]$ .

The procedure `f := stats::uniformPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x < a$  or  $x > b$  can be decided, then `f(x)` returns 0. If  $a \leq x$  and  $x \leq b$  can be decided, then `f(x)` returns the value  $1/(b - a)$ .

If  $x$  is a real floating-point number and both  $a$  and  $b$  can be converted to real floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x < a$ , or  $x > b$ , or  $a \leq x$  and  $x \leq b$ , then the corresponding values are returned.

`f(x)` returns the symbolic call `stats::uniformPDF(a, b)(x)` if it cannot be decided whether  $x$  lies in the interval  $[a, b]$ .

Numerical values for  $a$  and  $b$  are only accepted if they are real and  $a \leq b$ .

**Environment Interactions**

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the probability density function on the interval  $[-3, 2\pi]$  at various points:

```
f := stats::uniformPDF(-3, 2*PI):
f(-infinity), f(-PI), f(-3.0), f(1/2), f(0.5), f(PI), f(infinity)
```

```
0, 0, 0.1077216458, $\frac{1}{2\pi + 3}$, 0.1077216458, $\frac{1}{2\pi + 3}$, 0
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $a \leq x \leq b$  hold. A symbolic function call is returned:

```
f := stats::uniformPDF(a, b): f(x)
```

```
stats::uniformPDF(a, b)(x)
```

With suitable properties, it can be decided whether  $a \leq x \leq b$  holds. An explicit expression is returned:

```
assume(x < a): f(x)
```

```
0
```

Note that `assume(x < a)` attached properties both to  $a$  and  $x$ . With the next call, we overwrite the property attached to  $x$ . However, the property attached to  $a$  has to be 'unassumed' as well to avoid inconsistent assumptions  $x < a$  and  $x > b$ :

```
unassume(a): assume(x > b): f(x)
```

```
0
```

```
assume(a <= x <= b): f(x)
```

$$-\frac{1}{a-b}$$

```
assume(b > a): f(a + (b - a)/3)
```

$$-\frac{1}{a-b}$$

```
unassume(x): unassume(a): unassume(b): delete f:
```

### Example 3

We use symbolic arguments:

```
f := stats::uniformPDF(a, b): f(x)
```

```
stats::uniformPDF(a, b)(x)
```

When numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 0: b := PI: f(3), f(3.0)
```

$$\frac{1}{\pi}, 0.3183098862$$

```
delete f, a, b:
```

# stats::uniformPDF

---

**Parameters**      **$a, b$**

arithmetical expressions representing real values;  $a \leq b$  is assumed.

**Return  
Values**

procedure.

**See Also**

**MuPAD  
Functions**

stats::uniformCDF | stats::uniformQuantile |  
stats::uniformRandom

## Purpose

Quantile function of the uniform distribution

## Syntax

```
stats::uniformQuantile(a, b)
```

## Description

`stats::uniformQuantile(a, b)` returns a procedure representing the quantile function (inverse) of the cumulative distribution function `stats::uniformCDF(a, b)` of the uniform distribution on the interval  $[a, b]$ . For  $0 \leq x \leq 1$ , the quantile function is given by  $x \rightarrow a + x(b - a)$ .

The procedure `f := stats::uniformQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If `x` is a real number between 0 and 1 and `a` and `b` can be converted to floating-point numbers, then `f(x)` returns the value  $a + x(b - a)$  as a floating-point number. Otherwise, this value is returned as a symbolic expression.

Numerical values of `x` are only accepted if  $0 \leq x \leq 1$ .

Numerical values for `a` and `b` are only accepted if they are real and  $a \leq b$ .

## Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function over the interval  $[2, \frac{11}{4}]$  at various points:

```
f := stats::uniformQuantile(2, 11/4):
f(0), f(1/10), f(0.5), f(1 - 10^(-5)), f(1)
```

```
2, $\frac{83}{40}$, 2.375, $\frac{1099997}{400000}$, $\frac{11}{4}$
```

```
delete f:
```

# stats::uniformQuantile

---

## Example 2

We use symbolic arguments:

```
f := stats::uniformQuantile(a, b): f(x), f(9/10)
```

$$a - x(a - b), \frac{a}{10} + \frac{9b}{10}$$

When positive real values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 3: b := 11/2: f(0.999), f(1 - sqrt(2)/10^5)
```

$$5.4975, \frac{11}{2} - \frac{\sqrt{2}}{40000}$$

```
delete f, a, b:
```

## Parameters

**$a, b$**

arithmetical expressions representing real values;  $a \leq b$  is assumed.

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::uniformCDF | stats::uniformPDF |  
stats::uniformRandom

**Purpose** Generate a random number generator for uniformly continuous deviates

**Syntax** `stats::uniformRandom(a, b, <Seed = s>)`

**Description** `stats::uniformRandom(a, b)` returns a procedure that produces uniformly continuous deviates (random numbers) on the interval  $[a, b)$ .

The procedure `f := stats::uniformRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` and `b` can be converted to floating-point numbers, then `f()` returns a floating point number between `a` and `b`.

In all other cases, `stats::uniformRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and  $a \leq b$ .

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the uniform distribution on the interval  $[a, b)$ . For any  $a \leq x \leq b$ , the probability that  $X \leq x$  is given

by  $\frac{(x-a)}{(b-a)}$ .

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

---

**Note** In contrast to the function `random`, the generators produced by `stats::uniformRandom` do not react to the environment variable `SEED`.

---

For efficiency, it is recommended to produce sequences of  $K$  random numbers via `f := stats::uniformRandom(a, b): f() $ k = 1..K` rather than by `stats::uniformRandom(a, b)() $ k = 1..K` The

# stats::uniformRandom

---

latter call produces a sequence of generators each of which is called once. Also note that

```
stats::uniformRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate uniform deviates on the interval [2, 7):

```
f := stats::uniformRandom(2, 7): f() $ k = 1..4
```

```
3.351790828, 6.155185894, 2.76578258, 6.974063904
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::uniformRandom(a, b): f()
```

```
stats::uniformRandom(a, b)()
```

When  $a$  and  $b$  evaluate to real numbers,  $f$  starts to produce random floating point numbers:

```
a := PI: b := 10: f() $ k = 1..4
```

```
4.967800682, 4.377232316, 6.242162399, 7.796955809
```

```
delete f, a, b:
```

### Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::uniformRandom(0, 10, Seed = 10^3): f() $ k = 1..4
```

```
8.633422729, 0.1225672185, 6.622938516, 5.069443372
```

```
g := stats::uniformRandom(0, 10, Seed = 10^3): g() $ k = 1..4
```

```
8.633422729, 0.1225672185, 6.622938516, 5.069443372
```

```
f() = g(), f() = g()
```

```
0.6809567809 = 0.6809567809, 0.0395345751 = 0.0395345751
```

```
delete f, g:
```

## Parameters

**a, b**

arithmetical expressions representing real values;  $a \leq b$  is assumed.

## Options

**Seed**

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `currentTime`, to make the seed depend on the current time.

# stats::uniformRandom

---

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed  $s$  which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters  $a$  and  $b$  must be convertible to floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

Uniform deviates on the interval  $[a, b)$  are produced via  $a + (b - a) * \text{frandom}()$ .

## See Also

## MuPAD Functions

`frandom` | `random` | `stats::uniformCDF` | `stats::uniformPDF` | `stats::uniformQuantile`

**Purpose** Extract columns from a list of lists

**Syntax** `stats::unzipCol(list)`

**Description** `stats::unzipCol` extracts the columns of a matrix structure encoded by a list of lists.

`stats::unzipCol` treats a list of lists like a list of rows of a `stats::sample` and extracts the columns. In conjunction with `stats::sample2list` it is useful for extracting the columns of a `stats::sample`.

`stats::unzipCol` is the inverse of `stats::zipCol`.

## Examples

### Example 1

We extract the columns from a list of rows representing a matrix structure:

```
stats::unzipCol([[a11, a12], [a21, a22], [a31, a32]])

[a11, a21, a31], [a12, a22, a32]
```

### Example 2

A list of rows is used to create a sample:

```
stats::sample([[123, s, 1/2], [442, s, -1/2], [322, p, -1/2]])

123 s 1/2
442 s -1/2
322 p -1/2
```

We re-convert the sample to a list of lists:

```
stats::sample2list(%)
```

# stats::unzipCol

---

```
[[[123, s, 1/2], [442, s, -1/2], [322, p, -1/2]]]
```

Finally, we extract the columns:

```
stats::unzipCol(%)
```

```
[123, 442, 322], [s, s, p], [1/2, -1/2, -1/2]
```

## Parameters

**list**

A list of lists.

## Return Values

Sequence of lists to be regarded as columns.

## See Also

## MuPAD Functions

stats::col | stats::sample2list | stats::zipCol

**Purpose**

Variance of a data sample

**Syntax**

```
stats::variance(x1, x2, ..., <Sample | Population>)
stats::variance([x1, x2, ...,], <Sample | Population>)
stats::variance(s, <c>, <Sample | Population>)
```

**Description**

stats::variance( x<sub>1</sub>, x<sub>2</sub>, ..., x<sub>n</sub>) returns the variance

$$\frac{1}{n-1} \left( \sum_{i=1}^n (x_i - \bar{x})^2 \right)$$

where  $\bar{x}$  is the arithmetic mean of the data  $x_i$ .

stats::variance( x<sub>1</sub>, x<sub>2</sub>, ..., x<sub>n</sub>, Population) returns

$$\frac{1}{n} \left( \sum_{i=1}^n (x_i - \bar{x})^2 \right)$$

The variance is the square of the standard deviation.

The column index `c` is optional, if the data are given by a `stats::sample` object containing only one non-string column. Cf. “Example 3” on page 29-470.

External statistical data stored in an ASCII file can be imported into a MuPAD session via `import::readdata`. In particular, see Example 1 of the corresponding help page.

**Examples****Example 1**

We calculate the variance of three values:

```
stats::variance(2, 3, 5)
```

## stats::variance

---

$$\frac{7}{3}$$

Alternatively, the data may be passed as a list:

```
stats::variance([2, 3, 5])
```

$$\frac{7}{3}$$

### Example 2

We create a sample:

```
stats::sample([[a1, b1, c1], [a2, b2, c2]])
```

```
a1 b1 c1
a2 b2 c2
```

The variance of the second column is:

```
expand(stats::variance(%, 2))
```

$$\frac{b1^2}{2} - b1 b2 + \frac{b2^2}{2}$$

### Example 3

We create a sample consisting of one string column and one non-string column:

```
stats::sample(["1996", 1242], ["1997", 1353], ["1998", 1142])
```

```
"1996" 1242
"1997" 1353
"1998" 1142
```

We compute the variance of the second column. In this case this column does not have to be specified, since it is the only non-string column:

```
float(stats::variance(%))
```

```
11140.33333
```

We repeat the computation with the option Population:

```
float(stats::variance(%2, Population))
```

```
7426.888889
```

## Parameters

**$x_1, x_2, \dots$**

The statistical data: arithmetical expressions

**s**

A sample of domain type stats::sample

**c**

An integer representing a column index of the sample s. This column provides the data  $x_1, x_2, \dots$

## Options

**Population, Sample**

With Sample, the data are regarded as a “sample”, not as a full population. The default is Sample.

## stats::variance

---

### **Return Values**

Arithmetical expression.

### **See Also**

### **MuPAD Functions**

`stats::geometricMean` | `stats::harmonicMean` | `stats::mean`  
| `stats::median` | `stats::modal` | `stats::quadraticMean` |  
`stats::stdev`

**Purpose** Cumulative distribution function of the Weibull distribution

**Syntax** `stats::weibullCDF(a, b)`

**Description** `stats::weibullCDF(a, b)` returns a procedure representing the cumulative distribution function

$$x \rightarrow 1 - e^{-\left(\frac{x}{b}\right)^a}$$

of the Weibull distribution with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure `f := stats::weibullCDF(a, b)` can be called in the form `f(x)` with an arithmetical expression  $x$ . The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x \geq 0$  can be decided, then `f(x)` returns the value  $1 - \exp(- (x/b)^a)$ .

If  $x$  is a floating-point number and both  $a$  and  $b$  can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If  $x$  is a symbolic expression with the property  $x \leq 0$  or  $x \geq 0$ , the corresponding values are returned.

The call `f(- infinity )` returns 0.

The call `f( infinity )` returns 1.

`f(x)` returns the symbolic call `stats::weibullCDF(a, b)(x)` if neither  $x \leq 0$  nor  $x \geq 0$  can be decided.

Numerical values for  $a$  and  $b$  are only accepted if they are real and positive.

# stats::weibullCDF

---

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by stats::weibullCDF reacts to properties of identifiers set via assume.

## Examples

### Example 1

We evaluate the cumulative distribution function with  $a = 2$  and  $b = 1$  at various points:

```
f := stats::weibullCDF(2, 1):
f(-infinity), f(-3), f(0.5), f(2/3), f(PI), f(infinity)
```

```
0, 0, 0.2211992169, 1 - e- $\frac{4}{9}$, 1 - e- π^2 , 1
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x \geq 0$  holds. A symbolic function call is returned:

```
f := stats::weibullCDF(a, b): f(x)
```

```
stats::weibullCDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x \geq 0$  holds. An explicit expression is returned:

```
assume(0 < x): f(x)
```

```
1 - e- $(\frac{x}{b})^a$
```

```
unassume(x): delete f:
```

## Example 3

We use symbolic arguments:

```
f := stats::weibullCDF(a, b): f(x)
```

```
stats::weibullCDF(a, b)(x)
```

When numerical values are assigned to a and b, the function f starts to produce numerical values:

```
a := 2: b := 1: f(3), f(3.0)
```

```
1 - e-9, 0.9998765902
```

```
delete f, a, b:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::weibullPDF | stats::weibullQuantile |  
stats::weibullRandom

# stats::weibullPDF

---

**Purpose** Probability density function of the Weibull distribution

**Syntax** stats::weibullPDF(a, b)

**Description** stats::weibullPDF(a, b) returns a procedure representing the probability density function

$$x \rightarrow \frac{a x^{a-1} e^{-\left(\frac{x}{b}\right)^a}}{b^a}$$

of the Weibull distribution with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure `f := stats::weibullPDF(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number or a symbolic expression:

If  $x \leq 0$  can be decided, then `f(x)` returns 0. If  $x > 0$  can be decided, then `f(x)` returns the value  $a \cdot x^{a-1} / b^a \cdot \exp^{-(x/b)^a}$ .

If `x` is a floating-point number and both `a` and `b` can be converted to positive floating-point numbers, then these values are returned as floating-point numbers. Otherwise, symbolic expressions are returned.

The function `f` reacts to properties of identifiers set via `assume`. If `x` is a symbolic expression with the property  $x \leq 0$  or  $x > 0$ , the corresponding values are returned.

`f(-infinity)` and `f(infinity)` return 0.

`f(x)` returns the symbolic call `stats::weibullPDF(a, b)(x)` if neither  $x \leq 0$  nor  $x > 0$  can be decided.

Numerical values for `a` and `b` are only accepted if they are real and positive.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision. The procedure generated by stats::weibullPDF reacts to properties of identifiers set via assume.

## Examples

### Example 1

We evaluate the probability density function with  $a = 2$  and  $b = 1$  at various points:

```
f := stats::weibullPDF(2, 1): f(1/5), f(0.5), f(-1), f(x)
```

```
 $\frac{2 e^{-\frac{1}{25}}}{5}$, 0.7788007831, 0, stats::weibullPDF(2, 1)(x)
```

```
delete f:
```

### Example 2

If  $x$  is a symbolic object without properties, then it cannot be decided whether  $x > 0$  holds. A symbolic function call is returned:

```
f := stats::weibullPDF(a, b): f(x)
```

```
stats::weibullPDF(a, b)(x)
```

With suitable properties, it can be decided whether  $x > 0$  holds. An explicit expression is returned:

```
assume(0 < x): f(x)
```

```
 $\frac{a x^{a-1} e^{-\left(\frac{x}{b}\right)^a}}{b^a}$
```

# stats::weibullPDF

---

```
unassume(x): delete f:
```

## Example 3

We use symbolic arguments:

```
f := stats::weibullPDF(a, b): f(x), f(3)
```

$$\text{stats::weibullPDF}(a, b)(x), \frac{3^{a-1} a e^{-\left(\frac{3}{b}\right)^a}}{b^a}$$

When numerical values are assigned to a and b, the function f starts to produce numerical values:

```
a := 2: b := 1: f(3), f(3.0)
```

```
6 e-9, 0.0007404588245
```

```
delete f, a, b:
```

## Parameters

### MuPAD Functions

stats::weibullCDF | stats::weibullQuantile |  
stats::weibullRandom

# stats::weibullQuantile

---

**Purpose** Quantile function of the Weibull distribution

**Syntax** `stats::weibullQuantile(a, b)`

**Description** `stats::weibullQuantile(a, b)` returns a procedure representing the quantile function (inverse)

$$x \rightarrow b (-\ln(1 - x))^{1/a}$$

of the cumulative distribution function `stats::weibullCDF(a, b)`. For  $0 \leq x \leq 1$ , the solution of  $stats::weibullCDF(a, b)(y) = x$  is given by

$$y = stats::weibullQuantile(a, b)(x)$$

The procedure `f := stats::weibullQuantile(a, b)` can be called in the form `f(x)` with an arithmetical expression `x`. The return value of `f(x)` is either a floating-point number, `infinity`, or a symbolic expression:

If `x` is a real float point number between 0 and 1 and `a` and `b` can be converted to positive floating-point numbers, then `f(x)` returns a floating-point number.

The calls `f(1)` and `f(1.0)` produce `infinity`.

In all other cases, `f(x)` returns the symbolic expression  $a - \ln(1 - x)/b$ .

Numerical values of `x` are only accepted if  $0 \leq x \leq 1$ .

Numerical values of `a` and `b` are only accepted if they are real and positive.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

## Examples

### Example 1

We evaluate the quantile function with  $a = 2$  and  $b = \frac{3}{4}$  at various points:

```
f := stats::weibullQuantile(2, 3/4):
f(0), f(1/10), f(0.5), f(1 - 10^(-10)), f(1)
```

$$0, \frac{3 \sqrt{-\ln\left(\frac{9}{10}\right)}}{4}, 0.6244159584, \frac{3 \sqrt{\ln(10000000000)}}{4}, \infty$$

The value  $f(x)$  satisfies  $\text{stats::weibullCDF}(2, 3)(f(x)) = x$ :

```
stats::weibullCDF(2, 3/4)(f(0.987654321))
```

$$0.987654321$$

```
delete f:
```

### Example 2

We use symbolic arguments:

```
f := stats::weibullQuantile(a, b): f(x), f(1/PI), f(0.99)
```

$$b (-\ln(1-x))^{1/a}, b \left(-\ln\left(1 - \frac{1}{\pi}\right)\right)^{1/a}, 4.605170186^{1/a} b$$

When suitable numerical values are assigned to  $a$  and  $b$ , the function  $f$  starts to produce numerical values:

```
a := 7: b := 1/8: f(0.999), f(999/1000)
```

# stats::weibullQuantile

---

0.1647461562,  $\frac{\ln(1000)^{1/7}}{8}$

Numerical values for  $x$  are only accepted if  $0 \leq x \leq 1$ :

`f(0.5)`

0.1186235162

`f(2)`

Error: An argument  $x$  with  $0 \leq x \leq 1$  is expected. [f]

`delete f, a, b:`

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

The scale parameter: an arithmetical expression representing a positive real value

## Return Values

procedure.

## See Also

## MuPAD Functions

stats::weibullCDF | stats::weibullPDF |  
stats::weibullRandom

## Purpose

Generate a random number generator for Weibull deviates

## Syntax

`stats::weibullRandom(a, b, <Seed = s>)`

## Description

`stats::weibullRandom(a, b)` returns a procedure that produces Weibull deviates (random numbers) with shape parameter  $a > 0$  and scale parameter  $b > 0$ .

The procedure `f := stats::weibullRandom(a, b)` can be called in the form `f()`. The return value of `f()` is either a floating-point number or a symbolic expression:

If `a` and `b` can be converted to positive floating-point numbers, then `f()` returns a nonnegative floating-point number.

In all other cases, `stats::weibullRandom(a, b)()` is returned symbolically.

Numerical values of `a` and `b` are only accepted if they are real and positive.

The values  $X = f()$  are distributed randomly according to the cumulative distribution function of the Weibull distribution with parameters `a` and `b`. For any  $0 \leq x$ , the probability that  $X \leq x$  is given by

$$1 - \frac{1}{\left(\frac{x}{b}\right)^a}$$

Without the option `Seed = s`, an initial seed is chosen internally. This initial seed is set to a default value when MuPAD is started. Thus, each time MuPAD is started or re-initialized with the `reset` function, random generators produce the same sequences of numbers.

**Note** In contrast to the function `random`, the generators produced by `stats::weibullRandom` do not react to the environment variable `SEED`.

For efficiency, it is recommended to produce sequences of  $K$  random numbers via

# stats::weibullRandom

---

```
f := stats::weibullRandom(a, b): f() $k = 1..K;
```

rather than by

```
stats::weibullRandom(a, b)() $k = 1..K;
```

The latter call produces a sequence of generators each of which is called once. Also note that

```
stats::weibullRandom(a, b, Seed = n)() $k = 1..K;
```

does not produce a random sequence, because a sequence of freshly initialized generators would be created each of them producing the same number.

## Environment Interactions

The function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We generate Weibull deviates with parameters  $a = 2$  and  $b = \frac{3}{4}$ .

```
f := stats::weibullRandom(2, 3/4): f() $ k = 1..4
```

```
0.8577612188, 0.3226575883, 1.027334357, 0.05408701056
```

```
delete f:
```

### Example 2

With symbolic parameters, no random floating-point numbers can be produced:

```
f := stats::weibullRandom(a, b): f()
```

```
stats::weibullRandom(a, b)()
```

When positive real numbers are assigned to `a` and `b`, the function `f` starts to produce random floating point numbers:

```
a := PI: b := 1/8: f() $ k = 1..4
```

```
0.1366558143, 0.148384594, 0.1161455634, 0.09243509442
```

```
delete f, a, b:
```

### Example 3

We use the option `Seed = s` to reproduce a sequence of random numbers:

```
f := stats::weibullRandom(PI, 3, Seed = 1): f() $ k = 1..4
```

```
2.503931345, 1.888623862, 3.833514832, 3.584419593
```

```
g := stats::weibullRandom(PI, 3, Seed = 1): g() $ k = 1..4
```

```
2.503931345, 1.888623862, 3.833514832, 3.584419593
```

```
f() = g(), f() = g()
```

```
1.742746285 = 1.742746285, 5.240957365 = 5.240957365
```

```
delete f, g:
```

## Parameters

**a**

The shape parameter: an arithmetical expression representing a positive real value

**b**

# stats::weibullRandom

---

The scale parameter: an arithmetical expression representing a positive real value

## Options

### Seed

Option, specified as `Seed = s`

Initializes the random generator with the integer seed `s`. `s` can also be the option `currentTime`, to make the seed depend on the current time.

This option serves for generating generators that return predictable sequences of pseudo-random numbers. The generator is initialized with the seed `s` which may be an arbitrary integer. Several generators with the same initial seed produce the same sequence of numbers.

When this option is used, the parameters `a` and `b` must be convertible to positive floating-point numbers at the time when the random generator is generated.

## Return Values

procedure.

## Algorithms

The implemented algorithm for the computation of the Weibull deviates uses the quantile function of the Weibull distribution applied to uniformly distributed random numbers on the interval  $[0, 1)$ .

## See Also

## MuPAD Functions

`stats::weibullCDF` | `stats::weibullPDF` |  
`stats::weibullQuantile`

<b>Purpose</b>	Convert a sequence of columns to a list of lists
<b>Syntax</b>	<code>stats::zipCol(column1, column2, )</code>
<b>Description</b>	<p><code>stats::zipCol(..)</code> converts a sequence of columns to a format suitable for creating a <code>stats::sample</code>.</p> <p><code>stats::zipCol</code> is useful for converting column data given in lists to a list of lists accepted by <code>stats::sample</code>.</p> <p><code>stats::zipCol</code> is the inverse of <code>stats::unzipCol</code>.</p>

## Examples

### Example 1

We convert a single column to a nested list:

```
stats::zipCol([a, b, c])
```

```
[[a], [b], [c]]
```

This list is accepted by `stats::sample`:

```
stats::sample(%)
```

```
a
b
c
```

### Example 2

We build a sample consisting of two columns:

```
column1 := [122, 442, 322]: column2 := [s, s, p]:
stats::zipCol(column1, column2)
```

# stats::zipCol

---

```
[[122, s], [442, s], [322, p]]
```

```
stats::sample(%)
```

```
122 s
```

```
442 s
```

```
322 p
```

**Parameters**     `column1, column2, ...`

Lists.

**Return Values**     List of lists.

**See Also**

**MuPAD Functions**     `stats::sample2list` | `stats::unzipCol`

# stringlib – Manipulating Strings

---

```
stringlib::collapseWhitespace
stringlib::contains
stringlib::format
stringlib::formatf
stringlib::formatTime
stringlib::lower
stringlib::maskMeta
stringlib::order
stringlib::pos
stringlib::random
stringlib::readText
stringlib::remove
stringlib::split
stringlib::subs
stringlib::subsop
stringlib::upper
stringlib::validIdent
```

# stringlib::collapseWhitespace

---

**Purpose** Collapse whitespace in strings

**Syntax** `stringlib::collapseWhitespace(string)`

**Description** `stringlib::collapseWhitespace(string)` replaces each whitespace sequence in `string` by one space.

The characters " " (space), "\n" (newline), "\t" (tabulator) and "\r" (return) are called whitespace.

`stringlib::collapseWhitespace(string)` replaces all whitespace characters by one space and following all sequences of spaces by one space in `string`.

When `string` contains no whitespace or only single space characters, the string is returned without changes.

`stringlib::collapseWhitespace` is a function of the system kernel.

## Examples

### Example 1

In the following examples all whitespace is collapsed:

```
stringlib::collapseWhitespace(" ")
```

```
""
```

```
stringlib::collapseWhitespace("MuPAD is nice.")
```

```
"MuPAD is nice."
```

```
stringlib::collapseWhitespace(" ")
```

```
""
```

In this example no whitespace can be collapsed:

```
stringlib::collapseWhitespace(" "),
stringlib::collapseWhitespace("12345"),
stringlib::collapseWhitespace("MuPAD is nice.")
```

```
"" , "12345", "MuPAD is nice."
```

## Example 2

`stringlib::collapseWhitespace` can be useful for output MuPAD code. The procedure is only an example:

```
f:= proc(x) local y; begin y:= 2*x; x + y end
```

```
proc f(x) ... end
```

```
print(f)
```

```
proc f(x) ... end
```

```
expr2text(f)
```

```
"proc(x) name f; local y; begin y := 2*x; x + y end_proc"
```

```
stringlib::collapseWhitespace(%)
```

```
"proc(x) name f; local y; begin y := 2*x; x + y end_proc"
```

## Parameters

**string**

Any MuPAD string

# stringlib::collapseWhitespace

---

## **Return Values**

Given string with collapsed whitespace

## **See Also**

## **MuPAD Functions**

`subs` | `stringlib::subs` | `stringlib::remove`

**Purpose** Test for substring

**Syntax** `stringlib::contains(string1, string2, options)`

**Description** `stringlib::contains(string1, string2)` checks, whether `string1` contains another string `string2`.

**Examples** **Example 1**

If called without options, `stringlib::contains` simply returns `TRUE` or `FALSE`.

```
stringlib::contains("abcdeabcdeabcde", "bc")
```

```
TRUE
```

```
stringlib::contains("abcdeabcdeabcde", "cb")
```

```
FALSE
```

```
stringlib::contains("abcdeabcdeabcde", "bc", Index)
```

```
2
```

```
stringlib::contains("abcdeabcdeabcde", "cb", Index)
```

```
FALSE
```

```
stringlib::contains("abcdeabcdeabcde", "bc", IndexList)
```

```
[2, 7, 12]
```

# stringlib::contains

---

```
stringlib::contains("abcdeabcdeabcde", "cb", IndexList)
```

```
[]
```

## Example 2

The following call does *not* return [1,2] because the first matching substring has not ended when the second begins.

```
stringlib::contains("aaa", "aa", IndexList)
```

```
[1]
```

## Parameters

**string1, string2**

Non empty string

## Options

**Index**

Causes the first index position at which `string2` appears in `string1` to be returned as integer. The return value is `FALSE`, if `string2` occurs nowhere in `string1`.

**IndexList**

Causes the list of all positions at which `string2` appears in `string1` to be returned. The returned list is empty if `string2` occurs nowhere in `string1`.

An occurrence of `string2` is not detected if overlapped by the tail of a previously detected occurrence. See “Example 2” on page 30-6.

## Return Values

`TRUE`, an integer, or a list of integers that determines the position (if an option is given), when `string1` contains `string2`, otherwise `FALSE` or an empty list.

## See Also

## MuPAD Functions

`contains` | `stringlib::pos` | `strmatch`

# stringlib::format

---

**Purpose** Formatting a string

**Syntax** `stringlib::format(string1, width, <Left | Center | Right>, <fill_char>)`

**Description** `stringlib::format` adjusts the length of a string.

If `width` is less than the length of the given string `string1`, the substring consisting of the first `width` characters of `string1` is returned.

If `width` exceeds the length of `string1`, the given string will be filled with the necessary number of spaces or the optional `fill_char`. These are inserted at the end in case of left alignment, or at the beginning in case of right alignment. In case of centering, the same number of filling characters is placed at the beginning and at the end, but one more is placed at the end if their total number is odd.

If alignment is not given, left alignment is used by default.

## Examples

### Example 1

By default, a string of length 5 is adjusted to length 10 by inserting five space characters at the end. Since white spaces are collapsed in typesetting output, we use `print`:

```
print(Plain, stringlib::format("abcde", 10))
```

```
"abcde "
```

In the case of centering, three spaces are inserted at the end and two at the beginning.

```
print(Plain, stringlib::format("abcde", 10, Center))
```

```
" abcde "
```

Instead of the space character, also any other character may be used as a filling character.

```
stringlib::format("abcde", 10, Right, ".")
```

```
".....abcde"
```

```
stringlib::format("abcde", 10, ".")
```

```
"abcde....."
```

## Parameters

### **string1**

String

### **width**

Integer that determines the length of the returned string

### **fill\_char**

One-character string to fill up the result string

## Options

### **Left**

Determines that the string will be aligned left

### **Center**

Determines that the string will be centered

### **Right**

Determines that the string will be aligned right

## Return Values

String of length width containing the given string

# stringlib::format

---

## See Also

## MuPAD Functions

`stringlib::formatf`

## Purpose

Convert a floating-point number to a string

## Syntax

```
stringlib::formatf(f, digits, <strlength>)
```

## Description

`stringlib::formatf(f, d)` converts the floating point number `f` into a string after rounding it to `d` digits after the decimal point.

If `d` is a positive integer, a rounded fixed-point representation with `d` digits after the decimal point is returned. If `d` is zero, then a rounded fixed-point representation with one zero after the decimal point is returned. If `d` is negative, then `f` is rounded to `-d` digits before the decimal point and a fixed-point representation with one zero after the decimal point is returned.

The representation of a negative number starts with the sign and no additional spaces. The representation of a nonnegative number starts with a single space character.

If a third argument is specified, then the string returned consists of exactly `strlength` characters. If the converted number `f` requires less room, then it is padded on the left with spaces. If the converted number `f` requires more room, then the last characters are truncated.

## Examples

### Example 1

Convert the number 123.456 with two characters after the point into a string. Since white spaces are collapsed in typesetting output, we use `print`:

```
print(Plain, stringlib::formatf(123.456, 2))
```

```
" 123.46"
```

The same for -123.456:

```
print(Plain, stringlib::formatf(-123.456, 2))
```

# stringlib::formatf

---

```
" -123.46"
```

Convert the number 123.456 with two characters after the point into a string of the length 10:

```
print(Plain, stringlib::formatf(123.456, 2, 10))
```

```
" 123.46"
```

If the string should only have the length 3, the whole number does not fit into the string:

```
print(Plain, stringlib::formatf(123.456, 2, 3))
```

```
" 12"
```

Rounding to no number after point:

```
print(Plain, stringlib::formatf(123.456, 0))
```

```
" 123.0"
```

Rounding to one number in front of point:

```
print(Plain, stringlib::formatf(123.456, -1))
```

```
" 120.0"
```

## Parameters

**f**

Floating point number

**digits**

Integer which determines the precision of the number

**strlength**

Integer which determines the length of the returned string

## Return Values

stringlib::formatf returns a string.

## See Also

## MuPAD Functions

stringlib::format

# stringlib::formatTime

---

**Purpose** Textual description of a time length

**Syntax** `stringlib::formatTime(t)`

**Description** `stringlib::formatTime` returns a textual description such as “5 minutes, 20 seconds” of a time value such as `320 * unit::sec` given as its argument.

When given an integer or floating-point number, `stringlib::formatTime` interprets it as milliseconds, for compatibility with `time`. Cf. “Example 2” on page 30-14.

`stringlib::formatTime` rounds its input to only use two types of unit, cf. “Example 1” on page 30-14.

## Examples

### Example 1

`stringlib::formatTime` takes a time description and renders it as English text:

```
stringlib::formatTime(1234*unit::sec)
```

```
"20 minutes, 34.0 seconds"
```

Excessive precision is avoided:

```
stringlib::formatTime(12345678*unit::sec)
```

```
"4 months, 3.26 weeks"
```

### Example 2

`time` and `rtime` return integers interpreted as milliseconds. `stringlib::formatTime` thus interprets integers (and, for consistency, floating-point numbers) as milliseconds:

```
stringlib::formatTime(1)
```

```
"0.001 seconds"
```

```
stringlib::formatTime(runtime(system("sleep 2")))
```

```
"2.411 seconds"
```

## Parameters

**t**

The time to convert: An integer or floating-point value (regarded as milliseconds) or an expression involving time units.

## Return Values

string.

## See Also

## MuPAD Functions

runtime | time

# stringlib::lower

---

**Purpose** Convert to lower-case

**Syntax** `stringlib::lower(string1)`

**Description** `stringlib::lower(string1)` converts each upper-case letter in the string `string1` to lower-case. All other characters remains unchanged.  
If the string contains no upper-case letters, the given string is returned unchanged.

**Examples** **Example 1**

Convert a string to lower-case:

```
stringlib::lower("MuPAD"),
stringlib::lower("Mupad"),
stringlib::lower("MUPAD"),
stringlib::lower("mupad")
```

```
"mupad", "mupad", "mupad", "mupad"
```

**Example 2**

Compare strings not case sensitive:

```
str_eq:= (str1, str2) ->
 bool(stringlib::lower(str1) = stringlib::lower(str2)):
str_eq("MuPAD", "mupad"), str_eq("Mupad", "MUPAD")
```

```
TRUE, TRUE
```

**Parameters** **string1**

Any string

**Return Values**

String

**See Also****MuPAD Functions**

`stringlib::format` | `stringlib::upper`

# stringlib::maskMeta

---

**Purpose** Mask regular expression special characters

**Syntax** `stringlib::maskMeta(str)`

**Description** `stringlib::maskMeta(str)` generates a regular expression (for use with `strmatch`) that matches exactly the string `str`.

As of MuPAD version 3.2, `strmatch` uses regular expression matching. To search for some verbatim substring therefore requires “escaping” special characters such as `*` or `()`. `stringlib::maskMeta` performs this task.

## Examples

### Example 1

Trying to find "a+b" in the string "a+b+c" via `strmatch` fails due to the special nature of "+" in regular expressions, but, for almost the same reason, "a\*b" is found:

```
strmatch("a+b+c", "a+b"),
strmatch("a+b+c", "a*b")
```

```
FALSE, TRUE
```

Using `stringlib::maskMeta`, we lose the ability of using regular expressions, but can easily search for verbatim strings:

```
strmatch("a+b+c", stringlib::maskMeta("a+b")),
strmatch("a+b+c", stringlib::maskMeta("a*b"))
```

```
TRUE, FALSE
```

The output of `stringlib::maskMeta` is just another string, so combinations with other strings (containing regular expression meta-characters) is possible:

```
strmatch("a+b+c", "^".stringlib::maskMeta("a+b")),
strmatch("a+b+c", "^".stringlib::maskMeta("b+c"))
```

TRUE, FALSE

## Parameters

**str**

Non empty string

## Return Values

String

## See Also

## MuPAD Functions

strmatch | stringlib::subs | stringlib::pos

# stringlib::order

---

**Purpose**            Sorting procedure for Sort

**Syntax**            `stringlib::order(options)`

**Description**       `stringlib::order()` returns a procedure that compares two strings and returns TRUE when they are in lexicographical order, otherwise FALSE. This procedure can be used as second argument or `sort`.

**Examples**            **Example 1**

Sort strings in lexicographical order:

```
sort(["ab", "a", "abc", "B", "ba", "Ca", "bB", "bb"],
 stringlib::order())
```

```
["B", "Ca", "a", "ab", "abc", "bB", "ba", "bb"]
```

Sort strings in lexicographical order without case sensitivity:

```
sort(["ab", "a", "abc", "B", "ba", "Ca", "bB", "bb"],
 stringlib::order(Nocase))
```

```
["a", "ab", "abc", "B", "ba", "bb", "bB", "Ca"]
```

Sort strings in reverse lexicographical order:

```
sort(["ab", "a", "abc", "B", "ba", "Ca", "bB", "bb"],
 stringlib::order(Reverse))
```

```
["bb", "ba", "bB", "abc", "ab", "a", "Ca", "B"]
```

Sort strings in reverse lexicographical order without case sensitivity:

```
sort(["ab", "a", "abc", "B", "ba", "Ca", "bB", "bb"],
 stringlib::order(ReverseNocase))
```

```
["Ca", "bB", "bb", "ba", "B", "abc", "ab", "a"]
```

## Options

### Lexicographical

Return a procedure that yields TRUE when the two given strings are in lexicographical order.

### Nocase

Return a procedure that yields TRUE when the two given strings are in lexicographical order without case sensitivity.

### Reverse

Return a procedure that yields TRUE when the two given strings are in reverse lexicographical order.

### ReverseNocase

Return a procedure that yields TRUE when the two given strings are in reverse lexicographical order without case sensitivity.

## Return Values

Procedure that can be used as second argument of sort

## See Also

## MuPAD Functions

sort

# stringlib::pos

---

**Purpose** Position of a substring

**Syntax** `stringlib::pos(string1, string2, <pos>)`

**Description** `stringlib::pos` returns the position of a substring in a string. The third optional argument must be less than the length of `string1`. If `string1` does not contain `string2`, then `FAIL` will be returned.

**Examples**      **Example 1**

In case of several occurrences of the substring, the position of the first is returned.

```
stringlib::pos("abcdeabcdeabcde", "bc")
```

```
2
```

**Example 2**

If a starting point for the search is given, `stringlib::pos` returns the first position at which the substring occurs after that starting point.

```
stringlib::pos("abcdeabcdeabcde", "bc", 5)
```

```
7
```

**Example 3**

The result is `FAIL` if the substring does not occur at all or after the given starting point.

```
stringlib::pos("abcdeabcdeabcde", "bc", 14)
```

```
FAIL
```

**Parameters**

**string1, string2**

Non empty string

**pos**

Integer that determines the first position to search

**Return Values**

Integer that determines the position or FAIL.

**See Also****MuPAD Functions**

stringlib::contains | length

# stringlib::random

---

**Purpose** Create a random string

**Syntax** `stringlib::random(<l>, <characters>, options)`

**Description** `stringlib::random()` returns a random string of the default length 7. `stringlib::random(l)` with a number or a range `l` returns a random string with length `l` or length in the given range. When the prefix and/or suffix is longer than the given length, `stringlib::random` raises an error message.

`stringlib::random(characters)` with a given list oder set of characters builds the random string of the given characters. When the characters are strings, they are used as single characters, however, the length is exceeded.

`stringlib::random(l, characters)` is a combination of the both last calls. When both parameters are given, the order is significant.

`stringlib` defines the lists `stringlib::lowerLetters`, `stringlib::upperLetters`, `stringlib::digits` and `stringlib::punctuation` with the characters lower letters, upper letters, digits and punctuation.

## Examples

### Example 1

Create a random string of the default length 7:

```
stringlib::random()
```

```
"jaR<2oH"
```

Create a random string of the length 3:

```
stringlib::random(3)
```

```
"uRT"
```

Create a random string of the length 2 only of digits:

```
stringlib::random(2, stringlib::digits)
```

```
"53"
```

Create a random string of the length 3 only of digits with prefix "+":

```
stringlib::random(3, stringlib::digits, Prefix = "+")
```

```
"+70"
```

Create a random string of the length 5 only of digits with suffix ".0":

```
stringlib::random(5, stringlib::digits, Suffix = ".0")
```

```
"456.0"
```

Create a random strings of the length 3 to 8 only of letters:

```
stringlib::random(3..8, stringlib::lowerLetters.
 stringlib::upperLetters) $ k = 1..5
```

```
"BDkkIz", "zkkvYp", "mFobeC", "Vxsjuk", "HHTJbWh"
```

Create a random string of the length 2 to 8 with letters and casual a punctuation:

```
stringlib::random(2..8, (stringlib::lowerLetters.
```

# stringlib::random

---

```
stringlib::upperLetters $ 4).
stringlib::punctuation) $ k = 1..12
```

```
"<v|v|<a", "rF xv u", "GUHEBR", "fP", "d|qxr", "wO"Md", "RdFdRlqH", "nv)", "Bo", "HGaiqPt&"
```

Create a random string of the length 6 to 8 with letters and equivalent punctuation:

```
stringlib::random(6..8, (stringlib::lowerLetters.
stringlib::upperLetters).
(stringlib::punctuation $ 2)) $ k = 1..10
```

```
"n^iY)E", "=l_?sZ", "{i^(Gh>h", "/A+#}/", "L-DM&G-U", "(,^JzNL;", "ZH;|%:i", ")t^[^}T", "
"\:AdF{R"
```

Create random names of the length 4 to 6:

```
stringlib::random(4..6, Name) $ k = 1..12
```

```
"pbg1", "A98HWb", "eAaR1", "ve_6", "rtxoi", "Iwaw", "Td8cQR", "PASudJ", "a4AN", "d2ixaC", "
"yTMCa5"
```

Create a random password of the length 8 to 10, but without some special characters:

```
EX := {"\\", "\"", "|", "'", "?", "*", "[", "]" }:
stringlib::random(8..10, Exclude = EX)
```

```
"NRpjhuRkc"
```

## Parameters

**l**

The length of the returned string: a nonnegative integer or a range of nonnegative integers

### characters

A list or set of characters

### options

Any of the described options

## Options

### Exclude

Option, specified as `Exclude = characters`

The returned string does not contain characters given in the set or list characters.

### Name

The returned string is a valid MuPAD object name.

### Prefix

Option, specified as `Prefix = string`

Adds `string` in front of each random string. The length of the returned string is the given length or the default length including the prefix.

### Suffix

Option, specified as `Suffix = string`

Appends `string` to each random string. The length of the returned string is the given length or the default length including the suffix.

## Return Values

Random string of the given length or the default length including the prefix resp. suffix.

# stringlib::random

---

## See Also

## MuPAD Functions

random | SEED | stringlib::lower | stringlib::upper |  
substring

**Purpose** Reading text file

**Syntax**  
`stringlib::readText(filename)`  
`stringlib::readText(filename, String, <NoNL>)`  
`stringlib::readText(filename, String, <Separator = string>)`

**Description** `stringlib::readText(filename)` reads all lines of the text file with name `filename` and returns a list of strings, one string per line. The linebreaks are not included at the end of each string.

The file must be a text file, otherwise the file cannot be read.

**Examples**      **Example 1**

First create a text file that can be read:

```
fprint(Unquoted, Text, "test.txt",
 "This file contains three lines.\n",
 "// this line is a MuPAD comment\n",
 ".....\n");
```

By default, `stringlib::readText` returns a list of all lines:

```
stringlib::readText("test.txt")
```

```
["This file contains three lines.", "// this line is a MuPAD comment", ".....", ""]
```

Because the third line was ended by a newline, the file contains four lines, the last line is empty.

The file can be read as *one* string:

```
stringlib::readText("test.txt", String)
```

```
"This file contains three lines.[]// this line is a MuPAD comment[].....[]"
```

# stringlib::readText

---

When the newlines should be removed, option NoNL can be used:

```
stringlib::readText("test.txt", String, NoNL)
```

```
"This file contains three lines.// this line is a MuPAD comment....."
```

Otherwise the newlines can be replaced by another separator:

```
stringlib::readText("test.txt", String, Separator = " ;; ")
```

```
"This file contains three lines. ;; // this line is a MuPAD comment ;; ;; "
```

## Parameters

### filename

The name of a file as string

### string

Any string

## Options

### String

With this option, `stringlib::readText` returns *one* string that contains all contents of the read file, including the line breaks as separator of the lines.

### NoNL

With option NoNL, the returned string does not contain the linebreaks between the lines.

### Separator

Option, specified as `Separator = string`

This option causes `stringlib::readText`, to separate each all lines by `string`, instead of the line break `"\n"`.

**Return Values**

List of strings, or one string

**See Also****MuPAD Functions**

`fTextInput` | `fPrint` | `stringlib::subs`

# stringlib::remove

---

**Purpose** Delete substrings

**Syntax** `stringlib::remove(string1, string2, <First>)`

**Description** With `stringlib::remove`, a substring can be deleted from another string.  
After `string2` has been found, the search for further occurrences of it continues after its last letter; hence only the first of several overlapping occurrences is detected. See “Example 3” on page 30-32.

## Examples

### Example 1

By default, out of several occurrences of the given substring *all* are removed.

```
stringlib::remove("abcdeabcdeabcde", "bc")

"adeadeade"
```

### Example 2

Using the option `First` causes `stringlib::remove` to remove only the first occurrence of the given substring.

```
stringlib::remove("abcdeabcdeabcde", "bc", First)

"adeabcdeabcde"
```

### Example 3

In the following example, the given substring occurs twice, where both instances of it do overlap. Only the first occurrence is removed.

```
stringlib::remove("aaa", "aa")
```

"a"

## Parameters

**string1, string2**

Non empty string

## Options

**First**

Determines that only the first appearance of string2 in string1 will be deleted

## Return Values

Given string without the deleted parts

## See Also

## MuPAD Functions

delete | stringlib::subs | stringlib::subsop

# stringlib::split

---

**Purpose** Split a string

**Syntax** `stringlib::split(string, <separator>)`

**Description** `stringlib::split(string, separator)` splits `string` in all parts separated by the string given as `separator`, that is not included in the returned strings.

If no separator is given, a single space is used as separator.

A returned part can be the empty string.

When the given string does not contain the separator, a list with the unchanged string is returned.

## Examples

### Example 1

The given string is splitted into the numbers separated by comma:

```
stringlib::split("1,2,3,4,5", ",")
```

```
["1", "2", "3", "4", "5"]
```

In the next example is the separator a comma followed by a space:

```
stringlib::split("1, 2, 3, 4, 5", ", ")
```

```
["1", "2", "3", "4", "5"]
```

Without separator a single space is used as separator:

```
stringlib::split("1, 2, 3, 4, 5")
```

```
["1,", "2,", "3,", "4,", "5"]
```

## Example 2

The parts can be empty strings – five empty strings separated by four single spaces:

```
stringlib::split(" ", " ")
```

```
["", "", "", "", ""]
```

The following string (five spaces) consists of two empty strings and a single space separated by two double spaces:

```
stringlib::split(" ", " ")
```

```
["", "", " "]
```

## Example 3

When the string does not contain the separator, a list with the unchanged string is returned:

```
stringlib::split("1,2,3,4,5", ",.")
```

```
["1,2,3,4,5"]
```

## Parameters

**string, separator**

Any non-empty MuPAD string

## Return Values

List of all parts of `string` without all parts separator; the string itself, if `string` does not contain separator.

# stringlib::split

---

## See Also

## MuPAD Functions

stringlib::collapseWhitespace | stringlib::contains |  
strmatch | substring

## Purpose

Substitution in a string

## Syntax

```
stringlib::subs(string, substring = replacement, <First>)
```

## Description

stringlib::subs substitutes a substring by another string.

By default, every occurrence of the string `substring` in `string` is replaced by `replacement`. The option `First` causes only the first appearance of `substring` to be replaced.

The result is not searched again for instances of `substring`. See “Example 3” on page 30-38.

Among several overlapping occurrences of `substring`, the leftmost one is replaced.

## Examples

### Example 1

The string replacement may be empty.

```
stringlib::subs("abcdeabcdeabcde", "bc" = "")
```

```
"adeadeade"
```

### Example 2

Every substring is replaced unless the option `First` is given.

```
stringlib::subs("abcdeabcdeabcde", "bc" = "xxx")
```

```
"axxxdeaxxxdeaxxxde"
```

```
stringlib::subs("abcdeabcdeabcde", "bc" = "xxx", First)
```

```
"axxxdeabcdeabcde"
```

# stringlib::subs

---

## Example 3

The substitution may produce a new instance of substring, but this one is not replaced.

```
stringlib::subs("aab", "ab"="b")
```

```
"ab"
```

## Example 4

Collapse all whitespace in strings (see stringlib::collapseWhitespace):

```
f := proc(x) local y; begin y := 2*x; x + y end_proc:
string := expr2text(f)
```

```
"proc(x) name f; local y; begin y := 2*x; x + y end_proc"
```

```
string := stringlib::subs(string, "\n" = " "):
string := stringlib::subs(string, " " = " "):
string := stringlib::subs(string, " " = " ")
```

```
"proc(x) name f; local y; begin y := 2*x; x + y end_proc"
```

## Parameters

### string

Non empty string

### substring

Non empty string that should be replaced

### replacement

Any string that replaced substring

## Options

### First

Determines that only the first appearance of substring in string will be replaced

## Return Values

Given string with substring replaced by replacement

## See Also

## MuPAD Functions

subs | stringlib::subsop | stringlib::pos | stringlib::remove

# stringlib::subsop

---

**Purpose** Substitution in a string

**Syntax** `stringlib::subsop(string, index = replacement)`

**Description** `stringlib::subsop` removes one or more characters at a given position and inserts another substring at that position instead.

The char with index `index` in `string` (if `index` is an integer) or the range of chars (if `index` is a range of integers) is removed. Instead `replacement` is inserted at that position. The inserted string need not have the same length.

## Examples

### Example 1

Delete the first character:

```
stringlib::subsop("abcdeabcdeabcde", 1 = "")
```

```
"bcdeabcdeabcde"
```

The 2nd to 3rd character will be replaced by "xxx":

```
stringlib::subsop("abcdeabcdeabcde", 2..3 = "xxx")
```

```
"axxxdeabcdeabcde"
```

Delete the characters 2 to 11:

```
stringlib::subsop("abcdeabcdeabcde", 2..11 = "")
```

```
"abcde"
```

**Parameters** `string`

Non empty string

**index**

Integer or range of integers that determines the chars to be replaced

**replacement**

Any string to replace the given char or range

**Return Values**

Given string with the replacement

**See Also**

**MuPAD Functions**

subsop | stringlib::pos | stringlib::remove | stringlib::subs

# stringlib::upper

---

**Purpose** Convert to upper-case

**Syntax** `stringlib::upper(string1)`

**Description** `stringlib::upper(string1)` converts each lower-case letter in the string `string1` to upper-case. All other characters remains unchanged. If the string contains no lower-case letters, the given string is returned unchanged.

**Examples** **Example 1**

Convert a string to upper-case:

```
stringlib::upper("MuPAD"),
stringlib::upper("Mupad"),
stringlib::upper("MUPAD"),
stringlib::upper("mupad")
```

```
"MUPAD", "MUPAD", "MUPAD", "MUPAD"
```

**Example 2**

Compare strings not case sensitive:

```
str_eq:= (str1, str2) ->
 bool(stringlib::upper(str1) = stringlib::upper(str2)):
str_eq("MuPAD", "mupad"), str_eq("Mupad", "MUPAD")
```

```
TRUE, TRUE
```

**Parameters** **string1**

Any string

**Return Values**

String

**See Also****MuPAD Functions**

`stringlib::format` | `stringlib::lower`

# stringlib::validIdent

---

**Purpose** Validate identifier name

**Syntax** `stringlib::validIdent(string)`

**Description** `stringlib::validIdent(string)` returns TRUE, when `string` is a valid identifier name, otherwise FALSE.

A valid identifier name in MuPAD must follow the rules:

- The first character must be a letter or the character "\_".
- All following characters must be letters or digits or the character "\_".
- An identifier consists of at least one character up to 512 characters.

Names in backticks ` are not determined as valid names.

## Examples

### Example 1

The example splits a set of names into valid identifier names and invalid identifier names:

```
split({"a", "1", "_111", "____", "A0b.C", "MuPAD", "1ABCDE", "xyz00"},
 stringlib::validIdent)
```

```
[{"MuPAD", "_111", "____", "a", "xyz00"}, {"1", "1ABCDE", "A0b.C"}, ∅]
```

`stringlib::random` called with option `Name` returns always valid identifier names. The function `map` applies `stringlib::validIdent` to each of the 1000 generated random names:

```
map({stringlib::random(1..10, Name) $ k = 1..1000},
 stringlib::validIdent)
```

```
{TRUE}
```

**Parameters**     **string**  
                    A string

**Return Values**     TRUE or FALSE

**See Also**

**MuPAD Functions**     domtype | stringlib::random

## **stringlib::validIdent**

---

# Symbol – Typesetting Symbols

---

Symbol::accentPrime  
Symbol::accentAsterisk  
Symbol::accentTilde  
Symbol::accentHat  
Symbol::accentRightArrow  
Symbol::accentDot  
Symbol::accentDoubleDot  
Symbol::accentTripleDot  
Symbol::accentOverBar  
Symbol::accentUnderBar  
Symbol::new  
Symbol::subScript  
Symbol::subSuperScript  
Symbol::superScript

# Symbol::accentPrime

---

**Purpose** Adds a prime accent to an identifier

**Syntax** `Symbol::accentPrime(a)`

**Description** Creates a new identifier with a prime accent, such as  $a'$ .

**Examples** **Example 1**

Symbol::accentPrime adds a “prime” to an identifier:

`Symbol::accentPrime(x) = x + f(x)`

$x' = x + f(x)$

**Parameters** **a**  
An identifier

**Return Values**  
Identifier

**Purpose** Adds an asterisk accent to an identifier

**Syntax** `Symbol::accentAsterisk(a)`

**Description** Creates a new identifier with an asterisk accent, such as  $a^*$ .

**Examples** **Example 1**

Asterisk accents are often used to denote special values:

`f(Symbol::accentAsterisk(x)) = 0`

$f(x^*) = 0$

**Parameters** **a**  
An identifier

**Return Values** Identifier

# Symbol::accentTilde

---

**Purpose** Adds a tilde accent to an identifier

**Syntax** `Symbol::accentTilde(a)`

**Description** Creates a new identifier with a tilde accent, such as  $\tilde{a}$ .

**Examples** **Example 1**

The most common use of the tilde accent is to denote an approximation:

```
x = Symbol::accentTilde(x) + O(h^2)
```

$$x = \tilde{x} + O(h^2)$$

**Parameters** **a**  
An identifier

**Return Values** Identifier

**Purpose** Adds a hat accent to an identifier

**Syntax** `Symbol::accentHat(a)`

**Description** Creates a new identifier with a hat accent, such as  $\hat{a}$ .

**Examples** **Example 1**

One of the common uses of the hat (or circumflex) accents is to denote Laplace transforms:

```
f = sin(x) ==> Symbol::accentHat(f)
= laplace(sin(x), x, t)
```

$$f = \sin(x) \Rightarrow \hat{f} = \frac{1}{t^2 + 1}$$

**Parameters** **a**  
An identifier

**Return Values** Identifier

# Symbol::accentRightArrow

---

**Purpose** Adds a right arrow accent to an identifier

**Syntax** `Symbol::accentRightArrow(a)`

**Description** Creates a new identifier with a right arrow accent, such as  $\vec{a}$ .

**Examples** **Example 1**

Arrow accents are usually used to denote vectors:

```
Symbol::accentRightArrow(b)
= matrix([1, 2, Symbol::dots, n])
```

$$\vec{b} = \begin{pmatrix} 1 \\ 2 \\ \dots \\ n \end{pmatrix}$$

To denote  $\vec{0}$ , the null vector, start with the *identifier* 0:

```
Symbol::accentRightArrow(`0`)
```

$\vec{0}$

**Parameters** **a**  
An identifier

**Return Values**  
Identifier

**Purpose** Adds a dot accent to an identifier

**Syntax** `Symbol::accentDot(a)`

**Description** Creates a new identifier with a dot accent, such as  $\dot{a}$ .

**Examples** **Example 1**

In physics, a dot accent is often used as a shorthand for the derivative with respect to time:

```
Symbol::accentDot(y) =
- Symbol::omega^2 * sin(x)
```

$$\dot{y} = -\omega^2 \sin(x)$$

**Parameters** **a**  
An identifier

**Return Values** Identifier

# Symbol::accentDoubleDot

---

**Purpose** Adds a double dot accent to an identifier

**Syntax** `Symbol::accentDoubleDot(a)`

**Description** Creates a new identifier with a double dot accent, such as  $a''$ .

## Examples

### Example 1

In physics, the double dot accent usually denotes the second derivative with respect to time:

`Symbol::accentDoubleDot(x) = -x`

$$\ddot{x} = -x$$

**Parameters** **a**

An identifier

## Return Values

Identifier

**Purpose** Adds a triple dot accent to an identifier

**Syntax** `Symbol::accentTripleDot(a)`

**Description** Creates a new identifier with a triple dot accent, such as  $\ddot{a}$ .

**Examples** **Example 1**

Triple dots, where used, usually denote the third derivative with respect to time:

```
Symbol::accentTripleDot(x)(t) = diff(x(t), t$3)
```

$$\ddot{X}(t) = \frac{\partial^3}{\partial t^3} X(t)$$

**Parameters** **a**  
An identifier

**Return Values** Identifier

# Symbol::accentOverBar

---

**Purpose** Adds an overbar to an identifier

**Syntax** `Symbol::accentOverBar(a)`

**Description** Creates a new identifier with an overbar, such as  $\bar{a}$ .

**Examples** **Example 1**

The overbar is used in statistics to denote the arithmetical mean of an observable quantity:

`Symbol::accentOverBar(x) = sum(x[i], i=1..n)/n`

$$\bar{X} = \frac{\sum_{i=1}^n X_i}{n}$$

**Parameters** **a**  
An identifier

**Return Values** Identifier

**Purpose** Adds an underbar to an identifier

**Syntax** `Symbol::accentUnderBar(a)`

**Description** Creates a new identifier with an underbar, such as a.

**Examples** **Example 1**

One of the areas where the underbar is used frequently is interval analysis, where an interval is usually given as follows:

```
x = [Symbol::accentUnderBar(x),
 Symbol::accentOverBar(x)]
```

```
x = [x, \bar{x}]
```

**Parameters** **a**  
An identifier

**Return Values** Identifier

# Symbol::new

---

**Purpose** Functional access to symbols

**Syntax** `Symbol(x)`

**Description** `Symbol::new(symname)` or simply `Symbol(symname)` creates the typesetting symbol corresponding to `symname`.

The typesetting symbols can be accessed in two different ways: Most symbols can be input by typing `Symbol::symname`, where `symname` is taken from the lists in the introduction. For some symbol names (such as `not` or `I`), this is not possible in the MuPAD language. What is possible in any case is to invoke `Symbol` as a function, taking a string representation as its argument, as in `Symbol("not")`.

## Examples

### Example 1

The symbols accessed via `Symbol` can be used like ordinary identifiers:

```
Symbol::heartsuit in
 {Symbol::heartsuit, Symbol::spades}
```

```
♥ ∈ {♥, ♠}
```

```
expand((Symbol::alpha + Symbol::beta)^4);
```

```

$$\alpha^4 + 4\alpha^3\beta + 6\alpha^2\beta^2 + 4\alpha\beta^3 + \beta^4$$

```

Some symbol names are MuPAD keywords and can not be accessed via slot calls. They can be given as function calls:

```
Symbol("minus"), Symbol("div"), Symbol("in"),
Symbol("and"), Symbol("subset"), Symbol("NIL"),
Symbol("UNKNOWN"), Symbol("FAIL"), Symbol("E"),
Symbol("I"), Symbol("not")
```

*- , /, €, ^, c, Nil, unknown, Fail, E, I, ↵*

## Parameters

**symname**

A symbol name: a string

## Return Values

identifier

## See Also

## MuPAD Functions

print

# Symbol::subScript

---

**Purpose** Combines two expressions to a new subscripted identifier

**Syntax** `Symbol::subScript(a, b)`

**Description** Creates a new subscripted identifier, such as  $a_b$ . If the arguments are not yet identifiers, they are first converted into identifiers. You can also use `_`, `^`, `$`, `{`, and `}` to create arguments with superscript and subscript. For these arguments a new subscripted identifier appears on top of the

existing ones:  $a_{bc}$  or  $a_{a_d}$ . If you want to create identifiers in which these five special characters appear explicitly, use string arguments:

```
Symbol::subScript("a", "b_c")
```

$a_{b_c}$

## Examples

### Example 1

Even if  $X1$  and  $X2$  look identical, only  $X1$  is an identifier whereas  $X2$  is an `_index`-expression:

```
X1 := Symbol::subScript(x, 1): X2 := x[1]:
X1, X2; domtype(X1), domtype(X2)
```

$X_1, X_1$

DOM\_IDENT, DOM\_EXPR

Pre-scripts are possible by subscripting the empty identifier ```` and appending an identifier:

```
Symbol::subScript(``, 1).x
```

$x_i$

## Example 2

You can use the nested form of the function:

```
Symbol::subScript(x, Symbol::subScript(i, j))
```

$x_{ij}$

### Parameters

**a, b**

Arbitrary expressions

### Return Values

Identifier

# Symbol::subSuperScript

---

**Purpose** Combines three expressions to a new combined sub- and superscripted identifier

**Syntax** `Symbol::subSuperScript(a, b, c)`

**Description** Creates a new combined sub- and superscripted identifier, such as  $a_b^c$ . If the arguments are not yet identifiers, they are first converted into identifiers. You can also use `_`, `^`, `$`, `{`, and `}` to create arguments with superscript and subscript. For these arguments a new indexed identifier appears on top of the existing ones:  $a_{b,c}^d$  or  $a_{b,c}^e$ . If you want to create identifiers in which these five special characters appear explicitly, use string arguments:

```
Symbol::subSuperScript("a", "b_c", "d_e")
```

$a_{b_c}^{d_e}$

## Examples **Example 1**

Input of an identifier with sub- and superscript:

```
X1 := Symbol::subSuperScript(x, 1, 2):
X1, domtype(X1)
```

$x_1^2$ , DOM\_IDENT

Pre-scripts are possible by subsuperscripting the empty identifier `` and appending an identifier:

```
Symbol::subSuperScript(``, 1, 2).X
```

$${}_1^2X$$

And at last scripts all around X:

```
Symbol::subSuperScript(``, 1, 2).Symbol::subSuperScript(X, 3, 4)
```

$${}_1^2X_3^4$$

## Example 2

You can use the nested form of the function:

```
Symbol::subSuperScript(x, a, Symbol::subSuperScript(b, i, j))
```

$$X_a^{b^j}$$

### Parameters

**a, b, c**

Arbitrary expressions

### Return Values

Identifier

# Symbol::superScript

---

**Purpose** Combines two expressions to a new superscripted identifier

**Syntax** `Symbol::superScript(a, b)`

**Description** Creates a new superscripted identifier, such as  $a^b$ . If the arguments are not yet identifiers, they are first converted into identifiers. You can also use `_`, `^`, `$`, `{`, and `}` to create arguments with superscript and subscript. For these arguments a new superscripted identifier appears on top of the existing ones:  $a^{b^c}$  or  $a^{b^d}$ . If you want to create identifiers in which these five special characters appear explicitly, use string arguments:

```
Symbol::superScript("a", "b^c")
```

$a^{b^c}$

## Examples

### Example 1

Even if  $X1$  and  $X2$  look identical, only  $X1$  is an identifier whereas  $X2$  is a `_power`-expression:

```
X1 := Symbol::superScript(x, 2): X2 := x^2:
X1, X2; domtype(X1), domtype(X2)
```

$x^2, x^2$

`DOM_IDENT, DOM_EXPR`

Pre-scripts are possible by superscripting the empty identifier ``` and appending an identifier:

```
Symbol::superScript(`, 1).x
```

$$x^1$$

## Example 2

You can use the nested form of the function:

```
Symbol::superScript(x, Symbol::superScript(i, j))
```

$$x^{i^j}$$

### Parameters

**a, b**

Arbitrary expressions

### Return Values

Identifier

**Symbol::superScript**

---

# Type – Type Checking and Mathematical Properties

Type::Set  
Type::Singleton  
Type::TableOfEntry  
Type::TableOfIndex  
Type::TableOf  
Type::Union  
Type::Unknown  
Type::Zero

**Purpose** Type representing algebraic constants

**Syntax** `testtype(obj, Type::AlgebraicConstant)`

**Description** `Type::AlgebraicConstant` represents algebraic constants. In MuPAD, algebraic constants are characterized as follows: a complex number is an algebraic constant, if both its real part and its imaginary part are rational. Sums and products of algebraic constants are again algebraic constants. Further, rational powers of algebraic constants are again algebraic constants.

Taken together, these rules characterize algebraic constants over the rationals defined as usual, i.e., as roots of polynomial expressions.

This type does not represent a property: it cannot be used in `assume` to mark an identifier as an algebraic constant.

## Examples

### Example 1

The following number is composed of radicals involving rational numbers and therefore is an algebraic constant:

```
testtype((3^(1/2)*I + 1/8)^(1/7), Type::AlgebraicConstant)
```

TRUE

The following objects are not algebraic constants:

```
testtype(2^I, Type::AlgebraicConstant),
testtype(PI, Type::AlgebraicConstant)
```

FALSE, FALSE

### Example 2

Symbolic objects cannot represent algebraic constants:

```
testtype(x, Type::AlgebraicConstant)
```

# Type::AlgebraicConstant

---

FALSE

## Example 3

The following call selects the algebraic constants in an expression:

```
select(x + PI + 2^(1/2) + I, testtype, Type::AlgebraicConstant)
```

$\sqrt{2} + i$

## Parameters

**obj**

Any MuPAD object

## Return Values

See testtype

## See Also

## MuPAD Functions

testtype | Type::Constant

**Purpose** Type representing arbitrary MuPAD objects

**Syntax** `testtype(obj, Type::AnyType)`

**Description** `Type::AnyType` represents arbitrary MuPAD objects.  
This type is meant to represent arbitrary MuPAD objects in constructors of composite types such as `Type::ListOf`.  
This type does not represent a property: it cannot be used in `assume`.

## Examples **Example 1**

Any object matches this type:

```
testtype(3, Type::AnyType),
testtype(x, Type::AnyType),
testtype(array(1..1, [x]), Type::AnyType),
testtype(Dom::Matrix(), Type::AnyType)
```

```
TRUE, TRUE, TRUE, TRUE
```

This type is meant for constructing composite types. The following call tests, whether an object is a list with arbitrary elements:

```
testtype([3, x, array(1..1, [x]), Dom::Matrix()],
 Type::ListOf(Type::AnyType))
```

```
TRUE
```

**Parameters** **obj**  
Any MuPAD object

# Type::AnyType

---

## **Return Values**

testtype always returns TRUE

## **See Also**

## **MuPAD Functions**

testtype

**Purpose** Type representing arithmetical objects

**Syntax** `testtype(obj, Type::Arithmetical)`

**Description** `Type::Arithmetical` represents arithmetical objects.

In MuPAD, arithmetical objects are objects that represent complex numbers if all identifiers in them also represent complex numbers. Arithmetical objects include numbers, most expressions, and elements of certain library domains. In particular, the latter include `rectform` objects and series expansions of domain type `Series::Puisseux`.

Certain infinite objects such as `dirac(0)`, `infinity`, or `complexInfinity` are also defined to be arithmetical expressions.

The following objects are *not* regarded as arithmetical objects:

- equations and inequalities,
- Boolean objects and Boolean expressions involving `and`, `or`, `not`,
- lists,
- sets and set expressions involving `union`, `intersect`, `minus`,
- polynomials of domain type `DOM_POLY`,
- functions and procedures,
- arrays and tables.

This type does not represent a property: it cannot be used in `assume` to mark an identifier as an arithmetical object.

## Examples **Example 1**

The expression  $\frac{BAB}{A}$  may represent a matrix if  $A$  and  $B$  are matrices, or it may represent a number if  $A$  and  $B$  are numbers. However, MuPAD regards identifiers as numbers: hence they commute with each other, and a product of identifiers represents a number, too:

# Type::Arithmetical

---

```
A^(-1) * B * A * B
```

```
B2
```

```
testtype(%, Type::Arithmetical)
```

```
TRUE
```

## Example 2

Numbers and expressions are regarded as arithmetical objects:

```
testtype(3 + I, Type::Arithmetical),
testtype(x + sqrt(2) + I*PI, Type::Arithmetical),
testtype(x/y + y/x, Type::Arithmetical)
```

```
TRUE, TRUE, TRUE
```

Equations and inequalities are not regarded as arithmetical objects:

```
testtype(x^2 = 2, Type::Arithmetical),
testtype(x <> 2, Type::Arithmetical),
testtype(x < 2, Type::Arithmetical),
testtype(x >= 2, Type::Arithmetical)
```

```
FALSE, FALSE, FALSE, FALSE
```

Sets, lists, tables and arrays are not arithmetical:

```
testtype({a, b, c}, Type::Arithmetical),
testtype(array(1..1, [x]), Type::Arithmetical)
```

FALSE, FALSE

Most domain objects such as matrices of some matrix domain are not arithmetical:

```
testtype(Dom::Matrix()([[1, 2], [3, 4]]), Type::Arithmetical)
```

FALSE

## Parameters

**obj**

Any MuPAD object

## Return Values

See `testtype`

## See Also

## MuPAD Functions

`testtype`

# Type::Boolean

---

**Purpose** Type representing boolean expressions

**Syntax** `testtype(obj, Type::Boolean)`

**Description** `Type::Boolean` represents logical formulas.

Boolean expressions are all of the following objects: the Boolean constants `TRUE`, `FALSE`, and `UNKNOWN`; identifiers; equations and inequalities; expressions with operator `and`, `or`, `not`, `xor`, `_implies`, `_equiv` if each operand is a Boolean expression; or results returned by `solveLib::isEmpty`.

## Examples **Example 1**

Identifiers and boolean constants are Boolean expressions:

```
testtype(TRUE, Type::Boolean), testtype(a, Type::Boolean)
```

```
TRUE, TRUE
```

## **Example 2**

In order that an expression be Boolean, it is not sufficient that only its operator is a logical operator; also its operands must be Boolean expressions.

```
testtype(a >= 3 and b, Type::Boolean);
testtype(a+b and c, Type::Boolean)
```

```
TRUE
```

```
FALSE
```

**Parameters** `obj`

Any MuPAD object

## **Return Values**

See `testtype`

## **See Also**

## **MuPAD Functions**

`testtype`

# Type::Complex

---

**Purpose** Type and property representing complex numbers

**Syntax**  
`testtype(obj, Type::Complex)`  
`assume(x, Type::Complex)`  
`is(ex, Type::Complex)`

**Description** `Type::Complex` represents complex numbers. This type can also be used as a property to mark identifiers as complex numbers.

The call `testtype(obj, Type::Complex)` checks, whether `obj` is a complex number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` and `DOM_COMPLEX`. This does not include arithmetical expressions such as `exp(1)`, which are not identified as of type `Type::Complex`.

The call `assume(x, Type::Complex)` marks the identifier `x` as a complex number.

The call `is(ex, Type::Complex)` derives, whether the expression `ex` is a complex number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::Complex`:

```
testtype(2, Type::Complex),
testtype(3/4, Type::Complex),
testtype(0.123, Type::Complex),
testtype(1 + I/3, Type::Complex),
testtype(1.0 + 2.0*I, Type::Complex)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

The following expressions are exact representations of complex numbers. Syntactically, however, they are not of type `Type::Complex`:

```
testtype(exp(3), Type::Complex),
testtype(PI^2 + 5, Type::Complex),
testtype(sin(2) + PI*I, Type::Complex)
```

```
FALSE, FALSE, FALSE
```

## Example 2

Identifiers may be assumed to represent a complex number:

```
assume(x, Type::Complex): is(x, Type::Complex)
```

```
TRUE
```

The real numbers are a subset of the complex numbers:

```
assume(x, Type::Real): is(x, Type::Complex)
```

```
TRUE
```

Without further information, it cannot be decided whether a complex number is real:

```
assume(x, Type::Complex): is(x, Type::Real)
```

```
UNKNOWN
```

```
unassume(x):
```

## Parameters

**obj**

# Type::Complex

---

Any MuPAD object

**x**

An identifier

**ex**

An arithmetical expression

## **Return Values**

See `assume`, `is` and `testtype`

## **See Also**

## **MuPAD Functions**

`assume` | `is` | `testtype` | `Type::Imaginary` | `Type::Property`  
| `Type::Real`

<b>Purpose</b>	Set of constant identifiers in MuPAD
<b>Syntax</b>	<code>contains(Type::ConstantIdents, obj)</code>
<b>Description</b>	<p><code>Type::ConstantIdents</code> is the set { CATALAN , E , EULER , I , PI }.</p> <p><code>Type::ConstantIdents</code> is the set of identifiers that represent constants. As of version 4.0, these are CATALAN, E (= <code>exp(1)</code>), EULER, I, PI.</p> <p>These constants will be returned by the function <code>indets</code>, but they cannot be treated like other identifiers. For example, they cannot have properties or be the left-hand side of an assignment.</p> <p>See “Example 1” on page 32-15 for an application.</p> <p><code>Type::Constant</code> makes use of <code>Type::ConstantIdents</code>, see “Example 2” on page 32-16.</p>

## Examples

### Example 1

MuPAD implements  $\pi$  as the identifier PI.

```
domtype(PI)
```

```
DOM_IDENT
```

However, PI is constant (although rumors keep raising their heads that China, Alabama, or whoever it may be next time had tried to change its value by means of a legislative process):

```
testtype(PI, Type::Constant)
```

```
TRUE
```

## Type::ConstantIds

---

Still, `indets` regards `PI` as an identifier with no value (which is syntactically correct), and you can even use `PI` as an indeterminate of a polynomial:

```
indets(PI/2*x);
poly(PI/2*x)
```

```
{π, x}
```

```
poly($\frac{\pi X}{2}$, [π, x])
```

To find the “real” indeterminates, use the following call:

```
indets(PI/2*x) minus Type::ConstantIds
```

```
{x}
```

### Example 2

In the following, the `solve` command solves for all identifiers found in the equation:

```
solve(x^2 = KHINTCHINE)
```

```
{[KHINTCHINE = z2, x = z]}
```

Assume you want MuPAD to regard the identifier `KHINTCHINE` as a constant. (Probably, it should represent the Khintchine constant  $K$ , which is approximately 2.685452, but we will not implement this.) First of all, you should make sure that the identifier does not have a value yet and protect it:

```
testtype(KHINTCHINE, DOM_IDENT);
protect(KHINTCHINE, ProtectLevelError)
```

```
TRUE
```

```
ProtectLevelNone
```

Next, add KHINTCHINE to Type::ConstantIdents (note that we have to unprotect the identifier Type, because Type::ConstantIdents is a slot of it):

```
old_protection := unprotect(Type):
Type::ConstantIdents := Type::ConstantIdents union {KHINTCHINE}:
protect(Type, old_protection):
Type::ConstantIdents
```

```
{i, CATALAN, EULER, KHINTCHINE, π , e}
```

Now, MuPAD regards KHINTCHINE as a constant:

```
testtype(sin(PI + KHINTCHINE), Type::Constant)
```

```
TRUE
```

After clearing the remember table of solve, we now obtain:

```
solve(Remember, Clear):
solve(x^2 = KHINTCHINE)
```

```
{[$x = \sqrt{\text{KHINTCHINE}}$], [$x = -\sqrt{\text{KHINTCHINE}}$]}
```

# Type::ConstantIdents

---

**Parameters**    **obj**  
                  Any MuPAD object

**Return Values**    See contains

**See Also**

**MuPAD Functions**    contains | indets | Type::Constant | Type::Indeterminate

<b>Purpose</b>	Type representing constant objects
<b>Syntax</b>	<code>testtype(obj, Type::Constant)</code>
<b>Description</b>	<p>Type::Constant represents constant objects, i.e., objects not containing symbolic identifiers.</p> <p>Numbers, strings, Boolean constants, NIL, FAIL and the identifiers PI, EULER and CATALAN in the set <code>Type::ConstantIdents</code> are regarded as constant objects. A composite object is constant, if all its operands are constant.</p> <p>Any function is identified as a constant, if all arguments are constant, also if the function is not defined (e.g., an identifier).</p> <p>This type does not represent a property: it cannot be used in <code>assume</code> to mark an identifier as a constant.</p>

## Examples

### Example 1

The following objects are elementary constants:

```
testtype(3, Type::Constant),
testtype(sin(3/2), Type::Constant),
testtype(TRUE, Type::Constant),
testtype("MuPAD", Type::Constant),
testtype(FAIL, Type::Constant)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

The following expression contains an indeterminate  $x$  and, consequently, is not a constant object:

```
testtype(exp(x + 1), Type::Constant)
```

```
FALSE
```

# Type::Constant

---

All constant operands of an expression are selected:

```
select(x^2 + 3*x - 2, testtype, Type::Constant)
```

```
-2
```

Any function call is considered constant, if the arguments are constant:

```
testtype(f(1, 2, 3, 4), Type::Constant)
```

```
TRUE
```

## Parameters

**obj**

Any MuPAD object

## Return Values

See testtype

## See Also

## MuPAD Functions

testtype

**Purpose** Type representing equations

**Syntax** `testtype(obj, Type::Equation(<lhs_type, <rhs_type>>))`

**Description** `Type::Equation` represents equations. The types of the left hand side and the right hand side can be specified.

The call `testtype(obj, Type::Equation(lhs_type, rhs_type))` checks whether `type(obj)` yields `"_equal "` and `testtype(lhs(obj), lhs_type)` and `testtype(rhs(obj), rhs_type)` both yield `TRUE` and returns `TRUE`, if all holds, otherwise `FALSE`.

The two optional parameters `lhs_type` and `rhs_type` determine the types of the left hand side and the right hand side, respectively.

The default values of `lhs_type` and `rhs_type` are `Type::AnyType`.

---

**Note** The equations `lhs=rhs` and `rhs=lhs` are considered different! E.g., the equation `x=3` matches the type `Type::Equation(DOM_IDENT,DOM_INT)`, but it does not match the type `Type::Equation(DOM_INT,DOM_IDENT)`.

---

This type does not represent a property, it cannot be used in an `assume` call.

**Examples** **Example 1**

The following object is an equation:

```
testtype(x = 3, Type::Equation())
```

```
TRUE
```

# Type::Equation

---

The following calls test, whether the object is an equation with an unknown on the left hand side and a positive integer on the right hand side:

```
testtype(x = 3, Type::Equation(Type::Unknown, Type::PosInt)),
testtype(x = 0, Type::Equation(Type::Unknown, Type::PosInt))
```

TRUE, FALSE

## Parameters

**obj**

Any MuPAD object

**lhs\_type**

The type of the left hand side; a type can be an object of the library Type or one of the possible return values of domtype and type

**rhs\_type**

The type of the right hand side

## Return Values

See testtype

## See Also

## MuPAD Functions

testtype

<b>Purpose</b>	Type and property representing even integers
<b>Syntax</b>	<pre>testtype(obj, Type::Even) assume(x, Type::Even) is(ex, Type::Even)</pre>
<b>Description</b>	<p>Type::Even represents even integers. This type can also be used as a property to mark identifiers as even integers.</p> <p>The call <code>testtype(obj, Type::Even)</code> checks, whether <code>obj</code> is an even number and returns <code>TRUE</code>, if it holds, otherwise <code>FALSE</code>.</p> <p><code>testtype</code> only performs a syntactical test identifying MuPAD objects of type <code>DOM_INT</code> and checks, if <code>bool(domtype(x/2) = DOM_INT)</code> holds.</p> <p>The call <code>assume(x, Type::Even)</code> marks the identifier <code>x</code> as an even number.</p> <p>The call <code>is(ex, Type::Even)</code> derives, whether the expression <code>ex</code> is an even number (or this property can be derived).</p> <p>This type represents a property that can be used in <code>assume</code> and <code>is</code>.</p>

**Examples****Example 1**

The following numbers are of type `Type::Even`:

```
testtype(2, Type::Even),
testtype(-4, Type::Even),
testtype(8, Type::Even),
testtype(-11114, Type::Even),
testtype(4185296581467695598, Type::Even)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

**Example 2**

We use this type as a property:

# Type::Even

---

```
assume(x, Type::Even):
```

The following calls to `is` derive the properties of a composite expression from the properties of its indeterminates:

```
is(3*x^2, Type::Even), is(x + 1, Type::Even)
```

```
TRUE, FALSE
```

```
is(x, Type::Integer), is(2*x, Type::Integer),
is(x/2, Type::Integer), is(x/3, Type::Integer)
```

```
TRUE, TRUE, TRUE, UNKNOWN
```

```
assume(y, Type::Odd): is(x + y, Type::Even)
```

```
FALSE
```

```
is(2*(x + y), Type::Even)
```

```
TRUE
```

```
delete x, y:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## **Return Values**

See `assume`, `is` and `testtype`

## **See Also**

## **MuPAD Functions**

`is` | `assume` | `testtype` | `Type::Odd` | `Type::Property`

# Type::Function

---

**Purpose** Type representing functions

**Syntax** `testtype(obj, Type::Function)`

**Description** `Type::Function` represents all MuPAD functions (procedures, executable objects etc).

The call `testtype(obj, Type::Function)` checks, whether `obj` is an executable MuPAD object. The call returns `TRUE` or `FALSE`, respectively.

“Executable objects” in MuPAD are procedures (of type `DOM_PROC`), function environments (of type `DOM_FUNC_ENV`), and pure kernel functions (of type `DOM_EXEC`).

Additionally, symbolic function iterates `f@@n` (representing the map  $x \rightarrow f(\dots(f(x))\dots)$ ) and symbolic function compositions `f@g` (representing the function  $x \rightarrow f(g(x))$ ) are regarded as executable objects.

This type does not represent a property.

## Examples

### Example 1

`Type::Function` accepts procedures:

```
testtype(proc(x) begin x^2 end, Type::Function)
```

`TRUE`

`Type::Function` accepts simple procedures generated with the “arrow operator” `->`, too:

```
testtype(x -> x^2, Type::Function)
```

`TRUE`

`sin` is a function environment, accepted by `Type::Function`:

```
testtype(sin, Type::Function)
```

```
TRUE
```

The first operand of the function environment `print` is a pure kernel function, accepted by `Type::Function`:

```
testtype(op(print, 1), Type::Function)
```

```
TRUE
```

The 3-fold iterate of the function `diff` is accepted by `Type::Function`:

```
testtype(diff@@3, Type::Function)
```

```
TRUE
```

The composition of functions is accepted by `Type::Function`:

```
testtype(f@g, Type::Function)
```

```
TRUE
```

Any other MuPAD object is determined as non executable object by `Type::Function`:

```
map([1, TRUE, x, {}], testtype, Type::Function)
```

```
[FALSE, FALSE, FALSE, FALSE]
```

# Type::Function

---

**Parameters**    **obj**  
                  Any MuPAD object

**Return Values**    See testtype

**See Also**

**MuPAD Functions**    testtype

**Purpose** Type and property representing imaginary numbers

**Syntax** `testtype(obj, Type::Imaginary)`  
`assume(x, Type::Imaginary)`  
`is(ex, Type::Imaginary)`

**Description** `Type::Imaginary` represents complex numbers with vanishing real part. This type can also be used as a property to mark identifiers as imaginary numbers.

The call `testtype(obj, Type::Imaginary)` checks, whether `obj` is an imaginary number (or zero) and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_COMPLEX` and checks, whether `iszero(Re(obj))` holds, or whether `iszero(obj)` is `TRUE`. This does not include arithmetical expressions such as `I*exp(1)`, which are not identified as of type `Type::Imaginary`.

The call `assume(x, Type::Imaginary)` marks the identifier `x` as an imaginary number.

The call `is(ex, Type::Imaginary)` derives, whether the expression `ex` is an imaginary number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

The call `assume(Re(x) = 0)` has the same meaning as `assume(x, Type::Imaginary)`.

## Examples

### Example 1

The following numbers are of type `Type::Imaginary`:

```
testtype(5*I, Type::Imaginary),
testtype(3/2*I, Type::Imaginary),
testtype(-1.23*I, Type::Imaginary)
```

# Type::Imaginary

---

```
TRUE, TRUE, TRUE
```

The following expressions are exact representations of imaginary numbers. However, syntactically they are not of type `Type::Imaginary`, because their domain type is not `DOM_COMPLEX`:

```
testtype(exp(3)*I, Type::Imaginary),
testtype(PI*I, Type::Imaginary),
testtype(sin(2*I), Type::Imaginary)
```

```
FALSE, FALSE, FALSE
```

In contrast to `testtype`, the function `is` performs a semantical test:

```
is(exp(3)*I, Type::Imaginary),
is(PI*I, Type::Imaginary),
is(sin(2*I), Type::Imaginary)
```

```
TRUE, TRUE, TRUE
```

## Example 2

Identifiers may be assumed to represent an imaginary number:

```
assume(x, Type::Imaginary): is(x, Type::Imaginary), Re(x), Im(x)
```

```
TRUE, 0, -x i
```

The imaginary numbers are a subset of the complex numbers:

```
is(x, Type::Complex)
```

TRUE

`unassume(x) :`

## Parameters

**obj**

Any MuPAD object

**x**

An identifier

**ex**

An arithmetical expression

**obj**

Any MuPAD object

## Return Values

See `assume`, `is` and `testtype`

## See Also

## MuPAD Functions

`assume` | `is` | `testtype` | `Type::Complex` | `Type::Property`

# Type::IndepOf

---

**Purpose** Type representing objects that do not contain given identifiers

**Syntax** `testtype(obj, Type::IndepOf(x))`  
`testtype(obj, Type::IndepOf({x1, x2, ...}))`

**Description** `Type::IndepOf(x)` represents objects that do not contain the identifier `x`.

`Type::IndepOf({x1, x2, ...})` represents objects that do not contain any of the identifiers `x1, x2` etc.

The call `testtype(obj, Type::IndepOf(x))` checks, whether `obj` does not contain the identifier `x` and returns a corresponding `TRUE` or `FALSE`.

`Type::IndepOf` uses `has` to check whether the object contains at least one of the specified identifiers.

This type does not represent a property.

## Examples

### Example 1

The following expression depends on `x`:

```
testtype(x^2 - x + 3, Type::IndepOf(x))
```

`FALSE`

It is independent of `y`:

```
testtype(x^2 - x + 3, Type::IndepOf(y))
```

`TRUE`

The following expression is independent of `x` and `y`:

```
testtype(2*(a + b)/c, Type::IndepOf({x, y}))
```

TRUE

The following call selects all operands of the expression that are independent of  $x$ :

```
select(sin(y) + x^2 - 3*x + 2, testtype, Type::IndepOf(x))
```

$\sin(y) + 2$

## Parameters

**obj**

Any MuPAD object

**x, x1, x2**

Identifiers of domain type DOM\_IDENT

## Return Values

See testtype

## See Also

## MuPAD Functions

has | indets | testtype | Type::Indeterminate

# Type::Indeterminate

---

**Purpose** Type representing indeterminates

**Syntax** `testtype(obj, Type::Indeterminate)`

**Description** `Type::Indeterminate` represents all objects that MuPAD regards as indeterminates: identifiers except those in `Type::ConstantIdsents`, plus indexed identifiers.

This type does not represent a property: it cannot be used in `assume` to mark an identifier as an algebraic constant.

## Examples

### Example 1

The following call selects all indeterminates from a list:

```
delete x:
testtype(x, Type::Indeterminate),
testtype(sqrt(2), Type::Indeterminate);
```

```
TRUE, FALSE
```

```
l := [x, x[2], x[sqrt(2) + I], x[x], PI, PI[1], sin(x), 3.0];
select(l, testtype, Type::Indeterminate)
```

```
[X, X2, X√2+i, Xx, π, π1, sin(X), 3.0]
```

```
[X, X2, X√2+i, Xx, π1]
```

Note that `testtype` evaluates its arguments:

```
y := 5;
testtype(y, Type::Indeterminate),
testtype(hold(y), Type::Indeterminate);
```

5

FALSE, TRUE

## Parameters

**obj**

Any MuPAD object

## Return Values

See `testtype`

## See Also

## MuPAD Domains

DOM\_IDENT

## MuPAD Functions

`indets` | `_index` | `testtype` | `Type::ConstantIdents` | `Type::IndepOf`

# Type::Integer

---

**Purpose** Type and property representing integers

**Syntax** `testtype(obj, Type::Integer)`  
`assume(x, Type::Integer)`  
`is(ex, Type::Integer)`

**Description** `Type::Integer` represents integers. This type can also be used as a property to mark identifiers as integers.

The call `testtype(obj, Type::Integer)` checks, whether `obj` is an integer number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT`.

The call `assume(x, Type::Integer)` marks the identifier `x` as an integer number.

The call `is(ex, Type::Integer)` derives, whether the expression `ex` is an integer number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::Integer`:

```
testtype(0, Type::Integer), testtype(55, Type::Integer),
testtype(-111, Type::Integer)
```

```
TRUE, TRUE, TRUE
```

### Example 2

We use this type as a property:

```
assume(x, Type::Integer):
```

The following calls to `is` derive the properties of a composite expression from the properties of its indeterminates:

```
is(3*x, Type::Real), is(2*x, Type::Even), is(x/2, Type::Integer)
```

```
TRUE, TRUE, UNKNOWN
```

```
assume(y, Type::Integer): is(x + y^2, Type::Integer)
```

```
TRUE
```

```
unassume(x), unassume(y):
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `assume`, `is` and `testtype`

## See Also

## MuPAD Functions

`assume` | `is` | `testtype` | `Type::Real` | `Type::Property`

# Type::Intersection

---

**Purpose** Type representing the intersection of several types

**Syntax** `testtype(obj, (obj_type, ))`

**Description** `Type::Intersection(type1, type2, ...)` represents all objects having all of the types `type1, type2, ...`

The call `testtype(obj, Type::Intersection(obj_types, ...))` checks, whether `obj` has all the given types `obj_types, ...`

The call `testtype(obj, Type::Intersection(obj_types, ...))` is thus equivalent to the call `_lazy_and(map(obj_types, x -> testtype(obj, x)))`, testing `obj` against all types in turn.

`obj_types, ...` must be a (nonempty) sequence of types (see `testtype`).

This type does not represent a property.

## Examples

### Example 1

Check, whether the given object is a positive and odd integer:

```
testtype(1, Type::Intersection(Type::PosInt, Type::Odd))
```

```
TRUE
```

2 however, is not a positive and a odd number:

```
testtype(2, Type::Intersection(Type::PosInt, Type::Odd))
```

```
FALSE
```

### Example 2

`testtype` is used to select positive and odd integers:

```
SET:= {-2, -1.5, -1, -0.5, 0, 0.5, 1, 1.5, 2, 3}:
```

```
select(SET, testtype, Type::Intersection(Type::PosInt, Type::Odd
```

```
{1, 3}
```

```
delete SET:
```

## Parameters

**obj**

Any MuPAD object

**obj\_type, ...**

A sequence of types; a type can be an object of the library Type or one of the possible return values of domtype and type

## Return Values

See testtype

## See Also

## MuPAD Functions

testtype

# Type::Interval

---

**Purpose** Property representing intervals

**Syntax** `Type::Interval(a, b, <ndomain>)`  
`Type::Interval([a], b, <ndomain>)`  
`Type::Interval(a, [b], <ndomain>)`  
`Type::Interval([a], [b], <ndomain>)`  
`Type::Interval([a, b], <ndomain>)`

**Description** `Type::Interval(a, b, ...)` represents the interval  $(a, b)$ .  
`Type::Interval([a], b, ...)` represents the interval  $[a, b)$ .  
`Type::Interval(a, [b], ...)` represents the interval  $(a, b]$ .  
`Type::Interval([a], [b], ...)` represents the interval  $[a, b]$ .  
`Type::Interval([a, b], ...)` represents the interval  $[a, b]$ .  
With the default domain `Type::Real`, the type object created by `Type::Interval` represents a real interval, i.e., the set of all real numbers between the border points  $a$  and  $b$ . If another domain is specified, then the type object represents the intersection of the real interval with the set represented by the domain. E.g., `Type::Interval(a, b, Type::Rational)` represents the set of all rational numbers between  $a$  and  $b$ , and `Type::Interval([a, b], Type::Residue(0, 2))` represents the set of all even integers between  $a$  and  $b$  including  $a$  and  $b$ .  
The type object represents a property that may be used in `assume` and `is`. With  
`assume(x, Type::Interval(a, b, ndomain))`  
the identifier  $x$  is marked as a number from the interval represented by the type object. With  
`is(x, Type::Interval(a, b, ndomain))`  
one queries, whether  $x$  is contained in the interval.

Interval types should not be used in `testtype`. No MuPAD object matches these types syntactically, i.e., `testtype` always returns `FALSE`.

## Examples

### Example 1

The following type object represents the open interval  $(-1, 1)$ :

```
Type::Interval(-1, 1)
```

```
Type::Interval(-1, 1, Type::Real)
```

The following calls are equivalent: both create the type representing a closed interval:

```
Type::Interval([-1], [1]), Type::Interval([-1, 1])
```

```
Type::Interval([-1], [1], Type::Real), Type::Interval([-1], [1], Type::Real)
```

The following call creates the type representing the set of all integers from  $-10$  to  $10$ :

```
Type::Interval([-10, 10], Type::Integer)
```

```
Type::Interval([-10], [10], Type::Integer)
```

The following call creates the type representing the set of all rational numbers in the interval  $[0, 1)$ :

```
Type::Interval([0], 1, Type::Rational)
```

```
Type::Interval([0], 1, Type::Rational)
```

# Type::Interval

---

The following calls create the types representing the sets of all even/odd integers in the interval  $[-10, 10]$ :

```
Type::Interval([-10], [10], Type::Even),
Type::Interval([-10], [10], Type::Odd)
```

```
Type::Interval([-10], [10], Type::Residue(0, 2, Type::Integer)),
Type::Interval([-10], [10], Type::Residue(1, 2, Type::Integer))
```

## Example 2

We use intervals as a property. The following call marks  $x$  as a real number from the interval  $[0, 2]$ :

```
assume(x, Type::Interval([0], 2)):
```

Consequently,  $x^2 + 1$  lies in the interval  $[1, 5]$ :

```
is(x^2 + 1 >= 1), is(x^2 + 1 < 5)
```

```
TRUE, TRUE
```

The following call marks  $x$  as an integer larger than  $-10$  and smaller than  $100$ :

```
assume(x, Type::Interval(-10, 100, Type::Integer)):
```

Consequently,  $x^3$  is an integer larger than  $-730$  and smaller than  $970300$ :

```
is(x^3, Type::Integer), is(x^3 >= -729), is(x^3 < 970300),
is(x^3, Type::Interval(-10^3, 100^3, Type::Integer))
```

```
TRUE, TRUE, TRUE, TRUE
```

```
is(x <= -730), is(x^3 >= 970300)
```

```
FALSE, FALSE
```

```
is(x > 0), is(x^3, Type::Interval(0, 10, Type::Integer))
```

```
UNKNOWN, UNKNOWN
```

```
unassume(x):
```

## Parameters

**a, b**

The borders of the interval: arithmetical objects

**ndomain**

A type object such as `Type::Real`, `Type::Integer` or `Type::Rational` representing a subset of the real numbers or a property representing a residue class as `Type::Residue(0, 2)`. The default domain is `Type::Real`.

## Return Values

Type object

## See Also

## MuPAD Functions

`assume` | `is` | `testtype` | `Type::Integer` | `Type::Rational` | `Type::Real` | `Type::Residue`

# Type::ListOf

---

**Purpose** Type representing lists of objects with the same type

**Syntax** `testtype(obj, (obj_type, <min_nr, <max_nr>>))`

**Description** `Type::ListOf` describes lists of objects of a specified type.

The call `testtype(obj, Type::ListOf(obj_types, ...))` checks, whether `obj` is a list with elements of the given type `obj_type`, ... and returns `TRUE`, if it holds, otherwise `FALSE`.

The two optional parameters `min_nr` and `max_nr` determine the minimum and maximum number of elements in the analyzed list. If the numbers are not be given, the number of elements in the list will not be checked. If only the minimum is given, only the minimal number of elements in the list is checked.

Note especially that `Type::Union` provides a way to allow more than one type for the list elements.

This type does not represent a property.

## Examples

### Example 1

Is the given list a list of identifiers?

```
testtype([a, b, c, d, e, f], Type::ListOf(DOM_IDENT))
```

`TRUE`

Is the given list a list of at least five real numbers?

```
testtype([0, 0.5, 1, 1.5, 2, 2.5, 3], Type::ListOf(Type::Real, 5))
```

`TRUE`

**Example 2**

testtype is used to select lists with exactly two identifiers:

```
S := {[a], [a, b], [d, 1], [0, d], [e], [d, e]}:
select(S, testtype, Type::ListOf(DOM_IDENT, 2, 2))
```

```
{[a, b], [d, e]}
```

**Parameters****obj**

Any MuPAD object

**obj\_type**

The type of the objects; a type can be an object of the library Type or one of the possible return values of domtype and type

**min\_nr**

The minimal number of objects as nonnegative integer

**max\_nr**

The maximal number of objects as nonnegative integer

**Return Values**

See testtype

**See Also****MuPAD Domains**

DOM\_LIST

**MuPAD Functions**

testtype | Type::ListProduct | Type::SetOf | Type::Union

# Type::ListProduct

---

**Purpose** Type representing lists

**Syntax** `testtype(obj, Type::ListProduct(typedef, ))`

**Description** With `Type::ListProduct`, lists with different object types can be identified.

The call `testtype(obj, Type::ListProduct(typedef))` checks, whether `obj` is a list of objects, which have the types given by `typedef` and returns `TRUE`, if it holds, otherwise `FALSE`.

`obj` must have the same number of arguments as the sequence `typedef`. The elements of `obj` are checked one after another: the first element of `obj` is checked against the type given by the first element of `typedef`, and so on. All elements and types must match.

`typedef, ...` must be a nonempty sequence of types. A type can be an object of the library `Type` or one of the possible return values of `domtype` and `type`.

This type does not represent a property.

## Examples

### Example 1

The argument is a list of a positive integer followed by an identifier:

```
testtype([5, x], Type::ListProduct(Type::PosInt, Type::Unknown))
```

`TRUE`

Is the argument is a sequence of five positive integers?

```
testtype([5, 3, 5, -1, 0], Type::ListProduct(Type::PosInt $ 5))
```

`FALSE`

## Parameters

**obj**

Any MuPAD object

**typedef**

A sequence of types; a type can be an object of the library `Type` or one of the possible return values of `domtype` and `type`

## Return Values

See `testtype`

## See Also

## MuPAD Functions

`testtype` | `Type::ListOf` | `Type::Product`

# Type::NegInt

---

**Purpose** Type and property representing negative integers

**Syntax** `testtype(obj, Type::NegInt)`  
`assume(x, Type::NegInt)`  
`is(ex, Type::NegInt)`

**Description** `Type::NegInt` represents negative integers. `Type::NegInt` is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::NegInt)` checks, whether `obj` is a negative integer number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT` and checks, if `bool(obj < 0)` holds.

The call `assume(x, Type::NegInt)` marks the identifier `x` as a negative integer number.

The call `is(ex, Type::NegInt)` derives, whether the expression `ex` is a negative integer number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::NegInt`:

```
testtype(-2, Type::NegInt),
testtype(-3, Type::NegInt),
testtype(-55, Type::NegInt),
testtype(-1, Type::NegInt),
testtype(-111111111, Type::NegInt)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

### Example 2

Assume an identifier is a negative integer:

```
assume(x, Type::NegInt):
is(x, Type::NegInt)
```

TRUE

Negative integers are integers, of course:

```
assume(x, Type::NegInt):
is(x, Type::Integer)
```

TRUE

However, integers can be negative or not:

```
assume(x, Type::Integer):
is(x, Type::NegInt)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`

# Type::NegInt

---

## See Also

## MuPAD Functions

`testtype` | `is` | `assume` | `Type::Property`

## Purpose

Type and property representing negative rational numbers

## Syntax

```
testtype(obj, Type::NegRat)
assume(x, Type::NegRat)
is(ex, Type::NegRat)
```

## Description

Type::NegRat represents negative rational numbers. Type::NegRat is a property, too, which can be used in an assume call.

The call testtype(obj, Type::NegRat) checks, whether obj is a negative rational number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM\_INT and DOM\_RAT and checks, if bool(obj < 0) holds.

The call assume(x, Type::NegRat) marks the identifier x as a negative rational number.

The call is(ex, Type::NegRat) derives, whether the expression ex is a negative rational number (or this property can be derived).

This type represents a property that can be used in assume and is.

## Examples

### Example 1

The following numbers are of type Type::NegRat:

```
testtype(-2, Type::NegRat),
testtype(-3/4, Type::NegRat),
testtype(-55/111, Type::NegRat),
testtype(-1, Type::NegRat),
testtype(-111/111111, Type::NegRat)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

### Example 2

Assume an identifier is negative rational:

# Type::NegRat

---

```
assume(x, Type::NegRat):
is(x, Type::NegRat)
```

TRUE

Also negative rational numbers are rational:

```
assume(x, Type::NegRat):
is(x, Type::Rational)
```

TRUE

However, rational numbers can be negative rational or not:

```
assume(x, Type::Rational):
is(x, Type::NegRat)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See testtype, assume and is

## See Also

## MuPAD Functions

testtype | is | assume | Type::Property

# Type::Negative

---

**Purpose** Type and property representing negative numbers

**Syntax** `testtype(obj, Type::Negative)`  
`assume(x, Type::Negative)`  
`is(ex, Type::Negative)`

**Description** `Type::Negative` represents negative numbers. `Type::Negative` is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::Negative)` checks, whether `obj` is a negative real number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT`, `DOM_RAT` and `DOM_FLOAT` and checks, if `bool(obj < 0)` holds. This does not include arithmetical expressions such as `-exp(1)`, which are not identified as of type `Type::Negative`.

The call `assume(x, Type::Negative)` marks the identifier `x` as a negative real number.

The call `is(ex, Type::Negative)` derives, whether the expression `ex` is a negative real number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

Instead of `Type::Negative` the assumption can also be `assume(x < 0)`.

## Examples

### Example 1

The following numbers are of type `Type::Negative`:

```
testtype(-2, Type::Negative),
testtype(-3/4, Type::Negative),
testtype(-0.123, Type::Negative),
testtype(-1, Type::Negative),
testtype(-1.02, Type::Negative)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

The following expressions are exact representations of negative numbers, but syntactically they are not of `Type::Negative`:

```
testtype(-exp(1), Type::Negative),
testtype(-PI^2 - 5, Type::Negative),
testtype(-sin(2), Type::Negative)
```

```
FALSE, FALSE, FALSE
```

## Example 2

Assume an identifier is negative:

```
assume(x, Type::Negative):
is(x, Type::Negative)
```

```
TRUE
```

This is equal to:

```
assume(x < 0):
is(x < 0)
```

```
TRUE
```

Also negative numbers are real:

```
assume(x, Type::Negative):
is(x, Type::Real)
```

```
TRUE
```

However, real numbers can be negative or not:

# Type::Negative

---

```
assume(x, Type::Real):
is(x, Type::Negative)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`

## See Also

## MuPAD Functions

`testtype` | `is` | `assume` | `Type::Real` | `Type::Property`

## Purpose

Type and property representing nonnegative integers

## Syntax

```
testtype(obj, Type::NonNegInt)
assume(x, Type::NonNegInt)
is(ex, Type::NonNegInt)
```

## Description

Type::NonNegInt represents nonnegative integers. Type::NonNegInt is a property, too, which can be used in an assume call.

The call testtype(obj, Type::NonNegInt) checks, whether obj is a nonnegative integer number and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test identifying MuPAD objects of type DOM\_INT and checks, if bool(obj >= 0) holds.

The call assume(x, Type::NonNegInt) marks the identifier x as a nonnegative integer number.

The call is(ex, Type::NonNegInt) derives, whether the expression ex is a nonnegative integer number (or this property can be derived).

This type represents a property that can be used in assume and is.

## Examples

### Example 1

The following numbers are of type Type::NonNegInt:

```
testtype(2, Type::NonNegInt),
testtype(3/4, Type::NonNegInt),
testtype(55/111, Type::NonNegInt),
testtype(1, Type::NonNegInt),
testtype(111/111111, Type::NonNegInt)
```

```
TRUE, FALSE, FALSE, TRUE, FALSE
```

### Example 2

Assume an identifier is nonnegative rational:

# Type::NonNegInt

---

```
assume(x, Type::NonNegInt):
is(x, Type::NonNegInt)
```

TRUE

Also nonnegative integers are integers:

```
assume(x, Type::NonNegInt):
is(x, Type::Integer)
```

TRUE

However, integers can be nonnegative or not:

```
assume(x, Type::Integer):
is(x, Type::NonNegInt)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

---

**Purpose** Type and property representing nonnegative rational numbers

**Syntax** `testtype(obj, Type::NonNegRat)`  
`assume(x, Type::NonNegRat)`  
`is(ex, Type::NonNegRat)`

**Description** `Type::NonNegRat` represents nonnegative rational numbers. `Type::NonNegRat` is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::NonNegRat)` checks, whether `obj` is a nonnegative rational number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT` and `DOM_RAT` and checks, if `bool(obj >= 0)` holds.

The call `assume(x, Type::NonNegRat)` marks the identifier `x` as a nonnegative rational number.

The call `is(ex, Type::NonNegRat)` derives, whether the expression `ex` is a nonnegative rational number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::NonNegRat`:

```
testtype(2, Type::NonNegRat),
testtype(3/4, Type::NonNegRat),
testtype(55/111, Type::NonNegRat),
testtype(0, Type::NonNegRat),
testtype(111/111111, Type::NonNegRat)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

## Example 2

Assume an identifier is nonnegative rational:

```
assume(x, Type::NonNegRat):
is(x, Type::NonNegRat)
```

TRUE

Also nonnegative rational numbers are rational:

```
assume(x, Type::NonNegRat):
is(x, Type::Rational)
```

TRUE

However, rational numbers can be nonnegative rational or not:

```
assume(x, Type::Rational):
is(x, Type::NonNegRat)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

# Type::NonNegRat

---

## **Return Values**

See `testtype`, `assume` and `is`

## **See Also**

## **MuPAD Functions**

`testtype` | `is` | `assume` | `Type::Rational` | `Type::Property`

<b>Purpose</b>	Type and property representing nonnegative numbers
<b>Syntax</b>	<pre>testtype(obj, Type::NonNegative) assume(x, Type::NonNegative) is(ex, Type::NonNegative)</pre>
<b>Description</b>	<p>Type::NonNegative represents nonnegative numbers. This does not include arithmetical expressions such as <code>exp(1)</code>, which are not identified as of type <code>Type::NonNegative</code>.</p> <p>The call <code>assume(x, Type::NonNegative)</code> marks the identifier <code>x</code> as a nonnegative real number.</p> <p>The call <code>is(ex, Type::NonNegative)</code> derives, whether the expression <code>ex</code> is a nonnegative real number (or this property can be derived).</p> <p>This type represents a property that can be used in <code>assume</code> and <code>is</code>.</p> <p>Instead of <code>Type::NonNegative</code> the assumption can also be <code>assume(x &gt;= 0)</code>.</p>

## Examples

### Example 1

The following numbers are of type `Type::NonNegative`:

```
testtype(2, Type::NonNegative),
testtype(3/4, Type::NonNegative),
testtype(0.123, Type::NonNegative),
testtype(0, Type::NonNegative),
testtype(1.02, Type::NonNegative)
```

# Type::NonNegative

---

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

The following expressions are exact representations of nonnegative numbers, but syntactically they are not of `Type::NonNegative`:

```
testtype(exp(1), Type::NonNegative),
testtype(PI^2 + 5, Type::NonNegative),
testtype(sin(2), Type::NonNegative)
```

```
FALSE, FALSE, FALSE
```

The function `is`, however, can find these expressions to be nonnegative:

```
is(exp(1), Type::NonNegative),
is(PI^2 + 5, Type::NonNegative),
is(sin(2), Type::NonNegative)
```

```
TRUE, TRUE, TRUE
```

## Example 2

Assume an identifier is nonnegative:

```
assume(x, Type::NonNegative):
is(x, Type::NonNegative)
```

```
TRUE
```

This is equal to:

```
assume(x >= 0):
is(x >= 0)
```

TRUE

Also nonnegative numbers are real:

```
assume(x, Type::NonNegative):
is(x, Type::Real)
```

TRUE

But real numbers can be nonnegative or not:

```
assume(x, Type::Real):
is(x, Type::NonNegative)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`

# Type::NonNegative

---

## See Also

## MuPAD Functions

`testtype` | `is` | `assume` | `Type::Real` | `Type::Property`

## Purpose

Type and property representing “unequal to zero”

## Syntax

```
testtype(obj, Type::NonZero)
assume(x, Type::NonZero)
is(ex, Type::NonZero)
```

## Description

Type::NonZero is a type of objects unequal to zero. Type::NonZero is a property, too, which can be used in an assume call.

The call testtype(obj, Type::NonZero) checks, whether obj is *not* zero and returns TRUE, if it holds, otherwise FALSE.

testtype only performs a syntactical test and uses the function iszero to determine, whether the object is not zero. This implies that identifiers without a value, for example, are considered as being different from zero, see “Example 1” on page 32-67.

The call assume(x, Type::NonZero) marks the identifier x as a complex number unequal to zero.

The call is(ex, Type::NonZero) derives, whether the expression ex is a complex number unequal to zero (or this property can be derived).

This type represents a property that can be used in assume and is.

The call assume(x <> 0) has the same meaning as assume(x, Type::NonZero).

## Examples

### Example 1

Usage of Type::NonZero with testtype:

```
testtype(1.0, Type::NonZero)
```

```
TRUE
```

Since iszero(x) returns FALSE, the following call returns TRUE:

```
testtype(x, Type::NonZero)
```

# Type::NonZero

---

TRUE

## Example 2

Usage of Type::NonZero with assume and is:

```
is(x, Type::NonZero)
```

UNKNOWN

Assumption: x is Type::NonZero:

```
assume(x, Type::NonZero):
is(x, Type::NonZero)
```

TRUE

The same again:

```
assume(x <> 0):
is(x <> 0)
```

TRUE

The difference between testtype and is:

```
delete x:
is(x, Type::NonZero), testtype(x, Type::NonZero)
```

UNKNOWN, TRUE

x could be zero:

```
assume(x >= 0):
is(x, Type::NonZero), testtype(x, Type::NonZero)
```

```
UNKNOWN, TRUE
```

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See testtype, assume and is

## See Also

## MuPAD Functions

testtype | is | assume | Type::Zero

# Type::Numeric

---

**Purpose** Type representing numerical objects

**Syntax** `testtype(obj, Type::Numeric)`

**Description** With `Type::Numeric`, numeric objects (numbers) can be identified. The call `testtype(obj, Type::Numeric)` checks, whether `obj` is a number and returns `TRUE`, if it holds, otherwise `FALSE`.  
A number has the domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`.  
This type does not represent a property.

## Examples **Example 1**

The following objects are numbers.

```
testtype(2, Type::Numeric),
testtype(3/4, Type::Numeric),
testtype(0.123, Type::Numeric),
testtype(1 + I/3, Type::Numeric),
testtype(1.0 + 2.0*I, Type::Numeric)
```

`TRUE, TRUE, TRUE, TRUE, TRUE`

The following objects are not numerical objects.

```
testtype(ln(2), Type::Numeric),
testtype(sin(3/4), Type::Numeric),
testtype(x + I/3, Type::Numeric)
```

`FALSE, FALSE, FALSE`

**Parameters** `obj`

Any MuPAD object

## **Return Values**

See `testtype`

## **See Also**

## **MuPAD Functions**

`assume` | `is` | `testtype` | `Type::Complex`

# Type::Odd

---

**Purpose** Type and property representing odd integers

**Syntax** `testtype(obj, Type::Odd)`  
`assume(x, Type::Odd)`  
`is(ex, Type::Odd)`

**Description** `Type::Odd` represents odd integers. `Type::Odd` is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::Odd)` checks, whether `obj` is an odd number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT` and checks, if `bool(domtype((x-1)/2) = DOM_INT)` holds.

The call `assume(x, Type::Odd)` marks the identifier `x` as an odd number.

The call `is(ex, Type::Odd)` derives, whether the expression `ex` is an odd number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::Odd`:

```
testtype(1, Type::Odd),
testtype(-3, Type::Odd),
testtype(7, Type::Odd),
testtype(-11113, Type::Odd),
testtype(4185296581467695597, Type::Odd)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

### Example 2

Assume an identifier is odd:

```
assume(x, Type::Odd):
is(x, Type::Odd)
```

TRUE

All odd numbers are integer:

```
assume(x, Type::Odd):
is(x, Type::Integer)
```

TRUE

However, integers can be odd or not:

```
assume(x, Type::Integer):
is(x, Type::Odd)
```

UNKNOWN

However, even numbers are not odd:

```
assume(x, Type::Odd):
is(2*x, Type::Odd)
```

FALSE

```
assume(n, Type::Even):
is(x*n, Type::Odd)
```

FALSE

# Type::Odd

---

```
is(x*n + 1, Type::Odd)
```

```
TRUE
```

```
delete x, n:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`

## See Also

## MuPAD Functions

`testtype` | `is` | `assume` | `Type::Even` | `Type::Property`

<b>Purpose</b>	Type representing polynomial expressions
<b>Syntax</b>	<code>testtype(obj, Type::PolyExpr(unknowns, &lt;coeff_type&gt;))</code>
<b>Description</b>	<p>With <code>Type::PolyExpr</code>, polynomial expressions can be identified.</p> <p>The call <code>testtype(obj, Type::PolyExpr(unknowns))</code> checks, whether <code>obj</code> is a polynomial expression in the indeterminates <code>unknowns</code> and, if so, returns <code>TRUE</code>, otherwise <code>FALSE</code>.</p> <p>A polynomial expression in <code>indet</code> is an expression, where <code>indet</code> occurs only as operand of <code>_plus</code> or <code>_mult</code> expressions and in the base of <code>_power</code> with a positive integer exponent.</p> <p>A polynomial expression is a representation of a polynomial, but it has the MuPAD type <code>DOM_EXPR</code> and is not produced by the function <code>poly</code>.</p> <p><code>indets</code> must be an identifier or a list of identifiers.</p> <p>The optional argument <code>coeff_type</code> determines the type of the coefficients. If it is not given, <code>Type::AnyType</code> will be used.</p> <p>This type does not represent a property.</p>

## Examples

### Example 1

Is the object a polynomial expression with variable `x`?

```
X := -x^2 - x + 3:
testtype(X, Type::PolyExpr(x))
```

```
TRUE
```

But `X` is not a MuPAD polynomial in `x`:

```
testtype(X, Type::PolyOf(x))
```

# Type::PolyExpr

---

FALSE

Is the object a polynomial expression with variables x and y and with integer coefficients?

```
X := -x^2 - x + 3:
testtype(X, Type::PolyExpr([x, y], Type::Integer))
```

TRUE

The next example too?

```
X := -x^2 - y^2 + 3*x + 3*y - 1:
testtype(X, Type::PolyExpr([x, y], Type::Integer))
```

TRUE

```
delete X:
```

## Parameters

### obj

Any MuPAD object

### unknowns

An indeterminate or a list of indeterminates

### coeff\_type

The type of the coefficients; a type can be an object of the library Type or one of the possible return values of domtype and type

## Return Values

See testtype

## See Also

### MuPAD Functions

`testtype` | `Type::PolyOf` | `poly` | `indets`

# Type::PolyOf

---

**Purpose** Type representing polynomials

**Syntax** `testtype(obj, Type::PolyOf(coeff_type, <num_ind>))`

**Description** With `Type::PolyOf`, polynomials can be identified.

The call `testtype(obj, Type::PolyOf(coeff_type))` checks, whether `obj` is a polynomial with coefficients of type `coeff_type` and, if so, returns `TRUE`, otherwise `FALSE`.

---

**Note** Only polynomials of type `DOM_POLY` can be identified with `Type::PolyOf`, see `Type::PolyExpr` for polynomial expressions.

---

`coeff_type` determines the type of the coefficients.

The optional argument `num_ind` determines the number of indeterminates. If this argument is not given, the polynomial may have any number of indeterminates.

This type does not represent a property.

## Examples

### Example 1

Is the object a polynomial with integer coefficients?

```
P := poly(-x^2 - x + 3):
testtype(P, Type::PolyOf(Integer))
```

TRUE

Is the object a polynomial with integer coefficients and two indets?

```
P := poly(-x^2 - x + 3, [x, y]):
testtype(P, Type::PolyOf(Integer, 2))
```

TRUE

delete P:

## Parameters

**obj**

Any MuPAD object

**coeff\_type**

The type of the coefficients; a type can be an object of the library Type or one of the possible return values of domtype and type

**num\_ind**

The number of indeterminates

## Return Values

See testtype

## See Also

## MuPAD Functions

testtype | poly | indets

# Type::PosInt

---

**Purpose** Type and property representing positive integers

**Syntax** `testtype(obj, Type::PosInt)`  
`assume(x, Type::PosInt)`  
`is(ex, Type::PosInt)`

**Description** `Type::PosInt` represents positive integers. `Type::PosInt` is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::PosInt)` checks, whether `obj` is a positive integer number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT` and checks, if `bool(obj > 0)` holds.

The call `assume(x, Type::PosInt)` marks the identifier `x` as a positive integer number.

The call `is(ex, Type::PosInt)` derives, whether the expression `ex` is a positive integer number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::PosInt`:

```
testtype(2, Type::PosInt),
testtype(3, Type::PosInt),
testtype(55, Type::PosInt),
testtype(1, Type::PosInt),
testtype(111, Type::PosInt)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

### Example 2

Assume an identifier is positive integer:

```
assume(x, Type::PosInt):
is(x, Type::PosInt)
```

TRUE

Also positive integers are integers:

```
assume(x, Type::PosInt):
is(x, Type::Integer)
```

TRUE

However, integers can be positive or not:

```
assume(x, Type::Integer):
is(x, Type::PosInt)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`

# Type::PosInt

---

## See Also

## MuPAD Functions

`testtype` | `is` | `assume` | `Type::Property`

## Purpose

Type and property representing positive rational numbers

## Syntax

```
testtype(obj, Type::PosRat)
assume(x, Type::PosRat)
is(ex, Type::PosRat)
```

## Description

Type::PosRat represents positive rational numbers. Type::PosRat is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::PosRat)` checks, whether `obj` is a positive rational number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT` and `DOM_RAT` and checks, if `bool(obj > 0)` holds.

The call `assume(x, Type::PosRat)` marks the identifier `x` as a positive rational number.

The call `is(ex, Type::PosRat)` derives, whether the expression `ex` is a positive rational number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::PosRat`:

```
testtype(2, Type::PosRat),
testtype(3/4, Type::PosRat),
testtype(55/111, Type::PosRat),
testtype(1, Type::PosRat),
testtype(111/111111, Type::PosRat)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

### Example 2

Assume an identifier is positive rational:

# Type::PosRat

---

```
assume(x, Type::PosRat):
is(x, Type::PosRat)
```

TRUE

Also positive rational numbers are rational:

```
assume(x, Type::PosRat):
is(x, Type::Rational)
```

TRUE

However, rational numbers can be positive rational or not:

```
assume(x, Type::Rational):
is(x, Type::PosRat)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See testtype, assume and is

## See Also

## MuPAD Functions

testtype | is | assume | Type::Property

# Type::Positive

---

**Purpose** Type and property representing positive numbers

**Syntax** `testtype(obj, Type::Positive)`  
`assume(x, Type::Positive)`  
`is(ex, Type::Positive)`

**Description** `Type::Positive` represents positive numbers. `Type::Positive` is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::Positive)` checks, whether `obj` is a positive real number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT`, `DOM_RAT` and `DOM_FLOAT` and checks, if `bool(obj > 0)` holds. This does not include arithmetical expressions such as `exp(1)`, which are not identified as of type `Type::Positive`.

The call `assume(x, Type::Positive)` marks the identifier `x` as a positive real number.

The call `is(ex, Type::Positive)` derives, whether the expression `ex` is a positive real number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

Instead of `Type::Positive` the assumption can also be `assume(x > 0)`.

## Examples

### Example 1

The following numbers are of type `Type::Positive`:

```
testtype(2, Type::Positive),
testtype(3/4, Type::Positive),
testtype(0.123, Type::Positive),
testtype(1, Type::Positive),
testtype(1.02, Type::Positive)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

The following expressions are exact representations of positive numbers, but syntactically they are not of `Type::Positive`:

```
testtype(exp(1), Type::Positive),
testtype(PI^2 + 5, Type::Positive),
testtype(sin(2), Type::Positive)
```

```
FALSE, FALSE, FALSE
```

This function `is`, however, realizes that they are, indeed, positive:

```
is(exp(1), Type::Positive),
is(PI^2 + 5, Type::Positive),
is(sin(2), Type::Positive)
```

```
TRUE, TRUE, TRUE
```

## Example 2

Assume an identifier is positive:

```
assume(x, Type::Positive):
is(x, Type::Positive)
```

```
TRUE
```

This is equivalent to:

```
assume(x > 0):
is(x > 0)
```

```
TRUE
```

# Type::Positive

---

Also positive numbers are real:

```
assume(x, Type::Positive):
is(x, Type::Real)
```

TRUE

But real numbers can be positive or not:

```
assume(x, Type::Real):
is(x, Type::Positive)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`

## See Also

## MuPAD Functions

`testtype` | `is` | `assume` | `Type::Property`

## Purpose

Type for testing object satisfying a given predicate

## Syntax

```
testtype(obj, Type::Predicate(<pname>, predicate,
<p1, p2, >))
```

## Description

Type::Predicate(predicate) represents the MuPAD objects which satisfy the predicate predicate.

The call testtype(obj, pname, Type::Predicate(< pname >, predicate , < p1 , p2 >)) test whether obj satisfies predicate; that is it returns predicate(obj, p1, p2, ...).

Type::Predicate(predicate), Type::Predicate(name, predicate), Type::Predicate ( predicate( p1 , p2 , )), and Type::Predicate(name, predicate p1 , p2 , , ) are respectively pretty printed as Type::Predicate(predicate), Type::name, Type::Predicate(p, p1, p2, ...), and Type::name(p1, p2, ...).

## Examples

### Example 1

We define a type which contains any MuPAD object:

```
t := Type::Predicate(x -> TRUE):
testtype(1, t), testtype(2, t), testtype(x, t)
```

```
TRUE, TRUE, TRUE
```

We define a type which contains all the MuPAD object which are solution of  $(x-1)*(x+1)=0$ :

```
t := Type::Predicate(x -> bool((x - 1)*(x + 1) = 0)):
testtype(1, t), testtype(2, t), testtype(x, t)
```

```
TRUE, FALSE, FALSE
```

# Type::Predicate

---

We define a type for partitions, that is, decreasing lists of integers:

```
part :=
 Type::Predicate(1 -> _lazy_and(testtype(1, Type::ListOf(Type::I
 bool(revert(sort(1)) = 1))):
testtype(a, part), testtype([3, 6, 1], part), testtype([3, 2, 2], p

FALSE, FALSE, TRUE
```

Using the naming facility is recommended to improve the readability of error messages:

```
part :=
 Type::Predicate("Partition",
 1 -> _lazy_and(testtype(1, Type::ListOf(Type::I
 bool(revert(sort(1)) = 1))):
f := proc(p: part) begin end:
f(3);
```

```
Error: The type of argument number 1 must be 'Type::Partition'. The
Evaluating: f
```

## Parameters

### **pname**

A string which will be used for pretty printing the type

### **predicate**

A function of one argument which can return TRUE, FALSE or FAIL

### **obj, p1, p2, ...**

Any MuPAD objects

## Return Values

See testtype

## See Also

### MuPAD Functions

`testtype`

# Type::Prime

---

**Purpose** Type representing prime numbers

**Syntax** `testtype(obj, Type::Prime)`

**Description** `Type::Prime` represents prime numbers.  
The call `testtype(obj, Type::Prime)` returns `TRUE` if `obj` is a prime number, and `FALSE` otherwise.  
`testtype` only performs a syntactical test whether `obj` is an integer and `isprime(obj)` holds.

**Examples**      **Example 1**

The following numbers are of type `Type::Prime`:

```
testtype(2, Type::Prime),
testtype(3, Type::Prime),
testtype(7, Type::Prime),
testtype(11113, Type::Prime),
testtype(4185296581467695597, Type::Prime)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

**Parameters**    **obj**  
Any MuPAD object

**Return Values**    See `testtype`

**See Also**

**MuPAD Functions**    `testtype` | `isprime`

**Purpose** Type representing sequences

**Syntax** `testtype(obj, Type::Product(typedef, ))`

**Description** `Type::Product` is the type of sequences of objects of different types. The call `testtype(obj, Type::Product( typedef , ))` checks, whether `obj` is a sequence of objects, which have the types given by `typedef` and returns `TRUE`, if it holds, otherwise `FALSE`.

`obj` must have the same number of arguments as the sequence `typedef`. The elements of `obj` are checked one after another: the first element of `obj` is checked against the type given by the first element of `typedef` and so on. All elements and types must match.

`typedef, ...` must be a nonempty sequence of types. A type can be an object of the library `Type` or one of the possible return values of `domtype` and `type`.

This type does not represent a property.

## Examples

### Example 1

The argument is a sequence of a positive integer followed by an identifier:

```
testtype((5, x), Type::Product(Type::PosInt, Type::Unknown))
```

`TRUE`

Is the argument is a sequence of five positive integers?

```
testtype((5, 3, 5, -1, 0), Type::Product(Type::PosInt $ 5))
```

`FALSE`

# Type::Product

---

## Parameters

**obj**

Any MuPAD object

**typedef**

A sequence of types; a type can be an object of the library `Type` or one of the possible return values of `domtype` and `type`

## Return Values

See `testtype`

## See Also

## MuPAD Functions

`testtype` | `Type::ListProduct`

**Purpose** Type representing any property

**Syntax** `testtype(obj, Type::Property)`

**Description** With `Type::Property`, properties can be identified. The call `testtype(obj, Type::Property)` checks, whether the MuPAD object `obj` is a property and returns `TRUE`, if it holds, otherwise `FALSE`. Some elements of the library `Type` serve two functions. One is to perform syntactical tests to identify the type of an object (with `testtype`), the other is to occur as a property within `assume` and `is`.

---

**Note** `Type::Property` itself is not a property.

---

To determine whether an element of `Type` is a property, `Type::Property` can be used with `testtype`.

This type does not represent a property.

## Examples

### Example 1

Is `Type::PosInt` a property?

```
testtype(Type::PosInt, Type::Property)
```

```
TRUE
```

Also an interval created with `Type::Interval` is a property:

```
testtype(Type::Interval(0, 1), Type::Property)
```

```
TRUE
```

# Type::Property

---

Is `Type::Constant` a property?

```
testtype(Type::Constant, Type::Property)
```

```
FALSE
```

`Type::Constant` is not a property and cannot be used as argument of `assume`:

```
assume(x, Type::Constant)
```

```
Error: The second argument must be a property. [assume]
```

The next example shows the usage of `testtype` to select properties among operands of `Type`:

```
T := Type::Numeric, Type::PosInt, Type::Unknown, Type::Zero:
select(T, testtype, Type::Property)
```

```
Type::PosInt, Type::Zero
```

```
delete x, T:
```

## Parameters

**obj**

Any MuPAD object

## Return Values

See `testtype`

## See Also

### MuPAD Functions

`testtype` | `is`

# Type::RatExpr

---

**Purpose** Type representing rational expressions

**Syntax** `testtype(obj, Type::RatExpr(indet, <coeff_type>))`

**Description** With `Type::RatExpr`, rational expressions can be identified.

The call `testtype(obj, Type::RatExpr(indet))` checks, whether `obj` is a rational expression in the indeterminate `indet`, i.e., the quotient of two polynomial expressions in `indet`. If it is, the result is `TRUE`, otherwise `FALSE`.

A rational expression in `indet` is a expression, and `indet` occurs only as operand of `_plus` or `_mult` expressions and in `_power` with an integer exponent.

`indet` must be an identifier, and `coeff_type` a type for the coefficients of the rational expression.

This type does not represent a property.

## Examples

### Example 1

A polynomial expression in `x` is also a rational expression in `x`:

```
testtype(-x^2 - x + 3, Type::RatExpr(x))
```

`TRUE`

`testtype` is used to select all rational operands in `x` with positive integer coefficients:

```
EX := sin(x) + x^2 - 3*x + 2 + 3/x:
select(EX, testtype, Type::RatExpr(x, Type::PosInt))
```

$\frac{3}{x} + x^2 + 2$

`delete EX:`

## Parameters

**obj**

Any MuPAD object

**indet**

An indeterminate

**coeff\_type**

A type for the coefficients; a type can be an object of the library Type or one of the possible return values of `domtype` and `type`

## Return Values

See `testtype`

## See Also

## MuPAD Functions

`testtype` | `indets`

# Type::Rational

---

**Purpose** Type and property representing rational numbers

**Syntax** `testtype(obj, Type::Rational)`  
`assume(x, Type::Rational)`  
`is(ex, Type::Rational)`

**Description** `Type::Rational` represents rational numbers. `Type::Rational` is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::Rational)` checks, whether `obj` is a rational number and returns `TRUE`, if it holds, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT` and `DOM_RAT`.

The call `assume(x, Type::Rational)` marks the identifier `x` as a rational number.

The call `is(ex, Type::Rational)` derives, whether the expression `ex` is a rational number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::Rational`:

```
testtype(2, Type::Rational),
testtype(3/4, Type::Rational),
testtype(-1/2, Type::Rational),
testtype(-1, Type::Rational),
testtype(1024/11111, Type::Rational)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

### Example 2

Integers are rational:

```
assume(x, Type::Integer):
is(x, Type::Rational)
```

TRUE

However, rational numbers can be integer or not:

```
assume(x, Type::Rational):
is(x, Type::Integer)
```

UNKNOWN

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`

## See Also

## MuPAD Functions

`testtype` | `is` | `assume` | `Type::Property`

# Type::Real

---

**Purpose** Type and property representing real numbers

**Syntax**  
`testtype(obj, Type::Real)`  
`assume(x, Type::Real)`  
`is(ex, Type::Real)`

**Description** `Type::Real` represents real numbers. `Type::Real` is a property, too, which can be used in an `assume` call.

The call `testtype(obj, Type::Real)` checks, whether `obj` is a real number and, if it is, returns `TRUE`, otherwise `FALSE`.

`testtype` only performs a syntactical test identifying MuPAD objects of type `DOM_INT`, `DOM_RAT` and `DOM_FLOAT`. This does not include arithmetical expressions such as `exp(1)`, which are not identified as of type `Type::Real`.

The call `assume(x, Type::Real)` marks the identifier `x` as a real number.

The call `is(ex, Type::Real)` derives, whether the expression `ex` is a real number (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

## Examples

### Example 1

The following numbers are of type `Type::Real`:

```
testtype(2, Type::Real),
testtype(3/4, Type::Real),
testtype(0.123, Type::Real),
testtype(-1, Type::Real),
testtype(-1.02, Type::Real)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

The following expressions are exact representations of real numbers, but syntactically they are not of `Type::Real`:

```
testtype(exp(1), Type::Real),
testtype(PI^2 + 5, Type::Real),
testtype(sin(2), Type::Real)
```

FALSE, FALSE, FALSE

The function `is` performs a semantical, mathematically more useful check:

```
is(exp(1), Type::Real),
is(PI^2 + 5, Type::Real),
is(sin(2), Type::Real)
```

TRUE, TRUE, TRUE

## Example 2

Integers are real numbers:

```
assume(x, Type::Integer):
is(x, Type::Real)
```

TRUE

But real numbers can be integer or not:

```
assume(x, Type::Real):
is(x, Type::Integer)
```

UNKNOWN

# Type::Real

---

The sine of a real number is a real number in the interval  $[-1, 1]$ :

```
getprop(sin(x))
```

```
[-1, 1]
```

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`

## See Also

## MuPAD Functions

`testtype` | `is` | `assume` | `Type::Property`

**Purpose** Type representing relations

**Syntax** `testtype(obj, Type::Relation)`

**Description** With `Type::Relation`, relational expression can be identified. The call `testtype(obj, Type::Relation)` checks, whether `obj` is a relational expression and returns `TRUE`, if it is, otherwise `FALSE`. A relation in MuPAD is an expression of the type "`_equal`", "`_unequal`", "`_less`" and "`_leequal`".

---

**Note** Expressions with the operations `>=` and `>` will be interpreted as expressions with `<=` and `<` by exchanging the operands (see “Example 2” on page 32-105).

---

This type does not represent a property.

## Examples

### Example 1

`x > 3` is a relation, while `TRUE` is not:

```
testtype(x > 3, Type::Relation),
testtype(TRUE, Type::Relation)
```

```
TRUE, FALSE
```

### Example 2

MuPAD always interprets expressions with the operations `>=` and `>` as expressions with `<=` and `<` with the operands exchanged:

```
x > 3;
prog::exptree(x > 3):
```

# Type::Relation

---

```
3 < x
```

```
_less
|
+-- 3
|
-- x
```

The operator is *not* `>`, but `<`, and the operands have been swapped:

```
op(x > 3, 0..2)
```

```
_less, 3, x
```

## Parameters

**obj**

Any MuPAD object

## Return Values

See `testtype`

## See Also

## MuPAD Functions

`testtype`

## Purpose

Property representing a residue class

## Syntax

```
assume(x, (rem, class, <sub_set>))
is(ex, (rem, class, <sub_set>))
testtype(ex, (rem, class, <sub_set>))
```

## Description

`Type::Residue(rem, class)` represents the integers  $n$  for which  $n - rem$  is divisible by `class`.

The call `assume(x, Type::Residue(rem, class))` marks the identifier `x` as an integer divisible by `class` with remainder `rem`.

The call `is(ex, Type::Residue(rem, class))` derives, whether the expression `ex` is an integer divisible by `class` with remainder `rem` (or this property can be derived).

This type represents a property that can be used in `assume` and `is`.

`Type::Even` and `Type::Odd` are objects created by `Type::Residue`.

The call `testtype(obj, Type::Residue(rem, class))` checks, whether `obj` is an integer and is divisible by `class` with remainder `rem`. If the optional argument `sub_set` is given, `testtype` checks additionally `testtype(obj, sub_set)`.

## Examples

### Example 1

`Type::Residue` can be used in `testtype`:

```
testtype(6, Type::Residue(2, 4)),
testtype(13, Type::Residue(1, 20))
```

```
TRUE, FALSE
```

### Example 2

`x` is assumed to be divisible by 3 with remainder 1:

```
assume(x, Type::Residue(1, 3))
```

# Type::Residue

---

Which properties has  $x + 2$  got?

```
getprop(x + 2)
```

```
{3 k | k ∈ ℤ}
```

$x$  is an integer, but it may be odd or not:

```
is(x, Type::Integer), is(x, Type::Odd)
```

```
TRUE, UNKNOWN
```

This example restricts possible values of  $x$  to odd integers:

```
assume(x, Type::Residue(1, 4));
is(x, Type::Odd),
is((-1)^x < 0)
```

```
TRUE, TRUE
```

## Parameters

**x**

An identifier or a mathematical expression containing identifiers

**rem**

Remainder as integer number between 0 and `class - 1`; an integer larger than `class - 1` will be divided by `class` and `rem` gets the remainder of this division

**class**

The divider as positive integer

**sub\_set**

A subset of the integers (e.g., `Type::PosInt`); otherwise `Type::Integer` is used

**ex**

An arithmetical expression

**obj**

Any MuPAD object

**Return Values**

See `assume`, `is` and `testtype`

**See Also**

**MuPAD Functions**

`assume` | `is` | `testtype` | `Type::Even` | `Type::Integer` | `Type::Odd`

# Type::SequenceOf

---

**Purpose** Type representing sequences

**Syntax** `testtype(obj, (obj_type, <min_nr, <max_nr>>))`

**Description** With `Type::SequenceOf`, sequences with specified objects can be identified.

The call `testtype(obj, Type::SequenceOf(obj_type))` checks, whether `obj` is a sequence with elements of the given type `obj_type`. In that case, it `TRUE`, otherwise `FALSE`.

A sequence has the domain type `DOM_EXPR` and the type `"_exprseq"`.

The two optional parameters `min_nr` and `max_nr` determine the minimum and maximum number of arguments of the analysed sequence, respectively. If the numbers are not be given, the number of elements of the sequence will not be checked. If only the minimum is given, the sequence must have at least `min_nr` elements for the test to succeed.

This type does not represent a property.

## Examples

### Example 1

Is the given sequence a sequence of identifiers?

```
testtype((a, b, c, d, e, f), Type::SequenceOf(DOM_IDENT))
```

`TRUE`

Is the given sequence a sequence of at least five real numbers?

```
testtype((0, 0.5, 1, 1.5, 2, 2.5, 3), Type::SequenceOf(Type::Real,
```

`TRUE`

## Parameters

### **obj**

Any MuPAD object

### **obj\_type**

The type of the objects; a type can be an object of the library `Type` or one of the possible return values of `domtype` and `type`

### **min\_nr**

The minimal number of objects as nonnegative integer

### **max\_nr**

The maximal number of objects as nonnegative integer

## Return Values

See `testtype`

## See Also

## MuPAD Functions

`_exprseq` | `testtype` | `Type::ListOf`

# Type::Series

---

**Purpose** Type representing truncated Puiseux, Laurent, and Taylor series expansions

**Syntax**

```
testtype(obj, (Puisseux | Laurent | Taylor))
testtype(obj, (Puisseux | Laurent | Taylor, x))
testtype(obj, (Puisseux | Laurent | Taylor, x = x0))
testtype(obj, (Puisseux | Laurent | Taylor, x, Undirected
| Real | Right | Left))
testtype(obj, (Puisseux | Laurent | Taylor, x = x0,
Undirected | Real | Right | Left))
```

**Description** `Type::Series(Puisseux)`, `Type::Series(Laurent)`, and `Type::Series(Taylor)` represent truncated Puiseux series, Laurent series, and Taylor series, respectively.

The call `testtype(obj, Type::Series(T))` checks, whether `obj` is a truncated series expansion of domain type `Series::Puisseux` and of mathematical type `T`.

The call `testtype(obj, Type::Series(T, x = x0))` checks in addition, whether the series variable is `x` and the expansion point is `x0`. If `x0` is omitted, `x0 = 0` is assumed.

The call `testtype(obj, Type::Series(T, x = x0, dir))` checks in addition, whether the direction of expansion is compatible with the specified direction `dir`. See the help pages of `series` and `Series::Puisseux` for more details about the direction.

See “Example 1” on page 32-113 and “Example 3” on page 32-116.

If `obj` is of domain type `Series::Puisseux`, but not a Puiseux expansion in the mathematical sense, then `testtype(obj, Type::Series(T))` returns `FALSE`. This is the case if the coefficients of `obj` depend on the series variable, or if the type flag of `obj` is 1. See “Example 2” on page 32-114, and the help page of `Series::Puisseux` for more details.

A Laurent series is a Puiseux series with integral exponents. If the expansion point is finite, then a Taylor series is a Puiseux series with nonnegative integral exponents. If the expansion point is `complexInfinity`, then a Taylor series is a Puiseux series with

nonpositive integral exponents. See “Example 1” on page 32-113 and “Example 4” on page 32-117.

For the expansion points `infinity` and `-infinity`, the directions `Left` and `Right`, respectively, are implicitly assumed.

Specifying `x0 = infinity` is equivalent to `x0 = complexInfinity` and `dir = Left`, and similarly `x0 = -infinity` is equivalent to `x0 = complexInfinity` and `dir = Right`.

See “Example 4” on page 32-117.

This type does not represent a property: it cannot be used in `assume` to mark an identifier as a truncated series expansion.

## Examples

### Example 1

The following call returns a Puiseux series:

```
s := series(sin(sqrt(x)), x);
domtype(s);
```

$$\sqrt{x} - \frac{x^{3/2}}{6} + \frac{x^{5/2}}{120} + O(x^{7/2})$$

Series::Puiseux

However, `s` is not a Laurent series:

```
testtype(s, Type::Series(Puiseux)),
testtype(s, Type::Series(Laurent)),
testtype(s, Type::Series(Taylor))
```

TRUE, FALSE, FALSE

A Laurent series that is not a Taylor series:

# Type::Series

---

```
s := series(1/sin(x), x);
domtype(s);
```

$$\frac{1}{x} + \frac{x}{6} + \frac{7x^3}{360} + \mathcal{O}(x^5)$$

Series::Puisseux

```
testtype(s, Type::Series(Puisseux)),
testtype(s, Type::Series(Laurent)),
testtype(s, Type::Series(Taylor))
```

TRUE, TRUE, FALSE

The inverse of **s** is a Taylor series:

```
1/s;
testtype(1/s, Type::Series(Puisseux)),
testtype(1/s, Type::Series(Laurent)),
testtype(1/s, Type::Series(Taylor))
```

$$x - \frac{x^3}{6} + \frac{x^5}{120} + \mathcal{O}(x^7)$$

TRUE, TRUE, TRUE

## Example 2

Type::Series represents only objects of domain type Series::Puisseux:

```
s := 1 + x + 2*x^2 + 0(x^3);
domtype(s), testtype(s, Type::Series(Puisseux));
```

$$x + 2x^2 + 1 + O(x^3)$$

DOM\_EXPR, FALSE

```
s := series(exp(x + 1/x), x = infinity, 3);
domtype(s), testtype(s, Type::Series(Puiseux));
```

$$e^x + \frac{e^x}{x} + \frac{e^x}{2x^2} + O\left(\frac{e^x}{x^3}\right)$$

Series::gseries, FALSE

For objects of domain type `Series::Puiseux`, whose coefficients contain the series variable or whose type flag is 1, the result is FALSE as well:

```
s := series(psi(x), x = infinity);
domtype(s), coeff(s, 0), testtype(s, Type::Series(Puiseux));
```

$$\ln(x) - \frac{1}{2x} - \frac{1}{12x^2} + \frac{1}{120x^4} + O\left(\frac{1}{x^6}\right)$$

Series::Puiseux, ln(x), FALSE

```
s := series(sin(sqrt(-x)), x);
domtype(s), testtype(s, Type::Series(Puiseux));
```

$$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O(x^{7/2})$$

Series::Puisseux, FALSE

### Example 3

By specifying further arguments, you can check for the series variable, the expansion point, and the direction of expansion as well:

```
s := series(sin(sqrt(-x)), x, Left);
testtype(s, Type::Series(Puisseux, y)),
testtype(s, Type::Series(Puisseux, x)),
testtype(s, Type::Series(Puisseux, x = 0)),
testtype(s, Type::Series(Puisseux, x = 2));
```

$$-\sqrt{x}i - \frac{x^{3/2}i}{6} - \frac{x^{5/2}i}{120} + O(x^{7/2})$$

FALSE, TRUE, TRUE, FALSE

```
Series::Puisseux::direction(s),
testtype(s, Type::Series(Puisseux, x, Undirected)),
testtype(s, Type::Series(Puisseux, x, Real)),
testtype(s, Type::Series(Puisseux, x, Right)),
testtype(s, Type::Series(Puisseux, x, Left));
```

Left, FALSE, FALSE, FALSE, TRUE

```
s := series(x^5/(x - 2), x = 2, 3);
testtype(s, Type::Series(Laurent, x)),
testtype(s, Type::Series(Laurent, x = 2)),
testtype(s, Type::Series(Laurent, x = 3));
```

$$\frac{32}{x-2} + 80 + 80(x-2) + O((x-2)^2)$$

FALSE, TRUE, FALSE

If you specify a direction, `testtype` checks whether it is compatible with the direction of the series:

```
Series::Puisseux::direction(s),
testtype(s, Type::Series(Puisseux, x = 2, Undirected)),
testtype(s, Type::Series(Puisseux, x = 2, Real)),
testtype(s, Type::Series(Puisseux, x = 2, Right)),
testtype(s, Type::Series(Puisseux, x = 2, Left));
```

Undirected, TRUE, TRUE, TRUE, TRUE

#### Example 4

The following example is a Laurent series around infinity, but not a Taylor series:

```
s := series(z*exp(1/z), z = infinity);
testtype(s, Type::Series(Puisseux)),
testtype(s, Type::Series(Laurent)),
testtype(s, Type::Series(Taylor))
```

$$z + 1 + \frac{1}{2z} + \frac{1}{6z^2} + \frac{1}{24z^3} + \frac{1}{120z^4} + O\left(\frac{1}{z^5}\right)$$

TRUE, TRUE, FALSE

# Type::Series

---

The expansion point is `infinity`, or equivalently, `complexInfinity` from the left:

```
Series::Puisseux::point(s), Series::Puisseux::direction(s);
testtype(s, Type::Series(Laurent, z)),
testtype(s, Type::Series(Laurent, z = 0)),
testtype(s, Type::Series(Laurent, z = infinity)),
testtype(s, Type::Series(Laurent, z = -infinity)),
testtype(s, Type::Series(Laurent, z = complexInfinity));
```

`complexInfinity, Left`

`FALSE, FALSE, TRUE, FALSE, TRUE`

```
testtype(s, Type::Series(Laurent, z = complexInfinity, Undirected))
testtype(s, Type::Series(Laurent, z = complexInfinity, Real)),
testtype(s, Type::Series(Laurent, z = complexInfinity, Right)),
testtype(s, Type::Series(Laurent, z = complexInfinity, Left));
```

`FALSE, FALSE, FALSE, TRUE`

Mathematically, the expression is even an undirected expansion around `complexInfinity`:

```
s := series(z*exp(1/z), z = complexInfinity);
Series::Puisseux::point(s), Series::Puisseux::direction(s);
```

$$z + 1 + \frac{1}{2z} + \frac{1}{6z^2} + \frac{1}{24z^3} + \frac{1}{120z^4} + O\left(\frac{1}{z^5}\right)$$

`complexInfinity, Undirected`

```
testtype(s, Type::Series(Laurent, z)),
testtype(s, Type::Series(Laurent, z = infinity)),
testtype(s, Type::Series(Laurent, z = -infinity)),
testtype(s, Type::Series(Laurent, z = complexInfinity));
```

FALSE, TRUE, TRUE, TRUE

```
testtype(s, Type::Series(Laurent, z = complexInfinity, Undirected)),
testtype(s, Type::Series(Laurent, z = complexInfinity, Real)),
testtype(s, Type::Series(Laurent, z = complexInfinity, Right)),
testtype(s, Type::Series(Laurent, z = complexInfinity, Left));
```

TRUE, TRUE, TRUE, TRUE

## Parameters

### **obj**

Any MuPAD object

### **x**

The series variable: an identifier

### **x0**

The expansion point: an arithmetical expression

## Options

### **Laurent, Puiseux, Taylor**

The type of series

### **Left, Real, Right, Undirected**

The direction of the expansion

## Return Values

See `testtype`

# Type::Series

---

## See Also

### MuPAD Functions

[series](#) | [Series::Puisseux](#) | [testtype](#) | [Type::PolyExpr](#) |  
[Type::PolyOf](#)

**Purpose** Type representing sets

**Syntax** `testtype(obj, (obj_type, <min_nr, <max_nr>>))`

**Description** `Type::SetOf(obj_type)` describes sets of elements of type `obj_type`.

The call `testtype(obj, Type::SetOf(obj_type))` checks, whether `obj` is a set with elements of the given type `obj_type`. If it is, the function returns `TRUE`, otherwise `FALSE`.

A set has the domain type `DOM_SET`.

The two optional parameters `min_nr` and `max_nr` determine the minimum and maximum number of elements in the analysed set. If the numbers are not be given, the number of elements in the set will not be checked. If only the minimum is given, the set must contain at least `min_nr` elements for the test to succeed.

This type does not represent a property.

## Examples

### Example 1

Is the given set a set of identifiers?

```
testtype({a, b, c, d, e, f}, Type::SetOf(DOM_IDENT))
```

`TRUE`

Is the given set a set of at least five real numbers?

```
testtype({0, 0.5, 1, 1.5, 2, 2.5, 3}, Type::SetOf(Type::Real, 5))
```

`TRUE`

### Example 2

`testtype` is used to select sets with exactly two identifiers:

# Type::SetOf

---

```
S := {{a}, {a, b}, {d, 1}, {0, d}, {e}, {d, e}}:
select(S, testtype, Type::SetOf(DOM_IDENT, 2, 2))
```

```
{{d, e}, {a, b}}
```

## Parameters

### **obj**

Any MuPAD object

### **obj\_type**

The type of the objects; a type can be an object of the library `Type` or one of the possible return values of `domtype` and `type`

### **min\_nr**

The minimal number of objects as nonnegative integer

### **max\_nr**

The maximal number of objects as nonnegative integer

## Return Values

See `testtype`

## See Also

## MuPAD Domains

`DOM_SET`

## MuPAD Functions

`testtype` | `Type::ListOf` | `Type::Union`

<b>Purpose</b>	Type representing set-theoretic expressions
<b>Syntax</b>	<code>testtype(obj, Type::Set)</code>
<b>Description</b>	<p>Type::Set comprises all expressions in which the operators are set-theoretic operations</p> <p>A set-theoretic expression is defined to be any of the following: a set constant, an identifier, an unevaluated call to a set-valued function, or the composition of set-theoretic expressions by the operator union, intersect, or minus.</p> <p>The following objects are set constants: finite sets of type DOM_SET, intervals, the universe, and every object that belongs to a domain of category Cat::Set.</p> <p>The following functions are set-valued: solve, discount, RootOf, and solvelib::Union.</p> <p>The union, intersection, or difference of objects is not a set-theoretic expression unless each of the objects is. See “Example 2” on page 32-123.</p>

## Examples

### Example 1

Sets are set-theoretic expressions.

```
testtype({3}, Type::Set)
```

```
TRUE
```

### Example 2

Unions, intersections, and differences are set-theoretic expressions if and only if all operands are.

```
testtype(a union {4}, Type::Set)
```

# Type::Set

---

```
TRUE
```

```
testtype(a+1 union {4}, Type::Set)
```

```
FALSE
```

## Example 3

If the call to a set-valued function as `solve` returns unevaluated, then the result is a set-theoretic expression.

```
solve(x^2 = sin(x + 1), x)
```

```
solve($x^2 - \sin(x + 1) = 0$, x)
```

```
testtype(%, Type::Set)
```

```
TRUE
```

## Parameters

**obj**

Any MuPAD object

## Return Values

See `testtype`

## See Also

## MuPAD Functions

`testtype`

**Purpose** Type representing exactly one object

**Syntax** `testtype(obj, (t_obj))`

**Description** `testtype(x, Type::Singleton(y))` is equivalent to `bool(x = y)`.  
The call `testtype(obj, Type::Singleton(t_obj))` is equivalent to `bool(x = y)`, but the latter is faster.  
`Type::Singleton` can be used to create combined types, especially in conjunction with `Type::Union`, `Type::Equation` and other types expecting type information for subexpressions (see “Example 2” on page 32-125).  
This type does not represent a property.

## Examples **Example 1**

Check, if x is really x:

```
testtype(x, Type::Singleton(x))
```

```
TRUE
```

But the next call does the same:

```
bool(x = x)
```

```
TRUE
```

## **Example 2**

`Type::Singleton` exists to create special testing expressions:

```
T := Type::Union(Type::Singleton(hold(All)), Type::Constant):
```

# Type::Singleton

---

With the type T the option All and any constant can be identified with one call of testtype:

```
testtype(4, T), testtype(hold(All), T), testtype(x, T)
```

```
TRUE, TRUE, FALSE
```

But (e.g., in procedures) the following example works faster:

```
test := X -> testtype(X, Type::Constant) or bool(X = hold(All)):
test(4), test(hold(All)), test(x)
```

```
TRUE, TRUE, FALSE
```

One way to test a list of options for syntactical correctness is the following:

```
T := Type::Union(
 // Name = "..."
 Type::Equation(Type::Singleton(hold(Name)), DOM_STRING),
 // Mode = n, n in {1, 2, 3}
 Type::Equation(Type::Singleton(hold(Mode)),
 Type::Interval([1,3], Type::Integer)),
 // Quiet
 Type::Singleton(hold(Quiet))
):
```

```
testtype((Name = "abcde", Quiet), Type::SequenceOf(T))
```

```
TRUE
```

We only allow the values 1, 2, and 3 for Mode, however:

```
testtype((Quiet, Mode = 0), Type::SequenceOf(T))
```

```
FALSE
```

Obviously, it would be a good idea to tell the user which options we could not grok:

```
error("Unknown option(s): ".expr2text(
 select((Quiet, Mode = 0),
 not testtype, Type::SequenceOf(T))))
```

```
Error: Unknown option(s): Mode = 0
```

```
delete T, test:
```

## Parameters

**obj**

Any MuPAD object

**t\_obj**

Any object to identify

## Return Values

See `testtype`

## See Also

## MuPAD Functions

`_equal` | `bool` | `testtype` | `Type::Union`

# Type::TableOfEntry

---

**Purpose** Type representing tables with specified entries

**Syntax** `testtype(obj, (obj_type))`

**Description** `Type::TableOfEntry(obj_type)` describes tables with *entries* of type `obj_type`.

The call `testtype(obj, Type::TableOfEntry(obj_type))` checks, whether `obj` is a table and all entries of this table are of the type `obj_type`. If both conditions are met, the call returns `TRUE`, otherwise `FALSE`.

The entries of a table are the right hand sides of the operands of a table.

This type does not represent a property.

## Examples

### Example 1

The following table uses identifiers as keys and integers as entries:

```
T := table(a = 1, b = 2, c = 3, d = 4):
testtype(T, Type::TableOfEntry(DOM_INT))
```

`TRUE`

`Type::TableOfEntry` only checks the type of the entries, not the keys:

```
T := table(a = 1, b = 2, c = 3, d = 4):
testtype(T, Type::TableOfEntry(DOM_IDENT))
```

`FALSE`

```
delete T:
```

**Parameters** `obj`

Any MuPAD object

## **obj\_type**

The type of the entries; can be an object of the library Type or one of the possible return values of domtype and type

## **Return Values**

See testtype

## **See Also**

## **MuPAD Functions**

testtype | table | Type::TableOfIndex

# Type::TableOfIndex

---

**Purpose** Type representing tables with specified indices

**Syntax** `testtype(obj, (obj_type))`

**Description** `Type::TableOfIndex(obj_type)` represents tables with *indices* (keys) of type `obj_type`.

The call `testtype(obj, Type::TableOfIndex(obj_type))` checks, whether `obj` is a table and all indices (keys) are of the type `obj_type`. If both conditions are met, the call returns `TRUE`, otherwise `FALSE`.

The indices of a table are the left hand sides of the operands of a table.

This type does not represent a property.

## Examples

### Example 1

The following table uses identifiers as keys and integers as values:

```
T := table(a = 1, b = 2, c = 3, d = 4):
testtype(T, Type::TableOfIndex(DOM_IDENT))
```

`TRUE`

`Type::TableOfIndex` only checks the types of the keys of the table, so the following call returns `FALSE`:

```
T := table(a = 1, b = 2, c = 3, d = 4):
testtype(T, Type::TableOfIndex(DOM_INT))
```

`FALSE`

```
delete T:
```

**Parameters** `obj`

Any MuPAD object

## **obj\_type**

The type of the indices; can be an object of the library Type or one of the possible return values of domtype and type

## **Return Values**

See testtype

## **See Also**

## **MuPAD Functions**

testtype | table | Type::TableOfEntry

# Type::TableOf

---

**Purpose** Type representing tables

**Syntax** `testtype(obj, (<indices_type, <entries_type>>))`

**Description** `Type::TableOf` represents tables; the types of the *indices* and of the *entries* can be specified.

The call `testtype(obj, Type::TableOf(indices_type, entries_type))` checks, whether `obj` is a table with indices of type `indices_type` and entries of type `entries_type`.

The *indices* (resp. the *entries*) of a table are the left (resp. right) hand sides of the operands of a table.

`indices_type` and `entries_type` default to `Type::AnyType`

This type does not represent a property.

## Examples

### Example 1

We test if the following objects are tables:

```
testtype(x, Type::TableOf());
testtype(table(), Type::TableOf())
```

FALSE

TRUE

We test if the following objects are tables with integer indexes:

```
testtype(table(a = 1), Type::TableOf(Type::Integer));
testtype(table(1 = 2), Type::TableOf(Type::Integer))
```

FALSE

TRUE

We test if the following objects are tables with integer entries:

```
testtype(table(a = a), Type::TableOf(Type::AnyType, Type::Integer))
testtype(table(a = 2), Type::TableOf(Type::AnyType, Type::Integer))
```

FALSE

TRUE

We test if the following objects are tables with integer indexes and entries:

```
testtype(table(a = a), Type::TableOf(Type::Integer, Type::Integer))
testtype(table(1 = 2), Type::TableOf(Type::Integer, Type::Integer))
```

FALSE

TRUE

## Example 2

Test if the following table uses identifiers as indexes:

```
T := table(a = 1, b = 2, c = 3, d = 4):
testtype(T, Type::TableOf(DOM_IDENT))
```

TRUE

Test if the following table uses integers as indexes:

# Type::TableOf

---

```
T := table(a = 1, b = 2, c = 3, d = 4):
testtype(T, Type::TableOf(DOM_INT))
```

FALSE

```
delete T:
```

### Example 3

The following table uses identifiers as keys and integers as entries:

```
T := table(a = 1, b = 2, c = 3, d = 4):
testtype(T, Type::TableOf(Type::AnyType, DOM_INT))
```

TRUE

Type::TableOf only checks the type of the entries, not the keys:

```
T := table(a = 1, b = 2, c = 3, d = 4):
testtype(T, Type::TableOf(Type::AnyType, DOM_IDENT))
```

FALSE

```
delete T:
```

### Parameters

#### **obj**

Any MuPAD object

#### **indices\_type**

The type of the indices. It can be an object of the library Type or one of the possible return values of domtype and type

#### **entries\_type**

The type of the entries.

## **Return Values**

See `testtype`

## **See Also**

## **MuPAD Functions**

`testtype` | `table` | `Type::TableOfIndex` | `Type::TableOfEntry`

# Type::Union

---

<b>Purpose</b>	Type representing several types as one type object
<b>Syntax</b>	<code>testtype(obj, (obj_types, ))</code>
<b>Description</b>	<p><code>Type::Union ( type1 , type2 , )</code> represents all objects having at least one of the types <code>type1, type2, ...</code></p> <p>The call <code>testtype(obj, Type::Union( obj_types , ))</code> checks, whether <code>obj</code> has the type of at least one of the given types <code>obj_types, ...</code>. If such a type is found, the call returns <code>TRUE</code>, otherwise <code>FALSE</code>.</p> <p>The call <code>testtype(Type::Union( obj , obj_types , ))</code> is thus equivalent to the call <code>_lazy_or(map(obj_types, x -&gt; testtype(obj, x)))</code>, testing <code>obj</code> against all types in turn until one is found which matches.</p> <p><code>obj_types, ...</code> must be a (nonempty) sequence of types (see <code>testtype</code>).</p> <p>This type does not represent a property.</p>

## Examples

### Example 1

Check, whether the given object is a positive or negative integer:

```
testtype(2, Type::Union(Type::PosInt, Type::NegInt))
```

```
TRUE
```

`x` however, is neither a positive nor a negative number:

```
testtype(x, Type::Union(Type::Positive, Type::Negative))
```

```
FALSE
```

### Example 2

`testtype` is used to select positive and negative integers:

```
SET:= {-2, -1.5, -1, -0.5, 0, 0.5, 1, 1.5, 2}:
select(SET, testtype, Type::Union(Type::PosInt, Type::NegInt))
```

```
{-2, -1, 1, 2}
```

```
delete SET:
```

## Parameters

### **obj**

Any MuPAD object

### **obj\_types**

A sequence of types; a type can be an object of the library Type or one of the possible return values of domtype and type

## Return Values

See testtype

## MuPAD Functions

testtype

# Type::Unknown

---

**Purpose** Type representing variables

**Syntax** `testtype(obj, Type::Unknown)`

**Description** `Type::Unknown` represents identifiers and indexed identifiers.

The call `testtype(obj, Type::Unknown)` checks, whether `obj` is an identifier or an indexed identifier with an integer index. If it is, the call returns `TRUE`, otherwise `FALSE`.

An identifier has the domain type `DOM_IDENT`. An indexed identifier is an expression with `type_index` and two operands, the first of which is an identifier and the second one is an integer. A local variable is not of type `Type::Unknown`.

This type does not represent a property.

## Examples

### Example 1

`Type::Unknown` accepts identifiers:

```
testtype(x, Type::Unknown)
```

```
TRUE
```

`x[0]` is an indexed identifier accepted by `Type::Unknown`:

```
testtype(x[0], Type::Unknown)
```

```
TRUE
```

The index must be an integer:

```
testtype(x[-1], Type::Unknown),
testtype(x[1.0], Type::Unknown)
```

TRUE, FALSE

**Parameters**    **obj**  
                  Any MuPAD object

**Return Values**    See testtype

# Type::Zero

---

**Purpose** Type and property representing zero

**Syntax**  
`testtype(obj, Type::Zero)`  
`assume(x, Type::Zero)`  
`is(ex, Type::Zero)`

**Description**  
`testtype(obj, Type::Zero )` is equivalent to `iszero(obj)`.  
`Type::Zero` is a property, too, which can be used in an `assume` call.  
The call `testtype(obj, Type::Zero)` is equivalent to `iszero(obj)`, which performs a syntactical test if `obj` is zero. If it is, the call returns `TRUE`, otherwise, `FALSE` is returned.  
The call `assume(x, Type::Zero)` marks the identifier `x` as zero.  
The call `is(ex, Type::Zero)` derives, whether the expression `ex` is zero (or this property can be derived).  
This type represents a property that can be used in `assume` and `is`.  
The call `assume(x = 0)` has the same meaning as `assume(x, Type::Zero)`.

## Examples

### Example 1

`testtype` determines the syntactical equality to zero:

```
testtype(0.0, Type::Zero)
```

```
TRUE
```

```
testtype(x, Type::Zero)
```

```
FALSE
```

### Example 2

`Type::Zero` can be used within `assume` and `is`:

```
is(x, Type::Zero)
```

```
UNKNOWN
```

Assumption that x is zero:

```
assume(x, Type::Zero):
is(x^2, Type::Zero)
```

```
TRUE
```

The next example shows the difference between `testtype` and `is`:

```
is(x, Type::Zero), testtype(x, Type::Zero)
```

```
TRUE, FALSE
```

Now the property of x is removed:

```
delete x:
is(x, Type::Zero), testtype(x, Type::Zero)
```

```
UNKNOWN, FALSE
```

A positive number cannot be zero:

```
assume(x > 0):
is(x, Type::Zero), testtype(x, Type::Zero)
```

```
FALSE, FALSE
```

# Type::Zero

---

But in the next example  $x$  could be zero:

```
assume(x >= 0):
is(x, Type::Zero), testtype(x, Type::Zero)
```

```
UNKNOWN, FALSE
```

```
delete x:
```

## Parameters

**obj**

Any MuPAD object

**x**

An identifier or a mathematical expression containing identifiers

**ex**

An arithmetical expression

## Return Values

See `testtype`, `assume` and `is`
