If you do not specify indeterminates (the variables for which you want to solve an equation), the solver uses the set of all indeterminates that it can find in that equation:

```
solve(x^2 = 3)
```

```
 $\{[x = \sqrt{3}], [x = -\sqrt{3}]\}$
```

The solver does not regard operators and indices as indeterminates. Therefore, the solver does not treat  $f$  and  $y$  as indeterminates in the following equation:

```
solve(f(x[y]) = 7)
```

```
solve([f(xy) = 7], [xy])
```

### Example 13

If you set an assumption on the variable for which you want to solve an equation, the solver returns only the results compatible with that assumption. For example, assume that  $x$  represents a real positive number. Then, solve the following equation:

```
assume(x, Type::Positive): solve(x^4 = 1, x)
```

```
{1}
```

Without that assumption, the solver returns all complex solutions:

```
unassume(x): solve(x^4 = 1, x)
```

```
{-1, 1, -i, i}
```

### Example 14

To obtain the multiplicities of the roots of a polynomial, use the `Multiple` option. For example, the polynomial  $x^3 + 2x^2 + x$  has two roots. The multiplicity of  $x = -1$  is 2. The multiplicity of  $x = 0$  is 1:

```
solve(x^3 + 2*x^2 + x, x, Multiple)
```

```
{[-1, 2], [0, 1]}
```

### Example 15

Suppose, you want to solve the following system of equations for two variables,  $x$  and  $y$ . Suppose, you want to avoid backward substitutions while solving this system. To disable backward substitutions, use the option `BackSubstitution = FALSE`. Specify the list of variables so that  $x$  appears to the right of  $y$ . Now, the solution for the variable  $y$  can contain the variable  $x$ :

# solve

```
solve({x^2 + y = 1, x - y = 2}, [y, x], BackSubstitution = FALSE)
```

$$\left\{ \left[ y = x - 2, x = -\frac{\sqrt{13}}{2} - \frac{1}{2} \right], \left[ y = x - 2, x = \frac{\sqrt{13}}{2} - \frac{1}{2} \right] \right\}$$

```
solve({x^2 + y = 1, x - y = 2}, {x, y})
```

$$\left\{ \left[ x = -\frac{\sqrt{13}}{2} - \frac{1}{2}, y = -\frac{\sqrt{13}}{2} - \frac{5}{2} \right], \left[ x = \frac{\sqrt{13}}{2} - \frac{1}{2}, y = \frac{\sqrt{13}}{2} - \frac{5}{2} \right] \right\}$$

If MuPAD cannot express the result as a set of lists, then `BackSubstitution` has no effect:

```
solve({x^2 + y = 1, x - y = 2}, [y, x],
BackSubstitution = FALSE, MaxDegree = 1)
```

$$\left( \frac{y}{x} \right) \in \left\{ \left( \frac{x-2}{z_1} \right) \mid z_1 \in \text{RootOf}(z^2 + z - 3, z) \right\}$$

## Example 16

If the input contains floating-point numbers, MuPAD uses the symbolic solver `solve`, and then calls the `float` function for the obtained solution:

```
solve(x^3 + 3.0*x + 1, x)
```

$$\{-0.3221853546, 0.1610926773 + 1.75438096 i, 0.1610926773 - 1.75438096 i\}$$

If the symbolic solver fails to solve such equation or system, MuPAD calls the numeric solver `numeric::solve`:

```
solve({sin(x) + 1/2*cos(sqrt(2)*y) = 1, cos(x) + sin(y) = 0.1}, {x,
```

```
{[x = 0.7780082473, y = - 0.6589827125]}
```

The numeric solver can return an incomplete set of solutions. For details, see the `numeric::solve` help page.

### Example 17

If a numerator contains a factored polynomial with the multiplicities greater than 1, the solutions might give zeros in a denominator:

```
solve((x - 1)^2/(x - 1) = 0, x)
```

```
{1}
```

To eliminate these solutions, expand a numerator:

```
f := expand((x - 1)^2): solve(f/(x - 1) = 0, x)
```

```
∅
```

### Example 18

You can use the `solve` function to solve Diophantine equations. For example, solve the following linear Diophantine equation:

```
S := solve(30*x + 56*y = 2, [x, y], Domain = Z_)
```

$$\begin{pmatrix} x \\ y \end{pmatrix} \in \left\{ \begin{pmatrix} -28k - 13 \\ 15k + 7 \end{pmatrix} \mid k \in \mathbb{Z} \right\}$$

### Example 19

You can use the `solve` function to solve equation given in the form of memberships. For example, solve the following equation:

```
solve(x^2 in Z_, x)
```

$$\{\sqrt{k} \mid k \in \mathbb{Z}\} \cup \{-\sqrt{k} \mid k \in \mathbb{Z}\}$$

## Example 20

You can solve an equation with symbolic parameters, thus finding its general solution. Then you can evaluate the solution for any particular values of parameters or plot the solution with respect to the parameter values.

Solve this equation:

```
S := solve(x^5 + a = 1, x, Real)
```

$$\{-|a - 1|^{1/5} \operatorname{sign}(a - 1)\}$$

Plot the result for the values  $-10 < a < 10$ :

```
plot(S, a = -10..10)
```

Evaluate the result for  $a = 5$  using the operator `|` or its functional form `evalAt`:

```
S | a = 5
```

```
{ -41/5 }
```

Approximate the result with a floating-point value using `float`:

```
float(%)
```

```
{ -1.319507911 }
```

**Parameters**    `eq`

A single equation or an inequality of type `"_equal"`, `"_less"`, `"_leequal"`, or `"_unequal"`, or an equation in the form of membership (`_in`). Alternatively, any Boolean expression composed of equations or inequalities by the operators `"_and"`, `"_or"`, and `"_not"`. Also, the solver accepts an arithmetical expression and regards such expression as an equation without the right side. (Internally, the solver assumes that the right side is equal to 0.)

**x**

The indeterminate for which you solve an equation, an inequality of a system: an identifier or an indexed identifier

**a, b**

Arithmetical expressions

**vars**

A nonempty set or list of indeterminates for which you solve an equation, an inequality, or a system

**eqs**

A set, list, array, or table of equations, inequalities, arithmetical expressions, or any combination of these objects. The solver regards expressions as equations without the right side. (Internally, the solver assumes that the right side is equal to 0.)

**ODE**

An ordinary differential equation: an object of the `ode` type.

**REC**

A recurrence equation: an object of the `rec` type.

## Options

**MaxDegree**

Option, specified as `MaxDegree = n`

Do not use explicit formulas that involve radicals when solving polynomial equations of degree larger than  $n$ . Here  $n$  is a positive integer. By default,  $n = 2$ .

This option enables and disables the use of explicit formulas for the roots of polynomials. This option does not affect other methods, such as factorization. For polynomial equations, the given maximal degree  $n$  refers to the factors of the polynomials, not to the input polynomial.

When you solve a fifth- or higher-order polynomial equation, the solver might be unable to return the solution explicitly. In general, there are no explicit expressions for the roots of polynomials of degrees higher than 4. Setting the `MaxDegree` option to 4 or a higher value makes no difference.

### **BackSubstitution**

Option, specified as `BackSubstitution = b`

Enable or disable backward substitutions when solving algebraic systems. The value  $b$  must be `TRUE` or `FALSE`. By default,  $b = \text{TRUE}$ .

`BackSubstitution` only affects the results returned as sets of lists.

### **Multiple**

With this option, `solve` returns a set of type `Dom::Multiset`, indicating the multiplicity of polynomial roots. You can use this option only for polynomial equations and polynomial expressions.

Trying to solve the zero polynomial with the `Multiple` option causes an error because MuPAD does not support infinite multisets.

The solver ignores this option for the solutions of the `RootOf` type.

### **VectorFormat**

Return a set of vectors when solving a system of equations for a list of variables.

## PrincipalValue

With this option, the solver returns only one solution. The solver returns this solution as a set with one element. If an equation does not have a solution, the solver returns an empty set.

If the solver cannot find any solution and cannot prove that solutions do not exist, it returns an unresolved symbolic call to `solve`. For example, if the set of solutions is a piecewise function, and there are no elements that belongs to all cases, the solver cannot find a solution.

You also can use this option to solve equations for more than one variable. In this case, the solver returns a set that contains one list. This nested structure represents a solution vector.

## Domain

Option, specified as `Domain = d`

Return the set of all solutions that are elements of `d`. Here `d` must represent a subset of the complex numbers (for example, real numbers `Dom::Real` or integers `Dom::Integer`). Alternatively, `d` can be a domain over which you can factor polynomials (for example, `d` can be a finite field). In this case, you can use this option only when solving polynomial equations. Without this option, the solver returns all solutions in the set of complex numbers.

You can solve an equation or a system over the following domains:

- Subsets of the set of complex numbers `C_`.
- Domains over which you can factor polynomials. You can use these domains only when solving polynomial equations.

A subset of `C_` is any kind of set returned by `solve`. Instead of `C_`, `R_`, `Q_`, and `Z_`, you also can use the corresponding domains of the domains package `Dom::Complex`, `Dom::Real`, `Dom::Rational`, and `Dom::Integer`.

You can overload the solver for your custom domains by adding the `domsolve` method to those domains. If this method does not exist, MuPAD uses the `solve_eq` method to solve equations. The `solve_eq` method does not accept systems as arguments. Finally, if the `solve_eq` method does not exist, MuPAD uses the `solve_poly` method to solve polynomials. The `solve_poly` method accepts only polynomials as first arguments. This method regards any first argument of `solve` that cannot be converted to a polynomial as illegal.

The calling syntax for the `domsolve`, `solve_eq`, and `solve_poly` methods is `domsolve(eq, var, options)`. Here `var` is the same argument as in `solve`, and `options` is a table of options. For the `domsolve` method, `eq` is also the same as in `solve`. For the `solve_eq` method, `eq` must be an arithmetical expression. For `solve_poly`, `eq` must be a polynomial.

You cannot solve equations and systems in more than one variable over domains.

### **IgnoreProperties**

Include solutions that are not consistent with the properties of the variable `x`.

### **Real**

Return only the solutions for which every subexpression of `eq` represents a real number. Also, assume that every subexpression independent of `x` represents a real number.

With this option, the solver assumes that every subexpression independent of `x` represents a real number. In particular, the solver assumes that all symbolic parameters are real. When you use `Real`, the solver returns only the solutions for which every subexpression of `eq` is real. See “Example 7” on page 1-2104.

When you use this option, MuPAD restricts the domain of every function to real numbers. For example, it does not support the logarithms of negative numbers. For all returned solutions `x`, the input is defined over the real numbers.

This option is particularly useful for solving inequalities. Inequalities hold only when both sides represent real values.

This option does not affect some systems.

## IgnoreSpecialCases

If a solution requires case analysis, ignore cases for which one or more parameters in the equation are supposed to be an element of a comparatively small set (for example, with this option, MuPAD can ignore a membership in a fixed finite set or a set of integers  $\mathbb{Z}$ ).

With this option, the solver tries to reduce the number of branches in piecewise objects. MuPAD finds equations and memberships in comparatively small sets. First, MuPAD tries to prove such equations and memberships by using the property mechanism. If the property mechanism proves an equation or a membership is true, MuPAD keeps that statement. Otherwise, MuPAD can replace that statement with the value FALSE. For example, if the property mechanism cannot prove that a denominator is equal to zero, MuPAD regards this denominator as nonzero. This option can significantly reduce the number of piecewise objects in a solution.

## IgnoreAnalyticConstraints

Apply purely algebraic simplifications to expressions and equations. With this option, the solver applies the following rules to the expressions on both sides of an equation:

- $\ln(a) + \ln(b) = \ln(ab)$  for all values of  $a$  and  $b$ . In particular:

$$(a \cdot b)^c = e^{c \ln(a \cdot b)} = e^{c (\ln(a) + \ln(b))} = a^c \cdot b^c \text{ for all values of } a, b, \text{ and } c.$$

- $\ln(a^b) = b \ln(a)$  for all values of  $a$  and  $b$ . In particular:

$$(a^b)^c = e^{b \cdot c \ln(a)} = e^{\ln(a)^{b \cdot c}} = a^{b \cdot c} \text{ for all values of } a, b, \text{ and } c.$$

- If  $f$  and  $g$  are standard mathematical functions and  $f(g(x)) = x$  for all small positive numbers,  $f(g(x)) = x$  is assumed to be valid for all complex  $x$ . In particular:
  - 
  - $\ln(e^x) = x$ .
  - $\arcsin(\sin(x)) = x$ ,  $\arccos(\cos(x)) = x$ ,  $\arctan(\tan(x)) = x$ .
  - $\operatorname{arcsinh}(\sinh(x)) = x$ ,  $\operatorname{arccosh}(\cosh(x)) = x$ ,  $\operatorname{arctanh}(\tanh(x)) = x$ .
  - $W_k(x e^x) = x$  for all values of  $k$ .
- The solver can multiply both sides of an equation by any expression except 0.
- The solutions of polynomial equations must be complete.

Using this option, you can get simpler solutions for equations for which the direct call of the solver returns complicated results. Note that with this option the solver does not verify the correctness and completeness of the result. See “Example 8” on page 1-2105 and “Example 9” on page 1-2106.

### **DontRewriteBySystem**

Do not transform an equation to an equivalent system of equations. This option decreases the running time. With this option, the solver cannot solve some equations.

This option does not allow the solver to replace an equation with the equivalent system of equations. Typically, MuPAD replaces an equation by an equivalent system of equations when solving equations with nested roots. Solving the resulting system can be slow. Use this option to improve performance of the solver. When you use `DontRewriteBySystem`, the solver cannot solve some of the equations that it can solve without this option.

### **NoWarning**

Suppress all warning messages.

# solve

---

## Return Values

If  $x$  is an identifier, `solve(eq, x)` returns an object that represents a mathematical set (see the “Details” section). If  $x$  is a set or a list, or if you omit  $x$ , a call to `solve` returns a set of lists. Each list consists of equations. The left side of each equation is one of the variables for which you solve an equation, an inequality of a system. In this case, `solve` also can return an expression of the form  $x \text{ in } S$ , where  $x$  is a list of variables, and  $S$  is a set of vectors. When you solve a system providing the list of variables and the `VectorFormat` option, the solver returns a set of vectors.

**Purpose**

Sort a list

**Syntax**

`sort(list, <f>)`

**Description**

`sort(list)` returns a sorted copy of the list.

`sort` sorts the list in ascending order.

If you do not specify a procedure `f`, the `sort` command uses the following rules for sorting the lists:

- The command sorts a list of real numbers (`Type::Real`) numerically.
- The command sorts a list of character strings alphabetically.
- The command sorts an outer list containing inner lists with numeric first entries by these numeric first entries. See “Example 4” on page 1-2124.
- In all other cases, the command sorts a list according to the internal order: `sort(list)` is equivalent to `sort(list, sysorder)`. All MuPAD sessions use the same internal order. Between different versions of MuPAD, internal order might change.

When you sort strings, uppercase letters have a preference over lowercase letters. For example, `Z` appears before `abc`.

You can specify a procedure `f` to define the sorting criteria. `sort` calls the procedure `f` for every pair of the entries of the list. `f` must return a Boolean expression that the `bool` command can evaluate to `TRUE` or `FALSE`. If for the pair of entries the procedure `f(x, y)` returns `TRUE`, the sorted list displays `x` to the left of `y`. Otherwise, `x` appears to the right of `y`. The entries of the sorted list `L := sort(list, f)` satisfy `bool(f(L[i], L[j])) = TRUE` for `i < j`.

If two entries of a list are equal by the sorting criteria `f`, the `sort` command can swap these entries. For example, if you sort polynomials by their degrees, the `sort` command can return the polynomials with the same degree in the order different from their order in the input.

sort can be overloaded by kernel domains. For example, use the function `DOM_SET::sort` to sort sets. See “Example 3” on page 1-2123

The average runtime to sort a list containing  $n$  entries is  $O(n\log(n))$ .

## Examples

### Example 1

The sort command sorts real numbers (type `Type::Real`) numerically:

```
sort([4, -1, 2/3, 0.5])
```

```
[-1, 0.5, $\frac{2}{3}$, 4]
```

The sort command sorts strings alphabetically:

```
sort(["chip", "alpha", "Zip"])
```

```
["Zip", "alpha", "chip"]
```

If a list contains other types of objects the sort command sorts a list according to the internal order. The command also applies internal order to sort the lists with mixed types of entries:

```
sort([4, -1, 2/3, 0.5, "alpha"])
```

```
[-1, 0.5, $\frac{2}{3}$, 4, "alpha"]
```

```
sort([4, -1, 2/3, 0.5, I])
```

```
[-1, 0.5, $\frac{2}{3}$, 4, i]
```

## Example 2

Define your own criteria to sort a list. For example, sort the entries by their absolute values:

```
sort([-2, 1, -3, 4], (x, y) -> abs(x) < abs(y))
```

```
[1, -2, -3, 4]
```

## Example 3

When sorting sets, the `sort` command returns a list as a result:

```
sort({3, 12, 5, 30, 6, 43})
```

```
[3, 5, 6, 12, 30, 43]
```

The sorted set is equivalent to the corresponding sorted list:

```
bool(sort({3, 12, 5, 30, 6, 43}) = sort([3, 12, 5, 30, 6, 43]))
```

```
TRUE
```

To sort other data types, implement a `sort-slot` for them:

```
unprotect(DOM_INT):
DOM_INT::sort :=
proc(n)
 local str, i;
 begin
 str := expr2text(n);
 text2expr(_concat(op(sort([str[i] $ i = 1..length(str)]))))
 end;
sort(1703936)
```

# sort

---

```
133679
```

```
delete DOM_INT::sort: protect(DOM_INT):
```

## Example 4

If the list contains lists as entries, and all the inner lists start with numbers, the `sort` command uses these numbers to sort the outer list:

```
sort([[10 - i, i*x^i] $ i = 1..9])
```

```
[[1, 9 x9], [2, 8 x8], [3, 7 x7], [4, 6 x6], [5, 5 x5], [6, 4 x4], [7, 3 x3], [8, 2 x2], [9, x]]
```

Compare the sorted list with the internal order of its entries:

```
sort([[10 - i, i*x^i] $ i = 1..9], sysorder)
```

```
[[8, 2 x2], [7, 3 x3], [6, 4 x4], [5, 5 x5], [4, 6 x6], [3, 7 x7], [2, 8 x8], [1, 9 x9], [9, x]]
```

## Parameters

**list**

A list of arbitrary MuPAD objects

**f**

A procedure defining the ordering

## Return Values

List.

## Overloaded By

list

**Algorithms**

To implement the `sort` function, MuPAD uses a version of the Quicksort algorithm.

**See Also****MuPAD  
Functions**

`prog::sort` | `sysorder`

# split

---

**Purpose** Split an object

**Syntax** `split(object, f, <p1, p2, >)`

**Description** `split(object, f)` splits the object into a list of three objects. The first list entry is an object consisting of those operands of the input object that satisfy a criterion defined by the procedure `f`. The second list entry is built from the operands that violate the criterion. The third list entry is built from the operands for which it is unknown whether the criterion is satisfied.

The function `f` must return a value that can be evaluated to one of the Boolean values `TRUE`, `FALSE`, or `UNKNOWN`. It may either return one of these values directly, or it may return an equation or an inequality that can be simplified to one of these values by the function `bool`.

The function `f` is applied to all operands `x` of the input object via the call `f(x, p1, p2, ...)`. Depending on the result `TRUE`, `FALSE`, or `UNKNOWN`, this operand is inserted into the first, the second, or the third output object, respectively.

The output objects are of the same type as the input object, i.e., a list is split into three lists, a set into three sets, a table into three tables etc.

If the input object is an expression sequence, then neither the input sequence nor the output (a list containing three sequences) are flattened.

Also “atomic” objects such as numbers or identifiers can be passed to `split` as first argument. Such objects are handled like sequences with a single operand.

## Examples **Example 1**

The following command checks which of the integers in the list are prime:

```
split([1, 2, 3, 4, 5, 6, 7, 8, 9, 10], isprime)
```

```
[[2, 3, 5, 7], [1, 4, 6, 8, 9, 10], []]
```

The return value is a list of three lists. The first list contains the prime numbers, the second list contains all other numbers. The third list is empty, because for any number of the input list, it can be decided whether it is prime or not.

### Example 2

With the optional arguments `p1`, `p2`, ... one can use functions that need more than one argument. For example, `contains` is a handy function to be used with `split`. The following call splits a list of sets into those sets that contain `x` and those that do not:

```
split([a, x, b], {a}, {1, x}, contains, x)
```

```
[[{a, b, x}, {1, x}], [{a}], []]
```

The elements of the returned list are of type `DOM_LIST`, because the given expression was a list. If the given expression is of another type, e.g., `DOM_SET`, also the elements of the result are of type `DOM_SET`, too:

```
split({a, x, b}, {a}, {1, x}, contains, x)
```

```
[[{1, x}, {a, b, x}], {{a}}, ∅]
```

### Example 3

We use the function `is` to split an expression sequence into sub-sequences. This function returns `UNKNOWN` if it cannot derive the queried property:

```
split((-2, -1, a, 0, b, 1, 2), is, Type::Positive)
```

# split

---

```
[1, 2, -2, -1, 0, a, b]
```

## Example 4

We split a table of people marked as male or female:

```
people := table("Tom" = "m", "Rita" = "f", "Joe" = "m");
[male, female, dummy] := split(people, has, "m");
```

male

```
┌"Joe"┆"m"┐
└"Tom"┆"m"┘
```

female

```
┌"Rita"┆"f"┐
```

dummy

```
└┘
```

```
delete people, male, female, dummy:
```

## Parameters

### object

A list, a set, a table, an expression sequence, or an expression of type DOM\_EXPR

### f

A procedure returning a Boolean value

### p1, p2, ...

Any MuPAD objects accepted by `f` as additional parameters

**Return Values**

List with three objects of the same type as the input object.

**Overloaded By**

object

**See Also****MuPAD Functions**

`map` | `op` | `select` | `zip`

# sqrt

---

**Purpose** Square root function

**Syntax** `sqrt(z)`

**Description** `sqrt(z)` represents the square root of  $z$ .

$x = \sqrt{z}$  represents the solution of  $x^2 = z$  that has a nonnegative real part. In particular, it represents the positive root for real positive  $z$ . For real negative  $z$ , it represents the complex root with positive imaginary part.

A floating-point result is returned for floating-point arguments. Note that the branch cut is chosen as the negative real semi-axis. The values returned by `sqrt` jump when crossing this cut. Cf. “Example 2” on page 1-2131.

Certain simplifications of the argument may occur. In particular, positive integer factors are extracted from some symbolic products. Cf. “Example 3” on page 1-2132.

Note that  $\sqrt{z}$  cannot be simplified to  $x$  for all complex numbers (e.g.,  $\sqrt{x^2} = -x$  for real  $x < 0$ ). Cf. “Example 4” on page 1-2132.

Mathematically, `sqrt(z)` coincides with  $z^{(1/2)} = \text{\_power}(z, 1/2)$ . However, `sqrt` provides more simplifications than `\_power`. Cf. “Example 5” on page 1-2132.

**Environment Interactions** When called with a floating-point argument, the function is sensitive to the environment variable `DIGITS` which determines the numerical working precision.

**Examples** **Example 1**

We demonstrate some calls with exact and symbolic input data:

```
sqrt(2), sqrt(4), sqrt(36*7), sqrt(127)
```

$$\sqrt{2}, 2, 6\sqrt{7}, \sqrt{127}$$

sqrt(1/4), sqrt(1/2), sqrt(3/4), sqrt(25/36/7), sqrt(4/127)

$$\frac{1}{2}, \frac{\sqrt{2}}{2}, \frac{\sqrt{3}}{2}, \frac{5\sqrt{7}}{42}, \frac{2\sqrt{127}}{127}$$

sqrt(-4), sqrt(-1/2), sqrt(1 + I)

$$2i, \frac{\sqrt{2}i}{2}, \sqrt{1+i}$$

sqrt(x), sqrt(4\*x^(4/7)), sqrt(4\*x/3), sqrt(4\*(x + I))

$$\sqrt{x}, 2x^{2/7}, \sqrt{\frac{4x}{3}}, 2\sqrt{x+i}$$

## Example 2

Floating point values are computed for floating-point arguments:

sqrt(1234.5), sqrt(-1234.5), sqrt(-2.0 + 3.0\*I)

$$35.13545218, 35.13545218i, 0.8959774761 + 1.674149228i$$

A jump occurs when crossing the negative real semi axis:

sqrt(-4.0), sqrt(-4.0 + I/10^100), sqrt(-4.0 - I/10^100)

$$2.0i, 2.5 \cdot 10^{-101} + 2.0i, 2.5 \cdot 10^{-101} - 2.0i$$

### Example 3

The square root of symbolic products involving positive integer factors is simplified:

```
sqrt(20*x*y*z)
```

$$2\sqrt{5}\sqrt{xyz}$$

### Example 4

Square roots of squares are not simplified, unless the argument is real and its sign is known:

```
sqrt(x^2*y^4)
```

$$\sqrt{x^2 y^4}$$

```
assume(x > 0): sqrt(x^2*y^4)
```

$$x\sqrt{y^4}$$

```
assume(x < 0): sqrt(x^2*y^4)
```

$$-x\sqrt{y^4}$$

### Example 5

sqrt provides more simplifications than the `_power` function:

```
sqrt(4*x), (4*x)^(1/2) = _power(4*x, 1/2)
```

$$2\sqrt{x}, \sqrt{4x} = \sqrt{4x}$$

**Parameters****z**

An arithmetical expression

**Return Values**

Arithmetical expression.

**Overloaded By**

z

| <b>Purpose</b>     | Match a pattern in a character string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>      | <code>strmatch(text, pattern, &lt;Index&gt;, &lt;ReturnMatches&gt;, &lt;All&gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p><code>strmatch(text, pattern)</code> checks whether <code>text</code> matches the regular expression <code>pattern</code>.</p> <p><code>strmatch</code> performs regular expression matching on strings, using perl compatible regular expression (via the <code>pcre</code> library, for those interested in technical details).</p> <p>The following list is a rather technical description of the options available; the examples below also contain a mostly complete description and should be consulted as an introduction first.</p> <p>The pattern may contain wildcards forming a perl compatible regular expression. In these expressions, most characters just represent themselves (i.e., an “a” matches an “a”, cf. “Example 1” on page 1-2138), with the following exceptions:</p> <ul style="list-style-type: none"><li>• A dot (.) matches any character, except “\n”. With the <code>s</code> modifier (see below), a dot matches any character at all. Cf. “Example 3” on page 1-2141.</li><li>• A caret (^) matches the beginning of a line and a dollar (\$) matches the end of a line – usually, the beginning and end of the string, but with the <code>m</code> modifier (see below) also after/before a “\n”. Cf. “Example 4” on page 1-2142.</li><li>• A pattern enclosed in parentheses (()) is considered “grouped.” (See below for groups starting with a question mark.) Grouping is important for the following special characters.</li><li>• A vertical bar ( ) between two characters or groups (sub-regexes) denotes alternation: Either one of the alternatives matching is sufficient. Cf. “Example 5” on page 1-2143.</li><li>• A sub-regex followed by a number <i>n</i> enclosed in {} must match exactly <i>n</i> times.<br/>A sub-regex followed by {<i>n</i>,} must match at least <i>n</i> times.</li></ul> |

A sub-regex followed by  $\{n,m\}$  must match at least  $n$  and at most  $m$  times.

In any other context,  $\{$  and  $\}$  are treated as normal characters.

Cf. “Example 7” on page 1-2146.

- Following a sub-regex, a question mark ( $?$ ) works as  $\{0,1\}$ , making the sub-regex optional.

A plus ( $+$ ) in this context works as  $\{1,\}$  and allows an arbitrary positive number of repetitions.

An asterisk after an expression is equivalent to  $\{0,\}$  and allows an arbitrary number of repetitions, including zero.

Cf. “Example 6” on page 1-2145.

- By default,  $\{n,\}$  and its three short hand forms are “greedy” and match as many characters as possible. By following them with another question mark (i.e., “ $a(b[cd])\{2,\}?\text{bd}$ ”, “ $(0|1)^*\text{?12}$ ”), they can be made to “consume” the lowest number of characters consistent with the remainder of the pattern.
- While a backslash (which must be typed in as “ $\backslash$ ”) escapes any special character (including itself), it makes some characters following it special (cf. “Example 10” on page 1-2149):
  - “ $\backslash w$ ” matches a “word” character (alphanumeric or underline).
  - “ $\backslash W$ ” matches a character not matched by “ $\backslash w$ ”.
  - “ $\backslash s$ ” matches a whitespace character (space, tabulator; if the  $s$  modifier is active, also an end-of-line character).
  - “ $\backslash S$ ” matches a character not matched by “ $\backslash s$ ”.
  - “ $\backslash d$ ” matches a digit.
  - “ $\backslash D$ ” matches a non-digit.
  - “ $\backslash b$ ” matches the place between a word character and a non-word character, i.e., the place where a word starts or ends.

- "\\B" is also zero-width, but matches those places where "\\b" does not.
- "\\A" and "\\Z" match at the beginning and end of the string, respectively. "\\Z" ignores a "\\n" at the end of the string; "\\z" behaves like "\\Z", but does not ignore trailing "\\n".
- Characters enclosed between [ and ] form a character class. Cf. “Example 9” on page 1-2148.

A character class starting with ^ is negated and matches all the characters not listed. A ^ at any other place in the character class has no special meaning.

Inside a character class, the special characters noted above do not have any special meaning, but a hyphen (-) which is not the first character does: It creates a range of characters. Which characters this range encompasses, is dependent on the language settings of your operating system (technically speaking: the current locale), but probably every language setting will take "[0-9]" to represent any digit.

To denote character classes mostly independent of language settings, there is named access to POSIX character classes; use

- "[[:digit:]]" to match any digit,
- "[[:alpha:]]" to match characters (the language settings define what makes a character),
- "[[:alnum:]]" to match alpha-numerical characters,
- "[[:word:]]" for alpha-numerical characters plus the underline ( ),
- "[[:punct:]]" to reference punctuation characters such as dot or comma,
- "[[:ascii:]]" for characters in the ASCII range (decimal codes 32 through 127),
- "[[:blank:]]" for “horizontal blanks”, i.e., [ \t],

- "[[:space:]]" for blanks, including end-of-line et al.,
- "[[:cntrl:]]" for “control characters” such as newlines. Note that most control characters cannot be typed in into MuPAD, but can occur in strings read from files.
- "[[:graph:]]" denotes the class of alphanumeric or punctuation characters, i.e., those which have some sort of visual graphical representation.
- "[[:print:]]" is equivalent to "[[:graph:]]", i.e., it adds the space character to the graph class.
- "[[:lower:]]" and "[[:upper:]]" refer to the characters your language settings consider lower- and uppercase letters. (For example, a German system is more likely to know about ä being a lower-case letter than a US system.)
- "[[:xdigit:]]" matches hexadecimal digits, i.e., it is equivalent to [0123456789aAbBcCdDeEfF].

These classes can be combined with one another and with characters inside one character class, so you could, for example, match septadecimal digits with "[[:xdigit:]gG]" .

Posix character classes can be negated with a caret, as in "[[:^digit:]]" to match non-digits. (This is equivalent to "[^[:digit:]]", but "[0[:^digit:]]" to allow any non-digit or zero is more difficult to express otherwise.)

- Groups starting with (? have special meanings:
  - Groups starting with (?: behave like the other groups mentioned above, but do not create output matches for the ReturnMatches option.
  - "(?#text)" is a comment and effectively ignored.
  - Groups starting with (?:X:, where X is one of i, m, s, x, locally apply modifiers:
    - i causes all pattern matching to be case-insensitive (as defined by the system’s locale).

# strmatch

---

- `m` causes a “multiline” match, where `^` and `$` match after/before “`\n`” characters in the string.
- `s` makes the dot match newlines.
- `x` allows perl-style comments in the pattern: Blanks are ignored in most contexts and `#` characters start comments that extend to the end of the line.

These options, if set in an outer group, can be switched off by preceding them with a minus, as in “`(?-i:aB)`”.

- The string “`(?X)`”, where `X` is one of the characters listed above, switches the corresponding setting on up to the end of the enclosing group.
- `(?=` starts a positive zero-width lookahead assertion. This is a zero-width item (and hence does not add something to the output) which matches if its contents do match at the current position. Cf. “Example 12” on page 1-2151.
- `(?!` starts a zero-width negative lookahead assertion. It behaves almost identical to `(?=` except it matches if and only if `(?=` would not.
- `(?<=` starts a positive zero-width look-behind assertion, which is like `(?=` but looking into the other direction. Look-behind assertions must have a fixed width. Cf. “Example 13” on page 1-2152.
- `(?<!` starts a negative zero-width look-behind assertion, which matches if and only if a `(?<=` at the same place would not match.

The library `stringlib` provides further functions for handling strings.

## Examples

### Example 1

Most characters simply match themselves:

```
s := "Hamburg": strmatch(s, "Hamburg")
```

TRUE

strmatch usually matches substrings:

```
strmatch(s, "Ham"), strmatch(s, "burg")
```

TRUE, TRUE

```
strmatch("Ham", "Hamburg")
```

FALSE

delete s:

## Example 2

By default, strmatch only checks for a match and returns a Boolean value:

```
strmatch("aaaba", "a"), strmatch("aaaba", "c")
```

TRUE, FALSE

Using Index, we ask for the first place where a match occurs:

```
strmatch("aaaba", "a", Index),
strmatch("aaaba", "c", Index)
```

[1, 1], FALSE

It is also possible to ask for the substrings matched (this will turn out to be very useful with more complicated regular expressions below):

# strmatch

---

```
strmatch("aaaba", "a", ReturnMatches),
strmatch("aaaba", "c", ReturnMatches)
```

```
"a", FALSE
```

To find more than one match, use All:

```
strmatch("aaaba", "a", All),
strmatch("aaaba", "c", All)
```

```
{"a"}, ∅
```

With an expression that can match more than one specific text, this becomes more useful:

```
strmatch("aaaba", "a.", All)
```

```
{"aa", "ab"}
```

As we've just seen, All implies ReturnMatches, but only if Index has not been given:

```
strmatch("aaaba", "a", All, Index)
```

```
{[1, 1], [2, 2], [3, 3], [5, 5]}
```

Finally, let us combine all three options:

```
strmatch("aaaba", "a", All, Index, ReturnMatches)
```

```
{[1, 1, "a"], [2, 2, "a"], [3, 3, "a"], [5, 5, "a"]}
```

### Example 3

A dot (.) is a placeholder for any character (except "\n"):

```
strmatch("abcd", "a.c"), strmatch("ab\n cd", "ab.")
```

TRUE, FALSE

To denote an actual dot to match, it must be “escaped” with a backslash, which must be typed in as "\\":

```
strmatch("abcd", "a\\.c"),
strmatch("a.cd", "a\\.c")
```

FALSE, TRUE

Remember that a dot, like all special characters, has its special role only in the second argument of strmatch:

```
strmatch("a.c", "abc")
```

FALSE

Using the s modifier, a dot can be made to also match newlines:

```
strmatch("abcd", "(?s)a.c"), strmatch("ab\n cd", "(?s)ab.")
```

TRUE, TRUE

Note that a dot matches only a single character:

```
strmatch("abcd", "a.d"), strmatch("abcd", "a.b")
```

# strmatch

---

FALSE, FALSE

## Example 4

To avoid matching at any place inside a string, use the caret sign (^) and the dollar sign (\$) to mark the beginning and the end of the string, respectively:

```
strmatch("abcd", "a"),
strmatch("abcd", "c"),
strmatch("abcd", "d"),
strmatch("abcd", "abcd")
```

TRUE, TRUE, TRUE, TRUE

```
strmatch("abcd", "^a"),
strmatch("abcd", "^c"),
strmatch("abcd", "^d"),
strmatch("abcd", "^abcd")
```

TRUE, FALSE, FALSE, TRUE

```
strmatch("abcd", "a$"),
strmatch("abcd", "c$"),
strmatch("abcd", "d$"),
strmatch("abcd", "abcd$")
```

FALSE, FALSE, TRUE, TRUE

```
strmatch("abcd", "^a$"),
strmatch("abcd", "^c$"),
strmatch("abcd", "^d$"),
strmatch("abcd", "^abcd$")
```

```
FALSE, FALSE, FALSE, TRUE
```

Using the `m` modifier (cf. “Example 11” on page 1-2150), we can change the meaning from “begin/end of string” to “begin/end of line”:

```
s := "ab\n cd":
strmatch(s, "b$"),
strmatch(s, "(?m)b$")
```

```
FALSE, TRUE
```

### Example 5

Using the vertical bar (`|`), a regular expression can contain alternatives which match if one of them does:

```
strmatch("abcd", "abc|xyz")
```

```
TRUE
```

```
strmatch("abcd", "a|f|j")
```

```
TRUE
```

As the first example above shows, the alternatives encompass everything between vertical bars. To limit the extent of alternatives, use parentheses:

```
strmatch("abcd", "ab(c|xy)z"),
strmatch("abcd", "ab(c|xy)(z|d)")
```

# strmatch

---

```
FALSE, TRUE
```

With the option `ReturnMatches`, we can ask `strmatch` about the substrings matched by each pair of parentheses:

```
strmatch("abcd", "ab(c|xy)(z|d)", ReturnMatches)
```

```
["abcd", "c", "d"]
```

With alternatives, more than one match is possible:

```
strmatch("abracadabra", "a(b|c|d)", All)
```

```
{"ab", "b"}, {"ac", "c"}, {"ad", "d"}
```

To group alternatives without clobbering the output of `strmatch` with `ReturnMatches` or `All`, use `(?:...)`:

```
strmatch("abracadabra", "a(?:b|c|d)", All)
```

```
{"ab", "ac", "ad"}
```

As with a dot, the characters `"|"`, `"("`, and `)"` must be “escaped” to match themselves:

```
strmatch("ab(c)d", "\\((c|d)\\)", ReturnMatches)
```

```
["(c)", "c"]
```

### Example 6

A subexpression (a single character or something in parentheses or in brackets) followed by a question mark is optional:

```
strmatch("abcd", "abc?d"),
strmatch("abd", "abc?d")
```

TRUE, TRUE

A subexpression followed by an asterisk (\*) may be repeated an arbitrary number of times (including zero):

```
strmatch("abcd", "a.*d"),
strmatch("abcd", "a.*c")
```

TRUE, TRUE

A subexpression followed by a plus sign may be repeated an arbitrary number of times, excluding zero:

```
strmatch("abcd", "a.+d"),
strmatch("abcd", "a.+b")
```

TRUE, FALSE

When checking the matched substrings, we note that the asterisk and the plus are “greedy” and return the longest possible substring:

```
strmatch("abracadabra", "a.*a", ReturnMatches)
```

"abracadabra"

# strmatch

---

By appending another question mark, the asterisk and plus can be switched to non-greedy matching:

```
strmatch("abracadabra", "a.*?a", ReturnMatches)
```

```
"abra"
```

Note that this does not return the shortest possible match (which would have been "aca" or "ada"). The call does return the first possible match looking from left to right for the starting position.

## Example 7

Using curly braces, it is possible to request a number of repetitions of a subexpression (a single character or something in parentheses or in brackets):

```
strmatch("abracadabra", "(a(b|c|d)){2}"),
strmatch("abracadabra", "(a(b|c|d)){3}"),
strmatch("abracadabra", "(a(b|c|d)){4}")
```

```
TRUE, TRUE, FALSE
```

These repetitions must be adjacent:

```
strmatch("abracadabra", "(abr){2}")
```

```
FALSE
```

To get non-adjacent repetitions, we can use the ".\*" from above which denotes "anything without newlines":

```
strmatch("abracadabra", "(abr.*){2}")
```

TRUE

### Example 8

By placing a comma inside curly braces, it is possible to indicate a range of possible repetitions. As an example, we present an expression accepting binary numbers with 3 to 5 digits:

```
strmatch("11001", "^((0|1){3,5})$"),
strmatch("1100111", "^((0|1){3,5})$"),
strmatch("11", "^((0|1){3,5})$"),
strmatch("11021", "^((0|1){3,5})$")
```

TRUE, FALSE, FALSE, FALSE

Above, we have used the form  $\{m,n\}$  to denote a range. Leaving out the  $m$  in front of the comma (which is still required) has the same effect as writing  $\{0,n\}$ , while leaving out the  $n$  after the comma effectively removes the upper bound. If that were legal in a regular expression, it would be the same as writing  $\{m,\text{infinity}\}$  – but that’s not possible.

The following regular expression checks whether there is an "a" followed by at least three "b" followed by a "c" somewhere in the input string:

```
strmatch("abcd", "ab{3,}c"),
strmatch("abbbcd", "ab{3,}c"),
strmatch("abcdabbbc", "ab{3,}c")
```

FALSE, TRUE, TRUE

Just like the asterisk and plus sign discussed above, repetitions in general are by default “greedy” and can be switched to non-greedy with a following question mark:

# strmatch

---

```
strmatch("abcdabcdabcd", "a.{2,8}d", ReturnMatches),
strmatch("abcdabcdabcd", "a.{2,8}?d", ReturnMatches)
```

```
"abcdabcd", "abcd"
```

## Example 9

Characters enclosed in brackets ( [ ] ) form a “character class”, which matches any of the characters in the class (similar to an alternation between these characters):

```
strmatch("abc", "ab[cde]"),
strmatch("abd", "ab[cde]"),
strmatch("aba", "ab[cde]")
```

```
TRUE, TRUE, FALSE
```

Inside character classes, special characters are completely different: A dot, asterisk, plus, dollar, parentheses, or curly braces match themselves, but a character class starting with a caret is “negated” and matches any character *not* listed:

```
strmatch("abcd", "[^ab]", All)
```

```
{"c", "d"}
```

A caret not being the first character in a class represents itself:

```
strmatch("x^2", "[*^]2")
```

```
TRUE
```

A dash (-) not being the first character inside a class (apart from the caret) denotes a range of characters. Thus, we can check for a number with at least five digits in the following way:

```
strmatch("x = 123456...", "[0-9]{5,}", ReturnMatches)

"123456"
```

The exact meaning of a range depends on the language settings of your computer. (Technically, on the “collating”, which may be different for the same language on different versions of the same operating system.) For example, “[a-z]” may match only lowercase ASCII characters on one computer, while on the next one it also matches the uppercase characters from A through Y and on the third one includes the uppercase characters from B through Z. For this reason, it is usually a good idea to use the named character classes listed in the details above instead:

```
strmatch("some words", "[[:word:]]+", All)

{"some", "words"}
```

### Example 10

Some character classes are important enough to have received a short form. These short forms have the form “\x” where x is w, W, s, S, d, or D. (The uppercase letters denote the negation of the lowercase letters.):

```
strmatch("abcd", "\\w"),
strmatch("abcd", "\\W"),
strmatch("abcd", "\\d"),
strmatch("abcd", "\\D")

TRUE, FALSE, FALSE, TRUE
```

# strmatch

---

“Negation” here means: A character not matching whatever is negated:

```
strmatch("abcd 1", "\\w"),
strmatch("abcd 1", "\\W"),
strmatch("abcd 1", "\\d"),
strmatch("abcd 1", "\\D")
```

TRUE, TRUE, TRUE, TRUE

In addition to these short forms, there are "\\A" and "\\Z", which behave like "^" and "\$" except they do not react to the m modifier. What is more interesting is the "\\b" (and its negated form, "\\B") expression, which is a zero-width expression matching the place between a “word” and the spaces surrounding it (or the beginning and end of string etc.). We use this to look for words starting with an a:

```
strmatch("abc cbd cba (aa) b", "\\ba\\w*", All)
```

{"aa", "abc"}

In the same way, "\\b" also matches the end of a word:

```
strmatch("abc cbd cba (aa) b", "\\w*a\\b", All)
```

{"aa", "cba"}

## Example 11

As we have seen in the first example, it is possible to change the behaviour of `strmatch` with some modifier flags. The most important example is the `i` modifier that switches on case-insensitive matching. (The precise effects of case-insensitive matching depend on your language settings, for example, most English computers won't regard the German umlauts “ä” and “Ä” as being the same up to case.) To

switch case-insensitive matching on for the whole expression, simply prefix it with "(?i)":

```
strmatch("ABC", "(?i)ab")
```

TRUE

To limit the effect of the modifier to some part of the expression, we wrap the expression inside "(?i:...)":

```
strmatch("ABC", "(?i:a)b"),
strmatch("abc", "(?i:a)b"),
strmatch("Abc", "(?i:a)b")
```

FALSE, TRUE, TRUE

### Example 12

When using the results of `strmatch` with option `ReturnMatches` or `All`, it is often desirable to limit the matches beyond what is returned. Assume, for example, that we want to extract all the “words” used as function symbols (to keep things simple, we mean by this: followed by optional spaces and an opening parenthesis). Just for looking at the result, the following may be sufficient:

```
s := "f(sin (x) + abc + def(x))":
strmatch(s, "\\b\\w+\\s*\\(", All)
```

{"def(", "f(", "sin ("}

To extract the function symbols themselves, we could use another match:

```
map(strmatch(s, "\\b\\w+\\s*\\(", All),
```

# strmatch

---

```
strmatch, "\\w+", ReturnMatches)
```

```
{"def", "f", "sin"}
```

However, there is a simpler way: Regular expressions can contain “zero-width assertions”, which ensure that something does or does not follow, without actually including it or moving the conceptual pointer behind it. The syntax is to wrap the corresponding expression in “(?=...)”:

```
strmatch(s, "\\b\\w+(?=\\s*\\()", All)
```

```
{"def", "f", "sin"}
```

## Example 13

In the same way as in “Example 12” on page 1-2151, regular expressions can also make zero-width assertions with respect to preceding text. (But those must be of fixed width.) As an example, assume we want to extract the amount of money mentioned in the following text:

```
s := "In March 2005, we've spent $1192.23 on light.":
strmatch(s, "(?<=\\$)\\d+(?:\\.\\d\\d)?", All)
```

```
{"1192.23"}
```

## Example 14

To detect where in the input string matches are found, include the option `Index` in the call:

```
strmatch("abc", "b", Index)
```

```
[2, 2]
```

The returned list contains two numbers, the beginning and end of the match. If no match is found, FALSE is returned:

```
strmatch("abc", "d", Index)
```

```
FALSE
```

When combined with ReturnMatches, the indices are followed by the match information in the list:

```
strmatch("abc", "b.", ReturnMatches, Index)
```

```
[2, 3, "bc"]
```

### Example 15

The option All causes the return value to be a set, each entry of which is of the same form as if option All had not been given:

```
strmatch("abc", ".", All),
strmatch("abc", ".", Index, All),
strmatch("abc", ".", ReturnMatches, All)
```

```
{"a", "b", "c"}, {[1, 1], [2, 2], [3, 3]}, {"a", "b", "c"}
```

## Parameters

**text, pattern**

character strings

## Options

**Index**

Return the position of the match found. If the pattern is not found, FALSE is returned. Otherwise, the location of the match is returned as a list of two integers, [i, j] meaning that text[i..j] is the substring matched.

# strmatch

---

## ReturnMatches

Return the substrings matched. If the regular expression contains groups (parenthesized subexpressions, see below), return lists containing the matched substring and the strings matched by the groups, in order of opening parentheses.

## All

By default, `strmatch` returns only the first match. With option `All`, further matches are sought and returned. If `Index` is not given, `All` implies `ReturnMatches`.

## Return Values

Without options, either `TRUE` or `FALSE` is returned. With `Index`, a list of two nonnegative integers or `FALSE` is returned. With option `ReturnMatches`, a string or a list of strings is returned, depending on whether the pattern contains groups. With both `Index` and `ReturnMatches` given, a list starting with the indices of the match, followed by the string or strings of `ReturnMatches`, is returned. With option `All`, a set of elements of the types just described is returned.

## MuPAD Functions

`_concat` | `length` | `substring` | `stringlib::contains` | `stringlib::maskMeta` | `stringlib::pos`

## Purpose

Print into string

## Syntax

```
strprint(<All>, <Unquoted>, <NoNL>, <KeepOrder>,
object1, object2,)
```

## Description

strprint(objects) returns the string print(objects) would display on the screen.

strprint returns a string that contains the output print would have sent to the screen for the same arguments. This string contains '\n' characters if the output would have consisted of multiple lines.

On Windows systems, each \n is preceded by \r, because that is the traditional end-of-line combination since that is the end-of-line combination inherited from CP/M. The examples in this documentation assume a system like UNIX. Also note that with Typesetting activated, \r, \n, \t, and \b will not be displayed in a string.

All options and dependencies on variables are interpreted as described in the documentation of print. Especially, this means PRETTYPRINT affects the output of strprint. Overloading of print is taken into account. See ?print for details.

## Environment Interactions

strprint is sensitive to the environment variables DIGITS, PRETTYPRINT, and TEXTWIDTH, and to the output preferences Pref::floatFormat, Pref::keepOrder, and Pref::trailingZeroes.

## Examples

### Example 1

The string returned by strprint, when printed with option Unquoted, yields the same output as the operands would have in the first place:

```
s := strprint(a*x^2-7):
print(Unquoted, s)
```

```

 2
a x - 7
```

# strprint

---

This can be used to combine multiple outputs:

```
s1 := strprint(a*x^2-7):
s2 := _concat("-" $ TEXTWIDTH)."\n":
s3 := strprint(sin(1/x)):
print(Unquoted, s1.s2.s3)
```

```
 2
a x - 7

sin| / 1 \
 | - |
 | x |
```

In the example above, you can see that the output of `strprint` does not contain the spaces usually used for centering. The output in the first example was centered, because it used only a fraction of the text width, while the string `s1.s2.s3` in the second example spans the whole width of the line and is therefore printed flush left.

## Example 2

`strprint` is useful for constructing pretty-print output of function environments and domains. For example, `conjugate` uses this method for non-typeset output:

```
expose(op(conjugate, 2))
```

```
proc(x)
 local pretty_arg;
begin
 if PRETTYPRINT then
 pretty_arg := strprint(All, op(x));
```

```

if pretty_arg[2] <> pretty_arg[4] then
 FAIL
else
 stdlib::Exposed(("_" $ pretty_arg[3])."\n".pretty_arg[1])
end_if
else
 FAIL
end_if
end_proc

```

First of all, if PRETTYPRINT is FALSE, the procedure returns FAIL, indicating that it doesn't want to do the overloading. This causes standard output. The same result is given in the case of multiline output, which is detected by comparing the second and the fourth element of the return value of strprint. If the operand of the conjugate call, i.e., op(x), renders into one line at the current setting of TEXTWIDTH, stdlib::Exposed is used to encapsulate the string composed of this rendering and a line of "\_" above it. The net result:

```

conjugate(x), conjugate(f(1/x)),
conjugate(f(expand(sin(8*x))))

```

$$\bar{x}, f\left(\frac{1}{x}\right), f(128 \sin(x) \cos(x)^7 - 192 \sin(x) \cos(x)^5 + 80 \sin(x) \cos(x)^3 - 8 \sin(x) \cos(x))$$

Note that the “baselines” of the expressions are intact, since the `b' have not been touched.

### Example 3

For demonstrative purposes, let us write a domain that puts an expression into a box. We make use of the fact that strprint returns strings starting with a newline, of output::fence and of indexed assignment to strings:

```

domain box

```

# strprint

```
print := proc(e)
 local ex, str, w;
 save TEXTWIDTH;
 begin
 if TEXTWIDTH > 15 then
 TEXTWIDTH := TEXTWIDTH - 4;
 end_if;
 ex := extop(e, 1);
 str := strprint(All, ex);
 w := str[5]+4;
 str := output::fence("| ", " |",
 "\n".str[1]."\n",
 str[5], str[6]+1);
 str[1..w] := "+"._concat("-" $w-2)."+";
 str[-w-1..-2] := "+"._concat("-" $w-2)."+";
 str;
 end_proc;

 new := x -> new(dom, x);
end_domain

print(Plain, box(a), box(sin(1/x)))
```

```
+---+ +-----+
| a |, | sin | / 1 \ |
+---+ | \ x / |
 +-----+
```

```
print(Plain, box(box(hold(E=m*c^2))))
```

```
+-----+
| +-----+ |
| | 2 | |
```

```
| | E = m c | |
| +-----+ |
+-----+
```

### Example 4

As a last example, we implement a print-method for matrices over  $\mathbb{Z}_5$ :

```
M5 := Dom::Matrix(Dom::IntegerMod(5))
```

```
Dom::Matrix(Dom::IntegerMod(5))
```

The standard output function simply puts “mod 5” behind every entry, inherited from the output method of `Dom::IntegerMod(5)`:

```
A := M5([[1,2,3,4],[5,6,7,8],[-2,-3,0,1]])
```

```
(1 mod 5 2 mod 5 3 mod 5 4 mod 5
 0 mod 5 1 mod 5 2 mod 5 3 mod 5
 3 mod 5 2 mod 5 0 mod 5 1 mod 5)
```

We now replace this method:

```
M5::print := proc(A)
 local str, h1, w1, h, w, b;
 begin
 [str, h1, w1, h, w, b] := strprint(All, expr(A));
 _concat(str, " " $ w, "[mod 5]");
 end_proc;
```

```
print(A):
```

```
+ - - +
```

# strprint

---

```
| 1, 2, 3, 4 |
| 0, 1, 2, 3 |
| 3, 2, 0, 1 |
+-----+
[mod 5]
```

Alternatively, we can set the [mod 5] right beneath the brackets:

```
M5::print := proc(A)
 local str;
 begin
 str := strprint(expr(A));
 str[-1..-1] := " [mod 5]";
 str
 end_proc;

print(A):
```

```
+-----+
| 1, 2, 3, 4 |
| 0, 1, 2, 3 |
| 3, 2, 0, 1 |
+-----+ [mod 5]
```

## Parameters

**object<sub>1</sub>, object<sub>2</sub>, ...**

Any MuPAD objects

## Options

### All

When the option `All` is given, `strprint` returns additional information on the string generated by printing. More specifically, it returns a list consisting of

- 1** the formatted string,
- 2** the height (in characters) of the first line,
- 3** the width of the first line,
- 4** the height of the complete string,
- 5** the width of the complete string,
- 6** the baseline, counted from top to bottom.

Examples “Example 2” on page 1-2156 and “Example 3” on page 1-2157 contain sample code that makes use of this information.

### Unquoted

Display character strings without quotation marks and with expanded control characters `'\n'`, `'\t'`, and `'\b'`.

### NoNL

Like `Unquoted`, but no newline is put at the end. `PRETTYPRINT` is implicitly set to `FALSE`.

### KeepOrder

Display operands of sums (of type `"_plus"`) always in the internal order.

## Return Values

`DOM_STRING` or a list of a `DOM_STRING` and five integers.

# strprint

---

**Overloaded  
By**

**See Also**

**MuPAD  
Functions**

`doprint` | `expose` | `expr2text` | `fprint` | `funcenv` |  
`output::fence` | `print`

**Purpose**

Substitute into an object

**Syntax**

```
subs(f, old = new, <Unsimpified>)
subs(f, old1 = new1, old2 = new2, , options)
subs(f, [old1 = new1, old2 = new2,], options)
subs(f, {old1 = new1, old2 = new2, }, options)
subs(f, table(old1 = new1, old2 = new2,), options)
subs(f, s1, s2, , options)
```

**Description**

`subs(f, old = new)` searches `f` for operands matching `old`, and replaces `old` with `new`. See “Example 1” on page 1-2164.

The `subs` function returns a modified copy of the object. The function does not change the object itself.

By default, the `subs` function does not evaluate the result of a substitution. To enforce evaluation of all modified subexpressions, use the `EvalChanges` option. Also, you can reevaluate the whole returned result by using the `eval` function. Evaluation of the returned result is slower and less efficient than evaluation of the modified subexpressions. See “Example 3” on page 1-2165 and “Example 4” on page 1-2166.

The call `subs(f, old1 = new1, old2 = new2, ...)` applies the specified substitutions in a sequence from left to right (sequential substitution). This call applies each substitution (except for the first substitution) to the result of the previous substitution. See “Example 5” on page 1-2167.

The call `subs(f, [old1 = new1, old2 = new2, ...])` applies all specified substitutions to the operands of the original input object `f` (parallel substitution). This call does not use the results of any previous substitutions. If you specify multiple substitutions of the same operand, this call computes only the first substitution. Specifying substitutions by lists, sets, or tables invokes parallel substitution. See “Example 6” on page 1-2167.

The call `subs(f, s1, s2, ...)` is a general form of substitution that can combine sequential and parallel substitutions. This call is equivalent to `subs(... subs(subs(f, s1), s2), ...)`. MuPAD

treats each substitution step as a sequential or a parallel substitution depending on the form of the parameters  $s_1, s_2, \dots$ . See “Example 7” on page 1-2169.

`subs` replaces only those operands that you can access via the function `op` (“syntactical substitution”). To apply a more “semantical” substitution, use the `subsex` function. The `subsex` function also identifies and replaces partial sums and products. See “Example 8” on page 1-2169.

You can use `subs` to replace operands of expression sequences. The `subs` function does not flatten such objects. See “Example 9” on page 1-2170.

If you do not specify substitutions, `subs` returns the original expression without modifications. For example, `subs(f)` returns `f`.

## Examples

### Example 1

Use the `subs` function to substitute the operands in the following expressions:

```
subs(a + b*a, a = 4)
```

```
4 b + 4
```

```
subs([a * (b + c), sin(b + c)], b + c = a)
```

```
[a2, sin(a)]
```

### Example 2

When replacing the sine function in an expression, use the `hold` command to prevent the evaluation of the identifier `sin`:

```
subs(sin(x), hold(sin) = cos);
domtype(hold(sin))
```

```
cos(x)
```

```
DOM_IDENT
```

Otherwise, MuPAD replaces `sin` by its value. The function environment (see `funcenv`) defines the value of `sin`:

```
subs(sin(x), sin = cos);
domtype(sin)
```

```
sin(x)
```

```
DOM_FUNC_ENV
```

Inside the expression `sin(x)`, the 0-th operand `sin` is the identifier, not the function environment:

```
domtype(op(sin(x), 0))
```

```
DOM_IDENT
```

### Example 3

The `subs` function evaluates the original expression, performs a substitution, but does not evaluate the modified expression:

```
subs(y^2 + sin(x), x = PI)
```

```
y2 + sin(π)
```

To evaluate the modified subexpression, use the `EvalChanges` option:

# subs

---

```
subs(y^2 + sin(x), x = PI, EvalChanges)
```

$y^2$

Alternatively, use the eval function to evaluate the result returned by subs:

```
S := subs(y^2 + sin(x), x = PI):
eval(S)
```

$y^2$

## Example 4

The subs function with the EvalChanges option returns the same results as the evaluation of the whole expression:

```
eval(subs(sin(x + 3 - PI)*numeric::int(_plus(sin(k/y) $ k = 1..5),
subs(sin(x + 3 - PI)*numeric::int(_plus(sin(k/y) $ k = 1..5), y = 0
```

0

0

The evaluation of the returned result is slower and less efficient than the evaluation of the modified subexpressions:

```
time(eval(subs(sin(x + 3 - PI)*numeric::int(_plus(sin(k/y) $ k = 1..5),
time(subs(sin(x + 3 - PI)*numeric::int(_plus(sin(k/y) $ k = 1..5),
```

12218.75

6265.625

**Example 5**

The following call results in the sequential substitution  $x \rightarrow y \rightarrow z$ :

```
subs(x^3 + y*z, x = y, y = z)
```

$$z^3 + z^2$$
**Example 6**

The subs function lets you use sequential and parallel substitutions. For example, substitute the operand in the following expressions sequentially:

```
subs(a^2 + b^3, a = b, b = a)
```

$$a^3 + a^2$$

```
subs(a^2 + b^3, b = a, a = b)
```

$$b^3 + b^2$$

For the same expression, parallel substitution swaps the identifiers:

```
subs(a^2 + b^3, [a = b, b = a])
```

$$a^3 + b^2$$

# subs

---

In the following call, the substitution of  $y + x$  for  $a$  yields the intermediate result  $y + 2*x$ . From there, the substitution of  $z$  for  $x$  results in  $y + 2 z$ :

```
subs(a + x, a = x + y, x = z)
```

```
y + 2 z
```

Parallel substitution produces a different result. The following call substitutes  $a$  with  $x + y$ . Simultaneously, this call substitutes the operand  $x$  of *the original expression*  $a + x$  with  $z$ :

```
subs(a + x, [a = x + y, x = z])
```

```
x + y + z
```

If you specify the substitutions using a set of a table of equations, the `subs` function also performs a parallel substitution:

```
subs(a + x, {a = x + y, x = z})
```

```
x + y + z
```

```
T := table(): T[a] := x + y: T[x] := z: T
```

```
┌───┬───┐
a | x + y
x | z
```

```
subs(a + x, T)
```

```
x + y + z
```

delete T:

### Example 7

You can combine sequential and parallel substitutions:

```
subs(a + x, {a = x + y, x = z}, x = y)
```

$$2y + z$$

### Example 8

The subs function replaces only those operands that the op function can return. The following expression contains the subexpression  $x + y$  as the operand  $\text{op}(f, [1, 2])$ :

```
f := sin(z*(x + y)): op(f, [1, 2]);
```

$$x + y$$

Consequently, the subs function replaces this subexpression:

```
subs(f, x + y = z)
```

$$\sin(z^2)$$

Syntactically, the following sum does not contain the subexpression  $x + y$ . Therefore, the subs function does not replace it:

```
subs(x + y + z, x + y = z)
```

$$x + y + z$$

# subs

---

In contrast to `subs`, the `subsex` function finds and replaces partial sums and products:

```
subsex(x + y + z, x + y = z)
```

```
2 z
```

```
subs(a*b*c, a*c = 5), subsex(a*b*c, a*c = 5)
```

```
a b c, 5 b
```

```
delete f:
```

## Example 9

You can substitute operands of expression sequences. Enclose sequences in parentheses:

```
subs((a, b, a*b), a = x)
```

```
x, b, b x
```

## Example 10

The `Unsimplified` option suppresses simplification:

```
subs(a + b + 2, a = 1, b = 0, Unsimplified)
```

```
1 + 0 + 2
```

## Example 11

If you try to substitute something in a domain, MuPAD ignores the substitution. For example, define a new domain with the methods "foo" and "bar":

```
mydomain := newDomain("Test"):
mydomain::foo := x -> 4*x:
mydomain::bar := x -> 4*x^2:
```

Now try to replace every number 4 inside the domain with the number 3:

```
mydomain := subs(mydomain, 4 = 3):
```

That substitution does not have any effect:

```
mydomain::foo(x), mydomain::bar(x)
```

$4x, 4x^2$

To substitute objects in a domain method, you must substitute in the individual methods:

```
mydomain::foo := subs(mydomain::foo, 4 = 3):
mydomain::bar := subs(mydomain::bar, 4 = 3):
mydomain::foo(x), mydomain::bar(x)
```

$3x, 3x^2$

```
delete mydomain:
```

## Parameters

**f**

An arbitrary MuPAD object

**old, old<sub>1</sub>, old<sub>2</sub>, ...**

Arbitrary MuPAD objects

**new, new<sub>1</sub>, new<sub>2</sub>, ...**

Arbitrary MuPAD objects

# subs

---

$s_1, s_2, \dots$

Either equations `old = new`, or lists or sets of such equations, or tables whose entries are interpreted as such equations.

## Options

### EvalChanges

After substitution, evaluate all modified subexpressions.

By default, the `subs` function does not evaluate the modified object. The `EvalChanges` option enforces the evaluation of all modified subexpressions. See “Example 3” on page 1-2165 and “Example 4” on page 1-2166.

### Unsimplified

Do not simplify the result of a substitution.

As the last step of a substitution, MuPAD automatically simplifies (but does not evaluate) the modified object. The `Unsimplified` option suppresses the final simplification. See “Example 10” on page 1-2170.

## Return Values

Copy of the input object with replaced operands.

## Overloaded By

`f`

## See Also

## MuPAD Functions

`evalAt` | `extnops` | `extop` | `extsubsop` | `has` | `map` | `match` | `op` | `subsex` | `subsop`

**Purpose** Relation “is a subset of”

**Syntax** `A subset B`  
`_subset(A, B)`  
`not A subset B`  
`_notsubset(A, B)`

**Description** `A subset B` represents the expression  $A \subset B$ .

$A$  is a subset of  $B$  if  $x \in A \Rightarrow x \in B$ .

The function `_notsubset` exists for typesetting purposes. It is returned as the result of negating a `subset` expression. See “Example 4” on page 1-2174.

If called with symbolic arguments (anything but sets), these functions return a symbolic expression of type `_in` or the unevaluated input.

## Examples **Example 1**

When called with two sets, these functions return a Boolean value:

```
{1} subset {1,2,3},
{ } subset {1},
{1} subset {1},
{1} subset { }
```

```
TRUE, TRUE, TRUE, FALSE
```

## **Example 2**

Note: identifiers in sets are not assumed to be place-holders. See `?` for details on syntactic equality.

```
{x} subset {1,2}
```

```
FALSE
```

# subset, \_subset, \_notsubset

---

## Example 3

If one of the arguments is not a set, these functions return an equivalent symbolic expression:

```
{1} subset A, A subset {1}
```

```
 $1 \in A, A \subset \{1\}$
```

## Example 4

For “pretty typesetting”, the negation of subset is implemented in a special function environment:

```
not A subset B
```

```
 $A \not\subset B$
```

```
type(%)
```

```
"_notsubset"
```

### Parameters

**A, B**

MuPAD expressions

### Return Values

TRUE, FALSE, or an expression.

### Overloaded By

A, B

## See Also

## MuPAD Functions

in | intersect | minus | union

# subsex

---

## Purpose

Extended substitution

## Syntax

```
subsex(f, old = new, <Unsimpilified>)
subsex(f, old1 = new1, old2 = new2, , <Unsimpilified>)
subsex(f, [old1 = new1, old2 = new2,], <Unsimpilified>)
subsex(f, {old1 = new1, old2 = new2, }, <Unsimpilified>)
subsex(f, table(old1 = new1, old2 = new2,), <Unsimpilified>)
subsex(f, s1, s2, , <Unsimpilified>)
```

## Description

`subsex(f, old = new)` returns a copy of the object `f` in which all expressions matching `old` are replaced by the value `new`. In contrast to the function `subs`, `subsex` also replaces “incomplete” subexpressions.

`subsex` returns a modified copy of the object, but does not change the object itself.

`subsex(f, old = new)` searches `f` for subexpressions matching `old`. Each such subexpression is replaced by `new`.

In most cases, `subsex` leads to the same result as `subs`. However, in contrast to `subs`, `subsex` allows to replace “incomplete” subexpressions such as `a + b` in a sum `a + b + c`. In general, combinations of the operands of the n-ary “operators” `+`, `*`, and, `_exprseq`, `intersect`, or, `_lazy_and`, `_lazy_or`, and `union` can be replaced. In particular, partial sums and partial products can be replaced. Note that these operations are assumed to be commutative, e.g., `subsex(a*b*c, a*c = new)` does replace the partial product `a*c` by `new`. See “Example 1” on page 1-2177 and “Example 2” on page 1-2178.

`subsex` additionally replaces powers with the same base, if the exponent of the expression is an integer multiple of the replacement power, e.g. like in `subsex(a^4, a^2 = new)`. This rule also matches inverted expressions like in `subsex(1/sqrt(x), sqrt(x)=new)`, which is internally equivalent to `subsex(x^(-1/2), x^(1/2)=new)`. Cf. “Example 3” on page 1-2178.

`subsex` is much slower than `subs`! If `subs` can do the substitution, use `subs` rather than `subsex`.

The call `subsex(f, old1 = new1, old2 = new2, ...)` invokes a “sequential substitution”. See the `subs` help page for details.

The call `subsex(f, [old1 = new1, old2 = new2, ...])` invokes a “parallel substitution”. See the `subs` help page for details.

The call `subsex(f, s1, s2, ...)` describes the most general form of substitution which may combine sequential and parallel substitutions. This call is equivalent to `subsex(... subsex(subsex(f, s1), s2), ...)`. Depending on the form of `s1, s2, ...`, sequential or parallel substitutions are carried out in each step. An example can be found on the `subs` help page.

After substitution, the result is not evaluated. Use the function `eval` to enforce evaluation. Cf. “Example 5” on page 1-2180.

Operands of expression sequences can be replaced by `subsex`. Such objects are not flattened. Cf. “Example 6” on page 1-2181.

The call `subsex(f)` is allowed; it returns `f` without modifications.

## Examples

### Example 1

We demonstrate some simple substitutions; `subsex` finds and replaces partial sums and products:

```
subsex(a + b + c, a + c = x)
```

```
b + x
```

```
subsex(a*b*c, a*c = x)
```

```
b x
```

```
subsex(a * (b + c) + b + c, b + c = a)
```

# subsex

---

$$a^2 + a$$

`subsex(a + b*c*d + b*d, b*d = c);`

$$c^2 + c + a$$

## Example 2

We replace subexpressions inside an expression sequence and a symbolic union of sets:

`subsex((a, b, c, d), (b, d) = w)`

$$a, c, w$$

`subsex(a union b union c, a union b = w)`

$$c \cup w$$

The same can be achieved by using the functional equivalent union of the operator union:

`subsex(_union(a, b, c), _union(a, b) = w)`

$$c \cup w$$

## Example 3

subsex replaces powers with with the same base, if the exponent of the expression is an integer multiple of the replacement power:

`subsex(1/a^4, a^2 = X)`

$$\frac{1}{X^2}$$

This holds even for exponents which are expressions:

```
subsex(1/a^(6*x), a^(2*x) = X)
```

$$\frac{1}{X^3}$$

1/sqrt(x) is internally  $x^{-1/2}$ , so the replacement of sqrt(x) which is internally  $x^{1/2}$  works, too:

```
subsex(1/sqrt(n), sqrt(n) = X)
```

$$\frac{1}{X}$$

#### Example 4

subsex (and also subs) are often useful to convert the output of one command into a form required by the next one. As an example, we compute the Laplace transform of the two-dimensional ODE

$$x'(t) = x(t) + 2 y(t), x(0) = 1$$

$$y'(t) = 5 x(t) + 2 y(t), y(0) = -2$$

and transform the result into a form suitable for calling solve by replacing the unknown Laplace transforms by symbolic names:

```
xfrm1 := laplace(x'(t) = x(t) + 2*y(t), t, s);
```

# subsex

---

```
xfrm2 := laplace(y'(t) = 5*x(t) + 2*y(t), t, s)
```

```
s laplace(x(t), t, s) - x(0) = laplace(x(t), t, s) + 2 laplace(y(t), t, s)
```

```
s laplace(y(t), t, s) - y(0) = 5 laplace(x(t), t, s) + 2 laplace(y(t), t, s)
```

For readability, we give names to both substitutions:

```
sub_x := laplace(x(t),t,s) = X:
```

```
sub_y := laplace(y(t),t,s) = Y:
```

```
Leqn1 := subs(xfrm1, sub_x, sub_y, x(0) = 1);
```

```
Leqn2 := subs(xfrm2, sub_x, sub_y, y(0) = -2)
```

```
X s - 1 = X + 2 Y
```

```
Y s + 2 = 5 X + 2 Y
```

```
solve({Leqn1, Leqn2}, {X, Y})
```

$$\left\{ \begin{array}{ll} \emptyset & \text{if } s^2 = 3s + 8 \\ \left\{ \left[ X = -\frac{s-6}{-s^2+3s+8}, Y = \frac{2s-7}{-s^2+3s+8} \right] \right\} & \text{if } s^2 \neq 3s + 8 \end{array} \right.$$

(This example was suggested by MuPAD user Brad Cooper.)

## Example 5

The result of `subsex` is not evaluated. In the following call, the identifier `sin` is not replaced by its value, i.e., by the procedure defining

the behavior of the system's sine function. Consequently,  $\sin(2\pi)$  is not simplified to 0 by this procedure:

```
subsex(sin(2*x*y), x*y = PI)
```

```
sin(2 π)
```

The function `eval` enforces evaluation:

```
eval(subsex(sin(2*x*y), x*y = PI))
```

```
0
```

### Example 6

Operands of expression sequences can be substituted. Note that sequences need to be enclosed in brackets:

```
subsex((a, b, a*b*c), a*b = x)
```

```
a, b, c x
```

### Example 7

The option `Unimplified` suppresses simplification:

```
subsex(2 + a + b, a + b = 0, Unimplified)
```

```
2 + 0
```

## Parameters

**f**

An arbitrary MuPAD object

**old, old<sub>1</sub>, old<sub>2</sub>, ...**

# subsex

---

Arbitrary MuPAD objects

**new, new<sub>1</sub>, new<sub>2</sub>, ...**

Arbitrary MuPAD objects

**s<sub>1</sub>, s<sub>2</sub>, ...**

Either equations `old = new`, or lists or sets of such equations, or tables whose entries are interpreted as such equations.

## Options

### Unsimplified

Prevents simplification of the returned object after substitution

As the last step of a substitution, the modified object is simplified (however, not evaluated). This option suppresses this final simplification. An example can be found on the `subs` help page.

## Return Values

Copy of the input object with replaced operands.

## Overloaded By

f

## See Also

## MuPAD Functions

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Replace operands                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Syntax</b>      | <code>subsop(object, i<sub>1</sub> = new<sub>1</sub>, i<sub>2</sub> = new<sub>2</sub>, ..., &lt;Unsimplified&gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p><code>subsop</code> returns a modified copy of the object, but does not change the object itself.</p> <p><code>subsop(object, i = new)</code> replaces the operand <code>op(object, i)</code> by <code>new</code>. Operands are specified in the same way as with the function <code>op</code>: <code>i</code> may be an integer or a list of integers. E.g., <code>subsop(object, [j, k] = new)</code> replaces the suboperand <code>op(op(object, j), k)</code>. Cf. “Example 2” on page 1-2184. In contrast to <code>op</code>, ranges cannot be used in <code>subsop</code> to specify more than one operand to replace. Several substitution equations have to be specified instead.</p> <p>If several operands are to be replaced, the specified substitutions are processed in sequence from left to right. Each substitution is carried out and the result is processed further with the next substitution. The intermediate objects are not simplified.</p> <p>The result of <code>subsop</code> is not evaluated further. It can be evaluated via the function <code>eval</code>. Cf. “Example 3” on page 1-2184.</p> <p>Operands of expression sequences can be replaced by <code>subsop</code>. Such objects are not flattened.</p> <p>Note that the order of the operands may change by replacing operands and evaluating the result. Cf. “Example 4” on page 1-2185.</p> <p>FAIL is returned if an operand cannot be accessed.</p> <p>Substitution via <code>subsop</code> is faster than via <code>subs</code> or <code>subsex</code>.</p> <p>The call <code>subsop(object)</code> is allowed; it returns the object without modifications.</p> |
| <b>Examples</b>    | <p><b>Example 1</b></p> <p>We demonstrate how to replace one or more operands of an expression:</p> <pre>x := a + b: subsop(x, 2 = c)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# subsop

---

$a + c$

`subsop(x, 1 = 2, 2 = c)`

$c + 2$

Also the 0-th operand of an expression (the “operator”) can be replaced:

`subsop(x, 0 = _mult)`

$a b$

The variable `x` itself was not affected by the substitutions:

`x`

$a + b$

`delete x:`

## Example 2

The following call specifies the suboperand `c` by a list of integers:

`subsop([a, b, f(c)], [3, 1] = x)`

$[a, b, f(x)]$

## Example 3

This example demonstrates the effect of simplification. The following substitution replaces the first operand `a` by `2`. The result simplifies to `3`:

```
subsop(a + 1, 1 = 2)
```

```
3
```

The option `Unimplified` suppresses the simplification:

```
subsop(a + 1, 1 = 2, Unimplified)
```

```
2 + 1
```

The next call demonstrates the difference between *simplification* and *evaluation*. After substitution of `PI` for `x`, the identifier `sin` is not evaluated, i.e., the body of the system function `sin` is not executed:

```
subsop(sin(x), 1 = PI)
```

```
sin(π)
```

Evaluation of `sin` simplifies the result:

```
eval(%)
```

```
0
```

#### Example 4

The order of operands may change by substitutions. Substituting `z` for the identifier `b` changes the internal order of the terms in `x`:

```
x := a + b + c: op(x)
```

```
a, b, c
```

# subsop

---

```
x := subsop(x, 2 = z): op(x)
```

```
a, c, z
```

```
delete x:
```

## Parameters

**object**

Any MuPAD object

**i<sub>1</sub>, i<sub>2</sub>, ...**

Integers or lists of integers

**new<sub>1</sub>, new<sub>2</sub>, ...**

Arbitrary MuPAD objects

## Options

**Unsimplified**

As the last step of a substitution, the modified object is simplified (however, not evaluated). This option suppresses this final simplification. Cf. “Example 3” on page 1-2184.

## Return Values

Input object with replaced operands or FAIL.

## Overloaded By

object

## Algorithms

For overloading subsop, it is sufficient to handle the cases subsop(object) and subsop(object, i = new).

The case where the position of the operand to be replaced is given by a list is always handled recursively: First, op is called with the list bar the last element to find the object to substitute in (using the overloading of op if present, storing all the intermediate results), then the substitution is performed on that sub-object (using the overloading of subsop of

the form `subsop(subobj, i = new)`. The result is substituted into the last-but-one result of the recursive `op` call, again respecting any overloading of `subsop`, and so on up to the front of the list.

# substring

---

**Purpose** Extract a substring from a string

**Syntax**  
`substring(string, i)`  
`substring(string, i, l)`  
`substring(string, i .. j)`

**Description** `substring(string, i)` returns the *i*-th character of a string.  
`substring(string, i, l)` returns the substring of length *l* starting with the *i*-th character of the string.  
`substring(string, i..j)` returns the substring consisting of the characters *i* through *j*, inclusive.  
The empty string "" is returned if the length *l* = 0 is specified.  
`substring` is considered obsolete. You should use index access to strings instead.

## **Examples** **Example 1**

We extract individual characters from a string:

```
substring("123456789", i) $ i = 1..9
```

```
"1", "2", "3", "4", "5", "6", "7", "8", "9"
```

Substrings of various lengths are extracted:

```
substring("123456789", 1, 2), substring("123456789", 4, 4)
```

```
"12", "4567"
```

Substrings of length 0 are empty strings:

```
substring("123456789", 4, 0)
```

```
'''
```

Ranges may be used to specify the substrings:

```
substring("123456789", 1..9)
```

```
"123456789"
```

## Example 2

The following `while` loop removes all trailing blank characters from a string:

```
string := "MuPAD ":
while substring(string, length(string)) = " " do
 string := substring(string, 1..length(string) - 1)
end_while
```

```
"MuPAD"
```

## Parameters

**string**

A nonempty character string

**i**

An integer between 1 and `length(string)`

**l**

An integer between 1 and `length(string)`

**i**

An integer between `i` and `length(string)`

# substring

---

## **Return Values**

Character string

## **See Also**

## **MuPAD Functions**

`length` | `strmatch` | `stringlib::subs`

**Purpose** Subtract expressions

**Syntax** `_subtract(x, y)`

**Description** `_subtract(x, y)` subtracts  $y$  from  $x$ .

The difference operator `-` does not call `_subtract(x, y)`. The difference  $x - y$  is equivalent to  $x + (-y) = \text{\_plus}(x, \text{\_negate}(y))$ .

To implement the slot `d::_subtract` for your domain  $d$ , use the following convention:

- If both  $x$  and  $y$  are elements of  $d$ , the slot must return an appropriate difference of type  $d$ .
- If  $x$  or  $y$  is not an element of  $d$  and cannot be converted to an element of  $d$ , the slot must return FAIL.
- If  $x$  or  $y$  is not an element of  $d$ , but can be converted to type  $d$ , use the following approach. This object must be converted to an element of  $d$  only if the mathematical semantics is obvious to all users of  $d$ , including the users who treat this domain as a “black box”. For example, you can regard integers as rational numbers because of the natural mathematical embedding, but you must make sure that all users are aware of this approach. Otherwise, the “\_subtract” method must return FAIL instead of using implicit conversions. If you use implicit conversions for the elements of your domain, document these conversions.

In the MuPAD standard installation, most of the library domains comply with this convention.

`_subtract` can subtract polynomials of the `DOM_POLY` type from a polynomial of the same type. The polynomials must have the same indeterminates and the same coefficient ring.

`_subtract` can subtract finite sets from a finite set. For finite sets  $X$  and  $Y$ , the difference is the set  $\{x - y \mid x \in X, y \in Y\}$ .

# **`_subtract`**

---

## **Examples**

### **Example 1**

Compute the difference of the following arithmetical expressions by using the `_subtract` method. Then, compute the difference of the same expressions by using the difference operator:

```
_subtract(x, y), x - y
```

```
x - y, x - y
```

Although both `_subtract` and the difference operator return the same result for these expressions, the `_subtract` call is not equivalent to `x - y`:

```
type(hold(x - y)), type(hold(_subtract(x, y)))
```

```
"_plus", "_subtract"
```

### **Example 2**

Use the `_subtract` function when combining the following lists:

```
zip([a, b, c, d], [1, 2, 3, 4], _subtract)
```

```
[a - 1, b - 2, c - 3, d - 4]
```

## **Parameters**

**x, y**

arithmetical expressions, polynomials of type `DOM_POLY`, or sets

## **Return Values**

arithmetical expression, a polynomial, or a set.

**Overloaded  
By**     x, y

# sum

---

**Purpose** Definite and indefinite summation

**Syntax**  
`sum(f, i)`  
`sum(f, i = a .. b)`  
`sum(f, i = RootOf(p, x))`

**Description** `sum(f, i)` computes a symbolic antidifference of  $f(i)$  with respect to  $i$ .  
`sum(f, i = a .. b)` tries to find a closed form representation of the  
$$\text{sum} \sum_{i=a}^b f(i).$$
  
`sum` serves for simplifying *symbolic* sums (the discrete analog of integration). It should *not* be used for simply adding a finite number of terms: if  $a$  and  $b$  are integers of type `DOM_INT`, the call `_plus(f $ i = a .. b)` gives the desired result, while `sum(f, i = a .. b)` may return unevaluated. `expand` may be used to sum such an unevaluated finite sum. See “Example 3” on page 1-2196.

`sum(f, i)` computes the indefinite sum of  $f$  with respect to  $i$ . This is an expression  $g$  such that  $f(i) = g(i + 1) - g(i)$ .

It is implicitly assumed that  $i$  runs through integers only.

`sum(f, i = a .. b)` computes the definite sum with  $i$  running from  $a$  to  $b$ .

If  $a$  and  $b$  are numbers, then they must be integers.

If  $b - a$  is a nonnegative integer, then the explicit sum  $f(a) + f(a + 1) + \dots + f(b)$  is returned, provided that this sum has no more than 1000 terms.

`sum(f, i = RootOf(p, x))` computes the sum with  $i$  extending over all roots of the polynomial  $p$  with respect to  $x$ .

If  $f$  is a rational function of  $i$ , a closed form of the sum will be found. See “Example 2” on page 1-2196.

The system returns a symbolic call of `sum` if it cannot compute a closed form representation of the sum.

Infinite symbolic sums without symbolic parameters can be evaluated numerically via `float` or `numeric::sum`. Cf. “Example 4” on page 1-2198.

## Examples

### Example 1

We compute some indefinite sums:

```
sum(1/(i^2 - 1), i)
```

$$-\frac{1}{2(i-1)} - \frac{1}{2i}$$

```
sum(1/i/(i + 2)^2, i)
```

$$\frac{\psi'(i+2)}{2} - \frac{1}{4i+4} - \frac{1}{4i}$$

```
sum(binomial(n + i, i), i)
```

$$\begin{cases} 0 & \text{if } n = -1 \\ \frac{i \binom{i+n}{i}}{n+1} & \text{if } n \neq -1 \end{cases}$$

We compute some definite sums. Note that  $\pm\infty$  are valid boundaries:

```
sum(1/(i^2 + 21*i), i = 1..infinity)
```

$$\frac{18858053}{108636528}$$

## sum

---

```
sum(1/i, i = a .. a + 3)
```

$$\psi(a + 4) - \psi(a)$$

```
expand(%)
```

$$\frac{1}{a + 1} + \frac{1}{a + 2} + \frac{1}{a + 3} + \frac{1}{a}$$

### Example 2

We compute some sums over all roots of a polynomial:

```
sum(i^2, i = RootOf(x^3 + a*x^2 + b*x + c, x))
```

$$a^2 - 2b$$

```
sum(1/(z + i), i = RootOf(x^4 - y*x + 1, x))
```

$$\frac{4z^3 + y}{z^4 + yz + 1}$$

### Example 3

sum can compute finite sums if indefinite summation succeeds:

```
sum(1/(i^2 + i), i = 1..100)
```

$$\frac{100}{101}$$

```
sum(binomial(n, i), i = 0..1000)
```

$$\sum_{i=0}^{1000} \binom{n}{i}$$

You might use `expand` here to expand the sum and obtain a huge expression. If you really want to do that, we recommend using `_plus` directly.

However, if one of the boundaries is symbolic, then `_plus` cannot be used:

```
_plus(1/(i^2 + i) $ i = 1..n)
```

$$\_plus\left(\frac{1}{i^2 + i} \text{ \$ } i = 1..n\right)$$

```
_plus(binomial(n, i) $ i = 0..n)
```

$$\_plus\left(\binom{n}{i} \text{ \$ } i = 0..n\right)$$

```
sum(1/(i^2 + i), i = 1..n), sum(binomial(n, i), i = 0..n)
```

$$\frac{n}{n+1}, 2^n$$

## Example 4

The following infinite sum cannot be computed symbolically:

```
sum(ln(i)/i^5, i = 1..infinity)
```

$$\sum_{i=1}^{\infty} \frac{\ln(i)}{i^5}$$

We obtain a floating-point approximation via `float`:

```
float(%)
0.02857378051
```

Alternatively, the function `numeric::sum` can be used directly. This is usually much faster than applying `float`, since it avoids the overhead of `sum` attempting to compute a symbolic representation:

```
numeric::sum(ln(i)/i^5, i = 1..infinity)
0.02857378051
```

## Parameters

**f**

An arithmetical expression depending on `i`

**i**

The summation index: an identifier or indexed identifier

**a, b**

The boundaries: arithmetical expressions

**p**

A polynomial of type `DOM_POLY` or a polynomial expression

**x**

An indeterminate of `p`

# sum

---

## Return Values

arithmetical expression.

## Algorithms

The function `sum` implements Abramov's algorithm for rational expressions, Gosper's algorithm for hypergeometric expressions, and Zeilberger's algorithm for the definite summation of holonomic expressions.

## Related Examples

- “Compute Symbolic Sums”
- “Approximate Sums Numerically”

## Purpose

Add patterns for definite and indefinite summation

## Syntax

```
sum::addpattern(pat, k, res, <[var,], <[cond,]>>)
sum::addpattern(pat, k = a .. b, res, <[var,
], <[cond,]>>)
```

## Description

sum::addpattern(pat, k, res) teaches sum to make use of

$$\sum_k \text{pat} = \text{res.}$$

sum::addpattern(pat, k=a..b, res) teaches sum that

$$\sum_{x=a}^b \text{pat} = \text{res.}$$

A part of a computer algebra system's summation abilities stems from mathematical pattern matching. The MuPAD pattern matcher can be extended at runtime with sum::addpattern.

For definite summation, each bound is either an arithmetical expression which may contain pattern variables, or an identifier which can be used as a variable in the result and condition terms.

Users can include pattern variables and conditions on these by giving additional arguments. These conditions, as well as the result, are protected from premature evaluation, i.e., it is not necessary to write `hold( _not @ iszero )(a^2-b)`, a simple `not iszero(a^2-b)` suffices.

The difference between `not iszero(a^2-b)` and `a^2-b <> 0` when given as a condition is that the latter takes into account assumptions on the identifiers encountered, while the first does not. Cf. "Example 4" on page 1-2204.

Patterns introduced by sum::addpattern are also used in recursive calls of sum and are automatically extended to include simple applications of summation by change of variables. Cf. "Example 1" on page 1-2202.

## Environment Interactions

Calling sum::addpattern changes the expressions returned by future calls to sum.

# sum::addpattern

---

## Examples

### Example 1

Not surprisingly, MuPAD does not know how to do an indefinite summation with the function *foo*:

```
sum(foo(n), n)
```

$$\sum_n \text{foo}(n)$$

We add a pattern for this function:

```
sum::addpattern(foo(k), k, bar(k))
```

```
sum(foo(n), n)
```

```
bar(n)
```

Note that this pattern is also used indirectly:

```
sum(foo(k+3), k)
```

```
bar(k + 3)
```

### Example 2

Definite sums can be added similarly:

```
sum::addpattern(foo(k), k=1..infinity, bar(k))
```

```
sum(foo(k), k=1..infinity)
```

```
bar(k)
```

The above pattern will also match this definite sum with different bounds:

```
sum(foo(k), k=3..infinity)
```

```
bar(k) - foo(2) - foo(1)
```

Note that this pattern is also used indirectly:

```
sum(foo(k)+1/k^3, k=1..infinity)
```

```
ζ(3) + bar(k)
```

The bounds may also be variables occurring in the pattern or the result:

```
sum::addpattern(foo(k,a), k=0..a, bar(a), [a])
```

```
sum(foo(k,7), k=0..7)
```

```
bar(7)
```

### Example 3

The name of the summation variable used in the call to `sum::addpattern` does not restrict later calls to `sum`:

```
sum::addpattern(x^(2*i+1)/(2*i+1), i=0..infinity,
 piecewise([abs(x) < 1,
 arccoth(x) + PI/2*sqrt(-1/x^2)*x]),
 [x])
```

```
sum(x^(2*n+1)/(2*n+1),n=0..infinity)
```

## sum::addpattern

---

$$\left\{ \operatorname{arccoth}(x) + \frac{\pi x \sqrt{-\frac{1}{x^2}}}{2} \text{ if } |x| < 1 \right.$$

### Example 4

Conditions are checked using `is` and therefore react to assumptions:

```
sum::addpattern(binomial(-1/2, k) * x^(2*k^2+1)/(2*k+1), k = 0..inf,
 arcsinh(x), [x], [abs(x) < 1])
```

```
sum(binomial(-1/2, k) * x^(2*k^2+1)/(2*k+1),
 k = 0..infinity) assuming -1 < x < 1
```

`arcsinh(x)`

```
sum(binomial(-1/2, k) * x^(2*k^2+1)/(2*k+1),
 k = 0..infinity) assuming x > 1
```

$$\sum_{k=0}^{\infty} \frac{x^{2k^2+1} \binom{-\frac{1}{2}}{k}}{2k+1}$$

If MuPAD cannot decide whether the conditions are satisfied, a piecewise defined object is returned:

```
sum(binomial(-1/2, k) * x^(2*k^2+1)/(2*k+1),
 k = 0..infinity)
```

`{ arcsinh(x) if |x| < 1`

If either the conditions are not satisfied or substituting the values into the result yields an error, the pattern is ignored. There is no need to

include a condition to guard against an error, MuPAD simply computes the sum as usual:

```
sum::addpattern(c^k, k=0..n, (c^n-1)/(c-1), [c]);
sum(1^k, k=0..n)
```

$n + 1$

## Parameters

### **pat**

The pattern to match: an arithmetical expression in  $k$ .

### **k**

The summation index: an identifier.

### **a .. b**

The boundaries for a definite summation: arithmetical expressions or identifiers.

### **res**

The pattern for the result of the summation: an arithmetical expression

### **var, ...**

“pattern variables”: placeholders in `pat` and `res`, i.e., identifiers or indexed identifiers. They do not represent themselves but almost arbitrary MuPAD expressions not containing  $k$ . You may restrict them by the conditions in the 5th parameter.

### **cond, ...**

Conditions on the pattern variables

## Return Values

Object of type `DOM_NULL`

# sum::addpattern

---

| <b>Purpose</b>                  | N -th root                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>                   | surd(x, n)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>              | <p>For a complex number <math>x</math> and integer <math>n</math>, <code>surd(x, n)</code> returns the <math>n</math>-th root of <math>x</math> whose (complex) argument is closest to that of <math>x</math>.</p> <p>If <math>x</math> is a positive real number, <code>surd(x, n)</code> coincides with <math>x^{(1/n)}</math>. If <math>x</math> is a negative real number and <math>n</math> is odd, then <code>surd(x, n)</code> coincides with <math>- x ^{(1/n)}</math>.</p> <p><code>surd(x, n)</code> returns that complex solution <math>y</math> of <math>y^n = x</math> with polar angle closest to that of <math>x</math>; among two equally distant <math>y</math>'s, the one with smaller argument is chosen. In contrast, <math>x^{(1/n)}</math> represents the solution with the smallest absolute value of the polar angle in the range <math>(-\pi, \pi]</math>.</p> <p>If <math>n</math> is a numerical value, it must be a non-zero integer. If it is symbolic, it is understood to represent a non-zero integer.</p> <p><code>surd(x, 2)</code> is mathematically equivalent to <code>sqrt(x)</code>. Unlike <code>sqrt</code>, however, <code>surd</code> may return an unevaluated symbolic call.</p> |
| <b>Environment Interactions</b> | When called with a floating-point argument, the function is sensitive to the environment variable <code>DIGITS</code> which determines the numerical working precision.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Examples</b>                 | <p><b>Example 1</b></p> <p>If <math>n</math> is odd and <math>x</math> is real, then <code>surd(x, n)</code> is real, too. On the other hand, <math>x^{(1/n)}</math> is not real if <math>x</math> is negative:</p> <pre>surd(-27, 3), surd(-27.0, 3), (-27)^(1/3), (-27.0)^(1/3)</pre> <pre>-3, -3.0, (-27)<sup>1/3</sup>, 1.5 + 2.598076211 i</pre> <p><b>Example 2</b></p> <p><code>surd</code> may be called with symbolic arguments:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

# surd

---

`surd(3, n)`

$$3^{1/n}$$

Sometimes, `surd` returns an unevaluated function call:

`surd(x, 3)`, `surd(x, n^2 + n)`

$$\sqrt[3]{x}, n^2 \cdot n \sqrt{x}$$

## Parameters

**x**

An arithmetical expression

**n**

An arithmetical expression

## Return Values

Arithmetical expression.

## See Also

## MuPAD Functions

`_power` | `sqrt`

**Purpose** Name of the operating system

**Syntax** `sysname(<Arch>)`

**Description** `sysname()` returns information on the operating system on which MuPAD is currently executed. It can return one of the following strings:

- "UNIX" for UNIX operating systems including Mac OS X and Linux,
- "MSDOS" for MS-DOS® operating systems including Microsoft Windows,

`sysname(Arch)` returns a more specific name of the operating system as a character string.

## Examples

### Example 1

On a 64-bit Microsoft Windows operating system, `sysname` returns the following values:

```
sysname(), sysname(Arch)
```

```
"MSDOS", "win64"
```

On a 32-bit Microsoft Windows operating system, `sysname(Arch)` returns:

```
sysname(Arch)
```

```
"win32"
```

### Example 2

On a 64-bit Linux operating system, `sysname` returns the following values:

# sysname

---

`sysname()`, `sysname(Arch)`

"UNIX", "glnxa64"

## Example 3

On a 64-bit Apple Macintosh operating system, `sysname` returns the following values:

`sysname()`, `sysname(Arch)`

"UNIX", "maci64"

## Options

### Arch

Makes `sysname` return more specific information on the architecture

## Return Values

character string.

## See Also

## MuPAD Functions

system

**Purpose** Compare objects according to the internal order

**Syntax** `sysorder(object1, object2)`

**Description** `sysorder(object1, object2)` returns TRUE if the MuPAD internal order of object1 is less than or equal to the order of object2. Otherwise, FALSE is returned.

---

**Note** The exceptions are domains.

---

One should not try and use the internal order to sort objects according to specific criteria. E.g., its does not necessarily reflect the natural ordering of numbers or strings. Further, the internal order may differ between different MuPAD versions.

The only feature one may rely upon is its uniqueness. Cf. “Example 2” on page 1-2212.

## Examples

### Example 1

We give some examples how `sysorder` behaves in the current MuPAD version. For numbers, the internal order is equal to the natural order:

```
sysorder(3, 4) = bool(3 <= 4),
sysorder(45, 33) = bool(45 <= 33),
sysorder(0, 4) = bool(0 <= 4)
```

```
TRUE = TRUE, FALSE = FALSE, TRUE = TRUE
```

```
sysorder(1/3, 1/4) = bool(1/3 <= 1/4),
sysorder(-4, 2) = bool(-4 <= 2),
sysorder(-4, -2) = bool(-4 <= -2)
```

FALSE = FALSE, TRUE = TRUE, TRUE = TRUE

## Example 2

We give a simple application of `sysorder`. Suppose, we want to implement a function `f`, say, whose only known property is its skewness  $f(-x) = -f(x)$ . Expressions involving `f` should be simplified automatically, e.g.,  $f(x) + f(-x)$  should yield zero for any argument `x`. To achieve this, we use `sysorder` to decide, whether a call `f(x)` should return `f(x)` or `-f(-x)`:

```
f := proc(x) begin
 if sysorder(x, -x) then
 return(-procname(-x))
 else return(procname(x))
 end_if;
end_proc;
```

For numerical arguments, `f` prefers to rewrite itself with positive arguments:

`f(-3)`, `f(3)`, `f(-4.5)`, `f(4.5)`, `f(-2/3)`, `f(2/3)`

$-f(3)$ ,  $f(3)$ ,  $-f(4.5)$ ,  $f(4.5)$ ,  $-f\left(\frac{2}{3}\right)$ ,  $f\left(\frac{2}{3}\right)$

For other arguments, the result is difficult to predict:

`f(x)`, `f(-x)`, `f(sqrt(2) + 1)`, `f(-sqrt(2) - 1)`

$-f(-x)$ ,  $f(-x)$ ,  $f(\sqrt{2} + 1)$ ,  $-f(\sqrt{2} + 1)$

With this implementation, expressions involving `f` simplify automatically:

```
f(x) + f(-x) - f(3)*f(x) + f(-3)*f(-x) + sin(f(7)) + sin(f(-7))
```

```
0
```

```
delete f:
```

## Parameters

**object1, object2**

Arbitrary MuPAD objects

## Return Values

TRUE or FALSE.

## See Also

## MuPAD Functions

`_less` | `listlib::removeDupSorted` | `sort`

# system

---

**Purpose** Execute a command of the operating system

**Syntax** `! command`  
`system(command)`

**Description** `system("command")` executes a command of the operating system or a program, respectively.

`!command` is equivalent to `system("command")`; note that `!command` will suppress output of its return value.

The syntax `!command` is allowed during interactive input only, not when reading MuPAD input from a file. “!” must be the first character on the input line.

`system` is not available in all MuPAD versions. If not available, a call to `system` results in the following error message:

```
Error: Function not available for this client [system].
```

`system("command")` sends the command to the operating system. E.g., this command may start another application program on the computer. The return value 0 indicates that the command was executed successfully. Otherwise, an integer error code is returned which depends on the operating system and the command.

If the called command writes output to `stderr` on UNIX systems, the output will go to the MuPAD `stderr`. Outputs on the standard output channel will be inserted in the command's output, but are not accessible programmatically.

## Examples

### Example 1

On a UNIX system, the `date` command is executed. The command output is printed to the screen, the error code 0 for successful execution is returned to the MuPAD session:

```
errorcode := system("date");
```

```
Fri Sep 29 14:42:13 MEST 2000
```

```
errorcode
```

```
0
```

Now the `date` command is called with the command line option `'+%m'` in order to display the current month only:

```
errorcode := system("date +%m");
```

```
09
```

Missing the prefix `'+'` in the command line option of `date`, `date` and therefore `system` returns an error code. Note that the error output goes to `stderr`:

```
system("date '%m'")
```

```
1
```

```
delete errorcode:
```

## Example 2

The output of a program started with the `system` command cannot be accessed in MuPAD directly, but it can be redirected into a file and then be read using the `read` or `ftextinput` command:

```
system("echo communication example > comm_file");
ftextinput("comm_file")
```

```
"communication example"
```

```
system("rm -f comm_file");
```

# system

---

## Parameters

**command**

A command of the operating system or a name of a program as a MuPAD character string

## Return Values

“error code”: an integer.

## See Also

## MuPAD Functions

sysname

**Purpose**

Create a table

**Syntax**

```
table()
table(index1 = entry1, index2 = entry2, , <default>)
table(<list>, <set>, <tab>, , <default>)
```

**Description**

`table()` creates a new empty table.

`table(index1 = entry1, index2 = entry2, ...)` creates a new table with the given indices and entries.

In MuPAD, tables are the most flexible objects for storing data. In contrast to arrays or lists, arbitrary MuPAD objects can be used as indices. Indexed access to table entries is fast and nearly independent of the size of the table. Thus, tables are suitable containers for large data.

For a table  $T$ , say, an indexed call  $T[\text{index}]$  returns the corresponding entry. If no such entry exists, the default value of the table is returned, if the table has one. If no default value has been set and, the indexed expression  $T[\text{index}]$  is returned symbolically.

An indexed assignment of the form  $T[\text{index}] := \text{entry}$  adds a new entry to an existing table  $T$  or overwrites an existing entry associated with the index.

`table` can be used to create tables from other tables, lists or sets of equations. Cf. “Example 2” on page 1-2219.

`table` is used for the explicit creation of a table. There also is the following mechanism for creating a table implicitly.

If the value of an identifier  $T$ , say, is neither a table nor an array nor an hfarray nor a list, then an indexed assignment  $T[\text{index}] := \text{entry}$  is equivalent to  $T := \text{table}(\text{index} = \text{entry})$ . I.e., implicitly, a new table with one entry is created. Cf. “Example 3” on page 1-2220.

If the value of  $T$  was either a table or an array or an hfarray or a list, then the indexed assignment only inserts a new entry without changing the type of  $T$  implicitly.

# table

---

Table entries can be deleted with the function `delete`. Cf. “Example 4” on page 1-2220.

## Examples

### Example 1

The following call creates a table with two entries:

```
T := table(a = 13, c = 42)
```

|   |    |
|---|----|
| a | 13 |
| c | 42 |

The data may be accessed via indexed calls. Note the symbolic result for the index `b` which does not have a corresponding entry in the table:

```
T[a], T[b], T[c]
```

```
13, Tb, 42
```

Entries of a table may be changed via indexed assignments:

```
T[a] := T[a] + 10: T
```

|   |    |
|---|----|
| a | 23 |
| c | 42 |

Expression sequences may be used as indices or entries, respectively. Note, however, that they have to be enclosed in brackets when using them as input parameters for `table`:

```
T := table((a, b) = "hello", a + b = (50, 70))
```

|         |         |
|---------|---------|
| $a + b$ | 50, 70  |
| $a, b$  | "hello" |

T[a + b]

50, 70

Indexed access does not require additional brackets:

T[a, b] := T[a, b]. " world": T

|         |               |
|---------|---------------|
| $a + b$ | 50, 70        |
| $a, b$  | "hello world" |

delete T:

## Example 2

A table can be created from other tables, lists or sets:

```
table(table(a = 1, b = 2),
 {a = 3, c = 4},
 [b = 5, e = 6])
```

|   |   |
|---|---|
| a | 3 |
| b | 5 |
| c | 4 |
| e | 6 |

Please note that a set has no order of operands. When a set contains several values under the same index, the table entry is chosen “randomly”:

# table

---

```
table({a = 3, a = 4});
table({a = 4, a = 3})
```

$$\overline{a \mid 4}$$
$$\overline{a \mid 3}$$

### Example 3

Below, a new table is created implicitly by an indexed assignment using an identifier T without a value:

```
delete T: T[4] := 7: T
```

$$\overline{4 \mid 7}$$

```
delete T:
```

### Example 4

Use delete to delete entries:

```
T := table(a = 1, b = 2, (a, b) = (1, 2))
```

$$\overline{\begin{array}{l|l} a & 1 \\ b & 2 \\ a, b & 1, 2 \end{array}}$$

```
delete T[b], T[a, b]: T
```

$$\overline{a \mid 1}$$

delete T:

### Example 5

One of the uses of tables is to count the number of occurrences of some objects. In this situation, an implementation not using default values would have to look like this:

```
T := table():
L := [1,2,3,a,b,c,a,b,a]:
for i in L do
 if contains(T, i) then
 T[i] := T[i] + 1;
 else
 T[i] := 1;
 end_if;
end_for:
T
```

|   |   |
|---|---|
| 1 | 1 |
| 2 | 1 |
| 3 | 1 |
| a | 3 |
| b | 2 |
| c | 1 |

Note the test whether  $T[i]$  has already been set. If it has not, we cannot use its previous value, because that would remain symbolic:

```
T := table():
T[a] := T[a] + 1:
T
```

|   |           |
|---|-----------|
| a | $T_a + 1$ |
|---|-----------|

# table

---

By creating `T` as `table(0)` instead of `table()`, we can tell MuPAD to regard `T[i]` as 0 if it has not been told anything else and the code from above becomes substantially shorter and, much more important, much easier to read:

```
T := table(0):
L := [1,2,3,a,b,c,a,b,a]:
for i in L do
 T[i] := T[i] + 1;
end_for:
T
```

|   |   |
|---|---|
| 1 | 1 |
| 2 | 1 |
| 3 | 1 |
| a | 3 |
| b | 2 |
| c | 1 |

A slightly more complicated version counting all identifiers in an expression:

```
ex := sin(a*x+b)-cos(c+x):
cnt := table(0):
misc::maprec(ex,
 {DOM_IDENT} = (x -> (cnt[x] := cnt[x]+1; x))):
cnt
```

|       |   |
|-------|---|
| _mult | 2 |
| _plus | 3 |
| a     | 1 |
| b     | 1 |
| c     | 1 |
| cos   | 1 |
| sin   | 1 |
| x     | 2 |

**Parameters****index<sub>1</sub>, index<sub>2</sub>, ...**

The indices: arbitrary MuPAD objects

**entry<sub>1</sub>, entry<sub>2</sub>, ...**

The corresponding entries: arbitrary MuPAD objects

**list**

A list of equations

**set**

A set of equations

**tab**

A table

**default**

The default value: A MuPAD object which is not an equation, a list, a set, nor a table

**Return Values**

Object of type DOM\_TABLE.

**See Also****MuPAD Domains**

DOM\_ARRAY | DOM\_HFARRAY | DOM\_LIST | DOM\_TABLE

# taylor

---

**Purpose** Compute a Taylor series expansion

**Syntax**

```
taylor(f, x, <order>, <mode>, <NoWarning>)
taylor(f, x = x0, <order>, <mode>, <NoWarning>)
taylor(f, x, <AbsoluteOrder = order>, <NoWarning>)
taylor(f, x = x0, <AbsoluteOrder = order>, <NoWarning>)
taylor(f, x, <RelativeOrder = order>, <NoWarning>)
taylor(f, x = x0, <RelativeOrder = order>, <NoWarning>)
```

**Description** `taylor(f, x = x0)` computes the first terms of the Taylor series of `f` with respect to the variable `x` around the point `x0`.

Three cases can occur:

- 1** `taylor` is able to compute the corresponding Taylor series. In this case, the result is a series expansion of domain type `Series::Puisseux`. Use `expr` to convert it to an arithmetical expression of domain type `DOM_EXPR`. Cf. “Example 1” on page 1-2225.
- 2** `taylor` is able to decide that the corresponding Taylor series does not exist. In this case, an error is raised. Cf. “Example 2” on page 1-2226.
- 3** `taylor` is not able to determine whether the corresponding Taylor series exists or not. Internally, the function `series` is called; it returns a symbolical call. In this case, also `taylor` returns a symbolic expression of type `"taylor"`. Cf. “Example 3” on page 1-2227.

Mathematically, the expansion computed by `taylor` is valid in some open disc around the expansion point in the complex plane.

If `x0` is `complexInfinity`, then an expansion around the complex infinity, i.e., the north pole of the Riemann sphere, is computed. If `x0` is `infinity` or `-infinity`, a directed series expansion valid along the real axis is computed.

Such an expansion is computed as follows: The series variable `x` in `f` is replaced by  $x = \pm \frac{1}{u}$ . Then a directed series expansion at  $u = 0$  from the right is computed. If `x0 = complexInfinity`, then an undirected

expansion around  $u = 0$  is computed. Finally,  $u = \pm \frac{1}{x}$  is substituted in the result.

Mathematically, the result of an expansion around `complexInfinity` or `±infinity` is a power series in  $\frac{1}{x}$ . Cf. “Example 4” on page 1-2228.

With the default mode `RelativeOrder`, the number of requested terms for the expansion is `order` if specified. If no `order` is specified, the value of the environment variable `ORDER` is used. You can change the default value 6 by assigning a new value to `ORDER`.

The number of terms is counted from the lowest degree term on for finite expansion points, and from the highest degree term on for expansions around infinity, i.e., “order” has to be regarded as a “relative truncation order”.

If `AbsoluteOrder` is specified, `order` represents the truncation order of the series (i.e., the  $x$  power in the Big-Oh term).

`taylor` uses the more general series function `series` to compute the Taylor expansion. See the corresponding help page for `series` for details about the parameters and the data structure of a Taylor series expansion.

## Environment Interactions

The function is sensitive to the environment variable `ORDER`, which determines the default number of terms in series computations.

## Examples

### Example 1

We compute a Taylor series around the default point 0:

```
s := taylor(exp(x^2), x)
```

$$1 + x^2 + \frac{x^4}{2} + O(x^6)$$

The result of `taylor` is of the following domain type:

```
domtype(s)
```

```
Series::Puiseux
```

If we apply the function `expr` to a series, we get an arithmetical expression without the order term:

```
expr(s)
```

$$\frac{x^4}{2} + x^2 + 1$$

```
domtype(%)
```

```
DOM_EXPR
```

```
delete s:
```

## Example 2

A Taylor series expansion of  $f(x) = \frac{1}{x^2}$  around  $x = 1$  does not exist. Therefore, `taylor` responds with an `error` message:

```
taylor(1/(x^2 - 1), x = 1)
```

```
Error: Cannot compute a Taylor expansion of '1/(x^2 - 1)'. Try 'series'
```

Following the advice given in this error message, we try `series` to compute a more general series expansion. A Laurent expansion does exist:

```
series(1/(x^2 - 1), x = 1)
```

$$\frac{1}{2(x-1)} - \frac{1}{4} + \frac{x-1}{8} - \frac{(x-1)^2}{16} + \frac{(x-1)^3}{32} - \frac{(x-1)^4}{64} + O((x-1)^5)$$

### Example 3

If a Taylor series expansion cannot be computed, then the function call with evaluated arguments is returned symbolically together with a warning:

```
taylor(1/exp(x^a), x = 0)
```

Warning: Cannot compute a Taylor expansion of 'exp(-x^a)'. Try 's

```
taylor(e^{-x^a}, x = 0)
```

In this example, also `series` returns a symbolic function call. Even if you try one of the proposed options, `series` is not able to compute a series expansion.

Here is another example where no Taylor expansion can be computed. However, `series` with an optional argument yields a more general type of expansion in this case:

```
taylor(psi(1/x), x = 0)
```

Warning: Cannot compute a Taylor expansion of 'psi(1/x)'. Try 's

# taylor

---

$$\text{taylor}\left(\psi\left(\frac{1}{x}\right), x = 0\right)$$

`series(psi(1/x), x = 0, Right)`

$$-\ln(x) - \frac{x}{2} - \frac{x^2}{12} + \frac{x^4}{120} + O(x^6)$$

## Example 4

This is an example of a directed Taylor expansion along the real axis around infinity:

`taylor(exp(1/x), x = infinity)`

$$1 + \frac{1}{x} + \frac{1}{2x^2} + \frac{1}{6x^3} + \frac{1}{24x^4} + \frac{1}{120x^5} + O\left(\frac{1}{x^6}\right)$$

In fact, this is even an undirected expansion:

`taylor(exp(1/x), x = complexInfinity)`

$$1 + \frac{1}{x} + \frac{1}{2x^2} + \frac{1}{6x^3} + \frac{1}{24x^4} + \frac{1}{120x^5} + O\left(\frac{1}{x^6}\right)$$

## Parameters

**f**

An arithmetical expression representing a function in  $x$

**x**

An identifier or an indexed identifier

**x0**

The expansion point: an arithmetical expression. Also expressions involving `infinity` or `complexInfinity` are accepted.

If not specified, the default expansion point 0 is used.

### **order**

The truncation order (in conjunction with `AbsoluteOrder`) or, in conjunction with `RelativeOrder`, the number of terms to be computed, respectively. A nonnegative integer; the default order is given by the environment variable `ORDER` (default value 6).

### **mode**

One of the flags `AbsoluteOrder` or `RelativeOrder`. The default is `RelativeOrder`.

## **Options**

### **AbsoluteOrder**

With this flag, the integer value `order` is the truncation order of the computed series (i.e., the exponent of  $x$  in the Big-Oh term).

### **RelativeOrder**

With this flag, the exponents of  $x$  in the computed series range from some leading order  $v$  to the highest exponent  $v + \text{order} - 1$  (i.e., the exponent of  $x$  in the Big-Oh term is  $v + \text{order}$ ). In this case, `order` essentially is the “number of  $x$  powers” in the computed series if the series involves all integer powers of  $x$ .

### **NoWarning**

Suppresses warning messages printed during the series computation. This can be useful if `taylor` is called within user-defined procedures.

## **Return Values**

Object of domain type `Series::Puisseux` or a symbolic expression of type "taylor".

## **Overloaded By**

# tcoeff

---

**Purpose** Trailing coefficient of a polynomial

**Syntax** `tcoeff(p, <order>)`  
`tcoeff(f, <vars>, <order>)`

**Description** `tcoeff(p)` returns the trailing coefficient of the polynomial `p`.

The returned coefficient is “trailing” with respect to the lexicographical ordering, unless a different ordering is specified via the argument `order`. Cf. “Example 1” on page 1-2232.

A polynomial expression `f` is first converted to a polynomial with the variables given by `vars`. If no variables are given, they are searched for in `f`. See `poly` about details of the conversion. The result is returned as polynomial expression. `FAIL` is returned if `f` cannot be converted to a polynomial. Cf. “Example 3” on page 1-2233.

The result of `tcoeff` is not fully evaluated. Evaluation can be enforced by the function `eval`. Cf. “Example 2” on page 1-2233.

## Examples

### Example 1

We demonstrate how various orderings influence the result:

```
p := poly(5*x^2*y^3 + 4*x^3*y*z + 3*x*y^4*z, [x, y, z]):
tcoeff(p), tcoeff(p, DegreeOrder), tcoeff(p, DegInvLexOrder)
```

3, 5, 4

The following call uses the reverse lexicographical order on 3 indeterminates:

```
tcoeff(p, Dom::MonomOrdering(RevLex(3)))
```

4

```
delete p:
```

### Example 2

The result of tcoeff is not fully evaluated:

```
p := poly(27*x^2 + a*x, [x]): a := 5:
tcoeff(p), eval(tcoeff(p))
```

```
a, 5
```

```
delete p, a:
```

### Example 3

The expression 1/x may not be regarded as polynomial:

```
lterm(1/x)
```

```
FAIL
```

## Parameters

**p**

A polynomial of type DOM\_POLY

**f**

A polynomial expression

**vars**

A list of indeterminates of the polynomial: typically, identifiers or indexed identifiers

**order**

The term ordering: either LexOrder, or DegreeOrder, or DegInvLexOrder, or a user-defined term ordering of type Dom: MonomOrdering. The default is the lexicographical ordering LexOrder.

# **tcoeff**

---

## **Return Values**

Element of the coefficient domain of the polynomial or FAIL.

## **Overloaded By**

$p$

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Decide whether procedure arguments should be tested                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>      | <code>testargs()</code><br><code>testargs(b)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>Inside a procedure, <code>testargs</code> indicates whether the procedure should check its arguments.</p> <p>Checking the input parameters of a procedure may be costly. For this reason, most functions of the MuPAD libraries are implemented according to the following philosophy:</p> <p>If a procedure is called on the interactive level, i.e., if its parameters are supplied interactively by the user, then the parameters should be checked. If the input parameters do not comply with the documented specification of the procedure, then appropriate error messages should be returned to notify the user of wrong usage.</p> <p>If the procedure is called by another procedure, then no check of the parameters should be performed to improve efficiency. The calling procedure is supposed to make sure that appropriate parameters are passed.</p> <p><code>testargs</code> is the tool to check whether the arguments should be tested: called inside the body of a procedure, <code>testargs()</code> returns <code>TRUE</code> if the procedure was called on the interactive level. Otherwise, it returns <code>FALSE</code>.</p> <p><code>testargs</code> has two modes. In the “standard mode”, its functionality is as described above. In the “argument checking mode”, the call <code>testargs()</code> always returns <code>TRUE</code>. This supports the debugging of procedures: any function using <code>testargs</code> checks its parameters and returns useful error messages if called in an inappropriate way.</p> <p>The call <code>testargs(TRUE)</code> switches to the “argument checking mode”, i.e., parameter testing is switched on globally.</p> <p>The call <code>testargs(FALSE)</code> switches to the “standard mode”, i.e., parameter testing is used only on the interactive level.</p> <p>The call <code>testargs(b)</code> returns the previously set value.</p> |

# testargs

---

testargs should not be used to change the behavior of a function other than performing type-checks, since the user may have switched to “argument checking mode”.

Checking the input parameters of a procedure can also be controlled with the function `Pref::typeCheck`.

## Examples

### Example 1

The following example demonstrates how `testargs` should be used inside a procedure. The function `p` is to generate a sequence of `n` zeroes; its argument should be a positive integer:

```
p := proc(n)
begin
 if testargs() then
 if not testtype(n, Type::PosInt) then
 error("expecting a positive integer");
 end_if;
 end_if;
 return(0 $ n)
end_proc:
```

Its argument is checked when `p` is called on the interactive level:

```
p(13/2)
```

```
Error: expecting a positive integer [p]
```

Calling `p` from within a procedure with an inappropriate parameter does not invoke the argument testing. The following strange output is caused by the attempt to evaluate `0 $ n`:

```
f := proc(n) begin p(n) end_proc: f(13/2)
```

```
0 $ $\frac{13}{2}$
```

We switch on the “argument checking mode” of testargs:

```
testargs(TRUE):
```

Now also a non-interactive call to p produces an informative error message:

```
f(13/2)
```

```
Error: expecting a positive integer [p]
```

We clean up, restoring the “standard mode” of testargs:

```
testargs(FALSE): delete f, g:
```

## Parameters

**b**

TRUE or FALSE

## Return Values

TRUE or FALSE.

proc | testtype | Pref::typeCheck

# testeq

---

**Purpose** Check the mathematical equivalence of expressions

**Syntax** `testeq(ex1, options)`  
`testeq(ex1, ex2, options)`

**Description** `testeq(ex1, ex2)` checks whether the expressions `ex1` and `ex2` are mathematically equivalent.

`testeq(ex1, ex2)` returns `TRUE` if the difference `ex1 - ex2` can be simplified to zero.

`testeq` returns `FALSE` if `ex1` and `ex2` attain different values for at least one choice of variables contained in them.

By default, `testeq` performs five random tests. If randomly chosen values of the variables are inconsistent with the assumptions on these variables or the test returns the value `undefined`, the `testeq` function performs an additional test. The number of additional tests cannot exceed the number of initial tests. By default, the maximal total number of tests is 10. See “Example 4” on page 1-2241.

If the equivalence of `ex1` and `ex2` cannot be decided, `testeq` returns `UNKNOWN`.

If only one expression is passed to `testeq`, it is checked whether this expression is equivalent to zero.

`testeq` uses `Simplify(ex1 - ex2)` and `is(ex1 - ex2 = 0)` to determine its result. The result `UNKNOWN` can be caused by weaknesses of `Simplify` and `is`.

Using the options, the simplification process can be made stronger at the cost of increased run time.

## Examples

### Example 1

Check the mathematical equivalence of expressions:

```
testeq(sin(x)^2, 1 - cos(x)^2)
```

TRUE

```
testeq(sin(2*x), 2*sin(x)*cos(x))
```

TRUE

```
testeq((cos(a) + sin(a))^2, 2*(cos(PI/4 - a)^2))
```

TRUE

In order to be equivalent, two expressions must be equivalent for all values their variables can attain. For certain values of the parameter  $a$  the following two expressions are equivalent, but for other values they are not; therefore, they are not equivalent:

```
testeq((cos(a) + sin(a))^2, 3*(cos(PI/4 - a)^2))
```

FALSE

## Example 2

Applying `expand` and `rewrite` to an expression always produces an equivalent expression. However, with the default setting of 100 steps for the internal simplification procedure, the equivalence is not recognized in the following example:

```
f:= exp(arcsin(I*sin(x))):
g:= rewrite(expand(f), ln):
testeq(f, g)
```

UNKNOWN

After 1000 steps, however, the expressions are recognized as being equivalent:

```
testeq(f, g, Steps = 1000);
delete f, g:
```

TRUE

### Example 3

When trying to prove the equivalence of two expressions, the `testeq` command runs random tests before applying `IgnoreAnalyticConstraints`. If tests for random values of identifiers show that expressions are not equivalent, `testeq` disregards the `IgnoreAnalyticConstraints` option and returns FALSE:

```
testeq(x^(ln(a)) * x^(ln(b)) = x^(ln(a*b)), IgnoreAnalyticConstraints)
```

FALSE

If, for a given number of attempts, random tests do not find the inequality between expressions, `testeq` applies the `IgnoreAnalyticConstraints` option:

```
testeq(ln(a) + ln(b) = ln(a*b), IgnoreAnalyticConstraints)
```

TRUE

By default, random tests check the equality of expressions for five random sets of values of identifiers. Increasing the number of attempts can prove inequality:

```
testeq(ln(a) + ln(b) = ln(a*b), NumberOfRandomTests = 10, IgnoreAna
```

FALSE

#### Example 4

When `testeq` performs tests, it takes into account the assumptions on variables that you specify:

```
testeq(x, abs(x)) assuming x > 0
```

TRUE

If `testeq` chooses values of the variables that are inconsistent with the assumptions on these variables, it performs an additional test. The number of tests cannot exceed  $2n$ , where  $n$  is the original number of tests defined by the `NumberOfRandomTests` option. If `testeq` performs  $2n$  tests and all values of the variables are inconsistent with the assumptions on the variables, `testeq` returns UNKNOWN:

```
testeq(x, abs(x)) assuming x^2 + x + 7 = x^13 + 11
```

UNKNOWN

For this particular assumption, MuPAD cannot find a closed-form expression to substitute for  $x$ :

```
solve(x^2 + x + 7 = x^13 + 11, x)
```

```
RootOf(z13 - z2 - z + 4, z)
```

Therefore, increasing the number of tests does not help `testeq` decide if the expressions are equivalent:

```
testeq(x, abs(x), NumberOfRandomTests = 100) assuming x^2 + x +
```

## UNKNOWN

### Parameters

**ex1, ex2**

Any MuPAD expressions

### Options

#### Steps

Option, specified as `Steps = n`

This option is directly passed to `Simplify` and determines the maximum number of steps allowed for the internal simplification process. The default value of `n` is 100. Increasing the number of steps can give you a simpler result, often at the costs of increased runtime. For details, see the `Simplify` help page.

#### Seconds

Option, specified as `Seconds = t`

This option is directly passed to `Simplify` and sets a time limit `t` in seconds for the internal simplification process. The default setting is `infinity`, i.e., the simplification process will not terminate due to a time limitation, but due to other internal stopping criteria. See the documentation of `Simplify` for details.

#### RuleBase

Option, specified as `RuleBase = base`

This option is directly passed to `Simplify` and determines the rule base that is used for the internal simplification process. See the documentation of `Simplify` for details.

The default value of `base` is `Simplify`.

The advanced user can specify her own rule base (see `Simplify`). This allows the construction of specialized and fast tests for special classes of expressions.

#### NumberOfRandomTests

Option, specified as `NumberOfRandomTests = n`

This option determines the number of times `testeq` tries to disprove the equivalence of `ex1` and `ex2` by plugging in some random values for all identifiers.

The default value of `n` is 5. If randomly chosen values of the variables are inconsistent with the assumptions on these variables or the test returns the value `undefined`, the `testeq` function performs an additional test. The total number of tests does not exceed  $2n$ . See “Example 4” on page 1-2241.

### **IgnoreAnalyticConstraints**

This option applies purely algebraic simplifications to expressions `ex1` and `ex2`. For the list of rules, see the documentation of `Simplify`. These simplification rules are not generally valid.

Note that random tests have higher priority than `IgnoreAnalyticConstraints`. When trying to prove the equivalence of two expressions, the `testeq` command runs random tests before applying the `IgnoreAnalyticConstraints` option. If random tests prove the expressions are not equivalent, `testeq` returns the value `FALSE`. See “Example 3” on page 1-2240.

### **Return Values**

TRUE, FALSE, or UNKNOWN

### **See Also**

### **MuPAD Functions**

`is` | `Simplify` | `simplify`

### **Concepts**

- “Test Results”

# testtype

---

**Purpose** Syntactical type checking

**Syntax** `testtype(object, T)`

**Description** `testtype(object, T)` checks whether the object is syntactically of type T.

The type object T may be either a domain type such as `DOM_INT`, `DOM_EXPR` etc., a string as returned by the function `type`, or a `Type` object. The latter are probably the most useful predefined values for the argument T.

---

**Note** `testtype` performs a purely syntactical check. Use `is` for semantical checks taking into account properties of identifiers!

---

See the Algorithms section below for details on the overloading mechanism.

## Examples

### Example 1

The following call tests, whether the first argument is an expression. Expressions are basic objects of domain type `DOM_EXPR`:

```
testtype(x + y, DOM_EXPR)
```

```
TRUE
```

The `type` function distinguishes expressions. The corresponding type string is a valid type object for `testtype`:

```
type(x + y), testtype(x + y, "_plus")
```

```
"_plus", TRUE
```

The following call tests, whether the first argument is an integer by querying, whether it is of domain type `DOM_INT`:

```
testtype(7, DOM_INT)
```

```
TRUE
```

Note that `testtype` performs a purely syntactical test. Mathematically, the integer `7` is a rational number. However, the domain type `DOM_RAT` does not encompass `DOM_INT`:

```
testtype(7, DOM_RAT)
```

```
FALSE
```

The `Type` library provides more flexible type objects. E.g., `Type::Rational` represents the union of `DOM_INT` and `DOM_RAT`:

```
testtype(7, Type::Rational)
```

```
TRUE
```

The number `7` matches other types as well:

```
testtype(7, Type::PosInt), testtype(7, Type::Prime),
testtype(7, Type::Numeric), testtype(7, Type::Odd)
```

```
TRUE, TRUE, TRUE, TRUE
```

## Example 2

Subtypes of expressions can be specified via character strings:

# testtype

---

```
type(f(x)), type(sin(x))
```

```
"function", "sin"
```

```
testtype(sin(x), "function"), testtype(sin(x), "sin"),
testtype(sin(x), "cos")
```

```
TRUE, TRUE, FALSE
```

## Example 3

We demonstrate how to implement a customized type object “div3” which is to represent integer multiples of 3. One has to create a new domain with a “testtypeDom” attribute:

```
div3 := newDomain("divisible by 3?"):
div3::testtypeDom := x -> testtype(x/3, Type::Integer):
```

Via overloading, the command `testtype(object, div3)` calls this slot:

```
testtype(5, div3), testtype(6, div3), testtype(sin(1), div3)
```

```
FALSE, TRUE, FALSE
```

```
delete div3:
```

## Parameters

### object

Any MuPAD object

### T

A type object

**Return Values**

TRUE or FALSE.

**Overloaded By**

object, T

**Algorithms**

Overloading of `testtype` works as follows: First, it is checked whether `domtype(object) = T` or `type(object) = T` holds. If so, `testtype` returns TRUE.

Next, the method "`testtype`" of the domain `object::dom` is called with the arguments `object`, `T`. If this method returns a result other than FAIL, then `testtype` returns this value.

If the method `object::dom::testtype` does not exist or if this method returns FAIL, then overloading by the second argument is used:

- If `T` is a domain, then the method "`testtypeDom`" of `T` is called with the arguments `object`, `T`.
- If `T` is not a domain, then the method "`testtypeDom`" of `T::dom` is called with the arguments `object`, `T`.

**See Also****MuPAD Functions**

`coerce` | `domtype` | `hastype` | `is` | `type`

# text2expr

---

**Purpose** Convert a character string to an expression

**Syntax** `text2expr(text)`

**Description** `text2expr(text)` interprets the character string `text` as MuPAD input and generates the corresponding object.

The text must correspond to syntactically correct MuPAD input. Otherwise, `text2expr` produces an error. Typically, strings created from MuPAD objects via `expr2text` can be reconverted to corresponding objects.

The object is returned without being further evaluated. Evaluation can be enforced using the function `eval`.

The text does not need to be terminated with a “;” or a “:” character, respectively.

`text` cannot refer to local variables of an enclosing procedure by their name. The text is parsed as if entered interactively. Cf. “Example 4” on page 1-2250.

## Examples

### Example 1

A character string is converted to a simple expression. The newly created expression is not evaluated automatically:

```
text2expr("21 + 21")
```

```
21 + 21
```

It may be evaluated via `eval`:

```
eval(%)
```

```
42
```

**Example 2**

A character string is converted to a statement sequence:

```
text2expr("x:= 3; x + 2 + 1"); eval(%)
```

```
(x := 3;
x + 2 + 1)
```

```
6
```

```
x
```

```
3
```

```
delete x:
```

**Example 3**

A matrix is converted to a string:

```
matrix([[a11, a12], [a21, a22]])
```

```
(a11 a12
 a21 a22)
```

```
expr2text(%)
```

```
"matrix([[a11, a12], [a21, a22]])"
```

The string is reconverted to a matrix:

# text2expr

---

```
text2expr(%)
```

```
(a11 a12)
 (a21 a22)
```

```
eval(%)
```

```
(a11 a12)
 (a21 a22)
```

## Example 4

text2expr will not create a DOM\_VAR of an enclosing procedure from its name:

```
a := "global identifier":
g := proc()
 local a;
 begin
 a := "local variable";
 print(a);
 print(eval(text2expr("a")));
 end_proc:
g();
```

```
"local variable"
```

```
"global identifier"
```

## Parameters

**text**

A character string

## Return Values

MuPAD object.

## See Also

## MuPAD Functions

`coerce` | `expr2text` | `input` | `int2text` | `tbl2text` | `text2int`  
| `text2list` | `text2tbl`

# text2int

---

**Purpose** Convert a character string to an integer

**Syntax** `text2int(text, <b>)`

**Description** `text2int(text, b)` converts a character string corresponding to an integer in *b*-adic representation to an integer of type `DOM_INT`.

It must consist of the first *b* characters in 0, 1, ..., 9, *A*, *B*, ..., *Z*, *a*, *b*, ..., *z*. The letters are used to represent the *b*-adic digits larger than 9.

For bases larger than 10 but smaller than 37 the letters are not case sensitive. The lower case letters *a*, *b*, ..., *z* are accepted:  $a = A = 10$ , ...,  $z = Z = 35$ .

`text2int` is the inverse of `int2text`.

## Examples

### Example 1

Relative to the default base 10, `text2int` provides a mere datatype conversion from `DOM_STRING` to `DOM_INT`:

```
text2int("123"), text2int("-45678")
```

```
123, -45678
```

### Example 2

The characters of the input string are interpreted as digits with respect to the specified base, the return value is a standard MuPAD integer represented with respect to the decimal system. The following example converts integers from the base 2 and 16, respectively, to the base 10:

```
text2int("101", 2), text2int("101", 16)
```

```
5, 257
```

The digit “3” does not exist in a binary representation:

```
text2int("103", 2)
```

```
Error: The argument is invalid. [text2int]
```

### Example 3

For bases larger than 10 but smaller than 37, the letters are not case-sensitive:

```
text2int("3B9ACA00", 16), text2int("Z", 36) = text2int("z", 36)
```

```
1000000000, 35 = 35
```

For bases larger than 37 however, the case makes a difference:

```
text2int("Z", 62) <> text2int("z", 62)
```

```
35 ≠ 61
```

## Parameters

**text**

A character string

**b**

The base: an integer between 2 and 62. The default base is 10.

## Return Values

Integer.

## See Also

## MuPAD Functions

coerce | expr2text | genpoly | int2text | numlib::g\_adic |  
tbl2text | text2expr | text2list | text2tbl

# text2list

---

**Purpose** Split a character string into a list of substrings

**Syntax** `text2list(text, separators, <Cyclic>)`

**Description** `text2list` splits a character string into a list of substrings, using the strings in the list `separators` as delimiters. `text2list` returns a list containing the substrings.

Without the option `Cyclic`, the text is split as follows. The first occurrence of one of the delimiters in `separators` is located in `text`. If no delimiter is found, the full text is returned as the only substring. Otherwise, the substring up to the delimiter defines the first substring. The delimiter is the second substring. The remaining text is processed as above until there are no more characters left.

Without `Cyclic`, the result does not depend on the order of the delimiters.

With the option `Cyclic`, the first delimiter in `separators` is used to identify the first substring. The delimiter itself is the second substring. Then the second delimiter in `separators` is used to identify the third substring etc.

After using the last delimiter of the list, the first one is used again, until the whole text is processed or until the current delimiter is not found in the remaining text.

With `Cyclic`, the result depends on the order of the delimiters.

`text2list` is a function of the system kernel.

## Examples

### Example 1

The following example demonstrates the difference in calling `text2list` with and without the option `Cyclic`:

```
text2list("This is a simple example!", ["is", "mp"])
```

```
["Th", "is", " ", "is", " a si", "mp", "le exa", "mp", "le!"]
```

```
text2list("This is a simple example!", ["is", "mp"], Cyclic)

["Th", "is", " is a si", "mp", "le example!"]
```

## Example 2

The following example demonstrates the difference in calling `text2tbl` with and without the option `Cyclic`:

```
text2tbl("This is a simple example!", ["is", "mp"])
```

```
1 | "Th"
2 | "is"
3 | ""
4 | "is"
5 | " a si"
6 | "mp"
7 | "le exa"
8 | "mp"
9 | "le!"
```

```
text2tbl("This is a simple example!", ["is", "mp"], Cyclic)
```

```
1 | "Th"
2 | "is"
3 | " is a si"
4 | "mp"
5 | "le example!"
```

## Parameters

### **text**

The text to be analyzed: a character string

### **separators**

# text2list

---

Delimiters: a list of character strings. The empty string "" is not accepted as a delimiter.

## Options

### Cyclic

The delimiter list is used cyclicly

## Return Values

List, respectively a table, of character strings.

## See Also

## MuPAD Functions

text2tbl | coerce | expr2text | int2text | tbl2text |  
text2expr | text2int

**Purpose**

Split a character string into a table of substrings

**Syntax**

```
text2tbl(text, separators, <Cyclic>)
```

**Description**

`text2tbl` splits a character string into a table of substrings, using the strings in the list `separators` as delimiters. `text2tbl` returns a table, using the indices 1, 2, 3 etc.

Without the option `Cyclic`, the text is split as follows. The first occurrence of one of the delimiters in `separators` is located in `text`. If no delimiter is found, the full text is returned as the only substring. Otherwise, the substring up to the delimiter defines the first substring. The delimiter is the second substring. The remaining text is processed as above until there are no more characters left.

Without `Cyclic`, the result does not depend on the order of the delimiters.

With the option `Cyclic`, the first delimiter in `separators` is used to identify the first substring. The delimiter itself is the second substring. Then the second delimiter in `separators` is used to identify the third substring etc.

After using the last delimiter of the list, the first one is used again, until the whole text is processed or until the current delimiter is not found in the remaining text.

With `Cyclic`, the result depends on the order of the delimiters.

`tbl2text` restores strings split by `text2tbl`.

`text2tbl` is a function of the system kernel.

**Examples****Example 1**

The following example demonstrates the difference in calling `text2tbl` with and without the option `Cyclic`:

```
text2tbl("This is a simple example!", ["is", "mp"])
```

# text2tbl

---

```
["Th", "is", " ", "is", " a si", "mp", "le exa", "mp", "le!"]
```

```
text2list("This is a simple example!", ["is", "mp"], Cyclic)
```

```
["Th", "is", " is a si", "mp", "le example!"]
```

## Example 2

The following example demonstrates the difference in calling `text2tbl` with and without the option `Cyclic`:

```
text2tbl("This is a simple example!", ["is", "mp"])
```

```
1 | "Th"
2 | "is"
3 | "
4 | "is"
5 | " a si"
6 | "mp"
7 | "le exa"
8 | "mp"
9 | "le!"
```

```
text2tbl("This is a simple example!", ["is", "mp"], Cyclic)
```

```
1 | "Th"
2 | "is"
3 | " is a si"
4 | "mp"
5 | "le example!"
```

## Parameters `text`

The text to be analyzed: a character string

**separators**

Delimiters: a list of character strings. The empty string "" is not accepted as a delimiter.

**Options****Cyclic**

The delimiter list is used cyclicly

**Return Values**

List, respectively a table, of character strings.

**See Also****MuPAD Functions**

`text2list` | `coerce` | `expr2text` | `int2text` | `tbl2text` |  
`text2expr` | `text2int`

# textinput

---

**Purpose** Interactive input of text

**Syntax** `textinput(<prompt1>)`  
`textinput(<prompt1>, x1, <prompt2>, x2, )`

**Description** `textinput` allows interactive input of text.

`textinput()` displays the prompt “Please enter text:” and waits for input by the user. The input is converted to a character string, which is returned as the function’s return value.

`textinput(prompt1)` uses the character string `prompt1` instead of the default prompt “Please enter text:”.

`textinput( prompt1 x1)` converts the input to a character string and assigns this string to the identifier or local variable `x1`. The default prompt is used, if no prompt string is specified.

Several input values can be read with a single `textinput` command. Each identifier in the sequence of arguments makes `textinput` return a prompt, waiting for input to be assigned to the identifier or variable. A character string preceding the identifier or variable in the argument sequence replaces the default prompt. Cf. “Example 3” on page 1-2261. Arguments that are neither prompt strings nor identifiers or variables are ignored.

The input may extend over several lines. In the output string, MuPAD uses the character `\n` (carriage return) to separate lines.

Input characters with a leading `\` are not interpreted as control characters, but as two separate characters.

The identifiers or variables `x1` etc. may have values. These are overwritten by `textinput`.

## Examples

### Example 1

The default prompt is displayed, the input is converted to a character string and returned:

```
textinput()
```

```
Please enter text input: << myinput >>
```

```
"myinput"
```

## Example 2

A user-defined prompt is used, the input is assigned to the identifier x:

```
textinput("enter your name: ", x)
```

```
enter your name: << Turing >>
```

```
"Turing"
```

```
x
```

```
"Turing"
```

```
delete x:
```

## Example 3

If several values are to be read, separate prompts can be defined for each value:

```
textinput("She: ", hername, "He: ", hisname)
```

```
She: << Bonnie >> He: <<
Clyde >>
```

```
"Clyde"
```

```
hername, hisname
```

# textinput

---

```
"Bonnie", "Clyde"
```

```
delete hername, hisname:
```

## Parameters

**prompt1, prompt2, ...**

Input prompts: character strings

**x1, x2, ...**

identifiers or local variables

## Return Values

Last input, converted to a character string.

## See Also

## MuPAD Functions

```
finput | fname | fprintf | fread | ftextinput | input |
import::readbitmap | import::readdata | print | read |
text2expr | write
```

## Purpose

Maximum number of characters in an output line

## Description

The environment variable TEXTWIDTH determines the maximum number of characters in one line of screen output.

Possible values: Positive integer smaller than  $2^{31}$ .

Output is broken into several lines if it needs more than TEXTWIDTH characters per line.

Deletion via the statement “`delete TEXTWIDTH`” resets TEXTWIDTH to its default value. Executing the function `reset` also restores the default value.

The minimal value of TEXTWIDTH is 10.

TEXTWIDTH is set to its maximum value  $2^{31} - 1$  when printing to a text file using `fprint`. Thus, no additional line breaks occur in the output.

TEXTWIDTH does not influence the typesetting of expressions which is available for some user interfaces of MuPAD.

TEXTWIDTH is set to the new number of available columns every time the console is resized.

## Examples

### Example 1

Set the maximum number of characters in one line of screen output to 15:

```
TEXTWIDTH := 15:
```

Restore TEXTWIDTH to its default value:

```
delete TEXTWIDTH
```

### Example 2

The following procedure adds empty characters to produce output that is flushed right:

```
myprint := proc(x) local l; begin
```

# TEXTWIDTH

---

```
if domtype(x) <> DOM_STRING then
 x := expr2text(x);
end_if;
l := length(x);
print(Unquoted, _concat(" " $ TEXTWIDTH - l, x))
end_proc:
```

```
myprint("hello world"): myprint(30!): myprint("bye bye"):
```

hel

2652528598121910586363084

```
delete myprint:
```

## Related Examples

- “Set Line Length in Plain Text Outputs”

**Purpose** Theta series

**Syntax** theta(x)

**Description** theta(x) represents the value of the theta series  $\sum_{n=-\infty}^{\infty} e^{-\pi x n^2}$ .  
 The theta series converges for all complex numbers x with positive real part.  
 Floating-point results are computed for floating-point arguments. For other arguments, the function returns symbolically with the imaginary part of complex numbers normalized to lie between zero and 2.

**Environment Interactions** When called with a floating-point argument, the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

The theta series takes on large values for small positive arguments. Small values are taken on near  $I$ :

`theta(0.001), theta(0.001 + I)`

`31.6227766, 5.092623095 10-340`

### Example 2

Since the theta series is  $(2i)$ -periodic, the imaginary part of complex arguments may be reduced:

`theta(7 + 5*I)`

`theta(7 + i)`

# theta

---

For exact or symbolic arguments, a symbolic call is returned:

`theta(3), theta(x)`

`theta(3), theta(x)`

## Parameters

**x**

An arithmetical expression

## Return Values

Arithmetical expression

## See Also

## MuPAD Functions

`dedekindEta` | `zeta`

**Purpose** Measure real time

**Syntax** `rtime()`  
`rtime(a1, a2, ...)`

**Description** `rtime()` returns the real time in milliseconds that elapsed since the start of the current MuPAD session.

`rtime(a1, a2, ...)` returns the real time needed to evaluate all arguments.

The result of `rtime` is the real time. Thus, `rtime` can be used to measure the total time spent by the MuPAD process as well as by external processes spawned from inside the MuPAD session. Note that an interactive call of `rtime()` is not very useful, since the idle time of the user is included. However, `rtime(a1, a2, ...)` often yields a useful and more realistic timing than `time(a1, a2, ...)` if the evaluation of the arguments spawns external processes. Such a situation may arise in a numerical computation because some routines of the numeric library call external numerical tools using hardware floats. Cf. “Example 4” on page 6-92.

If no external process besides MuPAD are running, the timings returned by `rtime(a1, a2, ...)` and `time(a1, a2, ...)` roughly coincide.

On computers without “time-sharing”, such as the Macintosh computer, real time and CPU time roughly coincide.

`rtime` is a function of the system kernel.

**Examples**      **Example 1**

This example shows how to do a time measurement and assign the computed value to an identifier at the same time. Note that the assignment needs extra parenthesis when passed as argument:

```
time((a := int(exp(x)*sin(x), x)))
```

```
464.029
```

```
a
```

$$-\frac{e^x (\cos(x) - \sin(x))}{2}$$

```
delete a:
```

Alternatively, one may time groups of statements in the following way:

```
t0 := time():
command1
command2
...
time() - t0
```

## Example 2

Here we use `rtime` to compute the elapsed hours, minutes and seconds since this session was started:

```
t := rtime()/1000:
h := trunc(t/3600):
m := trunc(t/60 - h*60):
s := trunc(t - m*60 - h*3600):

print(Unquoted, "This session is running for " .
 h . " hours, " .
 m . " minutes and " .
 s . " seconds.")

This
session is running for 0 hours, 0 minutes and 10 seconds.

delete t, h, m, s:
```

### Example 3

To obtain a nicer output, the measured time can be multiplied with the appropriate time unit:

```
time(isprime(2^1000000000 - 1))*unit::msec
```

```
280.018 msec
```

Alternatively, use `stringlib::formatTime`:

```
stringlib::formatTime(time(isprime(2^1000000000 - 1)))
```

```
"0.280017 seconds"
```

#### Parameters

**a1, a2, ...**

Arbitrary MuPAD objects

#### Return Values

Nonnegative integer giving the elapsed time in milliseconds.

#### See Also

#### MuPAD Functions

`time` | `prog::profile`

#### Concepts

- “Measure Time”

# time

---

**Purpose** Measure CPU time

**Syntax** `time()`  
`time(a1, a2, ...)`

**Description** `time()` returns the total CPU time in milliseconds that was spent by the current MuPAD process.

`time(a1, a2, ...)` returns the CPU time needed by the current MuPAD process to evaluate all arguments.

The result of `time()` comprises all the computation time spent by the MuPAD process. This includes the time for system initialization and reading input (parsing). However, it excludes the time spent by other external processes, even if they were spawned from inside the MuPAD session or if they were started by a `system` command. Further, in an interactive session, the idle time between the execution of MuPAD commands is excluded.

If no external process besides MuPAD are running, the timings returned by `rtime(a1, a2, ...)` and `time(a1, a2, ...)` roughly coincide.

The time returned by `time` is computed in a system-dependent way, usually counting the number of clock ticks of the system clock. Hence, the result is a multiple of the system's time unit and cannot be more precise than 1 such unit. E.g., the time unit is 10 milliseconds for many UNIX systems.

On computers without "time-sharing", such as the Macintosh computer, real time and CPU time roughly coincide.

`time` is a function of the system kernel.

## Examples

### Example 1

This example shows how to do a time measurement and assign the computed value to an identifier at the same time. Note that the assignment needs extra parenthesis when passed as argument:

```
time((a := int(exp(x)*sin(x), x)))
```

```
464.029
```

```
a
```

$$-\frac{e^x (\cos(x) - \sin(x))}{2}$$

```
delete a:
```

Alternatively, one may time groups of statements in the following way:

```
t0 := time():
command1
command2
...
time() - t0
```

## Example 2

Here we use `rtime` to compute the elapsed hours, minutes and seconds since this session was started:

```
t := rtime()/1000:
h := trunc(t/3600):
m := trunc(t/60 - h*60):
s := trunc(t - m*60 - h*3600):

print(Unquoted, "This session is running for " .
 h . " hours, " .
 m . " minutes and " .
 s . " seconds.")
```

```
This
session is running for 0 hours, 0 minutes and 10 seconds.
```

```
delete t, h, m, s:
```

## Example 3

To obtain a nicer output, the measured time can be multiplied with the appropriate time unit:

```
time(isprime(2^1000000000 - 1))*unit::msec
```

```
280.018 msec
```

Alternatively, use `stringlib::formatTime`:

```
stringlib::formatTime(time(isprime(2^1000000000 - 1)))
```

```
"0.280017 seconds"
```

## Parameters

## Concepts

- “Measure Time”

**Purpose** Transpose of a matrix

**Syntax** `transpose(A)`

**Description** `transpose(A)` returns the transpose  $A^t$  of the matrix  $A$ .

The transpose of the  $m \ n$  matrix  $A$  is the  $n \ m$  matrix  $B$  with  $B_{i,j} = A_{j,i}$ .

If the input is a matrix of category `Cat::Matrix`, then `linalg::transpose` is called to compute the result. In contrast to the `linalg` routines, the function `transpose` also operates on arrays and `hfarrays`.

If the argument does not evaluate to a matrix of one of the types mentioned above, symbolic call `transpose(A)` is returned.

## Examples **Example 1**

The following matrix is real. Thus, the Hermitian transpose coincides with the transpose:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & \pi \end{pmatrix}$$

```
transpose(A) = htranspose(A)
```

$$\begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix} = \begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix}$$

In general, this does not hold for complex matrices:

```
A := hfarray(1..2, 1..3, [[1, I, 3 + I], [PI*I, 4, 5]])
```

# transpose

---

$$\begin{pmatrix} 1.0 & 1.0 i & 3.0 + 1.0 i \\ 3.141592654 i & 4.0 & 5.0 \end{pmatrix}$$

`transpose(A) <> htranspose(A)`

$$\begin{pmatrix} 1.0 & 3.141592654 i \\ 1.0 i & 4.0 \\ 3.0 + 1.0 i & 5.0 \end{pmatrix} \neq \begin{pmatrix} 1.0 & -3.141592654 i \\ -1.0 i & 4.0 \\ 3.0 - 1.0 i & 5.0 \end{pmatrix}$$

`delete A:`

## Example 2

We compute the product  $A^H A$  of a matrix given by a hardware float array. This data type allows matrix multiplication using the operator `*`:

`A := hffarray(1..2, 1..3, [[1, I, 3], [PI*I, 4, 5 + I]])`

$$\begin{pmatrix} 1.0 & 1.0 i & 3.0 \\ 3.141592654 i & 4.0 & 5.0 + 1.0 i \end{pmatrix}$$

`AH:= htranspose(A)`

$$\begin{pmatrix} 1.0 & -3.141592654 i \\ -1.0 i & 4.0 \\ 3.0 & 5.0 - 1.0 i \end{pmatrix}$$

The product  $A^H A$  is Hermitian:

`AH*A = htranspose(AH*A)`

$$\begin{pmatrix} 10.8696044 & -11.56637061 i & 6.141592654 - 15.70796327 i \\ 11.56637061 i & 17.0 & 20.0 + 1.0 i \\ 6.141592654 + 15.70796327 i & 20.0 - 1.0 i & 35.0 \end{pmatrix} = \begin{pmatrix} 10.8696044 & -11.56637061 i & 6.141592654 - 15.70796327 i \\ 11.56637061 i & 17.0 & 20.0 + 1.0 i \\ 6.141592654 + 15.70796327 i & 20.0 - 1.0 i & 35.0 \end{pmatrix}$$

delete A, AH:

### Example 3

If the input does not evaluate to a matrix, then symbolic calls are returned:

delete A, B:  
`transpose(A) + 2*htranspose(B)`

$$2 \overline{B}^t + A^t$$

## Parameters

**A**

A matrix: either a 2-dimensional array, a 2-dimensional harray, or an object of the category `Cat::Matrix`

## Return Values

Matrix of the same domain type as A.

## Overloaded By

A

# transpose

---

## See Also

## MuPAD Functions

`htranspose` | `linalg::transpose` | `linalg::htranspose`

## Concepts

- “Transpose Matrices”

**Purpose** The Hermitian transpose of a matrix

**Syntax** `htranspose(A)`

**Description** `htranspose(A)` returns the Hermitian transpose  $A^H$  of the matrix  $A$  (the complex conjugate of the transpose of  $A$ ).

The Hermitian transpose of the  $m \ n$  matrix  $A$  is the  $n \ m$  matrix  $B$  with  $B_{i,j} = \overline{A_{j,i}}$ .

If the input is a matrix of category `Cat::Matrix`, then `linalg::htranspose` is called to compute the result. In contrast to the `linalg` routines, the function `htranspose` also operates on arrays and `hfarrays`.

If the argument does not evaluate to a matrix of one of the types mentioned above, symbolic call `htranspose(A)` is returned.

## Examples **Example 1**

The following matrix is real. Thus, the Hermitian transpose coincides with the transpose:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & \pi \end{pmatrix}$$

```
transpose(A) = htranspose(A)
```

$$\begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix} = \begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix}$$

In general, this does not hold for complex matrices:

```
A := hfarray(1..2, 1..3, [[1, I, 3 + I], [PI*I, 4, 5]])
```

# htranspose

---

$$\begin{pmatrix} 1.0 & 1.0 i & 3.0 + 1.0 i \\ 3.141592654 i & 4.0 & 5.0 \end{pmatrix}$$

`transpose(A) <> htranspose(A)`

$$\begin{pmatrix} 1.0 & 3.141592654 i \\ 1.0 i & 4.0 \\ 3.0 + 1.0 i & 5.0 \end{pmatrix} \neq \begin{pmatrix} 1.0 & -3.141592654 i \\ -1.0 i & 4.0 \\ 3.0 - 1.0 i & 5.0 \end{pmatrix}$$

`delete A:`

## Example 2

We compute the product  $A^H A$  of a matrix given by a hardware float array. This data type allows matrix multiplication using the operator `*`:

`A := hfarrray(1..2, 1..3, [[1, I, 3], [PI*I, 4, 5 + I]])`

$$\begin{pmatrix} 1.0 & 1.0 i & 3.0 \\ 3.141592654 i & 4.0 & 5.0 + 1.0 i \end{pmatrix}$$

`AH:= htranspose(A)`

$$\begin{pmatrix} 1.0 & -3.141592654 i \\ -1.0 i & 4.0 \\ 3.0 & 5.0 - 1.0 i \end{pmatrix}$$

The product  $A^H A$  is Hermitian:

`AH*A = htranspose(AH*A)`

$$\begin{pmatrix} 10.8696044 & -11.56637061 i & 6.141592654 - 15.70796327 i \\ 11.56637061 i & 17.0 & 20.0 + 1.0 i \\ 6.141592654 + 15.70796327 i & 20.0 - 1.0 i & 35.0 \end{pmatrix} = \begin{pmatrix} 10.8696044 & -11.56637061 i & 6.141592654 - 15.70796327 i \\ 11.56637061 i & 17.0 & 20.0 + 1.0 i \\ 6.141592654 + 15.70796327 i & 20.0 - 1.0 i & 35.0 \end{pmatrix}$$

delete A, AH:

### Example 3

If the input does not evaluate to a matrix, then symbolic calls are returned:

delete A, B:  
`transpose(A) + 2*htranspose(B)`

$$2 \overline{B}^t + A^t$$

## Parameters

## MuPAD Functions

`transpose` | `linalg::transpose` | `linalg::htranspose`

## Concepts

- “Transpose Matrices”

**Purpose**

Trap errors

**Syntax**

```
traperror(object)
traperror(object, t)
traperror(object, MaxSteps = s)
```

**Description**

`traperror(object)` traps errors produced by the evaluation of `object`.

`traperror(object, t)` does the same. Moreover, it stops the evaluation if it is not finished after a real time of `t` seconds.

`traperror` traps errors caused by the evaluation of the object. Syntactical errors, i.e., errors on parsing the object, cannot be caught. The same holds true for fatal errors causing the termination of MuPAD.

`traperror` returns the error code 0 if no error happened. The error code is 1320 if the given time limit `t` is exceeded (“Execution time exceeded”) and 1321 if the given number of “execution steps” is exceeded. The error code is 1028 if the error was raised by the command `error`.

If `traperror` is called with a numerical second argument, this number is taken as a time limit, measured in seconds, of “process time” (see the documentation of the `time` function for a discussion of this term).

When using the option `MaxSteps = s`, the caller sets a time limit which is not system-dependent, but rather measured in terms of MuPAD evaluation steps.

The number `s` does *not* refer directly to evaluation steps, but rather to a fixed (large) number of steps which may change from one MuPAD release to the next, but is fixed within one release. The number `s` is twice the number of outputs caused by `Pref::report(9)` for a calculation using the maximum time allowed.

If `traperror` has no time limit set and an “Execution time exceeded” error is raised by an enclosing `traperror(..., t)` command, then this error is not trapped by the inner `traperror`. It is trapped by the `traperror` call that has set the time limit. Cf. “Example 5” on page 1-2284.

# traperror

---

The object can be an assignment which, for syntactical reasons, must be enclosed in additional brackets. The following code fragment demonstrates a typical application of traperror:

```
if traperror((x := SomeErrorProneFunction())) = 0 then
 DoSomethingWith(x);
else RespondToTheError();
end_if;
```

Use lasterror to reproduce the trapped error.

## Examples

### Example 1

Errors that happen during the execution of kernel functions have various error codes, depending on the problem. E.g., “Division by zero” produces the error code 1025:

```
y := 1/x: traperror(subs(y, x = 0))
```

```
1025
```

```
lasterror()
```

```
Error: Division by zero. [_power]
```

### Example 2

All errors raised using the function error have the error code 1028. Errors during the execution of library functions are of this kind:

```
traperror(error("My error!"))
```

```
1028
```

```
lasterror()
```

```
Error: My error!
```

### Example 3

We try to factor a polynomial, but give up after ten seconds:

```
traperror(factor(x^1000 + 4*x + 1), 10)
```

```
1320
```

```
lasterror()
```

```
Error: Execution time exceeded; Evaluating:
faclib::univ_mod_gcd
```

### Example 4

For use inside other routines, it is preferable to use MaxSteps instead of a time limit, to achieve consistent results across slower and faster machines:

```
traperror(factor(x^1000 + 4*x + 1), MaxSteps=10)
```

```
1321
```

```
lasterror()
```

```
Error: Execution MaxSteps exceeded [traperror];
Evaluating: faclib::ddf
```

# traperror

---

Note that evaluation steps may take vastly different amounts of time, so even on the same machine, different expressions evaluated with the same value of `MaxSteps` may be terminated after very different lengths of time:

```
time(traperror(factor(x^1000 + 4*x + 1), MaxSteps=1));
time(traperror(while TRUE do 1 end_while, MaxSteps=1));
time(traperror(int(1/sqrt(1/r-1/r0), r=0..r0), MaxSteps=1))
```

2204

40

468

## Example 5

Here we have two nested `traperror` calls. The inner call contains an unterminated loop and the outer call has a time limit of 2 seconds. When the execution time is exceeded, this special error is not trapped by the inner `traperror` call. Because of the error, `print(1)` is never executed:

```
traperror((traperror((while TRUE do 1 end)); print(1)), 2)
```

1320

```
lasterror()
```

Error: Execution time is exceeded.

**Parameters**    **object**

Any MuPAD object

**t**

The time limit: a positive integer

**s**

The execution limit: a positive integer

## **Return Values**

Nonnegative integer.

## **See Also**

## **MuPAD Functions**

getlasterror | error | lasterror

# triangularPulse

---

**Purpose** Triangular pulse function

**Syntax** `triangularPulse(a, b, c, x)`  
`triangularPulse(a, c, x)`

**Description** `triangularPulse(a, b, c, x)` represents the triangular function.

`triangularPulse(a, c, x)` is a shortcut for `triangularPulse(a, (a + c)/2, c, x)`.

`triangularPulse(x)` is a shortcut for `triangularPulse(-1, 0, 1, x)`.

`triangularPulse` represents the triangular pulse function. This function is also called the triangle function, hat function, tent function, or sawtooth function.

If `a`, `b`, and `c` are variables or expressions with variables, `triangularPulse` assumes that  $a \leq b \leq c$ . If `a`, `b`, and `c` are numerical values that do not satisfy this condition, `triangularPulse` throws an error.

If  $a < x < b$ , the triangular function equals  $(x - a) / (b - a)$ .

If  $b < x < c$ , the triangular function equals  $(c - x) / (c - b)$ .

Otherwise, it equals 0. See “Example 1” on page 1-2287 and “Example 2” on page 1-2287.

If  $a = b$  or  $b = c$ , the triangular function can be expressed in terms of the rectangular function. See “Example 3” on page 1-2287.

If  $a = b = c$ , `triangularPulse` returns 0. See “Example 4” on page 1-2288.

`triangularPulse(x)` is equivalent to `triangularPulse(-1, 0, 1, x)`. See “Example 5” on page 1-2288.

`triangularPulse(a, c, x)` is equivalent to `triangularPulse(a, (a + c)/2, c, x)`. See “Example 6” on page 1-2289.

`triangularPulse` also accepts infinities as its arguments. See “Example 9” on page 1-2290.

triangularPulse and tripulse are equivalent.

## Examples

### Example 1

Compute the triangular pulse function for these input arguments:

```
[triangularPulse(-2, 0, 2, -3), triangularPulse(-2, 0, 2, -1/2),
triangularPulse(-2, 0, 2, 0), triangularPulse(-2, 0, 2, 3/2),
triangularPulse(-2, 0, 2, 3)]
```

```
[0, 3/4, 1, 1/4, 0]
```

### Example 2

Compute the triangular pulse function for  $a < x < b$ :

```
triangularPulse(a, b, c, x) assuming a < x < b
```

$$\frac{a - x}{a - b}$$

Compute the triangular pulse function for  $b < x < c$ :

```
triangularPulse(a, b, c, x) assuming b < x < c
```

$$\frac{c - x}{b - c}$$

### Example 3

Compute the triangular pulse function for  $a = b$  and  $c = b$ :

```
triangularPulse(b, b, c, x) assuming b < c
```

# triangularPulse

---

$$\frac{(c - x) \text{rectangularPulse}(b, c, x)}{b - c}$$

triangularPulse(a, b, b, x) assuming a < b

$$\frac{(a - x) \text{rectangularPulse}(a, b, x)}{a - b}$$

## Example 4

For a = b = c, the triangular pulse function returns 0:

triangularPulse(a, a, a, x)

0

## Example 5

Use triangularPulse with one input argument as a shortcut for computing triangularPulse(-1, 0, 1, x):

triangularPulse(x)

triangularPulse(-1, 0, 1, x)

[triangularPulse(-10), triangularPulse(-3/4), triangularPulse(0),  
triangularPulse(2/3), triangularPulse(1)]

[0, 1/4, 1, 1/3, 0]

## Example 6

Use triangularPulse with three input arguments as a shortcut for computing triangularPulse(a, (a + c)/2, c, x):

```
triangularPulse(a, c, x)
```

```
triangularPulse(a, a/2 + c/2, c, x)
```

```
[triangularPulse(-10, 10, 3), triangularPulse(-1/2, -1/4, -2/3),
triangularPulse(2, 4, 6), triangularPulse(-1, 4, 0)]
```

```
[7/10, 0, 1, 0, 2/5]
```

## Example 7

Rewrite the triangular pulse function in terms of the Heaviside step function:

```
rewrite(triangularPulse(a, b, c, x), heaviside)
```

$$\frac{\text{heaviside}(x - a)(a - x)}{a - b} - \frac{\text{heaviside}(x - b)(a - x)}{a - b} - \frac{\text{heaviside}(x - b)(c - x)}{b - c} + \frac{\text{heaviside}(x - c)(c - x)}{b - c}$$

## Example 8

Plot the triangular pulse function:

```
plot(triangularPulse(x), x = -2..2)
```

# triangularPulse

---

## Example 9

Plot the triangular pulse function for which the argument  $c$  is a positive infinity:

```
plot(triangularPulse(-1, 1, infinity, x))
```

**Parameters**  $a, b, c, x$   
Arithmetical expressions.

**Return Values** Arithmetical expression.

**Overloaded By**  $x$

**See Also**

**MuPAD Functions** `heaviside` | `piecewise` | `rectangularPulse`

# tripulse

---

**Purpose**            Triangular pulse function

**Syntax**            `tripulse(a, b, c, x)`  
                      `tripulse(a, c, x)`

**Description**        `tripulse(a, b, c, x)` represents the triangular function.  
`tripulse(a, c, x)` is a shortcut for `tripulse(a, (a + c)/2, c, x)`.  
`tripulse(x)` is a shortcut for `tripulse(-1, 0, 1, x)`.  
`tripulse` and `triangularPulse` are equivalent. These functions represent the triangular pulse function. For details and examples, see `triangularPulse`.

**Parameters**        **a, b, c, x**  
                          Arithmetical expressions.

**Return Values**     Arithmetical expression.

**Overloaded By**     x

**See Also**

**MuPAD Functions**    `triangularPulse` | `heaviside` | `piecewise` | `rectangularPulse`

**Purpose**

Boolean constant TRUE

**Description**

MuPAD uses a three state logic with the Boolean constants TRUE, FALSE, and UNKNOWN.

The Boolean constants TRUE, FALSE, UNKNOWN are of domain type DOM\_BOOL.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as bool and is. These functions evaluate Boolean expressions such as equations and inequalities.

**Examples****Example 1**

The Boolean constants may be combined via and, or, and not:

```
(TRUE and (not FALSE)) or UNKNOWN
```

```
TRUE
```

**Example 2**

The function bool serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:

```
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)
```

```
TRUE
```

The function is evaluates symbolic Boolean expressions with properties:

```
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)
```

```
TRUE, FALSE, UNKNOWN
```

```
unassume(x):
```

### Example 3

Boolean constants occur in the conditional part of program control structures such as `if`, `repeat`, or `while` statements. The following loop searches for the smallest Mersenne prime larger than 500 (see `numlib::mersenne` for details). The function `isprime` returns `TRUE` if its argument is a prime, and `FALSE` otherwise. Once a Mersenne prime is found, the `while`-loop is interrupted by the `break` statement:

```
p := 500:
while TRUE do
 p := nextprime(p + 1):
 if isprime(2^p - 1) then
 print(p);
 break;
 end_if;
end_while:
```

521

Note that the conditional part of `if`, `repeat`, and `while` statements must evaluate to `TRUE` or `FALSE`. Any other value leads to an error:

```
if UNKNOWN then "true" else "false" end_if
```

```
Error: Cannot evaluate to Boolean. [if]
```

```
delete p:
```

# FALSE

---

**Purpose** Boolean constant FALSE

**Description** MuPAD uses a three state logic with the Boolean constants TRUE, FALSE, and UNKNOWN.  
The Boolean constants TRUE, FALSE, UNKNOWN are of domain type DOM\_BOOL.  
See and, or, not for the logical rules of the MuPAD three state logic.  
Boolean constants are returned by system functions such as bool and is. These functions evaluate Boolean expressions such as equations and inequalities.

**Examples** **Example 1**

The Boolean constants may be combined via and, or, and not:

```
(TRUE and (not FALSE)) or UNKNOWN
```

```
TRUE
```

**Example 2**

The function bool serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:

```
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)
```

```
TRUE
```

The function is evaluates symbolic Boolean expressions with properties:

```
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)
```

```
TRUE, FALSE, UNKNOWN
```

```
unassume(x):
```

### Example 3

Boolean constants occur in the conditional part of program control structures such as `if`, `repeat`, or `while` statements. The following loop searches for the smallest Mersenne prime larger than 500 (see `numlib::mersenne` for details). The function `isprime` returns `TRUE` if its argument is a prime, and `FALSE` otherwise. Once a Mersenne prime is found, the `while`-loop is interrupted by the `break` statement:

```
p := 500:
while TRUE do
 p := nextprime(p + 1):
 if isprime(2^p - 1) then
 print(p);
 break;
 end_if;
end_while:
```

521

Note that the conditional part of `if`, `repeat`, and `while` statements must evaluate to `TRUE` or `FALSE`. Any other value leads to an error:

```
if UNKNOWN then "true" else "false" end_if
```

```
Error: Cannot evaluate to Boolean. [if]
```

```
delete p:
```

# FALSE

TRUE | UNKNOWN | `_lazy_and` | `_lazy_or` | `and` | `bool` | `if` |  
`is` | `not` | `or` | `repeat` | `while`

## Purpose

Boolean constant UNKNOWN

## Description

MuPAD uses a three state logic with the Boolean constants TRUE, FALSE, and UNKNOWN.

The Boolean constants TRUE, FALSE, UNKNOWN are of domain type DOM\_BOOL.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as bool and is. These functions evaluate Boolean expressions such as equations and inequalities.

## Examples

### Example 1

The Boolean constants may be combined via and, or, and not:

```
(TRUE and (not FALSE)) or UNKNOWN
```

```
TRUE
```

### Example 2

The function bool serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:

```
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)
```

```
TRUE
```

The function is evaluates symbolic Boolean expressions with properties:

```
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)
```

```
TRUE, FALSE, UNKNOWN
```

```
unassume(x):
```

### Example 3

Boolean constants occur in the conditional part of program control structures such as `if`, `repeat`, or `while` statements. The following loop searches for the smallest Mersenne prime larger than 500 (see `numlib::mersenne` for details). The function `isprime` returns `TRUE` if its argument is a prime, and `FALSE` otherwise. Once a Mersenne prime is found, the `while`-loop is interrupted by the `break` statement:

```
p := 500:
while TRUE do
 p := nextprime(p + 1):
 if isprime(2^p - 1) then
 print(p);
 break;
 end_if;
end_while:
```

521

Note that the conditional part of `if`, `repeat`, and `while` statements must evaluate to `TRUE` or `FALSE`. Any other value leads to an error:

```
if UNKNOWN then "true" else "false" end_if
```

```
Error: Cannot evaluate to Boolean. [if]
```

```
delete p:
```

| not | or | repeat | while

# type

---

**Purpose** Type of an object

**Syntax** `type(object)`

**Description** `type(object)` returns the type of the object.

If `object` is not an expression of domain type `DOM_EXPR`, then `type(object)` is equivalent to `domtype(object)`, i.e., `type` returns the domain type of the object.

If `object` is an expression of domain type `DOM_EXPR`, then its type is determined by its 0-th operand (the “operator”). If the operator has a “type” slot, then `type` returns this value, which usually is a string. If the operator has no “type” slot, then `type` returns the string “function”.

In contrast to most other functions, `type` does not flatten arguments that are expression sequences. Cf. “Example 4” on page 1-2303.

## Examples

### Example 1

If an object is not an expression, its type equals its domain type:

```
type(3)
```

```
DOM_INT
```

### Example 2

The operator of a sum is `_plus`; the type slot of that operator is “`_plus`”:

```
type(x + y*z)
```

```
"_plus"
```

`type` evaluates its argument: thereby, the difference of `x` and `y` becomes the sum of `x` and `(-1)*y`. Its type is not “`_subtract`”, but “`_plus`”:

```
type(x - y)
```

```
"_plus"
```

### Example 3

If the operator of an expression is not a function environment having a type slot, the expression is of type "function":

```
type(f(2))
```

```
"function"
```

### Example 4

The following call to `type` is *not* regarded as a call with two arguments, because expression sequences in the argument are not flattened:

```
type((2, 3))
```

```
"_exprseq"
```

#### Parameters

**object**

Any MuPAD object

#### Return Values

Domain type of type `DOM_DOMAIN` or a character string.

#### Overloaded By

object

# type

---

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Delete the properties of an identifier                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Syntax</b>      | <code>unassume(x)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p><code>unassume(x)</code> deletes the properties of the identifier <code>x</code>.</p> <p><code>unassume</code> serves for deleting properties of identifiers set via <code>assume</code>. See “Properties” for a description of the property mechanism.</p> <p>If <code>x</code> is a list or a set of identifiers, then the properties of all specified identifiers are deleted.</p> <p>The command <code>delete x</code> deletes the value and the properties of the identifier <code>x</code>.</p> |
| <b>Examples</b>    | <p><b>Example 1</b></p> <p>Properties are attached to the identifiers <code>x</code> and <code>y</code>:</p> <pre>assume(x &gt; 0): assume(y &lt; 0): getprop(x), getprop(y)</pre> <pre>(0, ∞), (-∞, 0)</pre> <pre>sign(x), sign(y)</pre> <pre>1, -1</pre> <p><code>unassume</code> or <code>delete</code> deletes the properties:</p> <pre>unassume(x): delete y: getprop(x), getprop(y)</pre> <pre>ℂ, ℂ</pre> <pre>sign(x), sign(y)</pre>                                                              |

# unassume

---

`sign(x), sign(y)`

The properties of several identifiers can be deleted simultaneously by passing a list or a set to `unassume`:

```
assume(x > y): unassume([x, y]): getprop(x), getprop(y)
```

`ℂ, ℂ`

## Parameters

**x**

An identifier or a list or a set of identifiers

## Return Values

Void object `null()`.

## See Also

## MuPAD Functions

`assume` | `delete` | `getprop` | `is`

**Purpose**

Undefined value

**Description**

undefined indicates results of mathematically undefined operations.

MuPAD uses the special value `undefined` to indicate the results of operations that are not defined in mathematics.

You can use the `undefined` value as an input. Arithmetical operations involving `undefined` also return `undefined`. Multiplying infinities by 0 returns `undefined`.

For floating-point intervals, MuPAD uses the special value `RD_NAN` instead of `undefined`. If you use typeset mode, MuPAD displays `RD_NAN` as NaN in output regions. Multiplying infinities `RD_INF` and `RD_NINF` by 0 returns `RD_NAN`.

**Examples****Example 1**

Perform the following operations with infinities. MuPAD returns the `undefined` value for these operations:

```
0*infinity, infinity - infinity, infinity/infinity
```

```
undefined, undefined, undefined
```

**Example 2**

Compute the limit of the sine function at infinity. Since this limit does not exist (is not mathematically defined), MuPAD returns `undefined`:

```
limit(sin(x), x = infinity)
```

```
undefined
```

**Example 3**

Multiply infinities by 0:

# undefined

---

`infinity*0, -infinity*0`

`undefined, undefined`

`RD_INF*0, RD_NINF*0`

`NaN, NaN`

| <b>Purpose</b>     | Physical units                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>      | <code>unit::nam</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>Objects such as <code>unit::m</code>, <code>unit::kg</code>, <code>unit::sec</code> etc. represent the physical units “meters”, “kilograms”, “seconds” etc.</p> <p><code>unit</code> domain provides some methods for simplifying and converting arithmetical expressions involving such units.</p> <p><code>unit</code> objects such as <code>unit::m</code> or <code>unit::kg</code> serve for representing physical units. They are domain objects of domain type <code>unit</code>.</p> <p>These objects behave like symbolic names (identifiers) and can be used to build arithmetical expressions involving numbers and symbols such as <math>3*\text{unit}::\text{m}^2</math> or <math>a*\text{unit}::\text{cm} + b*\text{unit}::\text{inch}^2/\text{unit}::\text{mm}</math>.</p> <p>Expressions such as <math>20*\text{unit}::\text{cm} + 0.3*\text{unit}::\text{m}</math> involving several units of the same type (‘length,’ ‘mass,’ ‘time’ etc.) are <i>not</i> simplified automatically. Use <code>unit::convert</code>, <code>unit::simplify</code>, <code>simplify</code>, or <code>Simplify</code> to convert all subexpressions to common units. These routines are described further down below.</p> <p>On input, use the prefix <code>unit::</code> as in <code>unit::mm</code>, <code>unit::km</code> for millimeters, kilometers etc. On the screen, this prefix is stripped off. For example, <math>1.23*\text{unit}::\text{mm}</math> is displayed as 1.23 mm.</p> <p>The available units are listed further down below.</p> <p>Note that some units such as <code>unit::mm</code>, <code>unit::millimeter</code> and <code>unit::millimeters</code> represent the same physical unit. Use an interactive command such as <code>info(unit::oz)</code> to find information on <code>unit::oz</code> including all the alternative names that can be used in MuPAD. Cf. “Example 6” on page 1-2324.</p> |

---

**Note** Beware: If you mix different MuPAD units representing the same physical unit, *no automatic simplifications* are done! Use `simplify` to simplify an expression such as `2*unit::m + 3*unit::meter` to `5*unit::m`.

---

Expressions such as `unit::kg*(unit::m/unit::s)^2` can be used to represent a composite unit. You can convert them to other units such as `unit::Joule` via `unit::convert`.

Some of the conversion factors between the various units are given by exact rational numbers (e.g., `unit::inch = 127/50*unit::cm`), while others are linked by floating-point factors (e.g., `unit::cal = 4.1868*unit::Joule`). Use `float` to approximate exact values by floats. Use `numeric::rationalize` to approximate floats by rational numbers.

Most system functions such as `diff`, `factor`, `normal` etc. accept expressions containing units, treating the units like symbolic identifiers. See “Example 8” on page 1-2325.

The available units are listed below. If the required unit is not available, you can use `unit::newUnit` to add your own unit to the unit domain. See “Example 3” on page 1-2320.

Length:

- `am`, `f` (= Fermi = fermi), `XU` (= `Xu` = `xu` = `XE`), `pm`
- `Ao` (= Angstroem = angstroem = Angstrom = angstrom)
- `nm` (= nanometer = nanometers)
- `My` (= micron = microns = micrometer = micrometers)
- `mm` (= millimeter = millimeters), `cm` (= centimeter = centimeters)
- `dm` (= decimeter = decimeters), `m` (= meter = meters)
- `dam`, `hm`, `km` (= kilometer = kilometers), `Mm`, `Gm`, `Tm`, `Pm`, `Em`
- `pt` (= point = points), `inch` (= inches = zoll = Zoll)

- ft (= foot = feet), ft\_US (= foot\_US = feet\_US)
- yd (= yard = yards = Elle = Ellen), mile (= miles), nmile, inm (= INM)
- AU (= AE), ly (= lightyear = lightyears = Lj = lj), pc (= parsec)
- ch, fm (= fathom = fathoms), fur (= furlong = furlongs), gg, hand
- li (= link = links), line, mil, rod (= perch = pole), span

#### Mass:

- ag, fg, pg, ng, mcg (= mcgram = mcgrams = microgram = micrograms)
- mg (= milligram = milligrams), cg, dg, g (= gram = grams), hg
- kg (= kilogram = kilograms), Mg, Gg, Tg, Pg, Eg
- t, kt, Mt, ct (= carat = Kt = Karat = karat)
- oz (= ounce = ounces = Unze = Unzen = unze = unzen)
- lb (= pound = pounds), stone, cwt (= sh\_cwt)
- cwt\_UK (= long\_cwt = gross\_cwt), tn (= ton = short\_ton), ton\_UK
- long\_ton (= gross\_ton), slug, gr, dr, quarter, cental
- Pfd (= Pfund = pfund), Ztr (= Zentner = zentner)
- dz (= Doppelzentner = doppelzentner)

#### Time:

- as, fs, ps, ns (= nsec = nanosec = nanosecond = nanoseconds)
- mcsec (= mcsecond = mcseconds = microsec = microsecond = microseconds)
- ms (= msec = millisec = millisecond = milliseconds), cs, ds
- s (= sec = second = seconds = Sekunde = Sekunden), das, hs, ks
- Ms, Gs, Ts, Es, Ps, min (= minute = minutes = Minute = Minuten)

- h (= hour = hours = Stunde = Stunden), d (= day = days = Tag = Tage)
- week (= weeks = Woche = Wochen), month (= months = Monat = Monate)
- year (= years = Jahr = Jahre)

Temperature:

- K (= kelvin = Kelvin), Fahrenheit (= fahrenheit), Celsius (= celsius)
- Rankine (= rankine), Reaumur (= reaumur)

Plain Angle:

- degree (= degrees), rad (= radian)

Solid Angle:

- sr (= steradian)

Data Size, Storage Capacity:

- bit (= Bit) kbit (= kBit), Mbit (= MBit), Gbit (= GBit), Tbit (= TBit)
- byte (= Byte), kbyte (= kByte), Mbyte (= MByte), Gbyte (= GByte)
- Tbyte (= TByte)

Data Rate (Bits per Second):

- bps

Signal Rate (= Frequency):

- Bd (= Baud = baud)

Velocity:

- knot, knot\_UK, mach

Acceleration:

- Gal, gn

Force:

- aN, fN, nN, pN, mcN, mN, cN, dN, N (= Newton = newton), daN, hN, kN, MN, GN
- TN, PN, EN, p (= pond = Pond), kp (= kilopond = Kilopond), dyn, pdl, lbf
- ozf, tonf

Torque (= Energy):

- aNm, fNm, pNm, nNm, mcNm, mNm, cNm, dNm, Nm (= Newtonmeter = newtonmeter)
- daNm, hNm, kNm, MNm, GNm, TNm, PNm, ENm, kpm

Angular Momentum:

- aNms, fNms, pNms, nNms, mcNms, mNms, cNms, dNms
- Nms (= Newtonmetersec = newtonmetersec)
- daNms, hNms, kNms, MNms, GNms, PNms, ENms, TNms

Energy, Work:

- aJ (= aWs), fJ (= fWs), pJ (= pWs), nJ (= nWs), mcJ (= mcWs = microWs)
- mJ (= mJoule = mjoule = mWs), cJ (= cWs), dJ (= dWs)
- J (= Joule = joule = Ws), daJ (= daWs), hJ (= hWs)
- kJ (= kJoule = kjoule = kWs), MJ (= MJoule = Mjoule = MWs)

- GJ (= GWs), TJ (= TWs), PJ (= PWs), EJ (= EWs), Wh, kWh, MWh, GWh
- cal (= Calory = calory), kcal, aeV, feV, peV, neV, mceV, meV, ceV, deV, eV
- daeV, heV, keV, MeV, GeV, TeV, PeV, EeV, PSh, erg, Btu, therm

## Power:

- aW, fW, pW, nW, mcW (= mcWatt = mcwatt = microW = microWatt = microwatt)
- mW (= mWatt = mwatt), cW, dW, W (= Watt = watt), daW, hW
- kW (= kWatt = kwatt), MW (= MWatt = Mwatt), GW (= GWatt = Gwatt)
- TW, PW, EW, PS, hp (= bhp)

## Frequency:

- aHz, fHz, pHz, nHz, mcHz, mHz, cHz, dHz, Hz (= Hertz = hertz), daHz, hHz
- kHz (= kHzertz = khertz), MHz (= MHzertz = Mhertz)
- GHz (= GHzertz = Ghertz), THz, PHz, EHz

## Pressure, Stress:

- aPa, fPa, pPa, nPa, mcPa, mPa, cPa, dPa, Pa (= Pascal = pascal)
- daPa, hPa (= hPascal = hpascal), kPa, MPa, GPa, TPa, PPa, EPa
- mcbars (= mcBar = microbar = microBar), mbar (= mBar), bar (= Bar)
- kbar (= kBar), at (= ata = atu), atm, mmH<sub>2</sub>O (= mmWS), mH<sub>2</sub>O (= mWS)
- inH<sub>2</sub>O, ftH<sub>2</sub>O, mmHg, mHg, inHg, psi, Torr

## Area:

- a (= are = Ar), ac (= acre), b (= barn), ha (= hectare = Hektar)

- ro (= rood), township, circ\_mil, circ\_inch

#### Volume:

- al, fl, pl, nl, mcl, ml, cl, dl, l (= Liter = liter = Litre = litre), dal
- hl, kl, Ml, Gl, Tl, Pl, El, gal (= gallon), gal\_UK, barrel, bu\_UK, chaldron
- pottle, pint\_UK, pk\_UK, qt\_UK, gill, gill\_UK, floz, floz\_UK, fldr, fldr\_UK
- minim, minim\_UK, liq\_qt, liq\_pt, dry\_bu, dry\_pk, bbl, dry\_gal, dry\_qt, dry\_pt

#### European Currency:

- cent (= Cent), EUR (= EURO = Euro), ATS, DEM (= DM), BEF, ESP, FIM, FRF, LUF
- NLG, PTE, IEP, ITL

#### Molecular Substance:

- fmol, amol, pmol, nmol, mcmol (= mMol = micromol = microMol)
- mmol (= mMol), cmol, dmol, mol (= Mol), damol, hmol, kmol (= kMol), Mmol
- Gmol, Tmol, Pmol, Emol

#### Electric Current, Amperage:

- aA, fA, pA, nA (= nAmpere = nampere)
- mA (= microA = microAmpere = microampere), mA (= mAmpere = mampere)
- cA, dA, A (= ampere = Ampere), daA, hA, kA (= kAmpere = kampere), MA, GA

- TA, PA, EA, Bi (= Biot = biot), Gb (= Gilbert = gilbert)

## Electric Voltage:

- aV, fV, pV, nV (= nanoV = nVolt = nvolt)
- mV (= microV = mVolt = mvolt), V (= Volt = volt), dV, cV, dV
- V (= Volt = volt), daV, hV
- kV (= kVolt = kvolt)
- MV (= MVolt = Mvolt), GV (= GVolt = Gvolt), TV, PV, EV

## Electric Resistance:

- aOhm (= aohm), fOhm (= fohm), pOhm (= pohm), nOhm (= nohm)
- mOhm (= mcohm = microOhm = microohm)
- Ohm (= ohm), daOhm (= daohm), hOhm (= hohm), kOhm (= kohm), MOhm (= Mohm)
- GOhm (= Gohm), TOhm (= Tohm), POhm (= Pohm), EOhm (= Eohm)

## Electric Charge:

- aC, fC, pC, nC, mC, mC, cC, dC, C (= Coulomb = coulomb), daC, hC, kC, MC, GC, TC
- PC, EC

## Electric Capacity:

- aF, fF, pF (= pFarad = pfarad), nF (= nFarad = nfarad)
- mF (= mFarad = mfarad = microF = microFarad = microfarad)
- mF (= mFarad = mfarad), cF, dF, F (= Farad = farad), daF, hF
- kF (= kFarad = kfarad), MF, GF, TF, PF, EF

Electric Conductance:

- S (= Siemens = siemens)

Magnetic Inductance:

- H (= Henry = henry)

Magnetic Flux Density, Magnetic Inductivity:

- T (= Tesla = tesla), G (= Gauss = gauss)

Magnetic Flux:

- Wb (= Weber = weber), M (= Maxwell = maxwell)

Magnetic Field Strength:

- Oe (= Oersted = oersted)

Magnetomotive Force (= Electric Current):

- Gb (= Gilbert = gilbert)

Luminous Intensity:

- fcd, acd, pcd, ncd, mccd, mcd, ccd, dcd, cd (= candela = Candela),  
dacd, hcd
- kcd, Mcd, Gcd, Tcd, Pcd, Ecd, HK, IK

Luminance:

- sb (= stilb), asb (= apostilb)

Luminous Flux:

- lm (= lumen)

Illuminance:

- lx (= lux), ph (= phot), nx

Radiation:

- langley

Radioactivity:

- aBq, fBq, pBq, nBq, mCBq, mBq, cBq, dBq, Bq (= Becquerel = becquerel), daBq
- hBq, kBq, MBq, GBq, TBq, PBq, EBq, Ci (= Curie)

Equivalent Dosage:

- aSv, fSv, pSv, nSv, mCSv, mSv, cSv, dSv
- Sv (= Sievert = sievert), daSv, hSv, kSv, MSv, GSv, TSv, PSv, ESv
- arem, frem, prem, nrem, mcrem, mrem, crem, drem
- rem (= Rem), darem, hrem, krem, Mrem, Grem, Trem, Prem, Erem

Absorbed Dosage:

- aGy, fGy, pGy, nGy, mCGy, mGy, cGy, dGy, Gy (= Gray = gray), daGy, hGy, kGy, MGy, GGy
- TGy, PGy, EGy, rd

Ionising Dosage:

- R (= Roentgen)

Lens Power:

- dpt (= diopter = diopetre)

Dynamic Viscosity:

- P (= Poise)

Kinematic Viscosity:

- St (= Stokes)

Mass Per Length:

- tex, den (= denier)

## Examples

### Example 1

Units not convertible are left alone by `unit::convert`:

```
unit::convert(1.23*unit::kg*unit::inch^2/unit::mm, unit::cm)
```

79.35468 cm kg

```
unit::convert(unit::km/unit::hour, unit::m/unit::sec)
```

$$\frac{5 \frac{m}{sec}}{18}$$

### Example 2

`unit::simplify` favors kg over pounds:

```
unit::simplify(1.23*unit::kg^2/unit::pound*unit::inch^2/unit::mm)
```

68.87681995 inch kg

## Example 3

We add new velocity units to the unit domain:

```
unit::newUnit(SpeedOfLight = 300000*unit::km/unit::sec)
```

SpeedOfLight

Now, the unit `unit::SpeedOfLight` exists and can be used like any other unit in the unit domain. We use it to define yet another velocity unit:

```
unit::newUnit(Warp9 = 1.516*unit::SpeedOfLight)
```

Warp9

We convert the velocity of 123.4 miles per hour into the new speed units:

```
unit::convert(123.4*unit::mile/unit::hour, unit::SpeedOfLight)
```

0.0000001838824533 SpeedOfLight

```
unit::convert(123.4*unit::mile/unit::hour, unit::Warp9)
```

0.0000001212944943 Warp9

We verify the new units:

```
unit::convert(unit::SpeedOfLight, unit::km/unit::sec)
```

300000  $\frac{\text{km}}{\text{sec}}$

```
unit::convert(unit::Warp9, unit::SpeedOfLight)
```

```
1.516 SpeedOfLight
```

```
unit::convert(unit::Warp9, unit::km/unit::sec)
```

```
454800.0 $\frac{\text{km}}{\text{sec}}$
```

#### Example 4

We create a symbolic expression involving different units of type 'length':

```
27*unit::cm + 30*unit::mm
```

```
27 cm + 30 mm
```

This expression is not simplified automatically. We apply simplify:

```
simplify(%)
```

```
30 cm
```

We convert this length to inch:

```
unit::convert(%, unit::inch)
```

```
 $\frac{1500 \text{ inch}}{127}$
```

```
float(%)
```

11.81102362 inch

Here is another example for simplification and conversion:

```
1234*unit::g + 1.234*unit::kg*unit::m^2/unit::inch^2
```

$$1234 \text{ g} + 1.234 \frac{\text{kg m}^2}{\text{inch}^2}$$

```
simplify(%)
```

1913937.825 g

```
unit::convert(%, unit::ounce)
```

67512.17003 ounce

The target unit in `unit::convert` may be an expression:

```
unit::convert(unit::pound*unit::km/unit::hour,
 unit::kg*unit::m/unit::s)
```

$$\frac{45359237 \frac{\text{kg m}}{\text{s}}}{360000000}$$

## Example 5

The probably most interesting method of the unit domain is the conversion routine `unit::convert`. Given any expression involving units, you can specify a target unit which is to be used to express the units:

```
unit::convert(unit::ounce, unit::kilogram)
```

$$\frac{45359237 \text{ kilogram}}{1600000000}$$

The target unit needs not be of the same physical type as the expression that is to be rewritten. In the following example, we wish to rewrite a torque (given in “Newton meters”) in terms of units involving the power unit “Watt.” Note that a torque is an energy, i.e., “power” multiplied by “time”:

```
unit::convert(1.23*unit::Nm, unit::W)
```

$$1.23 \text{ W s}$$

We wish to rewrite “Newton meters” in terms of units involving “centimeters”:

```
unit::convert(unit::Nm, unit::cm)
```

$$10000 \frac{\text{cm}^2 \text{ kg}}{\text{s}^2}$$

The target unit may be a composite expression. We wish to rewrite “Newton meters” in terms of “grams,” “centimeters,” and “milliseconds”:

```
unit::convert(unit::Nm, unit::g*unit::cm^2/unit::msec^2)
```

$$10 \frac{\text{cm}^2 \text{ g}}{\text{msec}^2}$$

## Example 6

The `info` command provides information on units. In particular, it lists alternative names that can be used in MuPAD:

```
info(unit::nm)
```

```
nanometer: a length unit
```

```
Alternative names: unit::nanom, unit::nanometer, unit::nanometers,
```

```
info(unit::Joule)
```

```
joule: a unit of energy
```

```
Alternative names: unit::J, unit::Joule, unit::Newtonmeter, unit::N
```

## Example 7

We use `unit::convert2SIunits` to convert a mass expressed in non-metric units to SI base units:

```
mass := 2*unit::cal*unit::msec^2/unit::inch^2 - 45*unit::carat
```

$$2 \frac{\text{cal msec}^2}{\text{inch}^2} - 45 \text{ carat}$$

```
unit::convert2SIunits(mass)
```

0.003979105958 kg

delete mass:

### Example 8

Most system functions such as `diff`, `factor`, `normal` etc. treat units like ordinary symbolic identifiers:

`diff(x/unit::m*exp(-x^2/unit::m^2), x)`

$$e^{-x^2 \frac{1}{m^2}} \frac{1}{m} - \left( 2 x^2 e^{-x^2 \frac{1}{m^2}} \right) \frac{1}{m^3}$$

`factor(%)`

$$- \frac{2 x^2 - m^2}{e^{\frac{x^2}{m^2}}} \frac{1}{m^3}$$

`normal((4*unit::m^2 - a^2*unit::m^2)/(2*unit::m - a*unit::m))`

$$2 m + a m$$

## Parameters

**nam**

The name of the physical unit, see the list below. Some units such as `unit::mm` and `unit::millimeter` represent the same physical unit.

## Methods

**convert - Convert an expression to other units**

`convert(x, targetunit)` converts all units in the arithmetical expression `x` to multiples of the `targetunit` if possible. The `targetunit` may be one of the unit objects of type 'length,' 'mass' etc. It may also be an arithmetical expression such as `unit::km/unit::sec`. In this case, `x` is rewritten in terms of the units found in `targetunit`.

## **convert2SIunits - Rewrite to SI units**

`convert2SIunits(x)` rewrites all units in the arithmetical expression `x` in terms of corresponding SI base units.

## **simplify - Combine like units in an expression**

`unit::simplify(x)` converts all units in the arithmetical expression `x` to some basic unit found in `x`, i.e., all length units are expressed by the same length unit, all mass units are expressed by the same mass unit, all time units are expressed by the same time unit etc.

## **newUnit - Define a new unit**

`newUnit(newname = expression)`

`unit::newUnit(newname = f*oldunit)` creates a new unit that may be addressed by `unit::newname`. Its name `newname` must be an identifier. It is declared as the `f`-fold of some unit `oldunit` that must be an expression such as `unit::mm/unit::sec` involving units provided by the unit domain. The conversion factor `f` must be an arithmetical expression (typically, a numerical conversion factor).

## **display - Format for output**

`display(x)` formats the screen output of the arithmetical expression `x` such that the units appear as a separate factor at the end of each term.

## **findUnits - Find all units in expression**

`findUnits(x)` returns a set of all units found in the arithmetical expression `x`.

---

### **Celsius2Fahrenheit - Convert degrees Celsius to degrees Fahrenheit**

`unit::Celsius2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Fahrenheit.

### **Celsius2Kelvin - Convert degrees Celsius to Kelvin**

`unit::Celsius2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Kelvin.

### **Celsius2Rankine - Convert degrees Celsius to degrees Rankine**

`unit::Celsius2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Rankine.

### **Celsius2Reaumur - Convert degrees Celsius to degrees Reaumur**

`unit::Celsius2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Reaumur.

### **Fahrenheit2Celsius - Convert degrees Fahrenheit to degrees Celsius**

`unit::Fahrenheit2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Celsius.

### **Fahrenheit2Kelvin - Convert degrees Fahrenheit to Kelvin**

`unit::Fahrenheit2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Kelvin.

### **Fahrenheit2Rankine - Convert degrees Fahrenheit to degrees Rankine**

`unit::Fahrenheit2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Fahrenheit into a

numerical value representing this temperature in degrees Rankine.

## **Fahrenheit2Reaumur - Convert degrees Fahrenheit to degrees Reaumur**

`unit::Fahrenheit2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Reaumur.

## **Kelvin2Fahrenheit - Convert Kelvin to degrees Fahrenheit**

`unit::Kelvin2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Fahrenheit.

## **Kelvin2Celsius - Convert Kelvin to degrees Celsius**

`unit::Kelvin2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Celsius.

## **Kelvin2Rankine - Convert Kelvin to degrees Rankine**

`unit::Kelvin2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Rankine.

## **Kelvin2Reaumur - Convert Kelvin to degrees Reaumur**

`unit::Kelvin2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Reaumur.

## **Rankine2Fahrenheit - Convert degrees Rankine to degrees Fahrenheit**

`unit::Rankine2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Fahrenheit.

## **Rankine2Kelvin - Convert degrees Rankine to Kelvin**

---

`unit::Rankine2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Kelvin.

### **Rankine2Celsius - Convert degrees Rankine to degrees Celsius**

`unit::Rankine2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Celsius.

### **Rankine2Reaumur - Convert degrees Rankine to degrees Reaumur**

`unit::Rankine2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Reaumur.

### **Reaumur2Fahrenheit - Convert degrees Reaumur to degrees Fahrenheit**

`unit::Reaumur2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Fahrenheit.

### **Reaumur2Kelvin - Convert degrees Reaumur to Kelvin**

`unit::Reaumur2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Kelvin.

### **Reaumur2Rankine - Convert degrees Reaumur to degrees Rankine**

`unit::Reaumur2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Rankine.

### **Reaumur2Celsius - Convert degrees Reaumur to degrees Celsius**

`unit::Reaumur2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Celsius.

# universe

---

**Purpose** Set-theoretical universe

**Description** universe represents the set-theoretical universe of all objects.  
universe is the only element of the domain `stdlib::Universe`.  
The standard set operations such as union, intersection and subtraction can be used with universe.

**Examples** **Example 1**

We show some basic set operations involving universe:

```
universe union {a}
```

```
universe
```

```
universe intersect {a}
```

```
{a}
```

```
{a} minus universe
```

```
∅
```

**See Also**

**MuPAD Domains** DOM\_SET

**MuPAD Functions** union | intersect | minus

**Purpose** Remove protection of identifiers

**Syntax** `unprotect(x)`

**Description** `unprotect(x)` removes any write protection of the identifier `x`.  
`unprotect(x)` is equivalent to `protect(x, ProtectLevelNone)`.  
`unprotect` does not evaluate its argument. Cf. “Example 2” on page 1-2331.

**Examples** **Example 1**

`unprotect` allows to assign values to system functions:

```
unprotect(sign): sign(x) := 1
```

```
1
```

However, we strongly advise not to change identifiers protected by the system. We undo the previous assignment:

```
delete sign(x): protect(sign, ProtectLevelError):
```

**Example 2**

`unprotect` does not evaluate its argument. Here the identifier `x` is unprotected and not its value `y`:

```
x := y: protect(y): unprotect(x): y := 1
```

```
Warning: The protected variable 'y' is overwritten. [_assign]
```

```
1
```

# unprotect

---

```
Warning: Protected variable
'y' overwritten. [_assign]
```

```
1
```

```
unprotect(y): delete x, y:
```

## Example 3

The identifier `a` is protected with various levels. `unprotect` returns the previous protection level:

```
protect(a):
unprotect(a)
```

```
ProtectLevelWarning
```

```
protect(a, ProtectLevelError):
unprotect(a)
```

```
ProtectLevelError
```

At this place, `a` is not protected:

```
unprotect(a)
```

```
ProtectLevelNone
```

## Parameters

**x**

An identifier

## **Return Values**

Previous protection level of x: either `ProtectLevelError` or `ProtectLevelWarning` or `ProtectLevelNone` (see `protect`).

## **See Also**

## **MuPAD Functions**

`protect`

# use

---

**Purpose** Use library functions by a short name

**Syntax** `use(L, <Alias>, f1, f2, ...)`  
`use(L, <Alias>)`

**Description** `use(L, f)` 'exports' the public function `L::f` of the library `L` to the global namespace such that it can be accessed as `f` without the prefix `L`.

`use(L)` exports all public functions of the library `L`.

A library contains *public* functions which may be called by the user. The collection of these functions forms the *interface* of the library. (There may be other, private, functions, too, which are not intended to be called by the user directly, and are not documented.) The standard way of accessing the public function `f` from the library `L` is via `L::f`. When the function `f` is *exported*, it can be accessed more briefly as `f`. Technically, exporting means that the global identifier `f` is assigned the value `L::f`. Alternatively, when the option `Alias` is used, an *alias* is created.

Unexporting the library function `f` means that the value of the global identifier `f` is deleted. Afterwards, the library function is available only as `L::f`.

`use(L, f1, f2, ...)` exports the given functions `f1`, `f2`, ... of `L`. However, if one of the identifiers already has a value, the corresponding function is not exported. A warning is printed instead. An error is returned if one of the identifiers is not the name of a public library function.

`use(L)` exports all public functions of `L`.

A function that is already exported will not be exported twice.

`use` evaluates its first argument `L`, but it does not evaluate the remaining arguments `f1`, `f2`, ..., if any.

The function `info` displays the interface functions and the exported functions of a library.

Some libraries have functions that are always exported. These functions cannot be unexported. The function `append` from the library `listlib` is such an example.

## Environment Interactions

When a function is exported, it is assigned to the corresponding global identifier. When it is unexported, the corresponding identifier is deleted.

## Examples

### Example 1

We export the public function `invphi` of the library `numlib` and then undo the export:

```
numlib::invphi(4!)

[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

use(numlib, invphi):
invphi(4!)

[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

unuse(numlib, invphi):
invphi(4!)

invphi(24)
```

We export and unexport all public functions of the library `numlib`:

```
use(numlib):
invphi(100)
```

## use

---

```
Warning: Identifier 'contfrac' already has a value. It is not exported
```

```
[101, 125, 202, 250]
```

As you can see `use` issued a warning because `contfrac` already has a value. Here, the reason is the existence of a global function `contfrac` (which makes use of `numlib::contfrac` for numerical arguments).

```
unuse(numlib):
invphi(100)
```

```
invphi(100)
```

### Example 2

`use` issues a warning if a function cannot be exported since the corresponding identifier already has a value:

```
invphi := 17:
use(numlib, invphi)
```

```
Warning: Identifier 'invphi' already has a value. It is not exported
```

### Parameters

**L**

The library: a domain

**f1, f2, ...**

Public functions of L: identifiers

**Options****Alias**

Use `alias(f = L::f)` to create an alias `f` for `L::f` rather than exporting `L::f` by the assignment `f:= L::f`.

**Return Values**

Void object `null()` of type `DOM_NULL`.

**Algorithms**

The names of the public functions of a library `L` are stored in the set `L::interface`. This set is used by the function `info` and for exporting. The names of functions exported from a library `L` are stored in the set `L::_exported`.

**See Also****MuPAD Functions**

`unuse` | `:=` | `alias` | `delete` | `info` | `loadproc` | `package`

**Related Examples**

- “Avoid Name Conflicts Between MuPAD Objects and Library Functions”

# unuse

---

**Purpose** Undo the use command

**Syntax** `unuse(L, f1, f2, ...)`  
`unuse(L)`

**Description** `unuse(L, f)` undoes the export of the public function `L::f` of the library `L` such that it is no longer available as `f`.

`unuse(L)` undoes the export of all previously exported public functions of the library `L`.

A library contains *public* functions which may be called by the user. The collection of these functions forms the *interface* of the library. (There may be other, private, functions, too, which are not intended to be called by the user directly, and are not documented.) The standard way of accessing the public function `f` from the library `L` is via `L::f`. When the function `f` is *exported*, it can be accessed more briefly as `f`. Technically, exporting means that the global identifier `f` is assigned the value `L::f`. Alternatively, when the option `Alias` is used, an *alias* is created.

Unexporting the library function `f` means that the value of the global identifier `f` is deleted. Afterwards, the library function is available only as `L::f`.

`unuse(L, f1, f2, ...)` unexports all given functions of `L`. Note that `unuse` does not evaluate the identifiers. Thus, it is not necessary to use `hold` to protect them from being evaluated.

`unuse(L)` unexports all public functions of the library `L`.

`unuse` evaluates its first argument `L`, but it does not evaluate the remaining arguments `f1, f2, ...`, if any.

The function `info` displays the interface functions and the exported functions of a library.

Some libraries have functions that are always exported. These functions cannot be unexported. The function `append` from the library `listlib` is such an example.

## Environment Interactions

When a function is exported, it is assigned to the corresponding global identifier. When it is unexported, the corresponding identifier is deleted.

## Examples

### Example 1

We export the public function `invphi` of the library `numlib` and then undo the export:

```
numlib::invphi(4!)

[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

use(numlib, invphi):

invphi(4!)

[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

unuse(numlib, invphi):

invphi(4!)

invphi(24)
```

We export and unexport all public functions of the library `numlib`:

```
use(numlib):
invphi(100)
```

```
Warning: Identifier 'contfrac' already has a value. It is not ex
```

```
[101, 125, 202, 250]
```

As you can see `use` issued a warning because `contfrac` already has a value. Here, the reason in the existence of a global function `contfrac` (which makes use of `numlib::contfrac` for numerical arguments).

```
unuse(numlib):
invphi(100)
```

```
invphi(100)
```

## Example 2

`use` issues a warning if a function cannot be exported since the corresponding identifier already has a value:

```
invphi := 17:
use(numlib, invphi)
```

```
Warning: Identifier 'invphi' already has a value. It is not exported.
```

## Parameters

**L**

The library: a domain

**f1, f2, ...**

Public functions of L: identifiers

## Options

**Alias**

Use `alias(f = L::f)` to create an alias `f` for `L::f` rather than exporting `L::f` by the assignment `f:= L::f`.

**Return Values**

Void object `null()` of type `DOM_NULL`.

**Algorithms**

The names of the public functions of a library `L` are stored in the set `L::interface`. This set is used by the function `info` and for exporting.

The names of functions exported from a library `L` are stored in the set `L::_exported`.

**Concepts**

- “Use the MuPAD Libraries”

# userinfo

---

**Purpose** Print progress information

---

**Note** userinfo has been removed. Use print instead.

---

**Syntax**

```
userinfo(<Text>, <NoNL>, n, message1, message2,)
userinfo(<Text>, <NoNL>, n1 .. n2, message1, message2,)
```

**Description** userinfo(n, message) prints a message if an information level larger or equal to n is set via setuserinfo.

userinfo(n1..n2, message) prints a message if the information level set by setuserinfo is between n1 and n2.

userinfo must not be used on the interactive level. It should be built into the body of a procedure or of a domain method to print status information such as the chosen algorithm, intermediate results etc. If a userinfo command is built into a procedure by the name f, say, then it is activated by setting an appropriate information level via setuserinfo(f, n). The information is printed during subsequent calls to f.

The print output consists of the evaluation of the message arguments, possibly followed by the name of the procedure (see the function setuserinfo). Strings are printed without quotes. The pretty printer is not used. Unless one of the options Text or NoNL is given, the message arguments are separated by commas in the output. Unless the option NoNL is given, the print output is preceded by the string "Info: " and a new line is started after the output.

The information level of a single procedure, of all procedures of a domain, or, of all procedures in general can be specified using setuserinfo. All three levels may apply to a procedure simultaneously.

Most of the functions in the MuPAD library provide status information via userinfo.

**Environment Interactions**

userinfo prints the messages on the screen, if an appropriate information level is set.

**Parameters**

**n, n<sub>1</sub>, n<sub>2</sub>**

The information levels: positive integers

**message<sub>1</sub>, message<sub>2</sub>, ...**

Arbitrary MuPAD objects. Typically, character strings.

**Options**

**Text**

Do not separate the arguments by commas in the output

**NoNL**

Do not separate the arguments by commas in the output, do not start a new line after the output, and do not precede the output by the string "Info: ".

**Return Values**

Void object of type DOM\_NULL.

**Algorithms**

userinfo does not evaluate the messages unless they are printed.

The global table of information levels for all procedures can be obtained by the call `setuserinfo()`.

**See Also**

**MuPAD Functions**

`print` | `setuserinfo` | `warning`

# val

---

**Purpose** Value of an object

**Syntax** `val(object)`

**Description** `val(object)` replaces every identifier in `object` by its value.

`val` does not perform any simplification of the result.

If the result of `val` is a set, duplicate elements are removed from that set.

`val` does not work recursively, i.e., if the value of an identifier in turn contains identifiers, then these are not replaced by their values. See “Example 3” on page 1-2345.

`val` does not flatten its argument. Hence, an expression sequence is accepted as argument. Cf. “Example 2” on page 1-2345.

## Examples

### Example 1

`val` replaces identifiers by their values, but does not call arithmetical functions such as `_plus`:

```
a := 0: val(a*b + 4 + 0)
```

```
0 b + 4 + 0
```

Duplicate elements in sets are removed:

```
a := b: val({a, b, a*0})
```

```
{b, 0 b}
```

```
delete a:
```

### Example 2

`val` does not flatten its argument, nor does it remove void objects of type `DOM_NULL`:

```
a := null(): val((a, null()))
null(), null()
```

However, it is not legal to pass several arguments:

```
val(a, null())
```

```
Error: The number of arguments is incorrect. [val]
```

```
delete a:
```

### Example 3

`val` does not recursively substitute values for the identifiers:

```
delete a, b: a := b: b := c: val(a)

b
```

## Parameters

**object**

Any MuPAD object

## Return Values

“evaluated” object.

# val

---

## See Also

## MuPAD Functions

eval | hold | level | LEVEL | MAXLEVEL

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Vector potential of a three-dimensional vector field                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Syntax</b>      | <code>vectorPotential(j, [x<sub>1</sub>, x<sub>2</sub>, x<sub>3</sub>], &lt;Test&gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p><code>vectorPotential(j, x)</code> returns the vector potential of the vector field <math>\vec{j}(\vec{x})</math> with respect to <math>\vec{x}</math>. This is a vector field <math>\vec{v}</math> with <math>\text{curl}_{\vec{v}}(\vec{x}) = \vec{j}</math>.</p> <p>The vector potential of a vector function <math>j</math> exists if and only if the divergence of <math>j</math> is zero. It is uniquely determined.</p> <p>If the vector potential of <math>j</math> does not exist, then <code>vectorPotential</code> returns <code>FALSE</code>.</p> <p>If <math>j</math> is a vector then the component ring of <math>j</math> must be a field (i.e., a domain of category <code>Cat::Field</code>) for which definite integration can be performed.</p> <p>If <math>j</math> is given as a list of three arithmetical expressions, then <code>vectorPotential</code> returns a vector of the domain <code>Dom::Matrix()</code>.</p> <p><code>vectorPotential</code> and <code>linalg::vectorPotential</code> are equivalent.</p> |

## Examples

### Example 1

We check if the vector function  $\vec{j}(x, y, z) = \left(x^2 y, -\frac{y^2 x}{2}, -x y z\right)$  has a vector potential:

```
delete x, y, z:
vectorPotential(
 [x^2*y, -1/2*y^2*x, -x*y*z], [x, y, z], Test
)
```

TRUE

The answer is yes, so let us compute the vector potential of  $\vec{j}$ :

# vectorPotential

---

```
vectorPotential(
 [x^2*y, -1/2*y^2*x, -x*y*z], [x, y, z]
)
```

$$\begin{pmatrix} -\frac{x y^2 z}{2} \\ -x^2 y z \\ 0 \end{pmatrix}$$

We check the result:

```
curl(%, [x, y, z])
```

$$\begin{pmatrix} x^2 y \\ -\frac{x y^2}{2} \\ -x y z \end{pmatrix}$$

## Example 2

The vector function  $\vec{j} = (x^2, 2y, z)$  does not have a vector potential:

```
vectorPotential([x^2, 2*y, z], [x, y, z])
```

FALSE

## Parameters

**i**

A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3 1 or 1 3 matrix of a domain of category `Cat::Matrix`)

$x_1, x_2, x_3$

(indexed) identifiers

## Options

### Test

Check whether the vector field  $j$  has a vector potential and return TRUE or FALSE, respectively.

## Return Values

Vector with three components, i.e., an  $3 \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`, or a boolean value.

## MuPAD Functions

`curl` | `divergence` | `gradient` | `laplacian` | `potential`

# version

---

**Purpose** Version number of the MuPAD library

**Syntax** `version()`

**Description** `version()` returns the version number of the installed MuPAD library. The call `Pref::kernel()` returns the version number of the installed MuPAD kernel.

The version numbers of the kernel and the library may differ: `version` refers to the library, whereas the call `Pref::kernel()` returns the version number of the kernel.

**Examples** **Example 1**

The version of this MuPAD library is:

```
version()
```

```
[5, 11, 0]
```

**Return Values** Version number: a list of three nonnegative integers.

**See Also**

**MuPAD Functions** `buildnumber` | `Pref::kernel`

**Purpose** Print a warning message

**Syntax** `warning(message)`

**Description** `warning(message)` prints the message with the prefix “Warning:”.  
`warning` may be used to print information about potential problems in an algorithm. E.g., it is used in `limit` to provide hints.

**Examples** **Example 1**

A warning:

```
warning("You should not do this!");
```

```
Warning: You should not do this!
```

**Example 2**

This example shows a simple procedure which divides two numbers. If the second argument is omitted, a warning is printed and the computation continues:

```
mydivide := proc(x, y)
begin
 if args(0) < 2 then
 warning("Denominator not given, using 1.");
 y := 1;
 end_if:
 x/y
end_proc:
mydivide(10)
```

```
Warning: Denominator not given, using 1. [mydivide]
```

# warning

---

10

## Parameters

**message**

A character string

## Return Values

Void object of type DOM\_NULL.

## See Also

## MuPAD Functions

error | print

**Purpose** The Whittaker M function

**Syntax** whittakerM(a, b, z)

**Description** The whittakerM function  $M_{a,b}(z)$  is related to the confluent hypergeometric function  ${}_pF_q(a, b, z) = \Phi(a, b, z)$  by the formula:

$$M_{a,b}(z) = e^{-\frac{z}{2}} z^{\frac{1}{2}+b} \Phi\left(\frac{1}{2} + b - a, 1 + 2b, z\right)$$

The WhittakerM function is defined for complex arguments  $a$ ,  $b$ , and  $z$ .

For most of the values of the parameters, an unevaluated function call is returned. Cf. “Example 1” on page 1-2354.

Explicit symbolic expressions are returned for some particular values of the parameters. Cf. “Example 2” on page 1-2354.

---

**Note** MuPAD defines  ${}_1F_1(a, a, z) = e^z$  for all complex numbers  $a$ . As a consequence, the MuPAD whittakerM differs from the corresponding function in M. Abramowitz and I. A. Stegun, “Handbook of Mathematical Functions” when  $\frac{1}{2} + b - a$  and  $1 + 2b$  are negative integers and  $\frac{1}{2} + b - a \geq 1 + 2b$ . Some of the formulas in Chapter 13 of the “Handbook of Mathematical Functions” do not hold for the MuPAD whittakerM with such arguments. Cf. “Example 4” on page 1-2355.

---

## Environment Interactions

When called with floating-point arguments, these functions are sensitive to the environment variable DIGITS which determines the numerical working precision.

# whittakerM

---

## Examples

### Example 1

Unevaluated calls are returned for exact or symbolic arguments:

```
whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)
```

$$M_{a,b}(x), W_{-\frac{3}{2}, \frac{1}{2}}(1)$$

Floating point values are returned for floating-point arguments:

```
whittakerM(-2, 0.5, -50), whittakerW(-3/2, 1/2, 0.0)
```

```
0.00000001666553264, 0.7522527781
```

### Example 2

Explicit expressions are returned for some specific values of the parameters:

```
whittakerM(0, b, x), whittakerW(0, b, x), whittakerW(-3/2, 1/2, 0),
whittakerM(-3/2, 0, x), whittakerW(a, -a + 1/2, x)
```

$$4^b \sqrt{x} \Gamma(b+1) I_b\left(\frac{x}{2}\right), \frac{x^{b+\frac{1}{2}} K_b\left(\frac{x}{2}\right)}{\sqrt{\pi} x^b}, \frac{4}{3\sqrt{\pi}}, \sqrt{x} e^{\frac{x}{2}} (x+1), x^{1-a} x^{2a-1} e^{-\frac{x}{2}}$$

### Example 3

The functions `diff`, `float`, `limit`, and `series` handle expressions involving the Whittaker functions

```
diff(whittakerM(a,b,z),z), float(whittakerW(-3/2,1/2,0))
```

$$\frac{M_{a+1,b}(z) (a+b+\frac{1}{2})}{z} - \left(\frac{a}{z} - \frac{1}{2}\right) M_{a,b}(z), 0.7522527781$$

`series(whittakerW(-3/2,1/2,x),x,3)`

$$\frac{4}{3\sqrt{\pi}} + X \left( \frac{2(\text{EULER} - 2\ln(2) + \ln(x) + \frac{5}{3})}{\sqrt{\pi}} - \frac{2}{3\sqrt{\pi}} \right) + X^2 \left( \frac{2 \left( \frac{5\text{EULER}}{4} - \frac{5\ln(2)}{2} + \frac{5\ln(x)}{4} + \frac{17}{24} \right)}{\sqrt{\pi}} \right. \\ \left. - \frac{\text{EULER} - 2\ln(2) + \ln(x) + \frac{5}{3}}{\sqrt{\pi}} + \frac{1}{6\sqrt{\pi}} \right) + O(X^3)$$

#### Example 4

For some values of the input parameters, recurrence and differential relations in Chapter 13 of M. Abramowitz and I. A. Stegun, "Handbook of Mathematical Functions" may not hold for the MuPAD whittakerM functions. For example, Formula 13.4.32

$$z \frac{\partial}{\partial z} M_{a,b}(z) = \left(\frac{z}{2} - a\right) M_{a,b}(z) + \left(a + b + \frac{1}{2}\right) M_{a+1,b}(z)$$

is not satisfied for  $a = 0$  and  $b = -\frac{3}{2}$ :

`expand(x*diff(whittakerM(0, -3/2, x), x) <>  
x/2*whittakerM(0, -3/2, x) - whittakerM(1, -3/2, x))`

$$-e^{-\frac{x}{2}} - \frac{x e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x} \neq \frac{e^{-\frac{x}{2}}}{2} + \frac{x e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x}$$

**Parameters**    **a, b, z**

# whittakerM

---

arithmetical expressions

## Return Values

Arithmetical expression.

## Overloaded By

$z$

## Algorithms

$M_{a,b}(z)$  and  $W_{a,b}(z)$  satisfy Whittaker's differential equation:

$$\frac{\partial^2}{\partial z^2} y + \left( -\frac{1}{4} + \frac{a}{z} + \frac{\frac{1}{4} - b^2}{z^2} \right) y = 0$$

## See Also

## MuPAD Functions

whittakerW | hypergeom | kummerU

**Purpose** The Whittaker W function

**Syntax** whittakerW(a, b, z)

**Description** The whittakerW function  $W_{a,b}(z)$  is related to the confluent hypergeometric function  $kummerU(a, b, z) = U(a, b, z)$  by the formula:

$$W_{a,b}(z) = e^{-\frac{z}{2}} z^{\frac{1}{2}+b} U\left(\frac{1}{2} + b - a, 1 + 2b, z\right)$$

The WhittakerW function is defined for complex arguments  $a$ ,  $b$ , and  $z$ .

For most of the values of the parameters, an unevaluated function call is returned. Cf. “Example 1” on page 1-2357.

Explicit symbolic expressions are returned for some particular values of the parameters. Cf. “Example 2” on page 1-2358.

## Environment Interactions

When called with floating-point arguments, these functions are sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

Unevaluated calls are returned for exact or symbolic arguments:

```
whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)
```

$$M_{a,b}(x), W_{-\frac{3}{2}, \frac{1}{2}}(1)$$

Floating point values are returned for floating-point arguments:

```
whittakerM(-2, 0.5, -50), whittakerW(-3/2, 1/2, 0.0)
```

# whittakerW

0.00000001686553264, 0.7522527781

## Example 2

Explicit expressions are returned for some specific values of the parameters:

`whittakerM(0, b, x)`, `whittakerW(0, b, x)`, `whittakerW(-3/2, 1/2, 0)`,  
`whittakerM(-3/2, 0, x)`, `whittakerW(a, -a + 1/2, x)`

$$4^b \sqrt{x} \Gamma(b+1) I_b\left(\frac{x}{2}\right), \frac{x^{b+\frac{1}{2}} K_b\left(\frac{x}{2}\right)}{\sqrt{\pi} x^b}, \frac{4}{3\sqrt{\pi}}, \sqrt{x} e^{\frac{x}{2}} (x+1), x^{1-a} x^{2a-1} e^{-\frac{x}{2}}$$

## Example 3

The functions `diff`, `float`, `limit`, and `series` handle expressions involving the Whittaker functions

`diff(whittakerM(a,b,z),z)`, `float(whittakerW(-3/2,1/2,0))`

$$\frac{M_{a+1,b}(z) (a+b+\frac{1}{2})}{z} - \left(\frac{a}{z} - \frac{1}{2}\right) M_{a,b}(z), 0.7522527781$$

`series(whittakerW(-3/2,1/2,x),x,3)`

$$\frac{4}{3\sqrt{\pi}} + x \left( \frac{2(\text{EULER} - 2\ln(2) + \ln(x) + \frac{5}{3})}{\sqrt{\pi}} - \frac{2}{3\sqrt{\pi}} \right) + x^2 \left( \frac{2\left(\frac{5\text{EULER}}{4} - \frac{5\ln(2)}{2} + \frac{5\ln(x)}{4} + \frac{17}{24}\right)}{\sqrt{\pi}} \right. \\ \left. - \frac{\text{EULER} - 2\ln(2) + \ln(x) + \frac{5}{3}}{\sqrt{\pi}} + \frac{1}{6\sqrt{\pi}} \right) + O(x^3)$$

**Example 4**

For some values of the input parameters, recurrence and differential relations in Chapter 13 of M. Abramowitz and I. A. Stegun, “Handbook of Mathematical Functions” may not hold for the MuPAD whittakerM functions. For example, Formula 13.4.32

$$z \frac{\partial}{\partial z} M_{a,b}(z) = \left(\frac{z}{2} - a\right) M_{a,b}(z) + \left(a + b + \frac{1}{2}\right) M_{a+1,b}(z)$$

is not satisfied for  $a = 0$  and  $b = -\frac{3}{2}$ :

```
expand(x*diff(whittakerM(0, -3/2, x), x) <>
x/2*whittakerM(0, -3/2, x) - whittakerM(1, -3/2, x))
```

$$-\frac{e^{-\frac{x}{2}}}{2} - \frac{x e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x} \neq \frac{e^{-\frac{x}{2}}}{2} + \frac{x e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x}$$

**Parameters****a, b, z**

arithmetical expressions

**Return Values**

Arithmetical expression.

**Overloaded By**

z

**Algorithms** $M_{a,b}(z)$  and  $W_{a,b}(z)$  satisfy Whittaker's differential equation:

$$\frac{\partial^2}{\partial z^2} y + \left(-\frac{1}{4} + \frac{a}{z} + \frac{\frac{1}{4} - b^2}{z^2}\right) y = 0$$

# whittakerW

---

## See Also

## MuPAD Functions

[whittakerM](#) | [hypergeom](#) | [kummerU](#)

**Purpose** The Wright  $\omega$  function

**Syntax** `wrightOmega(x)`

**Description**  $\omega(X)$  is defined in terms of Lambert's  $W$  function as

$$\omega(X) = W_{\left[\frac{\Im(X) - \pi}{2\pi}\right]}(e^X).$$

For  $x \neq t - i\pi$  with  $t \leq -1$ ,  $y = \omega(X)$  is a solution of the equation  $y + \ln(y) = x$ . The complete solution set of this equation is

$$y = \begin{cases} \emptyset & \text{if } \Re(X) \leq -1 \wedge \Im(X) = -\pi \\ \{\omega(X), \omega(X - 2\pi i)\} & \text{if } \Re(X) \leq -1 \wedge \Im(X) = \pi \\ \{\omega(X)\} & \text{otherwise} \end{cases}$$

A floating-point value is computed if the argument is a floating point value. Unevaluated symbolic calls are returned for most exact arguments. For some special cases explicit symbolic representations are returned.

## Environment Interactions

When called with a floating-point argument, the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

Most calls with exact arguments return themselves unevaluated:

```
wrightOmega(1/2); wrightOmega(I*PI);
```

$$\omega\left(\frac{1}{2}\right)$$

# wrightOmega

---

$\omega(\pi i)$

Some special arguments return explicit symbolic representations:

```
wrightOmega(-1+I*PI); wrightOmega(ln(2)+6*PI*I);
```

- 1

$W_3(2)$

If the argument is a floating-point value, then a floating-point result will be returned:

```
wrightOmega(0.5)
```

0.7662486082

## Parameters

**x**

An arithmetical expression, the “argument”

## Return Values

Arithmetical expression

## See Also

## MuPAD Functions

`lambertW`

**Purpose**

Write the values of variables into a file

**Syntax**

```
write(<Bin | Text>, filename, <x1, x2, >)
write(n, <x1, x2, >)
```

**Description**

`write` serves for storing information from the current MuPAD session in a file. The file contains the values of identifiers of the current session. These identifiers are assigned the stored values when this file is read into another MuPAD session via the function `read`.

`write(filename, x1, x2, ...)` stores the current values of the identifiers  $x_1, x_2$  etc. to the file `filename`.

`write(filename)` stores the values of all identifiers defined in the current session to the file `filename`.

`write(n)` and `write(n, x1, x2, ...)` store the data in the file associated with the file descriptor `n`.

If the file is specified by its name, `write` creates a new file or overwrites an existing file; `write` opens and closes the file automatically.

If `WRITEPATH` does not have a value, `write` interprets the file name as a pathname relative to the “working directory”.

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Mac OS X systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

Also absolute path names are processed by `write`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. Cf. “Example 2” on page 1-2365. In this case, the data written by `write` are appended to the corresponding file. The file is not closed automatically by `write` and must be closed by a subsequent call to `fclose`.

# write

---

Note that `fopen(filename)` opens the file in read-only mode. A subsequent `write` command to this file causes an error. Use the `Write` or `Append` option of `fopen` to open the file for writing.

The file descriptor 0 represents the screen.

`write` stores procedures with the option `noExpose` in encrypted format.

---

**Note** `write` stores the *values* of the given identifiers, not *their full evaluation*! Cf. “Example 3” on page 1-2366.

---

## Environment Interactions

The function is sensitive to the environment variable `WRITEPATH`. If this variable has a value, the file is created in the corresponding directory. Otherwise, the file is created in the “working directory.”

## Examples

### Example 1

The variable `a` and its value `b + 1` are stored in a file named `test`:

```
a := b + 1:
fid := fopen(TempFile, Write, Text):
write(fid, a):
```

Use `fname` to return the name of the temporary file you created:

```
file := fname(fid):
```

The content of this file is displayed via `ftextInput`:

```
ftextInput(file)
```

```
"a := hold(_plus)(hold(b), 1):"
```

We delete the value of `a`. Reading the file `test` restores the previous value:

```
delete a:
read(file):
a
```

```
b + 1
```

For identifiers that have no value, `write` writes a delete command to the file:

```
delete a:
write(Text, 0, a):
```

```
delete a:
```

## Example 2

The file `test` is opened for writing using the MuPAD binary format:

```
fid := fopen(TempFile):
file := fname(fid):
n := fopen(file, Write)
```

```
17
```

This number is the descriptor of the file and can be used in a write command:

```
a := b + 1:
write(n, a):
fclose(n):
```

```
delete a:
read(file):
```

# write

---

a

$b + 1$

We clean up:

```
delete n, a:
```

### Example 3

The value  $b + 1$  is assigned to the identifier `a`. After assigning the value 2 to `b`, complete evaluation of `a` yields 3:

```
a := b + 1:
```

```
b := 2:
```

```
a
```

3

Note, however, that the value of `a` is the expression  $b + 1$ . This value is stored by a `write` command:

```
fid := fopen(TempFile, Write, Text):
```

```
write(fid, a):
```

```
file := fname(fid):
```

```
ftextinput(file)
```

```
"a := hold(_plus)(hold(b), 1):"
```

Consequently, this value is restored after reading the file into a MuPAD session:

```
delete a, b:
```

```
read(file):
```

```
a
```

```
b + 1
```

```
delete a:
```

#### Example 4

write, when writing binary format, can store procedures with the option noExpose set. They are encrypted before writing:

```
f := proc(a)
 option noExpose;
begin
 print(a, a^2, a*a);
end_proc:

write("hidden_proc.mb", f):

delete f:

read("hidden_proc.mb"):

f(-2...3);
expose(f)

- 2.0 ... 3.0, 0.0 ... 9.0, - 6.0 ... 9.0

proc(a)
 name f;
 option noDebug, noExpose;
begin
 /* Hidden */
end_proc
```

# write

---

This is the intention behind option `noExpose`: You can develop code you wish not to publish, then include option `noExpose` in your sources, rerun your tests, use `write` to write a binary version of your library and distribute that.

## Parameters

### **filename**

The name of a file: a character string

### **$x_1, x_2, \dots$**

identifiers

### **n**

A file descriptor provided by `fopen`: a nonnegative integer

## Options

### **Bin, Text**

With `Bin`, the data are stored in the MuPAD binary format. With `Text`, standard ASCII format is used. The default is `Bin`.

In ASCII format, assignments of the form `identifier := hold(value):` or `delete identifier:` are written into the file. See “Example 1” on page 1-2364.

## Return Values

Void object of type `DOM_NULL`.

## See Also

**Purpose** The Riemann zeta function

**Syntax** zeta(z)  
zeta(z, n)

**Description** zeta(z) represents the Riemann zeta function  $\zeta(z) = \sum_{k=1}^{\infty} \frac{1}{k^z}$ .  
zeta(z, n) represents the n-th derivative  $\sum_{k=1}^{\infty} \frac{(-\ln(k))^n}{k^z}$  of the zeta function.

The series converge only if the real part of z is greater than 1. The definition of the zeta function is extended to the entire complex plane, except for a simple pole  $z = 1$ , by analytic continuation.

The calls zeta(z) and zeta(z, 0) are equivalent.

A floating-point result is returned for floating-point arguments z.

The following special exact values are implemented:

$$\zeta(0) = -\frac{1}{2}, \quad \zeta(0, 1) = -\frac{\ln(\pi)}{2} - \frac{\ln(2)}{2},$$

$$\zeta(z) = 0 \text{ for even integers } z < 0,$$

$$\zeta(z) = -\frac{\text{bernoulli}(1-z)}{z} \text{ for odd integers } z \text{ satisfying } -\text{Pref::autoExpansionLimit}() \leq z < 0,$$

$$\zeta(z) = \frac{(2\pi)^z |\text{bernoulli}(z)|}{z} \text{ for even integers } z \text{ satisfying } 0 \leq z \leq \text{Pref::autoExpansionLimit}(),$$

$$\zeta(\infty) = 1, \quad \zeta(\infty, n) = 0 \text{ for } n > 0.$$

zeta returns a symbolic function call, if the argument does not evaluate to one of the above numbers.

---

**Note** Floating point evaluation is rather slow for large values of  $n$ . Further, for large  $n$ , evaluation for  $\Re(z) < 0$  is much slower than the evaluation for  $\Re(z) \geq 0$ .

---

## Environment Interactions

When called with a floating-point argument  $z$ , the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

## Examples

### Example 1

We demonstrate some calls with exact and symbolic input data:

`zeta(-6), zeta(-5), zeta(-4), zeta(-3), zeta(-2), zeta(-1)`

$$0, -\frac{1}{252}, 0, \frac{1}{120}, 0, -\frac{1}{12}$$

`zeta(0), zeta(2), zeta(3), zeta(4), zeta(5), zeta(6), zeta(7)`

$$-\frac{1}{2}, \frac{\pi^2}{6}, \zeta(3), \frac{\pi^4}{90}, \zeta(5), \frac{\pi^6}{945}, \zeta(7)$$

`zeta(1/2), zeta(1 + I, 1), zeta(z^2 - I, 2)`

$$\zeta\left(\frac{1}{2}\right), \zeta'(1 + i), \zeta''(z^2 - i)$$

Here are some values of the derivative of the zeta function:

`zeta(0, 1), zeta(infinity, 1)`

$$-\frac{\ln(2)}{2} - \frac{\ln(\pi)}{2}, 0$$

Floating point values are computed for floating-point arguments:

```
zeta(-1001.0), zeta(12.3, 1), zeta(0.5 + 14.13472514*I, 2)
- 1.348590824 101771, - 0.0001389996909, - 0.614409794 - 0.2297836439 i
```

zeta has a pole at the point  $z = 1$ :

```
zeta(1)
```

```
Error: Singularity. [zeta]
```

## Example 2

Looking for nontrivial roots of the Zeta function, we plot the function  $f(z) = |\zeta(z)|$  along the “critical line” of complex numbers with real part  $\frac{1}{2}$ :

```
plotfunc2d(abs(zeta(1/2 + y*I)), y = 0..30, Mesh = 500, AxesTitl
```

# zeta

The following calls search for numerical roots along the critical line:

```
numeric::solve(zeta(1/2 + I*y), y = 10..20),
numeric::solve(zeta(1/2 + I*y), y = 20..22),
numeric::solve(zeta(1/2 + I*y), y = 22..26)
```

```
{14.13472514}, {21.02203964}, {25.01085758}
```

## Parameters

**z**

An arithmetical expression

**n**

An arithmetical expression representing a nonnegative integer

## Return Values

Arithmetical expression.

**Overloaded  
By**      z

**See Also**

**MuPAD  
Functions**      bernoulli

# zip

---

**Purpose** Combine lists

**Syntax** `zip(list1, list2, f)`  
`zip(list1, list2, f, default)`

**Description** `zip(list1, list2, f)` combines two lists via a function `f`. It returns a list whose  $i$ -th entry is `f(list1[i], list2[i])`. Its length is the minimum of the lengths of the two input lists.

`zip(list1, list2, f, default)` returns a list whose length is the maximum of the lengths of the two input lists. The shorter list is padded with the `default` value.

If `f` produces the void object of type `DOM_NULL`, then this element is removed from the resulting list.

`zip` is recommended for fast manipulation of lists. It is a function of the system kernel.

## Examples **Example 1**

The fastest way of adding the entries of two lists is to 'zip' them via the function `_plus`:

```
zip([a, b, c, d], [1, 2, 3, 4], _plus)
```

```
[a + 1, b + 2, c + 3, d + 4]
```

If the input lists have different lengths, then the shorter list determines the length of the returned list:

```
zip([a, b, c, d], [1, 2], _plus)
```

```
[a + 1, b + 2]
```

The longer list determines the length of the returned list if a value for padding the shorter list is provided:

```
zip([a, b, c, d], [1, 2], _plus, 17)
```

```
[a + 1, b + 2, c + 17, d + 17]
```

**Parameters****list1, list2**

lists of arbitrary MuPAD objects

**f**

Any MuPAD object. Typically, a function of two arguments.

**default**

Any MuPAD object

**Return Values**

List.

**Overloaded By**

list1, list2

# ztrans

---

**Purpose** Z transform

**Syntax** ztrans(f, k, z)

**Description** ztrans(f, k, z) computes the Z transform of the expression f = f(k) with respect to the index k at the point z.

The Z transform F(z) of the function f(k) is defined as follows:

$$F(z) = \sum_{k=0}^{\infty} \frac{f(k)}{z^k}$$

If ztrans cannot find an explicit representation of the transform, it returns an unevaluated function call. See “Example 4” on page 1-2378.

If f is a matrix, ztrans applies the Z transform to all components of the matrix.

To compute the inverse Z transform, use iztrans.

## Examples

### Example 1

Compute the Z transform of these expressions:

`ztrans(1/k!, k, z)`

$$e^{\frac{1}{z}}$$

`ztrans(sin(k), k, z)`

$$\frac{z \sin(1)}{z^2 - 2 \cos(1) z + 1}$$

**Example 2**

Compute the Z transform of this expression and then simplify the result:

```
ztrans(cos(a*k + b), k, z)
```

$$\frac{z \cos(b) (z - \cos(a))}{z^2 - 2 \cos(a) z + 1} - \frac{z \sin(a) \sin(b)}{z^2 - 2 \cos(a) z + 1}$$

```
Simplify(%)
```

$$-\frac{z (\cos(a - b) - z \cos(b))}{z^2 - 2 \cos(a) z + 1}$$

**Example 3**

Compute the Z transform of this expression with respect to the variable k:

```
F := ztrans(2*k + 3, k, z)
```

$$\frac{3z}{z-1} + \frac{2z}{(z-1)^2}$$

Evaluate the Z transform of the expression at the points  $z = 2a + 3$  and  $z = 1 + i$ . You can evaluate the resulting expression F using | (or its functional form evalAt):

```
F | z = 2*a + 3
```

$$\frac{3(2a+3)}{2a+2} + \frac{2(2a+3)}{(2a+2)^2}$$

Also, you can evaluate the Z transform at a particular point directly:

```
ztrans(2*k + 3, k, 1 + I)
```

```
1 - 5i
```

## Example 4

If `ztrans` cannot find an explicit representation of the transform, it returns an unevaluated call:

```
ztrans(f(k), k, z)
```

```
ztrans(f(k), k, z)
```

`iztrans` returns the original expression:

```
iztrans(%, z, k)
```

```
f(k)
```

## Example 5

Compute the following Z transforms that involve Kronecker's Delta function and the Heaviside function:

```
ztrans(f(k)*kroneckerDelta(k, 1) + g(k)*kroneckerDelta(k, -5), k, z)
```

$$\frac{f(1)}{z}$$

```
ztrans(binomial(k, 2)*heaviside(5 - k), k, z)
```

$$\frac{z}{(z-1)^3} + \frac{5}{z^5} + \frac{6z - \frac{z^6}{(z-1)^3} + 3z^2 + z^3}{z^5}$$

Simplify the last expression using `simplify`:

```
simplify(%)
```

$$\frac{z^3 + 3z^2 + 6z + 5}{z^5}$$

### Example 6

Compute the Z transforms of this expression that involves the Heaviside function:

```
ztrans(heaviside(k - 3), k, z)
```

$$\frac{\frac{1}{z-1} + \frac{1}{2}}{z^3}$$

Note that MuPAD uses the value  $\text{heaviside}(0) = 1/2$ . You can define a different value for  $\text{heaviside}(0)$ :

```
unprotect(heaviside):
heaviside(0) := 1:
```

For better performance, MuPAD remembers the previously computed value of the Z transform. To force the system to recalculate the transform, clear its remember table:

```
ztrans(Remember, Clear):
```

For details about the remember mechanism, see Remember Mechanism.

Defining a different value for `heaviside(0)` produces a different value of the Z transform:

```
ztrans(heaviside(k - 3), k, z)
```

$$\frac{\frac{1}{z-1} + 1}{z^3}$$

For further computations, restore the original value:

```
heaviside(0) := 1/2:
protect(heaviside):
```

## Example 7

Compute the Z transforms of these expressions:

```
ztrans(k*f(k), k, z)
```

$$-z \frac{\partial}{\partial z} \text{ztrans}(f(k), k, z)$$

```
ztrans(f(k + 1), k, z)
```

$$z \text{ztrans}(f(k), k, z) - z f(0)$$

|                         |                                                                                                                                                                                                        |

# ztrans::addpattern

---

**Purpose** Add patterns for the Z transform

**Syntax** `ztrans::addpattern(pat, k, z, res, <vars, <conds>>)`

**Description** `ztrans::addpattern(pat, k, z, res)` teaches `ztrans` to return

$$\text{ztrans}(\text{pat}, k, z) = \sum_{k=0}^{\infty} \frac{\text{pat}}{k} = \text{res}.$$

The `ztrans` function uses a set of patterns for computing Z transforms. You can extend the set by adding your own patterns. To add a new pattern to the pattern matcher, use `ztrans::addpattern`. MuPAD does not save custom patterns permanently. The new patterns are available in the *current* MuPAD session only.

Variable names that you use when calling `ztrans::addpattern` can differ from the names that you use when calling `ztrans`. See “Example 2” on page 1-2383.

You can include a list of free parameters and a list of conditions on these parameters. These conditions and the result are protected from premature evaluation. This means that you can use `not iszero(a^2 - b)` instead of `hold( _not @ iszero )(a^2 - b)`.

The following conditions treat assumptions on identifiers differently:

- `a^2 - b <> 0` takes into account assumptions on identifiers.
- `not iszero(a^2 - b)` disregards assumptions on identifiers.

See “Example 3” on page 1-2384.

**Environment Interactions** Calling `ztrans::addpattern` changes the expressions returned by future calls to `ztrans`.

**Examples** **Example 1**

Compute the Z transform of the function `foo`. By default, MuPAD does not have a pattern for this function:

```
ztrans(foo(k), k, z)
```

```
ztrans(foo(k), k, z)
```

Add a pattern for the Z transform of foo using `ztrans::addpattern`:

```
ztrans::addpattern(foo(k), k, z, bar(z)):
```

Now `ztrans` returns the Z transform of foo:

```
ztrans(foo(k), k, z)
```

```
bar(z)
```

After you add a new transform pattern, MuPAD can use that pattern indirectly:

```
ztrans(foo(k + 3), k, z)
```

```

$$z^3 \text{bar}(z) - z \text{foo}(2) - z^2 \text{foo}(1) - z^3 \text{foo}(0)$$

```

## Example 2

Define the Z transform of `foo(x)` using the variables `x` and `y` as parameters:

```
ztrans::addpattern(x, x, y, y/(y^2-2*y+1)):
```

The `ztrans` function recognizes the added pattern even if you use other variables as parameters:

```
ztrans(s, s, t)
```

# ztrans::addpattern

---

$$\frac{t}{t^2 - 2t + 1}$$

### Example 3

Use assumptions when adding this pattern for the Z transform:

```
ztrans::addpattern(F00(x*k), k, z, sin(1/(x-1/2))*BAR(z), [x], [abs(x) < 1])
ztrans(F00(x*k), k, z) assuming -1 < x < 1
```

$$\sin\left(\frac{1}{x - \frac{1}{2}}\right) \text{BAR}(z)$$

If  $|x| \geq 1$ , you cannot apply this pattern:

```
ztrans(F00(x*k), k, z) assuming x >= 1
```

$$\text{ztrans}(\text{FOO}(k \ x), k, z)$$

If MuPAD cannot determine whether the conditions are satisfied, it returns a piecewise object:

```
ztrans(F00(x*k), k, z)
```

$$\left\{ \sin\left(\frac{1}{x - \frac{1}{2}}\right) \text{BAR}(z) \text{ if } |x| < 1 \right.$$

Note that the resulting expression defining the Z transform of  $F00(x*k)$  implicitly assumes that the value of  $x$  is not  $1/2$ . A strict definition of the pattern is:

```
ztrans::addpattern(BAR(x*k), k, z, sin(1/(x - 1/2))*F00(z), [x], [a
```

If either the conditions are not satisfied or substituting the values into the result gives an error, `ztrans` ignores the pattern. For this particular pattern, you can omit specifying the assumption  $x < 1/2$ . If  $x = 1/2$ , MuPAD throws an internal “Division by zero.” error and ignores the pattern:

```
ztrans(F00(s/2), s, t)
```

```
ztrans(F00($\frac{s}{2}$), s, t)
```

## Parameters

### **pat**

Arithmetical expression in the variable  $k$  representing the pattern to match

### **k**

Identifier or indexed identifier used as a variable in the pattern

### **z**

Identifier or indexed identifier used as a variable in the result

### **res**

Arithmetical expression in the variable  $k$  representing the pattern for the result of the transformation

### **vars**

List of identifiers or indexed identifiers used as “pattern variables” (placeholders in `pat` and `res`). You can use pattern variables as placeholders for almost arbitrary MuPAD expressions not containing  $k$  or  $z$ . You can restrict them by conditions given in the optional parameter `conds`.

### **conds**

List of conditions on the pattern variables

# ztrans::addpattern

---

## Return Values

Object of type DOM\_NULL

## See Also

## MuPAD Functions

ztrans | iztrans | iztrans::addpattern

# adt – Abstract Datatypes

---

adt::Heap  
adt::Queue  
adt::Stack  
adt::Tree

# adt::Heap

---

## Purpose

Abstract data type “Heap”

## Syntax

```
adt::Heap()
```

## Description

adt::Heap implements the abstract data type “Heap”.

A “heap” or “priority queue” is a data type that stores a collection of elements. Elements can be compared and the minimal element can be read and deleted from the heap.

In adt::Heap, each element is associated with a comparison key, typically a real number. The keys must be comparable with one another using <.

To get access to the largest element in an adt::Heap, you can simply negate the comparison keys.

adt::Heap returns a function environment. This object has slots "insert", "nops", "min\_pair", "min\_element", and "delete\_min" which allow operations on the heap. See the examples.

adt::Heap does not allow access to other elements than the minimal one.

## Examples

### Example 1

adt::Heap() creates an empty heap:

```
h := adt::Heap()
```

```
adt::Heap(...)
```

The slot "nops" of h shows the number of elements in the heap:

```
h::nops()
```

```
0
```

`h::insert` is the method to insert new elements. It expects two arguments: the comparison key and the data. For now, we simply insert some numbers, so we repeat the number in both arguments:

```
h::insert(3,3):
h::insert(1,1):
h::insert(2,2):
```

```
h::nops()
```

```
3
```

When retrieving the elements with `h::delete_min`, we see that they are returned in increasing order:

```
h::delete_min(), h::delete_min(), h::delete_min()
```

```
1, 2, 3
```

The heap is now empty:

```
h::nops()
```

```
0
```

Calling `delete_min` on an empty heap returns `FAIL`:

```
h::delete_min()
```

```
FAIL
```

# adt::Heap

---

## Algorithms

adt::Heap uses a complete binary tree stored in a list. Insertions operate in expected constant time, with a worst case time logarithmic in the number of elements in the heap. For "delete\_min", both the average and the worst-case running time are  $O(\log n)$ , with  $n$  the size of the heap.

## See Also

## MuPAD Functions

adt::Queue | adt::Stack | adt::Tree

**Purpose** Abstract data type “Queue”

**Syntax** `adt::Queue(queue)`

**Description** `adt::Queue` implements the abstract data type “Queue”. To create a queue, an expression sequence of any MuPAD objects can be given to initialize the queue, otherwise an empty queue is built.

---

**Note** The methods of all abstract data types must be called especially and will result changing the object itself as side effect.

---

With `Q := adt::Queue()` an empty queue is built and assigned to the variable `Q`.

Every queue will be displayed as `Queue` followed by a number. This name is generated by `genident`.

---

**Note** *All following methods changes the value of Q itself. A new assignment to the variable (in this example Q) is not necessary, in contrast to all other MuPAD functions and data types.*

---

The methods `clear`, `dequeue`, `empty`, `enqueue`, `front`, `length`, `reverse` are available for handling with queues.

## Examples

### Example 1

Create a new queue with strings as arguments.

```
Q := adt::Queue("1", "2", "3", "4")
```

```
Queue1
```

## adt::Queue

---

Show the length of the queue.

```
Q::length()
```

```
4
```

Fill up the queue with a new element. The queue will be changed by the method, no new assignment to Q is necessary!

```
Q::enqueue("5")
```

```
"5"
```

Show the front of the queue. This method does not change the queue.

```
Q::front(), Q::front()
```

```
"1", "1"
```

After twice getting an element of the queue, the third element is the new front of the queue, and the length is 3.

```
Q::dequeue(), Q::dequeue(), Q::front(), Q::length()
```

```
"1", "2", "3", 3
```

Now revert the queue. The last element will be the first element.

```
Q::reverse(): Q::front()
```

```
"5"
```

Enlarge the queue with "2".

```
Q::enqueue("2"):
Q::empty()
```

```
FALSE
```

Finally collect all elements of the queue in the list assigned to ARGS, until the queue is empty.

```
ARGS := []: while not Q::empty() do ARGS := append(ARGS, Q::dequeue())
ARGS
```

```
["5", "4", "3", "2"]
```

## Parameters

### queue

An expression sequence of objects to initialize the queue

## Methods

### clear - Clear the queue

```
clear()
```

### dequeue - Get an element from the queue

```
dequeue()
```

### empty - Is the queue empty

```
empty()
```

### enqueue - Fill up the queue

```
enqueue(x)
```

### front - Front of the queue

```
front()
```

### length - Length of the queue

## adt::Queue

---

length()

**reverse - Revert the queue**

reverse()

**Purpose** Abstract datatype “Stack”

**Syntax** `adt::Stack(stack)`

**Description** `adt::Stack` implements the abstract data type “Stack.” To create a stack, an expression sequence of any MuPAD objects can be given to initialize the stack, otherwise an empty stack is built.

---

**Note** The methods `adt::Stack`, like those of all abstract data types, change their argument as a side effect.

---

With `S := adt::Stack()` an empty stack is built and assigned to the variable `S`.

---

**Note** *All following methods change the value of `S` itself.* A new assignment to the variable (in this example `S`) is not necessary, in contrast to most other MuPAD functions and data types.

---

The stacks created in a session are named `Stack1`, `Stack2`, ... and printed as such.

## Examples

### Example 1

We create an empty stack, and fill it with some values:

```
S := adt::Stack();
S::push(a): S::push(b): S::push(c):
```

```
Stack1
```

The stack now contains 3 elements:

# adt::Stack

---

```
S::nops()
```

```
3
```

The top of the stack is the last valued pushed:

```
S::top()
```

```
c
```

Now, we fetch successively the values contains in S; they come back in reversed order:

```
S::pop();
```

```
S::pop();
```

```
S::pop()
```

```
c
```

```
b
```

```
a
```

Now, the stack is empty. Trying to pop again an element from it results in a FAIL value being returned:

```
S::pop()
```

```
FAIL
```

**Parameters****stack**

An expression sequence of objects to initialize the stack

**Return Values**Object of the domain `adt::Stack`**Methods****S::empty - Is the stack empty**

S::empty()

**S::nops - Size of the stack**

S::nops()

**S::depth - Depth of the stack**

S::depth()

**S::top - Top element of the stack**

S::top()

**S::push - Push an element on the stack**

S::push(x)

**S::pop - Pop an element from the stack**

S::pop()

**S::reverse - Revert the stack**

S::reverse()

**S::copy - Copy of the stack**

S::copy()

# adt::Tree

---

**Purpose** Abstract data type “Tree”

**Syntax** `adt::Tree(tree)`

**Description** `adt::Tree` implements the abstract data type “Tree”.

A tree must be given as a special MuPAD list. The first object of the list is the root of the tree. All further objects are leaves or subtrees of the tree. A subtree is again a special list (as described), and any other MuPAD object will be interpreted as leaf of the tree (see “Example 1” on page 2-13).

A tree can be used to display data in tree structure using the function `output::tree` (or the method “`print`” of a tree). The nodes and leaves of the tree will be printed by MuPAD when the tree will be displayed.

A tree can also be used as datatype to keep and handle any MuPAD data.

---

**Note** The methods of all abstract data types must be called especially and will result changing the object itself as side effect.

---

`T := adt::Tree([_plus, 3, 4, [_mult, 5, 3], 1])` builds a tree and assigns it to the variable `T`.

Every tree will be displayed as `Tree` followed by a number. This name is generated by `genident`.

To display the content of a tree, the function `expose` or the method “`print`” of the tree itself must be used.

---

**Note** *All following methods changes the value of T itself.* A new assignment to the variable (in this example `T`) is not necessary, in contrast to all other MuPAD functions and data types.

---

The methods `nops`, `op`, `expr`, `print`, `indent`, `chars` are now available for handling with trees.

## Examples

### Example 1

Creating a simple tree with only two leaves. To access and display a tree it must be assigned to a variable:

```
T := adt::Tree(["ROOT", "LEFT", "RIGHT"])
```

```
Tree1
```

The tree will only be printed by its name. To display the tree, the function `expose` or the method `print` of the tree must be used:

```
T::print()
```

```
ROOT
|
+-- LEFT
|
`-- RIGHT
```

```
expose(T)
```

```
ROOT
|
+-- LEFT
|
`-- RIGHT
```

The next tree contains two subtrees as leaves:

# adt::Tree

---

```
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],
 ["RROOT", "RLEFT", "RRIGHT"]]):
T::print()
```

```
ROOT
|
+-- LROOT
| |
| +-- LLEFT
| |
| \-- LRIGHT
|
|-- RROOT
| |
| +-- RLEFT
| |
| \-- RRIGHT
```

## Example 2

Get the operands of a tree: Also a subtree can be an operand:

```
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],
 "MIDDLE",
 ["RROOT", "RLEFT", "RRIGHT"]]):
T::op()
```

```
Tree4, "MIDDLE", Tree5
```

Use expose to display subtrees:

```
map(%, expose)
```

```
LROOT
```

```
RROOT
```

Get all operands including the root:

```

T::op(0..T::nops())

"ROOT", Tree6, "MIDDLE", Tree7

```

Access to various operands:

```

T::op(0);
T::op(2..3);
T::op([1, 2])

"ROOT"

"MIDDLE", Tree9

"LRIGHT"

```

### Example 3

The default characters are [ "|", "+", "-", " ", " " ]:

```

T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],
 ["RROOT", "RLEFT", "RRIGHT"]]);
T::print()

```

# adt::Tree

---

```
ROOT
|
+-- LROOT
|
| |-- LLEFT
| |-- LRIGHT
|
|-- RROOT
|
| |-- RLEFT
| |-- RRIGHT
```

The characters can be changed:

```
T::chars(["|", "|", "_", "|", " "]):
T::print()
```

```
ROOT
|
__ LROOT
|
| __ LLEFT
| __ LRIGHT
|
__ RROOT
|
| __ RLEFT
| __ RRIGHT
```

### Example 4

A tree visualizes the structure of an expression:

```
T:= adt::Tree([_plus, [_power, [sin, x], 2], [_power, [cos, x], 2]],
T::print()
```

A tree can be converted to a MuPAD expression:

```
T::expr(), simplify(T::expr())
```

```
cos(x)2 + sin(x)2, 1
```

### Parameters

**tree**

The tree, given as a special list (see details)

## Methods

### **nops - Number of operands**

nops()

In this example T has 4 operands, the numbers 3, 4, 1 and the subtree `adt::Tree([_mult, 5, 3])`.

### **op - Operand of a tree**

op(<n>)

`T::op(n)` returns the specified operands of the tree. `n` can be a number between 0 and `T::nops()` (0 gives the root of the tree), a sequence `i..j` (to return the *i*th to *j*th operand), or a list to specify operands of subtrees (exactly as for the kernel function `op`). `T::op()` returns all operands except the 0-th as expression sequence. See “Example 2” on page 2-14.

### **expr - Convert a tree to an expression**

expr()

### **print - Display a tree**

print()

### **indent - Indent width of each operand**

indent(<n>)

### **chars - Indent width of each operand**

chars(<list>)

# Ax – Axioms

---

Ax::canonicalOrder

Ax::canonicalRep

Ax::canonicalUnitNormal

Ax::closedUnitNormals

Ax::efficientOperation

Ax::indetElements

Ax::normalRep

Ax::noZeroDivisors

Ax::systemRep

# Ax::canonicalOrder

---

**Purpose** Axiom of canonically ordered sets

**Description** `Ax::canonicalOrder` states that a domain has an order `< (_less)` which is defined by the canonical order of the MuPAD expressions.  
This implies that the order of two elements is defined by the system function `_less`.

**Purpose**

Axiom of canonical representation

**Description**

`Ax::canonicalRep` states that domain elements are canonically represented, i.e. that each element of the domain has only one unique expression which represents it.

This axiom implies that for an abelian monoid the axiom `Ax::normalRep` also holds. This is not enforced by the category but must be stated by the implementor of a domain.

# Ax::canonicalUnitNormal

---

**Purpose** Axiom of canonical unit normals

**Description** Ax::canonicalUnitNormal states that the method "unitNormal" of an integral domain (category Cat::IntegralDomain) returns a unique unit normal.

This means that for each non-zero element  $x$  of the integral domain there exists a unique associate among the associate class of  $x$ , i.e. for any  $x$  and  $y$  of a domain  $\text{dom}$  of category Cat::IntegralDomain where  $\text{dom}::\text{associates}(x, y)$  returns TRUE the equation  $\text{dom}::\text{equal}(\text{dom}::\text{unitNormal}(x), \text{dom}::\text{unitNormal}(y)) = \text{TRUE}$  must hold.

Note that this axiom does not imply that the unit normals are canonically represented. The unit normals of  $x$  and  $y$  must be mathematically equal in the sense of the method "equal", they need not be structurally equal as MuPAD objects.

**Purpose**

Axiom of closed unit normals

**Description**

`Ax::closedUnitNormals` states that the unit normals of an integral domain are closed under multiplication, i.e., that `dom::equal(x, dom::unitNormal(a) * dom::unitNormal(b)) = TRUE` implies `dom::equal(x, dom::unitNormal(x)) = TRUE` for all elements `x`, `a` and `b` of the domain `dom`.

This axiom may be used only in conjunction with the axiom `Ax::canonicalUnitNormal`. If an integral domain has no unique unit normals, this axiom may not be stated.

# Ax::efficientOperation

---

|                    |                                                                                                                                                                                                                                                                                                                           |

| <b>Parameters</b>  | <p><b>oper</b></p> <p>A string which defines the efficient operation.</p>                                                                                                                                                                                                                                                 |

**Purpose**

Axiom that indeterminates may be elements

**Description**

`Ax::indetElements` states that there exist domain elements that may also be regarded as being transcendental over the domain.

`Ax::indetElements` has no mathematical meaning: elements of a ring are always algebraic (of degree 1) over the ring. However, since there are domains in MuPAD that comprise all MuPAD identifiers, insisting on this viewpoint would mean that polynomials over such domains could not be constructed. Hence MuPAD allows the user to regard an identifier as being transcendental over the set of all identifiers.

# Ax::normalRep

---

**Purpose** Axiom of normal representation

**Description** `Ax::normalRep` states that an abelian monoid has a canonical representation of its zero element, i.e., that there is only one unique expression to represent zero.

If the axiom `Ax::normalRep` holds for a domain `dom`, one may test for zero by comparing an element with `dom::zero` using the system function `_equal`.

**Purpose**

Axiom of rings with no zero divisor

**Description**

`Ax::noZeroDivisors` states that a ring without a unit has no zero divisors, i.e., that the product of two non-zero elements is never zero.

Note that an integral domain implicitly has no zero divisors.

# Ax::systemRep

---

## **Purpose**

Axiom of façade domains

## **Description**

`Ax::systemRep` states that domain elements are represented by elements of built-in domains.

There are principally two ways to represent the elements of a domain: On the one hand the elements may be created explicitly by the system function `new`, on the other hand one may use the built-in (or basic) domains of MuPAD (like `DOM_INT`) to represent the elements.

Domains which don't create elements of their own but use elements of basic domains instead are called *façade domains*.

The usage of basic domains for the representation has the advantage that system functions may be used directly as methods of the domain without the overhead caused by overloading and procedure calls. But it has some severe limitations, see the domain `Dom::Expression` for details.

The axiom `Ax::systemRep` is used to state that the elements of a domain are represented by basic domains and are not created by `new`.

Cat::SkewField  
Cat::SquareMatrix  
Cat::UnivariatePolynomial  
Cat::VectorSpace

**Purpose** Base category

**Description** `Cat::BaseCategory` is the most general super-category of all categories defined by the `Cat` package. Any domain in the `Dom` package is of this category.

The methods defined by `Cat::BaseCategory` are related to type conversion and equality testing, they are not related to an algebraic structure.

**Methods** Basic Methods

**convert - Convert into this domain**

```
convert(x)
```

**convert\_to - Convert to certain type**

```
convert_to(x, T)
```

**equal - Test for equality**

```
equal(x, y)
```

Note that this method does *not* overload the function `_equal`, i.e. the `=` operator. The function `_equal` cannot be overloaded.

**expr - Convert into expression**

```
expr(x)
```

Conversion Methods

**coerce - Coerce into this domain**

```
coerce(x)
```

The implementation provided tries to convert `x` into an element of this domain by first calling `dom::convert(x)` and then, if this fails, `x::dom::convert_to(x, dom)`; it returns `FAIL` if both methods fail.

**equiv - Test for equivalence**

```
equiv(x, y)
```

The implementation provided tries to convert  $x$  and  $y$  into elements of this domain and then calls `dom::equal` with these elements. It returns FAIL if the conversion fails or the equality test returns UNKNOWN.

## **new - Create element of this domain**

`new(x)`

Given a domain  $D$ , an expression of the form  $D(x, \dots)$  results in a call of the form `D::new(x, \dots)`.

The implementation provided here tries to convert  $x$  by calling `dom::convert(x)` and returns the result. It raises an error if `dom::convert` returns FAIL.

## **print - Return expression to print an element**

`print(x)`

Please do *not* print directly in this method by calling the function `print` for example!

The implementation provided here is `dom::expr`.

## **testtype - Test type of object**

`testtype(x, T)`

This method must return TRUE if it can decide that  $x$  is of type  $T$ , FALSE if it can decide that  $x$  is not of type  $T$  and FAIL if it can not decide the test.

This method is called in three different situations: Either if the argument  $x$  is of this domain, or if  $T$  is this domain, or if  $T$  is an element of this domain. Thus the following three situations can arise:

- $x$  is an element of the current domain.

In this case it must be tested if  $x$  may be regarded as an element of the type  $T$ , which may either be a domain or type expression. By default, this is only true if the domain type of  $x$  is  $T$ , or if  $T$

is a domain constructor for which `x::dom::hasProp(x, T)` is TRUE. In particular, `x` is, by default, not of type `T` if `T` is a type of the Type library.

- `T` is the current domain.

In this case it must be tested if `x` may be regarded as an element of this domain. By the default implementation provided, this is TRUE only if the domain type of `x` is `dom`.

- `T` is an element of the current domain.

In this case `T` is regarded as a type expression. The default implementation provided returns TRUE if the domain type of `x` is `T`, and FAIL if not. A special rule holds if `T` is a façade domain: in that case, `coerce(x, T)` is called, if this is successful TRUE is returned and FAIL if not.

## Technical Methods

### **new\_extelement - Create element of kernel or façade domain**

```
new_extelement(x,)
```

When an expression `new(D, x, ...)` is evaluated and `D` is a domain with method "new\_extelement", then `D::new_extelement(D, x, ...)` is evaluated and returned as result.

Kernel or façade domains must define this method because otherwise the function `new` would return a “container” element of `D` rather than a “raw” element as intended.

The implementation provided here returns the result of `D::new(x, ...)`.

# Cat::AbelianGroup

---

**Purpose**           Category of Abelian groups

**Description**       Cat::AbelianGroup represents the category of Abelian groups.  
A Cat::AbelianGroup is an Abelian monoid with cancellation law where the operation + is invertible.

**Categories**       Cat::CancellationAbelianMonoid

**Methods**           Basic Methods

**\_negate - Return opposite**

    \_negate(x)

**Mathematical Methods**

**equal - Test for equality**

    equal(x, y)

**intmult - Return integer multiple**

    intmult(x, n)

**\_subtract - Subtract two elements**

    \_subtract(x, y)

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                     |                                                                           |

# Cat::AbelianSemiGroup

---

**Purpose**            Category of Abelian semi-groups

**Description**     Cat::AbelianSemiGroup represents the category of Abelian semi-groups where the operation is written as addition. Hence an Cat::AbelianSemiGroup is a set with an associative and commutative operation + (`_plus`).

Note that non-Abelian semi-groups with operation \* have category Cat::SemiGroup.

**Categories**        Cat::BaseCategory

**Methods**            Basic Methods

**`_plus` - Return the sum of its arguments**

`_plus(x, )`

Mathematical Methods

**`intmult` - Return integer multiple**

`intmult(x, n)`

|                    |                                                                                                                                                                                                                                              |

| <b>Parameters</b>  | <b>R</b><br><p>A domain which is a commutative ring. The algebra will be an algebra over this ring.</p>                                                                                                                                      |

# Cat::CancellationAbelianMonoid

---

**Purpose** Category of abelian monoids with cancellation

**Description** `Cat::CancellationAbelianMonoid` represents the category of Abelian monoids with cancellation.

A `Cat::CancellationAbelianMonoid` is an Abelian monoid where the cancellation law holds according to the operation  $+$ , i.e.  $a + b = a + c$  implies  $b = c$ .

**Categories** `Cat::AbelianMonoid`

**Methods** Basic Methods

**`_subtract` - Subtract two elements**

`_subtract(x, y)`

Mathematical Methods

**`equal` - Test for equality**

`equal(x, y)`

The method "iszero" is used to test for zero.

**`_negate` - Negate element**

`_negate(x)`

**`intmult` - Return integer multiple**

`intmult(x, n)`

## Purpose

Category of commutative rings

## Description

`Cat::CommutativeRing` represents the category of commutative rings.

A `Cat::CommutativeRing` is a ring with unit `dom::one` where the multiplication `* (_mult)` is commutative. It is also a right module over itself.

This implementation additionally assumes that the elements are always constant with respect to differentiation and derivatives. One must re-implement the methods "diff" and "D" if this assumption is false.

## Categories

`Cat::Ring`, `Cat::RightModule(dom)`

## Methods

Mathematical Methods

### diff - Differentiate element

`diff(x, <v, >)`

### D - Return derivative

`D(1, x)`

# Cat::DifferentialRing

# Cat::EuclideanDomain

---

**Purpose**           Category of Euclidean domains

**Description**     Cat::EuclideanDomain represents the category of Euclidean domains. A Cat::EuclideanDomain is a principal ideal domain with an “Euclidean degree” function "euclideanDegree" and operations "quo" and "rem" computing the Euclidean quotient and Euclidean remainder. The Euclidean degree returns nonnegative integers such that for each non-zero  $x$  and  $y$  there exist  $s$  and  $r$  such that  $x = ys + r$  and either the Euclidean degree of  $r$  is less than that of  $s$  or  $r$  is zero. In addition  $s$  is equal to  $\text{quo}(x, y)$  and  $r$  is equal to  $\text{rem}(x, y)$ .

**Categories**       Cat::PrincipalIdealDomain

**Methods**           Basic Methods

**euclideanDegree - Return Euclidean degree**

euclideanDegree(x)

**divide - Division with remainder**

divide(x, y)

**Mathematical Methods**

**\_divide - Exact division**

\_divide(x, y)

**gcd - Greatest common divisor**

gcd(x, )

**gcdex - Extended greatest common divisor**

gcdex(x, y)

**idealGenerator - Generator of finitely generated ideal**

idealGenerator(x, )

## **quo - Euclidean quotient**

`quo(x, y)`

The default implementation provided here uses the basic method "divide".

## **rem - Euclidean remainder**

`rem(x, y)`

The default implementation provided here uses the basic method "divide".

# Cat::FactorialDomain

---

**Purpose**            Category of factorial domains

**Description**        `Cat::FactorialDomain` represents the category of factorial domains (i.e., unique factorization domains).

A `Cat::FactorialDomain` is an integral domain with gcd where an unique factorization can be computed.

The factorization methods are named "`factor`" and "`sqrfree`" and must return elements of the domain `Factored` over this domain.

**Categories**         `Cat::GcdDomain`

**Methods**            Basic Methods

**factor - Unique factorization**

`factor(x)`

See `Factored` for details about the representation of the factorization.

**Mathematical Methods**

**irreducible - Test if element is irreducible**

`irreducible(x)`

**sqrfree - Square-free factorization**

`sqrfree(x)`

See `Factored` for details about the representation of the factorization.

The default implementation provided here uses the method "`factor`" and therefore may be very inefficient.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**irreducible - Test if element is irreducible**

`irreducible(x)`

**isUnit - Test if element is an unit**

`isUnit(x)`

**quo - Return Euclidean quotient**

`quo(x, y)`

**rem - Return Euclidean remainder**

`rem(x, y)`

**sqrfree - Square-free factorization**

`sqrfree(x)`

**unitNormal - Unit normal form**

`unitNormal(x)`

**unitNormalRep - Unit normal representation**

`unitNormalRep(x)`

## Purpose

Category of finite collections

## Description

`Cat::FiniteCollection` represents the category of finite collections, i.e., the category of “universal” bags.

A finite collection is a data structure where each element represents a finite bag of “things” of any type.

The elements are numbered  $1, \dots, \text{nops}(c)$ , where  $\text{nops}(c)$  is the number of elements in the bag.

## Categories

`Cat::BaseCategory`

## Methods

Basic Methods

### **`_index` - Return element given its index**

```
_index(x, i)
```

### **`map` - Map function on elements**

```
map(x, f, <a, >)
```

### **`nops` - Return number of elements**

```
nops(x)
```

### **`op` - Return certain elements**

```
op(x)
```

```
op(x, i)
```

Must return the  $i$ -th element of  $x$  or FAIL if an element with the given index does not exist.

Operand ranges or paths need not be handled by this method because they are handled directly by `op`.

### **`set_index` - Change element with given index**

```
set_index(x, i, v)
```

Overloads the function `_assign` with an `_index` expression on the left hand side. The result is assigned to `x`.

## **subs - Substitute in elements**

```
subs(x, e = f)
```

## **subsop - Substitute operands**

```
subsop(x, i = v)
```

## **Technical Methods**

### **mapCanFail - Map function on elements**

```
mapCanFail(x, f, <a, >)
```

### **testEach - Test each element with a predicate**

```
testEach(x, f, <a, >)
```

### **testOne - Test if element exists fulfilling a predicate**

```
testOne(x, f, <a, >)
```

**Purpose** Category of integral domains with gcd

**Description** `Cat::GcdDomain` represents the category of integral domains with a gcd. A `Cat::GcdDomain` is an integral domain where the greatest common divisor of two elements can be computed by the method "gcd".

**Categories** `Cat::IntegralDomain`

**Methods** Basic Methods

**gcd - Greatest common divisor**

`gcd(x, y)`

The method must satisfy the following conditions:

- 1** `x` and `y` must divide `dom::gcd(x,y)`,
- 2** if `z` divides both `x` and `y`, then `z` must divide `dom::gcd(x,y)`,
- 3** if a domain has the axiom `Ax::canonicalUnitNormal` then `dom::gcd(x,y)` must be equal to `dom::unitNormal(dom::gcd(x,y))`.

Remember that `x` divides `y` if `_divide(x,y)` does not return FAIL.

**Mathematical Methods**

**lcm - Least common multiple**

`lcm(x, y)`

# Cat::Group

---

**Purpose**           Category of groups

**Description**       Cat::Group represents the category of groups.  
A Cat::Group is a (potentially non-Abelian) monoid where the group operation \* (\_mult) is invertible.

**Categories**       Cat::Monoid

**Methods**           Mathematical Methods  
**\_divide - Return quotient**  
                      \_divide(x, y)

# Cat::HomogeneousFiniteCollection

# Cat::HomogeneousFiniteProduct

---

**Purpose** Category of homogeneous finite products

**Syntax** `Cat::HomogeneousFiniteProduct(T)`

**Description** `Cat::HomogeneousFiniteProduct(T)` represents the category of homogeneous finite products of elements of the domain `T`.

A `Cat::HomogeneousFiniteProduct(T)` is a homogeneous finite collection where each collection has the same number of elements of the domain `T`.

The number of elements must be given by the entry "card", which must be defined by domains of this category. It is not given as a category parameter simply because it is not needed. Thus no unnecessary instances of the category are created.

One could principally implement all the algebraic operations here, but they will be slow if the methods "`_index`" and "`set_index`" are slow, which most often will be the case. So we avoid the work and let the domain implementors do it.

**Categories** `Cat::HomogeneousFiniteCollection(T)`

If `T` is a `Cat::DifferentialRing`, then `Cat::DifferentialRing`.

If `T` is a `Cat::PartialDifferentialRing`, then `Cat::PartialDifferentialRing`.

If `T` is a `Cat::CommutativeRing`, then `Cat::CommutativeRing`.

If `T` is a `Cat::SkewField`, then `Cat::SkewField`.

If `T` is a `Cat::Ring`, then `Cat::Ring`.

If `T` is a `Cat::Rng`, then `Cat::Rng`.

If `T` is a `Cat::AbelianGroup`, then `Cat::AbelianGroup`.

If `T` is a `Cat::CancellationAbelianMonoid`, then `Cat::CancellationAbelianMonoid`.

If `T` is a `Cat::AbelianMonoid`, then `Cat::AbelianMonoid`.

If T is a Cat::AbelianSemiGroup, then Cat::AbelianSemiGroup.

If T is a Cat::Group, then Cat::Group.

If T is a Cat::Monoid, then Cat::Monoid.

If T is a Cat::SemiGroup, then Cat::SemiGroup.

If T is a Cat::CommutativeRing, then Cat::Algebra(T).

If T is a Cat::Ring, then Cat::LeftModule(T).

If T is a Cat::Ring, then Cat::RightModule(T).

## Parameters T

A domain which must be from the category Cat::BaseCategory.  
This defines the domain of the products elements.

## Entries

|                  |                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------|
| "card"           | Must hold the number of elements of a collection.                                                       |
| "characteristic" | Defined if T is a ring: In this case the characteristic of the product domain is the same as that of T. |

## Methods

### Basic Methods

#### zip - Combine elements

zip(x, y, f)

#### zipCanFail - Combine elements, may fail

zipCanFail(x, y, f)

### Access Methods

#### nops - Return number of elements

nops(x)

# Cat::IntegralDomain

---

**Purpose** Category of integral domains

**Description** `Cat::IntegralDomain` represents the category of integral domains.

A `Cat::IntegralDomain` is a commutative and entire ring which has a “partial” division method `_divide`: If `b` divides `a` then `dom::_divide(a,b)` must return the quotient, otherwise FAIL. The result of the method `_divide` must be unique.

Use the axiom `Ax::canonicalUnitNormal` to state in addition that there exists a canonical unit normal form for each element of the ring. If a ring has the axiom `Ax::canonicalUnitNormal` the method `unitNormal` must return the unique unit normal for a ring element. If the axiom is not valid the method may return any associate.

Use the axiom `Ax::closedUnitNormals` in addition to state that the unit normals which are computed by the method `unitNormal` are closed under multiplication, i.e. that the product of two unit normals returns a unit normal.

These two axioms are not implicitly valid for an `Cat::IntegralDomain` because there are integral domains for which one can't compute a canonical unit normal for each element.

**Categories** `Cat::EntireRing`, `Cat::CommutativeRing`, `Cat::Algebra(dom)`

**Methods** Basic Methods

## divide - Return quotient

`_divide(x, y)`

The result must be unique:

**1** the product `y * dom::_divide(x,y)` must be equal to `x` provided that `y` is not zero and `y` divides `x`,

**2** if `x` is equal to `y * z` then `y` must divide `x`.

It is an error if `y` is zero.

## **isUnit - Test if element is a unit**

```
isUnit(x)
```

## **unitNormal - Return an associate**

```
unitNormal(x)
```

If the ring has the axiom `Ax::canonicalUnitNormal` the method must return the unique unit normal of `x`.

An implementation is provided if the ring has *not* the axiom `Ax::canonicalUnitNormal`: In this case simply `x` is returned.

## **Mathematical Methods**

### **associates - Test if elements are associates**

```
associates(x, y)
```

### **divides - Test if elements divides another**

```
divides(x, y)
```

### **unitNormalRep - Return the unit normal representation**

```
unitNormalRep(x)
```

If the ring has the axiom `Ax::canonicalUnitNormal` the method must return the unique unit normal of `x`. The default implementation uses the method "unitNormal" to compute the unit normal `n` in this case.

If the ring does not have the axiom `Ax::canonicalUnitNormal` the method simply returns `[x, dom::one, dom::one]`.

# Cat::LeftModule

---

**Purpose** Category of left R -modules

**Syntax** `Cat::LeftModule(R)`

**Description** `Cat::LeftModule(R)` represents the category of left R-modules.

A `Cat::LeftModule(R)` is an Abelian group together with a rng R (a ring without unit) and a left multiplication \* (`_mult`).

The left multiplication is an operation taking an element of rng R and a module element and returning a module element.

Given ring elements  $a, b$  and module elements  $x, y$  the following 3 distributive laws must hold:

**1**  $(ab)x = a(bx),$

**2**  $(a + b)x = ax + bx,$

**3**  $a(x + y) = ax + ay.$

Beware: The operation of a non-Abelian semi-group is also written as \* (`_mult`). The method "`_mult`" must handle the situation if a left module is also a non-Abelian semi-group. In such a case it must both implement the group operation and the left multiplication by elements of the rng.

**Categories** `Cat::AbelianGroup`

**Parameters** **R**

A domain which must be from the category `Cat::Rng`.

**Methods** Basic Methods

**`_mult` - Left multiplication by a rng element**

`_mult(r, x)`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Category of matrices                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Entries</b>     | <p><code>"coeffRing"</code> is set to <code>R</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Methods</b>     | <p><b>Basic Methods</b></p> <p><b><code>_index</code> - Matrix indexing</b></p> <p><code>_index(A, i, j)</code></p> <p><b><code>matdim</code> - Matrix dimension</b></p> <p><code>matdim(A)</code></p> <p><b><code>new</code> - Matrix definition</b></p> <p><code>new(m, n)</code></p>                                                                                                                                                                                                                                                                                                                                                                                                      |

Of course, this method may implement further possibilities to create matrices (for example, see the method "new" of the domain constructor `Dom::Matrix`).

## **set\_index - Setting matrix components**

```
set_index(A, i, j, x)
```

## **Mathematical Methods**

### **negate - Negate a matrix**

```
negate(A)
```

### **plus - Add matrices**

```
plus(A1, A2,)
```

The matrices must be of the same domain type, otherwise FAIL is returned.

### **subtract - Subtract two matrices**

```
subtract(A, B)
```

### **equal - Test on equality of matrices**

```
equal(A, B)
```

### **identity - Identity matrix**

```
identity(n)
```

It only exists if R is of category `Cat::Ring`, i.e., a ring with unit.

### **iszero - Test on zero matrices**

```
iszero(A)
```

Note that there may be more than one representation of the zero matrix of a given dimension if R does not have the axiom `Ax::canonicalRep`.

### **transpose - Transpose of a matrix**

```
transpose(A)
```

## Access Methods

### **col - Extracting columns**

```
col(A, c)
```

### **concatMatrix - Horizontal concatenation of matrices**

```
concatMatrix(A, B)
```

An error message is issued if the two matrices do not have the same number of rows.

### **delCol - Deleting columns**

```
delCol(A, c)
```

If A only consists of one column then NIL is returned.

### **delRow - Deleting rows**

```
delRow(A, r)
```

If A only consists of one row then NIL is returned.

### **row - Extracting rows**

```
row(A, r)
```

### **setCol - Replacing columns**

```
setCol(A, c, v)
```

### **setRow - Replacing rows**

```
setRow(A, r, v)
```

### **stackMatrix - Appending of matrices vertically**

```
stackMatrix(A, B)
```

An error message is issued if the two matrices do not have the same number of columns.

### **swapCol - Swapping matrix columns**

```
swapCol(A, c1, c2)
```

## **swapRow - Swapping matrix rows**

`swapRow(A, r1, r2)`

|                    |                                                                                                                                                                                                                                                                          |

**Purpose** Category of ordered sets

**Description** `Cat::OrderedSet` represents the category of ordered sets.  
An `Cat::OrderedSet` is a set with a (complete) order relation `< (_less)`.  
Use the axiom `Ax::canonicalOrder` to state that elements of a domain are canonically ordered as MuPAD expressions (i.e. ordered with respect to the kernel function `_less`).

**Categories** `Cat::BaseCategory`

**Methods** Basic Methods

**`_less` - Compare if element is less**

`_less(x, y)`

An implementation is provided if this domain has axiom `Ax::canonicalOrder`.

**Mathematical Methods**

**`_leequal` - Compare if element is less or equal**

`_leequal(x, y)`

The implementation provided uses the methods "`_less`" and "`equal`".

**`max` - Return maximum**

`max(x, )`

**`min` - Return minimum**

`min(x, )`

**`sort` - Sort list of elements**

`sort(l)`

# Cat::PartialDifferentialRing

---

**Purpose** Category of partial differential rings

**Description** `Cat::PartialDifferentialRing` represents the category of partial differential rings.

A `Cat::PartialDifferentialRing` is a commutative ring with a finite set of derivation operators `D_i`.

A derivation is a linear operator with product rule, i.e.  $D_i(f * g)$  equals  $D_i(f) * g + f * D_i(g)$  for all `f` and `g`.

For many partial differential rings the derivations are differentiations with respect to some indeterminates. Thus in order to support a natural notion it is also supposed that a method "`diff`" exists, such that `diff(f, x)` returns the partial derivation of `f` with respect to the indeterminate `x`.

**Categories** `Cat::CommutativeRing`

**Methods** Basic Methods

**D - Return derivative**

`D(l, x)`

**diff - Return partial derivative**

`diff(x, <v, >)`

| <b>Methods</b>     | Basic Methods<br><b>coeff - Return coefficients</b><br>coeff(p)                                                                                                                                                           |                                                                             |

`coeff(p, x, n)`

`coeff(p, n)`

Must return the coefficient of  $x^n$  of  $p$ , which is a polynomial in the remaining indeterminates.

Must return the coefficient of  $x^n$  of  $p$ , where  $x$  is the main variable of  $p$ .

## **degree - Return total degree**

`degree(p)`

`degree(p, x)`

Must return the degree of  $p$  with respect to the indeterminate  $x$ .

## **degreevec - Return degree vector**

`degreevec(p)`

## **evalp - Evaluate at a point**

`evalp(p, x = v, )`

More than one evaluation point may be given. The result must be a polynomial in the remaining indeterminates or an element of  $R$ .

## **indets - Return indeterminates**

`indets(p)`

## **lcoeff - Return leading coefficient**

`lcoeff(p)`

## **lmonomial - Return leading monomial**

`lmonomial(p)`

## **lterm - Return leading term**

`lterm(p)`

## **mainvar - Return main variable**

`mainvar(p)`

**mapcoeffs - Map coefficients**

```
mapcoeffs(p, f, <a, >)
```

**multcoeffs - Multiply coefficients**

```
multcoeffs(p, c)
```

**nterms - Return number of terms**

```
nterms(p)
```

**nthcoeff - Return n-th coefficient**

```
nthcoeff(p, n)
```

**nthmonomial - Return n-th monomial**

```
nthmonomial(p, n)
```

**nthterm - Return n-th term**

```
nthterm(p, n)
```

**tcoeff - Return trailing coefficient**

```
tcoeff(p)
```

**unitNormal - Return unit normal**

```
unitNormal(p)
```

An implementation is provided if R has the axiom `Ax::canonicalUnitNormal`: In this case p is multiplied by an unit of R such that the leading coefficient has unit normal representation in R.

**unitNormalRep - Return unit normal representation**

```
unitNormalRep(p)
```

An implementation is provided if R has the axiom `Ax::canonicalUnitNormal`.

**Mathematical Methods****content - Return content**

`content(p)`

**isUnit - Test if element is a unit**

`isUnit(p)`

**primpart - Return primitive part**

`primpart(p)`

**poly2list - Convert into a list**

`poly2list(p)`

**solve - Solve polynomial equation**

`solve(p, x, <opt, >)`

`solve(p, x = T, <opt, >)`

`solve(p)`

Solves the polynomial equation  $p = 0$  with respect to  $x$  over the domain  $T$ . See the function `solve` for details about the optional arguments `opt, ...`

The polynomial  $p$  must be univariate. Solves the polynomial equation  $p = 0$  with respect to the indeterminate of  $p$  over the domain  $R$ .

**Purpose**

Category of principal ideal domains

**Description**

`Cat::PrincipalIdealDomain` represents the category of principal ideal domains.

A `Cat::PrincipalIdealDomain` is an integral domain with `gcd` where each ideal is principal. Note that the method "`idealGenerator`" has to find generators for finitely generated ideals only.

**Categories**

`Cat::GcdDomain`

**Methods**

Basic Methods

**idealGenerator - Return generator of ideal**

```
idealGenerator(x,)
```

# Cat::QuotientField

## **\_less - Test if element is less**

`_less(x, y)`

## **retract - Return retracted element**

`retract(x)`

The default implementation uses the method "`_divide`" to divide numerator and denominator.

# Cat::RightModule

---

**Purpose** Category of right R-modules

**Syntax** `Cat::RightModule(R)`

**Description** `Cat::RightModule(R)` represents the category of right R-modules.

A `Cat::RightModule` is an Abelian group together with a ring `R` and a right multiplication `* (_mult)`.

The right multiplication is an operation taking an element of ring `R` and a module element and returning a module element.

Given ring elements  $a, b$  and module elements  $x, y$  the following 3 distributive laws must hold:

**1**  $x(ab) = (xa)b,$

**2**  $x(a + b) = xa + xb,$

**3**  $(x + y)a = xa + ya.$

Beware: The operation of a non-Abelian semi-group is also written as `* (_mult)`. The method `"_mult"` must handle the situation if a right module is also a non-Abelian semi-group. In such a case it must both implement the group operation and the right multiplication by elements of the ring.

**Categories** `Cat::AbelianGroup`

**Parameters** **R**

A domain which must be from the category `Cat::Ring`.

**Methods** Basic Methods

**`_mult` - Right multiplication by a ring element**

`_mult(x, r)`

**Purpose**

Category of rings

**Description**

`Cat::Ring` represents the category of rings.

A `Cat::Ring` is a ring with a unit `dom::one`, i.e., an Abelian group according to the operation `+` (`_plus`) and a non-Abelian monoid according to the operation `*` (`_mult`) where in addition the two distributive laws  $a(b + c) = ab + ac$  and  $(a + b)c = ac + bc$  hold.

A `Cat::Ring` is also a left module over itself. The left multiplication of the module is also written as `*` (`_mult`).

Note that a ring without unit is a `Cat::Rng`.

**Categories**

`Cat::Rng`, `Cat::Monoid`, `Cat::LeftModule(dom)`

**Entries**

"characteristic"

Must hold the characteristic of this ring.

# Cat::Rng

---

**Purpose**            Category of rings without unit

**Description**     `Cat::Rng` represents the category of rings without unit.

A `Cat::Rng` is a ring without a unit, i.e. an Abelian group according to the operation `+` (`_plus`) and a non-Abelian semi-group according to the operation `*` (`_mult`) where in addition the two distributive laws  $a(b + c) = ab + ac$  and  $(a + b)c = ac + bc$  hold.

Use the axiom `Ax::noZeroDivisors` to state that there are no zero divisors according to `*`, i.e. that the product of non-zero elements never is zero.

**Categories**        `Cat::AbelianGroup`, `Cat::SemiGroup`

## Purpose

Category of semi-groups

## Description

Cat::SemiGroup represents the category of semi-groups.

A Cat::SemiGroup represents the category of non-Abelian semi-groups, where the group operation is written as multiplication. Hence a Cat::SemiGroup is a set with an associative operation \* (`_mult`).

Note that Abelian semi-groups with operation + have category Cat::AbelianSemiGroup.

## Categories

Cat::BaseCategory

## Methods

Basic Methods

### **\_mult - Return product**

```
_mult(x,)
```

Mathematical Methods

### **\_power - Return integer power**

```
_power(x, n)
```

# Cat::Set

---

**Purpose** Category of sets of complex numbers

**Description** `Cat::Set` represents the category of subsets of the complex numbers. Sets of this category allow set-theoretic operations as well as pointwise arithmetical operations.

The main feature of `Cat::Set` is a particular overloading mechanism. It provides n-ary operators that can handle operands from different domains of category `Cat::Set`, as well as mixed input where some operands are of types not belonging to `Cat::Set`. *Hence, in the methods of `Cat::Set`, operands of arbitrary type are allowed.*

There are three kinds of operators: n-ary (associative and commutative), binary (not assumed to be commutative), and unary (mapping a function). `Cat::Set` provides generic methods for generating these kinds of operators, and uses them to define default methods overloading the common set-theoretic and arithmetical functions.

By default, any operation of sets is defined, but returns unevaluated since the arithmetical or set-theoretic expression cannot be simplified. Each domain of type `Cat::Set` must provide particular slots and tables in order to achieve simplifications in certain special cases.

Arithmetical operations are defined pointwise. It is not an error if some operation is not defined for all elements of a set.

`Cat::Set` is mainly used by domains of sets returned by `solve`.

**Categories** `Cat::BaseCategory`

**Methods** **Mathematical Methods**

**commassop - Return an n-ary commutative and associative operator for sets**

`commassop(operatorname)`

The returned procedure first sorts its operands (which it may do because of commutativity). Those operands not belonging to a domain of category `Cat::Set` are handled by the usual

overloading mechanism, i.e. by the slot `operatorname` of one of their domains. Out of the others, several operands belonging to the same domain are handled by the slot `"homog".operatorname` of that domain. Finally, the returned method tries to combine each possible pair of operands. If they are from the same domain, `"bin".operatorname` is called for them. The following is done if the operands are from different domains: let T1 and T2 be their types; then their `"inhomog".operatorname` slots are used. If such a slot exists in the domain T1, it must contain a table indexed by possible types T2, and the entry at that index must be a procedure that carries out the operation for exactly two arguments, the first being a T1, the second being a T2. Conversely, if such a slot exists in the domain T2, it must contain a table indexed by possible types T1, and the entry at that index must be a procedure that carries out the operation for exactly two arguments, the first being a T2, the second being a T1.

The slot `"homog".operatorname`, or a table entry in the slot `"inhomog".operatorname`, may return FAIL in order to indicate that it could not simplify its input; if they are missing, this indicates that a simplification is generally not possible for input of this type. In these cases, the returned procedure proceeds by trying to combine another two of the given arguments.

A slot `"bin".operatorname` usually won't exist, except for the case that there is no `"homog".operatorname`; usually the latter can also take care for the case of exactly two operands.

The whole process is repeated over and over until no new simplifications occur or only one operand is left. If no more simplifications occur, an unevaluated call to the operator is returned, the arguments being all remaining operands that could not be combined further.

### **binop - Return a binary operator for sets**

```
binop(operatorname)
```

The returned procedure uses the slot `"bin".operatorname` of its first argument if both arguments are of the same type. Otherwise it

uses the slot "inhomogleft".operatorname of its first argument; if that fails, it uses the slot "inhomogright".operatorname of its second argument; each of these slots, if it exists, must contain tables, indexed by the type of the other argument, such that slot(T1, "inhomogleft".operatorname)[T2] and slot(T2, "inhomogright".operatorname)[T1] carry out the operation for objects of type T1 and T2, in this order.

No commutativity of the operation is assumed.

If the slots or table entries do not exist or return FAIL, an unevaluated call to the operator is returned.

## **homogassop - Return an n-ary operator for sets belonging to the same domain**

homogassop(operatorname)

### **union - Union of sets**

union(S<sub>1</sub>, )

### **intersect - Intersection of sets**

intersect(S<sub>1</sub>, )

### **plus - Set of sums of set elements**

plus(S<sub>1</sub>, )

The sum of sets is computed by the commutative-associative operator generated by "commassop", using the slots "homog\_plus" and "inhomog\_plus" of the domains of its operands.

### **mult - Set of product of set elements**

mult(S<sub>1</sub>, )

The product of sets is computed by the commutative-associative operator generated by "commassop", using the slots "homog\_mult" and "inhomog\_mult" of the domains of its operands.

### **minus - Set of subtractions**

minus(S<sub>1</sub>, S<sub>2</sub>)

**\_power - Pointwise power**`_power(S1, S2)`

The power of sets is computed by the binary operator generated by "binop", using the slots "homog\_power", "inhomogleft\_power", and "inhomogright\_power" of its operands.

**map - Map an operation to a set**`map(S, f)`

By overloading this method in a particular domain, the behavior of sets changes whenever a special function is applied to them.

# Cat::SkewField

---

**Purpose**            Category of skew fields

**Description**     `Cat::SkewField` represents the category of skew fields (division rings).  
A `Cat::SkewField` represents a ring with unit where each non-zero element is invertible. This structure is also called division ring in the literature.

**Categories**        `Cat::Ring`

**Purpose** Category of square matrices

**Syntax** `Cat::SquareMatrix(R)`

**Description** `Cat::SquareMatrix(R)` represents the category of square matrices over the rng `R`.

A `Cat::SquareMatrix(R)` represents the rng (ring without unit) of square matrices over the coefficient domain `R`.

**Categories** `Cat::Rng`, `Cat::Matrix(R)`

If `R` has `Cat::Ring`, then `Cat::Ring`.

**Parameters** **R**

A domain which must be from the category `Cat::Rng`.

**Entries** "characteristic"

Defined if `R` is a ring: In this case the characteristic of the matrix domain is the same as that of `R`.

# Cat::UnivariatePolynomial

---

# combinat – Combinatorics

---

combinat::bell  
combinat::cartesianProduct  
combinat::catalan  
combinat::choose  
combinat::compositions  
combinat::modStirling  
combinat::partitions  
combinat::permute  
combinat::powerset  
combinat::stirling1  
combinat::stirling2  
combinat::subwords

# combinat::bell

---

**Purpose** Bell numbers

**Syntax** `combinat::bell(n)`  
`combinat::bell(expression)`

**Description** `combinat::bell(n)` computes the n-th Bell number.

The n-th Bell number is defined by the exponential generating function:

$$e^{e^x - 1} = \sum_{n=0}^{\infty} \frac{\text{bell}(n)}{n!} x^n$$

Often another definition is used. The n-th Bell number is the number of different ways of partitioning the set  $\{1, 2, \dots, n\}$  into disjoint nonempty subsets, and  $\text{bell}(0)$  is defined to be 1.

Bell numbers are computed using the formula:

- $\text{bell}(0) = 1$

$$\text{bell}(n + 1) = \sum_{i=0}^n \binom{n}{i} \text{bell}(i) \text{ for } n > 0$$

## Examples

### Example 1

The third Bell number is 5:

```
combinat::bell(3)
```

5

This means that you can partition the set  $\{1, 2, 3\}$  into disjoint subsets in 5 different ways. These are  $\{\{1, 2, 3\}\}$ ,  $\{\{1\}, \{2, 3\}\}$ ,  $\{\{2\}, \{1, 3\}\}$ ,  $\{\{3\}, \{1, 2\}\}$ , and  $\{\{1\}, \{2\}, \{3\}\}$ . Or, that you can write  $105 = 357$  as 5 different products. These are  $105 = 335 = 521 = 715 = 357$ .

## Example 2

If one uses a wrong argument, an error message is returned.

```
combinat::bell(3.4)
```

```
Error: A nonnegative integer is expected. [combinat::bell]
```

## Example 3

It can be useful to return the unevaluated function call.

```
a := combinat::bell(x);
x := 4;
a ;
delete(a);
```

```
combinat::bell(x)
```

```
4
```

```
15
```

## Parameters

**n**

Nonnegative integer

## expression

An expression of type `Type::Arithmetical` which must be a nonnegative integer if it is a number.

## Return Values

Positive integer value if `n` was a nonnegative integer. Otherwise `combinat::bell` returns the unevaluated function call.

# combinat::cartesianProduct

---

**Purpose** Cartesian product

**Syntax** `combinat::cartesianProduct(S1, ...)`

**Description** `combinat::cartesianProduct(S1, ...)` returns the cartesian product of the sets or lists  $S_1, \dots$  as a list of lists.

The cartesian product of  $S_1$  through  $S_n$  consists of all lists of length  $n$  whose  $i$ -th entry is an operand of the set or list  $S_i$ , for  $1 \leq i \leq n$ .

Any integer  $k$  among the arguments is identified with the set of the first  $k$  positive integers.

The ordering of the output is unspecified.

## Examples **Example 1**

The following calls are equivalent:

```
combinat::cartesianProduct({1, 2}, {a, b}),
combinat::cartesianProduct(2, [b, a])
```

```
[[1, a], [2, a], [1, b], [2, b]], [[1, b], [2, b], [1, a], [2, a]]
```

**Parameters** **S1**

Set, list, or nonnegative integer

**Return Values** List of lists, each of them having as many operands as there were arguments passed to `combinat::cartesianProduct`.

## Purpose

Catalan numbers

## Syntax

`combinat::catalan(n)`

## Description

`combinat::catalan(n)` returns the  $n$ -th Catalan number.

The Catalan numbers are ubiquitous in combinatorics. For example, `combinat::catalan(n)` counts the Dyck words of size  $n$ , the ordered trees with  $n$  nodes, the binary trees with  $n+1$  nodes, the complete binary trees with  $2n+1$  nodes, the standard tableaux with two rows of size  $n$ , the triangulations of a regular  $n+2$ -gone, or the non-crossing partitions of  $\{1, 2, \dots, n\}$ .

`combinat::catalan(n)` is calculated using the formula

$$\text{catalan}(n) = \frac{1}{n+1} \binom{2n}{n}$$

## Examples

### Example 1

We compute the first Catalan numbers:

```
combinat::catalan(n) $ n = 0..6
```

```
1, 1, 2, 5, 14, 42, 132
```

### Example 2

If one uses a wrong argument, an error message is returned

```
combinat::catalan(-1)
```

```
Error: The type of argument number 1 must be 'Type::NonNegInt'.
Evaluating: combinat::catalan
```

# combinat::catalan

---

**Parameters**    **n**  
Nonnegative integer

**Return Values**    Positive integer.

|                      |                                                                                                                                                                                                                               |

| <b>Return Values</b> | Sequence of sets.                                                                                                                                                                                                             |

# combinat::compositions

---

**Purpose** Compositions of an integer

**Syntax** `combinat::compositions(n, <MinPart = k>, <MaxPart = l>, <Length = m>)`

**Description** `combinat::compositions(n)` returns all compositions of the nonnegative integer  $n$ .

A *composition* of a nonnegative integer  $n$  is a list of positive integers with total sum  $n$ .

## Examples

### Example 1

We output all compositions of the integer 4:

```
combinat::compositions(4)
```

```
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

### Example 2

It is possible to output only the compositions of a certain length:

```
combinat::compositions(4, Length=2)
```

```
[[3, 1], [2, 2], [1, 3]]
```

### Example 3

The options `MinPart` and `MaxPart` can be used to set constraints on the sizes of all parts. Using `MaxPart`, you can select compositions having only small entries. This is the list of the compositions of 4 with all parts at most 2:

```
combinat::compositions(4, MaxPart=2)
```

```
[[2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

`MinPart` is complementary to `MaxPart` and selects compositions having only large parts (it takes a non-negative value). This is the list of the compositions of 4 with all parts at least 2:

```
combinat::compositions(4, MinPart=2)
```

```
[[4], [2, 2]]
```

By default, the parts of a composition have to be positive. This can be changed using the option `MinPart`. In the following example, the options `Length` and `MinPart` are combined together to obtain the list of the compositions of 4 with 3 nonnegative parts:

```
combinat::compositions(4, Length=3, MinPart=0)
```

```
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1], [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
[0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

If no length is given, `MinPart=0` is not allowed.

## Parameters

**n**

Nonnegative integer

## Options

**MinPart**

Option, specified as `MinPart = k`

Return only compositions consisting of integers greater or equal than `k`. The option `MinPart = 0` is only allowed if also the option `Length` is given. Default is 1.

# combinat::compositions

---

## **MaxPart**

Option, specified as `MaxPart = 1`

Return only compositions consisting of integers less or equal than 1.

## **Length**

Option, specified as `Length = m`

Return only compositions consisting of exactly `m` integers.

**Purpose** Modified Stirling numbers

**Syntax** `combinat::modStirling(q, n, k)`

**Description** `combinat::modStirling` computes the modified Stirling numbers. `combinat::modStirling(q,n,k)` takes the elementary symmetric polynomial in  $n$  variables of degree  $k$  and evaluates it for the values  $q + 1, \dots, q + n$ . Note that  $k$  must not be greater than  $n$ .

**Examples** **Example 1**

```
combinat::modStirling(2,4,2)
```

```
119
```

**Parameters** **q**  
The argument: an integer

**n**  
The number of variables: a nonnegative integer

**k**  
The degree: a nonnegative integer

**Return Values** Positive integer.

# combinat::partitions

---

**Purpose** Partitions of an integer

**Syntax** `combinat::partitions(n)`

**Description** `cominat::partitions(n)` returns the number of partitions of the integer  $n$ .

A *partition* of a nonnegative integer  $n$  is a non-increasing list of positive integers with total sum  $n$ .

**Examples** **Example 1**

There are 5 partitions of 4:

```
combinat::partitions(4)
```

```
5
```

**Parameters** **n**

Nonnegative integer

**Algorithms** Counting is done efficiently with Euler's pentagonal formula for small values of  $n$  and Hardy-Ramanujan-Rademacher's formula otherwise.

| <b>Purpose</b>     | Permutations of a list                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Syntax</b>      | <code>combinat::permute(l, &lt;Duplicate&gt;)</code><br><code>combinat::permute(n, &lt;Duplicate&gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>For a list <code>l</code>, the call <code>combinat::permute(l)</code> returns all permutations of <code>l</code>.</p> <p>For an integer <code>n</code>, the call <code>combinat::permute(n)</code> returns all permutations of the list <code>[1, ..., n]</code>.</p> <p>A permutation of a list is a list that contains the same elements, and each of them the same number of times, as the original list.</p> <p>Equivalently, a permutation of a list <code>l</code> of <math>n</math> elements is any <math>f(l)</math> where <math>f</math> is an element of the symmetric group <code>Dom::SymmetricGroup(n)</code>. Different <math>f</math> may produce the same <math>f(l)</math>; with the option <code>Duplicate</code>, every permutation is listed as many times as it occurs in that way; without that option, every permutation is listed only once.</p> |

## Examples

### Example 1

There are six permutations of three letters:

```
combinat::permute([a, b, c])
```

```
[[b, c, a], [c, b, a], [a, c, b], [c, a, b], [a, b, c], [b, a, c]]
```

To permute the first three integers, the following syntax is also possible:

```
combinat::permute(3)
```

```
[[2, 3, 1], [3, 2, 1], [1, 3, 2], [3, 1, 2], [1, 2, 3], [2, 1, 3]]
```

If some list entry occurs several times, the number of permutations decreases:

# combinat::permute

---

```
combinat::permute([a, a, b])
```

```
[[a, b, a], [b, a, a], [a, a, b]]
```

However, the same permutation is listed as often as it can be obtained by applying different elements of the symmetric group  $S_3$  if the option `Duplicate` is given.

```
combinat::permute([a, a, b], Duplicate)
```

```
[[a, b, a], [b, a, a], [a, b, a], [b, a, a], [a, a, b], [a, a, b]]
```

We could have achieved the same by permuting three different symbols and then setting two of them equal:

```
subs(combinat::permute([a, b, c]), c=a)
```

```
[[b, a, a], [a, b, a], [a, a, b], [a, a, b], [a, b, a], [b, a, a]]
```

## Parameters

**l**

List

**n**

Positive integer

## Options

**Duplicate**

List every permutation as often as it can be produced in different ways by applying some bijective mapping (element of the symmetric group) to the original list.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Subsets of a set                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Syntax</b>      | <code>combinat::powerset(S)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>If <math>S</math> is a set, <code>combinat::powerset(S)</code> returns the set of all subsets of <math>S</math>. If <math>l</math> is a list, <code>combinat::powerset(l)</code> returns the set of all sublists of <math>l</math>.</p> <p>The powerset of a list <math>l</math> is the set of all lists that can be obtained by deleting some elements of <math>l</math> and leaving the others in order.</p> <p><code>combinat::powerset</code> has been overloaded for multisets of type <code>Dom::Multiset</code>. The powerset of a multiset <math>S</math> consists of all multisets that contain only elements occurring also in <math>S</math>, each of them at most as many times as it occurs in <math>S</math>.</p> |
| <b>Examples</b>    | <p><b>Example 1</b></p> <p>Given a finite set, <code>combinat::powerset</code> returns the powerset (set of all subsets) of the input:</p> <pre>combinat::powerset({a, b, c})</pre> <pre>{∅, {c}, {a}, {b}, {b, c}, {a, b}, {a, c}, {a, b, c}}</pre> <p>The same works for multisets:</p> <pre>combinat::powerset(Dom::Multiset(a, a, b))</pre> <pre>{∅, {[a, 1]}, {[a, 2]}, {[b, 1]}, {[a, 1], [b, 1]}, {[a, 2], [b, 1]}}</pre> <p><b>Example 2</b></p> <p>The powerset of a list <math>l</math> of pairwise different elements is the same as the powerset of the set of these elements, except that it consists of lists in which the order of elements is the same as in <math>l</math>:</p>                                   |

# combinat::powerset

---

```
combinat::powerset([c, a, b])
```

```
{[], [a], [b], [c], [a, b], [c, a], [c, b], [c, a, b]}
```

In general, the powerset of a list `l` is the same as the powerset of the multiset of its elements, except that it consists of lists in which the original order is preserved:

```
combinat::powerset([a, b, a])
```

```
{[], [a], [b], [a, a], [a, b], [b, a], [a, b, a]}
```

## Parameters

**s**

Set

**l**

List

**Purpose** Stirling numbers of the first kind

**Syntax** `combinat::stirling1(n, k)`

**Description** `combinat::stirling1(n, k)` computes the Stirling numbers of the first kind.

Let  $S(n, k)$  be the number of permutations of  $n$  symbols that have exactly  $k$  cycles. Then `combinat::stirling1(n, k)` computes  $(-1)^{(n+k)}S(n, k)$ .

Let  $S_1(n, k)$  be the Stirling number of the first kind, then we have:

$$\sum_{k=0}^n S_1(n, k) x^k = x(x-1)\cdots(x-n+1)$$

## Examples **Example 1**

Let us have a look what's the result of  $x(x-1)(x-2)(x-3)(x-4)(x-5)$  written as a sum.

```
expand(x*(x-1)*(x-2)*(x-3)*(x-4)*(x-5))
```

$$x^6 - 15x^5 + 85x^4 - 225x^3 + 274x^2 - 120x$$

Now let us “prove” the formula mentioned in the “Details” section by calculating the proper Stirling numbers:

```
combinat::stirling1(6,1);
combinat::stirling1(6,2);
combinat::stirling1(6,3);
combinat::stirling1(6,4);
combinat::stirling1(6,5);
combinat::stirling1(6,6)
```

# combinat::stirling1

---

- 120

274

- 225

85

- 15

1

## Example 2

```
combinat::stirling1(3,-1)
```

```
Error: Nonnegative integers are expected. [combinat::stirling1]
```

## Parameters

**n, k**

Nonnegative integers

## Return Values

Integer.

## References

J.J. Rotman, An Introduction to the Theory of Groups, 3rd Edition, Wm. C. Brown Publishers, Dubuque, 1988

**Purpose** Stirling numbers of the second kind

**Syntax** `combinat::stirling2(n, k)`

**Description** `combinat::stirling2(n, k)` computes the number of ways of partitioning a set of  $n$  elements into  $k$  non-empty subsets.

`combinat::stirling2(n, k)` is calculated using the formula

$$\text{stirling2}(n, k) = \frac{1}{k!} \left( \sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n \right)$$

## Examples

### Example 1

One can partition the set  $\{1, 2, 3\}$  into  $\{1, 2, 3\} = \{1, 2\} \cup \{3\} = \{1, 3\} \cup \{2\} = \{2, 3\} \cup \{1\}$

```
combinat::stirling2(3,2)
```

```
3
```

### Example 2

```
combinat::stirling2(3)
```

```
Error: Two arguments are expected. [combinat::stirling2]
```

## Parameters

**n, k**

Nonnegative integers

## Return Values

Nonnegative integer.

# combinat::subwords

---

**Purpose** Subwords of a word

**Syntax** `combinat::subwords(w)`

**Description** The function `combinat::subwords(w)` returns a list of all subwords (sublists) of the list `w`.

A subword of a word  $w$  is a word obtained by deleting the letters at some of the positions in  $w$ . A subword is generated as many times as it appears in the word.

To obtain each subword only once, `combinat::powerset` should be used.

## **Examples** **Example 1**

There are 8 subwords of the word `[a, b, c]`:

```
combinat::subwords([a, b, c])
```

```
[[], [a], [b], [a, b], [c], [a, c], [b, c], [a, b, c]]
```

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>        | (symbolic, multidimensional) arrays                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>    | <p>DOM_ARRAY is a multidimensional container type, storing arbitrary MuPAD objects at integer indices.</p> <p>Arrays are a fundamental data type in many programming languages: For a fixed number of indices (“dimensions”), for each index an integer from a fixed range, an array provides space to store an arbitrary piece of data at this combination.</p>                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Function Calls</b> | <p>Using an array as a function symbol creates the list obtained by using each array entry as a function symbol for the operands used, i.e., <code>array(1..2, [f, g])(x, y)</code> results in <code>array(1..2, [f(x, y), g(x, y)])</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Operations</b>     | <p>As with any container, the most important operation on an array is reading and writing its entries, which is performed by indexed access, as in <code>A[1, 2]</code> or <code>B[1, 3, 2] := exp(x)</code>. Trying to access an element outside the boundaries of an array raises an error.</p> <p>The function <code>map</code> applies some function or transformation to each element of an array, returning an array of the same format as its input, with the results of the calls as its entries.</p> <p>If <code>A</code> is an array, <code>nops(A)</code> returns the number of elements in <code>A</code>.</p>                                                                                                         |
| <b>Operands</b>       | <p>If <code>A</code> is an array, the 0th operand of <code>A</code>, <code>op(A, 0)</code>, will be the sequence starting with the number of dimensions (an integer <math>n</math>) followed by <math>n</math> ranges of integers, which denote the acceptable ranges of indices for each dimension, including both numbers listed in the range.</p> <p>For <math>1 \leq i \leq nops(A)</math>, the <math>i</math>th operand of <code>A</code> is the <math>i</math>th entry of <code>A</code>, in the lexicographic order of indices.</p> <p>Uninitialized entries of arrays will be displayed symbolically while still in the array. When being accessed by <code>op</code> or indexed access, <code>NIL</code> is returned.</p> |
| <b>Output</b>         | <p>One-dimensional arrays are displayed as row vectors, two-dimensional arrays as matrices. Higher-dimensional arrays are written in functional form, using the <code>index = value</code> notation, and do not have a typesetting</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

# DOM\_ARRAY

---

version. This also causes typesetting to be disabled for any surrounding expression in the same output.

## Element Creation

The primary way of creating arrays is the function `array`. Beside that, obviously, `coerce` can convert a number of data types, such as matrices into arrays and a number of MuPAD functions, especially in the `numeric` library, return arrays.

|                         |                                                                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Boolean constants                                                                                                                                                       |
| <b>Description</b>      | DOM_BOOL is the data type of the truth values TRUE, FALSE, and UNKNOWN. MuPAD uses a three-valued logic system, with these values (constants) TRUE, FALSE, and UNKNOWN. |
| <b>Function Calls</b>   | Using a Boolean constant as a function returns that constant unchanged. The arguments of the call are <i>not</i> evaluated.                                             |
| <b>Operations</b>       | The most important operations on Boolean values are the logical operators and, not, or, xor, ==>, <=>, and using them in conditions of if or piecewise.                 |
| <b>Operands</b>         | Boolean constants are atomic.                                                                                                                                           |
| <b>Output</b>           | TRUE is displayed as <i>TRUE</i> , FALSE is displayed as <i>FALSE</i> , and UNKNOWN is shown as <i>UNKNOWN</i> .                                                        |
| <b>Element Creation</b> | The three constants can be types in as shown above. Additionally, many MuPAD functions returns Boolean values, the most generic/prominent two being bool and is.        |
| <b>See Also</b>         |                                                                                                                                                                         |
| <b>MuPAD Functions</b>  | bool   if   is                                                                                                                                                          |

# DOM\_COMPLEX

---

|                         |                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | (Simple) Complex Numbers                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>      | <p>DOM_COMPLEX is the type of complex numbers with integer, rational, or floating-point components.</p> <p>Complex numbers of type DOM_COMPLEX have two operands, their real and imaginary part. These are objects of type DOM_FLOAT, DOM_INT, or DOM_RAT. Complex numbers with other components (such as <math>\sqrt{2} + i\pi</math>) are not of domain type DOM_COMPLEX, but DOM_EXPR.</p> |
| <b>Function Calls</b>   | Calling a complex number as a function returns that number unchanged. The arguments of the call are <i>not</i> evaluated.                                                                                                                                                                                                                                                                     |
| <b>Operations</b>       | Most MuPAD functions operate on complex numbers. Use Re and Im to access the real and imaginary part, respectively.                                                                                                                                                                                                                                                                           |
| <b>Operands</b>         | Every object of type DOM_COMPLEX has two operands, the real and the imaginary part.                                                                                                                                                                                                                                                                                                           |
| <b>Output</b>           | Objects of type DOM_COMPLEX are essentially written as expressions in rectangular form. The imaginary unit is displayed as <i>I</i> .                                                                                                                                                                                                                                                         |
| <b>Element Creation</b> | Complex numbers can be constructed by typing in the corresponding expression, such as 3+4*I. The keyword for typing the imaginary unit <i>I</i> is I (a capital letter i).                                                                                                                                                                                                                    |
| <b>See Also</b>         |                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MuPAD Domains</b>    | DOM_FLOAT   DOM_INT   DOM_RAT                                                                                                                                                                                                                                                                                                                                                                 |

**Purpose**

Data type of data types

**Description**

DOM\_DOMAIN is the data type of datatypes.

Each MuPAD object has a unique data type. Since a data type is a MuPAD object, too, it must itself have a data type; the data type comprising all data types (including itself) is DOM\_DOMAIN.

There are two kinds of elements of DOM\_DOMAIN: data types of the kernel, and data types defined in the library or by the user (*domains*). Objects that have a data type of the latter kind are called *domain elements*.

A data type has the same internal structure as a table; its entries are called slots. One particular slot is the *key*; no two different data types can have the same key. Most of the other slots determine how arguments of that data type are handled by functions.

Once a user-defined domain has been constructed, it cannot be destroyed.

**Examples****Example 1**

Our first example stems from ethnology: some languages in Polynesia do not have words for numbers greater than three; every integer greater than three is denoted by the word “many”. Hence two plus two does not equal four but “many”. We are going to implement a domain for this kind of integers; in other words, we are going to implement a data type for the finite set  $\{1, 2, 3, \text{many}\}$ .

```
S := newDomain("Polynesian integer")
```

Polynesian integer

At this point, we have defined a new data type: a MuPAD object can be a Polynesian integer now. No operations are available yet; the domain consists of its key only:

```
op(S)
```

```
"key" = "Polynesian integer"
```

Even though there are no methods for input and output of domain elements yet, Polynesian integers can be entered and displayed right now. You have to use the function `new` for defining domain elements:

```
x := new(S, 5)
```

```
new(Polynesian integer, 5)
```

Now, `x` is a Polynesian integer:

```
type(x)
```

```
Polynesian integer
```

Of course, MuPAD cannot know what meaning a Polynesian integer has and what its internal structure should be. The arguments of the call to the function `new` are just stored as the zeroth, first, etc. operand of the domain element, without checking them. You may call `new` with as many arguments as you want:

```
new(S, 1, 2, 3, 4); op(%)
```

```
new(Polynesian integer, 1, 2, 3, 4)
```

```
1, 2, 3, 4
```

`new` cannot know that Polynesian integers should have exactly one operand and that we want 5 to be replaced by many. To achieve this, we implement our own method "new"; this also allows us to check the

argument. We have one more problem: domain methods should refer to the domain; but they should not depend on the fact that the domain is currently stored in `S`. For this purpose, MuPAD has a special local variable `dom` that always refers to the domain a procedure belongs to:

```
S::new :=
proc(i : Type::PosInt)
begin
 if args(0) <> 1 then
 error("There must be exactly one argument")
 end_if;
 if i > 3 then
 new(dom, hold(many))
 else
 new(dom, i)
 end_if
end_proc:
```

A function call to the domain such as `S(5)` now implicitly calls the "new" method:

```
S(5)
```

```
new(Polynesian integer, many)
```

```
S("nonsense")
```

```
Error: The type of argument number 1 must be 'Type::PosInt'. The
Evaluating: S::new
```

In the next step, we define our own output method. A Polynesian integer `i`, say, shall not be printed as `new(Polynesian integer, i)`, only its internal value 1, 2, 3, or many shall appear on the screen. Note that this value is the first operand of the data structure:

```
S::print :=
proc(x)
begin
 op(x, 1)
end_proc:
S(1), S(2), S(3), S(4), S(5)
```

1, 2, 3, many, many

By now, the input and output of elements of  $S$  have been defined. It remains to define how the functions and operators of MuPAD should react to Polynesian integers. This is done by *overloading* them. However, it is not necessary to overload each of the thousands of functions of MuPAD; for some of them, the default behavior is acceptable. For example, expression manipulation functions leave domain elements unaltered:

```
x := S(5): expand(x), simplify(x), combine(x); delete x:
```

many, many, many

Arithmetical operations handle domain elements like identifiers; they automatically apply the associative and commutative law for addition and multiplication:

```
(S(3) + S(2)) + S(4)
```

2 + 3 + many

In our case, this is not what we want. So we have to overload the operator  $+$ . Operators are overloaded by overloading the corresponding “underline-functions”; hence, we have to write a method “\_plus”:

```

S::_plus :=
proc()
local argv;
begin
 argv := map([args()], op, 1);
 if has(argv, hold(many)) then
 new(dom, hold(many))
 else
 dom(_plus(op(argv)))
 end_if
end_proc:

```

Now, the sum of Polynesian integers calls this slot:

```
S(1) + S(2), S(2) + S(3) + S(7)
```

### 3. many

Deleting the identifier `S` does not destroy our domain. It can still be reconstructed using `newDomain`.

```

delete S:
op(newDomain("Polynesian integer"))

```

```
"key" = "Polynesian integer", "new" = proc S::new(i) ... end, "print" = proc S::print(x) ... end
```

```
"_plus" = proc S::_plus() ... end
```

## Example 2

We could now give a similar example for more advanced Polynesian mathematics with numbers up to ten, say. This leads to the question whether it is necessary to enter all the code again and again whenever we decide to count a bit farther. It is not; this is one of the advantages of *domain constructors*. A domain constructor may be regarded as a

function that returns a domain depending on some input parameters. It has several additional features. Firstly, the additional keywords `category` and `axiom` are available for specifying the mathematical structure of the domain; in our case, we have the structure of a commutative semigroup where different domain elements have different mathematical meanings (we call this a domain with a canonical representation). Secondly, an initialization part may be defined that is executed exactly once for every domain returned by the constructor; it should at least check the parameters passed to the constructor. Each domain created in such a way may inherit methods from other domains, and it must at least inherit the methods of `Dom::BaseDomain`.

```
domain CountingUpTo(n : Type::PosInt)
 inherits Dom::BaseDomain;
 category Cat::AbelianSemiGroup;
 axiom Ax::canonicalRep;

 new := proc(x : Type::PosInt)
 begin
 if args(0) <> 1 then
 error("There must be exactly one argument")
 end_if;
 if x > n then
 new(dom, hold(many))
 else
 new(dom, x)
 end_if
 end_proc;

 print := proc(x) begin op(x, 1) end_proc;

 _plus := proc() local argv;
 begin
 argv:= map([args()], op, 1);
 if has(argv, hold(many)) then
 new(dom, hold(many))
 else
```

```
 dom(_plus(op(argv)))
 end_if
end_proc;

// initialization part
begin
 if args(0) <> 1 then
 error("Wrong number of arguments")
 end_if;
end:
```

Now, `CountingUpTo` is a domain constructor:

```
type(CountingUpTo)
```

`DomainConstructor`

We have defined the domain constructor `CountingUpTo`, but we have not created a domain yet. This is done by calling the constructor:

```
CountingUpToNine := CountingUpTo(9);
CountingUpToTen := CountingUpTo(10)
```

`CountingUpTo(9)`

`CountingUpTo(10)`

We are now able to create, output, and manipulate domain elements as in the previous example:

```
x := CountingUpToNine(3); y := CountingUpToNine(7):
x, x + x, y, x + y, y + y
```

3, 6, 7, many, many

```
x := CountingUpToTen(3): y := CountingUpToTen(7):
x, x + x, y, x + y, y + y
```

3, 6, 7, 10, many

```
delete CountingUpToNine, CountingUpToTen, CountingUpTo, x, y:
```

No domain constructor with the same name may be used again during the same session.

### Example 3

Suppose that your domain does not really depend on a parameter, but that you need some of the other features of domain constructors. Then you may define a domain constructor `dc`, say, that is called without parameters. From such a domain constructor, you can construct exactly one domain `dc()`. Instead of defining the constructor via `domain dc() ... end` first and then using `d := dc()` to construct the domain `d`, say, you may directly enter `domain d ... end`, thereby saving some work.

Continuing the previous examples, suppose that we want to count up to three, knowing that we never want to count farther. However, we want to declare our domain to be an Abelian semigroup with a canonical representation of the elements. This is not possible with a construction of the domain using `newDomain` as in “Example 1” on page 6-7: we have to use the keyword `domain`. You will notice at once that the following source code is almost identical to the one in the previous example—we just removed the dependence on the parameter `n`.

```
domain CountingUpToThree

inherits Dom::BaseDomain;
category Cat::AbelianSemiGroup;
axiom Ax::canonicalRep;
```

```
new := proc(x : Type::PosInt)
begin
 if args(0) <> 1 then
 error("There must be exactly one argument")
 end_if;
 if x > 3 then
 new(dom, hold(many))
 else
 new(dom, x)
 end_if
end_proc;

print := proc(x) begin op(x, 1) end_proc;

_plus := proc() local argv;
begin
 argv:= map([args()], op, 1);
 if has(argv, hold(many)) then
 new(dom, hold(many))
 else
 dom(_plus(op(argv)))
 end_if
end_proc;

end:
```

Now, `CountingUpToThree` is a domain and not a domain constructor:

```
type(CountingUpToThree)
```

## DOM\_DOMAIN

You may use this domain in the same way as `CountingUpTo(3)` in “Example 2” on page 6-11.

## Function Calls

When called as a function, the data type creates a new object of this data type out of the arguments of the call. E.g., the call `DOM_LIST(1, 2, x)` generates the list `[1, 2, x]` of domain type `DOM_LIST` (although, in this case, you probably prefer to type in `[1, 2, x]` directly which results in the same object). It depends on the particular type which arguments are admitted here.

In the case of a domain, the "new" method of that domain is called.

## Operations

You can obtain the slots of a domain using `slot`. The function `slot` can also be used on the left hand side of an assignment to define new slots, or to re-define existing slots. Use `delete` to delete slots.

## Operands

A data type consists of an arbitrary number of equations (objects of type "equal"). If `a = b` is among these equations, we say that the *slot* of the data type equals `b`. By convention, `a` is usually a string. Each domain has at least one slot indexed by "key".

## Element Creation

The names of the data types provided by the MuPAD kernel are of the form `DOM_XXX`, such as `DOM_ARRAY`, `DOM_HFARRAY`, `DOM_IDENT`, `DOM_INT`, `DOM_LIST`, `DOM_TABLE` etc.

You can create further data types using the function `newDomain` (cf. "Example 1" on page 6-7) or via the keyword `domain` (cf. "Example 3" on page 6-14).

You can also create new data types by calling a *domain constructor*. Various pre-defined domain constructors can be found in the library `Dom`. You can also define your own domain constructors using the keyword `domain`. Cf. "Example 2" on page 6-11.

The domain type (data type) of any MuPAD object can be queried by the function `domtype`.

## Algorithms

Only one domain with a given key may exist. If it is stored in two variables `S` and `T`, say, assigning or deleting a slot `slot(S, a)` implicitly also changes `slot(T, a)` (reference effect). This also holds if `a = "key"`.

---

**Note** You get no warning even if T is protected.

---

# DOM\_EXEC

---

## **Purpose**

Kernel functions

## **Description**

Objects of type `DOM_EXEC` represent kernel functions implemented in C++.

Unlike functions defined at the library level (which are stored in objects of type `DOM_PROC`), functions defined in C++ in the MuPAD kernel are represented by objects of type `DOM_EXEC`.

Users normally need not care about `DOM_EXEC`s except for the cases where explicitly testing the `domtype` of arguments; in those cases, `DOM_EXEC` should often be treated identically to `DOM_PROC`.

Most kernel functions are actually stored inside function environments of type `DOM_FUNC_ENV`, and therefore, you can see `DOM_EXEC` only when explicitly accessing the first or second operand of those function environments.

## **Function Calls**

An object of type `DOM_EXEC` essentially represents a function; using it in this way calls the corresponding function.

## **Operands**

The operands of a `DOM_EXEC` are used internally, may change at any time and remain undocumented.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Type of “general expressions”                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>DOM_EXPR is the data type of symbolic function calls. This includes expressions such as <math>a + b</math> which is internally stored as <code>_plus(a, b)</code>.</p> <p>In MuPAD, non-atomic symbolic expressions which are not elements of special domains have type DOM_EXPR.</p> <p>Objects of type DOM_EXPR have a 0th operand which contains the functor (the function symbol, the <math>f</math> in <math>f(x)</math>). This operand is not counted in the result of <code>nops</code>. The subsequent operands can be of arbitrary type (although most functions will limit the number and type of operands when evaluated).</p> <p>The 0th operand of a DOM_EXPR will be a procedure or function environment only in exceptional circumstances. In usual circumstances, expressions only have expressions, domain elements, or identifiers as their 0th operands.</p> |

**Examples****Example 1**

Function calls are of type DOM\_EXPR:

```
domtype(sin(x))
```

```
DOM_EXPR
```

The 0th operand of a function call is the function symbol:

```
op(sin(x), 0)
```

```
sin
```

This operand is taken into account neither by `nops` nor by `op` if called with one argument:

`nops(sin(x)), op(sin(x))`

`1, x`

## Function Calls

The effect of using an expression of type `DOM_EXPR` as a function to call depends on the 0th operand of the expression. For many system functions, the result is that of using all operands of the expression as functions, passing the *unevaluated* arguments. (These functions may in turn evaluate their arguments.)

## Operations

Most MuPAD functions (documented as accepting “arithmetical expressions”) are built to work on elements of type `DOM_EXPR`.

Often, the operands of an expression will be expressions themselves. This creates a so-called “expression tree” which can be visualized using `prog::expmtree`.

## Operands

All expressions are internally represented as function calls. The 0th operand is the function symbol of this call.

## Evaluation

Evaluating an expression results in calling the 0th operand as a function. For library functions without option `hold`, the operands are evaluated first.

| <b>Purpose</b>          | Real Floating Point Numbers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>      | <p>DOM_FLOAT is the type of (arbitrary precision) real floating-point numbers.</p> <p>Apart from exact symbolic calculations, MuPAD can also compute numerical approximations with arbitrary precision.</p> <p>MuPAD uses the values RD_INF and RD_NINF for real positive and negative infinities in floating-point intervals.</p> <p>MuPAD uses the value RD_NAN to indicate undefined values in floating-point intervals. If you use typeset mode, MuPAD displays this value as NaN in output regions.</p>                                                                                                                                                                              |
| <b>Function Calls</b>   | Calling a floating-point number as a function returns the number unchanged. The arguments of the call are <i>not</i> evaluated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Operations</b>       | Just about any arithmetical operation can be performed with floating-point numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Operands</b>         | DOM_FLOATs are atomic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Output</b>           | The output format of DOM_FLOAT depends on the setting of Pref::floatFormat and is documented there.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Element Creation</b> | <p>Floating point numbers are typed in with an optional sign (an arbitrary number of + and - signs), an optional integer part (consisting of digits), a decimal point (irrespective of locale settings of the operating system, MuPAD always expects a decimal point), a fractional part (one or more decimal digits) and optionally a decimal shift, written as the letter e followed by an optionally signed integer.</p> <p>The decimal shift is interpreted as a power of ten, i.e., 6.022e23 is the Avogadro number <math>6.02210^{23}</math>.</p> <p>Additionally, the function float and most calls to functions of the numeric library create floating-point numbers as well.</p> |

### MuPAD Functions

DIGITS | float

**Purpose**

Data type of function environments

**Description**

DOM\_FUNC\_ENV is the data type of function environments.

MuPAD uses function environments (domain type DOM\_FUNC\_ENV) to integrate functions into the system. All MuPAD library functions and most kernel functions are implemented as function environments.

A function environment stores special function attributes (slots) in an internal table. When an overloadable system function, such as `diff`, `expand`, or `float`, encounters an object of type DOM\_FUNC\_ENV, it searches the function environment for a corresponding slot.

**Operands**

A function environment consists of three operands. The first operand is a procedure that computes the return value of a function call. The second operand is a procedure for printing a symbolic function call on the screen. The third operand is a table that specifies how the system functions handle symbolic function calls.

**Element Creation**

`funcenv` and `fp::unapply` (or its equivalent `-->`) create function environments of type DOM\_FUNC\_ENV.

| <b>Purpose</b>        | Hardware floating-point arrays                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>    | <p>DOM_HFARRAY is a multidimensional container type, storing hardware floating-point numbers at integer indices.</p> <p>Unlike generic arrays, objects of type DOM_HFARRAY are containers of hardware floating-point numbers, real or complex. They take up considerably less space than the corresponding arrays of software floats (DOM_FLOAT) would, but the range of hardware floating-point numbers is much more limited.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Function Calls</b> | Using an hf-array as the symbol of a function call returns that hf-array unchanged. The arguments of the call are not evaluated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Operations</b>     | <p>Read and write access to an hf-array is performed using indexed access, as in <math>A[1]</math>, which automatically converts between hardware and software floats. Trying to write a value which cannot be converted into a hardware float into an hf-array causes an error to be raised, as does accessing an element out of bounds.</p> <p>The function <code>map</code> applies some function or transformation to each element of an hf-array, returning an hf-array of the same format as its input, with the results of the calls as its entries. If a result cannot be converted to a hardware float, an error is raised.</p> <p>If <math>A</math> is an hf-array, <code>nops(A)</code> returns the number of elements in <math>A</math>.</p> <p>Basic arithmetic works on hf-arrays: Addition and subtraction of hf-arrays of identical format combines the containers element-wise, addition and subtraction of constants is applied to the main diagonal. For two-dimensional hf-arrays, multiplication performs matrix multiplication. Division is possible for completeness, but should be avoided, as it numerically inverts the dividend first, and this is hardly ever the algorithmically “right” way to handle a numerical problem.</p> |
| <b>Operands</b>       | If $A$ is an hf-array, the 0th operand of $A$ , <code>op(A, 0)</code> , will be the sequence starting with the number of dimensions (an integer $n$ ) followed by $n$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

ranges of integers, which denote the acceptable ranges of indices for each dimension, including both numbers listed in the range.

For  $1 \leq i \leq nops(A)$ , the  $i$ th operand of  $A$  is the  $i$ th entry of  $A$ , in the lexicographic order of indices.

## Output

One-dimensional hf-arrays are displayed as row vectors, two-dimensional hf-arrays as matrices. Higher-dimensional hf-arrays are written in functional form, writing the entries as a flat list, and do not have a typesetting version. This also causes typesetting to be disabled for any surrounding expression in the same output.

## Element Creation

The primary way of creating hf-arrays is the function `hfarray`. Other important functions (optionally) returning hardware float arrays include several functions of the `numeric` library and `import::readbitmap`.

| <b>Purpose</b>        | Symbolic Identifiers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>    | <p>DOM_IDENT is the data type of symbolic identifiers, used for example for indeterminates.</p> <p>To perform symbolic computations, it is often necessary to represent indeterminates, which may or may not carry assumptions. These indeterminates (which in some contexts may also be bound identifiers and which may also be assigned specific values) are called “identifiers” in MuPAD and have the domain type DOM_IDENT.</p>                                                                                                                                                                                                                                                                                                                                                       |
| <b>Function Calls</b> | Calling a DOM_IDENT as a function creates a DOM_EXPR. If the identifier has a value, the evaluation of that DOM_EXPR may result in an arbitrary value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Operations</b>     | <p>Identifiers are valid arithmetical expressions, so most MuPAD functions happily accept identifiers.</p> <p>To get and analyze the name of an identifier, you can use <code>coerce(identifier, DOM_STRING)</code> and look at the resulting string. (The call <code>" ".identifier</code> returns the same string and is shorter to type.)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Operands</b>       | Identifiers are atomic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Output</b>         | <p>Identifiers are displayed with their names, with the following special cases in typesetting:</p> <ul style="list-style-type: none"><li>• The backticks used for input are not typeset. They are present with typesetting switched off such as when using <code>print</code> without the <code>Typeset</code> option.</li><li>• Underscores (<code>_</code>) in the middle of identifiers cause subscripting: <code>x_2</code> is displayed as <math>x_2</math>.</li><li>• Certain constructs of the form <code>`&amp;...;`</code> in identifiers are replaced by special typeset characters. For example, <code>`&amp;alpha;&amp;rarr;`</code> is displayed as <math>\bar{\alpha}</math>. To generate these identifiers, we suggest using the Symbol library, which would use</li></ul> |

`Symbol::accentRightArrow(Symbol::alpha)` for the example above.

## Element Creation

A sequence of characters, underscores and digits which does not start with a digit is considered an identifier. Examples: `x`, `x0`, `t_0`.

Additionally, an arbitrary string of characters enclosed in 'backticks' `` is also an identifier. Examples: ```x+y``, ```a plus 1``. If the string of characters between the back ticks is a valid identifier already, this input form creates the same identifier as the one without the backticks.

## Purpose

Floating point intervals

## Description

Object of type `DOM_INTERVAL` represents an interval of complex numbers. Either border may be *infinity* or  $-\infty$ . The borders are represented by floating point numbers (`DOM_FLOAT`).

Objects of type `DOM_INTERVAL` represent numerical enclosures of rectangles in the complex plane or finite unions thereof. Numerical enclosures of real intervals are an important special case.

Because an element of type `DOM_INTERVAL` contains floating-point numbers of type `DOM_FLOAT`, its exact value depends on the value of the environment variable `DIGITS` at the time of creation.

The result of all arithmetical operations on elements of type `DOM_INTERVAL` is rounded outwards, that is, the resulting (union of) rectangle(s) is *guaranteed* to contain the exact result. If the result interval is purely real, the lower bound of the result is guaranteed to be no larger than the exact value of the exact result, while the upper value of the result is guaranteed to be no smaller than the exact value. The exact values may not be representable as floating-point numbers. In this case, the result of a single operation such as `+` or `*` is the smallest representable interval containing the exact result. In other words, operations on `DOM_INTERVAL` are locally optimal.

Note that the representation of an element of `DOM_INTERVAL` on the screen is generated with outward rounding, too. This may lead to “apparent overestimation,” as you can see in “Example 1” on page 6-29.

For generating matrix or polynomial rings over floating-point intervals, use the façade domain `Dom::FloatIV`.

## Examples

### Example 1

An interval of type `DOM_INTERVAL` can only hold floating-point numbers, which are internally stored as binary numbers. For this reason, it cannot hold symbolic expressions as its operands:

```
iv := hull(PI)
```

# DOM\_INTERVAL

---

```
3.141592653 ... 3.141592654
```

This interval certainly does contain  $\pi$ . However, the value printed on the screen does not accurately describe the interval generated, as you can see when you print the same interval with a larger value of DIGITS:

```
DIGITS := 15: iv; delete DIGITS:
```

```
3.14159265358979 ... 3.1415926535898
```

In the first output, it looked as if the difference between the two borders (the width of the interval) was  $10^{-8}$ , while in the latter output we can see that it is at most  $10^{-13}$ . Actually, the difference is even smaller:

```
op(iv,2) - op(iv,1)
```

```
6.938893904 10-18
```

This rounding does not take place for symbolic values which can be represented exactly in both the internal (binary) and the on-screen (decimal) format:

```
iv := hull(1); op(iv,2) - op(iv,1)
```

```
1.0 ... 1.0
```

```
0.0
```

However, floating-point values in the input are assumed to be approximations up to the current computing precision:

```
iv := hull(1.0); op(iv,2) - op(iv,1)
```

```
0.9999999999 ... 1.000000001
```

```
5.204170428 10-18
```

## Example 2

If you convert `infinity` or `-infinity` into an interval of type `DOM_INTERVAL`, the resulting interval will contain the corresponding floating-point infinity, which are displayed as `RD_INF` or `RD_NINF`, respectively:

```
hull(infinity), hull(-infinity)
```

```
2.098578716 10323228496 ... RD_INF, RD_NINF ... -2.098578716 10323228496
```

Since the range of floating-point numbers is limited, also conversion of finite values may generate floating-point infinities. The exact limit of floating-point numbers may change from one MuPAD version to the next. Currently, the following command exceeds the representable range::

```
hull(exp(10^9))
```

```
2.098578716 10323228496 ... RD_INF
```

As for calculating with intervals with infinities as their borders, note that any multiplication where one factor is exactly zero and the other factor contains either infinity results in the interval encompassing the whole real axis:

# DOM\_INTERVAL

---

$(0 \dots 0) * (1e30 \dots \text{infinity})$

$RD\_NINF \dots RD\_INF$

### Example 3

Objects of type DOM\_INTERVAL represent rectangular subsets of the complex plane with the sides parallel to the coordinate axes or unions of such rectangles. In the following example, the exact result would be a rotated rectangle. Interval arithmetics returns the smallest non-rotated rectangle enclosing the precise result:

$(1 \dots 2+I) * (1+I)$

$0.0 \dots 2.0 + 1.0 \dots 3.0 i$

### Example 4

When computing with floating-point numbers, you can easily run into cancellation and round-off errors without noticing:

$(1+1e-18) - 1.0$

$0.0$

$\sin(1e42)$

$0.4587729978$

The fundamental problem of numerical computations is that there is no indication to these errors. Of course, you can get around most problems of this type by increasing the number of significant digits, if you know that problems are lurking:

## Operations

You can access the borders of an interval using `op`. See below for the details.

Intervals can be viewed as sets, and the corresponding functions `union`, `intersect`, and `minus` work on intervals, too.

As of version 2.5, MuPAD implements the following operations on elements of type `DOM_INTERVAL`:

- The basic arithmetical operations: `+`, `-`, `*`, `/`, `^`, `sqrt`.
- The trigonometric functions and their inverses: `sin`, `cos`, `tan`, `sec`, `csc`, `cot`, `arcsin`, `arccos`, `arctan`, `arccsc`, `arccot`.
- The exponential function and the logarithm.
- The hyperbolic functions and their inverses: `sinh`, `cosh`, `tanh`, `sech`, `csch`, `coth`, `arcsinh`, `arccosh`, `arctanh`, `arccsch`, `arccoth`.
- The functions `Re`, `Im` (real- and imaginary part), `abs`, `sign` and `arg` (the ‘argument’ = polar angle of a complex number).
- For real intervals, `gamma` and `beta`.
- `ceil`, `floor`, `trunc`, `round`.

For legal combinations of arguments, all computations are carried out in interval arithmetics, see “Example 4” on page 6-32.

## Operands

The operands of an interval depend on its value:

- An interval of type `DOM_INTERVAL` may be a union of rectangles in the complex plane. In this case, the 0th operand is the identifier `union`, while the remaining operands are the corresponding rectangles, which are of type `DOM_INTERVAL`.
- Rectangles with non-zero imaginary part, which are not unions, have two operands of type `DOM_INTERVAL`: Their real and imaginary parts, both of which are real intervals.
- Real intervals, i.e., non-union rectangles with vanishing imaginary part, have two operands, their left and right borders.

**Output**

A real interval is displayed in the form “left . . . right”, where “left” and “right” are the borders of the interval, printed as floating-point numbers.

A complex interval is displayed as “(real part) + (imaginary part) \* I”, with the real and imaginary part displayed as real intervals.

A union of rectangles is displayed as “interval union interval”, with the intervals inside written as specified above.

The output of an interval depends on the environment variable DIGITS as well as on the preference settings `Pref::floatFormat` and `Pref::trailingZeroes`.

Note that the borders are rounded outwards for printing. “Example 1” on page 6-29 shows how this effects the output.

**Element Creation**

Elements of type `DOM_INTERVAL` can be constructed in the following ways:

- With the function `hull`:

```
hull(PI, -3, 1/2), hull(1/3)
```

```
- 3.0 ... 3.141592654, 0.3333333333 ... 0.3333333334
```

- With the operator `...` (which in turn calls `hull`):

```
1 ... 4+I
```

```
1.0 ... 4.0 + 0.0 ... 1.0 i
```

- The function `interval` creates elements of type `DOM_INTERVAL` as well, but may return expressions:

```
interval(x^2+sin(1))
```

# DOM\_INTERVAL

---

$$x^2 + 0.8414709848 \dots 0.8414709849$$

Note that floating-point values in the input of `hull` or `interval` are considered to be approximations, even if the value displayed in the decimal system can be represented exactly in the internal binary format. This is because `hull` cannot decide whether, for example, `0.25` has actually been typed in as such or if it should have been some `0.25 + .` If you want zero-width intervals, use a rational number as input which can be represented exactly in binary:

## Algorithms

Intervals of type `DOM_INTERVAL` are always interpreted as *closed* intervals, i.e., the endpoints belong to the set. It is reasonable not to have open intervals included, since most operations will enlarge the resulting interval anyway (although only marginally so).

**Purpose**

Lists of Objects

**Description**

Lists (of domain type DOM\_LIST) are ordered collections of an arbitrary number of arbitrary MuPAD objects, except for sequences and the null object.

In MuPAD, the mathematical construct of an  $n$ -tuple is implemented as the data type DOM\_LIST. Lists consist of an arbitrary (finite) number of arbitrary objects, with the exception of expression sequences, which are split into their operands when placed into a list.

Unlike sets, lists can contain multiple copies of the same element. The order of elements in a list is preserved.

Lists can be empty.

**Examples****Example 1**

To create a list for our first example, we use the operator \$:

```
L := [x_.i $ i=1..10]
```

```
[X1, X2, X3, X4, X5, X6, X7, X8, X9, X10]
```

This list contains 10 elements:

```
nops(L)
```

```
10
```

The fifth element of the list is  $x_5$  and the list of elements from  $x_3$  through  $x_6$  can also be accessed very easily:

```
L[5], L[3..6]
```

## DOM\_LIST

---

$x_5, [x_3, x_4, x_5, x_6]$

To change an element of the list, we use the indexed form on the left hand side of an assignment:

$L[5] := 5$

$5$

$L$

$[x_1, x_2, x_3, x_4, 5, x_6, x_7, x_8, x_9, x_{10}]$

Note that this assignment only changes  $L$ , not  $x_5$ :

$x_5$

$x_5$

Likewise, we can change a sublist by assigning another list to it. This may change the length of the list:

$L[3..6] := [1, 2]$

$[1, 2]$

$\text{nops}(L), L$

$8, [x_1, x_2, 1, 2, x_7, x_8, x_9, x_{10}]$

## Function Calls

Using a list as a function symbol creates the list obtained by using each list element as a function symbol for the operands used, i.e.,  $[f, g](x, y)$  results in  $[f(x, y), g(x, y)]$ .

## Operations

Assuming that  $L$  is a list, the number of elements in  $L$  can be determined by calling `nops(L)`.

Individual elements of the list are accessed in the form  $L[1]$ ,  $L[2]$  etc. when counting from the beginning or  $L[-1]$ ,  $L[-2]$  etc. when counting from the end. Trying to access an element “outside” the list or  $L[0]$  raises an error.

Continuous sub-lists can be extracted by using a range in an indexed access:  $L[2..4]$  returns the list  $[L[2], L[3], L[4]]$ ;  $L[2..-2]$  returns the list  $L$  without its first and last element.

Both forms of indexed access can also be used as the left hand side of an assignment, cf. “Example 1” on page 6-37.

Lists can be concatenated with the dot operator, as in  $L1 . L2$  or its functional form, `_concat`.

The function `contains` finds the first occurrence of a given MuPAD object in a list. `select` and `split` can be used to extract those elements from a list fulfilling an arbitrary predicate.

Lists can be sorted with `sort` or `prog::sort`.

The function `map` applies a function to all elements of a list, returning the list of results. To combine two lists element-wise with some function, use `zip`.

Assigning a list to a list of identifiers is possible and results in a simultaneous assignment, cf. `?_assign`.

## Operands

The operands of a list are its elements.

## Element Creation

The most direct way of creating a list is to place a sequence of MuPAD objects (separated by commas) between rectangular brackets, as in  $[1, 2, 3]$ .

# DOM\_PROC\_ENV

---

**Purpose** Data type of procedure environments

**Description** Procedure environments are mostly ephemeral objects and are only rarely seen by the user (and even more rarely useful to examine). A procedure environment represents a procedure that is currently being executed: formal parameters and local variables have values.

Procedure environments do rarely become visible, and you do not need to manipulate them directly. They serve only one purpose: if a procedure is generated inside another procedure, variable names in the body of the inner procedure that are not declared local there refer to names in the outer procedure, provided they are declared local in the outer procedure. (See the Programming Manual for more information on the scoping rules for MuPAD.) Consequently, the inner procedure must contain information on the current values of local variables of the outer procedure. Hence, the status of the outer procedure is encoded into an object of type DOM\_PROC\_ENV, and that object is stored in the returned procedure as its twelfth operand.

You never need to generate objects of this type. There are no operations available.

## **Examples** **Example 1**

The only occasion on which you should come across a procedure environment is the following: an outer procedure returns an inner procedure depending on formal parameters or local variables of the outer procedure:

```
outer :=
proc(x)
option escape;
begin
 /* inner procedure to return : */
 y -> x + y
end_proc:
add5 := outer(5)
```

$y \rightarrow x + y$

In spite of the (slightly confusing) output, `x` has a special meaning here: it points to the parameter `x` of `outer`. That parameter currently has the value `5` and won't be changed any more. To be able to access that value, the particular instance of `outer` in the status of being executed has to be stored in `add5`:

```
expr2text(op(add5, 12))
```

```
"DOM_PROC_ENV(0x1f9d904)"
```

## Operands

The number of operands of a procedure environment depends on the number of local and saved variables of the outer procedure. Details about the operands remain undocumented.

## Algorithms

The integers appearing in the output of objects of type `DOM_PROC_ENV` have no mathematical meaning; they denote positions in memory.

# DOM\_RAT

---

**Purpose** Rational Numbers

**Description** DOM\_RAT is the data type of rational numbers.

**Examples** **Example 1**

The operands of a rational number are its numerator and denominator:

`op(2/3)`

`2, 3`

When substituting an operand, the resulting DOM\_RAT is again normalized:

`subsop(2/3, 2=6)`

$\frac{1}{3}$

**Function Calls** Using a rational number as a function returns that number unchanged. The function arguments are *not* evaluated.

**Operations** Rational numbers are arithmetical expressions and therefore valid inputs to most MuPAD functions.

The numerator and denominator of a rational number can be accessed using `num` and `denom` or by using `op` directly.

Elements of DOM\_RAT are always normalized, cf. “Example 1” on page 6-44.

**Operands** A rational number has two operands, which are integers: Its numerator and its denominator.

## **Element Creation**

The division of two integers results in an integer or a rational number.

DOM\_COMPLEX | DOM\_INT | DOM\_FLOAT | Dom::Rational

# DOM\_SET

---

## Purpose

Sets of Objects

## Description

Set of type DOM\_SET can store an arbitrary finite number of arbitrary MuPAD objects, except for sequences and the null object.

In MuPAD, finite sets are implemented with the data type DOM\_SET. Sets are unordered collections of arbitrary objects, with identical objects appearing only once. Sequences (objects separated by commas) are “flattened” when put into a set, i.e., instead of the sequence, its elements are placed into the set. The null object is treated as the empty sequence, i.e., it does not result in an element in the set.

Sets can be empty. The empty set is displayed as  $\emptyset$ .

## Function Calls

Using a set as a function symbol creates the set obtained by using each element as a function symbol for the operands used, i.e.,  $\{f, g\}(x, y)$  results in  $\{f(x, y), g(x, y)\}$ .

## Operations

Assuming that  $S$  is a set, the number of elements in  $S$  can be obtained by calling `nops(S)`.

Individual elements of the set can be obtained in two subtly different ways:

- 1 Using an indexed access, as in `S[2]`, returns the  $n$ -th element of the set, counted in the order as the set appears on the screen. This is a potentially slow operation, since it requires determining that order for each access, i.e., sorting the set.

Negative indices are accepted, counting from the end of the sequence of elements. Trying to access an element “outside” the set or `S[0]` raises an error.

- 2 Using `op`, as in `op(S, 2)`, returns the  $n$ -th element of the set, counted in the internal order. This is a fast operation ( $O(n)$  to get the  $n$ -th element, irrespective of the size of  $S$ ), but the internal order of two mathematically identical sets can be completely different and almost

any operation changing a set can completely change its internal order, so no assumptions should be made.

Both of these ways also accept ranges as indices. `S[2..4]` returns the set `{S[2], S[3], S[4]}`, while `op(S, 2..4)` returns the sequence `op(S, 2), op(S, 3), op(S, 4)`.

To iterate over all elements of a set in no particular order, using `map` or the `$` operator is highly superior to using a `for`-loop with either of the above element access methods. If a `for`-loop is required, you should use the form `for s in S`, which has linear complexity as well.

The usual set operations are provided as infix operations: `union`, `minus`, `intersect`.

To change an element of a set, the preferred method is to remove it using `minus` and adding a new one using `union`. It is also possible to replace an element with `subsop`; replacing an element with `null()` deletes it from the set. (Note that `subsop` does not do a side-effect assignment.)

The function `contains` checks for occurrence of a given MuPAD object in a set; see also the `in` operator for the same purpose, but with different evaluation semantics. `select` and `split` can be used to extract those elements from a set fulfilling an arbitrary predicate.

To get a list of the elements of a set, use `coerce`. To get such a list with the elements ordered in the same way as printed on the screen, use `DOM_SET::sort(S)`.

## Operands

The operands of a set are its elements, in the internal order. (See above for details.)

## Output

Sets are ordered for the output.

## Element Creation

The most direct way of creating a set is to place a sequence of MuPAD objects (separated by commas) between curly brackets, as in `{1, 2, 3}`.

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Texts (character strings)                                                                                                                                                                                                                       |
| <b>Description</b> | <p>Texts (which are not really “mathematical objects”, but useful to the programmer) in MuPAD are of domain type DOM_STRING.</p> <p>MuPAD can manipulate texts (strings of characters). These are primarily used for output and data input.</p> |

**Examples****Example 1**

As far as `op` is concerned, a string cannot be dissected:

```
s := "this is a string":
op(s, 1), op(s, 2)
```

```
"this is a string", FAIL
```

To access individual characters or substrings, use indexed access:

```
s[1], s[6..7]
```

```
"t", "is"
```

Assigning to a substring may change the length of a string:

```
s[6..7] := "changes";
s
```

```
"changes"
```

```
"this changes a string"
```

# DOM\_STRING

---

## Function Calls

Using a string as a function returns the string unchanged. The arguments are *not* evaluated.

## Operations

Strings can be concatenated using the dot operator or its functional equivalent, `_concat`.

The length of a string can be obtained using `length`.

Substrings and individual characters (which are strings of length 1) can be accessed using `substring` or indexed access, with indices starting at 1 and negative indices counting from the end of the string: `s[1]`, `s[3..-2]`. It is also possible to perform an indexed assignment to a string, cf. “Example 1” on page 6-49.

To convert a string into the MuPAD expression that would be obtained by using the string as an input, use `text2expr`. For simple MuPAD expressions, it is possible to get a string that evaluates to that expression using `expr2text`. Expressions that are not convertible in this way include all expressions containing local variables set with option `escape`. Also, expressions involving floating point numbers usually will change when being converted to strings and back.

## Operands

Strings are atomic, i.e., they have exactly one operand, the string itself.

## Output

The output form of strings is very similar to their input form. When typesetting, spaces at the beginning and the end of strings are ignored and multiple adjacent blanks as well as newlines are collapsed to a single space.

## Element Creation

A string is created by enclosing characters in a pair of typewriter quotes: `"this is a string"`. The following special sequences are supported (but see below for the typeset output; these are useful only for non-typeset output):

- `"\n"` denotes an end-of-line character.
- `"\b"` is almost identical to `"\n"`, except that for “pretty-printing” it encodes the baseline of the current object.

- "\t" is a tabulator.
- "\\" encodes a backslash.

See the documentation of `print` for details.

# DOM\_VAR

---

## Purpose

Local Variables in Procedures

## Description

Local variables (variables in the programming sense, with “lexical scoping”) are of domain type `DOM_VAR`.

When writing MuPAD functions, often intermediate results need to be stored and retrieved. Like most programming languages, MuPAD offers “local variables” for this purpose. These local variables do not conflict with global identifiers of the same name nor with other local variables of the same name used at other places.

Local variables use “lexical scoping”, i.e., they can be used in all program code that is written inside the body of the procedure declaring the local variable. Note that returning anything with a reference to a local variable requires the use of `option escape` in the procedure definition.

## Operations

Local variables can be assigned values and these values can later be retrieved.

## Element Creation

Local variables are created by using either the special names `dom` or `procname` or one of the names declared with the keyword `local` inside a procedure definition.

**Purpose** Simple algebraic field extensions

## Syntax

### Domain Creation

```
Dom::AlgebraicExtension(F, f)
Dom::AlgebraicExtension(F, f, x)
Dom::AlgebraicExtension(F, f1 = f2)
Dom::AlgebraicExtension(F, f1 = f2, x)
```

### Element Creation

```
Dom::AlgebraicExtension(F, f)(g)
Dom::AlgebraicExtension(F, f)(rat)
```

## Description

### Domain Creation

For a given field  $F$  and a polynomial  $f \in F[x]$ ,  
`Dom::AlgebraicExtension(F, f, x)` creates the residue class field  $F[x]/\langle f \rangle$ .

`Dom::AlgebraicExtension(F, f1=f2, x)` does the same for  $f = f_1 - f_2$ .

`Dom::AlgebraicExtension(F, f, x)` creates the field  $F[x]/\langle f \rangle$  of residue classes of polynomials modulo  $f$ . This field can also be written as  $F[x]/\langle f \rangle$ , the field of residue classes of rational functions modulo  $f$ .

The parameter  $x$  may be omitted if  $f$  is a univariate polynomial or a polynomial expression that contains exactly one indeterminate; it is then taken to be the indeterminate occurring in  $f$ .

The field  $F$  must have normal representation.

$f$  must not be a constant polynomial.

$f$  must be irreducible; this is *not* checked.

$f$  may be a polynomial over a coefficient ring different from  $F$ , or multivariate; however, it must be possible to convert it to a univariate polynomial over  $F$ . See “Example 2” on page 6-55.

### Element Creation

`Dom::AlgebraicExtension(F, f)(g)` creates the residue class of  $g$  modulo  $f$ .

# Dom::AlgebraicExtension

---

If `rat` has numerator and denominator `p` and `q`, respectively, then `Dom::AlgebraicExtension(F,f)(rat)` equals `Dom::AlgebraicExtension(F,f)(p)` divided by `Dom::AlgebraicExtension(F,f)(q)`.

**Superdomain** `Dom::BaseDomain`

**Axioms** If `F` has `Ax::canonicalRep`, then `Ax::canonicalRep`.

**Categories** `Cat::Field`, `Cat::Algebra(F)`, `Cat::VectorSpace(F)`  
If `F` is a `Cat::DifferentialRing`, then `Cat::DifferentialRing`.  
If `F` is a `Cat::PartialDifferentialRing`, then `Cat::PartialDifferentialRing`.

**Examples** **Example 1**

We adjoin a cubic root `alpha` of 2 to the rationals.

```
G := Dom::AlgebraicExtension(Dom::Rational, alpha^3 = 2)
 Dom::AlgebraicExtension(Dom::Rational, alpha^3 - 2 = 0, alpha)
```

The third power of a cubic root of 2 equals 2, of course.

```
G(alpha)^3
```

```
2
```

The trace of  $\alpha$  is zero:

```
G::conjTrace(G(alpha))
```

0

You can also create random elements:

```
G := random()
```

```
2 - 814 alpha^2 - 65 alpha + 824
```

## Example 2

The ground field may be an algebraic extension itself. In this way, it is possible to construct a tower of fields. In the following example, an algebraic extension is defined using a primitive element `alpha`, and the primitive element `beta` of a further extension is defined in terms of `alpha`. In such cases, when a minimal equation contains more than one identifier, a third argument to `Dom::AlgebraicExtension` must be explicitly given.

```
F := Dom::AlgebraicExtension(Dom::Rational, alpha^2 = 2):
G := Dom::AlgebraicExtension(F, bet^2 + bet = alpha, bet)
```

```
Dom::AlgebraicExtension(Dom::AlgebraicExtension(Dom::Rational, alpha^2 - 2 = 0, alpha),
= 0, bet)
```

## Example 3

We want to define an extension of the field of fractions of the ring of bivariate polynomials over the rationals.

```
P:= Dom::DistributedPolynomial([x, y], Dom::Rational):
F:= Dom::Fraction(P):
K:= Dom::AlgebraicExtension(F, alpha^2 = x, alpha)
```

# Dom::AlgebraicExtension

---

```
Dom::AlgebraicExtension(Dom::Fraction(Dom::DistributedPolynomial([x, y], Dom::Rational, 1
+ alpha^2 = 0, alpha)
```

Now  $K = Q[\sqrt{x}, y]$ . Of course, the square root function has the usual derivative; note that  $\frac{1}{\sqrt{x}}$  can be expressed as  $\frac{\alpha}{x}$ :

```
diff(K(alpha), x)
```

$$\frac{\alpha}{2x}$$

On the other hand, the derivative of  $\sqrt{x}$  with respect to  $y$  is zero, of course:

```
diff(K(alpha), y)
```

$$0$$

We must not use D here. This works only if we start our construction with a ring of univariate polynomials:

```
P:= Dom::DistributedPolynomial([x], Dom::Rational):
F:= Dom::Fraction(P):
K:= Dom::AlgebraicExtension(F, alpha^2 = x, alpha):
D(K(alpha))
```

$$\frac{\alpha}{2x}$$

## Parameters

**F**

The ground field: a domain of category `Cat::Field`

**f, f1, f2**

Polynomials or polynomial expressions

**x**

Identifier

**g**

Element of the residue class to be defined: polynomial over  $F$  in the variable  $x$ , or any object convertible to such.

**rat**

Rational function that belongs to the residue class to be defined: expression whose numerator and denominator can be converted to polynomials over  $F$  in the variable  $x$ . The denominator must not be a multiple of  $f$ .

## Entries

"zero"

the zero element of the field extension

"one"

the unit element of the field extension

"groundField"

the ground field of the extension

"minpoly"

the minimal polynomial  $f$

"deg"

the degree of the extension, i.e., of  $f$

"variable"

the unknown of the minimal polynomial  $f$

# Dom::AlgebraicExtension

---

|                        |                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "characteristic"       | the characteristic, which always equals the characteristic of the ground field. This entry only exists if the characteristic of the ground field is known.                               |
| "degreeOverPrimeField" | the dimension of the field when viewed as a vector space over the prime field. This entry only exists if the ground field is a prime field, or its degree over its prime field is known. |

## Methods

### Mathematical Methods

#### **plus - Sum of field elements**

`_plus(a, )`

This method overloads the function `_plus` of the system kernel.

#### **mult - Product of field elements**

`_mult(a, )`

This method overloads the function `_mult` of the system kernel.

#### **power - Raise to the nth power**

Inherited from `Cat::Monoid`.

#### **negate - Negate a field element**

`_negate(a)`

This method overloads the function `_negate` of the system kernel.

#### **subtract - Difference of field elements**

`_subtract(a, b)`

This method overloads the function `_subtract` of the system kernel.

## **equal - Test for mathematical equality**

Inherited from Dom::BaseDomain.

## **equiv - Test for equivalence**

Inherited from Cat::BaseCategory.

## **iszero - Test whether a field element is zero.**

iszero(a)

This method overloads the function iszero.

## **isone - Test if element is one**

Inherited from Cat::Monoid.

## **isUnit - Test if element is an unit**

Inherited from Cat::Field.

## **intmult - Multiply a field element by an integer**

intmult(a, b)

This method is more efficient than "\_mult" in this special case.

## **\_invert - Inverse of a field element**

\_invert(a)

This method overloads the function \_invert.

## **\_divide - Exact division**

Inherited from Cat::Field.

## **divide - Division with remainder**

Inherited from Cat::Field.

## **quo - Return Euclidean quotient**

Inherited from Cat::Field.

## **rem - Return Euclidean remainder**

Inherited from Cat::Field.

# Dom::AlgebraicExtension

---

## **euclideanDegree - Return Euclidean degree**

Inherited from `Cat::Field`.

## **idealGenerator - Generator of finitely generated ideal**

Inherited from `Cat::EuclideanDomain`.

## **divides - Test if division is exact**

Inherited from `Cat::Field`.

## **gcd - Gcd of field elements**

`gcd(a, )`

This method overloads the function `gcd`.

## **gcdex - Extended greatest common divisor**

Inherited from `Cat::EuclideanDomain`.

## **associates - Test for associate elements**

Inherited from `Cat::Field`.

## **unitNormal - Unit normal form**

Inherited from `Cat::Field`.

## **unitNormalRep - Unit normal representation**

Inherited from `Cat::Field`.

## **lcm - Least common multiple**

Inherited from `Cat::GcdDomain`.

## **sqrfree - Square-free factorization**

Inherited from `Cat::Field`.

## **irreducible - Test if element is irreducible**

Inherited from `Cat::Field`.

## **factor - Unique factorization**

Inherited from `Cat::Field`.

## **conjNorm - Norm of an element**

`conjNorm(a)`

## **conjTrace - Trace of an element**

`conjTrace(a)`

## **minimalPolynomial - Minimal polynomial of an element**

`minimalPolynomial(a)`

## **D - Differential operator**

`D(a)`

This method overloads the function `D`.

This method must not be called for inseparable extensions; note that MuPAD cannot check whether an extension is separable.

See “Example 3” on page 6-55.

## **diff - Partial differentiation**

`diff(a, x1, )`

Differentiation is defined to be the continuation of differentiation of the ground field; this method exists only if the ground field has a method “diff”, too.

Differentiation is not possible in inseparable extensions.

This method overloads the function `diff`.

This method must not be called for inseparable extensions; note that MuPAD cannot check whether an extension is separable.

See “Example 3” on page 6-55.

## **random - Random element of the field**

`random()`

The `random` method of the ground field is used to generate coefficients of a random polynomial of the ground field; the residue class of that polynomial is the return value. Hence the

# Dom::AlgebraicExtension

---

probability distribution of the elements returned depends on that of the random method of the ground field.

## Conversion Methods

### **convert - Convert into a field element**

`convert(x)`

If the conversion fails, then FAIL is returned.

### **convert\_to - Convert a field element into another type**

`convert_to(a, T)`

Field elements can be converted to polynomials or expressions. Field elements represented by constant polynomials can also be converted to the same types as the elements of the ground field; in particular, they can be converted to elements of the ground field.

### **coerce - Coerce into this domain**

Inherited from `Cat::BaseCategory`.

### **new - Create element of this domain**

Inherited from `Cat::BaseCategory`.

### **expr - Convert an element of the field into an expression**

`expr(a)`

This method overloads the function `expr`.

### **subs - Avoid substitution**

Inherited from `Dom::BaseDomain`.

### **subsex - Avoid extended substitution**

Inherited from `Dom::BaseDomain`.

### **testtype - Test type of object**

Inherited from `Cat::BaseCategory`.

### **print - Return expression to print an element**

Inherited from `Cat::BaseCategory`.

**printMethods - Print out methods**

Inherited from `Dom::BaseDomain`.

**TeX - Generate TeX output**

Inherited from `Dom::BaseDomain`.

**hasProp - Test for a certain property**

Inherited from `Dom::BaseDomain`.

**whichEntry - Return the domain or category implementing an entry**

Inherited from `Dom::BaseDomain`.

**allEntries - Return the names of all entries**

Inherited from `Dom::BaseDomain`.

**undefinedEntries - Return missing entries**

Inherited from `Dom::BaseDomain`.

**getAxioms - Return axioms stated in the constructor**

Inherited from `Dom::BaseDomain`.

**getSuperDomain - Return super-domain stated in the constructor**

Inherited from `Dom::BaseDomain`.

**allSuperDomains - Return all super-domains**

Inherited from `Dom::BaseDomain`.

**getCategories - Return categories stated in the constructor**

Inherited from `Dom::BaseDomain`.

**allAxioms - Return all axioms**

Inherited from `Dom::BaseDomain`.

**allCategories - Return all categories**

# Dom::AlgebraicExtension

---

Inherited from Dom::BaseDomain.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Domains of arithmetical expressions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Syntax</b>      | <code>Dom::ArithmeticalExpression(x)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p><code>Dom::ArithmeticalExpression</code> is a façade domain of arithmetical expressions built up by the system functions and operators like <code>+</code> and <code>*</code>.</p> <p>This domain has almost no algebraic structure because unqualified expressions have no normal form. (For example, there are rational expressions for zero which are not normalized to 0.) The main purpose of <code>Dom::ArithmeticalExpression</code> is to provide implementations for methods used by façade sub-domains like <code>Dom::Integer</code> which are represented by a subset of the arithmetical expressions.</p> <p>Elements of <code>Dom::ArithmeticalExpression</code> are usually not created explicitly. However, if one creates elements using the usual syntax, the input is converted to an expression using <code>expr</code>, then it is checked whether the result is an arithmetical expression.</p> |

**Superdomain** `Dom::Expression`

**Axioms** `Ax::systemRep`

**Categories** `Cat::BaseCategory`

**Examples** **Example 1**

For brevity, we will use `AE` as a shorthand notation for `Dom::ArithmeticalExpression`:

```
AE := Dom::ArithmeticalExpression
```

```
Dom::ArithmeticalExpression
```

An element of this domain can *not* be created as follows:

# Dom::ArithmeticalExpression

---

```
e := AE(2*sin(x) + f(x)/y)
```

$$2 \sin(x) + \frac{f(x)}{y}$$

Since Dom::ArithmeticalExpression is a façade domain, e is not a domain element, but an expression:

```
domtype(e)
```

```
DOM_EXPR
```

The fact that no error was returned yields the information that e is an arithmetical expression. This can also be checked as follows:

```
testtype(e,AE)
```

```
TRUE
```

In contrast to its super-domain Dom::Expression, this domain only allows elements which are valid arguments for the arithmetical functions, thus the following yields an error:

```
AE([a, b])
```

```
Error: The arguments are invalid. [Dom::ArithmeticalExpression::new
```

## Parameters

**x**

An arithmetical expression

## Entries

|        |                                                     |
|--------|-----------------------------------------------------|
| "key"  | The name of this domain.                            |
| "one"  | The neutral element w.r.t. "_mult": the constant 1. |
| "zero" | The neutral element w.r.t. "_plus": the constant 0. |

## Methods

### Mathematical Methods

#### **divide - Divide arithmetical expressions**

`_divide(f, g)`

This method overloads the function `_divide`.

For details, please see `_divide`.

#### **invert - Invert an arithmetical expression**

`_invert(f)`

This method overloads the function `_invert`.

For details, please see `_invert`.

#### **mult - Multiplie arithmetical expressions**

`_mult(<f, g, >)`

This method overloads the function `_mult`.

For details, please see `_mult`.

#### **negate - Negate an arithmetical expression**

`_negate(f)`

This method overloads the function `_negate`.

For details, please see `_negate`.

#### **plus - Add arithmetical expressions**

`_plus(<f, g, >)`

# Dom::ArithmeticalExpression

---

This method overloads the function `_plus`.

For details, please see `_plus`.

## **`_power` - Power operator**

`_power(f, g)`

This method overloads the function `_power`.

For details, please see `_power`.

## **`_subtract` - Subtract an arithmetical expression**

`_subtract(f, g)`

For details, please see `_subtract`.

## **`D` - Differential operator for functions**

`D(f)`

`D([c1, ...], f)`

This method overloads the function `D`.

For details, please see `D`.

## **`diff` - Differentiate an arithmetical expression**

`diff(f, <x, >)`

This method overloads the function `diff`.

For details, please see `diff`.

## **`equiv` - Test for equivalence**

Inherited from `Cat::BaseCategory`.

## **`intmult` - Multiplie an arithmetical expression with an integer**

`intmult(f, n)`

This method overloads the function `_mult`.

For details, please see `_mult`.

## **`iszero` - Test for zero**

`iszero(f)`

This method overloads the function `iszero`.

For details, please see `iszero`.

## **max - Maximum of numbers**

`max(x, <y, >)`

All numerical arguments must be real.

This method overloads the function `max`.

For details, please see `max`.

## **min - Minimum of numbers**

`min(x, <y, >)`

All numerical arguments must be real.

This method overloads the function `min`.

For details, please see `min`.

## **norm - Norm of an arithmetical expression**

`norm(f)`

This method overloads the function `abs`.

For details, please see `abs`.

## **random - Create random expression**

Inherited from `Dom::Expression`.

### **Access Methods**

#### **subs - Substitution**

Inherited from `Dom::Expression`.

#### **subsex - Extended substitution**

Inherited from `Dom::Expression`.

# Dom::ArithmeticalExpression

---

## Conversion Methods

### **coerce - Coerce into this domain**

Inherited from `Cat::BaseCategory`.

### **convert - Check for being an arithmetical expression**

`convert(x)`

### **convert\_to - Conversion to other domains**

Inherited from `Dom::Expression`.

### **expr - Just return the argument**

Inherited from `Dom::Expression`.

### **float - Convert numbers to floats**

Inherited from `Dom::Expression`.

## Technical Methods

### **allAxioms - Return all axioms**

Inherited from `Dom::BaseDomain`.

### **allCategories - Return all categories**

Inherited from `Dom::BaseDomain`.

### **allEntries - Return the names of all entries**

Inherited from `Dom::BaseDomain`.

### **allSuperDomains - Return all super-domains**

Inherited from `Dom::BaseDomain`.

### **testtype - Test type of object**

Inherited from `Cat::BaseCategory`.

### **undefinedEntries - Return missing entries**

Inherited from `Dom::BaseDomain`.

**whichEntry - Return the domain or category implementing an entry**

Inherited from Dom::BaseDomain.

**getAxioms - Return axioms stated in the constructor**

Inherited from Dom::BaseDomain.

**getCategories - Return categories stated in the constructor**

Inherited from Dom::BaseDomain.

**getSuperDomain - Return super-domain stated in the constructor**

Inherited from Dom::BaseDomain.

**hasProp - Test for a certain property**

Inherited from Dom::BaseDomain.

**info - Print short information about this domain**

Inherited from Dom::BaseDomain.

**new - Create element of this domain**

Inherited from Cat::BaseCategory.

**print - Return expression to print an element**

Inherited from Cat::BaseCategory.

**printMethods - Print out methods**

Inherited from Dom::BaseDomain.

**testtype - Test whether its argument is an expression**

Inherited from Dom::Expression.

**undefinedEntries - Return missing entries**

Inherited from Dom::BaseDomain.

**whichEntry - Return the domain or category implementing an entry**

# Dom::ArithmeticalExpression

---

Inherited from Dom::BaseDomain.

### MuPAD Domains

Dom::Expression

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Root of the domain hierarchy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>Dom::BaseDomain is the root of the domain hierarchy as defined by the Dom package. Every domain of the package inherits from it.</p> <p>The only purpose of Dom::BaseDomain is to supply all domains of the package with some basic methods like "hasProp". Elements of Dom::BaseDomain cannot be created.</p> <p>Unlike other super-domains this domain does not impose any restrictions on the representation of the elements of its sub-domains. Thus it may be a super-domain for any domain created by a domain constructor.</p>                                                                                                                                                                          |
| <b>Categories</b>  | Cat::BaseCategory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Entries</b>     | <p>"create_dom"</p> <p>This domain entry is used to revive the domain when it is read from a binary MCode stream.</p> <p>If this entry is present it is written to the MCode stream instead of the contents of the domain. When the stream is read it is used to create the domain.</p> <p>If this entry does not exist all entries of the domain are written to the stream and read in later to create the domain.</p> <p>Dom::BaseDomain defines "create_dom" to have the same value as the key of the domain, as stored in the entry "key". All domains of the Dom package inherit this entry, thus they must be created by the reader of the MCode stream by evaluating the expression stored in the key.</p> |

## Methods

### Mathematical Methods

#### **equal - Test for mathematical equality**

`equal(x, y)`

If this domain has the axiom `Ax::canonicalRep`, which implies that two domain elements are mathematically equal if and only if they are structurally equal, the kernel function `_equal` is used to decide the equality. In this case `UNKNOWN` is never returned.

If the axiom `Ax::canonicalRep` does not hold the method will return `TRUE` if `x` and `y` are structurally equal (in the sense of the function `_equal`) and `UNKNOWN` otherwise.

### Conversion Methods

#### **convert\_to - Convert element**

`convert_to(x, T)`

The implementation provided here can convert `x` to an element of this domain (the trivial case) or to an element of `Dom::Expression` (by using the method `"expr"`, see `Cat::BaseCategory`).

#### **TeX - Generate TeX output**

`TeX(x)`

The default implementation provided here converts `x` into an expression using the method `"expr"` and then uses the function `generate::TeX` to convert the expression.

### Access Methods

#### **allAxioms - Return all axioms**

`allAxioms()`

#### **allCategories - Return all categories**

`allCategories()`

#### **allEntries - Return the names of all entries**

`allEntries()`

## **allSuperDomains - Return all super-domains**

`allSuperDomains()`

The last, most general, super-domain of all domains of the Dom package is `Dom::BaseDomain`.

## **getAxioms - Return axioms stated in the constructor**

`getAxioms()`

## **getCategories - Return categories stated in the constructor**

`getCategories()`

## **getSuperDomain - Return super-domain stated in the constructor**

`getSuperDomain()`

## **hasProp - Test for a certain property**

`hasProp(d)`

`hasProp(dc)`

`hasProp(a)`

`hasProp(ac)`

`hasProp(c)`

`hasProp(cc)`

`hasProp(dc)` tests if this domain or a super-domain of it was defined by the domain constructor `dc`.

`hasProp(a)` tests if this domain has the axiom `a`.

`hasProp(ac)` tests if an axiom of this domain was defined by the axiom constructor `ac`.

`hasProp(c)` tests if this domain has the category `c`.

`hasProp(cc)` tests if a category of this domain was defined by the category constructor `cc`.

## **info - Print short information about this domain**

```
info()
```

It prints out the super-domains, categories, axioms and entry names of this domain.

If an entry "info\_str", which must be a string, is defined for this domain it is used to print the header line.

## **printMethods - Print out methods**

```
printMethods(<sort>, <Table>)
```

```
printMethods(<sort>, Tree)
```

If no sorting function is given, sort is used as default.

Similar as above, using Tree provides only that the names of the entries are inserted into a tree, an element of the domain `adt::Tree`. The tree is both printed out and returned by the method.

Using neither Table nor Tree the function does the same as `dom::printMethods(sort, Table)`.

## **subs - Avoid substitution**

```
subs(x, ,)
```

Sub-domains should provide a new implementation of this method with sensible semantics if possible.

## **subsex - Avoid extended substitution**

```
subsex(x, ,)
```

Sub-domains should provide a new implementation of this method with sensible semantics if possible.

## **undefinedEntries - Return missing entries**

```
undefinedEntries()
```

An entry is missing if it should have a definition according to a category of the domain, but the definition is not present.

**whichEntry - Return the domain or category implementing an entry**

`whichEntry(e)`

FAIL is returned if no entry with the given name is defined for this domain.

# Dom::Complex

| <b>Purpose</b>     | Field of complex numbers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Syntax</b>      | <code>Dom::Complex(x)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p><code>Dom::Complex</code> is the domain of complex constants represented by expressions of type <code>DOM_INT</code>, <code>DOM_RAT</code>, <code>DOM_FLOAT</code> or <code>DOM_COMPLEX</code>. An expression of type <code>DOM_EXPR</code> is considered a complex number if it is of type <code>Type::Arithmetical</code> and if it contains only indeterminates which are of type <code>Type::ConstantIdents</code> or if it contains no indeterminates, cf. "Example 2" on page 6-79.</p> <p><code>Dom::Complex</code> is of category <code>Cat::Field</code> due to pragmatism. This domain actually is not a field because <code>bool(1.0 = float(3) / float(3))</code> returns <code>FALSE</code>, for example.</p> <p>Elements of <code>Dom::Complex</code> are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted to a number. This means <code>Dom::Complex</code> is a facade domain which creates elements of domain type <code>DOM_INT</code>, <code>DOM_RAT</code>, <code>DOM_FLOAT</code>, <code>DOM_COMPLEX</code> or <code>DOM_EXPR</code>.</p> <p><code>Dom::Complex</code> has no normal representation, because 0 and 0.0 both represent the zero.</p> <p>Viewed as a differential ring, <code>Dom::Complex</code> is trivial. It only contains constants.</p> <p><code>Dom::Complex</code> has the domain <code>Dom::BaseDomain</code> as its super domain, i.e., it inherits each method which is defined by <code>Dom::BaseDomain</code> and not re-implemented by <code>Dom::Complex</code>. Methods described below are re-implemented by <code>Dom::Complex</code>.</p> |
| <b>Superdomain</b> | <code>Dom::ArithmeticalExpression</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Examples

### Example 1

Creating some complex numbers using `Dom::Complex`:

```
Dom::Complex(2/3)
```

$$\frac{2}{3}$$

```
Dom::Complex(2/3 + 4*I)
```

$$\frac{2}{3} + 4i$$

### Example 2

It's also possible to use expressions or constants for creating an element of `Dom::Complex`:

```
Dom::Complex(PI)
```

$$\pi$$

```
Dom::Complex(sin(2))
```

$$\sin(2)$$

```
Dom::Complex(sin(2/3*I) + 3)
```

$$3 + \sinh\left(\frac{2}{3}\right)i$$

If the expression cannot be converted to an element of `Dom::Complex` we will get an error message:

# Dom::Complex

---

`Dom::Complex(sin(x))`

`Error: The arguments are invalid. [Dom::Complex::new]`

## Parameters

**x**

An expression of type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, `DOM_COMPLEX`.  
An expression of type `DOM_EXPR` is also possible if it is of type `Type::Arithmetical` and if it contains only indeterminates which are of type `Type::ConstantIdents` or if it contains no indeterminates.

## Entries

"characteristic"

the characteristic of this field is 0.

"one"

the unit element; it equals 1.

"zero"

The zero element; it equals 0.

## Methods

**Mathematical Methods**

**`_divide` - Divide numbers**

`_divide(x, y)`

**`_invert` - Invert numbers**

`_invert(x)`

**`_mult` - Multiplie numbers**

`_mult(x, y, )`

**`_negate` - Negate numbers**

`_negate(x)`

**`_plus` - Add numbers**

`_plus(x, y, )`

## **\_power - Power operator**

`_power(x, y)`

## **\_unequal - Inequalities**

`_unequal(x, y)`

## **conjugate - Conversion to a basic type**

`conjugate(x)`

## **D - Differential operator**

`D(x)`

## **diff - Differentiates**

`diff(z, <x, >)`

## **equal - Equations**

`equal(x, y)`

## **expr - Conversion to a basic type**

`expr(x)`

## **iszero - Zero test**

`iszero(x)`

## **norm - Absolute value of a number**

`norm(x)`

## **random - Random number generation**

`random()`

`random(n)`

`random(m .. n)`

`random(n)` returns a random number generator which creates complex random numbers where the real parts and the imaginary parts are positive integers between 0 and  $n - 1$ .

# Dom::Complex

---

`random(m..n)` returns a random number generator which creates complex random numbers where the real parts and the imaginary parts are positive integers between  $m$  and  $n$ .

## **unequal - Inequalities**

`unequal(x, y)`

## **Conversion Methods**

### **convert - Conversion into this domain**

`convert(x)`

An arithmetical expression can be converted if it only contains subexpression of the types just mentioned.

If the conversion fails, FAIL is returned.

### **convert\_to - Conversion to other domains**

`convert_to(x, T)`

If the conversion fails, FAIL is returned.

The following domains are allowed for T: DOM\_INT, Dom::Integer, DOM\_RAT, Dom::Rational, DOM\_FLOAT, Dom::Float, Dom::Numerical, DOM\_COMPLEX and DOM\_EXPR.

### **normal - Normal form of objects**

`normal(x)`

## Description

### Domain Creation

`Dom::DenseMatrix(R)` creates domains of matrices over a component domain  $R$  of category `Cat::Rng` (a ring, possibly without unit).

If the optional parameter  $R$  is not given, the domain

`Dom::ExpressionField()` is used.

A vector with  $n$  entries is either an  $n \times 1$  matrix (a column vector), or a  $1 \times n$  matrix (a row vector).

Arithmetical operations with matrices can be performed by using the standard arithmetical operators of MuPAD.

E.g., if  $A$  and  $B$  are two matrices defined by `Dom::DenseMatrix(R)`,  $A + B$  computes the sum, and  $A * B$  computes the product of the two matrices, provided that the dimensions are correct.

## Dom::DenseMatrix

---

Similarly,  $A^{-1}$  or  $1/A$  computes the inverse of a square matrix  $A$  if it exists, and returns FAIL otherwise. See “Example 1” on page 6-87.

Many system functions have been overloaded for matrices, such as `map`, `subs`, `has`, `zip`, `conjugate` to compute the complex conjugate of a matrix, `norm` to compute matrix norms, or `exp` to compute the exponential of a matrix.

Most of the functions in the MuPAD linear algebra package `linalg` work with matrices. For example, to compute the determinant of a square matrix  $A$ , call `linalg::det(A)`. The command `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on  $A$  to transform  $A$  to its reduced row echelon form.

The domain `Dom::DenseMatrix(R)` represents matrices over  $R$  of arbitrary size, and it therefore does not have any algebraic structure (other than being a *set* of matrices).

The domain `Dom::SquareMatrix(n, R)` represents the *ring* of  $n \times n$  matrices over  $R$ . The domain `Dom::MatrixGroup(m, n, R)` represents the *Abelian group* of  $m \times n$  matrices over  $R$ .

We use the following notations for a matrix  $A$  (an element of `Dom::DenseMatrix(R)`):

- $nrows(A)$  denotes the number of rows of  $A$ .
- $ncols(A)$  denotes the number of columns of  $A$ .
- A *row index* is an integer in the range from 1 to  $nrows(A)$ .
- A *column index* is an integer in the range from 1 to  $ncols(A)$ .

---

**Note** The components of a matrix are no longer evaluated after the creation of the matrix, i.e., if they contain free identifiers they will not be replaced by their values.

---

## Element Creation

`Dom::DenseMatrix(R)(Array)` and `Dom::DenseMatrix(R)(Matrix)` create a new matrix with the dimension and the components of `Array` and `Matrix`, respectively.

The components of `Array` or `Matrix` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(List)` creates an  $m \times 1$  column vector with components taken from the nonempty list, where  $m$  is the number of entries of `List`.

`Dom::DenseMatrix(R)(ListOfRows)` creates an  $m \times n$  matrix with components taken from the nested list `ListOfRows`, where  $m$  is the number of inner lists of `ListOfRows`, and  $n$  is the maximal number of elements of an inner list. Each inner list corresponds to a row of the matrix. Both  $m$  and  $n$  must be non-zero.

If an inner list has less than  $n$  entries, then the remaining components in the corresponding row of the matrix are set to zero.

The entries of the inner lists are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::DenseMatrix(R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

The call `Dom::DenseMatrix(R)(m, n)` returns the  $m \times n$  zero matrix.

Use the method "identity" to create the  $n \times n$  identity matrix.

The call `Dom::DenseMatrix(R)(m, n, Array)` creates an  $m \times n$  matrix with components taken from `Array`, which must be an array or an `hfarray`. `Array` must have  $mn$  operands. The first  $m$  operands define the first row, the next  $m$  operands define the second row, etc. The formatting of the array is irrelevant. E.g., any array with 6 elements can be used to create a matrix of dimension  $1 \times 6$ , or  $2 \times 3$ , or  $3 \times 2$ , or  $6 \times 1$ .

# Dom::DenseMatrix

---

The call `Dom::DenseMatrix(R)(m, n, List)` creates an  $m \times n$  matrix with components taken from the list `List` with  $mn$  elements. The first  $m$  elements of the list define the first row, the next  $m$  elements of the list define the second row, etc.

The call `Dom::DenseMatrix(R)(m, n, ListOfRows)` creates an  $m \times n$  matrix with components taken from the list `ListOfRows`.

If  $m \geq 2$  and  $n \geq 2$ , then `ListOfRows` must consist of at most  $m$  inner lists, each having at most  $n$  entries. The inner lists correspond to the rows of the returned matrix.

If an inner list has less than  $n$  entries, then the remaining components of the corresponding row of the matrix are set to zero. If there are less than  $m$  inner lists, then the remaining lower rows of the matrix are filled with zeroes.

`Dom::DenseMatrix(R)(m, n, f)` returns the matrix whose  $(i, j)$ th component is the value of the function call `f(i, j)`. The row index  $i$  ranges from 1 to  $m$  and the column index  $j$  from 1 to  $n$ .

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(1, n, List)` returns the  $1 \times n$  row vector with components taken from `List`. The list `List` must have at most  $n$  entries. If there are fewer entries, then the remaining vector components are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(m, 1, List)` returns the  $m \times 1$  column vector with components taken from `List`. The list `List` must have at most  $m$  entries. If there are fewer entries, then the remaining vector components are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

**Superdomain** `Dom::BaseDomain`

**Axioms** If  $R$  has `Ax::canonicalRep`, then `Ax::canonicalRep`.

**Categories** `Cat::Matrix(R)`

## Examples **Example 1**

First we create the domain of matrices over the field of rational numbers:

```
MatQ := Dom::DenseMatrix(Dom::Rational)
```

```
Dom::DenseMatrix(Dom::Rational)
```

We assigned this domain to the identifier `MatQ`. Next we define the 2 2 matrix

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

by a list of two rows, where each row is a list of two elements:

```
A := MatQ([[1, 5], [2, 3]])
```

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

In the same way we define the following 2 3 matrix:

```
B := MatQ([[-1, 5/2, 3], [1/3, 0, 2/5]])
```

$$\begin{pmatrix} -1 & \frac{5}{2} & 3 \\ \frac{1}{3} & 0 & \frac{2}{5} \end{pmatrix}$$

## Dom::DenseMatrix

---

and perform matrix arithmetic using the standard arithmetical operators of MuPAD, e.g., the matrix product  $AB$ , the 4th power of  $A$  as well as the scalar multiplication of  $A$  times  $\frac{1}{3}$ :

`A * B, A ^ 4, 1/3 * A`

$$\begin{pmatrix} \frac{2}{3} & \frac{5}{2} & 5 \\ -1 & 5 & \frac{36}{5} \end{pmatrix}, \begin{pmatrix} 281 & 600 \\ 240 & 521 \end{pmatrix}, \begin{pmatrix} \frac{1}{3} & \frac{5}{3} \\ \frac{2}{3} & 1 \end{pmatrix}$$

The matrices  $A$  and  $B$  have different dimensions, and therefore the sum of  $A$  and  $B$  is not defined. MuPAD issues an error message:

`A + B`

`Error: The dimensions do not match. [(Dom::DenseMatrix(Dom::Rational`

To compute the inverse of  $A$ , just enter:

`1/A`

$$\begin{pmatrix} -\frac{3}{7} & \frac{5}{7} \\ \frac{2}{7} & -\frac{1}{7} \end{pmatrix}$$

If a matrix is not invertible, `FAIL` is the result of this operation. For example, the matrix:

`C := densematrix(2, 2, [[2]])`

$$\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

is not invertible, hence:

```
C^(-1)
```

```
FAIL
```

## Example 2

We create the domain of matrices over the reals:

```
MatR := Dom::DenseMatrix(Dom::Real)
```

```
Dom::DenseMatrix(Dom::Real)
```

Beside standard matrix arithmetic, the library `linalg` offers a lot of functions dealing with matrices. For example, if one wants to compute the rank of a matrix, use `linalg::rank`:

```
A := MatR([[1, 2], [2, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$$

```
linalg::rank(A)
```

```
1
```

Use `linalg::eigenvectors` to compute eigenvalues and eigenvectors of the matrix  $A$ :

```
linalg::eigenvectors(A)
```

$$\left[ \left[ 0, 1, \begin{pmatrix} -2 \\ 1 \end{pmatrix} \right], \left[ 5, 1, \begin{pmatrix} \frac{1}{2} \\ 1 \end{pmatrix} \right] \right]$$

Try `info(linalg)` for a list of available functions, or enter `help(linalg)` for details about the library `linalg`.

Some of the functions in the `linalg` package simply serve as “interface” functions for methods of a matrix domain described above. For example, `linalg::transpose` uses the method “transpose” to get the transposed matrix. The function `linalg::gaussElim` applies Gaussian elimination to a matrix, such as:

```
linalg::gaussElim(A)
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

The computation is performed by the method “gaussElim” as described above. Such functions of the `linalg` packages, in contrast to the corresponding methods of the domain `Dom::DenseMatrix(R)`, check their incoming parameters, and some of them offer extended functionalities.

### Example 3

In this example, we use the default matrix domain which is created by `Dom::DenseMatrix()`. This domain represents matrices whose components can be arbitrary arithmetical expressions (i.e., the component ring is the domain `Dom::ExpressionField()`).

This domain is already known to MuPAD by the name `matrix`:

```
A := densematrix(
 [[1, 2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]]
```

```
)

(1 2 3 4
 2 0 4 1
-1 0 5 2)
```

```
domtype(A)
```

```
Dom::DenseMatrix()
```

Matrix components can be extracted by the index operator []:

```
A[2, 1] * A[1, 2] - A[3, 1] * A[1, 3]
```

```
7
```

If one of the indices is not in its valid range, an error message is issued. Assignments to matrix components are performed similarly:

```
delete a:
A[1, 2] := a^2: A
```

```
(1 a^2 3 4
 2 0 4 1
-1 0 5 2)
```

Beside the usual indexing of matrix components, it is also possible to extract submatrices from a given matrix. The following call creates the submatrix of  $A$  which consists of the rows 2 to 3 and columns 1 to 3 of  $A$ :

```
A[2..3, 1..3]
```

## Dom::DenseMatrix

---

$$\begin{pmatrix} 2 & 0 & 4 \\ -1 & 0 & 5 \end{pmatrix}$$

The index operator does not allow to insert submatrices into a given matrix. This is implemented by the function `linalg::substitute`.

### Example 4

In the following examples, we demonstrate the different ways of creating matrices. We work with matrices defined over the field  $\mathbb{F}_{19}$ , i.e., the field of integers modulo 19. This component ring can be created with the domain constructor `Dom::IntegerMod`.

We start by giving a list of rows, where each row is a list of row entries:

```
MatZ19 := Dom::DenseMatrix(Dom::IntegerMod(19)):
MatZ19([[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

The elements of the two inner lists, the row entries, were converted into elements of the domain `Dom::IntegerMod(19)`.

The number of rows is the number of sublists of the argument, i.e.,  $m = 2$ . The number of columns is determined by the length of the inner list with the most entries, which is the first inner list with two entries. Missing entries in the other inner lists are treated as zero components. The call:

```
MatZ19(4, 4, [[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

fixes the dimension of the matrix. Missing entries and inner lists are treated as zero components and zero rows, respectively.

An error message is issued if one of the given entries cannot be converted into an element over  $_{19}$ :

```
MatZ19([[2, 3], [-1, I]])
```

```
Error: Cannot define a matrix over 'Dom::IntegerMod(19)'. [(Dom:
```

### Example 5

This example illustrates how to create a matrix with components given as values of an index function. First we create the 2 2 Hilbert matrix (see also the functions `linalg::hilbert` and `linalg::invhilbert`):

```
densematrix(2, 2, (i, j) -> 1/(i + j - 1))
```

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

Note the difference when working with expressions and functions. If you give an expression it is treated as a function in the row and column indices:

```
delete x:
densematrix(2, 2, x), densematrix(2, 2, (i, j) -> x)
```

# Dom::DenseMatrix

---

$$\begin{pmatrix} x(1, 1) & x(1, 2) \\ x(2, 1) & x(2, 2) \end{pmatrix}, \begin{pmatrix} X & X \\ X & X \end{pmatrix}$$

## Example 6

Diagonal matrices can be created with the option `Diagonal` and a list of diagonal components:

```
MatC := Dom::DenseMatrix(Dom::Complex):
MatC(3, 4, [1, 2, 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

Hence, to define the  $n \ n$  identity matrix, you can enter:

```
MatC(3, 3, [1 $ 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

or even call:

```
MatC(3, 3, x -> 1, Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The easiest way to create the identity matrix, however, is to use the method `"identity"`:

```
MatC::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

### Example 7

Toeplitz matrices can be defined with the option Banded. The following call defines a three-banded matrix with the component 2 on the main diagonal and the component - 1 on the first subdiagonals:

```
densematrix(4, 4, [-1, 2, -1], Banded)
```

$$\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

### Example 8

Some system functions can be applied to matrices, such as norm, expand, diff, conjugate, or exp.

For example, to expand the components of the matrix:

```
delete a, b:
A := densematrix(
 [[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a - b)*(a + b)]]
)
```

$$\begin{pmatrix} (a - b)^2 & a^2 + b^2 \\ a^2 + b^2 & (a + b)(a - b) \end{pmatrix}$$

# Dom::DenseMatrix

---

enter:

```
expand(A)
```

$$\begin{pmatrix} a^2 - 2 a b + b^2 & a^2 + b^2 \\ a^2 + b^2 & a^2 - b^2 \end{pmatrix}$$

If you want to differentiate the matrix components, then call for example:

```
diff(A, a)
```

$$\begin{pmatrix} 2 a - 2 b & 2 a \\ 2 a & 2 a \end{pmatrix}$$

To substitute matrix components by some values, enter:

```
subs(A, a = 1, b = -1)
```

$$\begin{pmatrix} 4 & 2 \\ 2 & 0 \end{pmatrix}$$

The function `zip` can also be applied to matrices. The following call combines two matrices  $A$  and  $B$  by dividing each component of  $A$  by the corresponding component of  $B$ :

```
A := densematrix([[4, 2], [9, 3]]):
B := densematrix([[2, 1], [3, -1]]):
zip(A, B, `/`)
```

$$\begin{pmatrix} 2 & 2 \\ 3 & -3 \end{pmatrix}$$

The quoted character `` is another notation for the function `_divide`, the functional form of the division operator `/`.

If one needs to apply a function to the components of a matrix, then use the function `map`. For example, to simplify the components of the matrix:

```
C := densematrix(
 [[sin(x)^2 + cos(x)^2, cos(x)*tan(x)],
 [(a^2 - b^2)/(a + b), 1]]
)
```

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & \cos(x) \tan(x) \\ \frac{a^2 - b^2}{a + b} & 1 \end{pmatrix}$$

call:

```
map(C, Simplify)
```

$$\begin{pmatrix} 1 & \sin(x) \\ a - b & 1 \end{pmatrix}$$

### Example 9

However, there may appear some unexpected results using the function `diff` in the context of matrices. The derivative of the following unspecified function `f` of a matrix is computed due to the chain rule:

```
diff(f(densematrix([[a*x^2, b], [c, d]])), x)
```

## Dom::DenseMatrix

---

$$\begin{pmatrix} 2 a x f' \left( \begin{pmatrix} a x^2 & b \\ c & d \end{pmatrix} \right) & 0 \\ 0 & 0 \end{pmatrix}$$

Usually, the function  $f$  would implicitly be assumed to be scalar. Hence, the derivative of  $f$  should be scalar as well. In the above situation the chain rule is applied for differentiation: the inner function is the matrix containing the symbolic components  $a \cdot x^2$ ,  $b$ ,  $c$  and  $d$ . Its derivative is computed by simply applying `diff` to each component of the matrix:

```
diff(densematrix([[a*x^2, b], [c, d]]), x)
```

$$\begin{pmatrix} 2 a x & 0 \\ 0 & 0 \end{pmatrix}$$

Finally, the exterior unspecified function  $f$  is implicitly assumed to be scalar, such that each component of the derivative of the inner function is multiplied by the exterior differentiation.

### Example 10

A column vector is represented as a 2 1 matrix:

```
MatR := Dom::DenseMatrix(Dom::Real):
v := MatR(2, 1, [1, 2])
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

The dimension of this vector is:

```
MatR::matdim(v)
```

[2, 1]

Use `linalg::vecdim`, or even call `nops(v)` to get the length of a vector:

```
linalg::vecdim(v)
```

2

The  $i$ th component of this vector can be extracted in two ways: either by `v[i, 1]` or by `v[i]`:

```
v[1], v[2]
```

1, 2

We get the 2-norm of  $v$  by the following call:

```
norm(v, 2)
```

$\sqrt{5}$

## Parameters

**R**

A ring, i.e., a domain of category `Cat::Rng`; default is `Dom::ExpressionField()`

**Array**

A one- or two-dimensional array or `hfarray`

**Matrix**

A matrix, i.e., an element of a domain of category `Cat::Matrix`

**m, n**

# Dom::DenseMatrix

---

Matrix dimension (positive integers)

## List

A list of matrix components

## ListOfRows

A list of at most  $m$  rows; each row given as a list of at most  $n$  matrix components

## f

A function or a functional expression with two parameters (the row and column index)

## g

A function or a functional expression with one parameter (the row index)

## Options

### Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function or a functional expression.

`Dom::DenseMatrix(R)(m, n, List, Diagonal)` creates the  $m \times n$  diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most  $\min(m, n)$  entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(m, n, g, Diagonal)` returns the matrix whose  $i$ th diagonal element is  $g(i, i)$ , where the index  $i$  runs from 1 to  $\min(m, n)$ .

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

## Banded

Create a banded Toeplitz matrix

`Dom::DenseMatrix(R)(m, n, List, Banded)` creates an  $m \times n$  banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say  $2h + 1$ , and must not exceed  $n$ . The resulting matrix has bandwidth at most  $2h + 1$ .

A Toeplitz matrix is a matrix where the elements of each band are identical. See also “Example 7” on page 6-95.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the  $i$ th subdiagonal are initialized with the  $(h + 1 - i)$ th element of `List`. All elements of the  $i$ th superdiagonal are initialized with the  $(h + 1 + i)$ th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

## Entries

"isSparse"

is always FALSE, as elements of `Dom::DenseMatrix(R)` use a dense representation of their matrix components.

"randomDimen"

is set to [10,10]. See the method "random" below for details.

## Methods

Mathematical Methods

**`_divide` - Divide matrices**

`_divide(A, B)`

An error message is issued if the dimensions of `A` and `B` do not match.

This method only exists if  $R$  is a commutative ring with a unit, i.e., a domain of category `Cat::Ring`.

This method overloads the function `_divide` for matrices, i.e., one may use it in the form  $A / B$ , or in functional notation: `_divide(A, B)`.

## **`_invert` - Compute the inverse of a matrix**

```
_invert(A, Normal = b)
```

If the component ring  $R$  is the domain `Dom::Float`, a floating-point approximation of the inverse matrix is computed by the function `numeric::inverse`.

This method only exists if  $R$  is a domain of category `Cat::Ring`.

This method overloads the function `_invert` for matrices, i.e., one may use it in the form  $1/A$  or  $A^{-1}$ , or in functional notation: `_invert(A)`.

If `Normal = TRUE`, then the matrix inverse is always returned in a normalized form. For details about normalization, see `normal`. If `Normal = FALSE`, then the matrix inverse can appear in a normalized form, but normalization is not guaranteed. By default `Normal = TRUE`.

`Normal` affects the results only if a matrix contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

## **`_mod` - Map the modulo operator to a matrix**

```
_mod(A, n)
```

$n$  must be non-zero, and `a mod n` must be defined for every entry  $a$  of  $A$ .

This method overloads the function `mod` for matrices; one may use it in the form  $A \bmod n$ , or in functional notation: `_mod(A, n)`.

## **`_mult` - Multiply matrices by matrices, vectors and scalars**

```
_mult(x, y)
```

`_mult(x, y)`

If `y` is of the domain type `R` or can be converted into such an element, the corresponding scalar multiplication is computed.

Otherwise, `y` is converted into a matrix of the domain type of `x`. If this conversion fails, then this method calls the method "`_mult`" of the domain of `y` giving all arguments in the same order.

If `x` is a matrix of the same domain type as `y`, then the matrix product `xy` is computed. An error message is issued if the dimensions of the matrices do not match.

If `x` is of the domain type `R` or can be converted into such an element, the corresponding scalar multiplication is computed.

Otherwise, `x` is converted into a matrix of the domain type of `y`. If this conversion fails, then `FAIL` is returned.

This method handles more than two arguments by calling itself recursively with the first half of all arguments and the last half of all arguments. Then the product of these two results is computed with the system function `_mult`.

This method overloads the function `_mult` for matrices, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.

## **`_negate` - Negate a matrix**

`_negate(A)`

This method overloads the function `_negate` for matrices, i.e., one may use it in the form `-A`, or in functional notation: `_negate(A)`.

## **`_plus` - Add matrices**

`_plus(A, B, ...)`

The arguments `A, B, ...` are converted into matrices of the domain type `Dom::DenseMatrix(R)`. `FAIL` is returned if one of these conversions fails.

This method overloads the function `_plus` for matrices, i.e., one may use it in the form `A + B`, or in functional notation: `_plus(A, B)`.

## **`_power` - Integer power of a matrix**

`_power(A, n)`

If the power `n` is a negative integer then `A` must be nonsingular and `R` must be a domain of category `Cat::IntegralDomain`. Otherwise `FAIL` is returned.

If `n` is zero and the component ring `R` is a ring with no unit (i.e., of category `Cat::Rng`, but not of category `Cat::Ring`), `FAIL` is returned.

This method overloads the function `_power` for matrices, i.e., one may use it in the form `A^n`, or in functional notation: `_power(A, n)`.

## **`conjugate` - Complex conjugate of a matrix**

`conjugate(A)`

This method only exists if `R` implements the method "conjugate", which computes the complex conjugate of an element of the domain `R`.

This method overloads the function `conjugate` for matrices, i.e., one may use it in the form `conjugate(A)`.

## **`cos` - Cosine of a matrix**

`cos(A)`

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `cos(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of `A` if `A` is defined over the domain `Dom::Float`.

If some eigenvalues of  $A$  do not exist in  $R$  or cannot be computed, then FAIL is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of  $A$ . In this case FAIL is returned.

This method only exists if  $R$  is a domain of category `Cat::Field`.

This method overloads the function `cos` for matrices, i.e., one may use it in the form `cos(A)`.

## **diff - Differentiation of matrix components**

```
diff(A,)
```

This method only exists if  $R$  implements the method "diff".

This method overloads the function `diff` for matrices, i.e., one may use it in the form `diff(A, ...)`. See "Example 8" on page 6-95 and "Example 9" on page 6-97.

## **equal - Equality test of matrices**

```
equal(A, B)
```

Note that if  $R$  has the axiom `Ax::systemRep` then `normal` is used to simplify the components of  $A$  and  $B$  before testing their equality.

## **exp - Exponential of a matrix**

```
exp(A, <t>)
```

If  $A$  is not square, an error message is issued. If the component domain of  $A$  does not allow the computation of `exp(elem)` for an arbitrary element `elem` of the component ring, FAIL is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of  $A$  if  $A$  is defined over the domain `Dom::Float` and if  $t = 1$ .

If some eigenvalues of  $A$  do not exist in  $R$  or cannot be computed, then FAIL is returned.

In the symbolic case the function `linalg::jordanForm` is called, which may not be able to compute the Jordan form of  $A$ . In this case `FAIL` is returned.

This method only exists if  $R$  is a domain of category `Cat::Field`.

This method overloads the function `exp` for matrices, i.e., one may use it in the form `exp(A, ...)`.

## **expand - Expand matrix components**

`expand(A)`

This method only exists if  $R$  implements the method "`expand`", or if  $R$  has the axiom `Ax::systemRep` (in this case, the system function `expand` is used).

This method overloads the function `expand` for matrices, i.e., one may use it in the form `expand(A)`.

## **factor - Scalar-matrix factorization**

`factor(A)`

The factor  $s$  is the gcd of all components of the matrix  $A$ . Hence, this method only exists if  $R$  is of category `Cat::GcdDomain`.

This method overloads the function `factor` for matrices, i.e., one may use it in the form `factor(A)`.

## **float - Floating-point approximation of the matrix components**

`float(A)`

This method only exists if  $R$  implements the method "`float`".

---

**Note** Usually the floating-point approximations are not elements of  $R$ ! For example, `Dom::Integer` implements such a method, but the floating-point approximation of an integer cannot be re-converted into an integer.

This method checks whether the resulting matrix can be converted into the domain type of  $A$  only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

Otherwise, one has to take care that the matrix returned is compatible to its component ring.

---

## **gaussElim - Gaussian elimination**

`gaussElim(A)`

If the matrix is not square, i.e., the determinant of  $A$  is not defined, then the third entry of the list returned is the value `FAIL`.

This method only exists if the component ring  $R$  is an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If  $R$  has the method `"pivotSize"`, then the pivot element of smallest size is chosen at every pivoting step, whereby `pivotSize` must return a positive integer representing the “size” of an element.

If no such method is defined, Gaussian elimination without a pivot strategy is applied to  $A$ .

If  $R$  has the axiom `Ax::efficientOperation("_invert")` and is of category `Cat::Field`, then ordinary Gaussian elimination is used. Otherwise, fraction-free elimination is performed on  $A$ .

If  $R$  implements the method `"normal"`, it is used to simplify subsequent computations of the Gaussian elimination process.

Note that if  $R$  does not implement the method `"normal"`, but the elements of  $R$  are represented by kernel domains, i.e.,  $R$  has

the axiom `Ax::systemRep`, the system function `normal` is used instead.

## **identity - Identity matrix**

`identity(n)`

This method only exists if the component ring `R` is of category `Cat::Ring`, i.e., a ring with unit.

## **int - Integration of matrix components**

`int(A, )`

This method only exists if `R` implements the method "int".

This method overloads the system function `int` for matrices, i.e., one may use it in the form `int(A, ...)`.

## **iszero - Test for zero matrices**

`iszero(A)`

Note that there may exist more than one representation of the zero matrix of a given dimension if `R` does not have `Ax::canonicalRep`.

If `R` implements the method "normal", it is used to simplify the components of `A` for the zero-test.

Note that if `R` does not implement such a method, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom `Ax::systemRep`, the system function `normal` is used instead.

This method overloads the function `iszero` for matrices, i.e., one may use it in the form `iszero(A)`.

## **matdim - Matrix dimension**

`matdim(A)`

## **norm - Norm of matrices and vectors**

`norm(A, Infinity)`

`norm(A, Maximum)`

`norm(v, Infinity)`

`norm(v, Maximum)`

`norm(A, Frobenius)`

`norm(A, 1)`

`norm(v, Euclidean)`

`norm(v, k)`

`norm(A, Maximum)` computes the maximum norm of the matrix  $A$ , which is the maximum row sum (the row sum is the sum of norms of each component in a row).

If the domain  $R$  does not implement the methods "max" and "norm", FAIL is returned.

Using `norm(v, Infinity)` for a vector  $v$  the maximum norm of all elements is returned.

If the domain  $R$  does not implement the methods "max" and "norm", FAIL is returned.

Using `norm(v, Maximum)` for a vector  $v$  the maximum norm of all elements is returned.

If the domain  $R$  does not implement the methods "max" and "norm", FAIL is returned.

`norm(A, Frobenius)` computes the Frobenius norm of  $A$ , which is the square root of the sum of the squares of the norms of each component.

If the result is no longer an element of the domain  $R$ , or if  $R$  does not implement the method "norm", FAIL is returned.

`norm(A, 1)` computes the 1-norm of the matrix  $A$ , which is the maximum sum of the norms of the elements of each column. If  $R$  does not implement the methods "max" and "norm", FAIL is returned.

`norm(v, Euclidean)` computes the Euclidean norm (2-norm) of the vector `v`, which is defined to be the square root of the sum of the norms of the elements of `v` raised to the square.

FAIL is returned if the result is no longer an element of the domain `R`. The function `linalg::scalarProduct` is used to compute the Euclidean norm of the vector `v`.

If `R` does not implement the method "norm", FAIL is returned.

`norm(v, k)` computes the  $k$ -norm of the vector `v`, which is defined to be the  $k$ th root of the sum of the norms of the elements of `v` raised to the  $k$ th power.

FAIL is returned if the result is no longer an element of the domain `R`. For  $k = 2$ , the function `linalg::scalarProduct` is used to compute the 2-norm of `v`.

If `R` does not implement the method "norm", FAIL is returned.

The method `norm` overloads the function `norm` for matrices, i.e., one may use it in the form `norm(A k)`, where `k` is either `Infinity`, `Frobenius`, or a positive integer. The default value of `k` is `Infinity`.

## **normal - Simplification of matrix components**

`normal(A)`

If `R` does not implement the method "normal", but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom `Ax::systemRep`, then the system function `normal` is applied to the components of `A`. Otherwise `normal(A)` returns `A` without any changes.

This method overloads the function `normal` for matrices, i.e., one may use it in the form `normal(A)`.

## **nonZeros - Number of non-zero components of a matrix**

`nonZeros(A)`

## **nonZeroes - Number of non-zero components of a matrix**

`nonZeroes(A)`

## **nonZeroOperands - Return a sequence of all non-zero operands**

`nonZeroOperands(A)`

This method is useful for retrieving information on the non-zero entries. For example, to find out the types of the entries in the matrix, one should not consider all operands `op(A)`, because this would also involve the zero entries. For large matrices with few entries, it is much more efficient to use this method to extract the entries.

## **random - Random matrix generation**

`random()`

This method only exists if `R` implements the method "random".

The dimension of the matrix is also chosen randomly, but it is limited by the values given in "randomDimen" (see "Entries" above).

To change the value of the entry "randomDimen" for a domain `MatR` created with `Dom::DenseMatrix`, one must first unprotect the domain `Dom` (see `unprotect` for details).

## **sin - Sine of a matrix**

`sin(A)`

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `sin(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of `A` if `A` is defined over the domain `Dom::Float`.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then `FAIL` is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of  $A$ . In this case `FAIL` is returned.

This method only exists if  $R$  is a domain of category `Cat::Field`.

This method overloads the function `sin` for matrices, i.e., one may use it in the form `sin(A)`.

## **sqrt - Square root of a matrix**

`sqrt(A, <sqrtfunc>)`

Returned is a matrix  $B$  with  $B^2 = A$  such that the eigenvalues of  $B$  are the square roots of the eigenvalues of  $A$  or `FAIL` if the square root of the matrix does not exist. For computing the square roots of the eigenvalues a function satisfying  $\text{sqrtfunc}(a)^2 = a$  for every element  $a$  of the coefficient ring of  $A$  can be given as optional second argument.

For details we refer to the help page of the function `linalg::sqrtMatrix`.

## **testeq - Testing for equality of two matrices**

`testeq(A, B)`

## **tr - Trace of a square matrix**

`tr(A)`

If  $A$  is not square, then an error message is issued.

## **transpose - Transpose of a matrix**

`transpose(A)`

## **Access Methods**

### **concat - Horizontal concatenation of matrices**

`_concat(A, B, )`

An error message is issued if the given matrices do not have the same number of rows.

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

## **`_index` - Matrix indexing**

```
_index(A, i, j)
_index(A, r1 .. r2, c1 .. c2)
_index(v, i)
_index(v, i1 .. i2)
```

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

---

**Note** Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

---

`_index(A, r1..r2, c1..c2)` returns the submatrix of `A` created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

`_index(v, i)` returns the  $i$ th entry of the vector `v`.

An error message is issued if `v` is not a vector.

If `i` is not an integer, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` is less than one or greater than the dimension of `v`.

---

**Note** Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

---

`_index(v, i1..i2)` returns the subvector of `v`, formed by the entries with index `i1` to `i2`. See also the method "op".

An error message is issued if `v` is not a vector.

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `v[i]` and `v[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

## **concatMatrix - Horizontal concatenation of matrices**

```
concatMatrix(A, B,)
```

## **col - Extracting a column**

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

## **delCol - Deleting a column**

```
delCol(A, c)
```

NIL is returned if `A` consists of only one column.

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

## **delRow - Deleting a row**

```
delRow(A, r)
```

NIL is returned if `A` consists of only one row.

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

## **evalp - Evaluating matrices of polynomials at a certain point**

`evalp(A, x = a, )`

This method is only defined if R is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

## **length - Length of a matrix**

`length(A)`

This method overloads the function `length` for matrices, i.e., one may use it in the form `length(A)`.

## **map - Apply a function to matrix components**

`map(A, func, <expr, >)`

---

**Note** Note that the function values are converted into elements of the domain R only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then one must guarantee that the function calls return elements of the domain type R, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain R!

---

This method overloads the function `map` for matrices, i.e., one may use it in the form `map(A, func, ...)`.

## **mapNonZeroes - Apply a function to the non-zero components of a matrix**

`mapNonZeroes(A, f, <p1, p2, >)`

## **nops - Number of components of a matrix**

`nops(A)`

This method overloads the function `nops` for matrices, i.e., one may use it in the form `nops(A)`.

## **op - Component of a matrix**

`op(A, i)`

`op(A)`

This method returns an expression sequence of all components of `A`.

See also the method "`_index`".

This method overloads the function `op` for matrices, i.e., one may use it in the form `op(A, i)` and `op(A)`, respectively.

## **row - Extracting a row**

`row(A, r)`

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

## **setCol - Replacing a column**

`setCol(A, c, v)`

An error message is issued if `c` is less than one or greater than the number of rows of `A`.

## **setRow - Replacing a row**

`setRow(A, r, v)`

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

## **stackMatrix - Vertical concatenation of matrices**

`stackMatrix(A, B, )`

An error message is issued if the given matrices do not have the same number of columns.

## **subs - Substitution of matrix components**

`subs(A, )`

---

**Note** Note that the function values are converted into elements of the domain  $R$  only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then one must guarantee that the function calls return elements of the domain type  $R$ , otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain  $R$ !

---

This method overloads the function `subs` for matrices, i.e., one may use it in the form `subs(A, ...)`.

### **subsex - Extended substitution of matrix components**

`subsex(A, )`

---

**Note** Note that the results of the substitutions are converted into elements of the domain  $R$  only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then one must guarantee that the results of the substitutions are of the domain type  $R$ , otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain  $R$ !

---

This method overloads the function `subsex` for matrices, i.e., one may use it in the form `subsex(A, ...)`.

### **subsop - Operand substitution of matrix components**

`subsop(A, i = x, )`

---

**Note** Note that  $x$  is converted into the domain  $R$  only if `testargs` returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns FALSE, then  $x$  must be an element of  $R$ , otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain  $R$ !

---

See also the method "set\_index".

This method overloads the function `subsop` for matrices, i.e., one may use it in the form `subsop(A, ...)`.

## **swapCol - Swapping matrix columns**

```
swapCol(A, c1, c2)
```

```
swapCol(A, c1, c2, r1 .. r2)
```

An error message is issued if one of the column indices is less than one or greater than the number of columns of  $A$ .

`swapCol(A, c1, c2, r1 .. r2)` swaps the column with index  $c1$  and the column with index  $c2$  of  $A$ , but by taking only those column components which lie in the rows with indices  $r1$  to  $r2$ .

An error message is issued if one of the column indices is less than one or greater than the number of columns of  $A$ , or if one of the row indices is less than one or greater than the number of rows of  $A$ .

## **swapRow - Swapping matrix rows**

```
swapRow(A, r1, r2)
```

```
swapRow(A, r1, r2, c1 .. c2)
```

An error message is issued if one of the row indices is less than one or greater than the number of rows of  $A$ .

`swapCol(A, r1, r2, c1..c2)` swaps the row with index `r1` and the row with index `r2` of `A`, but by taking only those row components which lie in the columns with indices `c1` to `c2`.

An error message is issued if one of the row indices is less than one or greater than the number of rows of `A`, or if one of the column indices is less than one or greater than the number of columns of `A`.

## **set\_index - Setting matrix components**

```
set_index(A, i, j, x)
```

```
set_index(v, i, x)
```

---

**Note** Note that `x` is converted into an element of the domain `R` only if `testargs` returns `TRUE` and `i` and `j` are integers (e.g., if one calls this method from the interactive level of MuPAD). If `x` is a matrix of the same type as `A` or can be converted into a matrix of the same type as `A` and the indices `i` or `j` are ranges corresponding to a submatrix of `A`, then `x` replaces the corresponding submatrix in `A`.

Otherwise one has to take care that `x` is of domain type `R`.

---

See also the method "subsop".

`set_index(v, i, x)` replaces the  $i$ th entry of the vector `v` by `x`.

`set_index` on vectors overloads the function `set_index` for matrices, i.e., one may use it in the form `A[i, j] := x` and `v[i] := x`, respectively, or in functional notation: `A := set_index(A, i, j, x)` or `v := set_index(v, i, x)`.

## **zip - Combine matrices component-wise**

```
zip(A, B, func, <expr, >)
```

The row number of the matrix returned is the minimum of the row numbers of A and B, and its column number is the minimum of the column numbers of A and B.

---

**Note** Note that the function values are converted into elements of the domain R only if `testargs` returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns FALSE, then one must guarantee that the function calls return elements of the domain type R, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain R!

---

This method overloads the function `zip` for matrices, i.e., one may use it in the form `zip(A, B, ...)`.

## Conversion Methods

### **convert - Conversion to a matrix**

`convert(x)`

FAIL is returned if the conversion fails.

x may either be an array, a matrix, or a list (of sublists, see the parameter `ListOfRows` in “Creating Elements” above). Their entries must then be convertible into elements of the domain R.

### **convert\_to - Matrix conversion**

`convert_to(A, T)`

T may either be `DOM_ARRAY`, `DOM_LIST`, or a domain constructed by `Dom::DenseMatrix` or `Dom::SquareMatrix`. The elements of A must be convertible into elements of the domain R.

Use the function `expr` to convert A into an object of a kernel domain (see below).

## **create - Defining matrices without component conversions**

```
create(x,)
```

This method works more efficient than if one creates matrices by calling the method "new" of the domain, because it avoids any conversion of the components. One must guarantee that the components have the correct domain type, otherwise run-time errors can be caused.

If  $x$  is a list of sublists, it might be a good idea first to create a two-dimensional array from that list before calling this method. This is due to the fact that creating a matrix from an array is the fastest way one can achieve.

Please note that when creating a two-dimensional array from a list of sublists, the sublists must have the same number of elements.

## **expr - Matrix conversion into an object of a kernel domain**

```
expr(A)
```

The result is an array representing the matrix  $A$  where each entry is an object of a kernel domain.

This method overloads the function `expr` for matrices, i.e., one may use it in the form `expr(A)`.

## **expr2text - Matrix conversion to a string**

```
expr2text(A)
```

This method overloads the function `expr2text` for matrices, i.e., one may use it in the form `expr2text(A)`.

## **TeX - TeX formatting of a matrix**

```
TeX(A)
```

Note that in the case of very large matrices the output will not be useful. For printing large matrices use the function "doprint".

The method "TeX" of the component ring  $R$  is used to get the TeX-representation of each component of  $A$ .

This method is used by the function `generate::TeX`.

## Technical Methods

### **assignElements - Multiple assignment to matrices**

```
assignElements(A, ...)
```

The assigned components must have the domain type  $R$ , an implicit conversion of the components into elements of domain type  $R$  is not performed.

This method overloads the function `assignElements` for matrices, i.e., one may use it in the form `assignElements(A, ...)`.

### **mkDense - Conversion of a matrix to an array**

```
mkDense(Array)
```

```
mkDense(List)
```

```
mkDense(r, c, List)
```

`mkDense(List)` tries to convert the list `List` into an array `a`. The result is either `FAIL` if this is not possible, or the list `[r, c, a]`, where the positive integers `r` and `c` give the dimension of `a`. See the parameters `List` and `ListOfRows` in “Creating Elements” above for admissible formats of `List`.

The array `a` has dimension one if `r` or `c` is equal to one. The entries of `a` have been converted into elements of the domain  $R$ .

`mkDense(r,c,List)` tries to convert the list `List` into an array `a` of the dimension `r` times `c`.

The result is either `FAIL` if this is not possible, or the list `[r, c, a]`.

The array `a` has dimension one if `r` or `c` is equal to one. The entries of `a` have been converted into elements of the domain  $R$ .

### **print - Printing matrices**

```
print(A)
```

---

**Note** Note that in general it is not useful to print very large matrices. Hence, a warning message is displayed if the size of the matrix oversteps a certain dimension – printing such matrices can be done by using the function "doprint".

---

## **doprint - Printing very large matrices**

```
doprint(A)
```

## **unapply - Create a procedure from a matrix**

```
unapply(A, <x, >)
```

This method overloads the function `fp::unapply` for matrices, i.e., one may use it in the form `fp::unapply(A)`.

## **See Also**

## **MuPAD Domains**

`Dom::Matrix` | `Dom::MatrixGroup` | `Dom::SquareMatrix`

# Dom::DihedralGroup

---

**Purpose** Dihedral groups

**Syntax** **Domain Creation**  
Dom::DihedralGroup(n)

**Element Creation**  
Dom::DihedralGroupn(1)

**Description** **Domain Creation**

Dom::DihedralGroup(n) creates the dihedral group of size  $n$ , i.e., the group of symmetries of a regular polygon with  $n$  edges.

Dom::DihedralGroup(n) creates the group of all congruent mappings of the plane that induce a bijective mapping of the set of corners of a regular  $n$ -angle to itself.

**Element Creation**

Dom::DihedralGroup(n)([a,b]) represents the group element " $t^a$  carried out after  $r^b$ ", where  $r$  is a rotation that maps each corner to its left neighbor, and  $t$  is a reflection w.r.t. some fixed central diagonal.

**Superdomain** Dom::BaseDomain

**Axioms** Ax::canonicalRep

**Categories** Cat::Group

**Examples** **Example 1**

Define the group  $D_6$ , i.e., the group of congruence mappings of the hexagon:

```
G := Dom::DihedralGroup(6)
```

```
Dom::DihedralGroup(6)
```

Then elements may be created as follows:

```
a := G([7, 19]);
```

```
[1, 1]
```

This means that 19 rotations—mapping each corner to its left neighbor—and 7 reflections have the same effect as one operation of either type.

## Parameters

**n**

Positive integer

**l**

List or array of two integers

## Entries

"size"

the number of elements, which equals  $2n$ .

"one"

the mapping leaving each point fixed.

## Methods

Mathematical Methods

### **\_mult - Functional composition of elements**

```
_mult(a,)
```

This method overloads the kernel function `_mult`.

### **\_invert - Inverse of an element**

```
_invert(a)
```

This method overloads the kernel function `_invert`.

### **\_power - Power of an element**

# Dom::DihedralGroup

---

`_power(a, n)`

It overloads the kernel function `_power`.

## **order - Order of a group element**

`order(a)`

## **random - Random element**

`random()`

## Conversion Methods

## **expr - Convert group element to list**

`expr(a)`

## **TeX - TeX output of a group element**

`TeX(a)`

## **equiv - Test for equivalence**

Inherited from `Cat::BaseCategory`.

## **new - Create element of this domain**

Inherited from `Cat::BaseCategory`.

## **coerce - Coerce into this domain**

Inherited from `Cat::BaseCategory`.

## **hasProp - Test for a certain property**

Inherited from `Dom::BaseDomain`.

## **whichEntry - Return the domain or category implementing an entry**

Inherited from `Dom::BaseDomain`.

## **isone - Test if element is one**

Inherited from `Cat::Monoid`.

## **printMethods - Print out methods**

Inherited from Dom::BaseDomain.

**info - Print short information about this domain**

Inherited from Dom::BaseDomain.

**\_divide - Return quotient**

Inherited from Cat::Group.

**getAxioms - Return axioms stated in the constructor**

Inherited from Dom::BaseDomain.

**getCategories - Return categories stated in the constructor**

Inherited from Dom::BaseDomain.

**equal - Test for mathematical equality**

Inherited from Dom::BaseDomain.

**allAxioms - Return all axioms**

Inherited from Dom::BaseDomain.

**undefinedEntries - Return missing entries**

Inherited from Dom::BaseDomain.

**allCategories - Return all categories**

Inherited from Dom::BaseDomain.

**testtype - Test type of object**

Inherited from Cat::BaseCategory.

**allEntries - Return the names of all entries**

Inherited from Dom::BaseDomain.

**getSuperDomain - Return super-domain stated in the constructor**

Inherited from Dom::BaseDomain.

**subs - Avoid substitution**

Inherited from Dom::BaseDomain.

# Dom::DihedralGroup

---

## **allSuperDomains - Return all super-domains**

Inherited from Dom::BaseDomain.

## **subsex - Avoid extended substitution**

Inherited from Dom::BaseDomain.

## Purpose

Domains of distributed polynomials

## Syntax

### Domain Creation

`Dom::DistributedPolynomial(<Vars, <R, <Order>>>)`

### Element Creation

`Dom::DistributedPolynomial(Vars, R, Order)(p)`

`Dom::DistributedPolynomial(Vars, R, Order)(lm)`

`Dom::DistributedPolynomial(Vars, R, Order)(lm, v)`

## Description

`Dom::DistributedPolynomial(Vars, R, ..)` creates the domain of polynomials in the variables of the list `Vars` over the commutative ring `R` in distributed representation.

`Dom::DistributedPolynomial(Vars, R, Order)` creates a domain of polynomials in the variables of the list `Vars` over a domain of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

If `Dom::DistributedPolynomial` is called without any argument, a polynomial domain in arbitrarily many indeterminates over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

If `Dom::DistributedPolynomial` is called only with the variable list `Vars` as argument, the polynomial domain in the variable list `Vars` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

---

**Note** Only commutative coefficient rings of type `DOM_DOMAIN` are allowed which inherit from `Dom::BaseDomain`. If `R` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

---

`Dom::DistributedPolynomial` accepts expressions as indeterminates, similar to the kernel domain `DOM_POLY`. Hence, for example, `[x, cos(x)]` is a valid variable list.

# Dom::DistributedPolynomial

---

If the variable list `Vars` is the empty list (`[]`), a polynomial domain in arbitrarily many indeterminates is created. In this case, when creating new elements from polynomials or polynomial expressions, the system function `indets` is first called to get the variables and then the polynomial is created with respect to these variables. Hence, in this case only identifiers can be valid indeterminates, because `indets` returns only identifiers.

It is not allowed to create polynomial domains in arbitrarily many indeterminates over another polynomial domain of category `Cat::Polynomial`, but it is possible to create multivariate polynomial domains with a given list of variables over any polynomial domain.

`Dom::DistributedPolynomial` represents polynomials over arbitrary commutative rings. It is intended as a basic domain for distributed polynomials from which it is easy to create new distributed polynomial domains.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computation.

---

**Note** It is highly recommended to use only coefficient rings with unique zero representation. Otherwise it can happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

---

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods.

**Superdomain** `Dom::BaseDomain`

**Axioms** If `R` has `Ax::normalRep`, then `Ax::normalRep`.

If `R` has `Ax::canonicalRep`, then `Ax::canonicalRep`.

## Categories

If `Vars` has exactly one variable, then `Cat::UnivariatePolynomial(R)`, else `Cat::Polynomial(R)`.

## Examples

### Example 1

The following call creates a polynomial domain in  $x$ ,  $y$  and  $z$ .

```
DP := Dom::DistributedPolynomial([x, y, z])
```

```
Dom::DistributedPolynomial([x, y, z], Dom::ExpressionField(normal, iszero ◦ normal), Lex
```

Since neither the coefficient ring nor the monomial ordering was specified, this domain is created with the default values for these parameters.

It is rather easy to create elements of this domain, as e.g.

```
a := DP(x + 2*y*z + 3)
```

$$x + 2 y z + 3$$

```
b := DP(z^4 - 2*y^2*x^2)
```

$$- 2 x^2 y^2 + z^4$$

In contrast to expressions all elements of this domain have a representation which is fixed by the chosen `Order`, the representation of the coefficient ring `R` and the way of representing monomials.

With these elements one can now perform usual arithmetic operations as, e.g., (scalar) multiplication, multiplication with integers and adding polynomials and ring elements:

```
4*b^2 + a/3 + 1/2
```

# Dom::DistributedPolynomial

---

$$16x^4y^4 - 16x^2y^2z^4 + \frac{x}{3} + \frac{2yz}{3} + 4z^8 + \frac{3}{2}$$

There are a lot of methods for manipulating polynomials and to get access to all parts of a polynomial. For example one has access to the leading monomial of a as follows:

`lmonomial(a)`

$$x$$

The leading monomial of a polynomial depends on the monomial ordering, so with respect to the degree order one gets a different result:

`lmonomial(a, DegreeOrder)`

$$2yz$$

To get a minus its leading monomial one may call:

`DP::reductum(a)`

$$2yz + 3$$

Obviously the following identity holds:

`a - lmonomial(a) - DP::reductum(a)`

$$0$$

There are also methods for converting elements of this domain into other domains, like a basic polynomial domain or the domain of arbitrary expressions:

`poly(a), domtype(poly(a))`

`poly(x + 2 y z + 3, [x, y, z], Dom::ExpressionField(normal, iszero • normal)), DOM_POLY`

`expr(b), domtype(expr(b))`

`z4 - 2 x2 y2, DOM_EXPR`

## Parameters

### Vars

A list of indeterminates. Default is [] (the empty list, indicating “arbitrary indeterminates”).

### R

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default is `Dom::ExpressionField(normal)`.

### Order

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder` or `DegInvLexOrder` or any object of type `Dom::MonomOrdering`. Default is `LexOrder`.

### P

A polynomial or a polynomial expression.

### lm

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

### v

# Dom::DistributedPolynomial

---

List of indeterminates. This parameter is only valid for `Vars = []`.

## Entries

## Methods

### Mathematical Methods

#### `_divide` - Exact polynomial division

```
_divide(a, b)
```

```
_divide(a, b)
```

```
_divide(a, b)
```

It overloads the function `_divide` for polynomials, i.e., one may use it either in the form `a / b`, or in functional form `_divide(a, b)`.

---

**Note** This method only exists if `R` is an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

---

## **`_invert` - Inverse of an element**

`_invert(a)`

## **`_mult` - Multiplie polynomials and coefficient ring elements**

`_mult(<a, b, >)`

This method overloads the function `_mult` for polynomials, i.e., one may use it either in the form `a * b * ...` or in functional notation `_mult(a, b, ...)`.

## **`_negate` - Negate a polynomial**

`_negate(a)`

This method overloads the function `_negate` for polynomials, i.e., one may use it either in the form `-a` or in functional notation `_negate(a)`.

## **`_plus` - Add polynomials and coefficient ring elements**

`_plus(<a, b, >)`

This method overloads the function `_plus` for polynomials, i.e., one may use it either in the form `a + b + ...` or in functional notation `_plus(a, b, ...)`.

## **`_power` - Nth power of a polynomial**

`_power(a, n)`

This method overloads the function `_power` for polynomials, i.e., one may use it either in the form `a^n` or in functional notation `_power(a,n)`.

## **`_subtract` - Subtract a polynomial or a coefficient ring element**

`_subtract(a, b)`

This method overloads the function `_subtract` for polynomials, i.e., one may use it either in the form `a - b` or in functional notation `_subtract(a, b)`.

## **`associates` - Test if elements are associates**

# Dom::DistributedPolynomial

---

Inherited from `Cat::IntegralDomain`.

## **content - Content of a polynomial**

`content(a)`

---

**Note** This method only exists if `R` is a domain of category `Cat::GcdDomain`.

---

## **D - Differential operator for polynomials**

`D(a)`

`D(l, a)`

## **Dpoly - Differential operator for polynomials**

`Dpoly(a)`

`Dpoly(l, a)`

`Dpoly(l, a)` computes the partial derivative of `a` with respect to `l`.  
For details see `polylib::Dpoly`.

This method overloads the function `polylib::Dpoly` for polynomials.

## **decompose - Functional decomposition of a polynomial**

`decompose(a, <var>)`

If `a` is a polynomial in only one variable, the second argument is not necessary.

This method overloads the function `polylib::decompose` for polynomials.

## **diff - Differentiate a polynomial**

`diff(a, varseq)`

If `varseq` is an empty sequence, `a` is returned unchanged.

If in `vareq` an expression occurs which is not a variable of `a`, the zero polynomial is returned.

This method overloads the function `diff` for polynomials.

## **dimension - Dimension of affine variety**

```
dimension(ais, <ord>)
```

```
dimension(ais, <ord>)
```

This method is merely an interface for the function `groebner::dimension`.

---

**Note** This method only exists if `R` is a field, i.e., a domain of category `Cat::Field` and `Vars` is not the empty list.

---

## **divide - Divide polynomials**

```
divide(a, b, <Quo | Rem | Exact>)
```

```
divide(a, b, var, <Quo | Rem | Exact>)
```

If no option is given, the quotient `s` and the remainder `r` are computed such that  $a = s*b + r$  and the degree of `r` in the relevant indeterminate is smaller than that of `b`. The sequence consisting of `s`, `r` is returned, otherwise `FAIL`.

If the option `Quo` is given, only the quotient `s` is returned.

If the option `Rem` is given, only the remainder `r` is returned.

If the option `Exact` is given, only the quotient `s` is returned, in case the remainder is zero, otherwise `FAIL`.

`divide(a,b,Exact)` divides the multivariate polynomial `a` by `b`. If `a` cannot be divided by `b`, the method returns `FAIL`.

This method overloads the function `divide` for polynomials.

# Dom::DistributedPolynomial

---

---

**Note** This method only exists if R is a field, i.e., a domain of category `Cat::Field` and either this domain is of category `Cat::UnivariatePolynomial(R)` or R has characteristic zero (`R::characteristic = 0`). If the first pair of conditions is true then the first call is valid otherwise the second one.

---

## **divides - Test if elements divides another**

Inherited from `Cat::IntegralDomain`.

## **equal - Test for mathematical equality**

Inherited from `Dom::BaseDomain`.

## **equiv - Test for equivalence**

Inherited from `Cat::BaseCategory`.

## **evalp - Evaluate a polynomial**

```
evalp(a, var = e)
```

This method overloads the function `evalp` for polynomials.

## **factor - Factor a polynomial**

```
factor(a)
```

This method overloads the function `factor` for polynomials.

---

**Note** This method only exists if R is a domain of category `Cat::Field` or if R is the domain `Dom::Integer`.

---

## **func\_call - Apply expressions to a polynomial**

```
func_call(a, e1, , en, <Expr>)
```

```
func_call(a, e1, , en, <Expr>)
```

```
func_call(a, e1, , en, <Expr>)
```

$a(e_1, \dots, e_n)$  applies the sequence  $e_1, \dots, e_n$  of either elements of this domain or elements of  $R$  with respect to  $Vars$  (where  $n$  is the number of variables) to the polynomial  $a$ . An element of this domain or an element of the coefficient ring respectively is returned.

$a(e_1, \dots, e_n, Expr)$  applies the sequence of expressions or of elements of this domain or of elements of  $R$  to the polynomial  $a$ . With this call  $a$  is first converted into an expression. Afterwards  $e_1, \dots, e_n$  is substituted into this expression with respect to  $Vars$ . The return value may be any object.

The number of variables must be equal to the number of applied expressions.

---

**Note** This method only exists if  $Vars$  has at least one indeterminate.

---

## **gcd - Greatest common divisor of polynomials**

`gcd(a, b, )`

This method overloads the function `gcd` for polynomials.

---

**Note** This method only exists if  $R$  is a domain of category `Cat::GcdDomain`.

---

## **gcdex - Extended Euclidean algorithm for polynomials**

`gcdex(a, b)`

This method overloads the function `gcdex` for polynomials. Especially, it only works for coefficient rings described there.

# Dom::DistributedPolynomial

---

---

**Note** This method only exists if R is a domain of category `Cat::GcdDomain`.

---

## **groebner - Reduced Gröbner basis**

```
groebner(ais, <ord>, <Reorder>)
```

```
groebner(ais, <ord>, <Reorder>)
```

If the option `Reorder` is given, the lexicographical order of variables may change to another one that is likely to decrease the running time.

---

**Note** Note that this may also cause a change of the returned list, which may now have polynomials over the same coefficient ring R but with a possibly re-ordered variable list. Thus, it may contain elements *not* belonging to this domain.

---

This method is merely an interface for the function `groebner::gbasis`.

---

**Note** This method only exists if R is a field, i.e., a domain of category `Cat::Field`, and `Vars` is not the empty list.

---

## **idealGenerator - Generator of finitely generated ideal**

Inherited from `Cat::EuclideanDomain`.

## **int - Definite and indefinite integration of a polynomial**

```
int(a, <x>)
```

```
int(a, <x = x0 .. x1>)
```

`int(a, x=x0..x1)` returns the definite integral  $\int_{x0}^{x1} a \, dx$  or FAIL, if the result is not an element of this domain or an element of a polynomial domain over `Dom::Fraction(R)`.

This method overloads the function `int` for polynomials.

## **intmult - Multiply a polynomial with an integer**

`intmult(a, z)`

This method is more efficient than using polynomial multiplication and is, e.g., necessary for the method "Dpoly".

## **irreducible - Test if element is irreducible**

Inherited from `Cat::FactorialDomain`.

## **isUnit - Test if element is a unit**

Inherited from `Cat::Polynomial`.

## **isone - Test for one**

`isone(a)`

---

**Note** The result can only be valid if the coefficients of `a` are in normal form (i.e., if zero has a unique representation in `R`). Thus, `R` should have at least `Ax::normalRep`.

---

## **iszero - Test for zero**

`iszero(a)`

---

**Note** The result can only be valid, if the coefficients of `a` are in normal form (i.e., if zero has a unique representation in `R`). Thus, the coefficient ring `R` should have at least `Ax::normalRep`.

---

## **lcm - Least common multiple of polynomials**

# Dom::DistributedPolynomial

---

`lcm(a, b, )`

This method overloads the function `lcm` for polynomials.

---

**Note** This method only exists if `R` is a domain of category `Cat::GcdDomain`.

---

## **makeIntegral - Make the coefficients fraction free**

`makeIntegral(a)`

---

**Note** This method only exists if `R` is a domain of category `Cat::GcdDomain` and `R` has the method "denom".

---

## **monic - Normalize a polynomial**

`monic(a)`

The zero polynomial returns itself.

---

**Note** This method only exists if `R` is a field, i.e., a domain of category `Cat::Field`.

---

## **normalForm - Complete reduction modulo an ideal**

`normalForm(a, ais, <ord>)`

`normalForm(a, ais, <ord>)`

This method is merely an interface for the function `groebner::normalf`.

---

**Note** This method only exists if  $R$  is a field, i.e., a domain of category `Cat::Field`, and `Vars` is not the empty list.

---

## **pdioe - Solve polynomial Diophantine equations**

`pdioe(a, b, c)`

This method overloads the function `solveLib::pdioe`.

---

**Note** This method only exists if  $R$  is a field, i.e., a domain of category `Cat::Field` and `Vars` consists of a single variable.

---

## **pdivide - Pseudo-division of polynomials**

`pdivide(a, b, <Quo | Rem>)`

If the option `Quo` is given, only the pseudo-quotient  $q$  is returned.

If the option `Rem` is given, only the pseudo-remainder  $r$  is returned.

This method overloads the function `pdivide` for polynomials.

---

**Note** This method only exists if `Vars` consists of a single variable.

---

## **pquo - Pseudo-quotient of polynomials**

`pquo(a, b)`

---

**Note** This method only exists if `Vars` consists of a single variable.

---

## **prem - Pseudo-remainder of polynomials**

`prem(a, b)`

# Dom::DistributedPolynomial

---

---

**Note** This method only exists if Vars consists of a single variable.

---

## **primpart - Return primitive part**

Inherited from `Cat::Polynomial`.

## **quo - Euclidean quotient**

Inherited from `Cat::EuclideanDomain`.

## **random - Create a random polynomial**

`random()`

With every call the global variable `SEED` is changed by a call of `random()`. Thus it is hard to create the same random sequence twice, see `random`.

If the parameter `Vars` is the empty list, first a list of 1 to 4 variables is generated randomly and the random polynomial is generated in these indeterminates afterwards.

This method overloads the function `polylib::randpoly` for polynomials.

## **rem - Euclidean remainder**

Inherited from `Cat::EuclideanDomain`.

## **resultant - Resultant of two polynomials**

`resultant(a, b, <var>)`

`resultant(a, b, var)` returns the resultant of `a` and `b` with respect to the variable `var`.

The value returned is a polynomial of this domain or `FAIL`.

This method overloads the function `polylib::resultant` for polynomials.

---

**Note** This method only exists if R has the method "\_divide".

---

## **ringmult - Multiplie a polynomial with a coefficient ring element**

```
ringmult(a, c)
```

## **solve - Zero of polynomials**

```
solve(a, <var>, <options>)
```

```
solve(a, <vars>, <options>)
```

```
solve(ais, <var>, <options>)
```

```
solve(ais, <vars>, <options>)
```

solve(ais, ..) tries to find the zeros of the polynomial system ais. The exact behavior depends on further arguments.

For a detailed description of possible return values and options see function solve.

This method overloads the function solve.

## **SPolynomial - Compute the S-polynomial of two polynomials**

```
SPolynomial(a, b, <ord>)
```

This method is merely an interface for the function groebner::spoly.

---

**Note** This method only exists if R is a field, i.e., a domain of category Cat::Field, and Vars is not the empty list.

---

## **sqrfree - Square-free factorization of polynomials**

```
sqrfree(a)
```

The ai are primitive and pairwise different square-free divisors of a and represented as elements of this domain. u is a unit of the

# Dom::DistributedPolynomial

---

coefficient ring and represented as an element of this domain. The  $e_i$  are integers.

This method overloads the function `polylib::sqrfree` for polynomials.

---

**Note** This method only exists if  $R$  is a field, i.e., a domain of category `Cat::Field`, or if  $R$  is `Dom::Integer`.

---

## **unitNormal - Return unit normal**

Inherited from `Cat::Polynomial`.

## **unitNormalRep - Return unit normal representation**

Inherited from `Cat::Polynomial`.

## Access Methods

### **coeff - Coefficient of a polynomial**

`coeff(a)`

`coeff(a, var, n)`

`coeff(a, n)`

`coeff(a, var, n)` returns the coefficient of the term  $\text{var}^n$ —as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring  $R$  if it is of `Cat::UnivariatePolynomial(R)`, where  $a$  is considered as a univariate polynomial in a valid variable `var`.

`coeff(a, n)` returns the coefficient of the term  $\text{var}^n$ —as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring  $R$  if it is of `Cat::UnivariatePolynomial(R)`, where  $a$  is considered as a univariate polynomial in `var` and `var` is the main variable of  $a$ , i.e., the variable returned by `dom::mainvar(a)`.

This method overloads the function `coeff` for polynomials.

## **degree - Degree of a polynomial**

`degree(a)`

`degree(a, var)`

`degree(a, var)` returns the degree of `a` with respect to `var`.

The degree of the zero polynomial is defined as zero.

This method overloads the function `degree` for polynomials.

## **degreevec - Vector of exponents of the leading term of a polynomial**

`degreevec(a, <ord>)`

The degree vector of the zero polynomial is defined as a list of zeros.

This method overloads the function `degreevec` for polynomials.

## **euclideanDegree - Euclidean degree function**

`euclideanDegree(a)`

---

**Note** This method only exists if `Vars` consists of a single variable.

---

## **ground - Ground term of a polynomial**

`ground(a)`

This method overloads the function `ground` for polynomials.

## **has - Existence of an object in a polynomial**

`has(a, obj)`

This method overloads the function `has`.

## **indets - Indeterminate of a polynomial**

`indets(<a>)`

In case `Vars` is not the empty list, `indets` can be called without argument.

Since this domain allows expressions as indeterminates, the returned set may contain expressions, too.

This method overloads the function `indets` for polynomials.

## **lcoeff - Leading coefficient of a polynomial**

`lcoeff(a)`

`lcoeff(a, <vars>, <ord>)`

`lcoeff(a, ord)` returns the leading coefficient of `a` with respect to the monomial ordering `ord` as an element of the coefficient ring `R`.

`lcoeff(a, vars, ord)` returns the leading coefficient of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring `R` if it is of `Cat::UnivariatePolynomial(R)`.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

This method overloads the function `lcoeff` for polynomials.

## **ldegree - Lowest degree of a polynomial**

`ldegree(a)`

`ldegree(a, x)`

`ldegree(a, x)` returns the lowest degree of the variable `x` in `a`.

This method overloads the function `ldegree` for polynomials.

## **lmonomial - Leading monomial of a polynomial**

`lmonomial(a, <ord>)`

`lmonomial(a, <vars>, <ord>, <Rem>)`

`lmonomial(a, vars, ord)` returns the leading monomial of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

`lmonomial(a, vars, ord, Rem)` returns the list consisting of the leading monomial and the reductum of `a` with respect to the variable list `vars` and the monomial ordering `ord` as a list of elements of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

---

**Note** In MuPAD a monomial denotes a coefficient together with a power product as, e.g.,  $3x^2$ .

---

This method overloads the function `lmonomial` for polynomials.

## **lterm - Leading term of a polynomial**

`lterm(a)`

`lterm(a, <vars>, <ord>)`

# Dom::DistributedPolynomial

---

`lterm(a, ord)` returns the leading coefficient of `a` with respect to the monomial ordering `ord` as an element of this domain.

`lterm(a, vars, ord)` returns the leading term of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

---

**Note** In MuPAD a term denotes a power product without a coefficient as, e.g.,  $x^2y^3z$ .

---

This method overloads the function `lterm` for polynomials.

## **mainvar - Main variable of a polynomial**

`mainvar(<a>)`

If `Vars` is not the empty list, `mainvar` can be called without argument.

## **mapcoeffs - Apply a function to the coefficients of a polynomial**

`mapcoeffs(a, f, <e1, >)`

This method overloads the function `mapcoeffs` for polynomials.

## **multcoeffs - Multiply the coefficients of a polynomial with a factor**

`multcoeffs(a, c)`

This method overloads the function `multcoeffs` for polynomials.

## **nterms - Number of terms of a polynomial**

`nterms(a)`

This method overloads the function `nterms` for polynomials.

## **nthcoeff - N-th coefficient of a polynomial**

`nthcoeff(a, n, <ord>)`

If `n` is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. `nthcoeff` returns FAIL when invoked on the zero polynomial.

This method overloads the function `nthcoeff` for polynomials.

## **nthmonomial - N-th monomial of a polynomial**

`nthmonomial(a, n, <ord>)`

If `n` is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. `nthmonomial` returns FAIL for the zero polynomial.

This method overloads the function `nthmonomial` for polynomials.

## **nthterm - N-th term of a polynomial**

`nthterm(a, n, <ord>)`

If `n` is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. `nthterm` returns FAIL when called with the zero polynomial.

This method overloads the function `nthterm` for polynomials.

## **orderedVariableList - Ordered list of indeterminates of a polynomial**

`orderedVariableList(<a>)`

# Dom::DistributedPolynomial

---

In case Vars is not the empty list, orderedVariableList can be called without an argument.

## **pivotSize - Size of a pivot element**

`pivotSize(a)`

This method is called if this domain is used as the component ring of a matrix domain to perform Gaussian elimination.

## **reductum - Reductum of a polynomial**

`reductum(a, <ord>)`

## **subs - Avoid substitution**

Inherited from Dom::BaseDomain.

## **subsex - Avoid extended substitution**

Inherited from Dom::BaseDomain.

## **tcoeff - Lowest coefficient of a polynomial**

`tcoeff(a, <ord>)`

This method overloads the function tcoeff for polynomials.

## **Conversion Methods**

### **coerce - Coerce into this domain**

Inherited from Cat::BaseCategory.

### **convert - Conversion to a polynomial**

`convert(p)`

### **convert\_to - Convert element**

Inherited from Dom::BaseDomain.

### **expr - Conversion to a basic type**

`expr(a)`

This method overloads the function expr.

## **poly - Convert to a basic polynomial domain**

`poly(a)`

This method overloads the function `poly`.

## **TeX - TeX formatting of a polynomial**

`TeX(a)`

## **TeXCoeff - TeX formatting of a polynomial coefficient**

`TeXCoeff(c)`

## **TeXIdent - TeX formatting of a polynomial indeterminate**

`TeXIdent(var)`

## **TeXTerm - TeX formatting of a polynomial term**

`TeXTerm(t)`

## Technical Methods

## **adaptIndets - Convert polynomials to common indeterminates**

`adaptIndets(<a, b, >)`

---

**Note** This method only exists if the parameter `Vars` is the empty list `([])`.

---

## **allAxioms - Return all axioms**

Inherited from `Dom::BaseDomain`.

## **allCategories - Return all categories**

Inherited from `Dom::BaseDomain`.

## **allEntries - Return the names of all entries**

Inherited from `Dom::BaseDomain`.

## **allSuperDomains - Return all super-domains**

# Dom::DistributedPolynomial

---

Inherited from Dom::BaseDomain.

## **getAxioms - Return axioms stated in the constructor**

Inherited from Dom::BaseDomain.

## **getCategories - Return categories stated in the constructor**

Inherited from Dom::BaseDomain.

## **getSuperDomain - Return super-domain stated in the constructor**

Inherited from Dom::BaseDomain.

## **hasProp - Test for a certain property**

Inherited from Dom::BaseDomain.

## **info - Print short information about this domain**

Inherited from Dom::BaseDomain.

## **isNeg - Test on leading output token**

isNeg(a)

## **mult - Multiplie polynomials**

mult(a, b, )

## **new - Create a new element**

new(p)

new(lm)

new(lm, v)

dom(p) creates an element of this domain from a polynomial or a polynomial expression p and returns that element. If this is not possible, an error message is given.

If Vars is chosen as the empty list ([ ]) then in creating new elements from a polynomial or polynomial expression the function indets is first called to get the identifiers. Afterwards the element is created with this list of identifiers. For creating an element from a constant the dummy variable \_dummy is introduced. The

drawback of this approach is that two mathematically equal polynomials may have variable lists which differ by the dummy variable.

`dom(lm)` creates, if `Vars` is not the empty list `[]`, a polynomial from the list `lm` of the form `[[c1, [e11, ... e1n]], ... [cm, [em1, ... emn]]]` where the `ci` are coefficients and the `eij` are the exponents with respect to `Vars`. For a univariate polynomial this list can be simplified to `[[c1, e1], ... [cm, em]]`.

`dom(lm, v)` creates, if `Vars = []`, a polynomial from the list `lm` of the form `[[c1, [e11, ... e1n]], ... [cm, [em1, ... emn]]]` where the `ci` are coefficients and the `eij` are the exponents with respect to `v`. For a univariate polynomial this list can be simplified to `[[c1, e1], ... [cm, em]]`. The list of indeterminates `v` must contain valid indeterminates.

## **plus - Add polynomials**

```
plus(a, b,)
```

## **print - Print polynomials**

```
print(a)
```

This method overloads the function `print`.

## **printMethods - Print out methods**

Inherited from `Dom::BaseDomain`.

## **printMonomial - Print a monomial in defined order**

```
printMonomial(c, d, v)
```

## **printTerm - Print a term in defined order**

```
printTerm(d)
```

```
printTerm(d, v)
```

`printTerm(d, v)` returns an ordered sequence of the indeterminates together with their powers as given in the variable list `v` and the degree vector `d` respectively.

# Dom::DistributedPolynomial

---

Note that this call is only valid if  $\text{nops}(v) = \text{nops}(d)$ .

## **Rep - Data representation of a polynomial**

`Rep(a)`

## **sign - Leading sign of a polynomial**

`sign(a)`

*Note:* this method does not have the meaning of a mathematical sign function!

## **testtype - Test type of object**

Inherited from `Cat::BaseCategory`.

## **undefinedEntries - Return missing entries**

Inherited from `Dom::BaseDomain`.

## **whichEntry - Return the domain or category implementing an entry**

Inherited from `Dom::BaseDomain`.

## **See Also**

### **MuPAD Domains**

`Dom::Polynomial` | `Dom::MultivariatePolynomial` |  
`Dom::UnivariatePolynomial`

# Dom::Expression

---

```
Dom::Expression((3, x))
```

```
Error: The number of arguments is incorrect. [expr]
Evaluating: Dom::Expression::new
```

## Parameters

**x**

An object of basic type consisting only of operands of built-in types, or any other object convertible to such using `expr`.

## Entries

"randomIdent"

an identifier used for creating random elements

## Methods

### Conversion Methods

#### **convert - Conversion of objects**

```
convert(x)
```

#### **convert\_to - Conversion to other domains**

```
convert_to(x, T)
```

#### **expr - Just return the argument**

```
expr(x)
```

#### **testtype - Test whether its argument is an expression**

```
testtype(x, Dom::Expression)
```

This method overloads `testtype`; since `Dom::Expression` has no domain elements, the overloading can only be caused by the second argument.

#### **float - Convert numbers to floats**

```
float(x)
```

## Technical Methods

### **subs - Substitution**

`subs(x, s, )`

### **subsex - Extended substitution**

`subsex(x, s, )`

### **random - Create random expression**

`random()`

## MuPAD Domains

`Dom::ExpressionField`

# Dom::ExpressionField

---

**Purpose** Domains of expressions forming a field

**Syntax** **Domain Creation**  
Dom::ExpressionField(<Normal, <IsZero>>)

**Element Creation**  
Dom::ExpressionField(Normal, IsZero)(e)

**Description** **Domain Creation**

Dom::ExpressionField(Normal, IsZero) creates a domain of expressions forming a field, where the functions Normal and IsZero are used to normalize expressions and test for zero.

The function Normal is used to normalize the expressions representing the elements, the function IsZero is used to test the expressions for zero. It is assumed that the field has characteristic 0.

The domain cannot decide if the element expressions—given the normalizing function and zero test—actually form a field. It is up to the user to choose correct functions for normalizing and zero test and to enter only valid expressions as domains elements.

One should view this domain constructor as a pragmatic way to create a field of characteristic 0 in an ad-hoc fashion. Note that the default of using id and iszero does not yield a field really, but it is often convenient and sensible to use the resulting structure as a field.

Normal must be a function which takes an expression representing a domain element and returns the normalized expression. Normal should return FAIL if the expression is not valid.

If Normal is not given, then the system function id is used, i.e., only the kernel simplifier is used to normalize expressions.

If a normalizing function other than id is given, it is assumed that this functions returns a normal form where the zero element is uniquely represented by the constant 0.

IsZero must be a function which takes an expression representing a domain element and returns TRUE if the expression represents zero and FALSE otherwise.

If IsZero is not given, then iszero @ Normal is used for zero testing. If Normal is equal to id this functional expression is simplified to iszero.

If Normal is equal to id and IsZero is equal to iszero, a façade domain is created, i.e., the domain elements are simply expressions and are not explicitly created by new.

Otherwise the elements of the domain are explicitly created by new. Each such element has one operand, which is the expression representing the domain element. The element expressions are normalized after each operation using the function Normal.

## Element Creation

Dom::ExpressionField(Normal, IsZero)(e) creates a field element represented by the expression e. The expression is normalized using the function Normal.

If Normal returns FAIL, it is assumed that the expression does not represent a valid field element. If this test is not fully implemented the domain cannot decide if the expression represents a valid field element. In this case it is up to the user to enter only valid expressions as field elements.

If Normal is equal to id and IsZero is equal to iszero, the domain is only a façade domain. In this case the expression e is returned after being simplified by the built-in kernel simplifier.

## Superdomain

If Normal = id and IsZero = iszero, then  
Dom::ArithmeticalExpression, else Dom::BaseDomain.

## Axioms

Ax::indetElements

If Normal = id and IsZero = iszero, then Ax::efficientOperation  
("\_divide"), Ax::efficientOperation("\_mult"),  
Ax::efficientOperation("\_invert"), else Ax::normalRep.

# Dom::ExpressionField

---

If Normal = id and IsZero = iszero and IsZero = iszero, then  
Ax::systemRep.

**Categories** Cat::Field, Cat::DifferentialRing

## Examples **Example 1**

Dom::ExpressionField(normal) creates a field of rational expressions over the rationals. The expressions representing the field elements are always normalized by normal:

```
Fn := Dom::ExpressionField(normal):
a := Fn((x^2 - 1)/(x - 1))
```

$x + 1$

The field elements are explicit elements of the domain:

```
domtype(a)
```

`Dom::ExpressionField(normal, iszero * normal)`

## **Example 2**

In the domain Dom::ExpressionField(id, iszero@normal) the expressions representing the elements are normalized by the kernel simplifier only:

```
Fi := Dom::ExpressionField(id, iszero@normal):
a := Fi((x^2 - 1)/(x - 1))
```

$\frac{x^2 - 1}{x - 1}$

The elements of this domain are not normalized (when viewed as rational expressions over the rationals), thus the domain does not have the axiom `Ax::normalRep`:

```
b := a/Fi(x + 1) - Fi(1)
```

$$\frac{x^2 - 1}{(x - 1)(x + 1)} - 1$$

But nevertheless this domain also represents the field of rational expressions over the rationals, because zero is detected correctly by the function `iszero @ normal`:

```
iszero(b)
```

```
TRUE
```

## Parameters

### Normal

A function used to normalize the expressions of the domain; default is `id`.

### IsZero

A function used to test the expressions of the domain for zero; default is `iszero @ Normal`.

### e

An expression representing a field element.

# Dom::ExpressionField

---

|------------------|------------------------------------------------------------------------------------------------|
| "characteristic" | The characteristic of the fields created by this constructor is assumed to be 0.               |
| "one"            | The element represented by the expression 1 is assumed to be a neutral element w.r.t. "_mult". |
| "zero"           | The element represented by the expression 0 is assumed to be a neutral element w.r.t. "_plus". |

## Methods

### Mathematical Methods

#### **abs - Absolute value**

`abs(x)`

Overloads the function `abs`, thus may be called via `abs(x)`.

#### **combine - Combine terms of the same algebraic structure**

`combine(x, <a>)`

Overloads the function `combine`, thus may be called via `combine(x, ...)`.

#### **conjugate - Complex conjugate**

`conjugate(x)`

Overloads the function `conjugate`, thus may be called via `conjugate(x)`.

#### **D - Differential operator**

`D(<l>, x)`

Overloads the function `D`, thus may be called via `D(x)` or `D(l, x)`.

#### **denom - Denominator**

`denom(x)`

Overloads the function `denom`, thus may be called via `denom(x)`.

## **diff - Differentiate an element**

`diff(x, <v, , >)`

Overloads the function `diff`, thus may be called via `diff(x, ...)`.

## **\_divide - Divide elements**

`_divide(x, y)`

Overloads the function `_divide`, thus may be called via `x/y` or `_divide(x, y)`.

## **equal - Test for mathematical equality**

`equal(x, y)`

## **expand - Expand an element**

`expand(x)`

Overloads the function `expand`, thus may be called via `expand(x)`.

## **factor - Factorize an element**

`factor(x)`

Overloads the function `factor`, thus may be called via `factor(x)`.

## **float - Floating-point approximation**

`float(x)`

Overloads the function `float`, thus may be called via `float(x)`.

## **gcd - Greatest common divisor**

`gcd(x, )`

Overloads the function `gcd`, thus may be called via `gcd(x, ...)`.

## **Im - Imaginary part of an element**

`Im(x)`

Overloads the function `Im`, thus may be called via `Im(x)`.

## **int - Definite and indefinite integration**

`int(x, <v>)`

Overloads the function `int`, thus may be called via `int(x, ...)`.

## **intmult - Integer multiple**

`intmult(x, n)`

## **\_invert - Invert an element**

`_invert(x)`

Overloads the function `_invert`, thus may be called via `1/x` or `_invert(x)`.

## **iszero - Test for zero**

`iszero(x)`

Overloads the function `iszero`, thus may be called via `iszero(x)`.

## **lcm - Least common multiple**

`lcm(x, )`

Overloads the function `lcm`, thus may be called via `lcm(x, ...)`.

## **\_leequal - Test if less or equal**

`_leequal(x, y)`

Please note that the function `_leequal` can only test numbers (in a syntactical sense), but not constant expressions like `PI` or `sqrt(2)`.

Overloads the function `_leequal`, thus may be called via `x <= y`, `y >= x` or `_leequal(x, y)`.

## **\_less - Test if element is less**

`_less(x, y)`

Please note that the function `_less` can only test numbers (in a syntactical sense), but not constant expressions like `PI` or `sqrt(2)`.

Overloads the function `_less`, thus may be called via `x < y`, `y > x` or `_less(x, y)`.

## **limit - Limit computation**

`limit(x, <v, >)`

Overloads the function `limit`, thus may be called via `limit(x, ...)`.

## **max - Maximum of arguments**

`max(x, )`

Overloads the function `max`, thus may be called via `max(x, ...)`.

## **min - Minimum of arguments**

`min(x, )`

Overloads the function `min`, thus may be called via `min(x, ...)`.

## **\_mult - Multiplie elements**

`_mult(x, )`

If all arguments are of this domain or can be coerced to this domain (using the method `coerce`), the product of the expressions representing the arguments is calculated using the function `_mult`.

If one of the arguments cannot be coerced, the arguments up to the offending one are multiplied and then the method `"_mult"` of the domain of the offending argument is called to multiply the remaining arguments.

Overloads the function `_mult`, thus may be called via `x*...` or `_mult(x, ...)`.

## **\_negate - Negate an element**

`_negate(x)`

Overloads the function `_negate`, thus may be called via `-x` or `_negate(x)`.

## **norm - Norm of an element**

`norm(x)`

Overloads the function `norm`, thus may be called via `norm(x)`.

Please note that the system function `norm`, applied to an expression, computes the norm of that expression interpreted as a polynomial expression and *not* the absolute value of the expression. This may be regarded as an inconsistency.

## **normal - Normal form**

`normal(x)`

Overloads the function `normal`, thus may be called via `normal(x)`.

## **numer - Numerator**

`numer(x)`

Overloads the function `numer`, thus may be called via `numer(x)`.

## **\_plus - Add elements**

`_plus(x, )`

If all arguments are of this domain or can be coerced to this domain (using the method `coerce`) the sum of the expressions representing the arguments is calculated using the function `_plus`.

If one of the arguments cannot be coerced the arguments up to the offending one are added and then the method "`_plus`" of the domain of the offending argument is called to add the remaining arguments.

Overloads the function `_plus`, thus may be called via `x+...` or `_plus(x,...)`.

## **\_power - Exponentiate arguments**

`_power(x, y)`

`_power(x, y)`

If both arguments are of this domain the power is calculated by mapping the function `_power` to the expressions representing the arguments.

If one of the arguments is not of this domain it is coerced to this domain, then the power is computed. If the coercion fails an error is raised.

Note that it is assumed that at least one of the arguments is of this domain.

Overloads the function `_power`, thus may be called via `x^y` or `_power(x, y)`.

## **radsimp - Simplifie radicals**

`radsimp(x)`

Overloads the function `radsimp`, thus may be called via `radsimp(x)`.

## **random - Create a random element**

`random()`

See `polylib::randpoly` for details about creating random polynomials.

## **Re - Real part of an element**

`Re(x)`

Overloads the function `Re`, thus may be called via `Re(x)`.

## **sign - Sign of an element**

`sign(x)`

Overloads the function `sign`, thus may be called via `sign(x)`.

## **simplify - General simplification of an element**

`simplify(x, <a>)`

Overloads the function `simplify`, thus may be called via `simplify(x, ...)`.

# Dom::ExpressionField

---

## **solve - Solve an equation**

`solve(x, <a, >)`

Note that this method will never return an element of this domain. See `solve` for details about results and optional additional arguments.

Overloads the function `solve`, thus may be called via `solve(x, ...)`.

## **sqrfree - Square-free factorization**

`sqrfree(x)`

Overloads the function `polylib::sqrfree`, thus may be called via `polylib::sqrfree(x)`.

## **\_subtract - Subtract elements**

`_subtract(x, y)`

Overloads the function `_subtract`, thus may be called via `x - y` or `_subtract(x, y)`.

## **Conversion Methods**

### **convert - Convert to this domain**

`convert(x)`

### **convert\_to - Convert to other domain**

`convert_to(x, T)`

### **expr - Convert to basic type**

`expr(x)`

This method is called by the function `expr` if a subexpression of the argument is an element of this domain.

### **new - Creating an element**

`new(x)`

Overloads the function call operator for this domain, thus may be called via  $F(x)$  where  $F$  is this domain.

## Access Methods

### **nops - Number of operands**

`nops(x)`

Overloads the function `nops`, thus may be called via `nops(x)`.

### **op - Get operands**

`op(x)`

`op(x, i)`

Returns the operand with index  $i$  of the expression representing  $x$ . If  $i$  is 0 then the operator of the expression is returned, which usually is not an element of this domain. The other operands are converted to elements of this domain.

This method is called by the function `op` when an element of this domain is contained, as a subexpression, in the first argument of `op`. Operand ranges and paths are handled by `op` and need not be handled by this method. See `op` for details.

### **subs - Substitute subexpressions**

`subs(x, e, )`

Maps `subs` to the expression representing  $x$ . The resulting expression is converted to an element of this domain.

This method is called by the function `subs` when an element of this domain is contained, as a subexpression, in the first argument of `subs`. See `subs` for details.

### **subsex - Extended substitution**

`subsex(x, e, , )`

Maps `subsex` to the expression representing  $x$ . The resulting expression is converted to an element of this domain.

# Dom::ExpressionField

---

This method is called by the function `subsex` when an element of this domain is contained, as a subexpression, in the first argument of `subsex`. See `subsex` for details.

## **subsop - Substitute operand**

`subsop(x, e, , )`

This method is called by the function `subsop` when an element of this domain is contained, as a subexpression, in the first argument of `subsop`. Operand ranges and pathes are handled by `subsop` and need not be handled by this method. See `subsop` for details.

## **Technical Methods**

### **indets - Identifier of an element**

`indets(x, <optionName>)`

Overloads the function `indets`, thus may be called via `indets(x)` and `indets(x, optionName)`, respectively.

### **length - Size of an element**

`length(x)`

Overloads the function `length`, thus may be called via `length(x)`.

### **map - Applie function to operands**

`map(x, f, <a, >)`

Overloads the function `map`, thus may be called via `map(x, f, ...)`.

### **rationalize - Approximate floating-point numbers by rationals**

`rationalize(x, <a, >)`

Note that this method does *not* overload the function `rationalize` from the standard library package, but the function `numeric::rationalize` from the `numeric` package instead. Thus the method may be called via `numeric::rationalize(x, ...)`.

### **pivotSize - Pivot size**

`pivotSize(x)`

# Dom::Float

| <b>Purpose</b>     | Real floating-point numbers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>      | <code>Dom::Float(x)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p><code>Dom::Float</code> is the set of real floating-point numbers represented by elements of the domain <code>DOM_FLOAT</code>.</p> <p><code>Dom::Float</code> is the domain of real floating point numbers represented by expressions of type <code>DOM_FLOAT</code>.</p> <p><code>Dom::Float</code> has category <code>Cat::Field</code> out of pragmatism. This domain actually is not a field because <code>bool(1.0 = float(3) / float(3))</code> returns <code>FALSE</code> for example.</p> <p>Elements of <code>Dom::Float</code> are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression may be converted to a floating point number. This means <code>Dom::Float</code> is a facade domain which creates elements of domain type <code>DOM_FLOAT</code>.</p> <p>Viewed as a differential ring <code>Dom::Float</code> is trivial, it contains constants only.</p> <p><code>Dom::Float</code> has the domain <code>Dom::Numerical</code> as its super domain, i.e., it inherits each method which is defined by <code>Dom::Numerical</code> and not implemented by <code>Dom::Float</code>. Methods described below are re-implemented by <code>Dom::Float</code>.</p> |
| <b>Superdomain</b> | <code>Dom::Numerical</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Examples

### Example 1

Creating some floating-point numbers using `Dom::Float`. This example also shows that `Dom::Float` is a facade domain.

```
Dom::Float(2.3); domtype(%)
```

```
2.3
```

```
DOM_FLOAT
```

```
Dom::Float(sin(2/3*PI) + 3)
```

```
3.868025404
```

```
Dom::Float(sin(x))
```

```
Error: The arguments are invalid. [Dom::Float::new]
```

### Example 2

By tracing the method `Dom::Float::testtypeDom` we can see the interaction between `testtype` and `Dom::Float::testtypeDom`.

```
prog::trace(Dom::Float::testtypeDom):
delete x:
testtype(x, Dom::Float);
testtype(3.4, Dom::Float);
prog::untrace(Dom::Float::testtypeDom):
```

```
enter Dom::Float::testtypeDom(x, Dom::Float)
computed FAIL
```

# Dom::Float

---

FALSE

```
enter Dom::Float::testtypeDom(3.4, Dom::Float)
computed TRUE
```

TRUE

## Parameters

**x**

An expression which can be converted to a DOM\_FLOAT by the function float.

## Entries

"one"

the unit element; it equals 1.0.

"zero"

The zero element; it equals 0.0.

## Methods

### Mathematical Methods

#### **pivotSize - Size of a pivot element**

`pivotSize(x)`

This method is called if this domain is used as the component ring of a matrix domain to perform Gaussian elimination.

#### **random - Random number generation**

`random()`

### Conversion Methods

#### **convert - Conversion of objects**

`convert(x)`

In general, if `float(x)` evaluates to a real floating-point number of type `DOM_FLOAT`, this number is the result of the conversion.

## **convert\_to - Conversion to other domains**

`convert_to(x, T)`

The following domains are allowed for `T`: `DOM_FLOAT`, `Dom::Float` and `Dom::Numerical`.

## **testtype - Type checking**

`testtype(x, T)`

In general this method is called from the function `testtype` and not directly by the user. “Example 2” on page 6-175 demonstrates this behavior.

| <b>Purpose</b>     | The “field” of Floating Point Intervals                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>      | <code>Dom::FloatIV(x, )</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p><code>Dom::FloatIV</code> is the inclusion algebra of (finite unions of) rectangular intervals in the complex plane.</p> <p><code>Dom::FloatIV</code> is the domain of kernel intervals of type <code>DOM_INTERVAL</code>.</p> <p><code>Dom::FloatIV</code> has category <code>Cat::Field</code> out of pragmatism. This domain actually is not a field because, for example, there is no additive inverse of <code>1...2</code>.</p> <p>Elements of <code>Dom::FloatIV</code> are usually not created explicitly. The syntax given above is equivalent to an <code>interval</code> call, with no check to ensure that the result is in fact an interval, it could, for example, also be an expression with all numerical coefficients replaced by intervals. Apart from this behavior of the constructor and the “convert” slot, <code>Dom::FloatIV</code> is a façade domain for elements of domain type <code>DOM_INTERVAL</code>.</p> <p>Viewed as a differential ring <code>Dom::FloatIV</code> is trivial, it contains constants only.</p> <p><code>Dom::FloatIV</code> has the domain <code>Dom::Numerical</code> as its super domain, i.e., it inherits each method which is defined by <code>Dom::Numerical</code> and not re-implemented by <code>Dom::FloatIV</code>. Methods described below are those implemented by <code>Dom::FloatIV</code>.</p> |
| <b>Superdomain</b> | <code>Dom::Numerical</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### **MuPAD Domains**

`Dom::Complex` | `Dom::Float` | `Dom::Integer` | `Dom::Interval` |  
`Dom::Numerical` | `Dom::Rational` | `Dom::Real`

**Purpose** Field of fractions of an integral domain

**Syntax** **Domain Creation**

Dom::Fraction(R)

**Element Creation**

Dom::Fraction(R)(r)

**Description** **Domain Creation**

Dom::Fraction(R) creates a domain which represents the field of fractions  $F = \left\{ \frac{x}{y} \mid x \in R, y \in R \setminus \{0\} \right\}$  of the integral domain  $R$ .

An element of the domain Dom::Fraction(R) has two operands, the numerator and denominator.

If Dom::Fraction(R) has the axiom Ax::canonicalRep (see below), the denominators have unit normal form and the gcds of numerators and denominators cancel.

The domain Dom::Fraction(Dom::Integer) represents the field of rational numbers. But the created domain is not the domain Dom::Rational, because it uses a different representation of its elements. Arithmetic in Dom::Rational is much more efficient than it is in Dom::Fraction(Dom::Integer).

**Element Creation**

If  $r$  is a rational expression, then an element of the field of fractions Dom::Fraction(R) is created by going through the operands of  $r$  and converting each operand into an element of  $R$ . The result of this

process is  $r$  in the form  $\frac{x}{y}$ , where  $x$  and  $y$  are elements of  $R$ . If  $R$  has Cat::GcdDomain, then  $x$  and  $y$  are coprime.

If one of the operands can not be converted into the domain  $R$ , an error message is issued.

**Superdomain** Dom::BaseDomain

# Dom::Fraction

---

**Axioms** Ax::normalRep

**Categories** Cat::QuotientField(R)

**Examples** **Example 1**

We define the field of rational functions over the rationals:

```
F := Dom::Fraction(Dom::Polynomial(Dom::Rational))
```

```
Dom::Fraction(Dom::Polynomial(Dom::Rational, LexOrder))
```

and create an element of F:

```
a := F(y/(x - 1) + 1/(x + 1))
```

$$\frac{x + y + x y - 1}{x^2 - 1}$$

To calculate with such elements use the standard arithmetical operators:

```
2*a, 1/a, a*a
```

$$\frac{2x + 2y + 2xy - 2}{x^2 - 1}, \frac{x^2 - 1}{x + y + xy - 1}, \frac{x^2 y^2 + 2x^2 y + x^2 + 2x y^2 - 2x + y^2 - 2y + 1}{x^4 - 2x^2 + 1}$$

Some system functions are overloaded for elements of domains generated by Dom::Fraction, such as diff, numer or denom (see the description of the corresponding methods "diff", "numer" and "denom" above).

For example, to differentiate the fraction a with respect to x enter:

```
diff(a, x)
```

$$\frac{-y - 2x + 2xy + x^2y + x^2 + 1}{x^4 - 2x^2 + 1}$$

If one knows the variables in advance, then using the domain `Dom::DistributedPolynomial` yields a more efficient arithmetic of rational functions:

```
Fxy := Dom::Fraction(
 Dom::DistributedPolynomial([x, y], Dom::Rational)
)
```

```
Dom::Fraction(Dom::DistributedPolynomial([x, y], Dom::Rational, LexOrder))
```

```
b := Fxy(y/(x - 1) + 1/(x + 1)):
b^3
```

$$\frac{(x^3 y^3 + 3x^3 y^2 + 3x^3 y + x^3 + 3x^2 y^3 + 3x^2 y^2 - 3x^2 y - 3x^2 + 3x y^3 - 3x y^2 - 3x y + 3 - 1)/(x^6 - 3x^4 + 3x^2 - 1)}$$

## Example 2

We create the field of rational numbers as the field of fractions of the integers, i.e.,  $\mathbb{Q} = \left\{ \frac{x}{y} \mid x \in \mathbb{Z}, y \in \mathbb{Z} \setminus \{0\} \right\}$ :

```
Q := Dom::Fraction(Dom::Integer):
Q(1/3)
```

$$\frac{1}{3}$$

# Dom::Fraction

---

`domtype(%)`

`Dom::Fraction(Dom::Integer)`

Another representation of `in` in MuPAD is the domain `Dom::Rational` where the rationals are of the kernel domains `DOM_INT` and `DOM_RAT`. Therefore it is much more efficient to work with `Dom::Rational` than with `Dom::Fraction(Dom::Integer)`.

## Parameters

**R**

An integral domain, i.e., a domain of category `Cat::IntegralDomain`

**r**

A rational expression, or an element of `R`

## Entries

|                  |                                                                                 |
|------------------|---------------------------------------------------------------------------------|
| "characteristic" | is the characteristic of <code>R</code> .                                       |

| "one"            | is the one of the field of fractions of <code>R</code> , i.e., the fraction 1.  |
| "zero"           | is the zero of the field of fractions of <code>R</code> , i.e., the fraction 0. |

## Methods

Mathematical Methods

### **`_divide` - Divide two fractions**

`_divide(x, y)`

This method overloads the function `_divide` for fractions, i.e., one may use it in the form `x / y` or in functional notation:

`_divide(x, y)`.

### **`_invert` - Invert a fraction**

`_invert(r)`

This method overloads the function `_invert` for fractions, i.e., one may use it in the form  $1/r$  or  $r^{-1}$ , or in functional notation: `_invert(r)`.

## **`_less` - Less-than relation**

`_less(q, r)`

An implementation is provided only if  $R$  is an ordered set, i.e., a domain of category `Cat::OrderedSet`.

This method overloads the function `_less` for fractions, i.e., one may use it in the form  $q < r$ , or in functional notation: `_less(q, r)`.

## **`_mult` - Multiplie fractions by fractions or rational expressions**

`_mult(q, r)`

If  $q$  is not of the domain type `Dom::Fraction(R)`, it is considered as a rational expression which is converted into a fraction over  $R$  and multiplied with  $q$ . If the conversion fails, `FAIL` is returned.

The same applies to  $r$ .

This method also handles more than two arguments. In this case, the argument list is splitted into two parts of the same length which both are multiplied with the function `_mult`. The two results are multiplied again with `_mult` whose result then is returned.

This method overloads the function `_mult` for fractions, i.e., one may use it in the form  $q * r$  or in functional notation: `_mult(q, r)`.

## **`_negate` - Negate a fraction**

`_negate(r)`

This method overloads the function `_negate` for fractions, i.e., one may use it in the form  $-r$  or in functional notation: `_negate(r)`.

## **`_power` - Integer power of a fraction**

`_power(r, n)`

This method overloads the function `_power` for fractions, i.e., one may use it in the form  $r^n$  or in functional notation: `_power(r, n)`.

## **`_plus` - Add fractions**

`_plus(q, r, )`

If one of the arguments is not of the domain type `Dom::Fraction(R)`, then FAIL is returned.

This method overloads the function `_plus` for fractions, i.e., one may use it in the form  $q + r$  or in functional notation: `_plus(q, r)`.

## **`D` - Differential operator**

`D(r)`

An implementation is provided only if  $R$  is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

This method overloads the operator `D` for fractions, i.e., one may use it in the form  $D(r)$ .

## **`denom` - Denominator of a fraction**

`denom(r)`

This method overloads the function `denom` for fractions, i.e., one may use it in the form `denom(r)`.

## **`diff` - Differentiation of fractions**

`diff(r, u)`

This method overloads the function `diff` for fractions, i.e., one may use it in the form `diff(r, u)`.

An implementation is provided only if  $R$  is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

## **equal - Test on equality of fractions**

`equal(q, r)`

## **factor - Factorize the numerator and denominator of a fraction**

`factor(r)`

The factors  $u, r_1, \dots, r_n$  are fractions of type `Dom::Fraction(R)`, the exponents  $e_1, \dots, e_n$  are integers.

The system function `factor` is used to perform the factorization of the numerator and denominator of  $r$ .

This method overloads the function `factor` for fractions, i.e., one may use it in the form `factor(r)`.

## **intmult - Integer multiple of a fraction**

`intmult(r, n)`

## **iszero - Test for zero**

`iszero(r)`

An element of the field `Dom::Fraction(R)` is zero if its numerator is the zero element of  $R$ . Note that there may be more than one representation of the zero element if  $R$  does not have `Ax::canonicalRep`.

This method overloads the function `iszero` for fractions, i.e., one may use it in the form `iszero(r)`.

## **numer - Numerator of a fraction**

`numer(r)`

This method overloads the function `numer` for fractions, i.e., one may use it in the form `numer(r)`.

## **random - Random fraction generation**

`random()`

The returning fraction is normalized (see the methods `"normalize"` and `"normalizePrime"`).

## Conversion Methods

### **convert\_to - Fraction conversion**

`convert_to(r, T)`

If the conversion fails, FAIL is returned.

The conversion succeeds if T is one of the following domains:  
Dom::Expression or Dom::ArithmeticalExpression.

Use the function `expr` to convert `r` into an object of a kernel domain (see below).

### **expr - Convert a fraction into an object of a kernel domain**

`expr(r)`

The result is an object of a kernel domain (e.g., DOM\_RAT or DOM\_EXPR).

This method overloads the function `expr` for fractions, i.e., one may use it in the form `expr(r)`.

### **TeX - TeX formatting of a fraction**

`TeX(r)`

The method `TeX` of the component ring `R` is used to get the TeX-representations of the numerator and denominator of `r`, respectively.

### **retract - Retraction to base domain**

`retract(r)`

## Technical Methods

### **normalize - Normalizing fractions**

`normalize(x, y)`

Normalization means to remove the gcd of `x` and `y`. Hence, `R` needs to be of category `Cat::GcdDomain`. Otherwise, normalization

cannot be performed and the result of this method is the fraction

$$\frac{x}{y}$$

### **normalizePrime - Normalizing fractions over integral domains with a gcd**

`normalizePrime(x, y)`

In rings of category `Cat::GcdDomain`, elements are assumed to be relatively prime. Hence, there is no need to normalize the

fraction  $\frac{x}{y}$ .

In rings not of category `Cat::GcdDomain`, normalization of elements can not be performed and the result of this method is

the fraction  $\frac{x}{y}$ .

# Dom::GaloisField

---

**Purpose** Finite fields

**Syntax**

**Domain Creation**

```
Dom::GaloisField(q)
Dom::GaloisField(p, n)
Dom::GaloisField(p, n, f)
Dom::GaloisField(F, n)
Dom::GaloisField(F, n, f)
```

**Element Creation**

```
Dom::GaloisField(p, n, f)(g)
```

**Description** **Domain Creation**

Dom::GaloisField(p, n, f) creates the residue class field  $\mathbb{Z}_p[X]/\langle f \rangle$ , a finite field with  $p^n$  elements. If f is not given, it is chosen at random among all irreducible polynomials of degree  $n$ .

Dom::GaloisField(q) (where  $q = p^n$ ) is equivalent to Dom::GaloisField(p,n).

Dom::GaloisField(F, n, f) creates the residue class field  $F[X]/\langle f \rangle$ , a finite field with  $|F|^n$  elements.

If f is not given, a random irreducible polynomial of appropriate degree is used; some free identifier is chosen as its variable, and this one must also be used when creating domain elements.

Although  $n = 1$  is allowed, Dom::IntegerMod should be used for representing prime fields.

If F is of type Dom::GaloisField, consisting of residue classes of polynomials, the variable of these polynomials must be distinct from the variable of f. If a tower several of Galois fields is constructed, the variable used in the uppermost Galois field must not equal any of those used in the tower. A special entry "VariablesInUse" serves to keep track of all variables appearing somewhere in the tower.

## Element Creation

Dom::GaloisField(p,n,f)(g) (or, respectively, Dom::GaloisField(F,n,f)(g)) creates the residue class of g modulo f. It is represented by the unique polynomial in that class that has smaller degree than f.

**Superdomain** Dom::AlgebraicExtension(Dom::IntegerMod(p), f)

**Axioms** Ax::canonicalRep

**Categories** Cat::Field, Cat::Algebra(F), Cat::VectorSpace(F)

## Examples **Example 1**

We define L to be the field with 4 elements. Then  $a^4 = a$  for every  $a \in L$ , by a well-known theorem.

```
L:=Dom::GaloisField(2, 2, u^2+u+1): L(u+1)^4
```

```
u + 1
```

## Parameters

**q**

Prime power

**p**

Prime

**n**

Positive integer

**f**

Univariate irreducible polynomial over Dom::IntegerMod(p) or F, or polynomial expression convertible to such

**F**

# Dom::GaloisField

---

Finite field of type `Dom::IntegerMod` or `Dom::GaloisField`.

**g**

Univariate polynomial over the ground field in the same variable as `f`, or polynomial expression convertible to such

## Entries

|                  |                                                                             |
|------------------|-----------------------------------------------------------------------------|
| "zero"           | the zero element of the field                                               |
| "one"            | the unit element of the field                                               |
| "characteristic" | the characteristic of the field                                             |
| "size"           | the number of elements of the field                                         |
| "PrimeField"     | the prime field, which equals <code>Dom::IntegerMod(p)</code> .             |
| "Variable"       | the variable of the polynomial <code>f</code> .                             |
| "VariablesInUse" | a list consisting of "Variable" and the variables used by the ground field. |

## Methods

### Mathematical Methods

#### **iszero - Test for zero**

`iszero(a)`

It overloads the function `iszero`.

#### **\_power - Integer power of an element**

`_power(a, n)`

It overloads `_power`.

#### **frobenius - Frobeniu map**

`frobenius(a)`

#### **conjugates - Conjugate of an element**

conjugates(a)

**order - Order of an element**

order(a)

**isSquare - Test whether an element is a square**

isSquare(a)

**ln - Discrete logarithm**

ln(a, b)

**elementNumber - Enumerate field elements**

elementNumber(a)

The inverse of this mapping has not been implemented.

**companionMatrix - Companion matrix of the Galois field over its ground field**

companionMatrix()

**companionPowers - Power of the companion matrix**

companionPowers()

**matrixRepresentation - Isomorphism to the algebra generated by the companion matrix**

matrixRepresentation(a)

If  $A$  is the companion matrix, the image of  $\sum_i a_i X^i$  is  $\sum_i a_i A^i$ .

**randomPrimitive - Choose a primitive element at random**

randomPrimitive()

**isBasis - Test elements for being a basis over the ground field**

isBasis(l)

**isNormal - Test whether a given field element is normal**

isNormal(a)

# Dom::GaloisField

---

**randomNormal - Choose normal element at random**

`randomNormal()`

**isPrimitivePolynomial - Test whether a polynomial over the field is primitive**

`isPrimitivePolynomial(h)`

**Conversion Methods**

**convert - Conversion from other types**

`convert(a)`

**convert\_to - Conversion to other types**

`convert_to(a, T)`

**See Also**

**MuPAD  
Domains**

`Dom::AlgebraicExtension` | `Dom::IntegerMod`

**Purpose** Domain of images of sets under mappings

**Syntax** **Domain Creation**

Dom::ImageSet()

**Element Creation**

Dom::ImageSet(f, x, S)

Dom::ImageSet(f, [x1, ], [S1, ])

**Description** **Domain Creation**

Dom::ImageSet is the domain of all sets of complex numbers that can be written as the set of all values taken on by some mapping, i.e., sets of the form  $\{f(x_1, \dots, x_n) \mid x_i \in S_i\}$  for some function  $f$  and some sets  $S_1, \dots, S_n$ .

Image sets are mainly used by solve to express sets like  $\{k \pi \mid k \in \mathbb{Z}\}$ .

Dom::ImageSet belongs to the category Cat::Set—arithmetical and set-theoretic operations are inherited from there.

**Element Creation**

Dom::ImageSet(f, x, S) represents the set of all values that can be obtained by substituting some element of S for x in the expression f.

Dom::ImageSet(f, [x1, ...], [S1, ...]) represents the set of all values that can be obtained by substituting, for each  $i$ , the identifier  $x_i$  by some element of  $S_i$  in the expression f.

Dom::ImageSet(f, x, S) represents the set  $\{f \mid x \in S\}$ .

Dom::ImageSet(f, [x1, ..., xn], [S1, ..., Sn]) represents the set  $\{f \mid x_i \in S_i, i = 1 \dots n\}$ .

f need not contain x; on the other hand, it may contain other identifiers (free variables).

If a list of several identifiers is given, the identifiers must be distinct.

# Dom::ImageSet

---

$S$  must be a set; see `solve` for an overview of the different kinds of sets in MuPAD.

`Dom::ImageSet` carries out some automatical simplifications that may produce a result of a type different from `Dom::ImageSet`.

`Dom::ImageSet` renames the variables  $x_1, \dots, x_n$ , in order to avoid naming conflicts as well as producing a nicer output.

**Superdomain** `Dom::BaseDomain`

**Categories** `Cat::Set`

**Examples** **Example 1**

We define  $S$  to be the set of all integer multiples of  $\pi$ .

```
S := Dom::ImageSet(ugly*PI, ugly, Z_)
```

$$\{\pi k \mid k \in \mathbb{Z}\}$$

Our ugly variable name has been replaced by a nicer one which suggests that it represents an integer.

We may now apply the usual set-theoretic operations.

```
S intersect Dom::Interval(3..7)
```

$$\{\pi, 2\pi\}$$

**Example 2**

An element of an image set may be obtained by substituting all parameters by some values:

```
S := Dom::ImageSet(a^7 + b^3 + C, [a, b], [Z_, Z_])
```

$$\{k^7 + l^3 + C \mid k \in \mathbb{Z}, l \in \mathbb{Z}\}$$

On calling the `evalParam` method, we have to take care that the variable names have been replaced.

```
Dom::ImageSet::evalParam(S, k = 3, l = 5)
```

$$C + 2312$$

The same may be achieved using the index operator:

```
S[3, 5]
```

$$C + 2312$$

Substituting only for one parameter, we obtain an image set in the other parameter:

```
Dom::ImageSet::evalParam(S, k = 3)
```

$$\{l^3 + C + 2187 \mid l \in \mathbb{Z}\}$$

A parameter may be substituted by itself, meaning that it becomes a free variable:

```
Dom::ImageSet::evalParam(S, k = k)
```

$$\{k^7 + l^3 + C \mid l \in \mathbb{Z}\}$$

The `evalParam` method cannot be used to substitute a free variable:

# Dom::ImageSet

---

```
Dom::ImageSet::evalParam(S, C = 3)
```

$$\{k^7 + l^3 + C \mid k \in \mathbb{Z}, l \in \mathbb{Z}\}$$

```
delete S:
```

## Parameters

**f**

Arithmetical expression

**x**

Identifier or indexed identifier

**S**

Set of any type

## Methods

### Mathematical Methods

#### **changevar - Change the name of a variable**

```
changevar(A, oldvar, newvar)
```

The new variable newvar must not equal any element of the list of variables; this is not checked!

#### **setvar - Set the name of the variable**

```
setvar(A, newvar)
```

```
setvar(A, newvar)
```

For an argument A that is not an image set, the method "setvar" is applied to all image sets contained in the expression A. A might be, for example, a union, intersection, etc. of image sets and other sets.

#### **homogpointwise - Define an n-ary pointwise operator for image sets**

```
homogpointwise(Op)
```

Op must accept arithmetical expressions as arguments.

## **isEmpty - Test whether a set is empty**

isEmpty(A)

## **substituteBySet - Substitute an ImageSet for a variable**

substituteBySet(a, x, A)

## **freeIndets - Free parameters of a set**

freeIndets(A)

If  $A = \{f(x_1, \dots, x_n, y_1, \dots, y_k) \mid x_i \in S_i\}$ , the  $x_i$  are called bound and the  $y_i$  are called free parameters.

Use the slot "variables" to obtain the bound parameters.

## **evalParam - Insert values for bound parameters**

evalParam(A(x = value, ))

If x is not a parameter, but a free variable of A, it is not substituted by value.

value may be an identifier or contain identifiers; in particular, it may contain x and/or some of the remaining parameters. This may be used to convert parameters into free variables.

Several parameters may be replaced in a single call.

See "Example 2" on page 6-198.

## **\_index - Extract element by inserting values for bound parameters**

\_index(A, value1, )

The number of values passed must match the number of variables of A.

It is not checked whether for each  $i$ , the value for the  $i$ th parameter belongs to the  $i$ th set.

See "Example 2" on page 6-198.

# Dom::ImageSet

---

## Access Methods

### **expr - Defining mapping as an expression**

expr(A)

This method overloads the function expr.

### **variables - List of variables**

variables(A)

The free parameters (identifiers appearing in  $f$  other than the  $x_i$ ) can be obtained using the "freeIndets" slot.

### **nvars - Number of variables**

nvars(A)

### **sets - List of sets**

sets(A)

## Technical Methods

### **print - Print image set**

print(A)

**Purpose** Ring of integer numbers

**Syntax** `Dom::Integer(x)`

**Description** `Dom::Integer` is the ring of integer numbers represented by elements of the domain `DOM_INT`.

Elements of `Dom::Integer` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is an integer number. This means that `Dom::Integer` is a façade domain which creates elements of domain type `DOM_INT`.

Viewed as a differential ring `Dom::Integer` is trivial, it contains constants only.

`Dom::Integer` has the domain `Dom::Numerical` as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Integer`. Methods described below are those implemented by `Dom::Integer`.

**Superdomain** `Dom::Numerical`

**Axioms** `Ax::canonicalRep`, `Ax::systemRep`, `Ax::canonicalOrder`,  
`Ax::canonicalUnitNormal`, `Ax::closedUnitNormals`,  
`Ax::efficientOperation("_divide")`,  
`Ax::efficientOperation("_mult")`

**Categories** `Cat::EuclideanDomain`, `Cat::FactorialDomain`,  
`Cat::DifferentialRing`, `Cat::OrderedSet`

**Examples** **Example 1**

Creating some integer numbers using `Dom::Integer`. This example also shows that `Dom::Integer` is a façade domain.

```
Dom::Integer(2); domtype(%)
```

# Dom::Integer

---

2

DOM\_INT

Dom::Integer(2/3)

Error: The arguments are invalid. [Dom::Integer::new]

## Example 2

By tracing the method `Dom::Integer::testtypeDom` we can see the interaction between `testtype` and `Dom::Integer::testtypeDom`.

```
prog::trace(Dom::Integer::testtypeDom):
delete x:
testtype(x, Dom::Integer);
testtype(3, Dom::Integer);
prog::untrace(Dom::Integer::testtypeDom):
```

```
enter Dom::Integer::testtypeDom(x, Dom::Integer)
computed FALSE
```

FALSE

```
enter Dom::Integer::testtypeDom(3, Dom::Integer)
computed TRUE
```

TRUE

## Parameters

**x**

An integer

## Methods

Mathematical Methods

**associates - Associate elements**

associates(x, y)

**\_divide - Division of two objects**

\_divide(x, y)

**\_divides - Decide if a number divides another one**

\_divides(x, y)

**euclideanDegree - Euclidean degree**

euclideanDegree(x)

**factor - Factorization**

factor(x)

**gcd - Gcd computation**

gcd(x1, x2, )

**gcdex - Apply the extended Euclidean algorithm**

gcdex(x, y)

**\_invert - Inverse of an element**

\_invert(x)

**irreducible - Prime number test**

irreducible(x)

**isUnit - Test if an element is a unit**

# Dom::Integer

---

isUnit(x)

**lcm - Compute the lcm**

lcm(x1, x2, ...)

**quo - Compute the euclidean quotient**

quo(x, y)

**random - Random number generation**

random()

random(n)

random(m .. n)

This methods returns a random number between 0 and  $n - 1$ .

This methods returns a random number between  $m$  and  $n$ .

**rem - Compute the Euclidean remainder**

rem(x, y)

**unitNormal - Unit normal part**

unitNormal(x)

**unitNormalRep - Unit normal representation**

unitNormalRep(x)

Conversion Methods

**convert - Conversion of objects**

convert(x)

**convert\_to - Conversion to other domains**

convert\_to(x, T)

The following domains are allowed for T: DOM\_INT, Dom::Integer, Dom::Rational, DOM\_FLOAT, Dom::Float and Dom::Numerical.

**testtype - Type checking**

`testtype(x, T)`

Usually, this method is called from the function `testtype` and not directly by the user. “Example 2” on page 6-204 demonstrates this behavior.

## MuPAD Domains

`Dom::Complex` | `Dom::Float` | `Dom::Numerical` | `Dom::Rational`  
| `Dom::Real`

# Dom::IntegerMod

---

**Purpose** Residue class rings modulo integers

**Syntax** **Domain Creation**  
`Dom::IntegerMod(n)`

**Element Creation**  
`Dom::IntegerMod(n)(a)`

**Description** **Domain Creation**  
`Dom::IntegerMod(n)` creates the residue class ring of integers modulo  $n$ .  
`Dom::IntegerMod(n)` creates the integer residue class rings  $\mathbb{Z}/n\mathbb{Z}$ .

**Element Creation**  
`Dom::IntegerMod(n)(a)` creates the residue class of  $a$  modulo  $n$ .

**Superdomain** `Dom::BaseDomain`

**Axioms** `Ax::normalRep, Ax::canonicalRep, Ax::noZeroDivisors,`  
`Ax::closedUnitNormals, Ax::canonicalUnitNormal,`  
`Ax::efficientOperation("_invert"),`  
`Ax::efficientOperation("_divide"),`  
`Ax::efficientOperation("_mult")`

**Categories** If  $n$  is prime, then `Cat::Field`, else `Cat::CommutativeRing`.

**Examples** **Example 1**

We define the residue class ring of the integers mod 7:

```
Z7:= Dom::IntegerMod(7)
```

```
Dom::IntegerMod(7)
```

Next, we create some elements:

```
a:= Z7(1); b:= Z7(2); c:= Z7(3)
```

```
1 mod 7
```

```
2 mod 7
```

```
3 mod 7
```

We may use infix notation for arithmetical operations since the operators have been overloaded:

```
a + b, a*b*c, 1/c, b/c/a/c
```

```
3 mod 7, 6 mod 7, 5 mod 7, 1 mod 7
```

a and b are squares while c is not:

```
Z7::isSquare(a), Z7::isSquare(b), Z7::isSquare(c)
```

```
TRUE, TRUE, FALSE
```

Indeed, c is a generator of the group of units:

```
Z7::order(a), Z7::order(b), Z7::order(c)
```

```
1, 3, 6
```

## Parameters

**n**

Positive integer greater than 1

# Dom::IntegerMod

---

## **a**

Any integer or a rational number whose denominator is coprime to  $n$

## **Entries**

|                  |                                                   |
|------------------|---------------------------------------------------|
| "characteristic" | the characteristic of the residue class ring, $n$ |
| "one"            | the unit element, $1 \bmod n$                     |
| "zero"           | the zero element, $0 \bmod n$                     |

## **Methods**

### **Mathematical Methods**

#### **divide - Division of two elements**

`_divide(element1, element2)`

#### **invert - Invert elements**

`_invert(element)`

#### **mult - Multiply elements**

`_mult(element, )`

#### **negate - Negate elements**

`_negate(element)`

#### **plus - Add elements**

`_plus(element, )`

#### **power - Power of elements**

`_power(element, power)`

#### **subtract - Subtraction of two elements**

`_subtract(element1, element2)`

#### **D - Return derivative**

Inherited from `Cat::CommutativeRing`.

**associates - Test for associate elements**

Inherited from `Cat::Field`.

**coerce - Coerce into this domain**

Inherited from `Cat::BaseCategory`.

**diff - Differentiate element**

Inherited from `Cat::CommutativeRing`.

**divide - Division with remainder**

Inherited from `Cat::Field`.

**divides - Test if division is exact**

Inherited from `Cat::Field`.

**equal - Test for mathematical equality**

Inherited from `Dom::BaseDomain`.

**equiv - Test for equivalence**

Inherited from `Cat::BaseCategory`.

**euclideanDegree - Return Euclidean degree**

Inherited from `Cat::Field`.

**factor - Unique factorization**

Inherited from `Cat::Field`.

**gcd - Greatest common divisor**

Inherited from `Cat::Field`.

**gcdex - Extended greatest common divisor**

Inherited from `Cat::EuclideanDomain`.

**idealGenerator - Generator of finitely generated ideal**

Inherited from `Cat::EuclideanDomain`.

**irreducible - Test if element is irreducible**

# Dom::IntegerMod

---

Inherited from `Cat::Field`.

## **isUnit - Test if element is an unit**

Inherited from `Cat::Field`.

## **isone - Test if element is one**

Inherited from `Cat::Monoid`.

## **lcm - Least common multiple**

Inherited from `Cat::GcdDomain`.

## **quo - Return Euclidean quotient**

Inherited from `Cat::Field`.

## **rem - Return Euclidean remainder**

Inherited from `Cat::Field`.

## **sqrfree - Square-free factorization**

Inherited from `Cat::Field`.

## **testtype - Test type of object**

Inherited from `Cat::BaseCategory`.

## **isSquare - Test for being a square**

`isSquare(element)`

## **iszero - Zero test**

`iszero(element)`

## **ln - Discrete logarithm**

`ln(element, base)`

The result is infinity if `element` is not in the subgroup generated by `base`.

The result is FAIL if `base` is not a unit.

## **order - Order**

`order(element)`

The result is FAIL if element is not a unit.

## Access Methods

### **subs - Avoid substitution**

Inherited from Dom::BaseDomain.

### **subsex - Avoid extended substitution**

Inherited from Dom::BaseDomain.

## Conversion Methods

### **TeX - TeX output**

`TeX(element)`

### **convert - Conversion**

`convert(number)`

The conversion fails if the denominator of number and the modulus n are not relatively prime.

### **convert\_to - Conversion**

`convert_to(element, d)`

### **expr - Convert an element to an expression**

`expr(element)`

## Technical Methods

### **allAxioms - Return all axioms**

Inherited from Dom::BaseDomain.

### **allCategories - Return all categories**

Inherited from Dom::BaseDomain.

### **allEntries - Return the names of all entries**

# Dom::IntegerMod

---

Inherited from Dom::BaseDomain.

## **allSuperDomains - Return all super-domains**

Inherited from Dom::BaseDomain.

## **getAxioms - Return axioms stated in the constructor**

Inherited from Dom::BaseDomain.

## **getCategories - Return categories stated in the constructor**

Inherited from Dom::BaseDomain.

## **getSuperDomain - Return super-domain stated in the constructor**

Inherited from Dom::BaseDomain.

## **hasProp - Test for a certain property**

Inherited from Dom::BaseDomain.

## **info - Print short information about this domain**

Inherited from Dom::BaseDomain.

## **new - Create element of this domain**

Inherited from Cat::BaseCategory.

random()

## **undefinedEntries - Return missing entries**

Inherited from Dom::BaseDomain.

## **unitNormal - Unit normal form**

Inherited from Cat::Field.

## **unitNormalRep - Unit normal representation**

Inherited from `Cat::Field`.

## **whichEntry - Return the domain or category implementing an entry**

Inherited from `Dom::BaseDomain`.

## **See Also**

## **MuPAD Domains**

`Dom::Integer` | `Dom::GaloisField`

# Dom::Interval

---

**Purpose** Intervals of real numbers

**Syntax** Dom::Interval(l, r)  
Dom::Interval([l], r)  
Dom::Interval(l, [r])  
Dom::Interval([l], [r])  
Dom::Interval([l, r])

**Description** Dom::Interval represents the set of all intervals of real numbers.

Dom::Interval(l, r) creates the interval of all real numbers between l and r. If a border is given as a list with l or r as the sole element, this border will be regarded as a closed border, otherwise the interval does not contain l and r.

A border can be any arithmetical expression that could represent a real number, e.g., sqrt(2\*x) and a + I. Properties are ignored.

The domain Dom::Interval provides fundamental operations to combine intervals with intervals and other mathematical objects.

The return value can be either an interval of type Dom::Interval or the empty set of type DOM\_SET, if the interval is empty.

Most mathematical operations are overloaded to work with intervals (such as sin). If  $f$  is a function of  $n$  real variables, its extension to intervals is defined to be  $f(J_1, \dots, J_n) = \{f(j_1, \dots, j_n) \mid j_i \in J_i\}$ . The return value of such an operation is in most cases an interval, a union of intervals, a Dom::ImageSet or a set. For example, the sine of an interval [a, b] is the interval {sin(x), x in [a, b]} that contains all sine values of the given interval. In general, you should expect the return value to be an interval larger than strictly necessary. Also note that, when using the same interval twice in one formula, the uses are regarded as independent, so interval1/interval1 does not return the interval [1, 1] as you might expect.

The functions overloaded in this way are:

- `_mult`, `_divide`, `_invert`, `_power`

- `_plus`, `_negate`, `_subtract`
- `abs`
- `cos`, `arccos`, `cosh`, `arccosh`, `cot`, `arccot`, `coth`, `arccoth`, `csc`, `arccsc`, `csch`, `arccsch`, `sec`, `arcsec`, `sech`, `arcsech`, `sin`, `arcsin`, `sinh`, `arcsinh`, `tan`, `arctan`, `tanh`, `arctanh`
- `dirac`, `heaviside`
- `exp`, `ln`
- `sign`

Furthermore, an interval is a special type of set. This is reflected by `Dom::Interval` having the category `Cat::Set`. Among the methods inherited from `Cat::Set`, the following are especially important: `intersect`, `minus` and `union`.

An interval can be open or closed. If one border is given as a list with one element `[x]`, then this element `x` is taken as border and the interval will be created as closed at this side. If the interval should be closed at both sides, one list with the both borders as arguments can be given.

**Superdomain** `Dom::BaseDomain`

**Categories** `Cat::Set`, `Cat::AbelianMonoid`

**Examples** **Example 1**

First create a closed interval between 0 and 1.

```
A:= Dom::Interval([0], [1])
```

```
[0, 1]
```

Now another open interval between -1 and 1.

```
B:= Dom::Interval(-1, 1)
```

# Dom::Interval

---

`(-1, 1)`

Intervals can be handled like other objects.

`A + B, A - B, A*B, A/B`

`(-1, 2), (-1, 2), (-1, 1), ℝ`

`2*A, 1 - A, (A - 1)^2`

`[0, 2], [0, 1], [0, 1]`

## Example 2

Standard functions are overloaded to work with intervals.

`sin(B), float(sin(B))`

`(-sin(1), sin(1)), (-0.8414709848, 0.8414709848)`

## Example 3

The next examples shows some technical methods to access and manipulate intervals.

Get the borders and open/closed information about intervals.

`A:= Dom::Interval([0], [1]):  
Dom::Interval::left(A), Dom::Interval::leftB(A)`

`0, [0]`

`Dom::Interval::isleftopen(A), Dom::Interval::subleft(A, -1)`

FALSE, [- 1, 1]

## Parameters

**l**

The left border. If given as a list of one element (the left border), the interval will be created as left closed.

**r**

The right border. If given as a list of one element (the right border), the interval will be created as right closed.

## Entries

"one"

the unit element; it equals the one-point interval [1, 1].

"zero"

the zero element; it equals the one-point interval [0, 0].

## Methods

**Mathematical Methods**

**Im - Imaginary part of an interval (this always equals zero)**

Im(interval)

**Re - Real part of an interval (this is the interval)**

Re(interval)

**\_divide - Divide intervals**

\_divide(interval1, interval2)

**\_intersect - Intersection of sets**

Inherited from Cat::Set.

**\_invert - Invert intervals**

\_invert(interval)

**\_minus - Set of subtractions**

# Dom::Interval

---

Inherited from `Cat::Set`.

## **`_mult` - Set of product of set elements**

Inherited from `Cat::Set`.

## **`_negate` - Negate intervals**

`_negate(interval)`

## **`_plus` - Set of sums of set elements**

Inherited from `Cat::Set`.

## **`_power` - Pointwise power**

Inherited from `Cat::Set`.

## **`_union` - Union of sets**

Inherited from `Cat::Set`.

## **`abs` - Absolute value of intervals**

`abs(interval)`

## **`arccos` - Inverse cosine of intervals**

`arccos(interval)`

## **`arccosh` - Area cosine of intervals**

`arccosh(interval)`

## **`arccot` - Inverse cotangent of intervals**

`arccot(interval)`

## **`arccoth` - Area cotangent of intervals**

`arccoth(interval)`

## **`arcsin` - Inverse sine of intervals**

`arcsin(interval)`

## **`arcsinh` - Area sine of intervals**

`arcsinh(interval)`

**arctan - Inverse tangent of intervals**

arctan(interval)

**arctanh - Area tangent of intervals**

arctanh(interval)

**coerce - Coerce into this domain**

Inherited from `Cat::BaseCategory`.

**contains - Containing an element**

contains(interval, element)

**cos - Cosinu of intervals**

cos(interval)

**cosh - Hyperbolic cosinus of intervals**

cosh(interval)

**cot - Cotangent of intervals**

cot(interval)

**coth - Hyperbolic cotangent of intervals**

coth(interval)

**dirac - Dirac distribution of an interval**

dirac(interval)

**equiv - Test for equivalence**

Inherited from `Cat::BaseCategory`.

**exp - Exponential function of an interval**

exp(interval)

**heaviside - Heaviside function**

heaviside(interval)

**intmult - Return integer multiple**

# Dom::Interval

---

Inherited from `Cat::AbelianMonoid`.

## **ln - Natural logarithm of an interval**

`ln(interval)`

## **max - Maximum of an interval**

`max(interval, )`

The maximum of intervals is the set of all possible results of the function `max` when applied to a sequence of arguments consisting of exactly one element of each interval.

## **min - Minimum of an interval**

`min(interval, )`

The minimum of intervals is defined analogously to their maximum.

## **new - Create an interval**

`new(left, right)`

`new([left], right)`

`new(left, [right])`

`new([left], [right])`

## **sign - Signum of an interval**

`sign(interval)`

## **sin - Sine of intervals**

`sin(interval)`

## **sinh - Hyperbolic sine of intervals**

`sinh(interval)`

## **tan - Tangent of intervals**

`tan(interval)`

## **tanh - Hyperbolic tangent of intervals**

`tanh(interval)`

## Access Methods

### **borders - Border of an interval**

`borders(interval)`

### **left - Left border of an interval**

`left(interval)`

### **leftB - Left border of an interval**

`leftB(interval)`

# Dom::LinearOrdinaryDifferentialOperator

---

## Purpose

Domain of linear ordinary differential operators

## Syntax

### Domain Creation

Dom::LinearOrdinaryDifferentialOperator(<Var,  
<DVar, <Ring>>>)

### Element Creation

Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(p)  
Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(l)  
Dom::LinearOrdinaryDifferentialOperator(Var,  
DVar, Ring)(eq, yx)

## Description

Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)  
creates the domain of linear ordinary differential operators with  
coefficients in the differential ring Ring and with derivation Var  
where DVar is the differential indeterminate. Elements of this  
domain are also called Ore polynomials and the multiplication  
of two elements is completely determined by the prescribed rule

$\text{Var } r = r \text{ Var} + \frac{\partial}{\partial \text{DVar}} r$  for every element  $r$  in Ring. And so  
Dom::LinearOrdinaryDifferentialOperator is a noncommutative  
ring.

---

**Note** Nevertheless, for some reasons, for every element  $r$  in Ring,  
 $\text{Var} * r$  is automatically rewritten as  $r * \text{Var}$ . See “Example 1” on page  
6-228.

---

If Dom::LinearOrdinaryDifferentialOperator is called  
without any argument, a domain with coefficients in  
Dom::ExpressionField(normal) with derivation Df and differential  
indeterminate x is created.

# Dom::LinearOrdinaryDifferentialOperator

---

---

**Note** Only commutative differential rings of type `DOM_DOMAIN` are allowed which inherit from `Dom::BaseDomain`. If `Ring` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

---

---

**Note** It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it can happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

---

## Examples

### Example 1

First we create the domain of linear ordinary differential operators:

```
lodo := Dom::LinearOrdinaryDifferentialOperator()
```

```
Dom::LinearOrdinaryDifferentialOperator(Df, x, Dom::ExpressionField(normal, iszero * normal))
```

by default the above domain has coefficients in the field `Dom::ExpressionField(normal)` with derivation `Df` and differential indeterminate `x`.

We can create elements of `lodo` in 3 ways: polynomials in `Df`, list of elements of `Dom::ExpressionField` and with a linear ordinary homogeneous differential equation:

```
lodo(Df^2 + (x + 1)*Df + 2*x), lodo([2*x, x + 1, 1]),
lodo(diff(y(x),x,x) + (x + 1)*diff(y(x),x) + 2*x*y(x), y(x))
```

```
Df2 + (x + 1) Df + 2 x, Df2 + (x + 1) Df + 2 x, Df2 + (x + 1) Df + 2 x
```

# Dom::LinearOrdinaryDifferentialOperator

It's easy to obtain the linear differential equation associated to a linear differential operator:

```
L := lodo((x + x^3)*Df^3 + (6*x^2 + 3)*Df^2 - 12):
L(y(x))
```

$$6x^2 \frac{\partial^2}{\partial x^2} y(x) - 12 y(x) + x \frac{\partial^3}{\partial x^3} y(x) + x^3 \frac{\partial^3}{\partial x^3} y(x) + 3 \frac{\partial^2}{\partial x^2} y(x)$$

and one can also evaluate a differential operator at an expression:

```
L(2*x^2 + 1), L(ln(x)), L(ln(x), Unsimplified)
```

$$0, -\frac{12x^2 \ln(x) + 4x^2 + 1}{x^2}, \frac{2(x^3 + x)}{x^3} - \frac{6x^2 + 3}{x^2} - 12 \ln(x)$$

Multiplication of elements of lodo is noncommutative but for every element  $r$  of the coefficients ring one has  $Df*r = r*Df$ :

```
lodo(x^2*Df), lodo(Df*x^2), lodo(Df)*lodo(x^2)
```

$$x^2 Df, x^2 Df, x^2 Df + 2x$$

## Example 2

Dom::LinearOrdinaryDifferentialOperator is a domain where the Euclidean division exists but one has to precise if the multiplication of 2 elements of this domain is made on the right or on the left side:

```
L1 := lodo(x*Df^3 + (x^2 - 3)*Df^2 + 4*x*Df + 2):
lodo::leftDivide(L1, lodo(x*Df + 1))
```

# Dom::LinearOrdinaryDifferentialOperator

---

|           |                                  |
|-----------|----------------------------------|
| quotient  | $Df^2 + \frac{Df(x^2-4)}{x} + 2$ |
| remainder | 0                                |

```
lodo(x*Df + 1) * %[quotient] = L1
```

$$x Df^3 + (x^2 - 3) Df^2 + (4 x) Df + 2 = x Df^3 + (x^2 - 3) Df^2 + (4 x) Df + 2$$

Hence one has the notions of greatest common divisor, least common multiple on the right and on the left, and a modified version of the extended Euclidean algorithm:

```
L2 := lodo(x*Df + 1):
ree := lodo::rightExtendedEuclid(L1,L2)
```

$$\left[ \left[ -\frac{12}{x^2}, 1, -Df^2 - \frac{x^2-6}{x} Df - \frac{2(x^2+6)}{x^2} \right], \left[ \frac{x^3}{12} Df + \frac{x^2}{4}, -\frac{x^3}{12} Df^3 + \left( \frac{x^2}{4} - \frac{x^4}{12} \right) Df^2 - \frac{x^3}{2} Df - \frac{x^2}{2} \right] \right]$$

The right greatest common divisor and the left least common multiple can be read from the above list:

```
iszero(lodo::rightGcd(L1,L2) - ree[1][1]),
iszero(ree[1][1] - (ree[1][2]*L1 + ree[1][3]*L2)),
iszero(lodo::leftLcm(L1,L2) - (-ree[2][1]*L1)),
iszero(-ree[2][1]*L1 - ree[2][2]*L2)
```

TRUE, TRUE, TRUE, TRUE

# Dom::LinearOrdinaryDifferentialOperator

## Example 3

One can compute polynomial, rational and exponential zeros of linear differential operators of any degree provided the ring Ring is the field of rational functions of x

```
L3 := lodo((x^2 + 1)*x*Df^3 + 3*(2*x^2 + 1)*Df^2 - 12):
lodo::rationalZeros(L3), lodo::exponentialZeros(L3)
```

$$\left\{x^2 + \frac{1}{2}\right\}, \left\{x^2 + \frac{1}{2}, x\sqrt{x^2 + 1}\right\}$$

even when the operator contains some parameters rationally:

```
lodo::exponentialZeros(
lodo(Df^4 + (b*1 - 2*a^2 - a*1*x)*Df^2 + a^4 - a^2*b*1 + a^3*1*x))
```

$$\left\{e^{ax}, e^{-ax}\right\}$$

## Example 4

One can factorize linear differential operators into irreducible factors when the ring Ring is the field of rational functions of x. Nevertheless, the algorithm is complete only for operators of degree at most 3; for higher degree only left and right factors of degree 1 are found:

```
factor(lodo((x^2 + 1)*x*Df^3 + 3*(2*x^2 + 1)*Df^2 - 12)),
factor(lodo(Df^3 + a*x*Df + a + b^3 + a*b*x))
```

$$\left((x(x^2 + 1))Df + 5x^2 + 3\right) \left(Df + \frac{x(6x^2 + 5)}{(x^2 + 1)(2x^2 + 1)}\right) \left(Df - \frac{4x}{2x^2 + 1}\right), (Df + b)(Df^2 - bDf + \dots)$$

Here the operator factors into two factors of degree 2 which cannot be found by MuPAD:

# Dom::LinearOrdinaryDifferentialOperator

---

```
factor(lodo(Df^2 + x^3 + 1/x^3) * lodo(Df^2 + x^2 - 1/x^3))
```

$$Df^4 + (x^2 + x^3) Df^2 + \frac{2(2x^5 + 3)}{x^4} Df + \frac{-12x + x^5 + x^6 + x^{11} - 1}{x^6}$$

## Example 5

Solving linear differential operators using the command solve is also possible:

```
solve(lodo(Df^2 + (3 - x)/(16*x^2)))
```

$$\left\{ x^{1/4} e^{-\frac{\sqrt{x}}{2}}, x^{1/4} e^{\frac{\sqrt{x}}{2}} \right\}$$

For certain cases, where the groups associated to the differential operators are finite primitive groups of degree 2, a polynomial is returned corresponding to the minimal polynomial of all zeros of the differential operator (they are algebraic over the base field):

```
solve(lodo(Df^2 + (-27*x + 32*x^2 + 27)/(144*x^2 - 288*x^3 + 144*x^4)))
```

$$\left\{ \text{RootOf}(y^{24} + (-4320 x^2 (x-1)^3) y^{16} + ((51840 \sqrt{3} i) x^3 (x-2) (x-1)^4) y^{12} + (-2799360 x^4 + ((4478976 \sqrt{3} i) x^5 (x-2) (x-1)^7) y^4 + 2985984 x^8 (x-1)^8), y) \right\}$$

For linear differential operators of degree greater than 3 only exponential zeros will be found:

```
solve(lodo(x*Df^4 + (-x + 4)*Df^3 - 3*Df^2 - x^2*Df - x + x^2))
```

# Dom::LinearOrdinaryDifferentialOperator

$$\left\{ \frac{e^x}{x} \right\}$$

Certain second degree linear differential operator can be solved in terms of some special functions (nonliouvillian functions) such as `airyAi`, `bessell` and `whittakerM`:

```
solve(lodo(Df^2 - (x + 1)/(x - 1)^5))
```

$$\left\{ \text{airyAi}\left(-\frac{2 \cdot 2^{1/3} \sqrt{3} i + 2 \cdot 2^{1/3} x + 2 \cdot 2^{1/3} + 2 \cdot 2^{1/3} \sqrt{3} x i}{8 x - 8}, 0\right) (x - 1), \right. \\ \left. \text{airyBi}\left(-\frac{2 \cdot 2^{1/3} \sqrt{3} i + 2 \cdot 2^{1/3} x + 2 \cdot 2^{1/3} + 2 \cdot 2^{1/3} \sqrt{3} x i}{8 x - 8}, 0\right) (x - 1) \right\}$$

```
solve(lodo(Df^2 - (243 + 4*x^8 + 162*x^2 + 19*x^4)/
 36/x^2/(x^2 + 3)^2))
```

$$\left\{ \frac{M_{\frac{1}{2}, -\frac{2}{3}}\left(\frac{x^2}{3} + 1\right)}{\sqrt{x}}, \frac{W_{\frac{1}{2}, -\frac{2}{3}}\left(\frac{x^2}{3} + 1\right)}{\sqrt{x}} \right\}$$

## Parameters

### Var

An indeterminate of type `DOM_IDENT`. Default is `Df`.

### DVar

A differential indeterminate of type `DOM_IDENT`. Default is `x`.

### Ring

An arbitrary commutative differential ring of characteristic zero. Default is `Dom::ExpressionField(normal)`.

# Dom::LinearOrdinaryDifferentialOperator

---

**p**

A polynomial expression in Var.

**l**

A list corresponding to the coefficients of the differential operator. If  $n$  is the length of  $l$  then the result returned is  $l[1] + l[2]*\text{Var} + \dots + l[n]*\text{Var}^{(n-1)}$ .

**eq**

A linear homogeneous differential equation.

**yx**

A function of DVar representing the dependent variable of the above linear differential equation.

## Methods

### Mathematical Methods

#### **\_mult - Multiply linear differential operators**

`_mult(<a, b, >)`

This method overloads the function `_mult` of the system kernel, i.e. one may use it either in the form `a * b * ...` or in functional notation `_mult(a, b, ...)`.

#### **\_negate - Negate a linear differential operator**

`_negate(a)`

This method overloads the function `_negate` of the system kernel, i.e. one may use it either in the form `-a` or in functional notation `_negate(a)`.

#### **\_plus - Add linear differential operators and coefficient ring elements**

`_plus(<a, b, >)`

# Dom::LinearOrdinaryDifferentialOperator

---

This method overloads the function `_plus` of the system kernel, i.e. one may use it either in the form `a + b + ...` or in functional notation `_plus(a, b, ...)`.

## **`_power` - Nth power of a linear differential operator**

`_power(a, n)`

This method overloads the function `_power` of the system kernel, i.e., one may use it either in the form `a^n` or in functional notation `_power(a,n)`.

## **`_subtract` - Subtract a linear differential operator**

`_subtract(a, b)`

This method overloads the function `_subtract` of the system kernel, i.e. one may use it either in the form `a - b` or in functional notation `_subtract(a, b)`.

## **`adjoint` - Adjoint of a linear differential operator**

`adjoint(a)`

## **`companionSystem` - Companion matrix of a linear differential operator**

`companionSystem(a)`

If `a` is not of positive degree, an error message is issued.

## **`D` - Derivative of a linear differential operator**

`D(<l>, a)`

## **`Dpoly` - Derivative of a linear differential operator**

`Dpoly(<l>, a)`

`Dpoly(l, a)` computes the partial derivative of `a` with respect to `l`. If `l = [1, ..., 1]` with `length(l) = n` then the method computes the `n`-th derivative `a`. If `l = []` then the result returned is `a`.

## **`evalLODO` - Apply an expression to a linear differential operator**

`evalLODO(a, f)`

# Dom::LinearOrdinaryDifferentialOperator

---

This method may be used either in the form  $a(f)$  or in functional notation `evalLODO(a, f)`.

## **exponentialZeros - Exponential zeros of a linear differential operator**

`exponentialZeros(a)`

---

**Note** This method only works when `Ring` is the field of rational functions in `DVar`.

---

## **factor - Factor a linear differential operator**

`factor(a)`

---

**Note** This method is only available when the base field `Ring` is the field of rational functions in `DVar`. If `a` is of degree greater than or equal to 4 then only left and right factors of degree 1 of `a` will be found. Otherwise, a complete factorization is returned.

---

This method overloads the function `factor` of the system kernel.

## **factors - List of irreducible factors of a linear differential operator**

`factors(a)`

## **func\_call - Apply an expression to a linear differential operator**

`func_call(a, f, <Unsimpified>)`

This method may be used either in the form  $a(f)$  or in functional notation `func_call(a, f)`.

## **leftDivide - Left division of 2 linear differential operators**

`leftDivide(a, b)`

# Dom::LinearOrdinaryDifferentialOperator

---

**leftExtendedEuclid** - Left extended Euclidean algorithm for linear differential operators

```
leftExtendedEuclid(a, b)
```

**leftExtendedGcd** - Coefficient in the left extended Euclidean algorithm

```
leftExtendedGcd(a, b)
```

**leftGcd** - Left greatest common divisor of linear differential operators

```
leftGcd(a, b)
```

**leftLcm** - Left least common multiple of linear differential operators

```
leftLcm(a, b)
```

**leftQuotient** - Left quotient of linear differential operators

```
leftQuotient(a, b)
```

**leftRemainder** - Left remainder of linear differential operators

```
leftRemainder(a, b)
```

**makeIntegral** - Integral form of a linear differential operator

```
makeIntegral(a)
```

**monic** - Normalize a linear differential operator

```
monic(a)
```

**polynomialZeros** - Polynomial zeros of a linear differential operator

```
polynomialZeros(a)
```

---

**Note** This method only works when Ring is the field of rational functions in DVar.

---

# Dom::LinearOrdinaryDifferentialOperator

---

## **rationalZeros - Rational zeros of a linear differential operator**

rationalZeros(a)

---

**Note** This method only works when Ring is the field of rational functions in DVar.

---

## **rightDivide - Right division of 2 linear differential operators**

rightDivide(a, b)

## **rightExtendedEuclid - Right extended Euclidean algorithm for linear differential operators**

rightExtendedEuclid(a, b)

## **rightExtendedGcd - Coefficient in the right extended Euclidean algorithm**

rightExtendedGcd(a, b)

## **rightGcd - Right greatest common divisor of linear differential operators**

rightGcd(a, b)

## **rightLcm - Right least common multiple of linear differential operators**

rightLcm(a, b)

## **rightQuotient - Right quotient of linear differential operators**

rightQuotient(a, b)

## **rightRemainder - Right remainder of linear differential operators**

rightRemainder(a, b)

## **solve - Zero of a linear differential operator**

solve(a, <Transform>, <Irreducible>)

# Dom::LinearOrdinaryDifferentialOperator

---

The algorithm for finding liouvillian solutions is complete for operators of degree at most 2 and enables to solve partially operators of higher degree (i.e. it finds all exponential solutions). The algorithm for finding solutions in terms of special functions (nonliouvillian solutions) is not complete even for the degree 2.

When option `Transform` is given the unimodular transformation is performed unconditionally and when option `Irreducible` is given, `a` is assumed to be irreducible.

---

**Note** This method only works when `Ring` is the field of rational functions in `DVar`.

---

This method overloads the function `solve` of the system kernel.

## **symmetricPower - Symmetric power of a linear differential operator**

`symmetricPower(a, m)`

## **unimodular - Unimodular transformation of a linear differential operator**

`unimodular(a, <Transform>)`

If the option `Transform` is given then `a` is transformed unconditionally even if `a` has yet a unimodular Galois group.

## **Access Methods**

### **coeff - Coefficient of a linear differential operator**

`coeff(a)`

`coeff(a, Var, n)`

`coeff(a, n)`

# Dom::LinearOrdinaryDifferentialOperator

---

`coeff(a, Var, n)` returns the coefficient of the term  $\text{Var}^n$  as an element of the coefficient ring `Ring`, where `a` is a linear differential operator in the variable `Var`.

`coeff(a, n)` returns the coefficient of the term  $\text{Var}^n$  as an element of the coefficient ring `Ring`, where `a` is a linear differential operator in the variable `Var`.

This method overloads the function `coeff` of the system kernel.

## **degree - Degree of a linear differential operator**

`degree(a)`

The degree of the zero polynomial is defined as zero.

This method overloads the function `degree` for polynomials.

## **vectorize - List of coefficients of a linear differential operator**

`vectorize(a)`

## **Conversion Methods**

### **convert - Conversion to a linear differential operator**

`convert(a)`

FAIL is returned if the conversion fails.

### **expr - Conversion into an object of a kernel domain**

`expr(a)`

This method overloads the function `expr` of the system kernel.

### **TeX - TeX formatting of a linear differential operator**

`TeX(a)`

This method is used by the function `generate::TeX`.

## **Algorithms**

Some references on linear differential equations/operators:

- `_mult, _divide, _invert, _power`

- `_plus, _negate, _subtract`
- `abs`
- `cos, arccos, cosh, arccosh, cot, arccot, coth, arccoth, csc, arccsc, csch, arccsch, sec, arcsec, sech, arcsech, sin, arcsin, sinh, arcsinh, tan, arctan, tanh, arctanh`
- `dirac, heaviside`
- `exp, ln`
- `sign`

## Description

### Domain Creation

`Dom::Matrix(R)` creates domains of matrices over a component domain `R` of category `Cat::Rng` (a ring, possibly without unit).

If the optional parameter `R` is not given, `Dom::ExpressionField()` is used as component domain. Matrices of this type accept arbitrary

MuPAD expressions (numbers, symbols etc.) as entries. The name `matrix` is an alias for this default matrix domain `Dom::Matrix()`.

A vector with  $n$  entries is either an  $n \times 1$  matrix (a column vector), or a  $1 \times n$  matrix (a row vector).

Arithmetical operations with matrices can be performed by using the standard arithmetical operators of MuPAD.

E.g., if  $A$  and  $B$  are two matrices defined by `Dom::Matrix(R)`,  $A + B$  computes the sum, and  $A * B$  computes the product of the two matrices, provided that the dimensions are appropriate.

Similarly,  $A^{-1}$  or  $1/A$  computes the inverse of a square matrix  $A$  if it exists. Otherwise, FAIL is returned. See “Example 1” on page 6-247.

Many system functions are overloaded for matrices, such as `map`, `subs`, `has`, `zip`. E.g., use `conjugate` to compute the complex conjugate of a matrix, `norm` to compute matrix norms, or `exp` to compute the exponential of a matrix.

Most of the functions in the MuPAD linear algebra package `linalg` work with matrices. For example, to compute the determinant of a square matrix  $A$ , call `linalg::det(A)`. The command `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on  $A$  to transform  $A$  to its reduced row echelon form.

See the documentation of `linalg` for a list of available functions of this package.

The domain `Dom::Matrix(R)` represents matrices over  $R$  of arbitrary size. Therefore, it does not have any algebraic structure (other than being a *set* of matrices).

In this help page, we use the following notations for a matrix  $A$  (an element of `Dom::Matrix(R)`):

- $nrows(A)$  denotes the number of rows of  $A$ .
- $ncols(A)$  denotes the number of columns of  $A$ .
- A *row index* is an integer in the range from 1 to  $nrows(A)$ .

- A *column index* is an integer in the range from 1 to  $ncols(A)$ .

---

**Note** The number of rows and columns, respectively, of a matrix must be less than  $2^{31}$ .

---

---

**Note** The components of a matrix are no longer evaluated after the creation of the matrix, i.e., if they contain free identifiers they will not be replaced by their values.

---

## Element Creation

`Dom::Matrix(R) (Array)` and `Dom::Matrix(R) (Matrix)` create a new matrix with the dimension and the components of `Array` and `Matrix`, respectively.

The components of `Array` or `Matrix` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

The creation of (sparse) matrices via arrays is useful for matrices of moderate size. Note that indexed assignments to arrays are much faster than the corresponding indexed assignments to matrices. However, since all elements of the array (including the zeroes) need to be filled in before conversion to a (sparse) matrix, memory is wasted for very large and very sparse matrices. In such a situation, one should define a table containing only the non-zero elements and convert the table to a matrix (see below).

`Dom::Matrix(R) (List)` creates an  $m \times 1$  column vector with components taken from the nonempty list, where  $m$  is the number of entries of `List`.

One may also use a list of equations to create an object of `Dom::Matrix`. In this case the entries of the list must be of the form  $(i, j) = \text{value}$ , where  $i$  and  $j$  denote the row and column index and `value` the coefficient of the matrix.  $i$  and  $j$  need to be positive integers.

`Dom::Matrix(R) (ListOfRows)` creates an  $m \ n$  matrix with components taken from the nested list `ListOfRows`, where  $m$  is the number of inner lists of `ListOfRows`, and  $n$  is the maximal number of elements of an inner list. Each inner list corresponds to a row of the matrix. Both  $m$  and  $n$  must be non-zero.

If an inner list has less than  $n$  entries, the remaining components in the corresponding row of the matrix are set to zero.

The entries of the inner lists are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

The call `Dom::Matrix(R) (m, n)` returns the  $m \ n$  zero matrix.

Use the method "identity" to create the  $n \ n$  identity matrix.

The call `Dom::Matrix(R) (m, n, Array)` creates an  $m \ n$  matrix with components taken from `Array`, which must be an array or an `harray`. `Array` must have  $mn$  operands. The first  $m$  operands define the first row, the next  $m$  operands define the second row, etc. The formatting of the array is irrelevant. E.g., any array with 6 elements can be used to create a matrix of dimension 1 6, or 2 3, or 3 2, or 6 1.

`Dom::Matrix(R) (m, n, List)` creates an  $m \ n$  matrix with components taken row after row from the non-empty list. The list must contain  $mn$  entries.

`Dom::Matrix(R) (m, n, ListOfRows)` creates an  $m \ n$  matrix with components taken from the list `ListOfRows`.

If  $m \geq 2$  and  $n \geq 2$ , then `ListOfRows` must consist of at most  $m$  inner lists, each having at most  $n$  entries. The inner lists correspond to the rows of the returned matrix.

If an inner list has less than  $n$  entries, the remaining components of the corresponding row of the matrix are set to zero. If there are less than  $m$  inner lists, the remaining lower rows of the matrix are filled with zeroes.

`Dom::Matrix(R) (m, n, Table)` creates an  $m \ n$  matrix with components taken from the table `Table`.

By defining the entries of the table first, one can easily create large and sparse matrices. The entry `Table[i, j]` of the table will be the entry in the  $i$ -th row and the  $j$ -th column of the matrix. Therefore, the table needs to be indexed by positive integers  $i$  and  $j$ .

`Dom::Matrix(R)(m, n, [(i1, j1) = value1, (i2, j2) = value2, ...])` is a further way to create a matrix specifying only the non-zero entries  $A[i1, j1] = \text{value1}$ ,  $A[i2, j2] = \text{value2}$  etc. The ordering of the entries in the input list is irrelevant.

`Dom::Matrix(R)(m, n, f)` returns the matrix whose  $(i, j)$ -th component is the value of the function call  $f(i, j)$ . The row index  $i$  ranges from 1 to  $m$  and the column index  $j$  from 1 to  $n$ .

The function values are converted to elements of the domain  $R$ . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, Array)` returns the  $1 \times n$  row vector with components taken from `Array`. The array or `hfarray` `Array` must have  $n$  entries.

The entries of the array are converted to elements of the domain  $R$ . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, List)` returns the  $1 \times n$  row vector with components taken from `List`. The list `List` must have at most  $n$  entries. If there are fewer entries, the remaining vector components are set to zero.

The entries of the list are converted to elements of the domain  $R$ . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, Table)` returns the  $1 \times n$  row vector with components taken from `Table`. The table `Table` must not have more than  $n$  entries. If there are fewer entries, the remaining vector components are regarded as zero.

`Dom::Matrix(R)(m, 1, Array)` returns the  $m \times 1$  column vector with components taken from `Array`. The array or `hfarray` `Array` must have  $m$  entries.

The entries of the array are converted to elements of the domain  $R$ . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, 1, List)` returns the  $m \times 1$  column vector with components taken from `List`. The list `List` must have at most  $m$  entries. If there are fewer entries, the remaining vector components are set to zero.

The entries of the list are converted to elements of the domain  $R$ . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, 1, Table)` returns the  $m \times 1$  column vector with components taken from `Table`. The table `Table` must have no more than  $m$  entries. If there are fewer entries, the remaining vector components are regarded as zero.

**Superdomain** `Dom::BaseDomain`

**Axioms** If  $R$  has `Ax::canonicalRep`, then `Ax::canonicalRep`.

**Categories** `Cat::Matrix(R)`

**Examples** **Example 1**

Whenever possible, one should use `Dom::ExpressionField()` as the coefficient domain of matrices – therefore `Dom::ExpressionField()` is the default coefficient domain of matrices.

The components of matrices over `Dom::ExpressionField()` can be arbitrary arithmetical expressions. Consider

```
Mat := Dom::Matrix()
```

```
Dom::Matrix()
```

We assigned the domain to the identifier `Mat` and now we can define a matrix  $A$  of two rows, where each row is a list of two elements by the following line:

## Dom::Matrix

---

```
A := Mat([[1, 5], [2, 3]])
```

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

In the same way, we define the following 2 3 matrix:

```
B := Mat([[-1, 5/2, 3], [1/3, 0, 2/5]])
```

$$\begin{pmatrix} -1 & \frac{5}{2} & 3 \\ \frac{1}{3} & 0 & \frac{2}{5} \end{pmatrix}$$

and perform matrix arithmetic using the standard arithmetical operators of MuPAD, e.g., the matrix product  $AB$ , the fourth power of  $A$  as well as the scalar multiplication of  $A$  times  $\frac{1}{3}$ :

```
A * B, A ^ 4, 1/3 * A
```

$$\begin{pmatrix} \frac{2}{3} & \frac{5}{2} & 5 \\ -1 & 5 & \frac{36}{5} \end{pmatrix}, \begin{pmatrix} 281 & 600 \\ 240 & 521 \end{pmatrix}, \begin{pmatrix} \frac{1}{3} & \frac{5}{3} \\ \frac{2}{3} & 1 \end{pmatrix}$$

The matrices  $A$  and  $B$  have different dimensions, and therefore the sum of  $A$  and  $B$  is not defined. MuPAD issues an error message:

```
A + B
```

```
Error: The dimensions do not match. [(Dom::Matrix(Dom::ExpressionFi
```

To compute the inverse of  $A$ , just enter:

`1/A`

$$\begin{pmatrix} -\frac{3}{7} & \frac{5}{7} \\ \frac{2}{7} & -\frac{1}{7} \end{pmatrix}$$

If a matrix is not invertible, FAIL is the result of this operation. For example, the matrix:

`C := Mat(2, 2, [[2]])`

$$\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

is not invertible, hence:

`C^(-1)`

FAIL

`delete A, B, C:`

### Example 2

We create the domain of matrices over the coefficient ring  
`Dom::ExpressionField():`

`Mat := Dom::Matrix()`

Dom::Matrix()

Beside standard matrix arithmetic, the library `linalg` offers many functions dealing with matrices. For example, if one wants to compute the rank of a matrix, use `linalg::rank`:

```
A := Mat([[1, 2], [2, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$$

```
linalg::rank(A)
```

```
1
```

Use `linalg::eigenvectors` to compute eigenvalues and eigenvectors of the matrix  $A$ :

```
linalg::eigenvectors(A)
```

$$\left[ \left[ 0, 1, \begin{pmatrix} -2 \\ 1 \end{pmatrix} \right], \left[ 5, 1, \begin{pmatrix} \frac{1}{2} \\ 1 \end{pmatrix} \right] \right]$$

Try `info(linalg)` for a list of available functions, or enter `help(linalg)` for details about the library `linalg`.

Some of the functions in the `linalg` package simply serve as “interface” functions for methods of a matrix domain described above. For example, `linalg::transpose` uses the method “`transpose`” to get the transposed matrix. The function `linalg::gaussElim` applies Gaussian elimination to a matrix by calling the method “`gaussElim`”:

```
linalg::gaussElim(A) = A::dom::gaussElim(A)[1]
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

In contrast to the methods of the domain `Dom::Matrix(R)`, the corresponding functions of the `linalg` packages do extended checking of their input parameters. Note that there might be minor differences in the functionality of the `linalg` functions and the matrix methods. E.g., the option `ColumnElimination` is not available in `linalg::gaussElim`, but only in the "gaussElim" method of the matrix domain:

```
A::dom::gaussElim(A, ColumnElimination)
```

$$\left[ \begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix}, 1, 0, \{1\} \right]$$

```
delete A:
```

### Example 3

We create the default matrix domain `Dom::Matrix()`. As a shortcut, this domain can also be created via `matrix`:

```
A := matrix([[1, 2, 3, 4],
 [2, 0, 4, 1],
 [-1, 0, 5, 2]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

```
domtype(A)
```

```
Dom::Matrix()
```

Matrix components can be extracted by the index operator [ ]:

```
A[2, 1] * A[1, 2] - A[3, 1] * A[1, 3]
```

```
7
```

If one of the indices is not in its valid range, an error message is issued. Assignments to matrix components are performed similarly:

```
delete a:
A[1, 2] := a^2: A
```

$$\begin{pmatrix} 1 & a^2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

Beside the usual indexing of matrix components, it is also possible to extract submatrices from a given matrix. The following call creates the submatrix of  $A$  which consists of the rows 2 to 3 and columns 1 to 3 of  $A$ :

```
A[2..3, 1..3]
```

$$\begin{pmatrix} 2 & 0 & 4 \\ -1 & 0 & 5 \end{pmatrix}$$

The index operator does not allow to insert submatrices into a given matrix. This is implemented by the function `linalg::substitute`.

```
delete A:
```

## Example 4

In the following examples, we demonstrate the different ways of creating matrices. We work with matrices defined over the field  $\mathbb{F}_{19}$ , i.e.,

the field of integers modulo 19. This component ring can be created with the domain constructor `Dom::IntegerMod`.

We start by giving a list of rows, where each row is a list of row entries:

```
MatZ19 := Dom::Matrix(Dom::IntegerMod(19)):
MatZ19([[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

The elements of the two inner lists, the row entries, were converted to elements of the domain `Dom::IntegerMod(19)`.

The number of rows is the number of sublists of the argument, i.e.,  $m = 2$ . The number of columns is determined by the length of the inner list with the most entries, which is the first inner list with two entries. Missing entries in the other inner lists are treated as zero components. The call:

```
MatZ19(4, 4, [[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

fixes the dimension of the matrix. Missing entries and inner lists are treated as zero components and zero rows, respectively.

An error message is issued if one of the given entries cannot be converted to an element over  $_{19}$ :

```
MatZ19([[2, 3], [-1, I]])
```

```
Error: Cannot define a matrix over 'Dom::IntegerMod(19)'. [(Dom::Ma
```

```
delete MatZ19:
```

## Example 5

This example illustrates how to create a matrix with components given as values of an index function. First we create the 2 2 Hilbert matrix (see also the functions `linalg::hilbert` and `linalg::invhilbert`):

```
Dom::Matrix()(2, 2, (i, j) -> 1/(i + j - 1))
```

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

Note the difference when working with expressions and functions. If you give an expression it is treated as a function in the row and column indices:

```
delete x:
```

```
Dom::Matrix()(2, 2, x), Dom::Matrix()(2, 2, (i, j) -> x)
```

$$\begin{pmatrix} x(1, 1) & x(1, 2) \\ x(2, 1) & x(2, 2) \end{pmatrix}, \begin{pmatrix} x & x \\ x & x \end{pmatrix}$$

## Example 6

Diagonal matrices can be created with the option `Diagonal` and a list of diagonal components:

```
Mat := Dom::Matrix():
Mat(3, 4, [1, 2, 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

Hence, to define the  $n \times n$  identity matrix, you can enter:

```
Mat(3, 3, [1 $ 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

or call:

```
Mat(3, 3, x -> 1, Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The easiest way to create the identity matrix, however, is to use the method "identity":

```
Mat::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

```
delete Mat:
```

### Example 7

Toeplitz matrices can be defined with the option Banded. The following call defines a three-banded matrix with the component 2 on the

main diagonal and the component - 1 on the first subdiagonal and superdiagonal:

```
Dom::Matrix()(4, 4, [-1, 2, -1], Banded)
```

$$\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

## Example 8

Some system functions can be applied to matrices, such as norm, expand, diff, conjugate, or exp.

For example, to expand the components of the matrix:

```
delete a, b:
A := Dom::Matrix()
 [[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a - b)*(a + b)]]
)
```

$$\begin{pmatrix} (a - b)^2 & a^2 + b^2 \\ a^2 + b^2 & (a + b)(a - b) \end{pmatrix}$$

enter:

```
expand(A)
```

$$\begin{pmatrix} a^2 - 2ab + b^2 & a^2 + b^2 \\ a^2 + b^2 & a^2 - b^2 \end{pmatrix}$$

If you want to differentiate the matrix components, then call for example:

```
diff(A, a)
```

$$\begin{pmatrix} 2a - 2b & 2a \\ 2a & 2a \end{pmatrix}$$

To substitute matrix components by some values, enter:

```
subs(A, a = 1, b = -1)
```

$$\begin{pmatrix} 4 & 2 \\ 2 & 0 \end{pmatrix}$$

The function `zip` can also be applied to matrices. The following call combines two matrices  $A$  and  $B$  by dividing each component of  $A$  by the corresponding component of  $B$ :

```
A := Dom::Matrix()([[4, 2], [9, 3]]):
B := Dom::Matrix()([[2, 1], [3, -1]]):
zip(A, B, `/`)
```

$$\begin{pmatrix} 2 & 2 \\ 3 & -3 \end{pmatrix}$$

The quoted character ``/`` is another notation for the function `_divide`, the functional form of the division operator `/`.

If one needs to apply a function to the components of a matrix, then use the function `map`. For example, to simplify the components of the matrix:

```
C := Dom::Matrix()(
 [[sin(x)^2 + cos(x)^2, cos(x)*tan(x)],
```

```
[(a^2 - b^2)/(a + b), 1]]
)
```

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & \cos(x) \tan(x) \\ \frac{a^2 - b^2}{a + b} & 1 \end{pmatrix}$$

call:

```
map(C, Simplify)
```

$$\begin{pmatrix} 1 & \sin(x) \\ a - b & 1 \end{pmatrix}$$

```
delete A, B, C:
```

## Example 9

However, there may appear some unexpected results using the function `diff` in the context of matrices. The derivative of the following unspecified function `f` of a matrix is computed due to the chain rule:

```
diff(f(matrix([[a*x^2, b], [c, d]])), x)
```

$$\begin{pmatrix} 2 a x f' \left( \begin{pmatrix} a x^2 & b \\ c & d \end{pmatrix} \right) & 0 \\ 0 & 0 \end{pmatrix}$$

Usually, the function `f` would implicitly be assumed to be scalar. Hence, the derivative of `f` should be scalar as well. In the above situation the chain rule is applied for differentiation: the inner function is the matrix

containing the symbolic components  $a*x^2$ ,  $b$ ,  $c$  and  $d$ . Its derivative is computed by simply applying `diff` to each component of the matrix:

```
diff(matrix([[a*x^2, b], [c, d]]), x)
```

$$\begin{pmatrix} 2ax & 0 \\ 0 & 0 \end{pmatrix}$$

Finally, the exterior unspecified function  $f$  is implicitly assumed to be scalar, such that each component of the derivative of the inner function is multiplied by the exterior differentiation.

### Example 10

A column vector is represented by a 2 1 matrix:

```
Mat := Dom::Matrix():
v := Mat(2, 1, [1, 2])
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

The dimension of this vector is:

```
Mat::matdim(v)
```

$$[2, 1]$$

The length of a vector may also be queried by `linalg::vecdim` or `nops(v)`:

```
linalg::vecdim(v)
```

2

The  $i$ th component of this vector can be extracted in two ways: either by `v[i, 1]` or by `v[i]`:

`v[1], v[2]`

1, 2

We compute the 2-norm of `v` by the following call:

`norm(v, 2)`

$\sqrt{5}$

`delete Mat, v:`

## Example 11

We create random matrices over the field of the rational numbers. Consider a random matrix `A1` with 3 rows and 3 columns:

```
Mat := Dom::Matrix(Dom::Rational):
A1 := Mat::random(3, 3)
```

$$\begin{pmatrix} -\frac{65}{824} & \frac{221}{72} & -\frac{245}{597} \\ \frac{741}{814} & \frac{229}{220} & \frac{747}{79} \\ \frac{764}{979} & -\frac{535}{617} & -\frac{535}{477} \end{pmatrix}$$

A second matrix `A2` should contain at most 2 non-zero entries. We can create such a matrix by using 2 as the third argument for `random`:

```
A2 := Mat::random(3, 3, 2)
```

$$\begin{pmatrix} 0 & 0 & \frac{905}{906} \\ 0 & 0 & 0 \\ 0 & \frac{4}{133} & 0 \end{pmatrix}$$

The product of these matrices is given by

```
C := A1 * A2
```

$$\begin{pmatrix} 0 & -\frac{140}{11343} & -\frac{58825}{746544} \\ 0 & \frac{2988}{10507} & \frac{223535}{245828} \\ 0 & -\frac{2140}{63441} & \frac{345710}{443487} \end{pmatrix}$$

By default, matrices are displayed like 'dense' arrays with zeroes in the empty places. For sparse matrices of large column and/or row dimension, such a 'dense' print mode is not appropriate: formatting of the print output would be very time consuming. Further, a 'dense' print output is not very informative for sparse matrices. For this reason, the "doprint" method provides a sparse output mode printing only the non-zero entries:

```
C::dom::doprint(C)
```

```
Dom::Matrix(Dom::Rational)(3,3, [(1, 2) = -140/11343, (1, 3) = -58825/746544, (2, 2) = 223535/245828, (3, 2) = -2140/63441, (3, 3) = 345710/443487])
```

With this method, one can also print large sparse matrices. We create a random sparse matrix with 100 rows, 200 columns and at most 6 non-zero entries:

## Dom::Matrix

---

```
X := Mat::random(100, 200, 6): print(X)
```

```
Warning: This matrix is too large for display. To see all nonzero e
```

```
Dom::Matrix(Dom::Rational)(100, 200, ["..."])
```

```
Warning: This matrix is too large for display.
If you want to see all nonzero entries of a matrix, say A, then call
'A::dom::doprint(A)'. [(Dom::Matrix(Dom::Rational))::print]
```

```
Warning: This matrix is too large for display.
If you want to see all nonzero entries of a matrix, say A, then call
'A::dom::doprint(A)'. [(Dom::Matrix(Dom::Rational))::print]
```

```
Dom::Matrix(Dom::Rational)(100, 200, ["..."])
```

The warning speaks for itself.  $X$  is regarded as 'too large for display' since, with the default 'dense' output mode, the sparse matrix would be printed as a huge array-like structure of dimension 100 200 with (integer) zeroes in the empty places. The sparse print mode should be used:

```
X::dom::doprint(X)
```

```
Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 34
= 433/49, (68, 176) = 451/483, (100, 97) = -235/174])
```

For convenience, there is a function `doprint` that calls this method by just entering:

```
doprint(X)
```

```
Dom::Matrix(Dom::Rational)(100,[]200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) =
= 433/49, (68, 176) = 451/483, (100, 97) = -235/174])
```

```
delete Mat, A1, A2, C, X:
```

## Parameters

### R

A ring, i.e., a domain of category `Cat::Rng`. The default ring is `Dom::ExpressionField()`.

### Array

A one- or two-dimensional array or `hfarray`

### Matrix

A matrix, i.e., an element of a domain of category `Cat::Matrix`

### m, n

Matrix dimension (positive integers)

### List

A list of matrix components

### ListOfRows

A list of at most `m` rows; each row given as a list of at most `n` matrix components

### Table

A table of coefficients of the matrix for sparse input

### f

A function or a functional expression with two parameters (the row and column index)

### g

A function or a functional expression with one parameter (the row index)

## Options

### Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function or a functional expression.

`Dom::Matrix(R)(m, n, List, Diagonal)` creates the  $m \times n$  diagonal matrix, whose diagonal elements are the entries of `List`.

`List` must have at most  $\min(m, n)$  entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, n, g, Diagonal)` returns the sparse matrix whose  $i$ th diagonal element is  $g(i, i)$ , where the index  $i$  runs from 1 to  $\min(m, n)$ .

The function values are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

### Banded

Create a Toeplitz matrix

`Dom::Matrix(R)(m, n, List, Banded)` creates an  $m \times n$  Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say  $2h + 1$ , and must not exceed  $2\min(m, n) - 1$ . The bandwidth of the resulting matrix is at most  $2h + 1$ .

A Toeplitz matrix is a matrix where the elements of each band are identical. See also “Example 7” on page 6-255.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the  $i$ -th subdiagonal are initialized with the  $(h + 1 - i)$ -th element of `List`. All elements of the  $i$ -th superdiagonal are initialized with the  $(h + 1 + i)$ -th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

## Entries

"isSparse" is always TRUE.

"randomDimen" is set to [10, 10]. See the method "random" below for details.

## Methods

### Mathematical Methods

#### **`_divide` - Divide matrices**

`_divide(A, B)`

An error message is issued if the dimensions of `A` and `B` do not match.

This method only exists if `R` is a commutative ring with a unit, i.e., a domain of category `Cat::Ring`.

This method overloads the system function `_divide` for matrices, i.e., one may use it in the form `A / B`, or in functional notation: `_divide(A, B)`.

#### **`_invert` - Compute the inverse of a matrix**

`_invert(A, Normal = b)`

This method only exists if `R` is a domain of category `Cat::Ring`.

This method overloads the system function `_invert` for matrices, i.e., one may use it in the form `1/A` or `A^(-1)`, or in functional notation: `_invert(A)`.

If `Normal = TRUE`, then the matrix inverse is always returned in a normalized form. For details about normalization, see `normal`. If `Normal = FALSE`, then the matrix inverse can appear in a normalized form, but normalization is not guaranteed. By default `Normal = TRUE`.

Normal affects the results only if a matrix contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

## **`_mod` - Map the modulo operator to the elements of a matrix**

`_mod(A, n)`

`n` must be non-zero, and `a mod n` must be defined for every entry `a` of `A`.

This method overloads the function `_mod` for matrices; one may use it in the form `A mod n`, or in functional notation: `_mod(A, n)`.

## **`_mult` - Multiply matrices by matrices, vectors and scalars**

`_mult(x, y)`

`_mult(x, y)`

If `y` is of the domain type `R` or can be converted to such an element, the corresponding scalar multiplication is computed.

Otherwise, `y` is converted to a matrix of the domain type of `x`. If this conversion fails, this method calls the method `"_mult"` of the domain of `y` giving all arguments in the same order.

If `x` is a matrix of the same domain type as `y`, the matrix product `xy` is computed. An error message is issued if the dimensions of the matrices do not match.

If `x` is of the domain type `R` or can be converted to such an element, the corresponding scalar multiplication is computed.

Otherwise, `x` is converted to a matrix of the domain type of `y`. If this conversion fails, `FAIL` is returned.

This method handles more than two arguments by calling itself recursively with the first half of all arguments and the last half of all arguments. Then the product of these two results is computed with the system function `_mult`.

This method overloads the system function `_mult` for matrices, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.

**\_negate - Negate a matrix**

`_negate(A)`

This method overloads the system function `_negate` for matrices, i.e., one may use it in the form `-A`, or in functional notation: `_negate(A)`.

**\_plus - Add matrices**

`_plus(A, B, ...)`

The arguments `A, B, ...` are converted to matrices of the domain type `Dom::Matrix(R)`. `FAIL` is returned if one of these conversions fails.

This method overloads the system function `_plus` for matrices, i.e., one may use it in the form `A + B`, or in functional notation: `_plus(A, B)`.

**\_power - Integer power of a matrix**

`_power(A, n)`

If the power `n` is a negative integer then `A` must be nonsingular and `R` must be a domain of category `Cat::IntegralDomain`. Otherwise `FAIL` is returned.

If `n` is zero and the component ring `R` is a ring with no unit (i.e., of category `Cat::Rng`, but not of category `Cat::Ring`), `FAIL` is returned.

This method overloads the system function `_power` for matrices, i.e., one may use it in the form `A^n`, or in functional notation: `_power(A, n)`.

**conjugate - Complex conjugate of a matrix**

`conjugate(A)`

This method only exists if `R` implements the method "conjugate", which computes the complex conjugate of an element of the domain `R`.

This method overloads the system function `conjugate` for matrices, i.e., one may use it in the form `conjugate(A)`.

## **cos - Cosine of a matrix**

`cos(A)`

If  $A$  is not square, an error message is issued. If the component domain of  $A$  does not allow the computation of `cos(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of  $A$  if  $A$  is defined over the domain `Dom::Float`.

If some eigenvalues of  $A$  do not exist in  $R$  or cannot be computed, then `FAIL` is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of  $A$ . In this case `FAIL` is returned.

This method only exists if  $R$  is a domain of category `Cat::Field`.

This method overloads the function `cos` for matrices, i.e., one may use it in the form `cos(A)`.

## **diff - Differentiation of matrix components**

`diff(A, )`

This method only exists if  $R$  implements the method `"diff"`.

This method overloads the system function `diff` for matrices, i.e., one may use it in the form `diff(A, ...)`. See “Example 8” on page 6-256 and “Example 9” on page 6-258.

## **equal - Equality test of matrices**

`equal(A, B)`

Note that if  $R$  has the axiom `Ax::systemRep` then `normal` is used to simplify the components of  $A$  and  $B$  before testing their equality.

## **exp - Exponential of a matrix**

`exp(A, <t>)`

If  $A$  is not square, an error message is issued. If the component domain of  $A$  does not allow the computation of `exp(elem)` for an arbitrary element `elem` of the component ring, FAIL is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of  $A$  if  $A \cdot t$  contains at least one floating-point number and all entries can be converted to floating-point numbers.

If some eigenvalues of  $A$  do not exist in  $R$  or cannot be computed, then FAIL is returned.

In the symbolic case, the function `linalg::jordanForm` is called, which may not be able to compute the Jordan form of  $A$ . In this case FAIL is returned.

This method only exists if  $R$  is a domain of category `Cat::Field`.

This method overloads the system function `exp` for matrices, i.e., one may use it in the form `exp(A, ...)`.

### **expand - Expand matrix components**

`expand(A)`

This method only exists if  $R$  implements the method "expand", or if  $R$  has the axiom `Ax::systemRep` (in this case, the system function `expand` is used).

This method overloads the system function `expand` for matrices, i.e., one may use it in the form `expand(A)`.

### **factor - Scalar-matrix factorization**

`factor(A)`

The factor  $s$  is the gcd of all components of the matrix  $A$ . Hence, this method only exists if  $R$  is of category `Cat::GcdDomain`.

This method overloads the system function `factor` for matrices, i.e., one may use it in the form `factor(A)`.

## **float - Floating-point approximation of the matrix components**

```
float(A)
```

This method only exists if  $R$  implements the method "float".

---

**Note** Usually the floating-point approximations are not elements of  $R$ ! For example, `Dom::Integer` implements such a method, but the floating-point approximation of an integer cannot be re-converted to an integer.

This method checks whether the resulting matrix can be converted to the domain type of  $A$  only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

Otherwise, one has to take care that the matrix returned is compatible with its component ring.

---

## **fourier - Fourier transform of the matrix components**

```
fourier(A, t, s)
```

This method overloads the function `fourier` for matrices.

## **gaussElim - Gaussian elimination for matrices**

```
gaussElim(A, <ColumnElimination>)
```

With the option `ColumnElimination`, the matrix  $A$  is reduced to a lower triangular echelon form via elementary *column* operations (without `ColumnElimination`, the Gauss algorithm uses elementary *row* operations to obtain the upper echelon form). The following relation holds: `transpose(gaussElim(A, ColumnElimination)[1]) = gaussElim(transpose(A))[1]`. With `ColumnElimination`, the last entry of the returned list is the set of characteristic *column* indices of  $A$ .

For very large  $m \times n$  matrices  $A$  with  $m$  much greater  $n$ , the column elimination is faster than the row elimination.

If the matrix is not square, i.e., the determinant of  $A$  is not defined, then the third entry of the returned list is the value FAIL.

This method only exists if the component ring  $R$  is an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If  $R$  has the method "`pivotSize`", the pivot element of smallest size is chosen at every pivoting step, whereby `pivotSize` must return a positive integer representing the "size" of an element.

If no such method is defined, Gaussian elimination without a pivot strategy is applied to  $A$ .

If  $R$  has the axiom `Ax::efficientOperation("_invert")` and is of category `Cat::Field`, ordinary Gaussian elimination is used. Otherwise, fraction-free elimination is performed on  $A$ .

If  $R$  implements the method "`normal`", it is used to simplify subsequent computations of the Gaussian elimination process.

Note that if  $R$  does not implement the method "`normal`", but the elements of  $R$  are represented by kernel domains, i.e.,  $R$  has the axiom `Ax::systemRep`, the system function `normal` is used instead.

### **identity - Identity matrix**

`identity(n)`

This method only exists if the component ring  $R$  is of category `Cat::Ring`, i.e., a ring with unit.

### **int - Integration of matrix components**

`int(A, )`

This method only exists if  $R$  implements the method "`int`".

This method overloads the system function `int` for matrices, i.e., one may use it in the form `int(A, ...)`.

### **ifourier - Inverse Fourier transform of the matrix components**

`ifourier(A, s, t)`

This method overloads the function `ifourier` for matrices.

## **ilaplace - Inverse Laplace transform of the matrix components**

```
ilaplace(A, s, t)
```

This method overloads the function `ilaplace` for matrices.

## **iszero - Test for zero matrices**

```
iszero(A)
```

Note that there may exist more than one representation of the zero matrix of a given dimension if `R` does not have `Ax::canonicalRep`.

If `R` implements the method `"normal"`, it is used to simplify the components of `A` for the zero-test.

Note that if `R` does not implement such a method, but the elements of `R` are represented by kernel domains, i.e., `R` has the axiom `Ax::systemRep`, the system function `normal` is used instead.

This method overloads the system function `iszero` for matrices, i.e., one may use it in the form `iszero(A)`.

## **laplace - Laplace transform of the matrix components**

```
laplace(A, t, s)
```

This method overloads the function `laplace` for matrices.

## **matdim - Matrix dimension**

```
matdim(A)
```

## **norm - Norm of matrices and vectors**

```
norm(A, Infinity)
```

```
norm(A, Maximum)
```

```
norm(v, Infinity)
```

```
norm(v, Maximum)
```

```
norm(A, Frobenius)
```

`norm(A, 1)`

`norm(v, Euclidean)`

`norm(v, k)`

`norm(A, Maximum)` computes the maximum norm of the matrix *A*, which is the maximum row sum (the row sum is the sum of norms of each component in a row).

If the domain *R* does not implement the methods "max" and "norm", FAIL is returned.

Using `norm(v, Infinity)` for a vector *v* the maximum norm of all elements is returned.

If the domain *R* does not implement the methods "max" and "norm", FAIL is returned.

Using `norm(v, Maximum)` for a vector *v* the maximum norm of all elements is returned.

If the domain *R* does not implement the methods "max" and "norm", FAIL is returned.

`norm(A, Frobenius)` computes the Frobenius norm of *A*, which is the square root of the sum of the squares of the norms of each component.

If the result is no longer an element of the domain *R*, or if *R* does not implement the method "norm", FAIL is returned.

`norm(A, 1)` computes the 1-norm of the matrix *A*, which is the maximum sum of the norms of the elements of each column. If *R* does not implement the methods "max" and "norm", FAIL is returned.

`norm(v, Euclidean)` computes the Euclidean norm (2-norm) of the vector *v*, which is defined to be the square root of the sum of the norms of the elements of *v* raised to the square.

FAIL is returned if the result is no longer an element of the domain R. The function `linalg::scalarProduct` is used to compute the Euclidean norm of the vector  $v$ .

If R does not implement the method "norm", FAIL is returned.

`norm(v, k)` computes the  $k$ -norm of the vector  $v$ , which is defined to be the  $k$ th root of the sum of the norms of the elements of  $v$  raised to the  $k$ th power.

FAIL is returned if the result is no longer an element of the domain R. For  $k = 2$ , the function `linalg::scalarProduct` is used to compute the 2-norm of  $v$ .

If R does not implement the method "norm", FAIL is returned.

The method `norm` overloads the function `norm` for matrices, i.e., one may use it in the form `norm(A k)`, where  $k$  is either Infinity, Frobenius, or a positive integer. The default value of  $k$  is Infinity.

### **normal - Simplification of matrix components**

`normal(A)`

If R does not implement the method "normal", but the elements of R are represented by kernel domains, i.e., R has the axiom `Ax::systemRep`, the system function `normal` is applied to the components of A. Otherwise `normal(A)` returns A without any changes.

This method overloads the system function `normal` for matrices, i.e., one may use it in the form `normal(A)`.

### **nonZeros - Number of non-zero components of a matrix**

`nonZeros(A)`

### **nonZeroes - Number of non-zero components of a matrix**

`nonZeroes(A)`

### **nonZeroOperands - Return a sequence of all non-zero operands**

`nonZeroOperands(A)`

This method is useful for retrieving information on the non-zero entries. For example, to find out the types of the entries in the matrix, one should not consider all operands `op(A)`, because this would also involve the zero entries. For large matrices with few entries, it is much more efficient to use this method to extract the entries.

### **random - Random matrix generation**

`random()`

`random(g)`

`random(m, n)`

`random(m, n, g)`

`random(m, n, p)`

`random(m, n, p, g)`

The dimension of the matrix is also chosen randomly. The matrix size is limited by the values "randomDimen" (see "Entries" above). To change the value of the entry "randomDimen", one must first unprotect the domain Dom (see `unprotect` for details).

When calling the "random" method with one parameter `g`, this parameter is regarded as a random generator. The matrix entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

The dimension of the matrix is chosen randomly as above.

When calling the "random" method with two positive integers `m` and `n`, a random matrix with `m` rows and `n` columns is created. Its elements are generated by the method "random" of the component ring `R`. If `R::random` does not exist, FAIL is returned.

`random(m,n,g)` creates a matrix with `m` rows and `n` columns. The third parameter `g` is regarded as a random generator. The matrix

entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

When calling the "random" method with positive integers `m`, `n` and a nonnegative integer `p`, a sparse matrix with `m` rows, `n` columns and at most `p` non-zero entries is created. These entries are generated by the function "random" of the component ring `R`. If `R::random` does not exist, FAIL is returned.

The integer `p` must satisfy  $0 \leq p \leq mn$ .

When calling the "random" method with four parameters, a sparse matrix with `m` rows, `n` columns and at most `p` non-zero entries is created. The fourth parameter `g` is regarded as a random generator. The matrix entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

The integer `p` must satisfy  $0 \leq p \leq mn$ .

### **sin - Sine of a matrix**

`sin(A)`

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `sin(elem)` for an arbitrary element `elem` of the component ring, FAIL is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of `A` if `A` is defined over the domain `Dom::Float`.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then FAIL is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of `A`. In this case FAIL is returned.

This method only exists if `R` is a domain of category `Cat::Field`.

This method overloads the function `sin` for matrices, i.e., one may use it in the form `sin(A)`.

**sqrt - Square root of a matrix**

```
sqrt(A, <sqrtfunc>)
```

Returned is a matrix  $B$  with  $B^2 = A$  such that the eigenvalues of  $B$  are the square roots of the eigenvalues of  $A$  or FAIL if the square root of the matrix does not exist. For computing the square roots of the eigenvalues a function satisfying  $\text{sqrtfunc}(a)^2 = a$  for every element  $a$  of the coefficient ring of  $A$  can be given as optional second argument.

For details we refer to the help page of the function `linalg::sqrtMatrix`.

**testeq - Testing for equality of two matrices**

```
testeq(A, B)
```

**tr - Trace of a square matrix**

```
tr(A)
```

If  $A$  is not square, an error message is issued.

**transpose - Transpose of a matrix**

```
transpose(A)
```

**Access Methods****concat - Horizontal concatenation of matrices**

```
concat(A, B, ...)
```

This method overloads the system function `concat` for matrices, i.e., one may use it in the form  $A \cdot B \cdot \dots$ , or in functional notation: `concat(A, B, ...)`.

**index - Matrix indexing**

```
index(A, i, j)
```

```
index(A, r1 .. r2, c1 .. c2)
```

```
index(v, i)
```

`_index(v, i1 .. i2)`

If `i` and `j` are not integers, the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

---

**Note** Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

---

`_index(A, r1..r2, c1..c2)` returns the submatrix of `A` created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

This method returns the *i*th entry of the vector `v`.

An error message is issued if `v` is not a vector.

If `i` is not an integer, the call of `_index(v, i)` returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` is less than one or greater than the dimension of `v`.

---

**Note** Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

---

`_index(v, i1..i2)` returns the subvector of `v`, formed by the entries with index `i1` to `i2`. See also the method "`op`".

An error message is issued if `v` is not a vector.

`_index` overloads the system function `_index` for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `v[i]` and `v[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

## **addCol - Addition of a multiple of one column to the multiple of another column**

```
addCol(A, i, j, f, <g>)
```

*i* and *j* must be positive integers smaller than or equal to the number of columns of the matrix *A*.

If *f* and *g* are not elements of the coefficient domain *R* of the matrix *A* and cannot be converted to *R*, FAIL is returned.

## **addRow - Addition of a multiple of one row to the multiple of another row**

```
addRow(A, i, j, f, g)
```

*i* and *j* must be positive integers smaller than or equal to the number of rows of the matrix *A*.

If *f* and *g* are not elements of the coefficient domain *R* of the matrix *A* and cannot be converted to *R*, FAIL is returned.

## **concatMatrix - Horizontal concatenation of matrices**

```
concatMatrix(A, B,)
```

## **col - Extracting a column of a matrix**

```
col(A, c)
```

An error message is issued if *c* is less than one or greater than the number of columns of *A*.

## **delCol - Deleting a column of a matrix**

```
delCol(A, c)
```

NIL is returned if *A* consists of only one column.

An error message is issued if *c* is less than one or greater than the number of columns of *A*.

## **delRow - Deleting a row of a matrix**

```
delRow(A, r)
```

NIL is returned if  $A$  consists of only one row.

An error message is issued if  $r$  is less than one or greater than the number of rows of  $A$ .

### **evalp - Evaluating matrices of polynomials at a certain point**

```
evalp(A, x = a,)
```

This method is only defined if  $R$  is a polynomial ring of category `Cat::Polynomial`.

This method overloads the system function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

### **length - Length of a matrix**

```
length(A)
```

This method overloads the system function `length` for matrices, i.e., one may use it in the form `length(A)`.

### **map - Apply a function to matrix components**

```
map(A, f, <p1, p2, >)
```

---

**Note** Note that values returned by  $f$  are converted to elements of the domain  $R$  only if `testargs()` returns `TRUE` (i.e., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that  $f$  returns elements of the domain type  $R$ . Otherwise, the resulting matrix will have components which are not elements of the component ring  $R$ !

---

---

**Note** If the function `f` does not map the zero element of the component ring to the zero element, a sparse matrix will change into a dense matrix. This may lead to memory problems when dealing with very large (sparse) matrices.

---

Note that there is the method "`mapNonZeroes`" which maps a function to the non-zero entries of the matrix only.

This method overloads the system function `map` for matrices, i.e., one may use it in the form `map(A, f p1 , p2 , , )`.

**mapNonZeroes - Apply a function to the non-zero components of a (sparse) matrix**

```
mapNonZeroes(A, f, <p1, p2, >)
```

**multCol - Multiplication of one column by a scalar factor**

```
multCol(A, i, f)
```

`i` must be a positive integer smaller than or equal to the number of columns of the matrix `A`.

If `f` is not an element of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

**multRow - Multiplication of one row by a scalar factor**

```
multRow(A, i, f)
```

`i` must be a positive integer smaller than or equal to the number of rows of the matrix `A`.

If `f` is not an element of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

**nops - Number of components of a matrix**

```
nops(A)
```

This method overloads the system function `nops` for matrices, i.e., one may use it in the form `nops(A)`.

## **op - Component of a matrix**

`op(A, i)`

`op(A)`

This method returns an expression sequence of all components of A.

See also the method "`_index`".

This method overloads the system function `op` for matrices, i.e., one may use it in the form `op(A, i)` and `op(A)`, respectively.

## **row - Extracting a row from a matrix**

`row(A, r)`

An error message is issued if `r` is less than one or greater than the number of rows of A.

## **setCol - Replacing a column of a matrix**

`setCol(A, c, v)`

An error message is issued if `c` is less than one or greater than the number of rows of A.

## **setRow - Replacing a row of a matrix**

`setRow(A, r, v)`

An error message is issued if `r` is less than one or greater than the number of rows of A.

## **stackMatrix - Vertical concatenation of matrices**

`stackMatrix(A, B, )`

An error message is issued if the given matrices do not have the same number of columns.

## **subs - Substitution of matrix components**

`subs(A, )`

---

**Note** Note that the function values are converted to elements of the domain  $R$  only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that `f` returns elements of the domain type  $R$ . Otherwise, the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain  $R$ !

---

This method overloads the system function `subs` for matrices, i.e., one may use it in the form `subs(A, ...)`.

### **subsex - Extended substitution of matrix components**

`subsex(A, ...)`

---

**Note** Note that the results of the substitutions are converted to elements of the domain  $R$  only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that the results of the substitutions are of the domain type  $R$ , otherwise the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain  $R$ !

---

This method overloads the system function `subsex` for matrices, i.e., one may use it in the form `subsex(A, ...)`.

### **subsop - Operand substitution of matrix components**

`subsop(A, i = x, ...)`

---

**Note** Note that  $x$  is converted to the domain  $R$  only if `testargs()` returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns FALSE,  $x$  must be an element of  $R$ , otherwise the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain  $R$ !

---

See also the method "set\_index".

This method overloads the system function `subsop` for matrices, i.e., one may use it in the form `subsop(A, ...)`.

### **swapCol - Swapping matrix columns**

```
swapCol(A, c1, c2)
```

```
swapCol(A, c1, c2, r1 .. r2)
```

An error message is issued if one of the column indices is less than one or greater than the number of columns of  $A$ .

`swapCol(A, c1, c2, r1 .. r2)` swaps the column with index  $c1$  and the column with index  $c2$  of  $A$ , but by taking only those column components which lie in the rows with indices  $r1$  to  $r2$ .

An error message is issued if one of the column indices is less than one or greater than the number of columns of  $A$ , or if one of the row indices is less than one or greater than the number of rows of  $A$ .

### **swapRow - Swapping matrix rows**

```
swapRow(A, r1, r2)
```

```
swapRow(A, r1, r2, c1 .. c2)
```

An error message is issued if one of the row indices is less than one or greater than the number of rows of  $A$ .

`swapCol(A, r1, r2, c1..c2)` swaps the row with index `r1` and the row with index `r2` of `A`, but by taking only those row components which lie in the columns with indices `c1` to `c2`.

An error message is issued if one of the row indices is less than one or greater than the number of rows of `A`, or if one of the column indices is less than one or greater than the number of columns of `A`.

### **set\_index - Setting matrix components**

```
set_index(A, i, j, x)
```

```
set_index(v, i, x)
```

---

**Note** Note that `x` is converted into an element of the domain `R` only if `testargs` returns `TRUE` and `i` and `j` are integers (e.g., if one calls this method from the interactive level of MuPAD). If `x` is a matrix of the same type as `A` or can be converted into a matrix of the same type as `A` and the indices `i` or `j` are ranges corresponding to a submatrix of `A`, then `x` replaces the corresponding submatrix in `A`.

Otherwise one has to take care that `x` is of domain type `R`.

---

See also the method "subsop".

`set_index(v, i, x)` replaces the  $i$ th entry of the vector `v` by `x`.

`set_index` on vectors overloads the function `set_index` for matrices, i.e., one may use it in the form `A[i, j] := x` and `v[i] := x`, respectively, or in functional notation: `A := set_index(A, i, j, x)` or `v := set_index(v, i, x)`.

### **zip - Combine matrices component-wise**

```
zip(A, B, f, <p1, p2, >)
```

The row number of the matrix returned is the minimum of the row numbers of A and B. Its column number is the minimum of the column numbers of A and B.

---

**Note** Note that the values returned by `f` are converted to elements of the domain `R` only if `testargs()` returns `TRUE` (i.e., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that `f` returns elements of the domain type `R`. Otherwise, the resulting matrix will have components which are not elements of the component ring `R`!

---

This method overloads the system function `zip` for matrices, i.e., one may use it in the form `zip(A, B, f p1 , p2 , , )`.

## Conversion Methods

### **convert - Conversion to a matrix**

`convert(x)`

`FAIL` is returned if the conversion fails.

`x` may either be an array, a matrix, or a list (of sublists, see the parameter `ListOfRows` in “Creating Elements” above). Their entries must then be convertible into elements of the domain `R`.

### **convert\_to - Matrix conversion**

`convert_to(A, T)`

`T` may either be `DOM_ARRAY`, `DOM_LIST`, or a domain constructed by `Dom::Matrix` or `Dom::SquareMatrix`. The elements of `A` must be convertible into elements of the domain `R`.

Use the function `expr` to convert `A` into an object of a kernel domain (see below).

**create - Defining matrices without component conversions**

```
create(x,)
```

This method works more efficiently than if one creates matrices by calling the method "new" of the domain, because it avoids any conversion of the components. One must guarantee that the components have the correct domain type, otherwise run-time errors can be caused.

**expr - Conversion of a matrix to an object of a kernel domain**

```
expr(A)
```

The result is an array representing the matrix A where each entry is an object of a kernel domain.

This method overloads the system function `expr` for matrices, i.e., one may use it in the form `expr(A)`.

**expr2text - Conversion of a matrix to a string**

```
expr2text(A)
```

This method overloads the system function `expr2text` for matrices, i.e., one may use it in the form `expr2text(A)`.

**TeX - TeX formatting of a matrix**

```
TeX(A)
```

Note that in the case of very large matrices the output will not be useful. For printing large matrices use the function "doprint" to obtain a sparse matrix output displaying all non-zero entries. Alternatively, use the matrix slot "setPrintMaxSize" to set the maximal size of matrices that will be printed like "dense" arrays with zero entries displayed as the integer 0.

The method "TeX" of the component ring R is used to get the TeX-representation of each component of A.

This method is used by the function `generate::TeX`.

## Technical Methods

### **assignElements - Multiple assignment to matrices**

```
assignElements(A, ...)
```

The assigned components must have the domain type  $R$ , an implicit conversion of the components into elements of domain type  $R$  is not performed.

This method overloads the system function `assignElements` for matrices, i.e., one may use it in the form `assignElements(A, ...)`.

### **mkSparse - Conversion of an array or a list of lists to a sparse structure**

```
mkSparse(Array)
```

```
mkSparse(List)
```

```
mkSparse(r, c, List)
```

The 'sparse structure' `s` is a list of `c` univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

`mkSparse(List)` tries to convert the list `List` into a sparse structure. The result is either `FAIL` if this is not possible, or the list `[s, [r, c]]`, where the positive integers `r` and `c` are the dimension of the corresponding matrix. The 'sparse structure' `s` is a list of univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

See the parameters `List` and `ListOfRows` in "Creating Elements" above for admissible formats of `List`.

The matrix is regarded as a column or a row vector, if `r` or `c` is equal to one. `T`

`mkSparse(r,c,List)` tries to convert the list `List` into a sparse structure representing a matrix of dimension `r` times `c`.

The result is either `FAIL` if this is not possible, or the list `[s, [r, c]]`. The 'sparse structure' `s` is a list of univariate polynomials

that is used to store the non-trivial elements of the columns of matrices.

The matrix is regarded as a column or a row vector, if `r` or `c` is equal to one. T

### **print - Printing matrices**

```
print(A)
```

---

**Note** Note that it will not be useful to print very large sparse matrices with lots of zero coefficients in this way – printing such matrices can be done by using the function "doprint".

---

Use the matrix slot "setPrintMaxSize" to set the maximal size of matrices that will be printed like “dense” arrays with zero entries displayed as the integer 0.

### **doprint - Printing large sparse matrices**

```
doprint(A)
```

### **setPrintMaxSize - Set the maximal size of matrices that will be printed like “dense” arrays**

```
setPrintMaxSize(printMaxSize)
```

The value of the parameter `printMaxSize` may also be infinity. In this case, matrices of arbitrary size are printed like “dense” arrays.

This method returns the previous value of `printMaxSize`.

The default value is `printMaxSize = 500`.

### **unapply - Create a procedure from a matrix**

```
unapply(A, <x, >)
```

This method overloads the system function `fp::unapply` for matrices, i.e., one may use it in the form `fp::unapply(A)`.

# Dom::Matrix

Dom::MatrixGroup(m, n, R)(<m, n>, g, <Diagonal>)  
Dom::MatrixGroup(m, n, R)(<m, n>, List, <Banded>)

**Description** **Domain Creation**

Dom::MatrixGroup(m, n, R) creates a domain which represents the Abelian group of  $m \times n$  matrices over the component ring R, i.e., it is a domain of category Cat::AbelianGroup.

The domain Dom::ExpressionField() is used as the component ring for the matrices if the optional parameter R is not given.

For matrices of a domain created by Dom::MatrixGroup(m, n, R), matrix arithmetic is implemented by overloading the standard arithmetical operators +, -, \*, / and ^. All functions of the linalg package dealing with matrices can be applied.

Dom::MatrixGroup(m, n, R) has the domain Dom::Matrix(R) as its super domain, i.e., it inherits each method which is defined by Dom::Matrix(R) and not re-implemented by Dom::MatrixGroup(m, n, R).

Methods described below are implemented by Dom::MatrixGroup.

The domain Dom::Matrix(R) represents matrices over R of arbitrary size, and it therefore does not have any algebraic structure (except of being a *set* of matrices).

# Dom::MatrixGroup

---

The domain `Dom::SquareMatrix(n, R)` represents the *ring* of  $n \times n$  matrices over  $R$ .

## Element Creation

`Dom::MatrixGroup(m, n, R)(Array)` and `Dom::MatrixGroup(m, n, R)(Matrix)` create a new matrix formed by the entries of `Array` and `Matrix`, respectively.

The components of `Array` and `Matrix`, respectively, are converted into elements of the domain  $R$ . An error message is issued if one of these conversions fails.

The call `Dom::MatrixGroup(m, n, R)( m , n )` returns the  $m \times n$  zero matrix. Note that the  $m \times n$  zero matrix can also be found in the entry "zero" (see below).

`Dom::MatrixGroup(m, n, R)( m , n List)` creates an  $m \times n$  matrix with components taken from the list `List`.

This call is only allowed for  $m = 1$  or  $1 \times n$  matrices, i.e., if either  $m$  or  $n$  is equal to one.

If the list has too few entries, the remaining components of the matrix are set to zero.

The entries of the list are converted into elements of the domain  $R$ . An error message is issued if one of these conversions fails.

`Dom::MatrixGroup(m, n, R)( m , n ListOfRows)` creates an  $m \times n$  matrix with components taken from the nested list `ListOfRows`. Each inner list corresponds to a row of the matrix.

If an inner list has less than  $n$  entries, the remaining components in the corresponding row of the matrix are set to zero. If there are less than  $m$  inner lists, the remaining lower rows of the matrix are filled with zeroes.

The entries of the inner lists are coerced into elements of the domain  $R$ . An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::MatrixGroup(m, n, R)`. This is due to the fact that creating a matrix from an array is the fastest way one

can achieve. However, in this case the sublists must have the same number of elements.

`Dom::MatrixGroup(m, n, R) ( m , n f )` returns the matrix whose  $(i, j)$ th component is the value of the function call `f(i, j)`. The row index  $i$  ranges from 1 to  $m$  and the column index  $j$  from 1 to  $n$ .

The function values are coerced into elements of the domain  $R$ . An error message is issued if one of these conversions fails.

**Superdomain** `Dom::Matrix(R)`

**Axioms** If  $R$  has `Ax::canonicalRep`, then `Ax::canonicalRep`.

**Categories** `Cat::Matrix(R)`, `Cat::AbelianGroup`

**Examples** **Example 1**

A lot of examples can be found on the help page of the domain constructor `Dom::Matrix`, and most of them are also examples for working with domains created by `Dom::MatrixGroup`. This example only highlights some differences with respect to working with matrices of the domain `Dom::Matrix(R)`.

The following command defines the abelian group of 3 4 matrices over the rationals:

```
MatGQ := Dom::MatrixGroup(3, 4, Dom::Rational)
```

```
Dom::MatrixGroup(3, 4, Dom::Rational)
```

```
MatGQ::hasProp(Cat::AbelianGroup), MatGQ::hasProp(Cat::Ring)
```

```
TRUE, FALSE
```

# Dom::MatrixGroup

---

MatGQ is a commutative group with respect to the addition of matrices. The unit of this group is the 3 4 zero matrix:

`MatGQ::zero`

$$\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Note that some operations defined by the domain MatGQ return matrices which are no longer elements of the matrix group. They return matrices of the domain Dom::Matrix(Dom::Rational), the super-domain of MatGQ.

For example, if we define the matrix:

`A := MatGQ([[1, 2, 1, 2], [-5, 3], [2, 1/3, 0, 1]])`

$$\begin{pmatrix} 1 & 2 & 1 & 2 \\ -5 & 3 & 0 & 0 \\ 2 & \frac{1}{3} & 0 & 1 \end{pmatrix}$$

and delete its third column, we get the matrix:

`MatGQ::delCol(A, 3)`

$$\begin{pmatrix} 1 & 2 & 2 \\ -5 & 3 & 0 \\ 2 & \frac{1}{3} & 1 \end{pmatrix}$$

which is of the domain type:

```
domtype(%)
```

```
Dom::Matrix(Dom::Rational)
```

As another example we create the 3 3 identity matrix using the method "identity" of our domain:

```
E3 := MatGQ::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

This is also a matrix of the domain `Dom::Matrix(Dom::Rational)`:

```
domtype(E3)
```

```
Dom::Matrix(Dom::Rational)
```

If we concatenate E3 to the right of the matrix A defined above, we get the 3 7 matrix:

```
B := A . E3
```

$$\begin{pmatrix} 1 & 2 & 1 & 2 & 1 & 0 & 0 \\ -5 & 3 & 0 & 0 & 0 & 1 & 0 \\ 2 & \frac{1}{3} & 0 & 1 & 0 & 0 & 1 \end{pmatrix}$$

which is of the domain type `Dom::Matrix(Dom::Rational)`:

```
domtype(B)
```

# Dom::MatrixGroup

---

Dom::Matrix(Dom::Rational)

## Example 2

We can convert a matrix from a domain created with Dom::MatrixGroup into or from another matrix domain, as shown next:

```
MatGR := Dom::MatrixGroup(2, 3, Dom::Real):
```

```
MatC := Dom::Matrix(Dom::Complex):
```

```
A := MatGR((i, j) -> i*j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$$

To convert A into a matrix of the domain MatC, enter:

```
coerce(A, MatC)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$$

```
domtype(%)
```

Dom::Matrix(Dom::Complex)

The conversion is done component-wise. For example, we define the following matrix:

```
B := MatC([[0, 1, 0], [exp(I), 0, 1]])
```

$$\begin{pmatrix} 0 & 1 & 0 \\ e^i & 0 & 1 \end{pmatrix}$$

The matrix  $B$  has one complex component and therefore cannot be converted into the domain MatGR:

```
coerce(B, MatGR)
```

```
FAIL
```

Note: The system function `coerce` uses the methods "convert" and "convert\_to" implemented by any domain created with `Dom::MatrixGroup` and `Dom::Matrix`.

## Parameters

**m, n**

Positive integers (matrix dimension)

**R**

A commutative ring, i.e., a domain of category

`Cat::CommutativeRing`; the default is `Dom::ExpressionField()`

**Array**

An  $m \ n$  array

**Matrix**

An  $m \ n$  matrix, i.e., an element of a domain of category

`Cat::Matrix`

**List**

A list of matrix components

**ListOfRows**

A list of at most  $m$  rows; each row is a list of at most  $n$  matrix components

**f**

A function or a functional expression with two parameters (the row and column index)

**g**

A function or a functional expression with one parameter (the row index)

## Options

### Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function.

`Dom::MatrixGroup(m, n, R)( m , n List, Diagonal)` creates the  $m \times n$  diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most  $\min(m, n)$  entries. If it has fewer elements, then the remaining diagonal elements are set to zero.

The entries of `List` are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::MatrixGroup(m, n, R)( m , n g, Diagonal)` returns the matrix whose  $i$ th diagonal element is  $g(i, i)$ , where the index  $i$  runs from 1 to  $\min(m, n)$ .

The function values are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

### Banded

Create a banded Toeplitz matrix

With the option `Banded`, banded matrices can be created.

A *banded matrix* has all entries zero outside the main diagonal and some of the adjacent sub- and superdiagonals.

`Dom::MatrixGroup(m, n, R)( m , n List, Banded)` creates an  $m \times n$  banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say  $2h + 1$ , and must not exceed  $n$ . The resulting matrix has bandwidth at most  $2h + 1$ .

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the  $i$ th subdiagonal are initialized with the  $(h + 1 - i)$ th element of `List`. All elements of the  $i$ th superdiagonal are initialized with the  $(h + 1 + i)$ th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

## Entries

|               |                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------|
| "one"         | is only defined if $m$ is equal to $n$ ; in that case it defines the $n \times n$ identity matrix. |
| "randomDimen" | is set to $[m, n]$ .                                                                               |
| "zero"        | is the $m \times n$ zero matrix.                                                                   |

## Methods

### Mathematical Methods

#### **evalp - Evaluating matrices of polynomials at a certain point**

`evalp(A, x = a, )`

This method is only defined if `R` is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

#### **identity - Identity matrix**

`identity(k)`

---

**Note** The matrix returned is of the domain `Dom::Matrix(R)`, if  $m \neq n$  or if  $k \neq n$ .

---

## **matdim - Matrix dimension**

`matdim(A)`

## **random - Random matrix generation**

`random()`

The components of the random matrix are randomly generated with the method "random" of the component ring R.

## **Access Methods**

### **\_concat - Horizontally concatenation of matrices**

`_concat(A, B, ...)`

An error message is issued if the given matrices do not have the same number of rows.

---

**Note** The returned matrix is of the domain `Dom::Matrix(R)`.

---

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

### **\_index - Matrix indexing**

`_index(A, i, j)`

`_index(A, r1 .. r2, c1 .. c2)`

`_index(A, i)`

`_index(A, i1 .. i2)`

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

---

**Note** Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

---

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]` or in functional notation: `_index(A, i, j)`.

Returns the submatrix of `A`, created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

---

**Note** The submatrix is of the domain `Dom::Matrix(R)`.

---

This method returns the *i*th entry of `A`.

If *i* is not an integer, then the call of this method returns in its symbolic form (of type `"_index"`) with evaluated arguments.

Otherwise an error message is given, if *i* is less than one or greater than the dimension of *v*.

This call is only allowed for  $1 \times n$  or  $m \times 1$  matrices, i.e., either *m* or *n* must be equal to one. Otherwise an error message is issued.

---

**Note** Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

---

This method returns the subvector of `A`, formed by the entries with index `i1` to `i2` (see also the method `"op"`).

This call is only allowed for  $1 \times n$  or  $m \times 1$  matrices, i.e., either *m* or *n* must be equal to one. Otherwise an error message is issued.

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `A[i]` or

$A[i1..i2]$ , respectively, or in functional notation: `_index(A, ...)`.

## **concatMatrix - Horizontally concatenation of matrices**

`concatMatrix(A, B, )`

## **col - Extracting a column**

`col(A, c)`

An error message is issued if  $c$  is less than one or greater than  $n$ .

## **delCol - Deleting a column**

`delCol(A, c)`

NIL is returned if  $A$  only consists of one column.

---

**Note** The returned matrix is of the domain `Dom::Matrix(R)`.

---

An error message is issued if  $c$  is less than one or greater than  $n$ .

## **delRow - Deleting a row**

`delRow(A, r)`

NIL is returned if  $A$  only consists of one row.

---

**Note** The returned matrix is of the domain `Dom::Matrix(R)`.

---

An error message is issued if  $r$  is less than one or greater than  $m$ .

## **row - Extracting a row**

`row(A, r)`

An error message is issued if  $r$  is less than one or greater than  $m$ .

## **stackMatrix - Concatenating of matrices vertically**

`stackMatrix(A, B, )`

An error message is issued if the given matrices do not have the same number of columns.

---

**Note** The matrix returned is of the domain `Dom::Matrix(R)`.

---

## Conversion Methods

### **convert - Conversion into a matrix**

`convert(x)`

FAIL is returned if the conversion fails.

$x$  may either be an  $m \ n$  array, or an  $m \ n$  matrix of category `Cat::Matrix`.

$x$  can also be a list. See the parameter `List` and `ListOfRows` in “Creating Elements” above for admissible values of  $x$ .

The entries of  $x$  must be convertible into elements of the domain  $R$ , otherwise FAIL is returned.

## See Also

### **MuPAD Domains**

`Dom::Matrix` | `Dom::SquareMatrix`

# Dom::MonomOrdering

---

**Purpose** Monomial orderings

**Syntax**

```
Dom::MonomOrdering(Lex(n))
Dom::MonomOrdering(RevLex(n))
Dom::MonomOrdering(DegLex(n))
Dom::MonomOrdering(DegRevLex(n))
Dom::MonomOrdering(DegInvLex(n))
Dom::MonomOrdering(WeightedLex(w1, ..., wn))
Dom::MonomOrdering(WeightedDegLex(w1, ..., wn))
Dom::MonomOrdering(WeightedDegRevLex(w1, ..., wn))
Dom::MonomOrdering(WeightedRevLex(w1, ..., wn))
Dom::MonomOrdering(Block(o1, ...))
Dom::MonomOrdering(Matrix(params))
```

**Description** Dom::MonomOrdering represents the set of all possible monomial orderings. A monomial ordering is a well-ordering of the set of all  $k$ -tuples of nonnegative integers for some  $k$ .

In MuPAD, a monomial ordering is implemented as a function that, when applied to two lists of nonnegative integers, returns -1, 0, or 1 if the first list is respectively smaller than, equal to, or greater than the second list. Each ordering can only compare lists of one fixed length, called its *order length*. Since the lists under consideration will be exponent vectors in most cases, their length is also referred to as the number of indeterminates.

Monomial orderings are used in algebraic geometry for comparing

terms  $\prod_{i=1}^n X_i^{\alpha_i}$  and  $\prod_{i=1}^n X_i^{\beta_i}$  in a polynomial ring. Since Dom::MonomOrdering works on the exponent vectors  $[\alpha_1, \dots, \alpha_n]$  and  $[\beta_1, \dots, \beta_n]$ , degreevec must be applied to the terms to be compared before applying Dom::MonomOrdering.

Elements of Dom::MonomOrdering can be used as arguments for lcoeff, lmonomial, lterm, and tcoeff as well as for the functions of the groebner package in order to specify the monomial ordering to be considered.

Monomial orderings are created by calling `Dom::MonomOrdering(someIdentifier(parameters))`, where `someIdentifier` is one of a certain set of predefined identifiers, as stated below. Converting `someIdentifier` into a string gives the *order type* of the monomial ordering.

`Dom::MonomOrdering(Lex(n))` creates the lexicographical order on  $n$  indeterminates.

`Dom::MonomOrdering(RevLex(n))` creates the reverse lexicographical order on  $n$  indeterminates, i.e.,

`Dom::MonomOrdering(RevLex(n))([a1, ..., an]) =`

`Dom::MonomOrdering(Lex(n))([an, ..., a1]).`

`Dom::MonomOrdering(DegLex(n))` creates the degree order on  $n$  indeterminates with the lexicographical order used for tie-break.

`Dom::MonomOrdering(DegRevLex(n))` creates the degree order on  $n$  indeterminates with the reverse lexicographical order used for tie-break

.

`Dom::MonomOrdering(DegInvLex(n))` creates the degree order on  $n$  indeterminates, with the tie break being the opposite to the lexicographical order.

`Dom::MonomOrdering(Weighted... (w1, ..., wn))` returns a weighted degree order with weights  $w_1$  through  $w_n$ . The word following the word `Weighted` specifies the tie-break used. Note that MuPAD uses the ordinary degree order as the first tie-break.

`Dom::MonomOrdering(Matrix(params))` creates a matrix order, with the order matrix defined by `Dom::Matrix()(params)`.

`Dom::MonomOrdering(Block(o1, ..., on))` or, equivalently,

`Dom::MonomOrdering([o1, ..., on])`, creates a block order such

that `Dom::MonomOrdering(o1)` is used on the first indeterminates,

then `Dom::MonomOrdering(o2)` is used as a tie-break on the following indeterminates etc.

Block orders may be nested, i.e., the blocks may be block orders, too.

# Dom::MonomOrdering

---

Weight vectors with negative entries and order matrices do not define well-orderings in general. You may enter such orderings, but it may cause trouble, e.g., to use them with the groebner package.

**Superdomain** Dom::BaseDomain

**Categories** Cat::BaseCategory

**Examples** **Example 1**

We define ORD by prescribing that lists  $[a, b, c]$  are ordered according to their weighted degrees  $5a + 2b + \pi c$ . For lists with equal weighted degree, the non-weighted degree  $a + b + c$  is used as a tie-break. Finally, the lexicographical order decides (in fact, this last step is not necessary because  $\pi$  is irrational).

```
ORD:=Dom::MonomOrdering(WeightedDegLex(5, 2, PI))
```

```
WeightedDegLex(5, 2, π)
```

With respect to ORD,  $[1, 6, 1]$  is smaller than  $[2, 1, 3]$ :

```
ORD([1,6,1], [2,1,3])
```

```
- 1
```

**Parameters**

**n**

Positive integer

**w<sub>1</sub>, ...**

Numerical expressions

**o<sub>1</sub>, ...**

Valid arguments to Dom::MonomOrdering

## **params**

A sequence valid as the sequence of arguments to `Dom::Matrix()`.

## **Methods**

### Mathematical Methods

#### **func\_call - Compare two lists of integers**

```
func_call(o, l1, l2)
```

The lengths of `l1` and `l2` must not exceed the order length of `o`. If `l1` or `l2` is too short, the necessary number of zeroes is appended.

### Access Methods

#### **ordertype - Return the type of an order**

```
ordertype(o)
```

If `o` equals `Dom::MonomOrdering(someIdentifier(params))`, then converting `someIdentifier` into a string gives the order type of `o`.

#### **orderlength - Return the length of an order**

```
orderlength(o)
```

#### **nops - Number of blocks**

```
nops(o)
```

#### **block - Get a particular block**

```
block(o, i)
```

#### **blocktype - Get the order type of a particular block**

```
blocktype(o, i)
```

#### **blocklength - Get the order length of a particular block**

```
blocklength(o, i)
```

# Dom::MonomOrdering

---

## Conversion Methods

**expr** - Return an expression from which the order can be restored

`expr(o)`

| <b>Purpose</b>     | Multisets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Syntax</b>      | <code>Dom::Multiset(&lt;s1, s2, &gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p><code>Dom::Multiset</code> is the domain of multisets, i.e., sets with possibly multiple identical elements.</p> <p>A multiset is represented by a set of lists of the form <math>[s, m]</math>, where <math>s</math> is an element of the multiset and <math>m</math> its multiplicity.</p> <p>Multisets can be returned by the system solver <code>solve</code>. For example, the input <code>solve(x^3 - 4*x^2 + 5*x - 2, x, Multiple)</code> gives all roots of the polynomial <math>x^3 - 4x^2 + 5x - 2</math> in form of the multiset <math>\{[1, 2], [2, 1]\}</math>.</p> <p>The standard set operations such as union, intersection and subtraction of sets have been extended to deal with multisets.</p> <p>These operations can handle different types of sets, such as sets of type <code>DOM_SET</code> and multisets. One may, for example, compute the union of the multiset <math>\{[a, 2], [b, 1]\}</math> and the set <math>\{c\}</math>, which results in the multiset <math>\{[a, 2], [b, 1], [c, 1]\}</math>.</p> <p>The elements of the multiset are sorted at the time where the multiset is created. The system function <code>sort</code> is used in order to guarantee that exactly one representation exists for a multiset, independent of the sequence in which the arguments appear.</p> <p><code>Dom::Multiset(s1, s2, ...)</code> creates the multiset consisting of the elements <math>s1, s2, \dots</math></p> <p>Multiple identical elements in <math>s1, s2, \dots</math> are collected. For example, the call <code>Dom::Multiset(a, b, a, c)</code> creates a multiset with the elements <math>a, b, c</math>. The element <math>a</math> has multiplicity two, the other two elements <math>b</math> and <math>c</math> both have multiplicity one.</p> |
| <b>Superdomain</b> | <code>Dom::BaseDomain</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Categories</b>  | <code>Cat::Set</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

# Dom::Multiset

---

## Examples

### Example 1

The multiset  $\{a, a, b\}$  consists of the two different elements  $a$  and  $b$ , where  $a$  has multiplicity two and  $b$  has multiplicity one:

```
delete a, b, c:
set1 := Dom::Multiset(a, a, b)
```

```
{[a, 2], [b, 1]}
```

We create another multiset:

```
set2 := Dom::Multiset(a, c, c)
```

```
{[a, 1], [c, 2]}
```

Standard set operations such as disjoint union, intersection or subtraction are implemented for multisets and can be performed using the standard set operators of MuPAD:

```
set1 union set2
```

```
{[a, 3], [b, 1], [c, 2]}
```

```
set1 intersect set2
```

```
{[a, 1]}
```

```
contains(set1, a), contains(set1, d)
```

```
TRUE, FALSE
```

## Example 2

Some system functions were overloaded for multisets, such as `expand`, `normal` or `split`.

If we apply `expand` to a multiset, for example, we get an expression sequence of all elements of the multiset (appearing in correspondence to their multiplicity):

```
delete a, b, c, d, e:
set := Dom::Multiset(a, b, c, a, c, d, c, e, c)
```

```
{[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]}
```

```
expand(set)
```

```
a, a, b, c, c, c, c, d, e
```

If you want to convert a multiset into an ordinary set of the domain type `DOM_SET`, use `coerce`:

```
coerce(set, DOM_SET)
```

```
{a, b, c, d, e}
```

Note: The system function `coerce` uses the methods `"convert"` and `"convert_to"` of the domain `Dom::Multiset`.

Compare the last result with the return value of the function `expr`, when it is applied for multisets:

```
expr(set)
```

# Dom::Multiset

---

`{[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]}`

The result is a set of the domain type `DOM_SET`, consisting of lists of the domain type `DOM_LIST` with two entries, an element of the multiset and the corresponding multiplicity of that element.

## Parameters `s1, s2, ...`

Objects of any type

## Entries

|                     |                                                                                                                                                        |

| "inhomog_union"     | a table of the form <code>T = Proc(multiset, setoftypeT)</code> . This entry is used internally by the implementation, and thus should not be touched. |

## Methods

### Mathematical Methods

#### **normal - Normalization of multisets**

`normal(set)`

This method overloads the function `normal` for multisets, i.e., one may use it in the form `normal(set)`.

#### **powerset - Power set of a multiset**

`powerset(set)`

The power set of `set` is returned as a set of multisets.

## **random - Random multiset generation**

```
random()
```

The number of elements created, including their multiplicities, is restricted to 20.

## **Access Methods**

### **`_index` - Multiset indexing**

```
_index(set, i)
```

See the method "op".

This method overloads the function `_index` for multisets, i.e., one may use it in the form `set[i]`, or in functional notation: `_index(set, i)`.

### **`contains` - Check on existence of set elements**

```
contains(set, s)
```

This method overloads the function `contains` for multisets, i.e., one may use it in the form `contains(set, s)`.

### **`equal` - Test on equality of multisets**

```
equal(set1, set2)
```

The system function `_equal` is used for the test.

### **`expand` - Expand a multiset to a sequence of its elements**

```
expand(set)
```

This method overloads the function `expand` for multisets, i.e., one may use it in the form `expand(set)`.

### **`getElement` - Extract one element from a multiset**

```
getElement(set)
```

Note that the elements of the multiset are sorted with the use of the system function `sort`, and thus the order of a multiset depends on the sorting criteria specified by this function.

This method overloads the function `solveLib::getElement`, i.e., one may use it in the form `solveLib::getElement(set)`.

## **has - Check on existence of (sub-)expressions**

```
has(set, expr)
```

To check whether `expr` is contained as an element of `set` and not as a subexpression of the elements of `set`, the function `contains` must be used.

This method overloads the function `has` for multisets, i.e., one may use it in the form `has(set, expr)`.

## **map - Apply a function to multiset elements**

```
map(set, func, <expr, >)
```

It overloads the function `map` for multisets, i.e., one may use it in the form `map(set, func, ...)`.

## **multiplicity - Multiplicity of an element**

```
multiplicity(set, s)
```

Elements which are not contained in `set` have multiplicity zero.

## **card - Number of elements in a multiset**

```
card(set)
```

This method overloads the function `card`.

## **nops - Number of different elements in a multiset**

```
nops(set)
```

This method overloads the function `nops` for multisets, i.e., one may use it in the form `nops(set)`.

## **op - Element of a multiset**

`op(set)`

`op(set, i)`

Returns the  $i$ -th element  $s$  of the multiset `set` and its multiplicity  $m$  in form of the list  $[s, m]$ .

See also the method "`_index`".

Note that the elements of the multiset are sorted with the use of the system function `sort`, and thus the order of a multiset depends on the sorting criteria specified by this function.

This method overloads the function `op` for multisets, i.e., one may use it in the form `op(s, i)`.

### **select - Selecting of multiset elements**

`select(set, func, <expr, >)`

This method overloads the function `select` for multisets, i.e., one may use it in the form `select(set, func, ...)`. See `select` for details.

### **split - Splitting a multiset**

`split(set, func, <expr, >)`

This method overloads the function `split` for multisets, i.e., one may use it in the form `split(set, func, ...)`. See `split` for details.

### **subs - Substitution of elements in multisets**

`subs(set, )`

This method overloads the function `subs` for multisets, i.e., one may use it in the form `subs(set, ...)`.

## **Conversion Methods**

### **convert - Conversion into a multiset**

`convert(x)`

FAIL is returned if the conversion fails.

Currently only sets of type `DOM_SET` can be converted into multisets.

## **convert\_to - Multiset conversion**

`convert_to(set, T)`

FAIL is returned if the conversion fails.

Currently `T` may either be `DOM_SET` to convert the multiset `set` into a set (losing the multiplicities and the order of the elements of `set`), or `DOM_EXPR` or `"_exprseq"` to convert `set` into an expression sequence (see the method `"expand"` for details).

See also the method `"expr"`.

## **expr - Multiset conversion into an object of a kernel domain**

`expr(set)`

This method overloads the function `expr` for multisets, i.e., one may use it in the form `expr(set)`.

## **sort - Sorting of multisets**

`sort(set)`

This method overloads the function `sort` for multisets, i.e., one may use it in the form `sort(set)`.

## **Technical Methods**

### **bin\_intersect - Intersection of two multisets**

`bin_intersect(set1, set2)`

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `intersect` for multisets. One may intersect two multisets directly by `set1 intersect set2`, or in functional notation by `_intersect(set1, set2)`.

### **bin\_minus - Subtraction of two multisets**

`bin_minus(set1, set2)`

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `minus` for multisets. One may subtract two multisets directly by `set1 minus set2`, or in functional notation by `_minus(set1, set2)`.

### **homog\_union - Union of multisets**

`homog_union(set, )`

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `union` for multisets. One may compute the union of two multisets directly by `set1 union set2`, or in functional notation by `_union(set1, set2)`.

### **nested\_union - Union of nested sets**

`nested_union(setofsets)`

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `union` for multisets and sets. One may compute the union of multisets and sets directly by `set1 union set2`, or in functional notation by `_union(set1, set2)`.

## **MuPAD Domains**

DOM\_SET | Dom::ImageSet

# Dom::MultivariatePolynomial

---

**Purpose** Domains of multivariate polynomials

## Syntax

### Domain Creation

`Dom::MultivariatePolynomial(<Vars, <R, <Order>>>)`

### Element Creation

`Dom::MultivariatePolynomial(Vars, R, Order)(p)`

`Dom::MultivariatePolynomial(Vars, R, Order)(lm)`

## Description

`Dom::MultivariatePolynomial(Vars, R, ..)` creates the domain of multivariate polynomials in the variable list `Vars` over the commutative ring `R` in distributed representation.

`Dom::MultivariatePolynomial` represents multivariate polynomials over arbitrary commutative rings.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computation and some classical construction tools used in invariant theory.

---

**Note** It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

---

`Dom::MultivariatePolynomial(Vars, R, Order)` creates a domain of multivariate polynomials in the variable list `Vars` over a domain `R` of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

`Dom::MultivariatePolynomial()` creates a polynomial domain in the variable list `[x,y,z]` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering.

`Dom::MultivariatePolynomial(Vars)` generates the polynomial domain in the variable list `Vars` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

---

**Note** Only commutative coefficient rings of type `DOM_DOMAIN` which inherit from `Dom::BaseDomain` are allowed. If `R` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

---

In contrast to the domain `Dom::DistributedPolynomial`, `Dom::MultivariatePolynomial` accepts only identifiers (`DOM_IDENT`) as indeterminates. This restriction enables some further methods described below.

Please note: For reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods. This may cause strange error messages.

**Superdomain** `Dom::DistributedPolynomial`

**Axioms** If `R` has `Ax::normalRep`, then `Ax::normalRep`.

If `R` has `Ax::canonicalRep`, then `Ax::canonicalRep`.

**Categories** If `Vars` has a single variable, then `Cat::UnivariatePolynomial(R)`, else `Cat::Polynomial(R)`.

**Examples** **Example 1**

To create the ring of multivariate polynomials in `x`, `y` and `z` over the rationals one may define

```
MP := Dom::MultivariatePolynomial([x, y, z], Dom::Rational)
```

```
Dom::MultivariatePolynomial([x, y, z], Dom::Rational, LexOrder)
```

The elementary symmetric polynomials of this domain are

# Dom::MultivariatePolynomial

---

```
s1 := MP(x + y + z)
```

$x + y + z$

```
s2 := MP(x*y + x*z + y*z)
```

$x y + x z + y z$

```
s3:=MP(x*y*z)
```

$x y z$

A polynomial is called symmetric if it remains unchanged under every possible permutation of variables as, e.g.:

```
s3=s3(MP(y), MP(z), MP(x))
```

$x y z = x y z$

These polynomials arise naturally in studying the roots of a polynomial. To show this, we first have to create an univariate polynomial, e.g., in  $U$  over  $MP$ , and generate a polynomial in  $U$  with roots in  $x$ ,  $y$  and  $z$ .

```
UP:=Dom::UnivariatePolynomial(U, MP)
```

```
Dom::UnivariatePolynomial(U, Dom::MultivariatePolynomial([x, y, z], Dom::Rational, LexOrd
```

```
f := UP((U - x)*(U - y)*(U - z))
```

$$U^3 + (-x - y - z) U^2 + (x y + x z + y z) U - x y z$$

$$UP(U^3) - s1*UP(U^2) + s2*UP(U) + (-1)^3*s3$$

$$U^3 + (-x - y - z) U^2 + (x y + x z + y z) U - x y z$$

This exemplifies that the coefficients of  $f$  are (elementary) symmetric polynomials in its roots.

From the fundamental theorem of symmetric polynomials we know that every symmetric polynomial can be written uniquely as a polynomial in the elementary symmetric polynomials. Thus we can rewrite the following symmetric polynomial  $s$  in the elementary symmetric polynomials  $s1$ ,  $s2$  and  $s3$ ,

$$s := MP(x^3*y + x^3*z + x*y^3 + x*z^3 + y^3*z + y*z^3)$$

$$x^3 y + x^3 z + x y^3 + x z^3 + y^3 z + y z^3$$

$$S := MP::rewritePoly(s, [s1=S1, s2=S2, s3=S3])$$

$$S1^2 S2 - S1 S3 - 2 S2^2$$

where these polynomials are represented by the three new variables  $S1$ ,  $S2$  and  $S3$  respectively. To see that this new polynomial  $S$  in the new variables indeed represents the old original polynomial  $s$ , we simply have to plug in the three elementary symmetric polynomials into  $S$ :

$$poly(S, Expr)(s1, s2, s3)$$

# Dom::MultivariatePolynomial

---

$$x^3 y + x^3 z + x y^3 + x z^3 + y^3 z + y z^3$$

When one has a given list of polynomials, e.g., like:

$$l := [3*s1, 2*s1, s1, s3]$$

$$[3x + 3y + 3z, 2x + 2y + 2z, x + y + z, xyz]$$

and one wants to sort them in an appropriate order, one may use one of the following two methods.

$$\text{MP}::\text{sortList}(l, \text{Dom}::\text{MonomOrdering}(\text{DegLex}(3)))$$

$$[xyz, 2x + 2y + 2z, x + y + z, 3x + 3y + 3z]$$

$$\text{MP}::\text{stableSort}(l, \text{Dom}::\text{MonomOrdering}(\text{DegLex}(3)))$$

$$[xyz, 3x + 3y + 3z, 2x + 2y + 2z, x + y + z]$$

In the first sorted list the order of the three polynomials of the same degree has changed, while with the second method this order remains stable.

## Example 2

Let  $G \subset \text{GL}(n, k)$  be a finite (matrix) subgroup of the general linear group. Then a polynomial  $f \in k[x_1, \dots, x_n]$  is called *invariant under G*, if for all  $A \in G$

$$f(x) = f(A \cdot x)$$

where  $X = (X_1 \dots X_n)$ . The symmetric polynomials  $s_1$ ,  $s_2$  and  $s_3$  from the previous example are invariants under the symmetric group  $S_3$ . In fact, these three fundamental invariants yet generate the whole ring of invariants of  $S_3$ .

Now let us examine the invariants of the famous icosahedral group. One may find a representation of this group on page 73 of H. F. Blichfeldt: Finite collineation groups, University of Chicago Press, 1917.

$$S' = \begin{pmatrix} \varepsilon^3 & 0 \\ 0 & \varepsilon^2 \end{pmatrix}, U' = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, T' = \begin{pmatrix} \alpha & \beta \\ \beta & -\alpha \end{pmatrix}, \varepsilon^5 = 1, \alpha = \frac{\varepsilon^4 - \varepsilon}{\sqrt{5}}, \beta = \frac{\varepsilon^2 - \varepsilon^3}{\sqrt{5}}$$

The group is generated from these three matrices, has 120 elements and is thus a finite subgroup, even of the special linear group  $SL(2, (\varepsilon))$ . It is also well known that

$$i_1 = X_1 X_2^{11} - X_1^6 X_2^6 - X_1^{11} X_2$$

is a fundamental invariant of degree 12 of this group. To declare  $i_1$  in MuPAD one has first to define the polynomial domain.

```
MP:=Dom::MultivariatePolynomial([x1,x2],Dom::Rational)
```

```
Dom::MultivariatePolynomial([x1, x2], Dom::Rational, LexOrder)
```

```
i1:=MP(x1*x2^(11) - 11*x1^6*x2^6 - x1^(11)*x2)
```

```
- x1^11 x2 - 11 x1^6 x2^6 + x1 x2^11
```

From the invariant  $i_1$  one can compute a further fundamental invariant  $i_2$  with

# Dom::MultivariatePolynomial

---

```
i2:=MP::hessianDet(i1)
```

$$-121 x_1^{20} + 27588 x_1^{15} x_2^5 - 59774 x_1^{10} x_2^{10} - 27588 x_1^5 x_2^{15} - 121 x_2^{20}$$

But to get more simple coefficients we choose  $i_2$  as

```
i2:=-1/121*MP::hessianDet(i1)
```

$$x_1^{20} - 228 x_1^{15} x_2^5 + 494 x_1^{10} x_2^{10} + 228 x_1^5 x_2^{15} + x_2^{20}$$

instead. Similar we obtain a third fundamental invariant  $i_3$  with

```
i3:=1/20*MP::jacobianDet([i1,i2])
```

$$x_1^{30} + 522 x_1^{25} x_2^5 - 10005 x_1^{20} x_2^{10} - 10005 x_1^{10} x_2^{20} - 522 x_1^5 x_2^{25} + x_2^{30}$$

In contrast to the symmetric groups, where all invariants can be uniquely represented by the fundamental invariants, the fundamental invariants of this group have an algebraic relation, a so-called syzygy between them. It is possible to represent  $i_3^2$  in two ways:

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3])
```

$$-1728 I_1^5 + I_2^3$$

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3],Unsorted)
```

$$I_3^2$$

And hence we get the syzygy:

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3],Unsorted) -
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3]) = 0
```

$$1728 I1^5 - I2^3 + I3^2 = 0$$

## Parameters

### Vars

A list of indeterminates. Default: [x,y,z].

### R

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default: `Dom::ExpressionField(normal)`.

### Order

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder`, or `DegInvLexOrder` or any object of type `Dom::MonomOrdering`. Default: `LexOrder`.

### P

A polynomial or a polynomial expression.

### Im

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

## Entries

|-------------|-------------------------------------------------------|
| "ordering"  | The monomial ordering defined by the parameter Order. |
| "variables" | The list of variables defined by the parameter Vars.  |
| "zero"      | The neutral element w.r.t. "_plus".                   |

## Methods

### Mathematical Methods

#### **D - Differential operator for polynomials**

Inherited from Dom::DistributedPolynomial.

#### **Dpoly - Differential operator for polynomials**

Inherited from Dom::DistributedPolynomial.

#### **SPolynomial - Compute the S-polynomial of two polynomials**

Inherited from Dom::DistributedPolynomial.

#### **\_divide - Exact polynomial division**

Inherited from Dom::DistributedPolynomial.

#### **\_invert - Inverse of an element**

Inherited from Dom::DistributedPolynomial.

#### **\_mult - Multiplie polynomials and coefficient ring elements**

Inherited from Dom::DistributedPolynomial.

#### **\_negate - Negate a polynomial**

Inherited from Dom::DistributedPolynomial.

#### **\_plus - Add polynomials and coefficient ring elements**

Inherited from Dom::DistributedPolynomial.

#### **\_power - Nth power of a polynomial**

Inherited from Dom::DistributedPolynomial.

## **\_subtract - Subtract a polynomial or a coefficient ring element**

Inherited from Dom::DistributedPolynomial.

## **associates - Test if elements are associates**

Inherited from Cat::IntegralDomain.

## **borderedHessianDet - Bordered Hessian determinant of a polynomial**

borderedHessianDet(a, b, <v>)

## **borderedHessianMat - Bordered Hessian matrix of a polynomial**

borderedHessianMat(a, b, <v>)

## **content - Content of a polynomial**

Inherited from Dom::DistributedPolynomial.

## **decompose - Functional decomposition of a polynomial**

Inherited from Dom::DistributedPolynomial.

## **degLex - Compare two polynomials w.r.t. the graded lexicographical order**

degLex(a, b)

## **degRevLex - Compare two polynomials w.r.t. the graded reverse lexicographical order**

degRevLex(a, b)

## **diff - Differentiate a polynomial**

Inherited from Dom::DistributedPolynomial.

## **dimension - Dimension of affine variety**

Inherited from Dom::DistributedPolynomial.

## **divide - Divide polynomials**

Inherited from Dom::DistributedPolynomial.

## **divides - Test if elements divides another**

# Dom::MultivariatePolynomial

---

Inherited from Cat::IntegralDomain.

**equal - Test for mathematical equality**

Inherited from Dom::BaseDomain.

**equiv - Test for equivalence**

Inherited from Cat::BaseCategory.

**evalp - Evaluate a polynomial**

Inherited from Dom::DistributedPolynomial.

**factor - Factor a polynomial**

Inherited from Dom::DistributedPolynomial.

**func\_call - Apply expressions to a polynomial**

Inherited from Dom::DistributedPolynomial.

**gcd - Greatest common divisor of polynomials**

Inherited from Dom::DistributedPolynomial.

**gcdex - Extended Euclidean algorithm for polynomials**

Inherited from Dom::DistributedPolynomial.

**groebner - Reduced Gröbner basis**

Inherited from Dom::DistributedPolynomial.

**hessianDet - Hessian determinant of a polynomial**

hessianDet(a, <v>)

**hessianMat - Hessian matrix of a polynomial**

hessianMat(a, <v>)

**homogeneousComponents - List of homogeneous components of a polynomial**

homogeneousComponents(a)

**idealGenerator - Generator of finitely generated ideal**

Inherited from `Cat::EuclideanDomain`.

## **int - Definite and indefinite integration of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **intmult - Multiply a polynomial with an integer**

Inherited from `Dom::DistributedPolynomial`.

## **irreducible - Test if element is irreducible**

Inherited from `Cat::FactorialDomain`.

## **isHomogeneous - Test if a polynomial is homogeneous**

`isHomogeneous(a)`

## **isUnit - Test if element is a unit**

Inherited from `Cat::Polynomial`.

## **isone - Test for one**

Inherited from `Dom::DistributedPolynomial`.

## **iszero - Test for zero**

Inherited from `Dom::DistributedPolynomial`.

## **jacobianDet - Jacobian determinant of a polynomial**

`jacobianDet(ais, <v>)`

## **jacobianMat - Jacobian matrix of a polynomial**

`jacobianMat(ais, <v>)`

## **lcm - Least common multiple of polynomials**

Inherited from `Dom::DistributedPolynomial`.

## **makeIntegral - Make the coefficients fraction free**

Inherited from `Dom::DistributedPolynomial`.

## **monic - Normalize a polynomial**

Inherited from `Dom::DistributedPolynomial`.

# Dom::MultivariatePolynomial

---

## **normalForm - Complete reduction modulo an ideal**

Inherited from Dom::DistributedPolynomial.

## **pdioe - Solve polynomial Diophantine equations**

Inherited from Dom::DistributedPolynomial.

## **pdivide - Pseudo-division of polynomials**

Inherited from Dom::DistributedPolynomial.

## **pquo - Pseudo-quotient of polynomials**

Inherited from Dom::DistributedPolynomial.

## **prem - Pseudo-remainder of polynomials**

Inherited from Dom::DistributedPolynomial.

## **primpart - Return primitive part**

Inherited from Cat::Polynomial.

## **quo - Euclidean quotient**

Inherited from Cat::EuclideanDomain.

## **random - Create a random polynomial**

Inherited from Dom::DistributedPolynomial.

## **rem - Euclidean remainder**

Inherited from Cat::EuclideanDomain.

## **resultant - Resultant of two polynomials**

Inherited from Dom::DistributedPolynomial.

## **rewriteHomPoly - Rewrite a polynomial in terms of other polynomials**

`rewriteHomPoly(a, ais, v)`

All the polynomials `a` and `ais` must be homogeneous.

The variables of `v` should be new variables.

## **rewritePoly - Rewrite a polynomial in terms of other polynomials**

`rewritePoly(a, [ai = vi], <Unsorted>)`

This method can be used for representing a polynomial with respect to a given polynomial basis.

When option `Unsorted` is given, the list `[ai=vi]` is not sorted. Otherwise, in a precomputation step this list will be sorted in the `ai`'s w.r.t. the graded lexicographical order ("`degLex`").

Please note: the algorithm depends on the order of `Vars` and `ais`.

All the polynomials `ai` must be homogeneous.

The variables of `vi` should be new variables.

## **ringmult - Multiply a polynomial with a coefficient ring element**

Inherited from `Dom::DistributedPolynomial`.

## **solve - Zero of polynomials**

Inherited from `Dom::DistributedPolynomial`.

## **sqrfree - Square-free factorization of polynomials**

Inherited from `Dom::DistributedPolynomial`.

## **unitNormal - Return unit normal**

Inherited from `Cat::Polynomial`.

## **unitNormalRep - Return unit normal representation**

Inherited from `Cat::Polynomial`.

## **Access Methods**

### **coeff - Coefficient of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

### **degree - Degree of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

# Dom::MultivariatePolynomial

---

**degreevec - Vector of exponents of the leading term of a polynomial**

Inherited from Dom::DistributedPolynomial.

**euclideanDegree - Euclidean degree function**

Inherited from Dom::DistributedPolynomial.

**ground - Ground term of a polynomial**

Inherited from Dom::DistributedPolynomial.

**has - Existence of an object in a polynomial**

Inherited from Dom::DistributedPolynomial.

**indets - Indeterminate of a polynomial**

Inherited from Dom::DistributedPolynomial.

**lcoeff - Leading coefficient of a polynomial**

Inherited from Dom::DistributedPolynomial.

**ldegree - Lowest degree of a polynomial**

Inherited from Dom::DistributedPolynomial.

**lmonomial - Leading monomial of a polynomial**

Inherited from Dom::DistributedPolynomial.

**lterm - Leading term of a polynomial**

Inherited from Dom::DistributedPolynomial.

**mainvar - Main variable of a polynomial**

Inherited from Dom::DistributedPolynomial.

**mapcoeffs - Apply a function to the coefficients of a polynomial**

Inherited from Dom::DistributedPolynomial.

**multcoeffs - Multiply the coefficients of a polynomial with a factor**

Inherited from Dom::DistributedPolynomial.

**nterms - Number of terms of a polynomial**

Inherited from Dom::DistributedPolynomial.

**nthcoeff - N-th coefficient of a polynomial**

Inherited from Dom::DistributedPolynomial.

**nthmonomial - N-th monomial of a polynomial**

Inherited from Dom::DistributedPolynomial.

**nthterm - N-th term of a polynomial**

Inherited from Dom::DistributedPolynomial.

**order - Compare two polynomials w.r.t. a given order**

`order(a, b, o)`

**orderedVariableList - Ordered list of indeterminates of a polynomial**

Inherited from Dom::DistributedPolynomial.

**pivotSize - Size of a pivot element**

Inherited from Dom::DistributedPolynomial.

**reductum - Reductum of a polynomial**

Inherited from Dom::DistributedPolynomial.

**sortList - Sort a list of polynomials w.r.t. a given order**

`sortList(ais, o)`

This sorting method may be not stable if `o` is not a total order.

**stableSort - Sort a list of polynomials w.r.t. a given order**

`stableSort(ais, o)`

This sorting method is stable, even if `o` is not a total order.

**subs - Avoid substitution**

# Dom::MultivariatePolynomial

---

Inherited from Dom::BaseDomain.

**subsex - Avoid extended substitution**

Inherited from Dom::BaseDomain.

**tcoeff - Lowest coefficient of a polynomial**

Inherited from Dom::DistributedPolynomial.

| <b>Examples</b>    | <p><b>Example 1</b></p> <p>Creating some integer numbers using <code>Dom::Natural</code>. This example also shows that <code>Dom::Natural</code> is a façade domain.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

# Dom::Natural

---

```
Dom::Natural(2); domtype(%)
```

```
2
```

```
DOM_INT
```

```
Dom::Natural(2/3)
```

```
Error: The arguments are invalid. [Dom::Natural::new]
```

## Example 2

By tracing the method `Dom::Natural::testtypeDom` we can see the interaction between `testtype` and `Dom::Natural::testtypeDom`.

```
prog::trace(Dom::Natural::testtypeDom):
delete x:
testtype(x, Dom::Natural);
testtype(3, Dom::Natural);
prog::untrace(Dom::Natural::testtypeDom):
```

```
enter Dom::Natural::testtypeDom(x, Dom::Natural)
computed FAIL
```

```
FALSE
```

```
enter Dom::Natural::testtypeDom(3, Dom::Natural)
computed TRUE
```

TRUE

## Parameters

**x**

An integer

## Methods

Mathematical Methods

**\_divide - Division of two objects**

`_divide(x, y)`

**\_divides - Decide if a number divides another one**

`_divides(x, y)`

**euclideanDegree - Euclidean degree**

`euclideanDegree(x)`

**factor - Factorization**

`factor(x)`

**gcd - Gcd computation**

`gcd(x1, x2, )`

**gcdex - Applie the extended Euclidean algorithm**

`gcdex(x, y)`

**\_invert - Inverse of an element**

`_invert(x)`

**irreducible - Prime number test**

`irreducible(x)`

**isUnit - Test if an element is a unit**

`isUnit(x)`

**lcm - Compute the lcm**

lcm(x1, x2, ...)

## **quo - Compute the euclidean quotient**

quo(x, y)

## **random - Random number generation**

random()

random(n)

random(m, ..., n)

This methods returns a random number between 0 and  $n - 1$ .

This methods returns a random number between  $m$  and  $n$ .

## **rem - Compute the Euclidean remainder**

rem(x, y)

## **unitNormal - Unit normal part**

unitNormal(x)

## **unitNormalRep - Unit normal representation**

unitNormalRep(x)

## **Conversion Methods**

### **convert - Conversion of objects**

convert(x)

### **convert\_to - Conversion to other domains**

convert\_to(x, T)

The following domains are allowed for for T: DOM\_INT, Dom::Natural, Dom::Rational, DOM\_FLOAT, Dom::Float and Dom::Numerical.

### **testtype - Type checking**

testtype(x, T)

Usually, this method is called from the function `testtype` and not directly by the user. “Example 2” on page 6-336 demonstrates this behavior.

## MuPAD Domains

`Dom::Complex` | `Dom::Float` | `Dom::Numerical` | `Dom::Rational`  
| `Dom::Integer`

# Dom::Numerical

---

**Purpose** Field of numbers

**Syntax** `Dom::Numerical(x)`

**Description** `Dom::Numerical` is the field of numbers.

`Dom::Numerical` is the domain of numbers represented by one of the kernel domains `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, or `DOM_COMPLEX`.

`Dom::Numerical` is of category `Cat::Field` due to pragmatism. This domain actually is not a field because `bool(1.0 = float(3) / float(3))` returns `FALSE`, for example.

Elements of `Dom::Numerical` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted into a number (see below).

This means that `Dom::Numerical` is a façade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`. Every system function dealing with numbers can be applied, and computations in this domain are performed efficiently.

`Dom::Numerical` has no normal representation, because 0 and 0.0 both represent zero.

Viewed as a differential ring, `Dom::Numerical` is trivial. It only contains constants.

If `x` is a constant arithmetical expression such as `sin(2)` or `PI + 2`, the system function `float` is applied to convert `x` into a floating-point approximation.

An error message is issued if the result of this conversion is not of domain type `DOM_FLOAT` or `DOM_COMPLEX`.

**Superdomain** `Dom::ArithmeticalExpression`

**Axioms** `Ax::canonicalRep`, `Ax::systemRep`,  
`Ax::efficientOperation("_divide")`,

```
Ax::efficientOperation("_mult"),
Ax::efficientOperation("_invert")
```

## Categories

```
Cat::DifferentialRing, Cat::Field
```

## Examples

### Example 1

Dom::Numerical contains numbers of the domains DOM\_INT, DOM\_RAT, DOM\_FLOAT and DOM\_COMPLEX:

```
Dom::Numerical(2), Dom::Numerical(2/3),
Dom::Numerical(3.141), Dom::Numerical(2 + 3*I)
```

```
2, $\frac{2}{3}$, 3.141, 2 + 3 i
```

Constant arithmetical expressions are converted into a real and complex floating-point number, respectively, i.e., into an element of the domain DOM\_FLOAT or DOM\_COMPLEX (see the function float for details):

```
Dom::Numerical(exp(5)), Dom::Numerical(sin(2/3*I) + 3)
```

```
148.4131591, 3.0 + 0.717158461 i
```

Note that the elements of this domain are elements of kernel domains, there are no elements of the domain type Dom::Numerical!

An error message is issued for non-constant arithmetical expressions:

```
Dom::Numerical(sin(x))
```

```
Error: The arguments are invalid. [Dom::Numerical::new]
```

## Example 2

`Dom::Numerical` is regarded as a field, and it therefore can be used as a coefficient ring of polynomials or as a component ring of matrices, for example.

We create the domain of matrices of arbitrary size (see `Dom::Matrix`) with numerical components:

```
MatN := Dom::Matrix(Dom::Numerical)
```

```
Dom::Matrix(Dom::Numerical)
```

Next we create a banded matrix, such as:

```
A := MatN(4, 4, [-PI, 0, PI], Banded)
```

```
(0 3.141592654 0 0
 -3.141592654 0 3.141592654 0
 0 -3.141592654 0 3.141592654
 0 0 -3.141592654 0)
```

and a row vector with four components as a 1 4 matrix:

```
v := MatN([[2, 3, -1, 0]])
```

```
(2 3 -1 0)
```

Vector-matrix multiplication can be performed with the standard operator `*` for multiplication:

```
v * A
```

```
(- 9.424777961 9.424777961 9.424777961 - 3.141592654)
```

Finally we compute the determinant of the matrix A, using the function `linalg::det` of the `linalg` package:

```
linalg::det(A)
```

```
97.40909103
```

## Parameters

**x**

An arithmetical expression

## Entries

"characteristic" is zero.

## Methods

### Mathematical Methods

#### **D - Differential operator for numbers**

`D(a)`

See the function `D` for details and further calling sequences.

#### **diff - Differentiation of numbers**

`diff(a, x)`

See the function `diff` for details and further calling sequences.

#### **norm - Absolute value of numbers**

`norm(a)`

#### **random - Random number generation**

`random()`

## Conversion Methods

### **convert - Conversion of objects into numbers**

`convert(x)`

If `x` is of the domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`, `x` is returned.

Otherwise `float(x)` is computed and the result is returned, if it is of the domain type `DOM_FLOAT` or `DOM_COMPLEX`. If it is not, `FAIL` is returned.

### **convert\_to - Conversion into other domains**

`convert_to(a, T)`

If the conversion fails, `FAIL` is returned.

It currently handles the following domains for `T`: `DOM_INT`, `Dom::Integer`, `DOM_RAT`, `Dom::Rational`, `DOM_FLOAT`, `Dom::Float` and `DOM_COMPLEX`.

### **testtype - Type checking**

`testtype(a, T)`

This method is called from the function `testtype`.

## See Also

### **MuPAD Domains**

`Dom::Complex` | `Dom::Float` | `Dom::Integer` | `Dom::Rational` |  
`Dom::Real`

**Purpose**

Domains of polynomials in arbitrarily many indeterminates

**Syntax****Domain Creation**

`Dom::Polynomial(<R, <Order>>)`

**Element Creation**

`Dom::PolynomialRorder(p)`

`Dom::PolynomialRorder(lm, v)`

**Description**

`Dom::Polynomial(R, ..)` creates the domain of polynomials in arbitrarily many indeterminates over the commutative ring `R` in distributed representation.

`Dom::Polynomial` represents polynomials in arbitrarily many indeterminates over arbitrary commutative rings.

It is simply a front end to the domain

`Dom::DistributedPolynomial([],R,Order)` and thus all usual algebraic and arithmetical polynomial operations are implemented. Please see the documentation for `Dom::DistributedPolynomial` for a list of methods.

`Dom::Polynomial(R, Order)` creates a domain of polynomials in arbitrarily many indeterminates over a domain of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

If `Dom::Polynomial` is called without any argument, a polynomial domain over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

---

**Note** Only commutative coefficient rings of type `DOM_DOMAIN` which inherit from `Dom::BaseDomain` are allowed. If `R` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

---

# Dom::Polynomial

---

Only identifiers should be used as polynomial indeterminates, since when creating a new element from a polynomial or a polynomial expression the function `indet`s is first called to get the identifiers and then the polynomial is created with respect to these identifiers.

---

**Note** It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

---

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular, this is true for many access methods, converting methods and technical methods. Thus, improper use of these methods may result in confusing error messages.

**Superdomain** `Dom::DistributedPolynomial`

**Axioms** `Ax::indetElements`

**Categories** `Cat::Polynomial(R)`

**Examples** **Example 1**

The following call creates the polynomial domain over the rationals.

```
PR:=Dom::Polynomial(Dom::Rational)
```

```
Dom::Polynomial(Dom::Rational, LexOrder)
```

Since the monomial ordering was not specified, this domain is created with the default value for this parameter.

It is rather easy to create elements of this domain, as, e.g.,

a := PR(x\*(2\*x + y^3) - 7/2)

$$2x^2 + xy^3 - \frac{7}{2}$$

b := PR(x\*(2\*t + z^3) - 6)

$$2tx + xz^3 - 6$$

c := a^2-b/3+3

$$-\frac{2tx}{3} + 4x^4 + 4x^3y^3 + x^2y^6 - 14x^2 - 7xy^3 - \frac{xz^3}{3} + \frac{69}{4}$$

## Parameters

**R**

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default: `Dom::ExpressionField(normal)`.

**Order**

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder`, or `DegInvLexOrder` or an element of the domain `Dom::MonomOrdering`. Default: `LexOrder`.

**P**

A polynomial or a polynomial expression.

**lm**

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

**v**

List of indeterminates.

# Dom::Polynomial

---

## Entries

|                  |                                                                                    |
|------------------|------------------------------------------------------------------------------------|
| "characteristic" | The characteristic of this domain, which is the characteristic of R.               |
| "coeffRing"      | The coefficient ring of this domain as defined by the parameter R.                 |
| "key"            | The name of the domain created.                                                    |
| "one"            | The neutral element w.r.t. " <code>_mult</code> ", which is <code>R::one</code> .  |
| "ordering"       | The monomial order as defined by the parameter <code>Order</code> .                |
| "zero"           | The neutral element w.r.t. " <code>_plus</code> ", which is <code>R::zero</code> . |

## Algorithms

To create polynomials from expressions with no suitable indeterminates the dummy variable `_dummy` is introduced. With this variable it is possible to create elements from constants which otherwise would fail. The drawback of this approach is that two mathematically equal polynomials may have variable lists which differ by this dummy variable.

### MuPAD Domains

`Dom::DistributedPolynomial` | `Dom::MultivariatePolynomial` | `Dom::UnivariatePolynomial`

**Purpose** Homogeneous direct products

**Syntax** **Domain Creation**  
Dom::Product(Set, <n>)  
Dom::ProductSetn(e1, e2, ..., en)  
Dom::ProductSetn(List)

**Description** Dom::Product(Set, n) is an n-fold direct product of the domain *Set*.  
Dom::Product(Set, n)(e1, e2, ..., en) creates the n-tuple  $(e_1, e_2, \dots, e_n)$ .  
The objects e1, e2, ..., en must be convertible into elements of the domain *Set*, otherwise an error message is issued.  
Dom::Product(Set, n)(List) creates the n-tuple  $(l_1, l_2, \dots, l_n)$ .  
The n elements  $l_i$  of List must be convertible into elements of the domain *Set*, otherwise an error message is issued.  
The list must consist of exactly n elements, otherwise an error message is issued.  
Following to the definition of a direct product many of the methods such as "D" and "\_negate" just map the operation to all the components of the tuple.  
Most n-ary methods like "\_plus" and "\_mult" apply the operation component-wise to the tuples.

**Superdomain** Dom::BaseDomain

**Axioms** If Set has Ax::canonicalRep, then Ax::canonicalRep.  
If Set has Cat::AbelianMonoid, then Ax::normalRep.

**Categories** Cat::HomogeneousFiniteProduct(Set)

# Dom::Product

---

## Examples

### Example 1

Define the 3-fold direct product of the rational numbers:

```
P3 := Dom::Product(Dom::Rational, 3)
```

```
Dom::Product(Dom::Rational, 3)
```

and create elements:

```
a := P3([1, 2/3, 0])
```

```
[1, 2/3, 0]
```

```
b := P3(2/3, 4, 1/2)
```

```
[2/3, 4, 1/2]
```

We use the standard arithmetical operators to calculate with such tuples:

```
a + b, a*b, 2*a
```

```
[5/3, 14/3, 1/2], [2/3, 8/3, 0], [2, 4/3, 0]
```

Some system functions were overloaded for such elements, such as `diff`, `map` or `zip` (see the description of the corresponding methods "diff", "map" and "zip" above).

For example, to divide each component of `a` by 2 we enter:

```
map(a, `/`, 2)
```

$$\left[\frac{1}{2}, \frac{1}{3}, 0\right]$$

The quoted character `/` is another notation for the function `_divide`, the functional form of the division operator `/`.

Be careful that the mapping function returns elements of the domain the product is defined over. This is not checked by the function `map` (for efficiency reasons) and may lead to “invalid” tuples. For example:

```
b := map(a, sin); domtype(b)
```

$$\left[\sin(1), \sin\left(\frac{2}{3}\right), 0\right]$$

$$\text{Dom::Product}(\text{Dom::Rational}, 3)$$

But the components of `b` are no longer rational numbers!

## Parameters

### Set

An arbitrary domain of elements, i.e., a domain of category `Cat::BaseCategory`

### n

The dimension of the product (a positive integer); default is 1

### e1e2, en, ...

Elements of `Set` or objects convertible into such

### List

A list of `n` elements of `Set` or objects convertible into such

# Dom::Product

---

## Entries

|             |                                                                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "dimen"     | is the dimension of <code>Dom::Product(Set, n)</code> , which is equal to <code>n</code> .                                                                                                                     |
| "coeffRing" | is the domain <code>S</code> .                                                                                                                                                                                 |
| "one"       | is the <code>n</code> -tuple <code>(Set::one, Set::one, ..., Set::one)</code> . This entry only exists if <code>Set</code> is a monoid, i.e., a domain of category <code>Cat::Monoid</code> .                  |
| "zero"      | is the <code>n</code> -tuple <code>(Set::zero, Set::zero, ..., Set::zero)</code> . This entry only exists if <code>Set</code> is an Abelian group, i.e., a domain of category <code>Cat::AbelianGroup</code> . |

## Methods

### Mathematical Methods

#### **\_divide - Divide tuples**

`_divide(x, y)`

This method only exists if `Set` is a (multiplicative) group, i.e., a domain of category `Cat::Group`.

This method overloads the function `_divide` for `n`-tuples, i.e., one may use it in the form `x / y`, or in functional notation:

`_divide(x, y)`.

#### **\_invert - Compute the inverse of a tuple**

`_invert(x)`

This method only exists if `Set` is a (multiplicative) group, i.e., a domain of category `Cat::Group`.

This method overloads the function `_invert` for `n`-tuples, i.e., one may use it in the form `1/x` or `x^(-1)`, or in functional notation:

`_inverse(x)`.

## **\_less - Less-than relation**

`_less(x, y)`

An implementation is provided only if `Set` is an ordered set, i.e., a domain of category `Cat::OrderedSet`.

This method overloads the function `_less` for n-tuples, i.e., one may use it in the form `x < y`, or in functional notation: `_less(x, y)`.

## **\_mult - Multiplie tuples by tuples and scalars**

`_mult(x, y, )`

If `x` is not of the type `Dom::Product(Set, n)`, it is considered as a scalar which is multiplied to each component of the n-tuple `y` (and vice versa).

This method only exists if `Set` is a semigroup, i.e., a domain of category `Cat::SemiGroup`.

This method also handles more than two arguments. In this case, the argument list is split into two parts of the same length which both are multiplied with the function `_mult`. These two result are multiplied again with `_mult` whose result then is returned.

This method overloads the function `_mult` for n-tuples, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.

## **\_negate - Negate an n-tuple**

`_negate(x)`

This method overloads the function `_negate` for n-tuples, i.e., one may use it in the form `-x`, or in functional notation: `_negate(x)`.

## **\_power - ith power of a tuple**

`_power(x, i)`

An implementation is provided only if `Set` is a semigroup, i.e., a domain of category `Cat::SemiGroup`.

This method overloads the function `_power` for n-tuples, i.e., one may use it in the form  $x^i$ , or in functional notation: `_power(x, i)`.

## **`_plus` - Add tuples**

`_plus(x, y, )`

The sum of two n-tuples  $x$  and  $y$  is defined component-wise as  $(x_1 + y_1, \dots, x_n + y_n)$ .

This method overloads the function `_plus` for n-tuples, i.e., one may use it in the form  $x + y$ , or in functional notation: `_plus(x, y)`.

## **D - Differential operator**

`D(x)`

An implementation is provided only if `Set` is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

This method overloads the operator `D` for n-tuples, i.e., one may use it in the form `D(x)`.

## **diff - Differentiation of n-tuples**

`diff(a, x)`

This method overloads the function `diff` for n-tuples, i.e., one may use it in the form `diff(a, x)`.

An implementation is provided only if `Set` is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

## **equal - Test on equality of n-tuples**

`equal(x, y)`

## **intmult - Multiple of a tuple**

`intmult(x, k)`

An implementation is provided only if `Set` is an Abelian semigroup, i.e., a domain of category `Cat::AbelianSemiGroup`.

## **iszero - Test on zero**

```
iszero(x)
```

Note that there may be more than one representation of the zero n-tuple if  $R$  does not have  $Ax :: \text{canonicalRep}$ .

This method overloads the function `iszero` for n-tuples, i.e., one may use it in the form `iszero(x)`.

## **random - Random tuple generation**

```
random()
```

## **Access Methods**

### **`_index` - Tuple indexing**

```
_index(x, i)
```

See also the method "op".

This method overloads the function `_index` for n-tuples, i.e., one may use it in the form `x[i]`, or in functional notation: `_index(x, i)`.

### **map - Apply a function to tuple components**

```
map(x, func, <expr, >)
```

---

**Note** Note that the function values will *not* be implicitly converted into elements of the domain `Set`. One has to take care that the function calls return elements of the domain type `Set`.

---

This method overloads the function `map` for n-tuples, i.e., one may use it in the form `map(x, func, ...)`.

### **mapCanFail - Apply a function to tuple components**

```
mapCanFail(x, func, <expr, >)
```

### **op - Component of a tuple**

`op(x, i)`

`op(x)`

See also the method "`_index`".

This method overloads the function `op` for n-tuples, i.e., one may use it in the form `op(x, i)`.

Returns a sequence of all components of `x`.

## **set\_index - Assigning tuple components**

`set_index(x, i, e)`

See also the method "`subsop`".

---

**Note** This method does not check whether `e` has the correct type.

---

This method overloads the indexed assignment `_assign` for n-tuples, i.e., one may use it in the form `x[i] := e`, or in functional notation: `_assign(x[i], e)`.

## **sort - Sorting the components of a tuple**

`sort(x)`

This method overloads function `sort` for tuples, i.e. one may use it in the form `sort(x)`.

## **subs - Substitution of tuple components**

`subs(x, )`

---

**Note** The objects obtained by the substitutions will not be implicitly converted into elements of the domain `Set`. One has to take care that the substitutions return elements of the domain `Set`.

---

This method overloads the function `subs` for n-tuples, i.e., one may use it in the form `subs(x, ...)`. See `subs` for details and calling sequences.

### **testEach - Check every component for a certain condition**

```
testEach(x, func, <expr, >)
```

`func` must return either `TRUE` or `FALSE`, otherwise a runtime error is raised.

### **testOne - Check an component for a certain condition**

```
testOne(x, func, <expr, >)
```

`func` must return either `TRUE` or `FALSE`, otherwise a runtime error is raised.

### **zip - Combine tuples component-wise**

```
zip(x, y, func, <expr, >)
```

---

**Note** The function values will not be implicitly converted into elements of the domain `Set`. One has to take care that the function calls return elements of the domain `Set`.

---

This method overloads the function `zip` for n-tuples, i.e., one may use it in the form `zip(x, y, func, ...)`.

### **zipCanFail - Combine tuples component-wise**

```
zipCanFail(x, y, func, <expr, >)
```

## **Conversion Methods**

### **convert - Conversion into an n-tuple**

```
convert(List)
```

```
convert(e1, <e2, >)
```

`FAIL` is returned if this conversion fails.

## Dom::Product

---

Tries to convert the arguments into an element of the domain `Dom::Product(Set, n)`. This can be done if exactly `n` arguments are given where each argument can be converted into an element of the domain `Set`.

FAIL is returned if this conversion fails.

### **expr - Conversion into an object of a kernel domain**

`expr(x)`

This method overloads the function `expr` for `n`-tuples, i.e., one may use it in the form `expr(x)`.

**Purpose** Skew field of quaternions

**Syntax** Dom::Quaternion(listi)  
Dom::Quaternion(ex)  
Dom::Quaternion(M)

**Description** Domain Dom::Quaternion represents the skew field of quaternions. Quaternions are usually defined to be complex 2 2 matrices of the special form

$$\begin{pmatrix} a + b i - c - d i \\ c - d i & a - b i \end{pmatrix},$$

where  $a, b, c, d$  are real numbers. Another usual notation is  $a + bi + cj + dk$ ; the subfield of those quaternions for which  $c = d = 0$  is isomorphic to the field of complex numbers.

The domain Dom::Quaternion regards these fields as being identical, and it allows both notations that have been mentioned, as well as simply  $[a, b, c, d]$ .

If you enter a quaternion as an arithmetical expression  $ex$ , the identifiers  $i, j$ , and  $k$  are understood in the way mentioned above;  $I, J$ , and  $K$  may be used alternatively, and you may also mix small and capital letters. Every subexpression of  $ex$  not containing one of these must be real and constant.

---

**Note** Be sure that you have not assigned a value to one of the identifiers mentioned.

---

Dom::Quaternion has the domain Dom::BaseDomain as its super domain, i.e., it inherits each method which is defined by

# Dom::Quaternion

---

Dom::BaseDomain and not re-implemented by Dom::Quaternion.  
Methods described below are re-implemented by Dom::Quaternion.

**Superdomain** Dom::BaseDomain

**Axioms** Ax::canonicalRep

**Categories** Cat::SkewField

**Examples** **Example 1**

Creating some quaternions.

```
Dom::Quaternion([1,2,3,4]),
Dom::Quaternion(11+12*i+13*j+14*k);
M := Dom::Matrix(Dom::Complex)([[3+4*I, -6-2*I],[6-2*I, 3-4*I]]):
M, Dom::Quaternion(M)
```

$$1 + 2i + 3j + 4k, 11 + 12i + 13j + 14k$$
$$\begin{pmatrix} 3 + 4i & -6 - 2i \\ 6 - 2i & 3 - 4i \end{pmatrix}, 3 + 4i + 6j + 2k$$

**Example 2**

Doing some standard arithmetic.

```
a:=Dom::Quaternion([1,2,3,4]):
b:=Dom::Quaternion([11,2,33.3,2/3]):
a*b, a+b, a^2/3, b^3;
```

$$-95.56666667 - 107.2 i + 72.96666667 j + 105.2666667 k, 12 + 4 i + 36.3 j + \frac{14 k}{3}, -\frac{28}{3}$$

$$-35409.03667 - 1500.668889 i - 24986.137 j - 500.222963 k$$

### Example 3

More mathematical operations:

```
a:=Dom::Quaternion([1,2,3,4]):
b:=Dom::Quaternion([11,2,33.3,2/3]):
Dom::Quaternion::nthroot(b,3);
abs(a), sign(b)
```

$$2.993953193 + 0.07959236197 i + 1.325212827 j + 0.02653078732 k$$

$$\sqrt{30}, 0.3130950929 + 0.05692638053 i + 0.9478242358 j + 0.01897546018 k$$

### Example 4

Some miscellaneous operations.

```
a:=Dom::Quaternion([1,2,3,4]):
Dom::Quaternion::matrixform(a);
map(a, sqrt), map(a, _plus, 1);
```

$$\begin{pmatrix} 1 + 2 i - 3 - 4 i \\ 3 - 4 i \quad 1 - 2 i \end{pmatrix}$$

$$1 + \sqrt{2} i + \sqrt{3} j + 2 k, 2 + 3 i + 4 j + 5 k$$

# Dom::Quaternion

---

## Parameters

**listi**

A list containing four elements of type `Type::Real`

**ex**

Arithmetical expression

**M**

A matrix of type `Dom::Matrix(Dom::Complex)`. It has to be of a special form described in the Details section.

## Entries

"characteristic"

the characteristic of this domain is 0

"one"

the unit element; it equals `Dom::Quaternion([1,0,0,0])`.

"size"

the number of quaternions is infinity.

"zero"

The zero element; it equals `Dom::Quaternion([0,0,0,0])`.

## Methods

Mathematical Methods

**`_mult` - Multiplie quaternions**

`_mult(x, y, )`

**`_plus` - Add quaternions**

`_plus(x, y, )`

**`_power` - n-th power of a quaternion**

`_power(x, n)`

**`Im` - Return the imaginary (vectorial) part of a quaternion.**

`Im(x)`

The result is still a quaternion.

## **Re - Return the real part of a quaternion.**

`Re(x)`

The result is of type `Type::Real`.

## **abs - Absolute value of a quaternion**

`abs(x)`

The result is of type `Type::Real`.

## **conjugate - Conjugate element**

`conjugate(x)`

## **intpower - Multiplie quaternions**

`intpower(x, {DOM_INT})`

The implementation uses “repeated squaring”.

`Dom::Quaternion` is used by “\_power”.

## **nthroot - N-th root of a quaternion**

`nthroot(x, n)`

The implementation uses “repeated squaring”.

`Dom::Quaternion` is used by “\_power”.

## **norm - Norm of a quaternion**

`norm(x)`

The result is of type `Type::Real`.

## **random - Random number generation**

`random()`

## **scalarmult - Scalar multiplication**

`scalarmult(s, x)`

## **scalarprod - Inner product**

# Dom::Quaternion

---

scalarprod(x, y)

## **sign - Sign of a quaternion**

sign(x)

The result is of type `Type::Real`.

## **Conversion Methods**

### **convert - Conversion of objects**

convert(x)

### **convert\_to - Conversion to other domains**

convert\_to(x, T)

It currently handles the following domains for T: `DOM_EXPR`, `DOM_LIST`, `Dom::Matrix(Dom::Complex)`.

### **expr - Convert a quaternion to an object of a kernel domain**

expr(x)

The result is an object of the kernel domain `DOM_EXPR`.

This method overloads the function `expr` for quaternions, i.e., you may use it in the form `expr(x)`.

### **matrixform - Convert a quaternion to a 2 x 2 matrix with complex entries.**

matrixform(x)

The result is an object of the domain `Dom::Matrix(Dom::Complex)`.

## **Technical Methods**

### **TeX - Generate TeX-formatted string**

TeX(x)

### **map - Apply a function to all components of a quaternion**

```
map(x, f, arg,)
```

If optional arguments are present, then each component  $co$  of  $x$  is replaced by  $f(co, arg\dots)$ . So for the quaternion  $x := a + bi + cj + dk$ , `Dom::Quaternion(x, f, arg, ...)` returns the quaternion  $f(a, arg, \dots) + f(b, arg, \dots)i + f(c, arg, \dots)j + f(d, arg, \dots)k$ .

## **simplify - Simplification of a quaternion**

```
simplify(x)
```

## **See Also**

## **MuPAD Domains**

`Dom::Complex`

# Dom::Rational

---

**Purpose** Field of rational numbers

**Syntax** `Dom::Rational(x)`

**Description** `Dom::Rational` is the domain of rational numbers represented by elements of the domains `DOM_INT` or `DOM_RAT`. `Dom::Rational` represents the field of rational numbers.

Elements of `Dom::Rational` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is of type `DOM_INT` or `DOM_RAT`. This means `Dom::Rational` is a façade domain which creates elements of domain type `DOM_INT` or `DOM_RAT`.

Viewed as a differential ring `Dom::Rational` is trivial, it contains constants only.

`Dom::Rational` has the domain `Dom::Numerical` as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Rational`. Methods described below are re-implemented by `Dom::Rational`.

**Superdomain** `Dom::Numerical`

**Axioms** `Ax::canonicalRep`, `Ax::systemRep`, `Ax::canonicalOrder`,  
`Ax::efficientOperation("_divide")`,  
`Ax::efficientOperation("_mult")`,  
`Ax::efficientOperation("_invert")`

**Categories** `Cat::QuotientField(Dom::Integer)`, `Cat::DifferentialRing`,  
`Cat::OrderedSet`

**Examples** **Example 1**

Creating some rational numbers using `Dom::Rational`. This example also shows that `Dom::Rational` is a façade domain.

```
Dom::Rational(2/3) ; domtype(%)
```

$\frac{2}{3}$

DOM\_RAT

Dom::Rational(2.0)

Error: The arguments are invalid. [Dom::Rational::new]

## Example 2

By tracing the method Dom::Rational::testtypeDom we can see the interaction between testtype and Dom::Rational::testtypeDom.

```
prog::trace(Dom::Rational::testtypeDom):
delete x:
testtype(x, Dom::Rational);
testtype(3/4, Dom::Rational);
prog::untrace(Dom::Rational::testtypeDom):
```

```
enter Dom::Rational::testtypeDom(x, Dom::Rational)
computed FAIL
```

FALSE

```
enter Dom::Rational::testtypeDom(3/4, Dom::Rational)
computed TRUE
```

# Dom::Rational

---

TRUE

## Parameters

**x**

An integer or a rational number

## Methods

Mathematical Methods

**denom - Denominator of a rational number**

denom(x)

**diff - Differentiates**

diff(z, <x, >)

**numer - Numerator of the rational number**

numer(x)

**random - Random number generation**

random()

**retract - Retract to an integer element**

retract(x)

Conversion Methods

**convert - Conversion of objects**

convert(x)

**convert\_to - Conversion to other domains**

convert\_to(x, T)

The following domains are allowed for T: DOM\_INT, Dom::Integer, Dom::Rational, DOM\_RAT, DOM\_FLOAT, Dom::Float and Dom::Numerical.

**testtype - Type checking**

`testtype(x, T)`

In general this method is called from the function `testtype` and not directly by the user. “Example 2” on page 6-367 demonstrates this behaviour.

### MuPAD Domains

`Dom::Complex` | `Dom::Float` | `Dom::Numerical` | `Dom::Rational`  
| `Dom::Real`

# Dom::Real

---

**Purpose** Field of real numbers

**Syntax** `Dom::Real(x)`

**Description** `Dom::Real` is the field of real numbers represented by elements of the kernel domains `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, and `DOM_EXPR`.

`Dom::Real` is the domain of real numbers represented by expressions of type `DOM_INT`, `DOM_RAT` or `DOM_FLOAT`. An expression of type `DOM_EXPR` is considered as a real number if it is of type `Type::Arithmetical` and if it contains no indeterminates which are not of type `Type::ConstantIdents` and if it contains no imaginary part. See “Example 2” on page 6-371.

`Dom::Real` has category `Cat::Field` due to practical reasons. This domain actually is not a field because `bool(1.0 = 1e100 + 1.0 - 1e100)` returns `FALSE` for example.

Elements may not have an unique representation, for example `bool(0 = sin(2)^2 + cos(2)^2 - 1)` returns `FALSE`.

Elements of `Dom::Real` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted to a number. This means `Dom::Real` is a façade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, or `DOM_EXPR`.

`Dom::Real` has no normal representation, because 0 and 0.0 both represent zero.

Viewed as a differential ring, `Dom::Real` is trivial, it contains constants only.

`Dom::Real` has the domain `Dom::Complex` as its super domain, i.e., it inherits each method which is defined by `Dom::Complex` and not re-implemented by `Dom::Real`. Methods described below are re-implemented by `Dom::Real`.

**Superdomain** `Dom::Complex`

**Axioms**

```
Ax::systemRep, Ax::canonicalOrder,
Ax::efficientOperation("_divide"),
Ax::efficientOperation("_mult"),
Ax::efficientOperation("_invert")
```

**Categories**

```
Cat::DifferentialRing, Cat::Field, Cat::OrderedSet
```

**Examples****Example 1**

The following lines demonstrate how to generate elements of `Dom::Real`. The rational and the floating-point numbers are elements of the real numbers:

```
Dom::Real(2/3)
```

$$\frac{2}{3}$$

```
Dom::Real(0.5666)
```

$$0.5666$$
**Example 2**

The numbers `PI` and `sin(2)` are real numbers whereas `sin(2/3 * I) + 3` and `sin(x)` for general symbolic `x` are not real numbers. If we try to create the elements `Dom::Real(sin(2/3 * I) + 3)` and `Dom::Real(sin(x))` an error message is produced.

```
Dom::Real(PI)
```

$$\pi$$

```
Dom::Real(sin(2))
```

# Dom::Real

---

```
sin(2)
```

```
Dom::Real(sin(2/3 * I) + 3)
```

```
Error: The arguments are invalid. [Dom::Real::new]
```

```
Dom::Real(sin(x))
```

```
Error: The arguments are invalid. [Dom::Real::new]
```

## Parameters

**x**

An expression of type DOM\_INT, DOM\_RAT, or DOM\_FLOAT. An expression of type DOM\_EXPR is also allowed if it is of type Type::Arithmetical and if it contains no indeterminates which are not of type Type::ConstantIdents and if it contains no imaginary part.

## Methods

Mathematical Methods

**\_less - Boolean operator "less"**

```
_less(x, y)
```

**\_leequal - Boolean operator "less or equal"**

```
_leequal(x, y)
```

**\_power - Power operator**

```
_power(z, n)
```

**conjugate - Complex conjugate**

```
conjugate(x)
```

**Im - Imaginary part of a real number**

`Im(x)`

**random - Random number generation**

`random()`

`random(n)`

`random(m .. n)`

This method returns a random number generator which creates positive integer between 0 and  $n - 1$ .

This method returns a random number generator which creates positive integer between  $m$  and  $n$ .

**Re - Real part of a real number**

`Re(x)`

**Conversion Methods****convert - Conversion of objects**

`convert(x)`

**convert\_to - Conversion to other domains**

`convert_to(x, T)`

The following domains are allowed for T: DOM\_INT, Dom::Integer, DOM\_RAT, Dom::Rational, DOM\_FLOAT, Dom::Float, Dom::Numerical, Dom::ArithmeticalExpression, Dom::Complex.

Domains**

Dom::Complex | Dom::Float | Dom::Integer | Dom::Numerical |  
Dom::Rational

# Dom::SparseMatrixF2

---

**Purpose** Domain of sparse matrices over the field with two elements

---

**Note** Dom::SparseMatrixF2 has been removed. Use Dom::Matrix(Dom::IntegerMod(2)) instead.

---

**Description** Dom::SparseMatrixF2 represents the set of all matrices over the finite field with two elements.

Dom::SparseMatrixF2( $m$ ,  $n$ , [ $s_1$ , ...,  $s_m$ ]) creates the  $m$  times  $n$  matrix  $(a_{ij})$  such that, for each  $i$ , the set of all  $j$  with  $a_{ij} = 1$  equals the set (or list)  $s_i$ .

The internal representation of Dom::SparseMatrixF2 guarantees that both storage and computing time required for the arithmetical operations depend on the number of non-zero entries. Therefore, Dom::SparseMatrixF2 is suitable for representing large matrices with few nonzero entries.

The matrices generated by Dom::SparseMatrixF2 are mathematically equivalent to the matrices generated by Dom::Matrix(Dom::IntegerMod(2)). We recommend to use Dom::Matrix(Dom::IntegerMod(2)).

**Superdomain** Dom::BaseDomain

**Axioms** Ax::canonicalRep

**Categories** Cat::Matrix(Dom::IntegerMod(2))

**Parameters** **m, n**

Positive integers

**s1, ...**

Sets or lists of integers between 1 and n

**f**

A procedure or another object that, when called with an integer between 1 and  $m$  and another integer between 1 and  $n$ , returns an element of `Dom::IntegerMod(2)`.

## Entries

|             |                                                                      |
|-------------|----------------------------------------------------------------------|
| "coeffRing" | The coefficient ring always equals <code>Dom::IntegerMod(2)</code> . |
| "isSparse"  | This entry is always set to TRUE.                                    |

## Methods

### Mathematical Methods

#### **zeroMatrix - Matrix of a given dimension, consisting of zeros**

```
zeroMatrix(m, n)
```

#### **\_plus - Add matrices**

```
_plus(A,)
```

This method overloads the function `_plus`.

#### **\_negate - Negate a matrix**

```
_negate(A)
```

#### **matrixvectorproduct - Multiply a matrix and a vector**

```
matrixvectorproduct(A, b)
```

#### **\_mult - Multiply a matrix and a vector**

```
_mult(A, b)
```

It overloads the function `_mult`.

---

**Note** The product of arbitrary sparse matrices (where  $b$  is not a vector) has *not* been implemented.

---

#### **randmatrix - Generate random matrix**

```
randmatrix(m, n, <s>)
```

## Access Methods

### **nrows - Number of rows**

```
nrows(A)
```

### **ncols - Number of rows**

```
ncols(A)
```

### **dimen - Number of rows and columns**

```
dimen(A)
```

### **body - Body of the matrix**

```
body(A)
```

### **row - Row of a matrix**

```
row(A, i)
```

### **col - Column of a matrix**

```
col(A, i)
```

### **\_index - Row or single entry of a matrix**

```
_index(A, i)
```

```
_index(A, i, j)
```

This method overloads the `_index` operator; `A[i]` may be entered equivalently.

returns the entry of `A` in the  $i$ -th row,  $j$ -th column.

Equivalently, `A[i, j]` may be entered.

### **set\_index - Assignment to a matrix entry**

```
set_index(A, i, j, v)
```

This method can be used for indexed assignments using the syntax `A[i, j]:=v`. In this case, the value of the identifier or local

variable `A` is changed as a side effect; `v` (but not the result of converting it to a field element!) is returned.

---

**Note** If the assignment stops with an error, the domain element stored in `A` is destroyed, and the new value of `A` is `FAIL`.

---

See `_assign` for more information about indexed assignments.

### Conversion Methods

#### **convert\_to - Conversion of a sparse matrix into another type**

`convert_to(A, T)`

### See Also

### MuPAD Domains

`Dom::IntegerMod` | `Dom::Matrix`

# Dom::SquareMatrix

---

**Purpose** Rings of square matrices

**Syntax** **Domain Creation**  
`Dom::SquareMatrix(n, <R>)`

**Element Creation**

`Dom::SquareMatrix(n, R)(Array)`  
`Dom::SquareMatrix(n, R)(Matrix)`  
`Dom::SquareMatrix(n, R)(<n, n>)`  
`Dom::SquareMatrix(n, R)(<n, n>, ListOfRows)`  
`Dom::SquareMatrix(n, R)(<n, n>, f)`  
`Dom::SquareMatrix(n, R)(<n, n>, List, <Diagonal>)`  
`Dom::SquareMatrix(n, R)(<n, n>, g, <Diagonal>)`  
`Dom::SquareMatrix(n, R)(<n, n>, List, <Banded>)`

**Description** **Domain Creation**

`Dom::SquareMatrix(n, R)` creates a domain which represents the ring of  $n \times n$  matrices over a component domain  $R$ . The domain  $R$  must be of category `Cat::Rng` (a ring, possibly without unit).

If the optional parameter  $R$  is not given, the domain `Dom::ExpressionField()` is used as the component ring for the square matrices.

For matrices of a domain created by `Dom::SquareMatrix(n, R)`, standard matrix arithmetic is implemented by overloading the standard arithmetical operators  $+$ ,  $-$ ,  $*$ ,  $/$  and  $^$ . All functions of the `linalg` package dealing with matrices can also be applied.

`Dom::SquareMatrix(n, R)` has the domain `Dom::Matrix(R)` as its super domain, i.e., it inherits each method which is defined by `Dom::Matrix(R)` and not re-implemented by `Dom::SquareMatrix(n, R)`.

Methods described below are re-implemented by `Dom::SquareMatrix`.

The domain `Dom::Matrix(R)` represents matrices over  $R$  of arbitrary size, and it therefore does not have any algebraic structure (except of being a *set* of matrices).

The domain `Dom::MatrixGroup(m, n, R)` represents the Abelian group of  $m \times n$  matrices over  $R$ .

## Element Creation

`Dom::SquareMatrix(n, R)(Array)` and `Dom::SquareMatrix(n, R)(Matrix)` create a new matrix formed by the entries of `Array` and `Matrix`, respectively.

The components of `Array` and `Matrix`, respectively, are converted into elements of the domain  $R$ . An error message is issued if one of these conversions fails.

The call `Dom::SquareMatrix(n, R)(n, n)` returns the  $n \times n$  zero matrix. Note that the  $n \times n$  zero matrix is also defined by the entry "zero" (see below).

`Dom::SquareMatrix(n, R)(n, n ListOfRows)` creates an  $n \times n$  matrix with components taken from the nested list `ListOfRows`. Each inner list corresponds to a row of the matrix.

If an inner list has less than  $n$  entries, the remaining components in the corresponding row of the matrix are set to zero. If there are less than  $n$  inner lists, the remaining lower rows of the matrix are filled with zeroes.

The entries of the inner lists are converted into elements of the domain  $R$ . An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::SquareMatrix(n, R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

`Dom::SquareMatrix(n, R)(n, n f)` returns the matrix whose  $(i, j)$ th component is the value of the function call `f(i, j)`. The row and column indices  $i$  and  $j$  range from 1 to  $n$ .

The function values are converted into elements of the domain  $R$ . An error message is issued if one of these conversions fails.

**Superdomain** `Dom::Matrix(R)`

# Dom::SquareMatrix

---

**Axioms**            If R has Ax::canonicalRep, then Ax::canonicalRep.

**Categories**        Cat::SquareMatrix(R)

**Examples**            **Example 1**

A lot of examples can be found on the help page of the domain constructor Dom::Matrix, and most of them are also examples for working with domains created by Dom::SquareMatrix.

These examples only concentrate on some differences with respect to working with matrices of the domain Dom::Matrix(R).

The following command defines the ring of two-dimensional matrices over the rationals:

```
SqMatQ := Dom::SquareMatrix(2, Dom::Rational)
```

```
Dom::SquareMatrix(2, Dom::Rational)
```

```
SqMatQ::hasProp(Cat::Ring)
```

```
TRUE
```

The unit is defined by the entry "one", which is the 2 2 identity matrix:

```
SqMatQ::one
```

```
 $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$
```

Note that some operations defined by the domain SqMatQ return matrices which are no longer square. They return therefore matrices of the domain Dom::Matrix(Dom::Rational), the super-domain of SqMatQ. For example, if we delete the first row of the matrix:

```
A := SqMatQ([[1, 2], [-5, 3]])
```

$$\begin{pmatrix} 1 & 2 \\ -5 & 3 \end{pmatrix}$$

we get the matrix:

```
SqMatQ::delRow(A, 1)
```

$$(-5 \ 3)$$

which is of the domain type:

```
domtype(%)
```

```
Dom::Matrix(Dom::Rational)
```

## Example 2

We can convert a square matrix into or from another matrix domain, as shown next:

```
SqMatR := Dom::SquareMatrix(3, Dom::Real):
```

```
MatC := Dom::Matrix(Dom::Complex):
```

```
A := SqMatR((i, j) -> sin(i*j))
```

$$\begin{pmatrix} \sin(1) & \sin(2) & \sin(3) \\ \sin(2) & \sin(4) & \sin(6) \\ \sin(3) & \sin(6) & \sin(9) \end{pmatrix}$$

To convert A into a matrix of the domain MatC, enter:

# Dom::SquareMatrix

---

```
coerce(A, MatC)
```

$$\begin{pmatrix} \sin(1) & \sin(2) & \sin(3) \\ \sin(2) & \sin(4) & \sin(6) \\ \sin(3) & \sin(6) & \sin(9) \end{pmatrix}$$

```
domtype(%)
```

```
Dom::Matrix(Dom::Complex)
```

The conversion is done component-wise, as the following examples shows:

```
B := MatC([[0, 1], [exp(I), 0]])
```

$$\begin{pmatrix} 0 & 1 \\ e^i & 0 \end{pmatrix}$$

The matrix  $B$  is square but has one complex component and therefore cannot be converted into the domain SqMatR:

```
coerce(B, SqMatR)
```

```
FAIL
```

## Parameters

**n**

A positive integer

**R**

A ring, i.e., a domain of category `Cat::Rng`; default is `Dom::ExpressionField()`

## **Array**

An  $n \times n$  array

## **Matrix**

An  $n \times n$  matrix, i.e., an element of a domain of category `Cat::Matrix`

## **List**

A list of matrix components

## **ListOfRows**

A list of at most  $n$  rows; each row is a list of at most  $n$  matrix components

## **f**

A function or a functional expression with two parameters (the row and column index)

## **g**

A function or a functional expression with one parameter (the row index)

## **Options**

### **Diagonal**

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function.

`Dom::SquareMatrix(n, R)( n , n List, Diagonal)` creates the  $n \times n$  diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most  $n$  entries. If it has fewer elements, the remaining diagonal elements are set to zero.

# Dom::SquareMatrix

---

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::SquareMatrix(n, R)( n , n g, Diagonal)` returns the matrix whose  $i$ th diagonal element is  $g(i)$ , where the index  $i$  runs from 1 to  $n$ .

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

## Banded

Create a banded Toeplitz matrix

`Dom::SquareMatrix(n, R)( n , n List, Banded)` creates an  $n$  banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say  $2h + 1$ , and must not exceed  $n$ . The resulting matrix has bandwidth at most  $2h + 1$ .

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the  $i$ th subdiagonal are initialized with the  $(h + 1 - i)$ th element of `List`. All elements of the  $i$ th superdiagonal are initialized with the  $(h + 1 + i)$ th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

## Entries

|               |                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "one"         | is the $n \ n$ identity matrix. This entry exists if the component ring <code>R</code> is a domain of category <code>Cat::Ring</code> , i.e., a ring with unit. |
| "randomDimen" | is set to <code>[n, n]</code> .                                                                                                                                 |
| "zero"        | is the $n \ n$ zero matrix.                                                                                                                                     |

## Methods

### Mathematical Methods

#### **evalp - Evaluating matrices of polynomials at a certain point**

`evalp(A, x = a, )`

This method is only defined if  $R$  is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

#### **identity - Identity matrix**

`identity(k)`

---

**Note** The matrix returned is of the domain `Dom::Matrix(R)` if  $k \neq n$ .

---

This method only exists if the component ring  $R$  is of category `Cat::Ring`, i.e., a ring with unit.

#### **matdim - Matrix dimension**

`matdim(A)`

#### **random - Random matrix generation**

`random()`

The components of the random matrix are generated with the method "random" of the component ring  $R$ .

### Access Methods

#### **\_concat - Horizontal concatenation of matrices**

`_concat(A, B, )`

An error message is issued if the given matrices do not have the same number of rows.

# Dom::SquareMatrix

---

---

**Note** The matrix returned is of the domain `Dom::Matrix(R)`!

---

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B . ...`, or in functional notation: `_concat(A, B, ...)`.

## **`_index` - Matrix indexing**

`_index(A, i, j)`

`_index(A, r1 .. r2, c1 .. c2)`

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

---

**Note** Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

---

Returns the submatrix of `A`, created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

---

**Note** The submatrix returned is of the domain `Dom::Matrix(R)`!

---

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]` and `A[r1..r2, c1..c2]`, respectively, or in functional notation: `_index(A, ...)`.

## **`concatMatrix` - Horizontal concatenation of matrices**

`concatMatrix(A, B, )`

## **`col` - Extracting a column**

`col(A, c)`

An error message is issued if `c` is less than one or greater than `n`.

### **delCol - Deleting a column**

`delCol(A, c)`

NIL is returned if `A` only consists of one column.

---

**Note** The matrix returned is of the domain `Dom::Matrix(R)`.

---

An error message is issued if `c` is less than one or greater than `n`.

### **delRow - Deleting a row**

`delRow(A, r)`

NIL is returned if `A` only consists of one row.

---

**Note** The matrix returned is of the domain `Dom::Matrix(R)`.

---

An error message is issued if `r` is less than one or greater than `n`.

### **row - Extracting a row**

`row(A, r)`

An error message is issued if `r` is less than one or greater than `n`.

### **stackMatrix - Vertical concatenation of matrices**

`stackMatrix(A, B, )`

An error message is issued if the given matrices do not have the same number of columns.

# Dom::SquareMatrix

---

---

**Note** The matrix returned is of the domain `Dom::Matrix(R)`!

---

## Conversion Methods

### **create - Defining matrices without component conversions**

`create(x, ...)`

This method should be used if the elements of the parameters `x, ...` are elements of the domain type `R`. This is often the case if a matrix is to be created whose components come from preceding matrix and scalar operations.

## See Also

### **MuPAD Domains**

`Dom::Matrix` | `Dom::MatrixGroup`

**Purpose** Symmetric groups

**Syntax** Dom::SymmetricGroup(n)  
Dom::SymmetricGroup(n)(1)

**Description** Dom::SymmetricGroup(n) creates the symmetric group of order  $n$ , that is, the domain of all the permutations of  $\{1, \dots, n\}$  elements.

A permutation of  $n$  elements is a bijective mapping of the set  $\{1, \dots, n\}$  onto itself.

The domain element Dom::SymmetricGroup(n)(1) represents the bijective mapping of the first  $n$  positive integers that maps the integer  $i$  to  $1[i]$ , for  $1 \leq i \leq n$ .

**Superdomain** Dom::BaseDomain

**Axioms** Ax::canonicalRep

**Categories** Cat::Group

**Examples** **Example 1**

Consider the group of permutations of the first seven positive integers:

```
G := Dom::SymmetricGroup(7)
```

```
Dom::SymmetricGroup(7)
```

We create an element of G by providing the image of 1, 2, etc.:

```
a:=G([2,4,6,1,3,5,7])
```

```
[2, 4, 6, 1, 3, 5, 7]
```

# Dom::SymmetricGroup

---

`a(3)`

`6`

## Parameters

**n**

Positive integer

**l**

List or array consisting of the first  $n$  integers in some order.

## Entries

"one"

the identical mapping of the set  $\{1, \dots, n\}$  to itself.

## Methods

**Mathematical Methods**

**`_mult` - Product of permutations**

`_mult(a1, )`

This method overloads the function `_mult`.

**`_invert` - Inverse of a permutation**

`_invert(a)`

This method overloads the function `_invert`.

**`func_call` - Function value of a permutation at a point**

`func_call(a, i)`

It computes the function value of  $a$  at  $i$ , i.e., the integer that  $i$  is mapped to by the permutation  $a$ ;  $i$  must be an integer between 1 and  $n$ .

**`cycles` - Cycle representation of a permutation**

`cycles(a)`

**order - Order of a permutation**

`order(a)`

**inversions - Number of inversions**

`inversions(a)`

**sign - Sign of a permutation**

`sign(a)`

**random - Random permutation**

`random()`

Access Methods

**allElements - Return all elements of the group**

`allElements()`

**size - Return the size of the group**

`size()`

Conversion Methods

**convert - Conversion of an object into a permutation**

`convert(x)`

**convert\_to - Conversion of a permutation into another type**

`convert_to(a, T)`

**expr - Convert a permutation into a list**

`expr(a)`

# Dom::UnivariatePolynomial

---

**Purpose** Domains of univariate polynomials

**Syntax** **Domain Creation**  
Dom::UnivariatePolynomial(<Var, <R, <Order>>>)

**Element Creation**  
Dom::UnivariatePolynomial(Var, R, Order)(p)  
Dom::UnivariatePolynomial(Var, R, Order)(lm)

**Description** Dom::UnivariatePolynomial(Var, R, ..) creates the domain of univariate polynomials in the variable Var over the commutative ring R.

Dom::UnivariatePolynomial represents univariate polynomials over arbitrary commutative rings.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computations.

Dom::UnivariatePolynomial(Var, R, Order) creates a domain of univariate polynomials in the variable Var over a domain of category Cat::CommutativeRing in sparse representation with respect to the monomial ordering Order.

Dom::UnivariatePolynomial() creates the univariate polynomial domain in the variable x over the domain Dom::ExpressionField(normal) with respect to the lexicographic monomial ordering.

Dom::UnivariatePolynomial(Var) creates the univariate polynomial domain in the variable Var over the domain Dom::ExpressionField(normal) with respect to the lexicographic monomial ordering.

---

**Note** Only commutative coefficient rings of type DOM\_DOMAIN which inherit from Dom::BaseDomain are allowed. If R is of type DOM\_DOMAIN but inherits not from Dom::BaseDomain, the domain Dom::ExpressionField(normal) will be used instead.

---

For this domain only identifiers are valid variables.

---

**Note** It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

---

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods. Therefore, using these methods inappropriately may result in strange error messages.

**Superdomain** Dom::MultivariatePolynomial

**Axioms** If R has Ax::normalRep, then Ax::normalRep.  
If R has Ax::canonicalRep, then Ax::canonicalRep.

**Categories** Cat::UnivariatePolynomial(R)

**Examples** **Example 1**

To create the ring of univariate polynomials in x over the integers one may define

```
UP:=Dom::UnivariatePolynomial(x,Dom::Integer)
```

```
Dom::UnivariatePolynomial(x, Dom::Integer, LexOrder)
```

Now, let us create two univariate polynomials.

```
a:=UP((2*x-1)^2*(3*x+1))
```

# Dom::UnivariatePolynomial

---

$$12x^3 - 8x^2 - x + 1$$

$$b := \text{UP}((2x-1)(3x+1))^2$$

$$36x^4 - 12x^3 - 11x^2 + 2x + 1$$

The usual arithmetical operations for polynomials are available:

$$a^2 + a*b$$

$$432x^7 - 288x^6 - 264x^5 + 200x^4 + 35x^3 - 36x^2 - x + 2$$

The leading coefficient, leading term, leading monomial and reductum of a are

$$\text{lcoeff}(a), \text{lterm}(a), \text{lmonomial}(a), \text{UP}::\text{reductum}(a)$$

$$12, x^3, 12x^3, -8x^2 - x + 1$$

and a is of degree

$$\text{degree}(a)$$

$$3$$

The method `gcd` computes the greatest common divisor of two polynomials

$$\text{gcd}(a, b)$$

$$12x^3 - 8x^2 - x + 1$$

and lcm the least common multiple:

`lcm(a,b)`

$$36x^4 - 12x^3 - 11x^2 + 2x + 1$$

Computing the definite and indefinite integral of a polynomial is also possible,

`int(a)`

$$3x^4 - \frac{8x^3}{3} - \frac{x^2}{2} + x$$

which is in the case of indefinite integration simply the antiderivative of the polynomial.

`D(int(a)), domtype(D(int(a)))`

$$12x^3 - 8x^2 - x + 1, \text{Dom::UnivariatePolynomial}(x, \text{Dom::Fraction}(\text{Dom::Integer}), \text{LexOrder})$$

But, since for representing the indefinite integral of a the coefficient ring chosen as the integers is not appropriate, the polynomial ring over its quotient field is used instead.

Furthermore, interpreting the polynomials as polynomial functions is also allowed in applying coefficient ring elements, polynomials of this domain or arbitrary expressions with option `Expr` to them:

`a(5)`

# Dom::UnivariatePolynomial

---

1296

a(b)

$$559872 x^{12} - 559872 x^{11} - 326592 x^{10} + 414720 x^9 + 73872 x^8 - 123120 x^7 - 9924 x^6 + 18408 x^5 - 1364 x^3 - 97 x^2 + 38 x + 4$$

a(sin(x), Expr)

$$12 \sin(x)^3 - 8 \sin(x)^2 - \sin(x) + 1$$

To get a vector of coefficients of a polynomial, which gives the dense representation of it, one may use the method `vectorize`.

`UP::vectorize(a)`, `UP::vectorize(a,6)`

`[1, -1, -8, 12]`, `[1, -1, -8, 12, 0, 0]`

## Parameters

### Var

An indeterminate given by an identifier; default is `x`.

### R

A commutative ring, i.e. a domain of category `Cat::CommutativeRing`; default is `Dom::ExpressionField(normal)`.

### Order

A monomial ordering, i.e. one of the predefined orderings `LexOrder`, `DegreeOrder` or `DegInvLexOrder` or an element of domain `Dom::MonomOrdering`; default is `LexOrder`.

## **P**

A polynomial or a polynomial expression.

## **lm**

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

## **Entries**

|                  |                                                                                  |
|------------------|----------------------------------------------------------------------------------|
| "characteristic" | The characteristic of this domain.                                               |
| "coeffRing"      | The coefficient ring of this domain as defined by the parameter <code>R</code> . |
| "key"            | The name of the domain created.                                                  |
| "one"            | The neutral element w.r.t. " <code>_mult</code> ".                               |
| "ordering"       | The monomial order as defined by the parameter <code>Order</code> .              |
| "variables"      | The list of the variable as defined by the parameter <code>Var</code> .          |
| "zero"           | The neutral element w.r.t. " <code>_plus</code> ".                               |

# Dom::UnivariatePolynomial

---

`coeff(a, Var, n)` returns the coefficient of the term  $\text{Var}^n$  as an element of  $R$ .

`coeff(a, n)` returns the coefficient of the term  $\text{Var}^n$  as an element of  $R$ .

This method overloads the function `coeff` for polynomials.

## **degree - Degree of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **degreevec - Vector of exponents of the leading term of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **euclideanDegree - Euclidean degree function**

Inherited from `Dom::DistributedPolynomial`.

## **ground - Ground term of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **has - Existence of an object in a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **indets - Indeterminate of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **lcoeff - Leading coefficient of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **ldegree - Lowest degree of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **lmonomial - Leading monomial of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

## **lterm - Leading term of a polynomial**

Inherited from `Dom::DistributedPolynomial`.

**mainvar - Main variable of a polynomial**

Inherited from Dom::DistributedPolynomial.

**mapcoeffs - Apply a function to the coefficients of a polynomial**

Inherited from Dom::DistributedPolynomial.

**multcoeffs - Multiplie the coefficients of a polynomial with a factor**

Inherited from Dom::DistributedPolynomial.

**nterms - Number of terms of a polynomial**

Inherited from Dom::DistributedPolynomial.

**nthcoeff - N-th coefficient of a polynomial**

Inherited from Dom::DistributedPolynomial.

**nthmonomial - N-th monomial of a polynomial**

Inherited from Dom::DistributedPolynomial.

**nthterm - N-th term of a polynomial**

Inherited from Dom::DistributedPolynomial.

**order - Compare two polynomials w.r.t. a given order**

Inherited from Dom::MultivariatePolynomial.

**orderedVariableList - Ordered list of indeterminates of a polynomial**

Inherited from Dom::DistributedPolynomial.

**pivotSize - Size of a pivot element**

Inherited from Dom::DistributedPolynomial.

**reductum - Reductum of a polynomial**

Inherited from Dom::DistributedPolynomial.

**sortList - Sort a list of polynomials w.r.t. a given order**

# Dom::UnivariatePolynomial

---

Inherited from Dom::MultivariatePolynomial.

**stableSort - Sort a list of polynomials w.r.t. a given order**

Inherited from Dom::MultivariatePolynomial.

**subs - Avoid substitution**

Inherited from Dom::BaseDomain.

**subsex - Avoid extended substitution**

Inherited from Dom::BaseDomain.

**tcoeff - Lowest coefficient of a polynomial**

Inherited from Dom::DistributedPolynomial.

**vectorize - Vectorized form of a polynomial**

vectorize(a, <n>)

| <b>Purpose</b>     | Objects kept in factored form                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>      | <code>Factored(list, &lt;type&gt;, &lt;ring&gt;)</code><br><code>Factored(f, &lt;type&gt;, &lt;ring&gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>Factored is the domain of objects kept in factored form, such as prime factorization of integers, square-free factorization of polynomials, or the factorization of polynomials in irreducible factors.</p> <p>The argument <code>list</code> must be a list of odd length and of the form <code>[u, f1, e1, f2, e2, ..., fr, er]</code>, where the entries <math>u</math> and <math>f_i</math> are elements of the domain <code>ring</code>, or can be converted into such elements. The <math>e_i</math> must be integers. Here, <math>i</math> ranges from 1 to <math>r</math>.</p> <p>See section “Operands” below for the meaning of the entries of that list.</p> <p>An error message is reported, if one of the list entries is of wrong type.</p> <p>An arithmetical expression <code>f</code> given as the first argument is the same as giving the list <code>[ring::one, f, 1]</code>.</p> <p>See section “Operands” below for the meaning of the entries of that list.</p> <p><code>f</code> must be an element of the domain <code>ring</code>, or must be convertible into such an element, otherwise an error message would be given.</p> <p>The argument <code>type</code> indicates what is known about the factorization. Currently, the following types are known:</p> <ul style="list-style-type: none"><li>• "unknown" – nothing is known about the factorization.</li><li>• "irreducible" – the <math>f_i</math> are irreducible over the domain <code>ring</code>.</li><li>• "squarefree" – the <math>f_i</math> are square-free over the domain <code>ring</code>.</li></ul> <p>If this argument is missing, then the type of the created factored object is set to "unknown".</p> <p>The type of factorization is known to any element of <code>Factored</code>. Use the methods <code>getType</code> and <code>setType</code> (see below) to read and set the type of factorization of a given factored object.</p> |

# Factored

---

The argument `ring` is the ring of factorization. It must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If this argument is missing, then the domain `Dom::ExpressionField()` is used.

The ring of factorization is known to any element of `Factored`. Use the methods `"getRing"` and `"setRing"` (see below) to read and set the ring of factorization of a given factored object.

You can use the index operator `[ ]` to extract the factors of an element `f` of the domain `Factored`. E.g., for  $f = uf_1^{e_1}f_2^{e_2}\dots$ , you have `f[1] = u`, `f[2] = f_1^{e_1}`, `f[3] = f_2^{e_2}` etc.

You can also use the methods `"factors"` and `"exponents"` (see below) to access the operands, i.e., the call `Factored::factors(f)` returns a list of the factors  $f_i$ , and `Factored::exponents(g)` returns a list of the exponents  $e_i$  ( $1 \leq i \leq r$ ).

The system functions `ifactor`, `factor` and `polylib::sqrfree` are the main application of this domain, they return their result in form of such factored objects (see their help pages for information about the type and ring of factorization).

There may be no need to explicitly create factored objects, but to work with the results of the mentioned system functions.

Note that an element of `Factored` is printed like an expression and behaves like that. As an example, the result of `f := factor(x^2 + 2*x + 1)` is an element of `Factored` and printed as  $(x + 1)^2$ . The call `type(f)` returns `"_power"` as the expression type of `f`.

For an element `f` of `Factored`, the call `Factored::convert(f, DOM_LIST)` gives a list of all operands of `f`.

## Examples

### Example 1

The following computes the prime factorization of the integer 20:

```
f := ifactor(20)
```

$2^2 5$ 

The result is an element of the domain Factored:

```
domtype(f)
```

```
Factored
```

which consists of the following five operands:

```
op(f)
```

```
1, 2, 2, 5, 1
```

They represent the integer 20 in the following form:  $20 = 12^25$ . The factors are prime numbers and can be extracted via `Factor::factors`:

```
Factored::factors(f)
```

```
[2, 5]
```

`ifactor` kept the information that the factorization ring is the ring of integers (represented by the domain `Dom::Integer`), and that the factors of `f` are prime (and therefore irreducible, because `is` an integral domain):

```
Factored::getRing(f), Factored::getType(f)
```

```
Dom::Integer, "irreducible"
```

# Factored

---

We can convert such an object into different forms, such as into a list of its operands:

```
Factored::convert_to(f, DOM_LIST)
```

```
[1, 2, 2, 5, 1]
```

or into an unevaluated expression, keeping the factored form:

```
Factored::convert_to(f, DOM_EXPR)
```

```
22 5
```

or back into an integer:

```
Factored::convert_to(f, Dom::Integer)
```

```
20
```

You may also use the system function `coerce` here, which has the same effect.

## Example 2

We compute the factorization of the integers 108 and 512:

```
n1 := ifactor(108); n2 := ifactor(512)
```

```
22 33
```

```
29
```

The multiplication of these two integers gives the prime factorization of  $55296 = 108512$ :

```
n1*n2
```

```
211 33
```

Note that the most operations on such objects lead to an un-factored form, such as adding these two integers:

```
n1 + n2
```

```
620
```

You may apply the function `ifactor` to the result, if you are interested in its prime factorization:

```
ifactor(%)
```

```
22 5 31
```

You can apply (almost) each function to factored objects, functions that mainly expect arithmetical expressions as their input. Note that, before the operation is applied, the factored object is converted into an arithmetical expression in un-factored form:

```
Re(n1)
```

```
108
```

### Example 3

The second system function which deals with elements of `Factored`, is `factor`, which computes all irreducible factors of a polynomial.

For example, if we define the following polynomial of  $_{101}$ :

```
p := poly(x^12 + x + 1, [x], Dom::IntegerMod(101)):
```

and compute its factorization into irreducible factors, we get:

```
f := factor(p)
```

```
poly(x^2 + 73 x + 29, [x], Dom::IntegerMod(101)) poly(x^5 + 62 x^4 + 64 x^3 + 63 x^2 + 58 x
+ 100, [x], Dom::IntegerMod(101)) poly(x^5 + 67 x^4 + 72 x^3 + 100 x^2 + 33 x
+ 94, [x], Dom::IntegerMod(101))
```

If we multiply the factored object with an element that can be converted into an element of the ring of factorization, then we get a new factored object, which then is of the factorization type "unknown":

```
x*f
```

```
poly(x^2 + 73 x + 29, [x], Dom::IntegerMod(101)) poly(x^5 + 62 x^4 + 64 x^3 + 63 x^2 + 58 x
+ 100, [x], Dom::IntegerMod(101)) poly(x^5 + 67 x^4 + 72 x^3 + 100 x^2 + 33 x
+ 94, [x], Dom::IntegerMod(101)) x
```

```
Factored::getType(%)
```

```
"unknown"
```

You may use the function `expand` which returns the factored object in expanded form as an element of the factorization ring:

```
expand(f)
```

```
poly(x12 + x + 1, [x], Dom::IntegerMod(101))
```

#### Example 4

The third system function which return elements of `Factored` is `polylib::sqrfree`, which computes the square-free factorization of polynomials. For example:

```
f := polylib::sqrfree(x2 + 2*x + 1)
```

```
(x + 1)2
```

The factorization type, of course, is "squarefree":

```
Factored::getType(f)
```

```
"squarefree"
```

#### Parameters

**list**

A list of odd length

**f**

An arithmetical expression

**type**

A string (default: "unknown")

## **ring**

A domain of category `Cat::IntegralDomain` (default:  
`Dom::ExpressionField()`)

## **Function Calls**

Calling a factored object as a function yields the object itself, regardless of the arguments. The arguments are *not* evaluated.

## **Operations**

You can apply (almost) every function to factored objects, functions that mainly expect arithmetical expressions as their input.

For example, one may add or multiply those objects, or apply functions such as `expand` and `diff` to them. But the result of such an operation then is usually not any longer of the domain `Factored`, as the factored form could be lost due to the operation (see examples below).

Call `expr(f)` to convert the factored object `f` into an arithmetical expression (as an element of a kernel domain).

The call `coerce(f, DOM_LIST)` returns a list of operands of the factored object `f` (see method "`convert_to`" below).

## **Operands**

An element  $f$  of `Factored` consists of the  $r + 1$  operands  $u, f_1, e_1, f_2, e_2, \dots, f_r, e_r$ , such that  $f = uf_1^{e_1}f_2^{e_2}\dots f_r^{e_r}$ .

The first operand  $u$  and the factors  $f_i$  are elements of the domain `ring`. The exponents  $e_i$  are integers.

## **Methods**

### **Mathematical Methods**

#### **`_mult` - Multiply factored objects**

`_mult(f, g, )`

Suppose that `g` is an element of the domain `ring` (or can be converted into such an element).

If  $g$  is a unit of `ring` or a factor of  $f$ , then the result is a factored object of the same factorization type as  $f$ . Otherwise, the result is an element of `Factored` with the factorization type "unknown".

If both  $f$  and  $g$  are factored objects with factorization type "irreducible", then the result is again a factored object of this type, i.e., the result is still in factored form.

Otherwise, the factored form of  $f$  is lost, and the result of this method is an element of `ring`.

This method overloads the function `_mult` for factored objects, i.e., one may use it in the form  $f*g*\dots$ , or in functional notation: `_mult(f, g, ...)`.

### **`_power` - Raise a factored object to a certain power**

```
_power(f, n)
```

If  $n$  is a positive integer and  $f$  a factored object with factorization type "irreducible" or "squarefree", then the result is still a factored object of this type.

Otherwise, the factored form of  $f$  is lost, and the result of this method is an element of `ring`.

This method overloads the function `_power` for factored objects, i.e., one may use it in the form  $f^n$ , or in functional notation: `_power(f, n)`.

### **`expand` - Expand a factored object**

```
expand(f)
```

### **`exponents` - Get the exponents of a factored object**

```
exponents(f)
```

### **`factor` - Factor a factored object**

```
factor(f)
```

If  $f$  already is of the factorization type "irreducible", then this method just return  $f$ .

Otherwise, this method converts  $f$  into an element of the domain ring and calls the method "factor" of ring.

This method returns a factored object of the domain Factored with factorization type "irreducible", if the factorization of  $f$  can be computed (otherwise, FAIL is returned).

This method overloads the function factor for factored objects, i.e., one may use it in the form `factor(f)`.

### **factors - Get the factors of a factored object**

`factors(f)`

### **irreducible - Test if a factored object is irreducible**

`irreducible(f)`

The test on irreducible is trivial, if  $f$  has the factorization type "irreducible".

Otherwise, this method converts  $f$  into an element of ring and calls the method "irreducible" of ring. The value FAIL is returned, if the domain ring cannot test if  $f$  is irreducible.

### **iszero - Test on zero for factored objects**

`iszero(f)`

This method overloads the function iszero for factored objects, i.e., one may use it in the form `iszero(f)`.

### **sqrfree - Compute a square-free factorization of a factored object**

`sqrfree(f)`

If  $f$  already is of the factorization type "squarefree", then this method just return  $f$ .

Otherwise, this method converts  $f$  into an element of the domain ring and calls the method "squarefree" of ring.

This method returns a factored object of the domain Factored with factorization type "squarefree", if the square-free factorization of  $f$  can be computed (otherwise, FAIL is returned).

This method overloads the function `polylib::sqrfree` for factored objects, i.e., one may use it in the form `polylib::sqrfree(f)`.

### Access Methods

#### **`_index` - Extract a term of a factored object**

```
_index(f, i)
```

Responds with an error message, if  $i$  is greater than the number of terms of  $f$ .

This method overloads the index operator `[ ]` for factored objects, i.e., one may use it in the form `f[i]`.

#### **`getRing` - Get the ring of factorization**

```
getRing(f)
```

#### **`getType` - Get the type of factorization**

```
getType(f)
```

#### **`has` - Existence of an object in a factored object**

```
has(f, x, ...)
```

This method overloads the function `has` for factored objects, i.e., one may use it in the form `has(f, x, ...)`.

#### **`map` - Map a function to the operands of factored objects**

```
map(f, func, ...)
```

See the system function `map` for details.

This method overloads the function `map` for factored objects, i.e., one may use it in the form `map(f, func, ...)`.

#### **`nops` - Number of operands of a factored object**

```
nops(f)
```

This method overloads the function `nops` for factored objects, i.e., one may use it in the form `nops(f)`.

## **op - Extract an operand of a factored object**

`op(f, i)`

Returns FAIL, if `i` is greater than the number of operands of `f`.

This method overloads the function `op` for factored objects, i.e., one may use it in the form `op(f, i)`.

## **select - Select operands of a factored object**

`select(f, func, )`

This method overloads the function `select` for factored objects, i.e., one may use it in the form `select(f, func, ...)`.

## **set\_index - Set/change a term of a factored object**

`set_index(f, i, x)`

Responds with an error message, if `i` is greater than the number of terms of `f`.

---

**Note** Make sure that `x` either is an element of the domain `ring`, or an integer.

---

This method overloads the index operator `[ ]` for factored objects, i.e., one may use it in the form `f[i] := x`.

## **setRing - Set the ring of factorization**

`setRing(f, ring)`

---

**Note** Use this method with caution! Make sure that the factorization of  $f$  is still valid over the new ring, and that the operands of  $f$  have the correct domain type.

ring must be a domain of category `Cat::IntegralDomain`, which is not checked by this method.

---

### **setType - Set the type of factorization**

```
setType(f, type)
```

---

**Note** Use this method with caution! Make sure that the factorization type corresponds with the factorization of  $f$ .

---

### **subs - Substitute subexpressions in the operands of a factored object**

```
subs(f, x = a, ...)
```

This method overloads the function `subs` for factored objects, i.e., one may use it in the form `subs(f, x = a, ...)`.

### **subsop - Substitute operands of a factored object**

```
subsop(f, i = a, ...)
```

This method overloads the function `subsop` for factored objects, i.e., one may use it in the form `subsop(f, i = a, ...)`.

### **type - Expression type of factored objects**

```
type(f)
```

### **Conversion Methods**

#### **convert - Convert an object into a factored object**

```
convert(x)
```

If the conversion fails, then FAIL is returned.

$x$  may either be a list of the form  $[u, f_1, e_1, \dots, f_r, e_r]$  of odd length (where  $u, f_1, \dots, f_r$  are of the domain type `ring`, or can be converted into such elements, and  $e_1, \dots, e_r$  are integers), or an element that can be converted into the domain `ring`. The latter case corresponds to the list `[ring::one, x, 1]`.

## **convert\_to - Convert factored objects into other domains**

```
convert_to(f, T)
```

If the conversion fails, then FAIL is returned.

If  $T$  is the domain `DOM_LIST`, then the list of operands of  $f$  is returned.

If  $T$  is the domain `DOM_EXPR`, then the unevaluated expression  $u * f_1^{e_1} * f_2^{e_2} * \dots * f_r^{e_r}$  is returned, where  $u, f_1, e_1, \dots$  are the operands of  $f$ .

Otherwise, the method "convert" of the domain  $T$  is called to convert  $f$  into an element of the domain  $T$  (which could return FAIL).

Use the function `expr` to convert  $f$  into an object of a kernel domain (see below).

## **create - Create simple and fast a factored objects**

```
create(list)
```

```
create(x)
```

This method creates a new factored object with the operands `ring::one, x, 1`.

## **expr - Convert a factored object into a kernel domain**

```
expr(f)
```

---

**Note** Note that the factored form of  $f$  may be lost due to this conversion.

---

### **expr2text - Convert a factored object into a string**

`expr2text(f)`

### **testtype - Type testing for factored objects**

`testtype(f, T)`

This method is called from the system function `testtype`.

### **TeX - LaTeX formatting of a factored object**

`TeX(f)`

The method "TeX" of the domain ring is used to get the LaTeX-representation of the corresponding operands of  $f$ .

This method is called from the system function `generate::TeX`.

## **Technical Methods**

### **\_concat - Concatenate operands of factored objects**

`_concat(f, g)`

$f$  and  $g$  must have the same factorization type and factorization ring, otherwise an error message is given.

### **maprec - Allow recursive mapping for factored objects**

`maprec(f, x, )`

First  $f$  is converted into the unevaluated expression  $u*f_1^{e_1}*f_2^{e_2}*\dots*f_r^{e_r}$ , where  $u$ ,  $f_1$ ,  $e_1$ ,  $\dots$  are the operands of  $f$ . Then the function `misc::maprec` is called with this expression as its first parameter.

Note that the result of this method is not longer an object of Factored!

## **print - Pretty-print routine for factored objects**

```
print(f)
```

## **unapply - Create a procedure from a factored object**

```
unapply(f, <x>)
```

This method overloads the function `fp::unapply` for factored objects, i.e., one may use it in the form `fp::unapply(f)`. See `fp::unapply` for details.

**Purpose** Truncated Puiseux series expansions

**Syntax** `Series::Puisseux(f, x, <order>, <dir>)`  
`Series::Puisseux(f, x =  $x_0$ , <order>, <dir>)`

**Description** `Series::Puisseux` is a domain for truncated series expansions. Elements of this domain represent initial segments of Taylor, Laurent, or Puiseux series expansions, as well as slightly more general types of series expansions.

The system function `series` is the main application of this domain. It tries to compute a Taylor, Laurent, or Puiseux series or a more general series expansion of a given arithmetical expression, and the result is returned as an element of `Series::Puisseux` or, possibly, of the more general domain `Series::gseries`.

There is usually no need for you to explicitly create elements of this domain. The methods described on this help page apply if you want to process a result returned by `series` further.

---

**Note** If you create elements explicitly as described above, then any special mathematical function, such as `sin` or `exp`, involving the series variable is considered as a coefficient. Use `series` to expand such functions as well, and use the constructor only if `f` does not contain any special mathematical functions. Cf. “Example 1” on page 6-418.

---

Use the type specifier `Type::Series` to determine for an element of this domain, which kind of series expansion it is.

---

**Note** The coefficients are allowed to depend sublinearly on the variable of the series expansion. For example, logarithmic terms in the series variable may appear as coefficients. Be aware that this is no Puiseux series in the mathematical sense. Cf. “Example 4” on page 6-427 and the help page for `series`.

---

# Series::Puisseux

---

## Environment Interactions

The function is sensitive to the global variable `ORDER`, which determines the default number of terms of the expansion.

## Examples

### Example 1

You can create objects of `Series::Puisseux` in various ways. The standard method is to use the constructor. The second argument specifies the series variable and the expansion point, with default 0 if omitted:

```
Series::Puisseux(x/(1 - x), x);
Series::Puisseux(x/(1 - x), x = 2);
Series::Puisseux(x/(1 - x), x = complexInfinity);
```

$$x + x^2 + x^3 + x^4 + x^5 + x^6 + O(x^7)$$

$$-2 + x - 2 - (x - 2)^2 + (x - 2)^3 - (x - 2)^4 + (x - 2)^5 + O((x - 2)^6)$$

$$-1 - \frac{1}{x} - \frac{1}{x^2} - \frac{1}{x^3} - \frac{1}{x^4} - \frac{1}{x^5} + O\left(\frac{1}{x^6}\right)$$

The third argument, if present, specifies the desired number of terms. If it is omitted, the value of the environment variable `ORDER` is used:

```
Series::Puisseux(x/(1 - x), x = 2, 4);
ORDER := 2;
Series::Puisseux(x/(1 - x), x);
delete ORDER;
```

$$-2 + x - 2 - (x - 2)^2 + (x - 2)^3 + O((x - 2)^4)$$

$$x + x^2 + O(x^3)$$

The methods `const`, `one`, and `zero` provide shortcuts for creating series expansions with only a constant term or no non-zero term at all. Specifying the order of the error term is mandatory:

```
Series::Puisseux::const(PI, x, 4);
Series::Puisseux::one(x = 2, 3);
Series::Puisseux::zero(x = 0, 3/2);
Series::Puisseux::zero(x = complexInfinity, 5);
```

$$\pi + O(x^4)$$

$$1 + O((x - 2)^3)$$

$$O(x^{3/2})$$

$$O\left(\frac{1}{x^5}\right)$$

Note that, e.g.,  $O(x^{3/2})$  is not an element of `Series::Puisseux`, but can be converted by the constructor:

```
f := O(x^(3/2));
g := Series::Puisseux(f, x);
domtype(f), domtype(g)
```

$$O(x^{3/2})$$

# Series::Puisseux

---

$$O(x^{3/2})$$

`O, Series::Puisseux`

Both the constructor `Series::Puisseux` and the method `const` regard special mathematical functions, such as `exp` or `sin`, as coefficients:

```
Series::Puisseux(sin(x)/(1 - x), x, 4);
Series::Puisseux::const(cos(x), x = 1, 3);
```

$$\sin(x) + x \sin(x) + x^2 \sin(x) + x^3 \sin(x) + O(x^4)$$

$$\cos(x) + O((x - 1)^3)$$

Use the system function `series` if you want to have special functions expanded as well:

```
series(sin(x)/(1 - x), x, 4);
```

$$x + x^2 + \frac{5x^3}{6} + \frac{5x^4}{6} + O(x^5)$$

The constructor returns `FAIL`, if it cannot convert the input into an element of `Series::Puisseux`. Then `series` may be able to produce a more general expansion:

```
delete a;
Series::Puisseux(x^a/(1 - x), x);
f := series(x^a/(1 - x), x);
domtype(f);
```

FAIL

$$x^a + x x^a + x^a x^2 + x^a x^3 + x^a x^4 + x^a x^5 + o(x^a x^6)$$

Series::gseries

The method `create` is a purely syntactical constructor, where the operands are specified explicitly. The sixth and seventh arguments are optional and default to 0 and `Undirected`, respectively:

```
Series::Puisseux::create(3, 1, 5, [1/2, 5], x) =
Series::Puisseux::create(3, 1, 5, [1/2, 5], x, 0, Undirected)
```

$$\frac{x^{1/3}}{2} + 5 x^{2/3} + o(x^{5/3}) = \frac{x^{1/3}}{2} + 5 x^{2/3} + o(x^{5/3})$$

```
Series::Puisseux::create(1, -2, 1, [ln(x), 0, 3], x, complexInfinity)
```

$$x^2 \ln(x) + 3 + o\left(\frac{1}{x}\right)$$

## Example 2

We demonstrate the internal structure of objects of type `Series::Puisseux`:

```
f := series(exp(x), x = 1);
g := series(sin(sqrt(1/x)), x = infinity);
h := series(sin(sqrt(-x))/x, x = 0)
```

## Series::Puisseux

$$e + e(x-1) + \frac{e(x-1)^2}{2} + \frac{e(x-1)^3}{6} + \frac{e(x-1)^4}{24} + \frac{e(x-1)^5}{120} + O((x-1)^6)$$

$$\frac{1}{\sqrt{x}} - \frac{1}{6x^{3/2}} + \frac{1}{120x^{5/2}} + O\left(\frac{1}{x^{7/2}}\right)$$

$$- \frac{1}{\sqrt{-x}} + \frac{\sqrt{-x}}{6} - \frac{(-x)^{3/2}}{120} + O(x^{5/2})$$

op(f);

op(g);

op(h)

$$0, 1, 0, 6, \left[ e, e, \frac{e}{2}, \frac{e}{6}, \frac{e}{24}, \frac{e}{120} \right], x = 1, \text{Undirected}$$

$$0, 2, 1, 7, \left[ 1, 0, -\frac{1}{6}, 0, \frac{1}{120} \right], x = \text{complexInfinity}, \text{Left}$$

$$1, 2, -1, 5, \left[ -\frac{1}{\sqrt{-x}}, 0, \frac{\sqrt{-x}}{6}, 0, -\frac{(-x)^{3/2}}{120} \right], x = 0, \text{Undirected}$$

The series f and g are of type 0, while h is of type 1:

op(f, 1), op(g, 1), op(h, 1)

$$0, 0, 1$$

The branching order of  $f$  is 1, and the branching order of both  $g$  and  $h$  is 2:

$\text{op}(f, 2), \text{op}(g, 2), \text{op}(h, 2)$

1, 2, 2

The third and the fourth operand determine the order of the leading term and the error term, respectively:

$\text{ldegree}(f) = \text{op}(f, 3)/\text{op}(f, 2),$   
 $\text{ldegree}(g) = \text{op}(g, 3)/\text{op}(g, 2),$   
 $\text{ldegree}(h) = \text{op}(h, 3)/\text{op}(h, 2);$   
 $\text{Series::Puisseux::order}(f) = \text{op}(f, 4)/\text{op}(f, 2),$   
 $\text{Series::Puisseux::order}(g) = \text{op}(g, 4)/\text{op}(g, 2),$   
 $\text{Series::Puisseux::order}(h) = \text{op}(h, 4)/\text{op}(h, 2);$

$$0 = 0, \frac{1}{2} = \frac{1}{2}, -\frac{1}{2} = -\frac{1}{2}$$

$$6 = 6, \frac{7}{2} = \frac{7}{2}, \frac{5}{2} = \frac{5}{2}$$

For series expansions of type 0, the fifth operand contains the coefficients of the expansion:

$\text{op}(f, 5) = [\text{coeff}(f)];$   
 $\text{op}(g, 5) = [\text{coeff}(g)];$

$$\left[ e, e, \frac{e}{2}, \frac{e}{6}, \frac{e}{24}, \frac{e}{120} \right] = \left[ e, e, \frac{e}{2}, \frac{e}{6}, \frac{e}{24}, \frac{e}{120} \right]$$

# Series::Puisseux

$$\left[1, 0, -\frac{1}{6}, 0, \frac{1}{120}\right] = \left[1, 0, -\frac{1}{6}, 0, \frac{1}{120}\right]$$

However, h is an expansion of type 1, and then the fifth operand stores the summands:

```
op(h, 5);
[coeff(h)];
```

$$\left[-\frac{1}{\sqrt{-x}}, 0, \frac{\sqrt{-x}}{6}, 0, -\frac{(-x)^{3/2}}{120}\right]$$

$$\left[-\frac{\sqrt{x}}{\sqrt{-x}}, 0, \frac{\sqrt{-x}}{6\sqrt{x}}, 0, -\frac{(-x)^{3/2}}{120x^{3/2}}\right]$$

The sixth operand contains the series variable and the expansion point:

```
op(f, 6), Series::Puisseux::indet(f), Series::Puisseux::point(f);
op(g, 6), Series::Puisseux::indet(g), Series::Puisseux::point(g);
op(h, 6), Series::Puisseux::indet(h), Series::Puisseux::point(h);
```

$$x = 1, x, 1$$

$$x = \text{complexInfinity}, x, \text{complexInfinity}$$

$$x = 0, x, 0$$

The expansions  $f$  and  $h$  are undirected, while  $g$  is a directed expansion from the left along the real line to the positive infinity:

```
op(f, 7) = Series::Puisseux::direction(f),
op(g, 7) = Series::Puisseux::direction(g),
op(h, 7) = Series::Puisseux::direction(h);
```

Undirected = Undirected, Left = Left, Undirected = Undirected

---

**Note** Since the internal structure may be subject to changes, accessing the operands of and element of `Series::Puisseux` via `op` should be avoided. Use the corresponding access methods instead.

---

### Example 3

Around branch points, the series expansions of type 1 can approximate a function in a wider range than those of type 0:

```
f := x -> arcsin(x + 1):
g := series(f(x), x, 2);
h := series(f(x), x, 2, Right);
```

$$\frac{\pi}{2} - \sqrt{2} \sqrt{-x} - \frac{\sqrt{2} (-x)^{3/2}}{12} + O(x^{5/2})$$

$$\frac{\pi}{2} - \sqrt{2} \sqrt{x} i + \frac{\sqrt{2} x^{3/2} i}{12} + O(x^{5/2})$$

The expansion  $g$ , of type 1, approximates  $f$  well in an open disc centered at the origin. However, the expansion  $h$ , of type 0, was requested for positive real values of  $x$  only, and in fact it does not approximate  $f$  on the negative real axis and in the upper half plane:

## Series::Puisseux

---

```
op(g);
op(h);
```

```
1, 2, 0, 5, $\left[\frac{\pi}{2}, -\sqrt{2}\sqrt{-x}, 0, -\frac{\sqrt{2}(-x)^{3/2}}{12}\right], x = 0, \text{Undirected}$
```

```
0, 2, 0, 5, $\left[\frac{\pi}{2}, -\sqrt{2}i, 0, \frac{\sqrt{2}i}{12}\right], x = 0, \text{Right}$
```

```
DIGITS := 4:
[f(0.01), f(0.01*I), f(-0.01), f(-0.01*I)];
map([g(0.01), g(0.01*I), g(-0.01), g(-0.01*I)], float);
map([h(0.01), h(0.01*I), h(-0.01), h(-0.01*I)], float);
delete DIGITS:
```

```
[1.571 - 0.1413 i, 1.471 + 0.1001 i, 1.429, 1.471 - 0.1001 i]
```

```
[1.571 - 0.1413 i, 1.471 + 0.1001 i, 1.429, 1.471 - 0.1001 i]
```

```
[1.571 - 0.1413 i, 1.671 - 0.1001 i, 1.712, 1.471 - 0.1001 i]
```

The method `convert01` converts a series expansion of type 0 into one of type 1:

```
h1 := Series::Puisseux::convert01(h);
op(h1);
```

```
 $\frac{\pi}{2} - \sqrt{2}\sqrt{x}i + \frac{\sqrt{2}x^{3/2}}{12}i + \mathcal{O}(x^{5/2})$
```

$$1, 2, 0, 5, \left[ \frac{\pi}{2}, -\sqrt{2} \sqrt{x} i, 0, \frac{\sqrt{2} x^{3/2} i}{12} \right], x = 0, \text{Right}$$

The reverse conversion, using the method `convert10`, is in not always possible:

```
op(Series::Puisseux::convert10(h1));
op(Series::Puisseux::convert10(g));
```

$$0, 2, 0, 5, \left[ \frac{\pi}{2}, -\sqrt{2} i, 0, \frac{\sqrt{2} i}{12} \right], x = 0, \text{Right}$$

$$1, 2, 0, 5, \left[ \frac{\pi}{2}, -\sqrt{2} \sqrt{-x}, 0, -\frac{\sqrt{2} (-x)^{3/2}}{12} \right], x = 0, \text{Undirected}$$

You can enforce a conversion by using properties:

```
assume(x > 0);
op(Series::Puisseux::convert10(g));
unassume(x);
```

$$0, 2, 0, 5, \left[ \frac{\pi}{2}, -\sqrt{2} i, 0, \frac{\sqrt{2} i}{12} \right], x = 0, \text{Undirected}$$

#### Example 4

Despite the name, elements of `Series::Puisseux` may contain coefficient functions depending on the series variable:

```
f := series(psi(x), x = infinity, 4);
domtype(f), coeff(f, 0)
```

## Series::Puisseux

---

$$\ln(x) - \frac{1}{2x} - \frac{1}{12x^2} + \mathcal{O}\left(\frac{1}{x^4}\right)$$

Series::Puisseux, ln(x)

With respect to differentiation, integration, and composition, such expansions behave like functions of the series variable and not like formal series:

```
diff(f, x) = series(diff(psi(x), x), x = infinity, 4)
```

$$\frac{1}{x} + \frac{1}{2x^2} + \frac{1}{6x^3} + \mathcal{O}\left(\frac{1}{x^5}\right) = \frac{1}{x} + \frac{1}{2x^2} + \frac{1}{6x^3} + \mathcal{O}\left(\frac{1}{x^5}\right)$$

```
int(f, x) = series(int(psi(x), x), x = infinity, 4)
```

$$x(\ln(x) - 1) - \frac{\ln(x)}{2} + \frac{1}{12x} + \mathcal{O}\left(\frac{1}{x^3}\right) = x(\ln(x) - 1) + \frac{\ln(2)}{2} + \frac{\ln(\pi)}{2} - \frac{\ln(x)}{2} + \frac{1}{12x} + \mathcal{O}\left(\frac{1}{x^3}\right)$$

```
f @ series(2*x, x = infinity) = series(psi(2*x), x = infinity, 4)
```

$$\ln(2) + \ln(x) - \frac{1}{4x} - \frac{1}{48x^2} + \mathcal{O}\left(\frac{1}{x^4}\right) = \ln(2) + \ln(x) - \frac{1}{4x} - \frac{1}{48x^2} + \mathcal{O}\left(\frac{1}{x^4}\right)$$

### Example 5

The basic arithmetical operations are implemented for elements of Series::Puisseux:

```
f := series(exp(x), x, 4);
g := series(sqrt(x)/(1 - x), x, 4);
```

```
h := series(cot(x), x, 4);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \mathcal{O}(x^4)$$

$$\sqrt{x} + x^{3/2} + x^{5/2} + x^{7/2} + \mathcal{O}(x^{9/2})$$

$$\frac{1}{x} - \frac{x}{3} + \mathcal{O}(x^3)$$

```
f + g + h;
_plus(f, g, h)
```

$$\frac{1}{x} + 1 + \sqrt{x} + \frac{2x}{3} + x^{3/2} + \frac{x^2}{2} + x^{5/2} + \mathcal{O}(x^3)$$

$$\frac{1}{x} + 1 + \sqrt{x} + \frac{2x}{3} + x^{3/2} + \frac{x^2}{2} + x^{5/2} + \mathcal{O}(x^3)$$

```
f - h = _subtract(f, h);
-g = _negate(g);
```

$$-\frac{1}{x} + 1 + \frac{4x}{3} + \frac{x^2}{2} + \mathcal{O}(x^3) = -\frac{1}{x} + 1 + \frac{4x}{3} + \frac{x^2}{2} + \mathcal{O}(x^3)$$

$$-\sqrt{x} - x^{3/2} - x^{5/2} - x^{7/2} + \mathcal{O}(x^{9/2}) = -\sqrt{x} - x^{3/2} - x^{5/2} - x^{7/2} + \mathcal{O}(x^{9/2})$$

```
f*g*h;
_mult(f, g, h)
```

## Series::Puisseux

---

$$\frac{1}{\sqrt{x}} + 2\sqrt{x} + \frac{13x^{3/2}}{6} + 2x^{5/2} + o(x^{7/2})$$

$$\frac{1}{\sqrt{x}} + 2\sqrt{x} + \frac{13x^{3/2}}{6} + 2x^{5/2} + o(x^{7/2})$$

```
f/g = _divide(f, g);
1/h = _invert(h);
```

$$\frac{1}{\sqrt{x}} - \frac{x^{3/2}}{2} - \frac{x^{5/2}}{3} + o(x^{7/2}) = \frac{1}{\sqrt{x}} - \frac{x^{3/2}}{2} - \frac{x^{5/2}}{3} + o(x^{7/2})$$

$$x + \frac{x^3}{3} + o(x^5) = x + \frac{x^3}{3} + o(x^5)$$

Operands that are not of type `Series::Puisseux` are implicitly converted into series expansions with the same expansion point via the constructor before the arithmetical operation is performed:

```
f - 1 - x;
h * (sin(x) + x);
```

$$\frac{x^2}{2} + \frac{x^3}{6} + o(x^4)$$

$$\frac{\sin(x)}{x} + 1 - \frac{x \sin(x)}{3} - \frac{x^2}{3} + o(x^3)$$

An error occurs when the expansion points differ or the directions of expansion are incompatible:

```
f := series(arccot(x), x = 0, Left);
g := series(sqrt(sin(x)), x = 0, Right);
f + g
```

$$-\frac{\pi}{2} - x + \frac{x^3}{3} - \frac{x^5}{5} + O(x^7)$$

$$\sqrt{x} - \frac{x^{5/2}}{12} + \frac{x^{9/2}}{1440} + O(x^{13/2})$$

Error: Inconsistent direction. [Series::Puisseux::plus]

```
h := series(1/x, x = 2, 4);
f * h
```

$$\frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4)$$

Error: Both series must use the same variables and expansion poi

If the directions are compatible, then the direction of the result specifies the minimal range where all operands are defined:

```
s := series(tanh(x), x, Real);
```

## Series::Puisseux

---

$$x - \frac{x^3}{3} + \frac{2x^5}{15} + o(x^7)$$

```
f + s;
Series::Puisseux::direction(%)
```

$$-\frac{\pi}{2} - \frac{x^5}{15} + o(x^7)$$

Left

### Example 6

The method `scalmult` implements multiplication by a constant or a single term:

```
f := series(1 + 2*x^3, x);
Series::Puisseux::scalmult(f, 5) = 5*f;
Series::Puisseux::scalmult(f, 5, 3) = 5*x^3*f;
```

$$1 + 2x^3 + o(x^6)$$

$$5 + 10x^3 + o(x^6) = 5 + 10x^3 + o(x^6)$$

$$5x^3 + 10x^6 + o(x^9) = 5x^3 + 10x^6 + o(x^9)$$

```
g := series(1 + 2*x^3, x = 2, 3);
Series::Puisseux::scalmult(g, 1, 3) = (x - 2)^3*g
```

$$17 + 24(x-2) + 12(x-2)^2 + O((x-2)^3)$$

$$17(x-2)^3 + 24(x-2)^4 + 12(x-2)^5 + O((x-2)^6) = 17(x-2)^3 + 24(x-2)^4 + 12(x-2)^5 + O((x-2)^6)$$

```
h := series(1 + 2*x^3, x = complexInfinity);
Series::Puiseux::scalmult(h, 1, 1/2) = x^(-1/2)*h
```

$$2x^3 + 1 + O\left(\frac{1}{x^3}\right)$$

$$2x^{5/2} + \frac{1}{\sqrt{x}} + O\left(\frac{1}{x^{7/2}}\right) = 2x^{5/2} + \frac{1}{\sqrt{x}} + O\left(\frac{1}{x^{7/2}}\right)$$

### Example 7

Exponentiation is implemented for integral and rational exponents:

```
f := series(exp(x), x, 3);
f^2 = _power(f, 2);
f^(1/3) = _power(f, 1/3)
```

$$1 + x + \frac{x^2}{2} + O(x^3)$$

$$1 + 2x + 2x^2 + O(x^3) = 1 + 2x + 2x^2 + O(x^3)$$

$$1 + \frac{x}{3} + \frac{x^2}{18} + O(x^3) = 1 + \frac{x}{3} + \frac{x^2}{18} + O(x^3)$$

## Series::Puisseux

---

Exponents are allowed to be non-rational, if the series expansion starts with a constant summand independent of the series variable:

```
f^I = series(exp(I*x), x, 3);
```

$$1 + x i - \frac{x^2}{2} + O(x^3) = 1 + x i - \frac{x^2}{2} + O(x^3)$$

```
g := series(sin(-x), x);
g^I
```

$$-x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^7)$$

Error: The exponent must be a rational number. [Series::Puisseux::\_p

If the exponent contains the series variable, then an error occurs:

```
f^x
```

Error: The exponent must not contain the series variable. [Series::

For undirected expansions and rational exponents that are not integral, the result has type 1 in general:

```
g^(1/2);
op(%, 1);
```

$$\sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O(x^{13/2})$$

1

The result simplifies when you specify one of the directions Left or Right:

```
g := series(sin(-x), x, Left):
g^(1/2);
op(%, 1);
```

$$-\sqrt{x}i + \frac{x^{5/2}i}{12} - \frac{x^{9/2}i}{1440} + O(x^{13/2})$$

0

```
g := series(sin(-x), x, Right):
g^(1/2);
```

$$\sqrt{x}i - \frac{x^{5/2}i}{12} + \frac{x^{9/2}i}{1440} + O(x^{13/2})$$

### Example 8

Functional composition of elements of Series::Puiseux is implemented by the method `_fconcat`:

```
f := series(ln(x), x = 1, 4);
g := series(cos(y), y = 0);
f@g = _fconcat(f, g);
```

## Series::Puisseux

---

```
series(ln(cos(y)), y = 0, 4);
```

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + o((x-1)^5)$$

$$1 - \frac{y^2}{2} + \frac{y^4}{24} + o(y^6)$$

$$-\frac{y^2}{2} - \frac{y^4}{12} + o(y^6) = -\frac{y^2}{2} - \frac{y^4}{12} + o(y^6)$$

$$-\frac{y^2}{2} - \frac{y^4}{12} + o(y^6)$$

If the left argument is not of type `Series::Puisseux`, it is implicitly expanded around the limit point of the right argument before the composition:

```
f := series(sin(-x), x = 0);
sqrt(y) @ f = Series::Puisseux(sqrt(y), y) @ f;
```

$$-x + \frac{x^3}{6} - \frac{x^5}{120} + o(x^7)$$

$$\sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + o(x^{13/2}) = \sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + o(x^{13/2})$$

If the right argument is not of type `Series::Puisseux`, it is implicitly expanded around the origin via the constructor before the composition:

```
f @ sqrt(y) = f @ Series::Puiseux(sqrt(y), y)
```

$$-\sqrt{y} + \frac{y^{3/2}}{6} - \frac{y^{5/2}}{120} + o(y^{7/2}) = -\sqrt{y} + \frac{y^{3/2}}{6} - \frac{y^{5/2}}{120} + o(y^{7/2})$$

This may not work if the argument to be converted contains special mathematical functions, but you can explicitly expand it into a series via `series` in this case:

```
f @ tan(y)
```

FAIL

```
f @ series(tan(y), y = 0)
```

$$-y - \frac{y^3}{6} + \frac{y^5}{40} + o(y^7)$$

Mathematically, the composition of series expansions is not defined if the limit point of the right argument is not the expansion point of the left argument:

```
g := series(y^2 - 1, y = 0);
f @ g
```

$$-1 + y^2 + o(y^6)$$

FAIL

```
f @ (y^2 - 1)
```

# Series::Puisseux

---

FAIL

```
f @ series(y^2 - 1, y = 1, 4)
```

$$-2(y-1) - (y-1)^2 + \frac{4(y-1)^3}{3} + 2(y-1)^4 + \mathcal{O}((y-1)^5)$$

The method `revert` computes the inverse of a truncated series expansion with respect to composition. The expansion point of the inverse is the limit point of the input and vice versa:

```
f := series(ln(x), x = 1, 4);
revert(f) = series(exp(x), x = 0, 5)
```

$$x-1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + \mathcal{O}((x-1)^5)$$

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \mathcal{O}(x^5) = 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \mathcal{O}(x^5)$$

```
f := series(cot(x), x = 0);
revert(f) = series(arccot(x), x = complexInfinity);
```

$$\frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} + \mathcal{O}(x^5)$$

$$\frac{1}{x} - \frac{1}{3x^3} + \frac{1}{5x^5} + \mathcal{O}\left(\frac{1}{x^7}\right) = \frac{1}{x} - \frac{1}{3x^3} + \frac{1}{5x^5} + \mathcal{O}\left(\frac{1}{x^7}\right)$$

```
f @ revert(f), revert(f) @ f
```

$$x + O\left(\frac{1}{x^5}\right), x + O(x^7)$$

If the series variable occurs in the coefficients or the type flag is 1, an error occurs:

```
f := series(ln(sin(x)), x);
g := series(arcsin(x + 1), x, 2);
```

$$\ln(x) - \frac{x^2}{6} - \frac{x^4}{180} + O(x^6)$$

$$\frac{\pi}{2} - \sqrt{2} \sqrt{-x} - \frac{\sqrt{2}(-x)^{3/2}}{12} + O(x^{5/2})$$

```
revert(f)
```

Error: Cannot compute the functional inverse. [Series::Puisseux::

```
revert(g)
```

Error: Cannot compute the functional inverse. [Series::Puisseux::

### Example 9

The methods `diff` and `int` implement term-by-term differentiation and integration:

```
f := series(ln(x), x = 1, 4);
g := diff(f, x);
```

# Series::Puisseux

---

```
series(1/x, x = 1, 4);
int(g, x);
```

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

$$1 - (x-1) + (x-1)^2 - (x-1)^3 + O((x-1)^4)$$

$$1 - (x-1) + (x-1)^2 - (x-1)^3 + O((x-1)^4)$$

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

If you specify a range of integration, then the result is an arithmetical expression plus a symbolic definite integral of the  $O$ -term:

```
int(f, x = 1..2);
```

$$\int_1^2 O((x-1)^5, x=1) dx + \frac{11}{30}$$

## Example 10

Most special mathematical functions are overloaded for `Series::Puisseux`:

```
f := series(x/(1 - x), x, 4);
exp(f) = series(exp(x/(1 - x)), x, 4);
ln(f) = series(ln(x/(1 - x)), x, 4);
```

$$x + x^2 + x^3 + x^4 + O(x^5)$$

$$1 + x + \frac{3x^2}{2} + \frac{13x^3}{6} + O(x^4) = 1 + x + \frac{3x^2}{2} + \frac{13x^3}{6} + O(x^4)$$

$$\ln(x) + x + \frac{x^2}{2} + \frac{x^3}{3} + O(x^4) = \ln(x) + x + \frac{x^2}{2} + \frac{x^3}{3} + O(x^4)$$

If the system is unable to compute the composition, it returns a symbolic function call with evaluated arguments:

```
delete g:
g(f)
```

$$g(x + x^2 + x^3 + x^4 + O(x^5))$$

```
exp(series(x + 1/x, x = infinity, 5))
```

$$e^{x + \frac{1}{x} + O\left(\frac{1}{x^4}\right)}$$

In this case, you can try `series` to compute the composition:

```
series(exp(x + 1/x), x = infinity, 5)
```

$$e^x + \frac{e^x}{x} + \frac{e^x}{2x^2} + \frac{e^x}{6x^3} + \frac{e^x}{24x^4} + O\left(\frac{e^x}{x^5}\right)$$

## Example 11

The system functions `Re`, `Im`, and `conjugate` work for all real series expansions:

```
f := series(exp(I*x), x, Real);
Re(f) = series(cos(x), x, Real);
Im(f) = series(sin(x), x, Real) + O(x^6);
conjugate(f) = series(exp(-I*x), x, Real);
```

$$1 + x i - \frac{x^2}{2} - \frac{x^3 i}{6} + \frac{x^4}{24} + \frac{x^5 i}{120} + O(x^6)$$

$$1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6) = 1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)$$

$$x - \frac{x^3}{6} + \frac{x^5}{120} + O(x^6) = x - \frac{x^3}{6} + \frac{x^5}{120} + O(x^6)$$

$$1 - x i - \frac{x^2}{2} + \frac{x^3 i}{6} + \frac{x^4}{24} - \frac{x^5 i}{120} + O(x^6) = 1 - x i - \frac{x^2}{2} + \frac{x^3 i}{6} + \frac{x^4}{24} - \frac{x^5 i}{120} + O(x^6)$$

Except in trivial cases, a symbolic function call is returned for an undirected expansion:

```
Re(series(PI, x));
Re(series(exp(I*x), x));
```

$$\pi + O(x^6)$$

$$\Re\left(1 + x i - \frac{x^2}{2} - \frac{x^3 i}{6} + \frac{x^4}{24} + \frac{x^5 i}{120} + O(x^6)\right)$$

**Example 12**

The method `contfrac` converts a series expansion into a continued fraction:

```
f := series(exp(x), x, 10);
contfrac(f);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + \frac{x^8}{40320} + \frac{x^9}{362880} + O(x^{10})$$

$$1 + \frac{X}{1 + \frac{x}{-2 + \frac{x}{-3 + \frac{x}{2 + \frac{x}{5 + \frac{x}{-2 + \frac{x}{-7 + \frac{x}{2 + \frac{x}{9 + O(x)}}}}}}}}}$$

```
g := series(tan(x), x = PI, 10);
contfrac(g);
```

$$x - \pi - \frac{(\pi - x)^3}{3} - \frac{2(\pi - x)^5}{15} - \frac{17(\pi - x)^7}{315} - \frac{62(\pi - x)^9}{2835} + O(-(\pi - x)^{11})$$

## Series::Puisseux

---

$$1 + \frac{-\pi + X}{(\pi - x)^2} \Big/ \left( -3 + \frac{(\pi - x)^2}{5 + \frac{(\pi - x)^2}{-7 + \frac{(\pi - x)^2}{9 + O((\pi - x)^2)}}} \right)$$

If the coefficients of a series expansion depend on the series variable, then so do the coefficients of the corresponding continued fraction:

```
h := series(ln(x + 1/x), x = infinity);
contfrac(h)
```

$$\ln(x) + \frac{1}{x^2} - \frac{1}{2x^4} + O\left(\frac{1}{x^6}\right)$$

$$\ln(x) + \frac{x^{-2}}{1 + \frac{x^{-2}}{2 + O(x^{-2})}}$$

### Example 13

For series expansions around the origin, the method `laplace`, overloading `laplace`, computes the Laplace transform term by term, if the second argument is the series variable. The result is a series expansion around infinity:

```
delete s;
f := series(exp(x), x);
g := laplace(f, x, s);
series(laplace(exp(x), x, s), s = infinity);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

$$\frac{1}{s} + \frac{1}{s^2} + \frac{1}{s^3} + \frac{1}{s^4} + \frac{1}{s^5} + \frac{1}{s^6} + O\left(\frac{1}{s^7}\right)$$

$$\frac{1}{s} + \frac{1}{s^2} + \frac{1}{s^3} + \frac{1}{s^4} + \frac{1}{s^5} + \frac{1}{s^6} + O\left(\frac{1}{s^7}\right)$$

Similarly, the method `ilaplace` computes the inverse Laplace transform term by term for series expansions around infinity, if the second argument is the series variable. The result is a series expansion around 0:

```
ilaplace(g, s, x)
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

The Laplace transform and the inverse Laplace transform, respectively, of a series do not make sense for expansion points other than 0 or infinity, respectively, and in these cases a symbolic function call is returned:

```
laplace(series(ln(x), x = 1, 2), x, s);
```

$$\text{laplace}\left(x - 1 - \frac{(x-1)^2}{2} + O((x-1)^3), x, s\right)$$

If the second argument is not the series variable, then the coefficients are transformed:

# Series::Puisseux

---

```
h := series(sin(x*y), x = 1, 2);
laplace(h, y, s);
```

$$\sin(y) + y \cos(y) (x - 1) + \mathcal{O}((x - 1)^2)$$

$$\frac{1}{s^2 + 1} - \left( \frac{1}{s^2 + 1} - \frac{2s^2}{(s^2 + 1)^2} \right) (x - 1) + \mathcal{O}((x - 1)^2)$$

## Example 14

When called with one argument, the method `coeff` returns the sequence of all coefficients of a series expansion:

```
f := series(tan(x), x);
coeff(f)
```

$$x + \frac{x^3}{3} + \frac{2x^5}{15} + \mathcal{O}(x^7)$$

$$1, 0, \frac{1}{3}, 0, \frac{2}{15}$$

```
g := series(1/(x - 1)^2, x = infinity);
coeff(g)
```

$$\frac{1}{x^2} + \frac{2}{x^3} + \frac{3}{x^4} + \frac{4}{x^5} + \frac{5}{x^6} + \frac{6}{x^7} + \mathcal{O}\left(\frac{1}{x^8}\right)$$

$$1, 2, 3, 4, 5, 6$$

When called with two arguments, `coeff` returns an individual coefficient:

```
coeff(f, -1), coeff(f, 1), coeff(f, 2), coeff(f, 13/2);
```

```
0, 1, 0, 0
```

If the second argument exceeds the order of the error term, `coeff` returns FAIL:

```
coeff(f, 10)
```

```
FAIL
```

When the expansion point is `complexInfinity`, `coeff(s, n)` returns the coefficient of  $\frac{1}{x^n}$ , where  $x$  is the series variable of  $s$ :

```
coeff(g, 2), coeff(g, -3), coeff(g, -15/2)
```

```
0, 2, 0
```

Specifying the series variable as second or third argument, respectively, is optional:

```
coeff(f) = coeff(f, x);
coeff(f, 3) = coeff(f, x, 3)
```

```
(1, 0, 1/3, 0, 2/15) = (1, 0, 1/3, 0, 2/15)
```

# Series::Puisseux

---

$$\frac{1}{3} = \frac{1}{3}$$

For series expansions of type 1, the “coefficients” in general involve the series variable:

```
h := series(sin(sqrt(-x)), x);
coeff(h);
coeff(h, 3/2);
```

$$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O(x^{7/2})$$

$$\frac{\sqrt{-x}}{\sqrt{x}}, 0, -\frac{(-x)^{3/2}}{6x^{3/2}}, 0, \frac{(-x)^{5/2}}{120x^{5/2}}$$

$$-\frac{(-x)^{3/2}}{6x^{3/2}}$$

## Example 15

The method `ldegree` returns the order of the leading term of a series expansion. When the expansion point is `complexInfinity` and the

leading term is  $\frac{1}{x^n}$ , then this is  $n$ :

```
f := series(x*sin(sqrt(-x)), x);
g := series(cot(x), x = PI);
h := series(2*arccot(x), x = infinity);
```

$$-(-X)^{3/2} + \frac{(-X)^{5/2}}{6} - \frac{(-X)^{7/2}}{120} + O(X^{9/2})$$

$$-\frac{1}{\pi - X} - \frac{X - \pi}{3} + \frac{(\pi - X)^3}{45} + O(-(\pi - X)^5)$$

$$\frac{2}{X} - \frac{2}{3X^3} + \frac{2}{5X^5} + O\left(\frac{1}{X^7}\right)$$

`ldegree(f)`, `ldegree(g)`, `ldegree(h)`

$$\frac{3}{2}, -1, 1$$

The method `lcoeff` returns the coefficient of the leading term. For an expansion of type 1, it generally involves the series variable:

`lcoeff(f)`, `lcoeff(g)`, `lcoeff(h)`

$$-\frac{(-X)^{3/2}}{X^{3/2}}, 1, 2$$

The method `lterm` returns the leading term itself:

`lterm(f)`, `lterm(g)`, `lterm(h)`

$$X^{3/2}, -\frac{1}{\pi - X}, \frac{1}{X}$$

# Series::Puisseux

---

Finally, the method `lmonomial` returns the whole summand:

```
lmonomial(f) = lcoeff(f)*lterm(f);
lmonomial(g) = lcoeff(g)*lterm(g);
lmonomial(h) = lcoeff(h)*lterm(h);
```

$$-(-X)^{3/2} = -(-X)^{3/2}$$

$$-\frac{1}{\pi - X} = -\frac{1}{\pi - X}$$

$$\frac{2}{X} = \frac{2}{X}$$

If the series expansion consists only of an  $O$ -term, all four methods return FAIL:

```
s := Series::Puisseux::zero(x, 6);
ldegree(s), lcoeff(s), lterm(s), lmonomial(s)
```

$$O(x^6)$$

FAIL, FAIL, FAIL, FAIL

## Example 16

The methods `nthcoeff`, `nthmonomial`, and `nthterm` return the  $n$ th non-zero coefficient, monomial, or term, respectively, of a series expansion. In contrast to polynomials, they count from the term of lowest order on, i.e., the ordering is ascending by exponent for finite expansion points and descending by exponent when the expansion point is `complexInfinity`:

```
f := series(x*sin(sqrt(-x)), x);
g := series(cot(x), x = PI);
h := series(2*arccot(x), x = infinity);
```

$$-(-X)^{3/2} + \frac{(-X)^{5/2}}{6} - \frac{(-X)^{7/2}}{120} + O\left(X^{9/2}\right)$$

$$-\frac{1}{\pi - X} - \frac{X - \pi}{3} + \frac{(\pi - X)^3}{45} + O\left(-(\pi - X)^5\right)$$

$$\frac{2}{X} - \frac{2}{3X^3} + \frac{2}{5X^5} + O\left(\frac{1}{X^7}\right)$$

```
nthcoeff(f, 1) = lcoeff(f);
nthmonomial(g, 1) = lmonomial(g);
nthterm(h, 1) = lterm(h);
```

$$-\frac{(-X)^{3/2}}{X^{3/2}} = -\frac{(-X)^{3/2}}{X^{3/2}}$$

$$-\frac{1}{\pi - X} = -\frac{1}{\pi - X}$$

$$\frac{1}{X} = \frac{1}{X}$$

```
nthcoeff(f, 3), nthmonomial(f, 3), nthterm(f, 3);
nthcoeff(g, 3), nthmonomial(g, 3), nthterm(g, 3);
nthcoeff(h, 3), nthmonomial(h, 3), nthterm(h, 3);
```

# Series::Puisseux

---

$$-\frac{(-X)^{7/2}}{120 X^{7/2}}, -\frac{(-X)^{7/2}}{120}, X^{7/2}$$

$$-\frac{1}{45}, \frac{(\pi - X)^3}{45}, -(\pi - X)^3$$

$$\frac{2}{5}, \frac{2}{5 X^5}, \frac{1}{X^5}$$

If the second argument is not positive or exceeds the number of non-zero summands, all three methods return FAIL:

```
nthcoeff(f, -4), nthterm(g, 0), nthmonomial(h, 4)
```

FAIL, FAIL, FAIL

## Example 17

We illustrate the difference between the ordering of terms in polynomials and series expansions. The ordering of the terms in a polynomial agrees with the ordering of the terms in a series expansion with expansion point `complexInfinity`:

```
f := poly(2*(x^2 + x)^3);
g := series(f, x = complexInfinity);
[lcoeff(f), lmonomial(f), lterm(f)];
[lcoeff(g), lmonomial(g), lterm(g)];
```

$$\text{poly}(2 x^6 + 6 x^5 + 6 x^4 + 2 x^3, [x])$$

$$2x^6 + 6x^5 + 6x^4 + 2x^3 + O(1)$$

$$[2, \text{poly}(2x^6, [x]), \text{poly}(x^6, [x])]$$

$$[2, 2x^6, x^6]$$

```
[nthcoeff(f, 2), nthmonomial(f, 3), nthterm(f, 4)];
[nthcoeff(g, 2), nthmonomial(g, 3), nthterm(g, 4)];
```

$$[6, \text{poly}(6x^4, [x]), \text{poly}(x^3, [x])]$$

$$[6, 6x^4, x^3]$$

For finite expansion points, however, the ordering of the terms in a series expansion is the reverse of the ordering of the terms in the corresponding polynomial:

```
h := series(f, x = 0);
[lcoeff(h), lmonomial(h), lterm(h)];
[nthcoeff(h, 2), nthmonomial(h, 3), nthterm(h, 4)];
```

$$2x^3 + 6x^4 + 6x^5 + 2x^6 + O(x^9)$$

$$[2, 2x^3, x^3]$$

$$[6, 6x^5, x^6]$$

## Example 18

The method `iszero` checks whether a series expansion has no non-zero summands apart from the  $O$ -term:

```
f := series(exp(x), x);
g := Series::Puisseux(0, x = 2, 4);
iszero(f), iszero(g)
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

$$O((x - 2)^4)$$

FALSE, TRUE

## Example 19

The methods `convert` tries to convert an arbitrary object into an element of `Series::Puisseux`. If the input does not suggest an expansion point, `convert` uses the origin:

```
f := asympt(1/(x + 1), x = infinity);
g := sin(x)/(1 - x);
h := poly((x + 1)^10);
u := O((x - 1)^3, x = 1);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

$$-\frac{\sin(x)}{x - 1}$$

```
poly(x10 + 10 x9 + 45 x8 + 120 x7 + 210 x6 + 252 x5 + 210 x4 + 120 x3 + 45 x2 + 10 x + 1, [x
```

```
o((x - 1)3, x = 1)
```

```
domtype(f), domtype(g), domtype(h), domtype(u)
```

```
Series::gseries, DOM_EXPR, DOM_POLY, O
```

```
F := Series::Puisseux::convert(f);
G := Series::Puisseux::convert(g);
H := Series::Puisseux::convert(h);
U := Series::Puisseux::convert(u);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

$$\sin(x) + x \sin(x) + x^2 \sin(x) + x^3 \sin(x) + x^4 \sin(x) + x^5 \sin(x) + O(x^6)$$

```
1 + 10 x + 45 x2 + 120 x3 + 210 x4 + 252 x5 + 210 x6 + 120 x7 + 45 x8 + 10 x9 + x10 + O(x16)
```

```
o((x - 1)3)
```

convert returns FAIL, if it is unable to convert the input, e.g., because the input contains no or more than one indeterminate:

```
Series::Puisseux::convert(sin(1)),
Series::Puisseux::convert([1, y, 3])
```

# Series::Puisseux

---

FAIL, FAIL

The method `convert_to` tries to convert an element of `Series::Puisseux` into a specified type:

```
Series::Puisseux::convert_to(F, Series::gseries);
Series::Puisseux::convert_to(F, contfrac);
Series::Puisseux::convert_to(G, DOM_EXPR);
Series::Puisseux::convert_to(H, DOM_POLY);
Series::Puisseux::convert_to(H, 0);
Series::Puisseux::convert_to(U, 0);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

$$\frac{x^{-1}}{1 + \frac{x^{-1}}{1 + O(x^{-5})}}$$

$$\sin(x) + x^2 \sin(x) + x^3 \sin(x) + x^4 \sin(x) + x^5 \sin(x) + x \sin(x)$$

$$\text{poly}(x^{10} + 10x^9 + 45x^8 + 120x^7 + 210x^6 + 252x^5 + 210x^4 + 120x^3 + 45x^2 + 10x + 1, [x])$$

$$O(1)$$

$$O((x-1)^3, x=1)$$

convert\_to returns FAIL, if it is unable to perform the requested conversion:

```
Series::Puisseux::convert_to(F, 0),
Series::Puisseux::convert_to(F, DOM_LIST)
```

FAIL, FAIL

### Example 20

The method expr converts an element of Series::Puisseux into an arithmetical expression, discarding the  $O$ -term. In general, the ordering of the summands is not preserved:

```
f := series(exp(x*y), x);
g := series(ln(x), x = 1, 3);
```

$$1 + x y + \frac{x^2 y^2}{2} + \frac{x^3 y^3}{6} + \frac{x^4 y^4}{24} + \frac{x^5 y^5}{120} + O(x^6)$$

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} + O((x-1)^4)$$

```
expr(f);
expr(g);
```

$$\frac{x^5 y^5}{120} + \frac{x^4 y^4}{24} + \frac{x^3 y^3}{6} + \frac{x^2 y^2}{2} + x y + 1$$

$$x - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - 1$$

# Series::Puisseux

---

The method `float` applies the system function `float` to all coefficients:

```
float(f);
float(g);
```

$$1.0 + x y + 0.5 x^2 y^2 + 0.1666666667 x^3 y^3 + 0.04166666667 x^4 y^4 + 0.008333333333 x^5 y^5$$

$$1.0 (x - 1) - 0.5 (x - 1)^2 + 0.3333333333 (x - 1)^3 + \mathcal{O}((x - 1)^4)$$

## Example 21

The methods `combine`, `expand`, and `normal` apply the corresponding system functions to all coefficients:

```
delete a, y;
f := series(y/(x + y^a), x, 4);
g := combine(f);
expand(g);
```

$$\frac{y}{y^a} - \frac{x y}{y^{2a}} + \frac{x^2 y}{y^{3a}} - \frac{x^3 y}{y^{4a}} + \mathcal{O}(x^4)$$

$$y^{1-a} - x y^{1-2a} + x^2 y^{1-3a} - x^3 y^{1-4a} + \mathcal{O}(x^4)$$

$$\frac{y}{y^a} - \frac{x y}{y^{2a}} + \frac{x^2 y}{y^{3a}} - \frac{x^3 y}{y^{4a}} + \mathcal{O}(x^4)$$

For efficiency reasons, the arithmetical methods of `Series::Puisseux` usually do not perform any symbolic simplifications. Use `expand` or `normal` to simplify the results:

```

h := series(exp(x), x, 4)^a;
expand(h);
normal(h);

```

$$1 + a x + x^2 \left( \frac{a}{2} + \frac{a(a-1)}{2} \right) + x^3 \left( \frac{a}{6} + \frac{\left( \frac{a}{2} + \frac{a(a-1)}{2} \right) (a-2)}{3} + \frac{a(2a-1)}{6} \right) + O(x^4)$$

$$1 + a x + \frac{a^2 x^2}{2} + \frac{a^3 x^3}{6} + O(x^4)$$

$$1 + a x + \frac{a^2 x^2}{2} + \frac{a^3 x^3}{6} + O(x^4)$$

```

u := series(arctanh(x + y), x, 4);
normal(u);

```

$$\operatorname{arctanh}(y) - \frac{x}{y^2 - 1} + \frac{x^2 y}{(y^2 - 1)^2} + \frac{x^3 (3 y^2 i + i) i}{3 (y^2 - 1)^3} + O(x^4)$$

$$\operatorname{arctanh}(y) - \frac{x}{y^2 - 1} + \frac{x^2 y}{(y^2 - 1)^2} - \frac{x^3 (3 y^2 + 1)}{3 (y^2 - 1)^3} + O(x^4)$$

Besides normalizing the coefficients, the method `normal` also removes leading and trailing zeroes from the coefficient list:

```

v := Series::Puiseux::create(1, 3, 10,
 [0, 1/2, 0, 5, 0, 0], x, 2);
coeff(v);
normal(v);

```

## Series::Puisseux

---

```
coeff(%);
```

$$\frac{(x-2)^4}{2} + 5(x-2)^6 + O((x-2)^{10})$$

$$0, \frac{1}{2}, 0, 5, 0, 0$$

$$\frac{(x-2)^4}{2} + 5(x-2)^6 + O((x-2)^{10})$$

$$\frac{1}{2}, 0, 5$$

The method `map` applies a given function to all coefficients. E.g., the system function `factor` is not overloaded for `Series::Puisseux`, but you can use `map` to express all coefficients in factored form:

```
map(u, factor);
```

$$\operatorname{arctanh}(y) - \frac{x}{(y-1)(y+1)} + \frac{yx^2}{(y-1)^2(y+1)^2} - \frac{\left(y^2 + \frac{1}{3}\right)x^3}{(y-1)^3(y+1)^3} + O(x^4)$$

In the next example, we use `map` to multiply all coefficients of a series expansion by a constant:

```
w := series(exp(x), x, 3);
map(w, _mult, PI) = PI*w
```

$$1 + X + \frac{X^2}{2} + O(X^3)$$

$$\pi + \pi X + \frac{\pi X^2}{2} + O(X^3) = \pi + \pi X + \frac{\pi X^2}{2} + O(X^3)$$

For series expansions of type 1, map applies the function to all non-zero coefficients as returned by coeff:

```
z := series(sin(sqrt(-x)), x);
coeff(z);
map(z, cos);
```

$$\sqrt{-X} - \frac{(-X)^{3/2}}{6} + \frac{(-X)^{5/2}}{120} + O(X^{7/2})$$

$$\frac{\sqrt{-X}}{\sqrt{X}}, 0, -\frac{(-X)^{3/2}}{6 X^{3/2}}, 0, \frac{(-X)^{5/2}}{120 X^{5/2}}$$

$$\sqrt{X} \cos\left(\frac{\sqrt{-X}}{\sqrt{X}}\right) + X^{3/2} \cos\left(\frac{(-X)^{3/2}}{6 X^{3/2}}\right) + X^{5/2} \cos\left(\frac{(-X)^{5/2}}{120 X^{5/2}}\right) + O(X^{7/2})$$

## Example 22

Three different methods can be used to substitute for the series variable: `_fconcat`, `func_call`, and `subs`. Suppose `f` is an element of `Series::Puisseux` and we want to substitute an expression `t` for the series variable `x`. Then `_fconcat` converts `t` into a series expansion

## Series::Puisseux

---

around the origin via the constructor, computes the functional composition, and returns the result as an element of `Series::Puisseux`:

```
f := series(exp(x), x = 0, 5);
Series::Puisseux::_fconcat(f, y) = f @ y;
f @ (y^2 + y);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + o(x^5)$$

$$1 + y + \frac{y^2}{2} + \frac{y^3}{6} + \frac{y^4}{24} + o(y^5) = 1 + y + \frac{y^2}{2} + \frac{y^3}{6} + \frac{y^4}{24} + o(y^5)$$

$$1 + y + \frac{3y^2}{2} + \frac{7y^3}{6} + \frac{25y^4}{24} + o(y^5)$$

The composition may fail if the limit point of `t` around the origin differs from the expansion point of `f` or if `t` contains special mathematical functions:

```
f @ (y + 1);
```

FAIL

```
f @ sin(y);
```

FAIL

Moreover, the composition does not work if the expression `t` is constant or contains more than one indeterminate:

```
f @ PI;
```

```
Error: Cannot compute composition. [Series::Puisseux::_fconcat]
```

```
f @ (x + y);
```

```
Error: Cannot compute composition. [Series::Puisseux::_fconcat]
```

You can enforce the composition by explicitly converting t into a series:

```
f @ series(y + 1, y = -1);
f @ series(sin(y), y = 0);
f @ series(x + y, x = -y);
```

$$1 + y + 1 + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + o((y+1)^5)$$

$$1 + y + \frac{y^2}{2} - \frac{y^4}{8} + o(y^5)$$

$$1 + x + y + \frac{(x+y)^2}{2} + \frac{(x+y)^3}{6} + \frac{(x+y)^4}{24} + o((x+y)^5)$$

Substitution with `func_call` always works. It discards the error term, `t` is substituted literally, and the result is an expression and not an object of type `Series::Puisseux`:

```
f(5) = Series::Puisseux::func_call(f, 5);
f(y) = Series::Puisseux::func_call(f, y);
```

## Series::Puisseux

---

$$\frac{523}{8} = \frac{523}{8}$$

$$\frac{y^4}{24} + \frac{y^3}{6} + \frac{y^2}{2} + y + 1 = \frac{y^4}{24} + \frac{y^3}{6} + \frac{y^2}{2} + y + 1$$

f(y<sup>2</sup> + y);  
f(y + 1);  
f(sin(y));  
f(PI);  
f(x + y);

$$y + \frac{(y^2 + y)^2}{2} + \frac{(y^2 + y)^3}{6} + \frac{(y^2 + y)^4}{24} + y^2 + 1$$

$$y + \frac{(y + 1)^2}{2} + \frac{(y + 1)^3}{6} + \frac{(y + 1)^4}{24} + 2$$

$$\frac{\sin(y)^4}{24} + \frac{\sin(y)^3}{6} + \frac{\sin(y)^2}{2} + \sin(y) + 1$$

$$\pi + \frac{\pi^2}{2} + \frac{\pi^3}{6} + \frac{\pi^4}{24} + 1$$

$$x + y + \frac{(x + y)^2}{2} + \frac{(x + y)^3}{6} + \frac{(x + y)^4}{24} + 1$$

Finally, if `subs` is used to substitute for the series variable, only very special substitutions are allowed (see the description of `subs` above for

more details). Then a change of variable is performed, and the result is again of type `Series::Puisseux`:

```
subs(f, x = y^2 + y)
```

```
Error: Invalid substitution. [Series::Puisseux::subs]
```

```
subs(f, x = y + 1)
```

$$1 + y + 1 + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + \mathcal{O}((y+1)^5)$$

```
subs(f, x = sin(y))
```

```
Error: Invalid substitution. [Series::Puisseux::subs]
```

```
subs(f, x = PI)
```

```
Error: The substitution is invalid. Exactly one indeterminate is
```

```
subs(f, x = x + y)
```

```
Error: The substitution is invalid. Exactly one indeterminate is
```

All three methods can handle the case where the series variable occurs in the coefficients:

```
s := series(ln(x^2 + x), x);
```

## Series::Puisseux

---

```
s @ (2*y);
s(2*y);
subs(s, x = 2*y);
```

$$\ln(x) + x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} + O(x^6)$$

$$\ln(2) + \ln(y) + 2y - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5} + O(y^6)$$

$$2y + \ln(2y) - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5}$$

$$\ln(2y) + 2y - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5} + O(y^6)$$

Of course, `subs` can also be used to substitute for other objects than the series variable in the coefficients and in the expansion point:

```
g := series(cos(x + y), x, 4);
h := series(1/x, x = y, 4);
```

$$\cos(y) - x \sin(y) - \frac{x^2 \cos(y)}{2} + \frac{x^3 \sin(y)}{6} + O(x^4)$$

$$\frac{1}{y} - \frac{x-y}{y^2} + \frac{(x-y)^2}{y^3} - \frac{(x-y)^3}{y^4} + O((x-y)^4)$$

```
subs(g, y = PI) = series(cos(x + PI), x, 4);
```

```
subs(h, y = 2) = series(1/x, x = 2, 4);
```

$$-1 + \frac{x^2}{2} + O(x^4) = -1 + \frac{x^2}{2} + O(x^4)$$

$$\frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4) = \frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4)$$

Even simultaneous substitutions are possible in the coefficients:

```
subs(g, [hold(sin) = cos, hold(cos) = sin, y = 2])
```

$$\sin(2) - x \cos(2) - \frac{x^2 \sin(2)}{2} + \frac{x^3 \cos(2)}{6} + O(x^4)$$

An error occurs, if the right hand side contains the series variable:

```
subs(h, y = x)
```

Error: The substitution is invalid. The right side must not contain

### Example 23

The method has checks, whether an object occurs syntactically in the coefficients, the series variable, the expansion point, or the direction of an element of Series::Puisseux:

```
f := series(sin(x + 2*y), x = PI, 2);
has(f, x), has(f, y), has(f, PI), has(f, 2), has(f, Undirected);
has(f, hold(sin)), has(f, 3), has(f, sin(2*y)), has(f, x - PI);
```

## Series::Puisseux

---

$$-\sin(2y) + \cos(2y)(\pi - x) + O((\pi - x)^2)$$

TRUE, TRUE, TRUE, TRUE, TRUE

TRUE, FALSE, TRUE, FALSE

The last call returns FALSE since the expression  $x - \pi$  occurs only in the screen output, but not in the internal representation of  $f$ .

```
g := series(sign(x), x, Right);
has(g, Right), has(g, Undirected);
```

$$1 + O(x^6)$$

TRUE, FALSE

### Example 24

The method truncate discards summands up to the given order:

```
f := series(x*sin(sqrt(x)), x);
Series::Puisseux::truncate(f, 10);
Series::Puisseux::truncate(f, 9/2);
Series::Puisseux::truncate(f, 7/2);
Series::Puisseux::truncate(f, 3);
Series::Puisseux::truncate(f, 3/2);
Series::Puisseux::truncate(f, 1);
```

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O(x^{9/2})$$

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O(x^{9/2})$$

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O(x^{9/2})$$

$$x^{3/2} - \frac{x^{5/2}}{6} + O(x^{7/2})$$

$$x^{3/2} - \frac{x^{5/2}}{6} + O(x^{7/2})$$

$$O(x^{3/2})$$

$$O(x^{3/2})$$

**Parameters****f**An arithmetical expression representing a function in  $x$ **x**

An identifier

**x<sub>0</sub>**

The expansion point: an arithmetical expression. If not specified, the default expansion point 0 is used.

**order**

The number of terms to be computed: a nonnegative integer. The default order is given by the environment variable `ORDER` (default value 6).

## **dir**

Either `Left`, `Right`, `Real`, or `Undirected`. This optional argument can be used to specify that the resulting expansion is possibly valid along the real line only. The default is `Undirected`, which means that the expansion is valid in a neighborhood of the expansion point in the complex plane.

## **Return Values**

an object of domain type `Series::Puisseux`, or the value `FAIL`, if the `f` cannot be converted, e.g., if powers with non-rational exponents occur in `f`.

## **Function Calls**

Calling an element of `Series::Puisseux` as a function discards the error term and substitutes the first argument for the series variable. See the description of the method `"func_call"` and "Example 22" on page 6-461.

## **Operations**

`Series::Puisseux` implements the basic arithmetic of truncated series expansions. Use the ordinary arithmetical operators `+`, `-`, `*`, `/`, `^`, and `@` for composition.

The arithmetical methods of `Series::Puisseux` usually do not perform any symbolic simplifications. Use `combine`, `expand`, or `normal` to request such simplifications explicitly.

See "Example 5" on page 6-428 and "Example 21" on page 6-458.

Special mathematical functions, such as `exp` or `sin`, are overloaded for elements of `Series::Puisseux`; cf. "Example 10" on page 6-440.

The system functions `coeff`, `lcoeff`, `nthcoeff`, `ldegree`, `lmonomial`, `nthmonomial`, `lterm`, and `nthterm` work on truncated series expansions. Note that in contrast to polynomials, coefficients, monomials, and terms are counted from the term of lowest order term on. Cf. "Example 17" on page 6-452.

Use the function `expr` to convert a series expansion to an arithmetical expression (as an element of a kernel domain).

## Operands

A series of the domain type `Series::Puisseux` has the following seven operands:

- 1** a *type flag*  $\{0, 1\}$ ,
- 2** the *branching order*  $b$ , a positive integer,
- 3** an integer  $v$  such that  $\frac{v}{b}$  is the order of the leading term,
- 4** an integer  $e \geq v$  such that  $\frac{e}{b}$  is the order of the error term,
- 5** a list of coefficients  $l_1, \dots, l_n$ ,
- 6** the *series variable*  $x$  and the *expansion point*  $x_0$  in form of an equation  $x = x_0$ ; the expansion point  $x_0$  may be `complexInfinity` as well,
- 7** a *direction*, `Undirected`, `Real`, `Left`, or `Right`.

The type flag distinguishes between two different internal representations.

If  $t = 0$ , then the operands above represent the truncated series expansion

$$\sum_{1 \leq i \leq n} \left( l_i (X - X_0)^{\frac{(v+i-1)}{b}} + O\left((X - X_0)^{e/b}\right) \right)$$

If the expansion point  $x_0$  is `complexInfinity`, then the operands represent the truncated expansion

# Series::Puisseux

---

$$\sum_{1 \leq i \leq n} \left( \frac{l_i}{X^{\frac{(i+v-1)}{b}}} + O\left(\frac{1}{X^{\frac{e}{b}}}\right) \right)$$

- A summand  $l_i(X - X_0)^{\frac{(v+i-1)}{b}}$  (or  $\frac{l_i}{x^{\frac{(i+v-1)}{b}}}$ , respectively) is called a *monomial* of the expansion,
- the power  $(X - X_0)^{\frac{(v+i-1)}{b}}$  (or  $\frac{1}{x^{\frac{(i+v-1)}{b}}}$ , respectively) is called a *term*,
- $l_i$  is the corresponding *coefficient*, and
- the exponent  $\frac{(v+i-1)}{b}$  is the *order* of the corresponding term or monomial.

If  $t = 1$ , then the operands above represent the expansion

$$\sum_{1 \leq i \leq n} \left( l_i + O\left((X - X_0)^{e/b}\right) \right)$$

In this case, the powers of  $x - x_0$  are explicitly stored in the list, and

$l_i$  contains only terms of growth order  $O\left((X - X_0)^{\frac{(v+i-1)}{b}}\right)$ . The corresponding expansion for  $x_0 = \text{complexInfinity}$  is

$$\sum_{1 \leq i \leq n} \left( l_i + O\left(\frac{1}{X^{\frac{e}{b}}}\right) \right)$$

and  $l_i$  contains only terms of growth order  $O\left(\frac{1}{(X-X_0)^{\frac{v+i-1}{b}}}\right)$ .  
 The notions term and order are the same as for  $t \neq 0$ , a summand  $l_i$  is called a monomial, and the corresponding coefficient is

$$\frac{l_i}{(X - X_0)^{\frac{v+i-1}{b}}}$$

(or

$$\frac{\frac{l_i}{1}}{x^{\frac{v+i-1}{b}}},$$

respectively).

The latter type of representation serves for correct expansions around branch points. For example, if we want to expand  $f(X) = \sqrt{X}$  around  $x = 0$ , then the truncated Puiseux series  $\sqrt{-1} \sqrt{X} + O(X^{13/2})$  does not approximate  $f(x)$  in the lower half of the complex plane. With  $t = 1$ , the expansion  $\sqrt{(-X)} + O(X^{13/2})$ , which approximates  $f(x)$  also in the lower part of the complex plane near the origin, can be represented as an object of domain type `Series::Puisseux`.

The direction  $d$  has the same meaning as the parameter `dir` of the constructor. If  $d = \textit{Undirected}$ , the operands above represent an expansion valid in some neighborhood of the expansion point in the complex plane. Usually, this is an open disc centered at  $x_0$ . If  $d \neq \textit{Undirected}$  and  $x_0$  represents a real number, this means that the

expansion is valid for real values of  $x$  only. If  $d = \textit{Left}$  or  $d = \textit{Right}$ , then the expansion is valid for  $x < x_0$  or  $x > x_0$ , respectively.

In the case  $x_0 = \textit{complexInfinity}$ , and if  $d = \textit{Undirected}$ , we have an expansion valid in the neighborhood of the north pole of the Riemann sphere, i.e., for all  $x \in \mathbb{C}$  of sufficiently large absolute value. If  $d = \textit{Left}$ , we have an expansion around the positive real infinity valid for sufficiently large real values of  $x$ . Similarly, if  $d = \textit{Right}$ , we have an expansion around the negative real infinity valid for sufficiently large negative real values of  $x$ . Finally, if  $d = \textit{Real}$ , the expansion is valid both around *infinity* and around  $-\infty$ .

Cf. “Example 2” on page 6-421.

## Element Creation

Typically, objects of type `Series::Puisseux` are generated by calls to `series` or `taylor`.

## Methods

### Mathematical Methods

#### **conjugate - Complex conjugation**

`conjugate(s)`

This method overloads the system function `conjugate`. Cf. “Example 11” on page 6-442.

#### **contfrac - Conversion into a continued fraction**

`contfrac(s)`

This method overloads the system function `contfrac`. Cf. “Example 12” on page 6-443.

#### **diff - Differentiation**

`diff(s, t)`

This method overloads the system function `diff`. Cf. “Example 9” on page 6-439.

#### **\_divide - Division**

`_divide(s, t)`

### **`_fconcat` - Functional composition**

`_fconcat(s, t)`

If both `s` and `t` are of type `Series::Puisseux`, then the functional composition can only be defined if the limit point of `t` for values close to its expansion point is equal to the expansion point of `s`. Otherwise, an error occurs.

At least one of the arguments must be of type `Series::Puisseux`. If one of the arguments is not of this type, then it is converted into an element of `Series::Puisseux` via the constructor. If `s` is not of type `Series::Puisseux`, then it is converted into a series expansion around the limit point of `t`. If `t` is not of type `Series::Puisseux`, then it is converted into a series expansion around 0. The implicit conversion is performed only if the corresponding expression contains exactly one free variable.

This method overloads the system function `_fconcat` for series expansions, i.e., you may use it in the form `s@t`. See “Example 8” on page 6-435 and “Example 22” on page 6-461.

### **`Im` - Imaginary part**

`Im(s)`

This method overloads the system function `Im`. Cf. “Example 11” on page 6-442.

### **`int` - Integration**

`int(s, t | t = a .. b)`

This method overloads the system function `int`. Cf. “Example 9” on page 6-439, and the help page of `int` for a description of further optional arguments.

### **`_invert` - Reciprocal of a series**

`_invert(s)`

This method overloads the system function `_invert`, i.e., you may use it in the form  $1/s$ .

## **ilaplace - Inverse Laplace transform**

`ilaplace(s, u, v)`

If `u` is not the series variable of `s`, then the coefficients of `s` are transformed, but not the expansion point. Otherwise, the expansion point of `s` must be infinity, `v` must be an identifier, and `s` is transformed term by term. The result is then a series expansion around  $v = 0$ .

This method overloads the function `ilaplace` for series expansions. Cf. “Example 13” on page 6-444.

## **laplace - Laplace transform**

`laplace(s, u, v)`

If `u` is not the series variable of `s`, then the coefficients of `s` are transformed, but not the expansion point. Otherwise, the expansion point of `s` must be 0, the order of the leading term of `s` must be nonnegative, `v` must be an identifier, and `s` is transformed term by term. The result is then a series expansion around  $v = \infty$ .

This method overloads the function `laplace` for series expansions. Cf. “Example 13” on page 6-444.

## **\_mult - Multiplication**

`_mult(s, t, , )`

Use the method `Series::Puisseux::scalmult` to multiply a series expansion `s` by a constant or a power of  $x - x_0$ .

This method overloads the system function `_mult` for series expansions, i.e., you may use it in the form `s*t*...` Cf. “Example 5” on page 6-428.

## **\_negate - Negation**

`_negate(s)`

This method overloads the system function `_negate`, i.e., you may use it in the form `-s`.

### **`_plus` - Addition**

`_plus(s, t, , )`

This method overloads the system function `_plus` for series expansions, i.e., you may use it in the form `s+t+...`. Cf. “Example 5” on page 6-428.

### **`_power` - Exponentiation**

`_power(s, n)`

If  $n$  is a rational number, the direction of  $s$  is `Undirected` or `Real`, and the leading coefficient of  $s$  is not positive, then the type flag of the result is 1 in general.

If  $n$  is not a rational number, then the leading summand of  $s$  must not contain the series variable. Otherwise, an error occurs.

This method overloads the system function `_power` for series expansions, i.e., you may use it in the form `s^n`. Cf. “Example 7” on page 6-433.

### **`Re` - Real part**

`Re(s)`

This method overloads the system function `Re`. Cf. “Example 11” on page 6-442.

### **`revert` - Functional inversion**

`revert(s)`

The expansion point of the inverse is the limit point of  $s$ .

This method overloads the system function `revert`. Cf. “Example 8” on page 6-435.

### **`scalmult` - Multiplication by a single monomial**

`Series::Puisseux::scalmult(s, a, k)`

## **series - Serie expansion**

```
series(s, y | y = y0, <order>, <dir>)
```

This method overloads the system function `series`.

## **\_subtract - Subtraction**

```
_subtract(s, t)
```

## **Access Methods**

### **coeff - Extract coefficients**

```
coeff(s, <x>, n)
```

```
coeff(s, <x>)
```

The second call returns the sequence of all coefficients of `s`, starting with the coefficient of lowest order. (This is the coefficient of the term with the highest exponent if  $x_0 = \text{complexInfinity}$ .)

Specifying the variable `x` is optional; if it is present, it must coincide with the series variable of `s`.

This method overloads the system function `coeff`. Cf. “Example 14” on page 6-446.

### **direction - Direction of expansion**

```
Series::Puisseux::direction(s)
```

### **indet - Serie variable**

```
Series::Puisseux::indet(s)
```

### **iszero - Zero test**

```
iszero(s)
```

This method overloads the system function `iszero`. Cf. “Example 18” on page 6-454.

### **lcoeff - Leading coefficient (of lowest order)**

```
lcoeff(s)
```

This method overloads the system function `lcoeff`. See “Example 15” on page 6-448 and “Example 17” on page 6-452.

## **ldegree - Leading degree**

`ldegree(s)`

This method overloads the system function `ldegree`. See “Example 2” on page 6-421 and “Example 15” on page 6-448.

## **lmonomial - Leading monomial (of lowest order)**

`lmonomial(s)`

This method overloads the system function `lmonomial`. See “Example 15” on page 6-448 and “Example 17” on page 6-452.

## **lterm - Leading term (of lowest order)**

`lterm(s)`

This method overloads the system function `lterm`. See “Example 15” on page 6-448 and “Example 17” on page 6-452.

## **nthcoeff - Extract coefficients**

`nthcoeff(s, n)`

This method overloads the system function `nthcoeff`. See “Example 16” on page 6-450 and “Example 17” on page 6-452.

## **nthmonomial - Extract monomials**

`nthmonomial(s, n)`

This method overloads the system function `nthmonomial`. See “Example 16” on page 6-450 and “Example 17” on page 6-452.

## **nthterm - Extract terms**

`nthterm(s, n)`

This method overloads the system function `nthterm`. See “Example 16” on page 6-450 and “Example 17” on page 6-452.

## **order - Order of the error term**

Series::Puisseux::order(s)

## **point - Expansion point**

Series::Puisseux::point(s)

## **Conversion Methods**

### **convert - Convert any object into a series expansion**

convert(f)

If no expansion point can be determined from *f*, the origin is used. Cf. “Example 19” on page 6-454.

### **convert\_to - Convert a series expansion into another domain**

convert\_to(s, T)

Use the function *expr* to convert *s* into an object of a kernel domain.

### **convert01 - Convert into a series expansion of type 1**

Series::Puisseux::convert01(s)

### **convert10 - Try to convert into a series expansion of type 0**

Series::Puisseux::convert10(s)

For undirected expansions, the conversion is not possible in general, and then *s* is returned. However, you can enforce a conversion (with a not necessarily equivalent result) by using properties. Cf. “Example 3” on page 6-425.

### **expr - Convert a series expansion into an element of a kernel domain**

expr(s)

This method overloads the system function *expr*. Cf. “Example 20” on page 6-457.

### **float - Convert numeric parts of the coefficients into floats**

float(s)

This method overloads the system function `float`. Cf. “Example 20” on page 6-457.

## Technical Methods

### **combine - Combine coefficients**

```
combine(s)
```

This method overloads the system function `combine`; see the corresponding help page for further optional arguments. Cf. “Example 21” on page 6-458.

### **const - Convert a constant expression into a truncated series**

```
Series::Puisseux::const(f, x | x = x0, n, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-418.

### **create - Syntactical constructor**

```
Series::Puisseux::create(b, v, e, l, x, <x0>, <d>)
```

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-418.

### **expand - Expand coefficients**

```
expand(s)
```

This method overloads the system function `expand`; see the corresponding help page for further optional arguments. Cf. “Example 21” on page 6-458.

### **func\_call - Evaluation at a point**

```
Series::Puisseux::func_call(s, t)
```

You may also use this method in the form  $s(t)$ . Cf. “Example 22” on page 6-461.

## **has - Check whether an object occurs syntactically**

```
has(s, t)
```

This method overloads the system function `has`. Cf. “Example 23” on page 6-467.

## **map - Apply a function to all non-zero coefficients**

```
map(s, f, <arg1, , >)
```

This method overloads the system function `map`. Cf. “Example 21” on page 6-458.

## **normal - Normal form**

```
normal(s)
```

This method overloads the system function `normal`. Cf. “Example 21” on page 6-458.

## **one - Create a truncated series with constant term 1**

```
Series::Puisseux::one(x, <x0>, n, <d>)
```

If the expansion point  $x_0$  is omitted,  $x_0 = 0$  is assumed. If the direction  $d$  is omitted,  $d = \text{Undirected}$  is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-418.

## **print - Pretty-print routine**

```
print(s)
```

## **truncate - Truncate a series expansion**

```
Series::Puisseux::truncate(s, n)
```

Cf. “Example 24” on page 6-468.

## **subs - Replace subexpressions**

```
subs(s, old = new)
```

```
subs(s, [old1 = new1, old2 = new2,])
```

If the series variable  $x$  of  $s$  does not occur in the left hand sides  $old$ ,  $old1$ ,  $old2$ ,  $\dots$ , then the substitution takes place in the coefficients and in the expansion point of  $s$ . The series variable must not occur in the right hand sides  $new$ ,  $new1$ ,  $new2$ ,  $\dots$ .

---

**Note** In contrast to the usual behavior of `subs`, the result of the substitution is subjected to an additional evaluation.

---

In the second call, the series variable  $x$  of  $s$  must not occur anywhere in the substitution equations. In the first call,  $x$  is allowed to occur in  $old$  only if  $old$  equals  $x$ . In this case, a change of variable is performed, and  $new$  must be of the form

$$x_0 + a*(b*y - c)^k$$

if  $x_0 \neq \text{complexInfinity}$  and

$$a*(b*y - c)^k$$

if  $x_0 = \text{complexInfinity}$ , where

- $x_0$  is the expansion point of  $s$
- $k$  is a non-zero rational number
- $y$  is an identifier, which may well be equal to  $x$ , and otherwise  $y$  must not occur in the coefficients of  $s$ .
- $a$ ,  $b$ ,  $c$  are arithmetical expressions not involving  $y$ , with  $a$ ,  $b$  being non-zero. If the direction of  $s$  is not `Undirected`, then  $a$  and  $b$  must represent real numbers.
- $c$  is zero if either  $x_0 \neq \text{complexInfinity}$  and  $k$  is positive or  $x_0 = \text{complexInfinity}$  and  $k$  is negative. In this case, the result of the substitution has expansion point `complexInfinity`.

- If  $c$  is non-zero, then the result of the substitution has expansion point  $c/b$ .

Use one of the methods `"_fconcat"` or `"func_call"` for more general substitutions for the series variable.

This method overloads the system function `subs`; Cf. “Example 22” on page 6-461.

### **zero - Create a truncated series with an error term only**

`Series::Puisseux::zero(x, <x0>, n, <d>)`

If the expansion point  $x_0$  is omitted,  $x_0 = 0$  is assumed. If the direction  $d$  is omitted,  $d = \text{Undirected}$  is assumed.

---

**Note** Although `Series::Puisseux::zero(x, n)` and  $0(x^n)$  are mathematically equivalent and are printed in the same way, they are different MuPAD objects. The former is an element of type `Series::Puisseux`, while the latter is an element of type `0`.

---

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-418.

## See Also

## MuPAD Functions

`Series::gseries` | `asympt` | `series`

**Purpose** Generalized series expansions

**Syntax** `Series::gseries(f, x, <order>, <Left | Right>)`  
`Series::gseries(f, x = a, <order>, <Left | Right>)`

**Description** `Series::gseries` is the domain of series expansions generalizing Taylor, Laurent and Puiseux expansions.

The call `Series::gseries(f, x)` computes a series expansion at the right hand side of  $x = 0$ .

The system functions `series` and `asymp` are the main application of this domain. The latter function only returns elements of this domain, whereas `series` can return an element of `Series::gseries` in cases, where a Puiseux series expansion does not exist.

There may be no need to explicitly create elements of this domain, but to work with the results of the mentioned system functions.

See the help page of the system function `asymp` for a detailed description of the parameters and examples for working with elements of the domain `Series::gseries`.

---

**Note** Note that elements of `Series::gseries` only represents *directional* (real) series expansions.

---

**Environment Interactions** The function is sensitive to the global variable `ORDER`, which determines the default number of terms of the expansion.

**Parameters**

- f**  
An arithmetical expression
- x**  
The series variable: an identifier
- a**

# Series::gseries

---

The expansion point: an arithmetical expression or  $\pm\text{infinity}$

## **order**

The truncation order: a nonnegative integer

## **Options**

### **Left**

Compute a series expansion that is valid for real  $x$  smaller than  $a$ .

### **Right**

Compute a series expansion that is valid for real  $x$  larger than  $a$  (the default case).

## **Return Values**

Object of domain type `Series::gseries`, or the value `FAIL`.

## **Function Calls**

Calling an element of `Series::gseries` as a function yields the object itself, regardless of the arguments. The arguments are *not* evaluated.

## **Operations**

`Series::gseries` implements standard arithmetic of generalized series expansions. Use the ordinary arithmetical operators `+`, `-`, `*`, `/`, and `^`.

The system functions `coeff`, `lcoeff`, `nthcoeff`, `lterm`, `nthterm`, `lmonomial`, `nthmonomial`, and `ldegree` work on generalized series expansions. See the corresponding help pages of these functions for calling parameters. See the description of these methods below for further details.

The method `"indet"` returns the series variable of the series expansion, i.e., if `s` is an object of the domain `Series::gseries`, then `s::dom::indet(s)` returns the series variable.

The method `"point"` returns the expansion point of the series.

Use the function `expr` to convert a generalized series expansion into an arithmetical expression (as an element of a kernel domain).

## Operands

A series of the domain type `Series::gseries` consists of four operands:

- 1 A list of pairs  $[c_i, f_i]$ . Each pair represents a *monomial*  $c_i f_i$  of the series expansion, where the  $c_i$  are the *coefficients* and  $f_i$  the *terms* of  $s$ . The coefficients do not contain the series variable.

This list can be empty, if the order of the expansion is zero.

- 2 An arithmetical expression  $g$  representing the *error term* of the form  $O(g)$ . It may be the integer 0, in which case the expansion is exact.
- 3 The *series variable*  $x$ .
- 4 The *expansion point*  $a$ .

## Methods

### Mathematical Methods

#### **`_divide` - Divide two series expansions**

```
_divide(s, t)
```

If the arguments are not of domain type `Series::gseries`, then they are converted into such objects. FAIL is returned, if one of these conversions fails.

This method overloads the function `_divide` for elements of `Series::gseries`, i.e., you may use it in the form  $s/t$ .

#### **`_invert` - Multiplicative inverse of a series expansion**

```
_invert(s)
```

This method overloads the function `_invert` for elements of `Series::gseries`, i.e., you may use it in the form  $1/s$ .

#### **`_mult` - Multiply series expansions**

```
_mult(s, t,)
```

If both  $s$  and  $t$  are series expansions of the domain `Series::gseries`, then the result is a series expansion of the domain `Series::gseries`, too. Both series expansions must have

the same series variable and expansion point, otherwise FAIL is returned.

If `s` or `t` is a series expansion of the domain `Series::Puisseux`, then it is converted into an object of `Series::gseries`. If this fails, then FAIL is returned. Otherwise, the product is computed and returned as an object of the domain `Series::gseries`.

If `s` is a series expansion and `t` is an arithmetical expression, then `t` is converted into a series expansion via the constructor `Series::gseries` (and vice versa).

Each argument of this method that is not of the domain type `Series::gseries` is converted into such an element, i.e., a generalized series expansion is computed. If this fails, then FAIL is returned.

This method overloads the function `_mult` for elements of `Series::gseries`, i.e., you may use it in the form `s*t*...`

## **`_negate` - Negative of a series expansion**

`_negate(s)`

This method overloads the function `_negate` for elements of `Series::gseries`, i.e., you may use it in the form `-s`.

## **`_plus` - Add series expansions**

`_plus(s, t, )`

If both `s` and `t` are series expansions of the domain `Series::gseries`, then the result is a series expansion of the domain `Series::gseries`, too. Both series expansions must have the same series variable and expansion point, otherwise FAIL is returned.

If `s` or `t` is a series expansion of the domain `Series::Puisseux`, then it is converted into an object of `Series::gseries`. If this fails, then FAIL is returned. Otherwise, the sum is computed and returned as an object of the domain `Series::gseries`.

If  $s$  is a series expansion and  $t$  is an arithmetical expression, then  $t$  is converted into a series expansion via the constructor `Series::gseries` (and vice versa).

Each argument of this method that is not of the domain type `Series::gseries` is converted into such an element, i.e., a generalized series expansion is computed. If this fails, then `FAIL` is returned.

This method overloads the function `_plus` for elements of `Series::gseries`, i.e., you may use it in the form `s+t+ ...`

## **`_power` - Exponentiation of a series expansion**

`_power(s, n)`

The exponent  $n$  must not involve the series variable of  $s$ . Otherwise, an error occurs.

If  $n$  is a positive integer, then repeated squaring is used for computing the  $n$ th power of  $s$ . Otherwise, the binomial theorem is applied after factoring out the leading monomial.

This method overloads the function `_power` for elements of `Series::gseries`, i.e., you may use it in the form `s^n`.

## **`_subtract` - Subtract two series expansions**

`_subtract(s, t)`

If the arguments are not of domain type `Series::gseries`, then they are converted into such objects. `FAIL` is returned, if one of these conversions fails.

This method overloads the function `_subtract` for elements of `Series::gseries`, i.e., you may use it in the form `s-t`.

## **Access Methods**

### **`coeff` - Extract coefficients**

`coeff(s, <n>)`

This method overloads the function `coeff` for elements of `Series::gseries`.

## **indet - Serie variable**

`Series::gseries::indet(s)`

Use the method "point" to get the expansion point of s.

## **iszero - Zero test**

`iszero(s)`

This method overloads the function `iszero` for elements of `Series::gseries`.

## **lcoeff - Leading coefficient**

`lcoeff(s)`

This method overloads the function `lcoeff` for elements of `Series::gseries`.

## **ldegree - Leading degree**

`ldegree(s)`

This method overloads the function `ldegree` for elements of `Series::gseries`.

## **lmonomial - Leading monomial**

`lmonomial(s)`

This method overloads the function `lmonomial` for elements of `Series::gseries`.

## **lterm - Leading term**

`lterm(s)`

This method overloads the function `lterm` for elements of `Series::gseries`.

## **nthcoeff - Extract a coefficient**

`nthcoeff(s, n)`

This method overloads the function `nthcoeff` for elements of `Series::gseries`.

## **nthmonomial - Extract a monomial**

```
nthmonomial(s, n)
```

This method overloads the function `nthmonomial` for elements of `Series::gseries`.

## **nthterm - Extract a term**

```
nthterm(s, n)
```

This method overloads the function `nthterm` for elements of `Series::gseries`.

## **point - Expansion point**

```
Series::gseries::point(s)
```

Use the method `"indet"` to get the series variable of `s`.

## **Conversion Methods**

### **convert - Convert an object into a generalized series expansion**

```
Series::gseries::convert(x)
```

### **convert\_to - Convert a generalized series expansion into other domains**

```
Series::gseries::convert_to(s, T)
```

`T` might be the domain `DOM_POLY`, where the sum of monomials is considered as a polynomial in the indeterminates of the third operand of `s`.

If `T` is the domain `DOM_EXPR`, then the conversion is the same as implemented by the method `"expr"` (see below).

If `T` is the domain `Series::Puiseux`, then the system tries to convert `s` into a Puiseux series. If the conversion is not possible, `FAIL` is returned.

# Series::gseries

---

Use the function `expr` to convert `s` into an object of a kernel domain.

## **create - Create simple and fast a generalized series expansion**

```
Series::gseries::create(list, errorTerm, x = a)
```

---

**Note** This method should be used with caution, because no argument checking is performed. Use it to *create*, not to compute elements of `Series::gseries`.

---

## **expr - Convert a generalized series expansion into an element of a kernel domain**

```
expr(s)
```

This method overloads the function `expr` for elements of `Series::gseries`.

## **series - Apply the function series to a generalized series expansion**

```
series(s, x | x = x0, <order>, <dir>)
```

This method overloads the function `series` for elements of `Series::gseries`. See the corresponding help page for a description of the possible arguments.

## **Technical Methods**

### **combine - Apply the function combine to all terms**

```
combine(s, <target>)
```

This method overloads the system function `combine`. See the corresponding help page for a description of the optional argument `target`.

### **has - Check whether an object occurs syntactically**

```
has(s, t)
```

This method overloads the system function `has`.

## **map - Map a function to the coefficients**

```
map(s, func,)
```

This method overloads the function `map` for elements of `Series::gseries`.

## **print - Pretty-print routine**

```
print(s)
```

## **subs - Substitute into a generalized series expansion**

```
subs(s, x = a,)
```

This method overloads the function `subs` for elements of `Series::gseries`.

## **TeX - LaTeX formatting**

```
Series::gseries::TeX(s)
```

This method is called by the system function `generate::TeX`.

`Series::Puisseux`

# Series::gseries

---

# export – Export Data

---

export::stl

# export::stl

---

## Purpose

Export STL data

## Syntax

```
export::stl(filename, [x, y, z], u = umin .. umax,
v = vmin .. vmax, options)
export::stl(n, [x, y, z], u = umin .. umax, v =
vmin .. vmax, options)
export::stl(filename, object1, <object2, >, options)
export::stl(n, object1, <object2, >, options)
```

## Description

`export::stl` is used to create a triangulation of a parametrized surface and write the triangulation data in STL format to an external file.

STL files contain triangulation data of 3D surfaces. Each triangle is stored as a unit normal and three vertices. The normal and the vertices are specified by three coordinates each, so there is a total of 12 numbers stored for each triangle. Read the “Background” section of this help page for further details.

If the surface is closed, it is regarded as the boundary of a 3D solid. The normals of the triangles written into the STL file should point from the inside of the body to the outside.

---

**Note** Note that the direction of the normals that `export::stl` writes into the STL file depend on the parametrization  $x(u, v), y(u, v), z(u, v)$ !

---

If  $p_1 = (x(u, v), y(u, v), z(u, v)), p_2 = (x(u + du, v), y(u + du, v), z(u + du, v)), p_3 = (x(u, v + dv), y(u, v + dv), z(u, v + dv))$  are the corners of a triangle, the normal associated with this triangle is the cross product of the side  $p_2 - p_1$  times the side  $p_3 - p_1$ . The routine `export::stl` chooses neighboring values of the surface parameters with  $du = (u_{\max} - u_{\min}) / (n_u - 1)$  and  $dv = (v_{\max} - v_{\min}) / (n_v - 1)$ , respectively.

---

**Note** Thus, if your parametrization is such that the cross product of the vectors  $p_2 - p_1$  and  $p_3 - p_1$  does not point to the outside of your body, you just need to let one of the parameters ( $u$ , say) run from  $u_{\max}$  to  $u_{\min}$  instead of from  $u_{\min}$  to  $u_{\max}$ . Just replace your call

```
export::stl(filename, [x,y,z], u = `u_{min}` .. `u_{max}`,
v = `v_{min}` .. `v_{max}`)
```

by

```
export::stl(filename, [x,y,z], u = `u_{max}` .. `u_{min}`,
v = `v_{min}` .. `v_{max}`).
```

---

Up to the irrelevant ordering in the STL file, the triangles generated by these calls are the same apart from the direction of the normal associated with each triangle.

If the file is specified by a character string, the corresponding file is opened and closed, automatically.

As an alternative to specifying the file by a string, the user may open the file herself via `fopen` in `Write` mode and pass the file descriptor returned by `fopen` to `export::stl`. If binary data are to be written to the file, make sure that it is opened with the `Raw`, i.e., call `fopen(filename, Write, Raw)`.

---

**Note** Note that `export::stl` does not close the file automatically if it is specified by a file descriptor. It remains open after `export::stl` has finished its job. The file needs to be closed explicitly by the user using `fclose`.

---

If the file is specified by a character string, the name may correspond to an absolute or a relative path name. In particular, the environment

variable `WRITEPATH` is taken into account. The details on the help page of `fopen` hold for `export::stl`, too.

---

**Note** With the option `Append`, the file is first opened for reading and, after reading of the data in the file, opened for writing. If no absolute pathname is used to specify the file, make sure that the environment variables `READPATH` and `WRITEPATH` point to the same folder. Alternatively, it is a good idea to place the file in the same folder as the MuPAD notebook which you are currently using. If this notebook is saved on the disk of your computer, the absolute path is available as the environment variable `NOTEBOOKPATH`. Thus, specifying a file named “myfile.stl”, say, by the absolute path name `NOTEBOOKPATH."myfile.stl"` ensures that the file is found in the same folder as your notebook.

---

Text files generated with the option `Text` or the equivalent `Ascii` can be opened and read with any text editor. However, binary files generated with the option `Bin` or the equivalent options `Binary` or `Raw` are faster to create and to process.

The file generated by `export::stl` can be read and visualized in MuPAD using the plot primitive `plot::SurfaceSTL`.

If the file name given ends in “.gz”, `export::stl` writes a compressed file which can be read by any program supporting `gzip` compression.

### Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. The current value of `DIGITS` determines the number of significant decimal digits with which the STL data are written to the specified file. (This holds for text files. In binary STL files all numerical values have a precision of about 7 decimal digits.) For the internal computation of the data by MuPAD, the value of `DIGITS` is temporarily increased by 10 to minimize round-off effects.

The STL data generated by `export::stl` are written to the specified file.

## Examples

### Example 1

We generate a sphere given by the following parametrization:

```
x:= cos(u)*sin(v):
y:= sin(u)*sin(v):
z:= cos(v):
```

We call `export::stl` to generate the STL data and write them into a file named “sphere.stl”. The file is to be generated in the same directory as the current MuPAD notebook that we are using. Hence, we specify an absolute path name for the file using the path of the current notebook. If this notebook was saved to the disk of your computer, this path is available in the environment variable `NOTEBOOKPATH`:

```
filename:= NOTEBOOKPATH."sphere.stl":
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, Text)
```

Since the file was created in Text format, it can be opened with any text editor. It should look like this:

```
solid MuPADtoSTL1
facet normal -0.06540070486 -0.008610166138 -0.9978219344
 outer loop
 vertex 100.0 100.0 300.0
 vertex 112.607862 103.3782664 298.7167292
 vertex 113.0526192 100.0 298.7167292
 endloop
endfacet
facet normal -0.1950260058 -0.02567566076 -0.9804619409
 outer loop
 vertex 113.0526192 100.0 298.7167292
 vertex 112.607862 103.3782664 298.7167292
 vertex 125.0 106.6987298 294.8888739
```

## export::stl

---

```
 endloop
 endfacet
 ...
endsolid MuPADtoSTL1
```

We reimport the STL data and visualize the surface using `plot::SurfaceSTL`:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

We reduce the number of significant output digits to a reasonable size. Further, we specify a mesh size and request a specific output box:

```
DIGITS:= 7:
```

```
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, MeshVisible,
 OutputBox = [-100 .. 100, -100 .. 100, -100 .. 100],
```

The file now should look like this:

```
solid MuPADtoSTL2
facet normal -0.1733024 -0.06307691 -0.9828467
 outer loop
 vertex -3.10912 0.000000002143114 100.0
 vertex 24.32249 22.66816 93.96926
 vertex 32.7003 0.000000002143114 93.96926
 endloop
endfacet

...

endsolid MuPADtoSTL2
```

We visualize the new content of the file:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

```
delete x, y, z, filename, DIGITS:
```

## Example 2

We specify the parametrization of the surface by a mixture of expressions and procedures:

```
x:= piecewise([0.1 < u < 0.9, u*cos(v)], [Otherwise, 0]):
y:= (u, v) -> piecewise([0.1 < u < 0.9, u*sin(v)], [Otherwise, 0]):
z:= (u, v) -> if u <= 0.1 then exp(-0.1)
 elif u < 0.9 then exp(-u)
 else exp(-0.9)
 end_if:
```

This is the surface that we wish to export to STL:

```
plot(plot::Surface([x, y, z], u = 0 .. 1, v = 0 .. 2*PI, Mesh = [10
```

We assume that there is no external file “sample.stl”. We create it by opening it in Write mode in the same directory as the current MuPAD notebook that we are using. Hence, we specify an absolute path name for the file using the path of the current notebook. If this notebook was saved to the disk drive of your computer, this path is available in the environment variable NOTEBOOKPATH. The file descriptor `n` returned by `fopen` is passed to `export::stl`:

```
filename:= NOTEBOOKPATH."sample.stl":
DIGITS:= 7:
export::stl(filename, [x, y, z], u = 0 .. 1, v = 0 .. 2*PI, MeshVisible)
```

We reimport the STL data and visualize the surface using `plot::SurfaceSTL`:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

## export::stl

---

We can append a further surface to the file using the option Append:

```
export::stl(filename, [x, y, -z], u = 0 .. 1, v = 0 .. 2*PI,
 Mesh = [30, 36], OutputBox = [0 .. 100, 0 .. 100, -100
 Append)
```

We visualize the new content of the file via plot::SurfaceSTL:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

```
delete x, y, z, filename, DIGITS:
```

### Example 3

We wish to create a closed surface consisting of a “bowl” with a “lid”.

```

bowl:= [u*cos(v), u*sin(v), u^2], u = 0 .. 1, v = 0 .. 2*PI:
lid:= [u*cos(v), u*sin(v), 1], u = 0 .. 1, v = 0 .. 2*PI:

```

```

filename:= NOTEBOOKPATH."sample.stl":
DIGITS:= 7:
export::stl(filename, bowl, Mesh = [30, 36]):
export::stl(filename, lid, Mesh = [30, 36], Append):
plot(plot::SurfaceSTL(filename), Scaling = Constrained):

```

`delete filename, DIGITS:`

## Example 4

We demonstrate the options `Scaling = Constrained` and `Scaling = Unconstrained`. With `Scaling = Constrained`, the coordinates given by the parametrization  $x$ ,  $y$ ,  $z$  are scaled by the same factor to fit the surface into the output box. Here, we create a sphere of radius 1. The output box is not a cube: the range for the  $z$  coordinate is notably larger than for  $x$  and  $y$ . Nevertheless, the sphere stays a sphere when using `Scaling = Constrained`. However, the output box is not completely filled by the sphere:

```
x:= cos(u)*sin(v):
y:= sin(u)*sin(v):
z:= cos(v):
DIGITS:= 7:
filename:= NOTEBOOKPATH."sphere.stl":
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI,
```

```
 OutputBox = [-1 .. 1, -1 .. 1, -3 .. 3],
 Scaling = Constrained):
plot(plot::SurfaceSTL(filename, Scaling = Constrained, MeshVisib
```

With `Scaling = Unconstrained`, the sphere is deformed to an ellipsoid filling the output box:

```
export:stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI,
 OutputBox = [-1 .. 1, -1 .. 1, -3 .. 3],
 Scaling = Unconstrained):
plot(plot::SurfaceSTL(filename, Scaling = Constrained, MeshVisib
```

`delete x, y, z, filename, DIGITS:`

## Parameters

### **filename**

A file name: a non-empty character string

### **n**

A file descriptor provided by `fopen`: a positive integer

### **object<sub>1</sub>, object<sub>2</sub>, ...**

3D graphical objects of the `plot` library

### **x, y, z**

The coordinate functions: arithmetical expressions or *piecewise* objects depending on the surface parameters  $u$  and  $v$ . Alternatively, procedures that accept 2 input parameters  $u, v$  and return a numerical value when the input parameters are numerical.

**u**

The first surface parameter: an identifier or an indexed identifier.

**u<sub>min</sub> .. u<sub>max</sub>**

The range for the parameter  $u$ :  $u_{\min}$ ,  $u_{\max}$  must be numerical real values.

**v**

The second surface parameter: an identifier or an indexed identifier.

**v<sub>min</sub> .. v<sub>max</sub>**

The range for the parameter  $v$ :  $v_{\min}$ ,  $v_{\max}$  must be numerical real values.

## Options

### Mesh

Option, specified as `Mesh = [nu, nv]`

Sets the mesh size: the integer  $n_u$  determines, how many equidistant points in the  $u$  direction are used to sample the parametrization  $x$ ,  $y$ ,  $z$  numerically. Correspondingly, the integer  $n_v$  determines, how many equidistant points in the  $v$  direction are used. Thus, a regular mesh of  $(n_u - 1)(n_v - 1)$  rectangles is used. Each rectangle is split into 2 triangles, resulting in a triangulation consisting of  $2(n_u - 1)(n_v - 1)$  triangles. The default is `Mesh = [25, 25]`.

### OutputBox

Option, specified as `OutputBox = [xmin .. xmax, ymin .. ymax, zmin .. zmax]`

By default, the coordinates of the mesh points defining the STL object are written into the file as provided by the parametrization of the surface. Thus, if several objects are written into the file via the option `Append`, the position of the objects in space is transparent and can be controlled by the user via a suitable parametrization. However, many devices such as Rapid

Prototyping tools with which the STL file shall be processed, impose severe restrictions on the data in the STL file. E.g., the original STL specification requires that the x, y, z coordinates of the mesh points are positive. Many devices require that the coordinates must lie in a prescribed range (between 0 and 100, say). The option `OutputBox` provides a simple mean to shift and scale the coordinates given by the parametrization to a prescribed range.

The option `OutputBox = [ xmin ·· xmax, ymin ·· ymax, zmin ·· zmax]` sets the output box defined by numerical values  $x_{\min}$ ,  $y_{\min}$ ,  $z_{\min}$ ,  $x_{\max}$ ,  $y_{\max}$ ,  $z_{\max}$ . The mathematical coordinates  $x(u, v)$ ,  $y(u, v)$ ,  $z(u, v)$  with  $u, v$  ranging from  $u_{\min}$  to  $u_{\max}$  and from  $v_{\min}$  to  $v_{\max}$ , respectively, are shifted and scaled such that the output coordinates written to the STL file range between the values  $x_{\min}$  and  $x_{\max}$ ,  $y_{\min}$  and  $y_{\max}$ ,  $z_{\min}$  and  $z_{\max}$ .

---

**Note** If several objects are written to the file via the option `Append`, only the very last call of `export::stl` should bear the option `OutputBox`!

---

This last call shifts and scales all coordinates of all surfaces inside the file such that the entire scene of objects fits into the output box. The relative size and positions of the objects are preserved.

See “Example 3” on page 7-11.

This option is rather expensive since all data in the STL file need to be modified!

This option is not available if the file was opened outside `export::stl` and passed by a file descriptor  $n$ .

## Scaling

Option, specified as `Scaling = Unconstrained` or `Scaling = Constrained`

With `Scaling = Unconstrained`, the surface is scaled by different factors in the x, y, and z direction, such that it fills the output box set by the option `OutputBox = [ `x_{min}` .. `x_{max}` , `y_{min}` .. `y_{max}` , `z_{min}` .. `z_{max}` ]`. Thus, the output coordinates of a sphere define an ellipsoid with diameters given by the side lengths of the output box. This is the default setting.

With `Scaling = Constrained`, the surface is scaled by the same factor in the x, y, and z direction such that it fits into the output box set by the option `OutputBox = [ `x_{min}` .. `x_{max}` , `y_{min}` .. `y_{max}` , `z_{min}` .. `z_{max}` ]`. A sphere will remain a sphere even if the sides of the output box have different lengths.

This option is ignored if not used in conjunction with the `OutputBox` option.

### **Ascii, Bin, Binary, Raw, Text**

With the synonymous flags `Bin`, `Binary`, or `Raw`, respectively, the STL file is created as a binary file. If a binary file is specified by a file descriptor `n`, make sure that it was opened by the command `n := fopen(filename, Write, Raw)`. With the synonymous flags `Text` and `Ascii`, respectively, the STL file is created as a text file. The default is `Bin`.

### **Append**

With this flag, the STL data of the surface are appended to an existing STL file named “filename”. If no such file exists, it is created and processed as without `Append`. This option is not available if the file was opened outside `export::stl` and passed by a file descriptor `n`.

## **Return Values**

`null()` object.

## Algorithms

There are two storage formats available for STL files, which are ASCII and BINARY. ASCII files are human-readable while BINARY files are smaller and faster to process. Both ASCII as well as BINARY files can be generated by `export::stl`. A typical ASCII STL file looks like this:

```
solid sample
 facet normal -4.470293E-02 7.003503E-01 -7.123981E-01
 outer loop
 vertex -2.812284E+00 2.298693E+01 0.000000E+00
 vertex -2.812284E+00 2.296699E+01 -1.960784E-02
 vertex -3.124760E+00 2.296699E+01 0.000000E+00
 endloop
 endfacet
 ...
endsolid sample
```

STL BINARY files have the following format:

| Bytes | Type  | Description                  |
|-------|-------|------------------------------|
| 80    | ASCII | header, no data significance |
| 4     | uint  | number of facets in file     |
| 4     | float | normal x - start of facet    |
| 4     | float | normal y                     |
| 4     | float | normal z                     |
| 4     | float | vertex1 x                    |
| 4     | float | vertex1 y                    |
| 4     | float | vertex1 z                    |
| 4     | float | vertex2 x                    |
| 4     | float | vertex2 y                    |
| 4     | float | vertex2 z                    |

```
4 float vertex3 x
4 float vertex3 y
4 float vertex3 z
2 byte not used - end of facet
...

```

Facet orientation: The facets define the surface of a 3D object. As such, each facet is part of the boundary between the interior and the exterior of the object. The orientation of the facets (which way is "out" and which way is "in") is specified redundantly in two ways which should be consistent. First, the direction of the normal is outward. Second, which is most commonly used nowadays, the facet vertices are listed in counter-clockwise order when looking at the object from the outside (right-hand rule).

Vertex-to-vertex rule: Each triangle must share two vertices with each of its adjacent triangles. In other words, a vertex of one triangle cannot lie on the side of another.

Axes: The format specifies that all vertex coordinates must be strictly positive numbers. However, it seems that – with a few exceptions – most software used today (MuPAD included) allow negative coordinates as well.

Units: The STL file does not contain any scale information; the coordinates may be interpreted in arbitrary units.

Further details about the STL file format are available in the web, e.g., at:

# fp – Functional Programming

---

fp::apply  
fp::bottom  
fp::curry  
fp::expr\_unapply  
fp::fixargs  
fp::fixedpt  
fp::fold  
fp::nest  
fp::nestvals  
fp::unapply

# fp::apply

---

**Purpose** Apply function to arguments

**Syntax** `fp::apply(f, <e, >)`

**Description** `fp::apply(f, a)` returns `f(a)`.  
`fp::apply` applies the function `f` to the arguments given by `e, ....`

**Environment Interactions** Same side effects as when calling `f(e, ...)` directly.

## Examples **Example 1**

Apply the function `f` to `x` and `y`:

```
fp::apply(f, x, y)
```

```
f(x, y)
```

## **Example 2**

Apply the functions of the first list to the arguments given by the second list:

```
zip([sin, cos], [x, y], fp::apply)
```

```
[sin(x), cos(y)]
```

## **Parameters** **f**

Function

**e**

Object used as argument

**Return  
Values**

Result of the function call  $f(e, \dots)$ .

# fp::bottom

---

**Purpose** Function that never returns

**Syntax** `fp::bottom()`

**Description** `fp::bottom()` never returns because it raises an error.

**Environment Interactions** Raises an error in any case.

**Examples** **Example 1**

Calling `fp::bottom` is equivalent to calling `error` with a fixed error string:

```
fp::bottom()
```

```
Error: The bottom is reached. [fp::bottom]
```

`fp::bottom` is used to indicate the bottom of a recursion inside a `traperror` call. In most cases, programs not using `fp::bottom` will be more readable.

**Return Values** This function never returns.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Curry an n-ary function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Syntax</b>      | <code>fp::curry(f, &lt;n&gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p><code>fp::curry(f)</code> returns the higher-order function <math>x \rightarrow (y \rightarrow f(x, y))</math>.</p> <p><code>fp::curry</code> returns the curried version of the n-ary function <code>f</code>. If no arity <code>n</code> is given, then the function is assumed to be binary.</p> <p>If <code>n</code> is smaller than 2 then <code>f</code> is returned. Otherwise, given a <i>n</i>-ary function <i>f</i>, <code>fp::curry</code> returns the function <math>X_1 \rightarrow ((X_2, \dots, X_n) \rightarrow f(X_1, \dots, X_n))</math></p> |

**Examples****Example 1**

Create curried versions of binary and 3-nary functions:

```
cf := fp::curry(f):
cf(x)(y)
```

*f(x, y)*

```
cg := fp::curry(g, 3):
cg(x)(y)(z)
```

*g(x, y, z)*

**Example 2**

A curried version of `_plus` may be used to create a function which increments its argument by 1:

```
inc := fp::curry(_plus)(1):
inc(x)
```

# fp::curry

---

$x + 1$

## Parameters

**f**

$n$ -ary function

**n**

Nonnegative integer

## Return Values

Unary higher-order function.

## Purpose

Create a functional expression from an expression

## Syntax

```
fp::expr_unapply(e, <x, >)
```

## Description

`fp::expr_unapply(e, x)` tries to interpret the expression `e` as a function in `x` and to return a functional expression computing that function.

`fp::expr_unapply` views the expression `e` as a function in the indeterminates `x, ...` and tries to return a functional expression computing that function. If `fp::expr_unapply` cannot find a functional expression FAIL is returned.

If no indeterminates are given, any indeterminates of `e` found by `indets` are used.

## Examples

### Example 1

Get the functional expression computing `sin(x)`:

```
fp::expr_unapply(sin(x), x)
```

`sin`

```
fp::expr_unapply(sin(x[1]), x[1])
```

`sin`

### Example 2

Get the functional expression computing `sin(x)^2+cos(x)^2`:

```
fp::expr_unapply(sin(x)^2 + cos(x)^2)
```

`sin2 + cos2`

# fp::expr\_unapply

---

## Parameters

**e**

Expression

**x**

Identifier or indexed identifier

## Return Values

Functional expression or FAIL.

## See Also

## MuPAD Functions

fp::unapply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create function by fixing all but one argument                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>      | <code>fp::fixargs(f, n, &lt;e, &gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p><code>fp::fixargs(f, 1, y)</code> returns the function <math>X \rightarrow f(X, y)</math>.</p> <p><code>fp::fixargs</code> returns an unary function, defined by fixing all but the <math>n</math>-th argument of the function <math>f</math> to the values given by <math>e \dots</math></p> <p>Thus, given a <math>m</math>-ary function <math>f</math> and <math>m - 1</math> values <math>e_1, \dots, e_{m-1}</math>, <code>fp::fixargs</code> returns the function</p> |

$$X \rightarrow f(e_1, \dots, e_{n-1}, X, e_n, \dots, e_{m-1})$$

## Examples

### Example 1

Fix the first and third argument of  $f$  to  $x1$  and  $x3$ :

```
fp::fixargs(f, 2, x1, x3)(y)
```

```
f(x1, y, x3)
```

### Example 2

Create a function which increments its argument by one:

```
inc := fp::fixargs(_plus, 1, 1):
inc(x)
```

```
x + 1
```

### Example 3

Create a function which tests the identifier  $x$  for a type:

```
type_of_x := fp::fixargs(testtype, 2, x):
```

# fp::fixargs

---

```
map([DOM_INT, DOM_IDENT], type_of_x)
```

```
[FALSE, TRUE]
```

## Parameters

**f**

Function

**n**

Positive integer defining free argument

**e**

Object used as fixed argument

## Return Values

Unary function.

**Purpose** Returns fixed point of a function

**Syntax** `fp::fixedpt(f)`

**Description** `fp::fixedpt(f)` returns the fixed point of the unary function `f`.  
`fp::fixedpt` is implemented as the *Y* combinator which is defined as follows:

$$Y: f \rightarrow g(f)(g(f))$$

where the function *g* is defined as

$$g: f \rightarrow h \rightarrow x \rightarrow f(h(h))(x)$$

## Examples **Example 1**

A function computing the Fibonacci numbers is created as a fixed point:

```
fb2 := (f,n) -> if n <= 2 then 1 else f(n-1) + f(n-2) end:
fib := fp::fixedpt(fp::curry(fb2)):
fib(i) $ i=1..9
```

1, 1, 2, 3, 5, 8, 13, 21, 34

**Parameters** **f**  
 Unary function

**Return Values** Unary function.

# fp::fold

---

**Purpose** Create function which iterates over sequences

**Syntax** `fp::fold(f, <e, >)`

**Description** `fp::fold` returns a function which repeatedly applies `f` to sequences of arguments, where the expressions `e...` are used as starting values.

Thus, given the function  $f$  and the starting values  $e_1, \dots, e_n$ , `fp::fold` returns the function which is defined by

$$(X_1, X_2, \dots, X_m) \rightarrow f(X_m, \dots f(X_2, f(X_1, e_1, \dots, e_n))\dots)$$

for any positive integer  $m$ . If the argument sequence is void (i.e.  $m = 0$ ) the function simply returns the sequence  $(e_1, \dots, e_n)$ .

## Examples

### Example 1

A call to `fp::fold` returns a function, which accepts an arbitrary number of arguments:

```
fp::fold(f, x)(y1, y2, y3)
```

```
f(y3, f(y2, f(y1, x)))
```

### Example 2

The function `pset` returns the power set of the set given by its arguments:

```
addelem := (x,y) -> y union map(y, _union, {x}):
pset := fp::fold(addelem, {{}}):
pset(a,b,c)
```

```
{}, {c}, {a}, {b}, {b, c}, {a, b}, {a, c}, {a, b, c}
```

**Parameters****f**

Function

**e**

Object used as starting value

**Return  
Values**

Function.

# fp::nest

---

**Purpose** Repeated composition of function

**Syntax** `fp::nest(f, n)`

**Description** `fp::nest(f, n)` returns the n-fold repeated composition of the function `f`.

Thus, given the function `f`, `fp::nest` returns the identity function `id` if `n` is 0 and otherwise the function

$$f(f(\dots f(x)\dots))$$

n-fold repeated.

Note that `fp::nest` is obsolete, one should use the `@@` operator or its functional form `_fnest` instead. It is only supported for compatibility with former versions of MuPAD.

## Examples

### Example 1

Apply the 3-fold repeated composition of `f` to `x`:

```
fp::nest(f, 3)(x)
```

$$f(f(f(x)))$$

### Example 2

Numerically finding a fixed point of the function `cos` by repeated application:

```
p :=fp::nest(cos, 100)(1.0):
p, cos(p)
```

$$0.7390851332, 0.7390851332$$

**Parameters****f**

Function

**n**

Nonnegative integer

**Return  
Values**

Function.

**See Also****MuPAD  
Functions**`_fconcat` | `_fnest` | `fp::nestvals`

# fp::nestvals

---

**Purpose** Repeated composition returning intermediate values

**Syntax** `fp::nestvals(f, n)`

**Description** `fp::nestvals(f, n)` returns a function which applies the function `f` repeatedly to its argument and returns the intermediate  $n + 1$  values as a list.

Thus `fp::nestvals` returns the function `[x, f(x), ..., f(f(...f(x)...))]`

The function returned is equivalent to `[_fnest(f, i) $i=0..n]`, but more efficient.

## Examples

### Example 1

Apply `f` 3 times nested to `x`:

```
fp::nestvals(f, 3)(x)
```

```
[x, f(x), f(f(x)), f(f(f(x)))]
```

### Example 2

Apply `cos` 4 times nested to `1.0` and return the result and intermediate values:

```
fp::nestvals(cos, 4)(1.0)
```

```
[1.0, 0.5403023059, 0.8575532158, 0.6542897905, 0.7934803587]
```

## Parameters

**f**

Function

**n**

Nonnegative integer

**Return Values**      Function.

**See Also**

| <b>MuPAD Functions</b> | <code>fp::expr_unapply</code>                                                                                                                                                                                                                                                                   |

# generate – Generate Input to Other Programs

---

generate::C  
generate::fortran  
generate::MATLAB  
generate::MathML  
generate::optimize  
generate::Simscape  
generate::TeX

# generate::C

---

**Purpose** Generate C formatted string

**Syntax** `generate::C(e, <NoWarning>)`

**Description** `generate::C(e)` generates C code for the MuPAD expression `e`.  
`generate::C` returns a C formatted string representing an expression, equation, list of equations or a matrix.

An equation represents an assignment in C code. The type of the assignment is `double`.

When generating C code for a matrix, the generator assigns only nonzero elements. See “Example 3” on page 9-3.

To print an output string to a file, use the `fprint` function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to C code. See “Example 5” on page 9-4.

The `NoWarning` option lets you suppress warnings. See “Example 6” on page 9-5.

## Examples

### Example 1

The code generator converts a list of equations to a sequence of assignments:

```
generate::C([x1 = y2^2*(y1 + sin(z)), x2 = tan(x1^4)]):
print(Unquoted, %)
```

```
x1 = (y2*y2)*(y1+sin(z));
x2 = tan(x1*x1*x1*x1);
```

## Example 2

MuPAD matrix and array indexing differs from C array indexing. By default, MuPAD array indices start with 1, and C array indices start with 0. To create the code compatible with the default indexing in C, the `generate::C` function decrements each index by one:

```
A:= matrix([[1,2],[3,4]]):
generate::C(A)."\n".
 generate::C(hold(Determinante = A[1,1]*A[2,2] - A[1,2]*A[2,1]))
print(Unquoted, %)
```

```
A[0][0] = 1.0;
A[0][1] = 2.0;
A[1][0] = 3.0;
A[1][1] = 4.0;
```

```
Determinante = A[0][0]*A[1][1]-A[0][1]*A[1][0];
```

## Example 3

Generated C code does not include assignments for zero elements of a matrix:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::C(A))
```

```
A[0][0] = 1.0;
A[1][2] = 1.0;
```

## Example 4

If the first index of an array is not 1, the `generate::C` function issues a warning:

# generate::C

---

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):
print(Unquoted, generate::C(A))
```

Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM

```
A[0][1] = 1.0;
A[0][2] = 2.0;
A[1][1] = 3.0;
A[1][2] = 4.0;
```

## Example 5

The `generate::C` function does not optimize your code:

```
print(Unquoted,
 generate::C([x = a + b, y = (a + b)^2])):

x = a+b;
y = pow(a+b,2.0);
```

You can use the `generate::optimize` function before converting your MuPAD expression to C code. For example, this function can reduce the number of operations by finding common subexpressions:

```
print(Unquoted,
 generate::C(
 generate::optimize([x = a + b, y = (a + b)^2])
)):

x = a+b;
y = x*x;
```

## Example 6

By default, the `generate::C` function can issue warnings:

```
print(Unquoted, generate::C(f(x)))
```

```
Warning: Function "f" is not verified to be a valid C function.
```

```
t0 = f(x);
```

If you started using `generate::C` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::C(f(x), NoWarning))
```

```
t0 = f(x);
```

### Parameters

**e**

An expression, equation, list of equations, or a matrix

### Options

**NoWarning**

Suppress warnings.

### Return Values

`generate::C` returns a string containing C code.

## **generate::C**

---

### **See Also**

### **MuPAD Functions**

`fprint` | `print` | `generate::optimize`

**Purpose** Generate FORTRAN formatted string

**Syntax** `generate::fortran(e, <NoWarning>)`

**Description** `generate::fortran(e)` generates FORTRAN code for the MuPAD expression `e`.

`generate::fortran` returns a FORTRAN formatted string representing an expression, equation, list of equations or a matrix.

An equation represents an assignment in FORTRAN code. The type of the assignment is `double`.

When generating FORTRAN code for a matrix, the generator assigns only nonzero elements. See “Example 2” on page 9-8.

To print an output string to a file, use the `fprint` function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to FORTRAN code. See “Example 4” on page 9-8.

The `NoWarning` option lets you suppress warnings. See “Example 5” on page 9-9.

## Examples **Example 1**

The code generator converts a list of equations to a sequence of assignments:

```
generate::fortran([x[1] = y[2 + i]^2*(y[1] + sin(z)), x[2] = tan
print(Unquoted,%)
```

```
x(1) = (sin(z)+y(1))*y(i+2)**2
x(2) = tan(x(1)**4)
```

## Example 2

Generated FORTRAN code does not include assignments for zero elements of a matrix:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::fortran(A))
```

```
A(1,1) = 1.0D0
A(2,3) = 1.0D0
```

## Example 3

If the first index of an array is not 1, the generate::fortran function issues a warning:

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):
print(Unquoted, generate::fortran(A))
```

```
Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM]
```

```
A(1,2) = 1.0D0
A(1,3) = 2.0D0
A(2,2) = 3.0D0
A(2,3) = 4.0D0
```

## Example 4

The generate::fortran function does not optimize your code:

```
print(Unquoted,
 generate::fortran([x = a + b, y = (a + b)^2])):
```

```
x = a+b
y = (a+b)**2
```

You can use the `generate::optimize` function before converting your MuPAD expression to FORTRAN code. For example, this function can reduce the number of operations by finding common subexpressions:

```
print(Unquoted,
 generate::fortran(
 generate::optimize([x = a + b, y = (a + b)^2])
)):
```

```
x = a+b
y = x**2
```

## Example 5

By default, the `generate::fortran` function can issue warnings:

```
print(Unquoted, generate::fortran(gamma(x)))
```

Warning: Function "gamma" requires a FORTRAN\_2008 compiler.

```
t0 = gamma(x)
```

If you started using `generate::fortran` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::fortran(gamma(x), NoWarning))
```

# generate::fortran

---

```
t0 = gamma(x)
```

## Parameters **e**

An expression, equation, list of equations, or a matrix

## Options **NoWarning**

Suppress warnings.

## Return Values

generate::fortran returns a string containing FORTRAN code.

| <b>Purpose</b>     | Generate MATLAB formatted string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>      | <code>generate::MATLAB(e, &lt;NoWarning&gt;)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p><code>generate::MATLAB(e)</code> generates MATLAB code for the MuPAD expression <code>e</code>.</p> <p><code>generate::MATLAB</code> returns a MATLAB formatted string representing an expression, equation, list of equations or a matrix.</p> <p><code>generate::MATLAB</code> assumes that the type of converted data is <code>double</code>. See “Example 1” on page 9-12.</p> <p>An equation represents an assignment in MATLAB code. See “Example 4” on page 9-13.</p> <p>When generating MATLAB code for a matrix, the generator produces a matrix of zeros, and then it substitutes nonzero elements. See “Example 2” on page 9-12.</p> <p>Use the <code>generate::optimize</code> function to optimize the MuPAD code before converting it to the MATLAB syntax. See “Example 5” on page 9-13.</p> <p>To display generated MATLAB code on screen, use the <code>print</code> function. Use the printing option <code>Unquoted</code> to remove quotation marks and to expand special characters like line breaks and tabs. If a generated code line is longer than the <code>TEXTWIDTH</code> setting, the <code>print</code> function breaks that line into several shorter lines. The inserted line continuation character (<code>\</code>) is not valid in MATLAB. To avoid inserting line continuation characters, increase the <code>TEXTWIDTH</code> setting or use the <code>fprint</code> function to write generated code to a file.</p> <p><code>generate::MATLAB</code> does not create a MATLAB function. You can print an output string to a file using the <code>fprint</code> function with the <code>Unquoted</code> option. See “Example 6” on page 9-14.</p> <p>Working from the MATLAB workspace you can create a MATLAB function containing your expression. To call the MuPAD expression from the MATLAB workspace, use <code>evalin</code> or <code>feval</code> functions. See “Create MATLAB Functions from MuPAD Expressions”.</p> |

If you work with the Simulink® products, you can copy the generated code and paste it into a Simulink block. Also, you can call the MuPAD expression from the MATLAB workspace using `evalin` or `feval` functions. Working from the MATLAB workspace you can automatically create a Simulink block containing your expression. See “Create MATLAB Function Blocks from MuPAD Expressions”.

The `NoWarning` option lets you suppress warnings. See “Example 7” on page 9-14.

## Examples

### Example 1

By default, MATLAB stores all numeric values as double-precision floating-point. In accordance with the default MATLAB data type, `generate::MATLAB` converts the elements of expressions, equations, and matrices to the `double` format:

```
print(Unquoted, generate::MATLAB(x^2 + y/3 + 1/6))
```

```
t0 = y*(1.0/3.0)+x^2+1.0/6.0;
```

### Example 2

The generator produces a matrix of zeros, and then it replaces nonzero elements:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::MATLAB(A))
```

```
A = zeros(2,3);
A(1,1) = 1.0;
A(2,3) = 1.0;
```

## Example 3

If the first index of an array is not 1, the `generate::MATLAB` function issues a warning:

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):
print(Unquoted, generate::MATLAB(A))
```

```
Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [
```

```
A = zeros(2,2);
A(1,2) = 1.0;
A(1,3) = 2.0;
A(2,2) = 3.0;
A(2,3) = 4.0;
```

## Example 4

When generating MATLAB code from equations, you get assignments instead of equations. For example, generate MATLAB code for the following list of equations:

```
f := generate::MATLAB([x = exp(t*s), y = sin(t)*cos(s)]):
print(Unquoted, f)
```

```
x = exp(s*t);
y = cos(s)*sin(t);
```

## Example 5

The `generate::MATLAB` function does not optimize your code:

```
print(Unquoted,
```

```
generate::MATLAB([x = a + b, y = (a + b)^2]):
```

```
x = a+b;
y = (a+b)^2;
```

You can use the `generate::optimize` function before converting your MuPAD code to MATLAB syntax. For example, this function can reduce the number of operations by finding common subexpressions:

```
f := generate::optimize([x = a + b, y = (a + b)^2]):
print(Unquoted,
 generate::MATLAB(f)):
```

```
x = a+b;
y = x^2;
```

## Example 6

To create a file with a MATLAB formatted string representing a symbolic expression, use the `fprint` function:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
fprint(Unquoted, Text, "matrixA.m", generate::MATLAB(A))
```

If the file `matrixA.m` already exists, `fprint` replaces the existing MATLAB code with the converted symbolic expression. You can open and edit the resulting file.

## Example 7

By default, the `generate::MATLAB` function can issue warnings:

```
print(Unquoted, generate::MATLAB(g(x)))
```

Warning: Function "g" is not verified to be a valid MATLAB function.

```
t0 = g(x);
```

If you started using `generate::MATLAB` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::MATLAB(g(x), NoWarning))
```

```
t0 = g(x);
```

## Parameters

**e**

An expression, equation, list of equations, or a matrix

## Options

**NoWarning**

Suppress warnings.

## Return Values

`generate::MATLAB` returns a string containing MATLAB code.

# generate::MathML

---

**Purpose** Generate MathML from expressions

**Syntax** `generate::MathML(e, options)`

**Description** `generate::MathML(e)` returns a MathML object representing `e`. This object may be printed to a file using `fprint`.

## **Examples** **Example 1**

`generate::MathML` generates an object containing the MathML code:

```
generate::MathML(hold(int)(exp(x^2)/x, x))
```

```
<math xmlns='http://www.w3.org/1998/Math/MathML'>
 <semantics>
 <mrow xref='ao7X0Bn'>
 <mo>⋅</mo>
 <mfrac xref='K5ZqTZC'>
 <msup xref='f9Ypr6T'>
 <mn>⋅</mn>
 <msup xref='amIZwNJ'>
 <mi xref='a5zFKQ0'>x</mi>
 <mn xref='BCapBxj'>2</mn>
 </msup>
 </msup>
 <mi xref='jS17Msi'>x</mi>
 </mfrac>
 <mo>⋅</mo>
 <mi xref='ZrsPUxf'>x</mi>
 </mrow>
 <annotation-xml encoding='MathML-Content'>
 <apply id='ao7X0Bn'>
 <int/>
 <bvar>
 <ci id='ZrsPUxf'>x</ci>
 </bvar>
 </apply>
 </annotation-xml>
 </semantics>
</math>
```

```

 <apply id='K5ZqTZC'>
 <divide/>
 <apply id='f9Ypr6T'>
 <exp/>
 <apply id='amIZwNJ'>
 <power/>
 <ci id='a5zFKQ0'>x</ci>
 <cn id='BCapBxj' type='integer'>2</cn>
 </apply>
 </apply>
 <ci id='jS17Msi'>x</ci>
 </apply>
 </annotation-xml>
 <annotation encoding='MuPAD'>
 int(exp(x^2)/x, x)
 </annotation>
</semantics>
</math>

```

The output of annotations and MathML presentation can be suppressed with the options `Presentation` and `Annotation`:

```

generate::MathML(hold(int)(exp(x^2)/x, x),
 Presentation = FALSE, Annotation = FALSE)

```

```

<math xmlns='http://www.w3.org/1998/Math/MathML'>
 <apply>
 <int/>
 <bvar>
 <ci>x</ci>
 </bvar>
 </apply>
 <divide/>
 <apply>

```

# generate::MathML

---

```
<exp/>
<apply>
 <power/>
 <ci>x</ci>
 <cn type='integer'>2</cn>
</apply>
</apply>
<ci>x</ci>
</apply>
</apply>
</math>
```

MathML output can be written into a file using `fprint`:

```
fprint(Text, "filename.mathml",
 generate::MathML(hold(int)(exp(x^2)/x, x))):
```

## Parameters

**e**

An arithmetical expression

## Options

### Annotation

Option, specified as `Annotation = FALSE`

Disables the output of annotations.

### Content

Option, specified as `Content = FALSE`

Disables the MathML Content output.

### Presentation

Option, specified as `Presentation = FALSE`

Disables the MathML Presentation output.

**Return Values**

generate::MathML returns an object containing MathML code.

**Overloaded By**

e

**See Also****MuPAD Functions**

fprint | print

# generate::optimize

---

**Purpose**           Generate optimized code

**Syntax**           generate::optimize(r)

**Description**     generate::optimize(r) returns a sequence of equations representing an “optimized computation sequence” for the input expression r. Each equation in the sequence corresponds to an assignment of a subexpression of the input expression to a “temporary variable.” Common subexpressions are computed only once, thus reducing the total operation count.

The number of operations, namely additions (or subtractions), multiplications (or divisions) and in particular functions calls of the output is usually lower than the number of such operations of the input. This facility is useful for code generation.

## Examples

### Example 1

In this first example, we show the effects of optimization for a simple expression:

```
generate::optimize(cos(x^2) + x^2*sin(x^2) + x^4)
```

```
[t2 = x2, t1 = cos(t2) + t2 sin(t2) + t22]
```

The “blind” computation of the input expression requires 7 multiplications, 2 additions and 2 function calls. The optimized version introduces a “temporary variable” t2 storing the subexpression x<sup>2</sup> that is used to compute the final result t1. This reduces the total cost to 3 multiplications, 2 additions and 2 function calls, albeit using 1 extra assignment to the temporary variable t2.

### Example 2

Here we repeat the exercise of the first example but with an array of expressions:

```
generate::optimize(array(1..2, 1..2, [[x^3, x^2],[x^2, x^4]]))
```

$$\left[ t2 = x^2, t1 = \begin{pmatrix} t2 x & t2 \\ t2 & t2^2 \end{pmatrix} \right]$$

The original input requires 6 multiplications. The optimized version needs only 3 multiplications and 1 extra assignment.

### Example 3

We optimize a list of equations representing a computation sequence for 3 variables  $t$ ,  $C[1]$ ,  $C[2]$ :

```
generate::optimize([t = u, C[1] = t*(u - w)^2, C[2] = 2*(u - w)^2])
```

$$[t = u, t1 = u - w, t2 = t1^2, C_1 = t t2, C_2 = 2 t1 t2]$$

The original computation requires 5 multiplications and 2 subtractions. The optimized version needs 4 multiplications and 1 subtraction.

Note that since these examples involve small expressions, the computational savings are slight. In the case of very large expressions, optimization can yield a considerable dividend.

## Parameters

**r**

An expression, array or list of equations

## Return Values

List of equations.

## Algorithms

A number of FORTRAN compilers provide optimizers. However, they use algorithms of complexity  $O(n^2)$  and  $O(n^3)$  where  $n$  is the size of the input expressions. For large amounts of code, these algorithms may “break.” MuPAD provides a reasonably good scalar

(as in non-vectorized and non-parallelized) optimizer which is limited to common subexpression optimization and using binary powering for integer powers. It uses hashing of expressions so that given a sub-expression, it can determine in constant time if this subexpression has already occurred. This results in an overall efficiency which is of lower complexity namely,  $O(n)$  i.e. linear in the size of the input expressions to be optimized, Hence overall efficiency is not compromised by very large expressions. This does mean that not all possible optimizations are made but nonetheless a number of reductions including the exploitation of some symmetries are possible.

It should be understood that “optimization” is meant in the sense of compiler optimization. The end-result rarely corresponds to the absolute irreducible minimum number of operations – or as in the case of FORTRAN code generation, the absolute minimum of floating-point operations (FLOPS). Achieving this limit can be extremely difficult if not impossible especially for large computational sequences. Nonetheless, in a number of real-life instances, the MuPAD optimizer can yield a very useful result. Additionally, MuPAD provides symbolic manipulation tools such as `factor` which can yield additional reduction in operation costs.

In many cases of optimization, it is most often a matter of how best to pose the problem so as to fully exploit every possible symmetry or useful natural property of the given problem.

**Purpose**

Generate Simscape equation

**Syntax**

`generate::Simscape(e, <NoWarning>)`

**Description**

`generate::Simscape(e)` generates Simscape™ code for the MuPAD expression `e`.

Simscape software extends the Simulink product line with tools for modeling and simulating multidomain physical systems, such as those with mechanical, hydraulic, pneumatic, thermal, and electrical components. Unlike other Simulink blocks, which represent mathematical operations or operate on signals, Simscape blocks represent physical components or relationships directly. With Simscape blocks, you build a model of a system just as you would assemble a physical system. For more information about Simscape software, see “Simscape”.

You can extend the Simscape modeling environment by creating custom components. When you define a component, use the equation section of the component file to establish the mathematical relationships among a component’s variables, parameters, inputs, outputs, time, and the time derivatives of each of these entities. MuPAD and Simscape software let you perform symbolic computations and use the results of these computations in the equation section. The `generate::Simscape` function translates the results of symbolic computations to Simscape language equations.

`generate::Simscape` returns a Simscape formatted string representing an expression, equation, list of expressions or equations, or a matrix.

`generate::Simscape` converts the identifier `t` to the variable `time` in the resulting Simscape code. However, the name `t` of a function call does not change during conversion. See “Example 1” on page 9-25 and “Example 2” on page 9-25.

`generate::Simscape` converts any derivative with respect to the variable `t` to the Simscape notation `x.der`, where `x` is the time-dependent variable. See “Example 3” on page 9-26.

`generate::Simscape` assumes that the type of converted data is `double`. See “Example 4” on page 9-26.

When generating Simscape code for a matrix, the generator produces a dense matrix. See “Example 5” on page 9-27.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to the Simscape syntax. See “Example 6” on page 9-27.

`generate::Simscape` converts piecewise expressions to Simscape code by using the `if` statements. See “Example 7” on page 9-28.

The equation section of a Simscape component file supports a limited number of functions. For details and the list of supported functions, see Simscape equations. If a symbolic equation contains the functions that are not available in the equation section of a Simscape component file, `generate::Simscape` cannot correctly convert these equations to Simscape equations. Such expressions do not trigger an error. The following types of expressions are prone to invalid conversion:

- Expressions with infinities
- Expressions that contain programming structures, such as loops, conditional statements (except for the `if` statement), and `map` function calls
- Expressions that contain intervals, sets, and lists

To display generated Simscape code on screen, use the `print` function. To remove quotation marks and to expand special characters like line breaks and tabs, use the printing option `Unquoted`. If a generated code line is longer than the `TEXTWIDTH` setting, the `print` function breaks that line into several shorter lines. The inserted line continuation character (`\`) is not valid in Simscape. To avoid inserting line continuation characters, increase the `TEXTWIDTH` setting or use the `fprint` function to write generated code to a file.

To write generated Simscape code to a file, use the `fprint` function with the `Unquoted` option. See “Example 8” on page 9-28.

The NoWarning option lets you suppress warnings. See “Example 2” on page 9-25.

## Examples

### Example 1

The `generate::Simscape` function replaces all instances of the MuPAD identifier `t` with the variable `time`. For example, convert the following equation to the Simscape equation:

```
e := A*sin(w*t) + B*cos(w*t) = 0;
print(Unquoted, generate::Simscape(e))
```

```
B*cos(time*w)+A*sin(time*w) == 0.0;
```

### Example 2

The `generate::Simscape` function does not change the function name `t` in function calls:

```
print(Unquoted, generate::Simscape([t(), t(0), t(x)]))
```

```
Warning: Function "t" is not verified to be a valid Simscape fun
```

```
Warning: Function "t" is not verified to be a valid Simscape fun
```

```
Warning: Function "t" is not verified to be a valid Simscape fun
```

```
t();
t(0.0);
```

```
t(x);
```

This example produces a few identical warnings. If you started using `generate::Simscape` recently, warnings can help you identify potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::Simscape([t(), t(0), t(x)], NoWarning))
```

```
t();
t(0.0);
t(x);
```

### Example 3

When generating Simscape code, the `generate::Simscape` function converts the derivatives with respect to the variable `t` to the Simscape notation `x.der`. Here `x` is the time-dependent variable. For example, generate the Simscape code for the equation `e` that has two time-dependent variables:

```
e := x'(t) + diff(y(t), t) + 2*x + 5 = 0:
print(Unquoted, generate::Simscape(e))
```

```
x*2.0+x.der+y.der+5.0 == 0.0;
```

### Example 4

By default, Simscape stores all numeric values as double-precision floating-point values. In accordance with this default data type, `generate::Simscape` converts the elements of expressions, equations, and matrices to the double format:

```
print(Unquoted, generate::Simscape(x^2 + y/3 + 1/6))
```

```
y*(1.0/3.0)+x^2+1.0/6.0;
```

### Example 5

`generate::Simscape` can generate Simscape code for a MuPAD matrix. In contrast to `generate::MATLAB` (which produces sparse matrices), the Simscape code generator produces dense matrices:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::Simscape(A))
```

```
A = [
1.0 0.0 0.0
0.0 0.0 1.0
];
```

### Example 6

The `generate::Simscape` function does not optimize your code:

```
print(Unquoted,
 generate::Simscape([x = a + b, y = (a + b)^2])):

x == a+b;
y == (a+b)^2;
```

You can use the `generate::optimize` function before converting your MuPAD code to Simscape syntax. For example, this function can reduce the number of operations by finding common subexpressions:

```
print(Unquoted,
 generate::Simscape(
 generate::optimize([x = a + b, y = (a + b)^2])
```

# generate::Simscape

---

```
)):
```

```
x == a+b;
y == x^2;
```

## Example 7

The `generate::Simscape` function also accepts piecewise expressions. The function uses `if` statements when generating Simscape code for piecewise expressions. For example, the Fourier transform of the following expression is a piecewise function:

```
FT := fourier(exp(-abs(x)*abs(t))*sin(t)/t, t, s)
```

$$\left\{ \arctan\left(\frac{s+1}{|x|}\right) - \arctan\left(\frac{s-1}{|x|}\right) \text{ if } x \neq 0 \right.$$

`generate::Simscape` converts this result to a valid Simscape expression:

```
print(Unquoted, generate::Simscape(FT))
```

```
if (x ~= 0.0),
 -atan((s-1.0)/abs(x))+atan((s+1.0)/abs(x));
else
 NaN;
end;
```

## Example 8

To create a text file with a Simscape formatted string representing a symbolic expression, use the `fprint` command:

```
e := x'(t) + 2*x + 5 = 0:
```

```
fprint(Unquoted, Text, "eqn.txt", generate::Simscape(e))
```

If the file `eqn.txt` already exists, `fprint` replaces the existing Simscape code with the converted symbolic expression. You can open and edit the resulting text file.

## Parameters

**e**

An expression, equation, list of equations, or a matrix

## Options

**NoWarning**

Suppress warnings.

## Return Values

`generate::Simscape` returns a string containing Simscape code. In case of invalid conversion, the returned value is an arbitrary string.

## MuPAD Functions

`fprint` | `print` | `generate::optimize` | `generate::MATLAB`

# generate::TeX

---

**Purpose** Generate formatted string from expressions

**Syntax** `generate::TeX(e)`

**Description** `generate::TeX(e)` returns a TeX formatted string representing `e`. This string may be printed to a file using `fprint`. Use the printing option `Unquoted` to remove quotes and to expand special characters like newlines and tabs.

The output string may be used in the math-mode of TeX. Note that `generate::TeX` doesn't break large formulas into smaller ones.

## Examples

### Example 1

`generate::TeX` generates a string containing the TeX code:

```
generate::TeX(hold(int)(exp(x^2)/x, x))
```

```
"\int \frac{\mathrm{e}^{x^2}}{x} \, \mathrm{d} x"
```

Use `print` with option `Unquoted` to get a more readable output:

```
print(Unquoted, generate::TeX(hold(int)(exp(x^2)/x, x)))
```

```
\int \frac{\mathrm{e}^{x^2}}{x} \, \mathrm{d} x
```

### Example 2

This example shows how to write a "TeX"-method for a domain. The domain elements represent open intervals. The "TeX"-method makes recursive use of `generate::TeX` in order to TeX-format its operands and concatenates the resulting strings to a new string containing the TeX output of the interval.

```
Interval := newDomain("Interval"):
```

```
Interval::TeX :=
 e -> "\\left].generate::TeX(extop(e, 1)).
 ", ".generate::TeX(extop(e, 2))."\\right[" :
print(Unquoted,
 generate::TeX(new(Interval, 1, x^(a+2))))):
```

```
\\left]1, x^{a + 2}\\right[
```

**Parameters****e**

An arithmetical expression

**Return Values**

generate::TeX returns a string containing TeX code.

**Overloaded By****e****Algorithms**

The TeX packages amsmath and amssymb are needed.

A domain overloading generate::TeX has to provide a function as its "TeX"-slot which translates its elements into a TeX formatted string. This function may use generate::TeX recursively. See “Example 2” on page 9-30.

**Purpose** Adds one or several edges to a graph

**Syntax** `Graph::addEdges(G, Edge)`  
`Graph::addEdges(G, Edge, <EdgeWeights = ew>, <EdgeCosts = ec>, <EdgeDescriptions = ed>)`

**Description** `Graph::addEdges` adds one or several edges to an already existing Graph. An edge is represented by a list containing two vertices of the graph. A warning is raised if one of the specified edges does already exist in the graph.

`Graph::addEdges(G, Edge)` adds the edge(s) `Edge` to the graph `G`. The two vertices of each edge must be vertices in the given graph. Otherwise an error is raised. If an edge is specified that already exists, a warning will be printed that this edge is not used.

With `Graph::addEdges(G, Edge, EdgeWeights=ew, EdgeCosts=ec, EdgeDescriptions=ed)` the weight, cost and description of each edge can be set to every edge additionally. If these specifications are missing, the default value 0(=None) is assumed. If a specification is used it has to hold exactly the same number of values as there are edges. Otherwise an error will be raised.

---

**Note** The value `None` can be used in the specification lists for every edge that is not to be specified explicitly.

---

## Examples

### Example 1

First, an undirected graph with two vertices and no edges is created. Then two edges are added:

```
G := Graph([a, b, c, d], []):
Graph::printEdgeInformation(G):
G := Graph::addEdges(G, [[a, b], [c, d]]):
Graph::printEdgeInformation(G)
```

No edges.

## Graph::addEdges

---

Edges existing in the graph:

-----  
[a, b], [c, d], [b, a], [d, c]

As you can see, [b, a] and [d, c] were inserted automatically.

```
G2 := Graph::addEdges(G, [[a,d]]):Graph::getEdges(G2)
```

```
[[a, d], [d, a], [a, b], [c, d], [b, a], [d, c]]
```

Now, what happens if an edge is inserted that already exists in the graph?

```
G := Graph::addEdges(G, [[d, c]])
```

```
Warning: The following edges were not used for operation: [[d, c]].
```

```
Graph(...)
```

Suppose, we try to insert an edge with a vertex not existing in the graph:

```
G := Graph::addEdges(G, [[a, 5]])
```

```
Error: One or more edges contain vertices that are not in list '[5]
```

Now let's see what happens when a directed graph is created:

```
G := Graph([a, b, c, d], [], Directed):
G := Graph::addEdges(G, [[a, b], [b, c], [c, d]],
 EdgeWeights = [2/8, -5, PI],
 EdgeCosts = [30, -40, None]):
Graph::printGraphInformation(G)
```

```
Vertices: [a, b, c, d]
Edges: [[a, b], [b, c], [c, d]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [a, b] = 1/4, [b, c] = -5, [c, d] = PI (other exist
Edge costs: [a, b] = 30, [b, c] = -40 (other existing edges have
Adjacency list (out): a = [b], b = [c], c = [d], d = []
Adjacency list (in): a = [], b = [a], c = [b], d = [c]
Graph is directed.
```

Have a close look at the Edge costs line. The edge [c,d] is not mentioned explicitly due to the value None:

```
G2 := Graph::addEdges(G, [[a, b], [a, d]], EdgeWeights=[10, 20],
 EdgeCosts = [80, 90],
 EdgeDescriptions = ["First way", "Second way"]
Graph::printGraphInformation(G2)
```

Warning: The following edges were not used for operation: [[a, b

```
Vertices: [a, b, c, d]
Edges: [[a, d], [a, b], [b, c], [c, d]]
Vertex weights: no vertex weights.
Edge descriptions: [a, d] = "Second way"
Edge weights: [a, b] = 1/4, [b, c] = -5, [c, d] = PI, [a, d] = 2
Edge costs: [a, b] = 30, [b, c] = -40, [a, d] = 90 (other existi
```

# Graph::addEdges

---

```
Adjacency list (out): a = [b, d], b = [c], c = [d], d = []
Adjacency list (in): a = [], b = [a], c = [b], d = [a, c]
Graph is directed.
```

If an edge has specifications, but exist already in the graph, the specifications will not change. (see Information for edge [a, b] above)

## Parameters

### **G**

Graph

### **Edge**

List of one or more edges

### **ew, ec**

Lists of numbers

### **ed**

List of texts

### **b**

Boolean value

## Options

### **EdgeWeights**

The weight(s) of the new edge(s). Default is 0.

### **EdgeCosts**

The cost(s) of the new edge(s). Default is 0.

### **EdgeDescriptions**

The description(s) for the new edge(s). Default is no text.

## Return Values

Graph with the correct edges inserted.

**Purpose**

Adds one or several vertices to a graph

**Syntax**

```
Graph::addVertices(G, Vertex, <VertexWeights = vw>)
```

**Description**

`Graph::addVertices` adds one or several vertices to an already existing graph. A vertex is represented by an arbitrary expression. A warning is raised if one of the specified vertices does already exist in the graph.

`Graph::addVertices(G, Vertex)` adds the vertices in `Vertex` to the graph `G`. If a vertex is specified that already exists, a warning will be printed that this vertex (and its vertex weight) is not used.

With `Graph::addVertices(G, Vertex, VertexWeights=vw)` the weight can be set to every vertex additionally. If these specifications are missing, the default value 0 (=None) is assumed. If a specification is used it has to hold exactly the same number of values as there are vertices. Otherwise an error will be raised.

---

**Note** The value `None` can be used in the specification lists for every edge that is not to be specified explicitly.

---

**Examples****Example 1**

First, an undirected graph with two vertices and no edges is created. Then two vertices are added:

```
G := Graph([a, b, c, d], []):
Graph::printVertexInformation(G):
G := Graph::addVertices(G, [e, f]):
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
```

```

Vertex a has weight None
Vertex b has weight None
```

## Graph::addVertices

---

```
Vertex c has weight None
Vertex d has weight None
```

```
Vertices existing in the graph:
```

```

Vertex a has weight None
Vertex b has weight None
Vertex c has weight None
Vertex d has weight None
Vertex e has weight None
Vertex f has weight None
```

No weights were specified, so every vertex has weight None. In the algorithms default-values will be used accordingly.

Now, what happens if a vertex is inserted that already exists in the graph?

```
G2 := Graph::addVertices(G, [a, g], VertexWeights=[10, 100]):
Graph::printVertexInformation(G2)
```

```
Warning: The following vertices already exist: [a]. [Graph::selectV
```

```
Vertices existing in the graph:
```

```

Vertex a has weight None
Vertex b has weight None
Vertex c has weight None
Vertex d has weight None
Vertex e has weight None
Vertex f has weight None
```

Vertex g has weight 100

If a vertex weight is specified for a vertex already existing, it will not be changed (see Vertex a above)

## Parameters

### **G**

Graph

### **Vertex**

List of one or more vertices

### **vw**

Lists of numbers

## Options

### **VertexWeights**

The weight(s) of the new vertex/vertices. Default is 0.

## Return Values

Graph with the correct vertices inserted.

# Graph::admissibleFlow

---

**Purpose** Checks a flow for admissibility in a Graph

**Syntax** Graph::admissibleFlow(G, f)

**Description** Graph::admissibleFlow(G, f) checks if the flow f is admissible in the Graph G according to its vertices and their capacities.

Graph::admissibleFlow checks whether a given flow is an admissible flow in the specified graph. A flow in a graph is a table t, where t[[i, j]] gives the number of units flowing from vertex i to vertex j. Graph::admissibleFlow returns TRUE if the flow is admissible. Otherwise FALSE is returned.

Graph::admissibleFlow does not check whether the flow is admissible, if a flow from vertex i to vertex j is allowed to pass through other vertices. See “Example 2” on page 10-10.

## Examples

### Example 1

In a cyclic graph with default capacities (1), the flow with one unit flowing from each vertex to its successor is certainly admissible:

```
G1 := Graph::createCircleGraph([v1, v2, v3, v4]):
Graph::admissibleFlow(G1, table([v1, v2] = 1,
 [v2, v3] = 1,
 [v3, v4] = 1,
 [v4, v1] = 1))
```

TRUE

### Example 2

The flow must be specified in whole. Graph::admissibleFlow does not include “hops”, like skipping vertices in the path:

```
Graph::admissibleFlow(Graph::createCircleGraph([v1, v2, v3]),
 table([v1, v3] = 1))
```

FALSE

## Parameters

**G**

Graph

**f**

The flow, specified in a table

## Return Values

Either TRUE or FALSE

# Graph::bipartite

---

**Purpose** Finds out if a graph is bipartite.

**Syntax** Graph::bipartite(G, <Bool | Lists>)

**Description** Graph::bipartite(G) finds out whether G is bipartite or not.  
Graph::bipartite(G, Sets): If G is bipartite, then a list containing two lists will be returned. Each of the lists contains the vertices belonging to the set. If G is not bipartite, then FAIL will be returned instead of any list.  
Graph::bipartite(G, Bool) offers the same result as Graph::bipartite(G). If G is bipartite, then TRUE will be returned, otherwise FALSE.

## Examples **Example 1**

A small graph containing 3 vertices with 2 edges connecting them is created:

```
G := Graph([a, b, c], [[a, b], [b, c]]):
Graph::bipartite(G, Lists);
Graph::bipartite(G, Bool)
```

```
[[b], [a, c]]
```

```
TRUE
```

Two lists with vertices are shown. Another word for bipartite is two-colorable. This means that the graph above can be colored with only two colors so that no two vertices have the same color if connected with an edge. The bottom output could also be accomplished without using the parameter Bool:

```
Graph::bipartite(G)
```

TRUE

The following example shows what happens when a graph is not bipartite (an edge is added to connect the vertices a and c):

```
G2 := Graph::addEdges(G, [[a, c]]):
Graph::bipartite(G2, Lists);
Graph::bipartite(G2, Bool)
```

FAIL

FALSE

## Parameters

**G**

Graph

## Options

**Lists**

If Lists is stated the return value will be a list of two lists containing the (sorted) vertices belonging to each set, or FAIL.

**Bool**

If Bool is stated the return value will be either TRUE or FALSE. This is the default.

## Return Values

Depending on the options either a boolean value or list-sets will be returned.

# Graph::breadthFirstSearch

---

**Purpose** Makes a breadth first Search in a graph.

**Syntax** Graph::breadthFirstSearch(G, <StartVertex = v>)

**Description** Graph::breadthFirstSearch traverses through a graph via breadth first search. The output shows the first time of identification and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

Graph::breadthFirstSearch(G, StartVertex = v) traverses through a graph via breadth first search starting from vertex v. The output shows the first time of identification and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

## Examples **Example 1**

A typical tree is created and drawn for a better understanding of the algorithm:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
 [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
 [d, h], [e, i], [e, j], [f, k], [g, l]],
 Directed);
plot(
 Graph::plotGridGraph(G, VerticesPerLine = [12, 12, 12, 12],
 VertexOrder = [
 None, None, None, None, None, None, a, None, None, None, None,
 None, None, b, None, None, None, None, None, None, c, None,
 None, d, None, None, e, None, None, f, None, None, g,
 h, None, None, i, None, j, None, None, k, None, None,
]
)
)
```

Now we call `breadthFirstSearch` to find out the starting times and predecessors

`Graph::breadthFirstSearch(G)`

<i>a</i>	1	<i>a</i>	0	<i>a</i>	<i>a</i>
<i>b</i>	2	<i>b</i>	1	<i>b</i>	<i>a</i>
<i>c</i>	3	<i>c</i>	1	<i>c</i>	<i>a</i>
<i>d</i>	4	<i>d</i>	2	<i>d</i>	<i>b</i>
<i>e</i>	5	<i>e</i>	2	<i>e</i>	<i>b</i>
<i>f</i>	6	<i>f</i>	2	<i>f</i>	<i>c</i>
<i>g</i>	7	<i>g</i>	2	<i>g</i>	<i>c</i>
<i>h</i>	8	<i>h</i>	3	<i>h</i>	<i>d</i>
<i>i</i>	9	<i>i</i>	3	<i>i</i>	<i>e</i>
<i>j</i>	10	<i>j</i>	3	<i>j</i>	<i>e</i>
<i>k</i>	11	<i>k</i>	3	<i>k</i>	<i>f</i>
<i>l</i>	12	<i>l</i>	3	<i>l</i>	<i>g</i>

# Graph::breadthFirstSearch

Vertex a is discovered first, then vertex b and so on. The right table shows the predecessor of every vertex. The backtracking from a single vertex is therefore really simple. a as the first vertex discovered in its component can not be backtracked any further. The distance of each vertex in its component can be read in the middle table. Root-vertices always have the value 0 (they are the roots).

## Example 2

What happens now, if there exist a vertex that has no connection to any other vertex. The upper example is taken and a single vertex is added without changing anything else. Then a breadth first search is invoked on the graph:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
 [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
 [d, h], [e, i], [e, j], [f, k], [g, l]],
 Directed):
```

```
G2 := Graph::addVertices(G, [m]):
Graph::breadthFirstSearch(G2, StartVertex = [a])
```

a	1	a	0	a	a
b	2	b	1	b	a
c	3	c	1	c	a
d	4	d	2	d	b
e	5	e	2	e	b
f	6	f	2	f	c
g	7	g	2	g	c
h	8	h	3	h	d
i	9	i	3	i	e
j	10	j	3	j	e
k	11	k	3	k	f
l	12	l	3	l	g
m	13	m	0	m	∞

The newly inserted vertex  $m$  has no predecessor. The predecessor therefore holds the value *infinity*.

### Example 3

If we start somewhere in the graph without knowing the root of the DAG, the results are of course different:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
 [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
 [d, h], [e, i], [e, j], [f, k], [g, l]],
 Directed):
```

```
Graph::breadthFirstSearch(G, StartVertex = [c])
```

a	6	a	0	a	a
b	7	b	1	b	a
c	1	c	0	c	c
d	8	d	2	d	b
e	9	e	2	e	b
f	2	f	1	f	c
g	3	g	1	g	c
h	10	h	3	h	d
i	11	i	3	i	e
j	12	j	3	j	e
k	4	k	2	k	f
l	5	l	2	l	g

The predecessor of  $c$  is  $c$ , but if we look at the graph it should be  $a$ . This is nevertheless not quite correct. Breadth first search takes the given vertex and uses this as the root of the graph (no in-vertices!). This explains also why the next call shows a *infinity* as predecessor to  $l$ .

### Parameters

**G**

Graph

**v**

# Graph::breadthFirstSearch

---

List containing one vertex.

## **Options**

### **StartVertex**

Defines a vertex from which to start the breadth first traversal.

## **Return Values**

List containing three tables. The first table holds the timestamp of the discovery. The second the distance to the root-vertex. The last table holds the predecessor vertices.

<b>Purpose</b>	Checks if all vertices in edges really exist.
<b>Syntax</b>	Graph::checkForVertices(Edge, Vertex)
<b>Description</b>	Graph::checkForVertices(Edge, Vertex) checks if all vertices out of Edge are in Vertex.

## Examples

### Example 1

What vertices are within the stated edges, but not in the vertex list?

```
Graph::checkForVertices([[a, b], [1, 2]], [a, 2])
```

```
[b, 1]
```

Neither b nor 1 were in the second list. a was in the first edge and 2 in the second.

### Example 2

A more complex example. The second list contains a vertex that does not exist in the graph at all. For the checking it does not matter though. Every vertex NOT in the second list is to be returned. In the end it does not matter if the vertex-list contains vertices that are not existent, because only existing vertices are returned.

```
G := Graph::createCompleteGraph(10):
Graph::checkForVertices(Graph::getEdges(G), [1, 2, 3, 11])
```

```
[4, 5, 6, 7, 8, 9, 10]
```

## Parameters

### Edge

List of one or more Edges

### Vertex

# Graph::checkForVertices

---

List of one or more vertices

## **Return Values**

List with the vertices out of the Edges that were not stated in Vertex.

**Purpose** Chromatic number of a graph

**Syntax** `Graph::chromaticNumber(G)`

**Description** `Graph::chromaticNumber(G)` returns the chromatic number of the graph `G`. The chromatic number of a graph is defined to be the number of colors necessary to color it such that no two adjacent vertices have the same color.

**Examples** **Example 1**

We compute the chromatic number of the complete graph with 5 vertices; it must be 5 since any two vertices are adjacent:

```
Graph::chromaticNumber(Graph::createCompleteGraph(5))
```

```
5
```

**Parameters** **G**  
An undirected graph

**Return Values** Positive integer

**Algorithms** Internally, the chromatic polynomial is used to compute the chromatic number.

**See Also**

**MuPAD Functions** `Graph::chromaticPolynomial`

# Graph::chromaticPolynomial

---

**Purpose**                Calculates a chromatic polynomial

**Syntax**                `Graph::chromaticPolynomial(G, x)`

**Description**        `Graph::chromaticPolynomial(G, x)` returns the chromatic polynomial of the graph `G`. Evaluating the result at  $x = n$ , for any integer  $n$ , gives the number of possible ways to color the graph `G` using  $n$  colors such that no two adjacent vertices have the same color.

`G` must be an undirected graph: if an edge goes from  $a$  to  $b$ , another edge must go from  $b$  to  $a$ , for any two vertices  $a, b$ .

## Examples                **Example 1**

We compute the chromatic polynomial of the complete graph with 5 vertices:

```
f := Graph::chromaticPolynomial(Graph::createCompleteGraph(5), x)
```

```
poly(x5 - 10 x4 + 35 x3 - 50 x2 + 24 x, [x])
```

There are 240 ways to color a complete graph with 5 vertices, since this is the number of bijective mappings between the set of colors and the set of vertices:

```
f(5)
```

```
120
```

```
delete f:
```

## **Example 2**

Now let us delete one edge from a complete graph:

```
G := Graph::createCompleteGraph(5):
```

```
G:= Graph::removeEdge(G, [[2, 3]]):
G:= Graph::removeEdge(G, [[3, 2]])
```

```
Graph(...)
```

Now there are some additional possible colourings: vertices 2 and 3 may now have the same color, in five different ways; in each case, there must be one of the four remaining colors that does not occur at all. In each of the 20 cases, we are left with 3 vertices that form a complete graph and 3 colors, such that there are 6 colourings. Altogether this gives us 120 additional colourings:

```
Graph::chromaticPolynomial(G, x)(5)
```

```
240
```

## Parameters

**G**

An undirected graph

**x**

An identifier

## Return Values

polynomial

## Algorithms

Computing the chromatic polynomial of a graph with  $n$  vertices reduces to computing two chromatic polynomials of graphs with  $n - 1$  vertices. The running time is hence roughly  $2^n$ .

See Birkhoff and Lewis, *Chromatic Polynomials*, Trans. AMS, Vol. 60, p.355–451, 1946.

# Graph::contract

---

**Purpose** Contracts vertices

**Syntax** Graph::contract(G, VertexTable)

**Description** Graph::contract(G, VertexTable) contracts the vertices for each entry in the table.

---

**Note** The graph to be contracted must not have edge weights, costs or descriptions. If it has, an error will be raised.

---

---

**Note** If VertexTable contains vertices not in G, these will be skipped.

---

## Examples

### Example 1

A simple example to see how a contraction is done.

```
ConG := Graph([a, b, c, d, e, f],
 [[a, c], [d, a], [f, c], [d, f], [e, b]],
 Directed):
Graph::printGraphInformation(ConG)
```

```
Vertices: [a, b, c, d, e, f]
Edges: [[a, c], [d, a], [d, f], [e, b], [f, c]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): a = [c], b = [], c = [], d = [a, f], e = [b],
Adjacency list (in): a = [d], b = [e], c = [a, f], d = [], e = [],
Graph is directed.
```

```
plot(
 Graph::plotGridGraph(ConG,
 VerticesPerLine = 3,
 VertexOrder = [None, b, None,
 a, None, c,
 None, e, None,
 d, None, f],
 EdgeColor = RGB::Black))
```

```
t := table(A = [a, b, c],
 B = [d, f])
```

A	[a, b, c]
B	[d, f]

```
newG := Graph::contract(ConG, t):
```

# Graph::contract

---

```
Graph::printGraphInformation(newG)
```

```
Vertices: [A, B, e]
Edges: [[A, A], [B, A], [B, B], [e, A]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): e = [A], A = [A], B = [A, B]
Adjacency list (in): e = [], A = [A, B, e], B = [B]
Graph is directed.
```

Since vertices  $a, b, c$  were contracted to vertex  $A$ , edge  $[a,c]$  was removed and edge  $[A, A]$  was created. Vertices  $d, f$  took care of the deletion of edges  $[d, a], [d, f], [f, c]$ . Instead edges  $[B, A]$  and  $[B, B]$  were created. In the end edge  $[e, b]$  was changed to  $[e, A]$  since vertex  $b$  does not exist any longer because it was replaced by  $A$ .

```
plot(Graph::plotGridGraph(newG,
 VerticesPerLine = 2,
 VertexOrder = [None, B,
 A, None,
 None, e]))
```

## Example 2

Graph::contract ignores vertices not in the graph:

```
Con2 := Graph([], []):
t := table(A = [a, b, c], B = [d, f]):
Graph::printGraphInformation(Graph::contract(Con2, t))
```

```
Vertices: no vertices.
Edges: []
Adjacency list (out): no edges.
Adjacency list (in): no edges.
Graph is undirected.
```

## Parameters

**G**

Graph

# Graph::contract

---

## **VertexTable**

A table with the name of the new vertex on the left side and a list of vertices to contract on the right side.

## **Return Values**

Graph consisting of the new vertices and edges.

**Purpose** Converts a Graph into a single source single sink Graph

**Syntax** `Graph::convertSSQ(G, q, s)`

**Description** `Graph::convertSSQ(G, q, s)` converts the graph `G` into a directed single source single sink graph. The specified vertices `q` and `s` are added to the graph. It is an error if they are already predefined. Otherwise they are connected to the other vertices of the graph in the following way:

A new edge `[q, i]` is added for every vertex `i` with a positive weight.  
A new edge `[i, s]` is added for every vertex `i` with a negative weight.  
The capacities of these edges are in each case the weight of node `i`.  
The edge weights are zero.

## Examples **Example 1**

A testexample to show the transformation.

```
V := [1, 2, 3, 4]:
Vw := [4, 0, 0, -4]:
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4]]:
Ec := [2, 2, 1, 3, 1]:
Ew := [4, 2, 2, 3, 5]:
G1 := Graph(V, Ed, VertexWeights = Vw,
 EdgeWeights = Ew, EdgeCosts = Ec):
G2 := Graph::convertSSQ(G1, [q], [s]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, q, s]
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [2, 4], [3, 1], [3, 2],
Vertex weights: 1 = 0, 2 = 0, 3 = 0, 4 = 0, q = 4, s = -4 (other
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = 4, [1, 3] = 2, [2, 3] = 2, [2, 4] = 3, [3,
3, [4, 3] = 5, [q, 1] = 4, [4, s] = 4 (other existing edges have
Edge costs: [1, 2] = 2, [1, 3] = 2, [2, 3] = 1, [2, 4] = 3, [3,
```

# Graph::convertSSQ

---

$[4, 3] = 1$ ,  $[q, 1] = 0$ ,  $[4, s] = 0$  (other existing edges have cost 1)  
Adjacency list (out): 1 = [2, 3], 2 = [1, 3, 4], 3 = [1, 2, 4], 4 = [1, 2, 3, q]  
Adjacency list (in): 1 = [2, 3, q], 2 = [1, 3, 4], 3 = [1, 2, 4], 4 = [1, 2, 3, q]  
Graph is directed.

The former undirected graph was transformed into a directed one!

## Parameters

**q, s**

Vertices not predefined in the Graph

**G**

A Graph

## Return Values

Directed augmented Graph

## Algorithms

Both, Bellman and Dijkstra expect a Graph without negative circles.  
Only Dijkstra may return erroneous results when negative edges (either weights or costs) are specified.

The Bellman algorithm originated from: Ahuja, Magnanti, Orlin:  
Dom::Graph Flows, Prentice-Hall, 1993 Section 5.4

## Purpose

Generates a circle Graph

## Syntax

```
Graph::createCircleGraph(L, <Directed | Undirected>)
Graph::createCircleGraph(N, <Directed | Undirected>)
```

## Description

Graph::createCircleGraph(L) generates a circle Graph

Graph::createCircleGraph([v1,...,vn]) generates a new graph which is the cycle [v1,v2], [v2,v3], ..., [vn,v1]. The values for the edge weights, edge costs and vertex weights can be set manually via Graph::setEdgeWeights, Graph::setEdgeCosts and Graph::setVertexWeights

Graph::createCircleGraph(3) generates a new graph which is the cycle [1,2], [2,3], [3,1]. The values for the edge weights, edge capacities and vertex weights can be set manually via Graph::setEdgeWeights, Graph::setEdgeCosts and Graph::setVertexWeights

Graph::createCircleGraph(3, Undirected) generates a new graph which includes the vertices [1,2], [2,3], [3,1][2,1], [3,2], [1,3].

## Examples

### Example 1

A (directed) circle graph with four vertices:

```
G1 := Graph::createCircleGraph(4):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4]
Edges: [[1, 2], [2, 3], [3, 4], [4, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [1]
Adjacency list (in): 1 = [4], 2 = [1], 3 = [2], 4 = [3]
```

# Graph::createCircleGraph

---

Graph is directed.

## Example 2

The same graph but this time with parameter Undirected:

```
G2 := Graph::createCircleGraph(4, Undirected):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4]
Edges: [[1, 2], [1, 4], [2, 1], [2, 3], [3, 2], [3, 4], [4, 1], [4, 3]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 4], 2 = [1, 3], 3 = [2, 4], 4 = [1, 3]
Adjacency list (in): 1 = [2, 4], 2 = [1, 3], 3 = [2, 4], 4 = [1, 3]
Graph is undirected.
```

## Example 3

The circle graph with predefined vertices:

```
G3 := Graph::createCircleGraph([a, b, c, d, 4, 5, 6]):
Graph::printGraphInformation(G3)
```

```
Vertices: [4, 5, 6, a, b, c, d]
Edges: [[4, 5], [5, 6], [6, a], [a, b], [b, c], [c, d], [d, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): a = [b], b = [c], c = [d], d = [4], 4 = [5],
Adjacency list (in): a = [6], b = [a], c = [b], d = [c], 4 = [d], 5 = [4],
Graph is directed.
```

## Parameters

**L**

List of vertices

**N**

A positive Integer

## Options

**Directed**

The Graph is created as a directed graph. Default.

**Undirected**

The Graph is created as an undirected graph.

## Return Values

Graph

# Graph::createCompleteGraph

---

**Purpose** Generates a complete graph

**Syntax** Graph::createCompleteGraph(n)

**Description** Graph::createCompleteGraph(n) generates the complete Graph with n vertices. A complete graph has a connection between each pair of vertices (except to itself).

The vertices of the generated graph are labeled with the numbers 1 to n.

## Examples **Example 1**

The complete Graph with three vertices has  $3 \cdot 2 = 6$  edges:

```
G := Graph::createCompleteGraph(3):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Graph is undirected.
```

**Parameters** **n**

A positive integer

**Return Values** Graph

# Graph::createGraphFromMatrix

## Purpose

Transfers a squared matrix into a directed graph

## Syntax

`Graph::createGraphFromMatrix(M)`

## Description

`Graph::createGraphFromMatrix(M)` generates a directed Graph where each  $m_{i,j}$  in the matrix defines an edge from  $i$  to  $j$ . The value of the cell defines the weight of the resulting edge.

The vertices of the generated graph are labeled with the numbers 1 to  $n$ , where  $n$  defines the column/row-dimension of the matrix. Since the matrix has to be squared,  $n$  stays the same.

## Examples

### Example 1

A matrix is defined and the resulting squared matrix is transferred into a Graph.

```
a := matrix([[3, 2, 4], [2, 3, 6], [4, 8, 3]]);
G := Graph::createGraphFromMatrix(a);
Graph::printGraphInformation(G)
```

$$\begin{pmatrix} 3 & 2 & 4 \\ 2 & 3 & 6 \\ 4 & 8 & 3 \end{pmatrix}$$

Vertices: [1, 2, 3]

Edges: [[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1],

Vertex weights: no vertex weights.

Edge descriptions: no edge descriptions.

Edge weights: [1, 1] = 3, [1, 2] = 2, [1, 3] = 4, [2, 1] = 2, [2, 2] = 3 (other existing edges have no weight)

Edge costs: no edge costs.

Adjacency list (out): 1 = [1, 2, 3], 2 = [1, 2, 3], 3 = [1, 2, 3]

Adjacency list (in): 1 = [1, 2, 3], 2 = [1, 2, 3], 3 = [1, 2, 3]

Graph is directed.

# Graph::createGraphFromMatrix

---

## Parameters

**M**

A matrix

## Return Values

Graph

# Graph::createRandomEdgeWeights

---

**Purpose** Sets random weights to edges

**Syntax** `Graph::createRandomEdgeWeights(G, r, <Dom::Integer  
| Dom::Real>)`

**Description** `Graph::createRandomEdgeWeights(G, x..y)` creates random integer edge weights within the range `x..y`.

`Graph::createRandomEdgeWeights(G, x..y, Dom::Integer)` does exactly the same.

`Graph::createRandomEdgeWeights(G, x..y, Dom::Real)` creates random real edge weights within the range `x..y`.

---

**Note** Already existing edge weights will be changed, too!

---

## Examples

### Example 1

Creating edge weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
```

```
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
```

```
Vertex weights: no vertex weights.
```

```
Edge descriptions: no edge descriptions.
```

```
Edge weights: no edge weights.
```

```
Edge costs: no edge costs.
```

```
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
```

```
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
```

```
Graph is directed.
```

# Graph::createRandomEdgeWeights

---

Now the weights are set within the range -100..50 (your output may differ due random assignment):

```
G2 := Graph::createRandomEdgeWeights(G1, -100..50):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = 47, [2, 3] = -12, [3, 4] = 28, [4, 5] = 1, [5, 1] = 1
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

If the weights should be of type Real it can be set optionally:

```
G2 := Graph::createRandomEdgeWeights(G1, -100..50, Dom::Real):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = -67.72964183, [2, 3] = -10.16896282, [3, 4] = 662729
(other existing edges have no weight)
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

# Graph::createRandomEdgeWeights

---

## Parameters

**G**

A graph

**r**

A range

## Return Values

Graph

# Graph::createRandomEdgeCosts

---

<b>Purpose</b>	Sets random costs to edges
<b>Syntax</b>	<code>Graph::createRandomEdgeCosts(G, r, &lt;Dom::Integer   Dom::Real&gt;)</code>
<b>Description</b>	<p><code>Graph::createRandomEdgeCosts(G, x..y)</code> creates random edge weights of type <code>Integer</code> within the range <code>x..y</code>.</p> <p><code>Graph::createRandomEdgeCosts(G, x..y, Dom::Integer)</code> does exactly the same.</p> <p><code>Graph::createRandomEdgeCosts(G, x..y, Dom::Real)</code> creates random edge weights of type <code>Real</code> within the range <code>x..y</code>.</p>

---

**Note** Already existing edge costs will be changed, too!

---

## Examples

### Example 1

Creating edge weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

# Graph::createRandomEdgeCosts

---

Now the costs are set within the range -100..50 (your output may differ due random assignment):

```
G2 := Graph::createRandomEdgeCosts(G1, -100..50):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: [1, 2] = 47, [2, 3] = -12, [3, 4] = 28, [4, 5] = 1,
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

If the costs should be of type Real it can be set optionally:

```
G2 := Graph::createRandomEdgeCosts(G1, -100..50, Dom::Real):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: [1, 2] = -67.72964183, [2, 3] = -10.16896282, [3, 4] =
2729 (other existing edges have costs zero)
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

# Graph::createRandomEdgeCosts

---

## Parameters

**G**

A graph

**r**

A range

## Return Values

Graph

## Purpose

Generates a random graph.

## Syntax

```
Graph::createRandomGraph(VertexNr, EdgeNr,
<Directed | Undirected>)
```

## Description

Graph::createRandomGraph generates a random graph.

Graph::createRandomGraph(VertexNr, EdgeNr) generates a random graph with VertexNr vertices and EdgeNr edges.

---

**Note** If the number EdgeNr is too great (i.e.

$EdgeNr \geq \frac{VertexNr (VertexNr - 1)}{2}$ ), a complete graph will be created.

---

Graph::createRandomGraph(VertexNr, EdgeNr, Undirected) generates a random graph with VertexNr vertices and  $2EdgeNr$  edges is created. This is due to the fact that no odd number of undirected edges could be created otherwise.

## Examples

### Example 1

The following graph was created randomly, meaning that your results will most probably differ:

```
G := Graph::createRandomGraph(5,6):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 4], [2, 1], [2, 4], [2, 5], [3, 1], [3, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [4], 2 = [1, 4, 5], 3 = [1, 4], 4 = []
Adjacency list (in): 1 = [2, 3], 2 = [], 3 = [], 4 = [1, 2, 3],
```

# Graph::createRandomGraph

---

Graph is directed.

## Example 2

The same number of vertices, but this time the edges are undirected (and therefore the number of Edges is  $(2EdgeNr)$ ). As you can clearly see, the edges differ from the edges created above:

```
G := Graph::createRandomGraph(5, 6, Undirected):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 4], [1, 5], [2, 3], [2, 4], [2, 5], [3, 2], [4, 1], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [4, 5], 2 = [3, 4, 5], 3 = [2], 4 = [1, 2, 5], 5 = [1, 2, 3, 4]
Adjacency list (in): 1 = [4, 5], 2 = [3, 4, 5], 3 = [2], 4 = [1, 2, 5], 5 = [1, 2, 3, 4]
Graph is undirected.
```

## Example 3

If the number of edges to be created extends the possible limit

( $\frac{\text{vertices}(\text{vertices}-1)}{2}$ ), a complete graph will be returned:

```
G := Graph::createRandomGraph(3, 6, Undirected):
Graph::printGraphInformation(G)
```

Warning: Cannot produce the required number of edges. Creating a complete graph.

```
Vertices: [1, 2, 3]
```

```
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Graph is undirected.
```

## Parameters

### VertexNr

Positive integer

### EdgeNr

Positive integer

## Options

### Directed

If Directed is stated, a directed Graph is created Default

### Undirected

If Undirected is stated, an undirected Graph is created.

## Return Values

Graph

# Graph::createRandomVertexWeights

---

<b>Purpose</b>	Sets random weights to vertices
<b>Syntax</b>	<code>Graph::createRandomVertexWeights(G, r, &lt;Int   Real&gt;)</code>
<b>Description</b>	<code>Graph::createRandomVertexWeights(G, x..y)</code> creates random vertex weights of type Integer within the range x..y. <code>Graph::createRandomVertexWeights(G, x..y, Real)</code> creates random vertex weights of type Real within the range x..y.

---

**Note** Already existing vertex weights will be changed, too!

---

## Examples

### Example 1

Creating vertex weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

Now the weights are set within the range -100..50 (your output may differ due random assignment):

# Graph::createRandomVertexWeights

```
G2 := Graph::createRandomVertexWeights(G1, -100..50):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: 1 = 47, 2 = -12, 3 = 28, 4 = 1, 5 = -36 (other e
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

If the weights should be of type Real it can be set optionally:

```
G2 := Graph::createRandomVertexWeights(G1, -100..50, Real):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: 1 = -67.72964183, 2 = -10.16896282, 3 = -72.8468
vertices have no weight)
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

## Parameters

**G**

A graph

**r**

# Graph::createRandomVertexWeights

---

A range

## Options

### Int

If stated, the weights are only of type integer. (Default)

### Real

If stated, the weights are only of type real.

## Return Values

Graph

## Purpose

Makes a depth first Search in a graph.

## Syntax

```
Graph::depthFirstSearch(G, <StartVertex = v>)
```

## Description

`Graph::depthFirstSearch` traverses through a graph via depth first search. The output shows the first time of identification, the finishing time and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

`Graph::depthFirstSearch(G, StartVertex=v)` traverses through a graph via depth first search starting from vertex *v*. The output shows the first time of identification, the finishing time and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

## Examples

### Example 1

A typical tree is created and drawn for a better understanding of the algorithm.

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
 [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
 [d, h], [e, i], [e, j], [f, k], [g, l]],
 Directed);
plot(
 Graph::plotGridGraph(G, VerticesPerLine = [12, 12, 12, 12],
 VertexOrder = [
 None, None, None, None, None, None, a, None, None, None, No
 None, None, b, None, None, None, None, None, None, c, No
 None, d, None, None, e, None, None, f, None, None, g,
 h, None, None, i, None, j, None, None, k, None, No
]
)
)
```

# Graph::depthFirstSearch

---

Now we call `Graph::depthFirstSearch` to find out the starting times, the finishing times and the predecessors of each vertex:

`Graph::depthFirstSearch(G)`

<i>a</i>	1	<i>a</i>	24	<i>a</i>	<i>a</i>
<i>b</i>	2	<i>b</i>	13	<i>b</i>	<i>a</i>
<i>c</i>	14	<i>c</i>	23	<i>c</i>	<i>a</i>
<i>d</i>	3	<i>d</i>	6	<i>d</i>	<i>b</i>
<i>e</i>	7	<i>e</i>	12	<i>e</i>	<i>b</i>
<i>f</i>	15,	<i>f</i>	18,	<i>f</i>	<i>c</i>
<i>g</i>	19	<i>g</i>	22	<i>g</i>	<i>c</i>
<i>h</i>	4	<i>h</i>	5	<i>h</i>	<i>d</i>
<i>i</i>	8	<i>i</i>	9	<i>i</i>	<i>e</i>
<i>j</i>	10	<i>j</i>	11	<i>j</i>	<i>e</i>
<i>k</i>	16	<i>k</i>	17	<i>k</i>	<i>f</i>
<i>l</i>	20	<i>l</i>	21	<i>l</i>	<i>g</i>

Vertex a is discovered first, then vertex b and so on. The table in the middle shows the finishing times. h for example has the finishing time of 5, meaning that vertices a, b, c, d and h itself were visited before it was recognized that h is a leaf (finishing time = starting time + 1). The right table shows the predecessor of every vertex. The backtracking from a single vertex is therefore really simple. a as the first vertex discovered in its component can not be backtracked any further.

## Example 2

What happens now, if there exist a vertex that has no connection to any other vertex. The upper example is taken and a single vertex is added without changing anything else. Then a depth first search is invoked on the graph:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
 [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
 [d, h], [e, i], [e, j], [f, k], [g, l]],
 Directed);

G2 := Graph::addVertices(G, [m]);
Graph::depthFirstSearch(G2, StartVertex = [a])
```

a	1	a	24	a	a
b	2	b	13	b	a
c	14	c	23	c	a
d	3	d	6	d	b
e	7	e	12	e	b
f	15	f	18	f	c
g	19	g	22	g	c
h	4	h	5	h	d
i	8	i	9	i	e
j	10	j	11	j	e
k	16	k	17	k	f
l	20	l	21	l	g
m	25	m	26	m	∅

# Graph::depthFirstSearch

The newly inserted vertex `m` has no predecessor. The predecessor holds therefore the value *infinity*.

## Example 3

If we start somewhere in the graph without knowing the root of the DAG, the results are of course different:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
 [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
 [d, h], [e, i], [e, j], [f, k], [g, l]],
 Directed):
```

```
Graph::depthFirstSearch(G, StartVertex = [c])
```

a	11	a	24	a	a
b	12	b	23	b	a
c	1	c	10	c	c
d	13	d	16	d	b
e	17	e	22	e	b
f	2	f	5	f	c
g	6	g	9	g	c
h	14	h	15	h	d
i	18	i	19	i	e
j	20	j	21	j	e
k	3	k	4	k	f
l	7	l	8	l	g

The predecessor of `c` is `c`, but if we look at the graph it should be `a`. This is nevertheless not quite correct. Breadth first search takes the given vertex and uses this as the root of the graph (no in-vertices!). This explains also why the next call shows a *infinity* as predecessor to `l`:

```
Graph::depthFirstSearch(G, StartVertex = [l])
```

<i>a</i>	3	<i>a</i>	24	<i>a</i>	<i>a</i>
<i>b</i>	4	<i>b</i>	15	<i>b</i>	<i>a</i>
<i>c</i>	16	<i>c</i>	23	<i>c</i>	<i>a</i>
<i>d</i>	5	<i>d</i>	8	<i>d</i>	<i>b</i>
<i>e</i>	9	<i>e</i>	14	<i>e</i>	<i>b</i>
<i>f</i>	17,	<i>f</i>	20,	<i>f</i>	<i>c</i>
<i>g</i>	21	<i>g</i>	22	<i>g</i>	<i>c</i>
<i>h</i>	6	<i>h</i>	7	<i>h</i>	<i>d</i>
<i>i</i>	10	<i>i</i>	11	<i>i</i>	<i>e</i>
<i>j</i>	12	<i>j</i>	13	<i>j</i>	<i>e</i>
<i>k</i>	18	<i>k</i>	19	<i>k</i>	<i>f</i>
<i>l</i>	1	<i>l</i>	2	<i>l</i>	$\infty$

## Parameters

**G**

Graph

**v**

List containing one vertex.

## Options

**StartVertex**

Defines a vertex from which to start the depth first traversal.

## Return Values

List containing three tables. The first table holds the first identification timestamp of each vertex, the second the finishing timestamp and the third the predecessor vertex.

# Graph::getAdjacentEdgesEntering

---

**Purpose** Returns the incident edges.

**Syntax** Graph::getAdjacentEdgesEntering(G, Vertex)

**Description** Graph::getAdjacentEdgesEntering(G, Vertex) returns a list with vertices  $v_1..v_n$ , where  $[v_1, \text{Vertex}] \dots [v_n, \text{Vertex}]$  are incident (incoming) Edges to Vertex.

## Examples **Example 1**

First, a complete graph is defined:

```
G1 := Graph::createCompleteGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2,
[4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2,
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2,
Graph is undirected.
```

Now we get the vertices that form all incident edges  $[2, 1] \dots [5, 1]$ :

```
Graph::getAdjacentEdgesEntering(G1, [1])

[2, 3, 4, 5]
```

# Graph::getAdjacentEdgesEntering

---

Now we get the vertices that form all incident edges [1, 5] .. [4, 5]:

```
Graph::getAdjacentEdgesEntering(G1, [5])
```

```
[1, 2, 3, 4]
```

## Parameters

### **G**

A graph

### **Vertex**

One vertex of G.

## Return Values

List

# Graph::getAdjacentEdgesLeaving

---

**Purpose** Returns the adjacent edges.

**Syntax** `Graph::getAdjacentEdgesLeaving(G, Vertex)`

**Description** `Graph::getAdjacentEdgesLeaving(G, Vertex)` returns a list with vertices `v1..vn`, where `[Vertex, v1] .. [Vertex, vn]` are adjacent (outgoing) Edges to Vertex.

## Examples **Example 1**

First, a complete graph is defined:

```
G1 := Graph::createCompleteGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2,
[4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2,
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2,
Graph is undirected.
```

Now we get the vertices that form all adjacent edges `[1, 2] .. [1, 5]`:

```
Graph::getAdjacentEdgesLeaving(G1, [1])

[2, 3, 4, 5]
```

# Graph::getAdjacentEdgesLeaving

---

Now we get the vertices that form all adjacent edges [2, 1] .. [2, 5]:

```
Graph::getAdjacentEdgesLeaving(G1, [2])
```

```
[1, 3, 4, 5]
```

## Parameters

### **G**

A graph

### **Vertex**

One vertex of G.

## Return Values

List

# Graph::getBestAdjacentEdge

---

**Purpose** Returns the "best" incident edges.

**Syntax** `Graph::getBestAdjacentEdge(G, Vertex, Vertices, <Min | Max>, <Weights | Costs>)`

**Description** `Graph::getBestAdjacentEdge(G, Vertex)` returns the best incident edge according to specified attributes.

`Graph::getBestAdjacentEdge(G, Vertex, Vertices)` returns a vertex *v* out of *Vertices*. The best edge is (Vertex, *v*) according to the specifications.

## Examples **Example 1**

Let us create a graph and find out the edge with the least weight:

```
G1 := Graph([1, a, 3, 4], [[1, a], [1, 3], [1, 4]],
 EdgeWeights = [10, 20, 30],
 EdgeCosts = [30, 20, 10]):
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1)),
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Min, We
```

*a, a*

The result shows that edge [1, a] has the least weight. It also shows that `Min` and `Weights` are the defaults if omitted. Next, we want to know the edge with maximum weight:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Max)
```

*4*

The vertex with maximum weight is edge [1,4]. Now we have a look at the costs. The minimum cost edge can be found with:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Cost
```

```
4
```

So the vertex with maximum weight is also the edge with minimum costs. Finally let us search for the edge with maximum costs:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Cost
```

```
a
```

## Parameters

### **G**

A graph

### **Vertex**

One vertex of G.

### **Vertices**

Vertices in G.

## Options

### **Min**

If stated, the edge with the minimum attribute will be found. (Default)

### **Max**

If stated, the edge with the maximum attribute will be found.

### **Weights**

If stated, edge weights will be used for comparison. (Default)

### **Costs**

If stated, edge costs will be used for comparison.

# Graph::getBestAdjacentEdge

---

**Return  
Values**

Vertex

## Purpose

Returns a table with the edge costs.

## Syntax

Graph::getEdgeCosts(G)

## Description

Graph::getEdgeCosts(G) returns a table with the edge costs of the graph G. Thus Graph::getEdgeCosts(G) returns the costs of all edges in G.

---

**Note** Costs will most probably only be defined, if transportation problems occur.

---

---

**Note** If FAIL is returned, no costs were defined (this way both, network and graph algorithms handle this situation correct.)

---

## Examples

### Example 1

First lets define a graph without edge costs:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeCosts(G1)
```

FAIL

FAIL was returned, because no edge costs were defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeCosts(G1)
```

[[1, 2], [2, 3], [3, 1]]

# Graph::getEdgeCosts

---

```
[1, 2] | 5
[3, 1] | 1/2
```

The first output shows all the edges and the second one the assigned edge costs.

## Parameters

**G**

A graph

## Return Values

Table

**Purpose** Returns a table with the edge descriptions.

**Syntax** `Graph::getEdgeDescriptions(G)`

**Description** `Graph::getEdgeDescriptions(G)` returns a table with the edge descriptions of the graph G. Thus `Graph::getEdgeDescriptions(G)` returns the weight of all edges in G.

---

**Note** Descriptions will most probably only be defined, if transportation problems occur.

---

---

**Note** If FAIL is returned, no descriptions were defined (this way both, network and graph algorithms handle this situation correct.)

---

## Examples

### Example 1

First lets define a graph without edge descriptions:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeDescriptions(G1)
```

FAIL

FAIL was returned, because no edge descriptions were defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],
 ["Shortcut", "Highway 66"]):
Graph::getEdgeDescriptions(G1)
```

# Graph::getEdgeDescriptions

---

```
[[1, 2], [2, 3], [3, 1]]
```

```

[1, 2] | "Shortcut"
[3, 1] | "Highway 66"
```

The first output shows all the edges and the second one the assigned edge descriptions.

## Parameters **G**

A graph

## Return Values

Table

**Purpose** Returns a list with all edges

**Syntax** `Graph::getEdges(G)`

**Description** `Graph::getEdges(G)` returns a list containing all edges of the graph G. Each edge is represented by a list containing the two connected vertices.

**Examples** **Example 1**

`Graph::getEdges` only returns the edges, without their capacities:

```
G1 := Graph::createCircleGraph([v1, v2, v3, v4]):
Graph::getEdges(G1)
```

```
[[v1, v2], [v2, v3], [v3, v4], [v4, v1]]
```

```
G2 := Graph::createCompleteGraph(3):
Graph::getEdges(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

**Parameters** **G**

A Graph

**Return Values** List of all edges, a list of lists

# Graph::getEdgesEntering

---

**Purpose** Returns the incoming edges

**Syntax** Graph::getEdgesEntering(G)

**Description** Graph::getEdgesEntering(G) returns a table with the adjacency lists for incident (incoming) edges. Thus Graph::getEdgesEntering(G) returns a table containing all those vertices w for which there is an edge [w, v] in G.

## Examples **Example 1**

A small directed graph is created to show the incoming (incident) edges:

```
V := [1, 2, 3, 4, 5]:
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:
G1 := Graph(V, Ed, Directed):
Graph::getEdgesEntering(G1)
```

```
1 | []
2 | [1]
3 | [1, 2]
4 | [2, 3]
5 | [3, 4]
```

In an undirected graph the output could look like this:

```
G1 := Graph::createCompleteGraph(5):
Graph::getEdgesEntering(G1)
```

1	[2, 3, 4, 5]
2	[1, 3, 4, 5]
3	[1, 2, 4, 5]
4	[1, 2, 3, 5]
5	[1, 2, 3, 4]

## Parameters

**G**

A graph

## Return Values

Table

# Graph::getEdgesLeaving

---

**Purpose** Returns the outgoing edges

**Syntax** Graph::getEdgesLeaving(G)

**Description** Graph::getEdgesLeaving(G) returns a table with the adjacency lists for adjacent (outgoing) edges. Thus Graph::getEdgesLeaving(G) returns a table containing all those vertices w for which there is an edge [v,w] in G.

## Examples **Example 1**

A small directed graph is created to show the outgoing (adjacent) edges:

```
V := [1, 2, 3, 4, 5]:
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:
G1 := Graph(V, Ed, Directed):
Graph::getEdgesLeaving(G1)
```

```
1 [2, 3]
2 [3, 4]
3 [4, 5]
4 [5]
5 []
```

In an undirected graph the output could look like this:

```
G1 := Graph::createCompleteGraph(5):
Graph::getEdgesLeaving(G1)
```

1	[2, 3, 4, 5]
2	[1, 3, 4, 5]
3	[1, 2, 4, 5]
4	[1, 2, 3, 5]
5	[1, 2, 3, 4]

## Parameters

**G**

A graph

## Return Values

Table

# Graph::getEdgeNumber

---

**Purpose** Returns the number of edges.

**Syntax** `Graph::getEdgeNumber(G)`

**Description** `Graph::getEdgeNumber(G)` returns a number representing the number of edges in G.

## Examples **Example 1**

Let us create a graph and find out the number of edges:

```
G1 := Graph([1, a, 3, 4], [[1, a], [1, 3], [1, 4]]):
Graph::getEdgeNumber(G1)
```

6

We know that a complete graph consists of  $|Vertices|^2 - |Vertices|$  edges:

```
G2 := Graph::createCompleteGraph(4):
Graph::getEdgeNumber(G2)
```

12

**Parameters** **G**

A graph

**Return Values** Number

**Purpose** Returns a table with the edge weights.

**Syntax** Graph::getEdgeWeights(G)

**Description** Graph::getEdgeWeights(G) returns a table with the edge weights of the graph G. Thus Graph::getEdgeWeights(G) returns the weight of all edges in G.

---

**Note** Weights will most probably only be defined, if transportation problems occur.

---

---

**Note** If FAIL is returned, no weights were defined (this way both, network and graph algorithms handle this situation correct.)

---

## Examples

### Example 1

First lets define a graph without edge weights:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeWeights(G1)
```

FAIL

FAIL was returned, because no edge weights were defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeWeights(G1)
```

[[1, 2], [2, 3], [3, 1]]

# Graph::getEdgeWeights

---

```
[1, 2] | 5
[3, 1] | 1/2
```

The first output shows all the edges and the second one the assigned edge weights.

## Parameters

**G**

A graph

## Return Values

Table

## Purpose

Returns a subgraph.

## Syntax

```
Graph::getSubGraph(G, Vertex)
```

## Description

`Graph::getSubGraph(G, Vertex)` returns a subgraph according to the specified vertices.

`Graph::getSubGraph(G)` returns a graph that only holds the specified vertices and the belonging edges.

## Examples

### Example 1

First, a complete graph is defined with some additional settings:

```
G1 := Graph::createCompleteGraph(5):
G1 := Graph::setEdgeWeights(G1, [[1,2]], [20]):
G1 := Graph::setEdgeCosts(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeDescriptions(G1, [[1, 2]], ["Shortcut"]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4],
 [4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut", [2, 1] = "Shortcut"
Edge weights: [1, 2] = 20, [2, 1] = 20 (other existing edges have
Edge costs: [1, 2] = 20, [2, 1] = 20 (other existing edges have
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1,
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1,
Graph is undirected.
```

Now we get the subgraph for the vertices 1,2,4:

```
G2 := Graph::getSubGraph(G1, [1, 2, 4]):
Graph::printGraphInformation(G2)
```

# Graph::getSubGraph

---

```
Vertices: [1, 2, 4]
Edges: [[1, 2], [1, 4], [2, 1], [2, 4], [4, 1], [4, 2]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut", [2, 1] = "Shortcut"
Edge weights: [1, 2] = 20, [2, 1] = 20 (other existing edges have no weights)
Edge costs: [1, 2] = 20, [2, 1] = 20 (other existing edges have no costs)
Adjacency list (out): 1 = [2, 4], 2 = [1, 4], 4 = [1, 2]
Adjacency list (in): 1 = [2, 4], 2 = [1, 4], 4 = [1, 2]
Graph is undirected.
```

The subgraph for the vertices 1,3,4 looks like:

```
G2 := Graph::getSubGraph(G1, [1, 3, 4]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 3, 4]
Edges: [[1, 3], [1, 4], [3, 1], [3, 4], [4, 1], [4, 3]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, 4], 3 = [1, 4], 4 = [1, 3]
Adjacency list (in): 1 = [3, 4], 3 = [1, 4], 4 = [1, 3]
Graph is undirected.
```

## Parameters **G**

A graph

## Vertex

A list containing one or more vertices of G.

## Return Values

Graph

# Graph::getVertexNumber

---

**Purpose** Returns the number of vertices.

**Syntax** `Graph::getVertexNumber(G)`

**Description** `Graph::getVertexNumber(G)` returns a number representing the number of vertices in G.

**Examples** **Example 1**

An example with 100 vertices:

```
G1 := Graph::createCompleteGraph(100):
Graph::getVertexNumber(G1)
```

```
100
```

**Parameters** **G**  
A graph

**Return Values**  
Number

**Purpose** Returns a table with the vertex weights.

**Syntax** `Graph::getVertexWeights(G)`

**Description** `Graph::getVertexWeights(G)` returns a table with the vertex weights of the graph `G`. Thus `Graph::getVertexWeights(G)` returns the weight of all vertices in `G`.

---

**Note** If `FAIL` is returned, no weights were defined (this way both, network and graph algorithms handle this situation correct.)

---

## Examples

### Example 1

First lets define a graph without vertex weights:

```
G1 := Graph::createCircleGraph(3):
Graph::getVertexWeights(G1)
```

`FAIL`

`FAIL` was returned, because no vertex weights were defined.

```
Graph::getVertices(G1);
G1 := Graph::setVertexWeights(G1, [1, 3], [5, 1/2]):
Graph::getVertexWeights(G1)
```

`[1, 2, 3]`

```
┌───┐
1 | 5
3 | 1/2
```

# Graph::getVertexWeights

---

The first output shows all the vertices and the second one the assigned vertex weights.

## Parameters

**G**

A graph

## Return Values

Table

**Purpose** Returns a list with all vertices

**Syntax** `Graph::getVertices(G)`

**Description** `Graph::getVertices(G)` returns the list of all vertices of the Graph G.

**Examples** **Example 1**

A small creation of two different graphs and the output `getVertices` generates:

```
G1 := Graph::createCompleteGraph(10):
Graph::getVertices(G1)
```

```
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

```
G2 := Graph::createCircleGraph([x.i $ i = 1..12]):
Graph::getVertices(G2)
```

```
[x1, x2, x3, x4, x5, x6, x7, x8, x9, x10, x11, x12]
```

**Parameters** **G**  
A graph

**Return Values** List

# Graph::inDegree

---

**Purpose** Returns the indegree of one or more vertices.

**Syntax** `Graph::inDegree(G, <Vertex>)`

**Description** `Graph::inDegree(G, Vertex)` returns the indegree of the vertex `Vertex` in the Graph `G`, i.e., the number of edges `[u, Vertex]`.  
`Graph::inDegree(G, [v1, v2, ..., vn])` returns a table in which the keys are `v1, v2, ..., vn` and the corresponding values are the indegrees.

`Graph::inDegree(G)` returns a table in which each node of `G` is mapped to its indegree. `Graph::inDegree(G)` is equivalent to `Graph::inDegree(G, Graph::getVertices(G))`.

## Examples

### Example 1

In a complete graph of  $n$  vertices, each vertex has indegree  $n - 1$ :

```
G := Graph::createCompleteGraph(5):
Graph::inDegree(G, [2, 4, 5]), Graph::inDegree(G),
Graph::inDegree(G, Graph::getVertices(G))
```

		1	4	1	4
2	4	2	4	2	4
4	4'	3	4'	3	4
5	4	4	4	4	4
		5	4	5	4

The first table shows what happens, if some vertices are specified. The second and third table return all indegrees, but with two different calls (the second is redundant).

### Example 2

Remember that also only one vertex needs to be specified as a list!

```
G := Graph::createCompleteGraph(5):
```

`Graph::inDegree(G, [2])`

2|4

## Parameters

**G**

A Graph

**Vertex**

A list containing one or more vertices.

## Return Values

Table containing all the indegrees of the specified vertices.

# Graph::isConnected

---

**Purpose** Finds out if the graph is connected

**Syntax** Graph::isConnected(G)

**Description** Graph::isConnected(G) returns TRUE if G is connected, FALSE otherwise.

**Examples**      **Example 1**

A circle graph is made to create a connected Graph:

```
G1 := Graph::createCircleGraph(3):
Graph::isConnected(G1)
```

TRUE

After adding a single vertex to the graph, it is not connected any more:

```
G2 := Graph::addVertices(G1, [4]):
Graph::isConnected(G2)
```

FALSE

**Parameters**      **G**

A graph

**Return Values**      TRUE or FALSE

**Purpose** Finds out if the graph is directed

**Syntax** `Graph::isDirected(G)`

**Description** `Graph::isDirected(G)` returns TRUE if G is directed, FALSE otherwise.

**Examples** **Example 1**

A circle graph is made to create a directed Graph:

```
G1 := Graph::createCircleGraph(3):
Graph::isDirected(G1)
```

TRUE

**Example 2**

Now a complete graph is created in order to get an undirected graph:

```
G1 := Graph::createCompleteGraph(3):
Graph::isDirected(G1)
```

FALSE

**Parameters** **G**

A graph

**Return Values** TRUE or FALSE

# Graph::isEdge

---

**Purpose** Finds out if the edges exists

**Syntax** Graph::isEdge(G, Edge)

**Description** Graph::isEdge(G) returns TRUE if ALL specified edges exist in G, FALSE otherwise.

## **Examples** **Example 1**

A circle graph is made to create a directed Graph:

```
G1 := Graph::createCircleGraph(3):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

First let us check for an existing single edge:

```
Graph::isEdge(G1, [[1, 2]])
```

```
TRUE
```

Now we check if several edges exist:

```
Graph::isEdge(G1, [[1, 2], [2, 3]])
```

TRUE

What about a non existing edge?

```
Graph::isEdge(G1, [[3, 2]])
```

FALSE

Finally a list of some existing and non existing edges is checked:

```
Graph::isEdge(G1, [[1, 2], [2, 3], [3, 2]])
```

FALSE

## Parameters

**G**

A graph

**Edge**

A list containing one or more edges

## Return Values

TRUE or FALSE

# Graph::isVertex

---

**Purpose** Finds out if special vertices exist in the Graph

**Syntax** Graph::isVertex(G, Vertex)

**Description** Graph::isVertex(G) returns TRUE if ALL specified vertices exist in G, FALSE otherwise.

## Examples **Example 1**

A circle graph is made to create a directed Graph:

```
G1 := Graph::createCircleGraph(3):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

First, let us check for an existing vertex:

```
Graph::isVertex(G1, [1])
```

```
TRUE
```

Now we check if several vertices exist:

```
Graph::isVertex(G1, [1, 2])
```

TRUE

What about a non existing vertex?

```
Graph::isVertex(G1, [4])
```

FALSE

Finally a list of some existing and non existing vertices is checked:

```
Graph::isVertex(G1, [1, 2, 4])
```

FALSE

## Parameters

### **G**

A graph

### **Vertex**

A list containing one or more vertices

## Return Values

TRUE or FALSE

# Graph::longestPath

---

**Purpose** Longest paths from one single node

**Syntax** Graph::longestPath(G, v, <w>, <Length>, <Path>)

**Description** Graph::longestPath(G, v) returns a table with the length of longest paths from v to all other nodes in the Graph with respect to the edge weight.

Graph::longestPath(G, v, w) returns the length of a longest path from v to w.

If the optional argument Path is given, a table with longest paths is returned. If both Length and Path are given, then both the length of the longest paths and the paths are returned. Paths are given as lists of nodes in reverse order.

If Path is not given, the option Length has no effect.

---

**Note** The Graph G must be directed and should not contain cycles.

---

## Examples

### Example 1

We construct a Graph and try a few calls to Graph::longestPath:

```
V := [1, 2, 3, 4, 5]:
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:
Ew := [7, 6, 5, 4, 2, 2, 1]:
G := Graph(V, Ed, EdgeWeights = Ew, Directed):
Graph::longestPath(G, 1)
```

```
1 | 0
2 | 7
3 | 12
4 | 14
5 | 15
```

```
Graph::longestPath(G, 1, Path)
```

```
2 [2, 1]
3 [3, 2, 1]
4 [4, 3, 2, 1]
5 [5, 4, 3, 2, 1]
```

## Parameters

**G**

A Graph

**v, w**

Vertices in G

## Options

**Length**

Return a table with the lengths of shortest paths

**Path**

Return a table with the paths themselves

## Return Values

Table, an integer or a list of nodes

## Algorithms

The implemented algorithm is a variation of the algorithm of Bellman.

# Graph::maxFlow

---

**Purpose**                Computes a maximal flow through a graph

**Syntax**                `Graph::maxFlow(G, s, t)`

**Description**           `Graph::maxFlow(G, s, t)` computes a maximal flow from `s` to `t` in `G` with respect to the edge capacities. `s` and `t` must be nodes in `G`.

`Graph::maxFlow(G, s, t)` returns a sequence containing the flow value, that is the inflow of `s`, which equals the outflow of `s`, and the flow itself in form of table `tbl` with the flow from vertex `v` to vertex `w` is `tbl[[v,w]]`.

## Examples

### Example 1

In the complete Graph with four vertices and default capacities of 1, the maximum flow from one vertex to another one consists of sending one unit through each of the remaining vertices and one directly, which makes three units altogether:

```
G1 := Graph::createCompleteGraph(4):
Graph::maxFlow(G1, [1], [4])
```

	[1, 2]	1
	[2, 1]	0
	[1, 3]	1
	[3, 1]	0
	[1, 4]	1
3.	[2, 3]	0
	[3, 2]	0
	[4, 1]	0
	[2, 4]	1
	[4, 2]	0
	[3, 4]	1
	[4, 3]	0

## Example 2

As a more complex example, the following graph shows that this function also finds flows through multiple edges, unlike `Graph::admissibleFlow`, which only works on completely described flows:

```
V := [1, 2, 3, s, t]:
Edge := [[s, 1], [t, 2], [1, 2], [1, 3], [2, 3], [3, t]]:
up := [5, 5, 2, 6, 6, 1]:
G2 := Graph(V, Edge, EdgeCosts = up, Directed):
Graph::maxFlow(G2, [s], [t])
```

# Graph::maxFlow

---

	[1, 2]	0
	[1, 3]	1
1,	[2, 3]	0
	[s, 1]	1
	[t, 2]	0
	[3, t]	1

## Parameters

**G**

Graph

**s, t**

Expressions (vertices in G)

## Return Values

List, containing a number and a table

## Algorithms

The implemented algorithm is the preflow-push algorithm of Goldberg & Tarjan with the FIFO selection strategy and an exact distance labeling (“A new approach to the maximum-flow problem”, Journal of the ACM 35(4), 1988).

The running time is  $O(n^3)$ , where  $n$  is the number of vertices in the Graph.

**Purpose** Computes a minimal cost flow

**Syntax** `Graph::minCost(G)`

**Description** `Graph::minCost(G)` computes a minimal cost flow in `G` with respect to the edge capacities, the edge weights and the vertex weights of `G`.

The vertex weights are interpreted as supply and demand. The edge weights give restrictions for the flow on every edge. The edge costs are the cost for one unit flow over an edge.

The algorithm computes a flow, if there is any, which is possible and satisfactory, i.e., it is within the supply and demand range, which respects the capacities and which has minimal cost.

## Examples **Example 1**

We construct a `Graph` with five vertices and seven edges. One of the vertices is a pure source (1), another one is a pure sink (5). No other vertices supply or demand any goods, they only serve as transportation junctions:

```
V := [1, 2, 3, 4, 5]:
Vw := [25, 0, 0, 0, -25]:
edges := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]
Ec := [7, 6, 5, 4, 2, 2, 1]:
Ew := [30, 20, 25, 10, 20, 25, 20]:
G1 := Graph(V, edges, EdgeCosts = Ec, EdgeWeights = Ew,
 VertexWeights = Vw, Directed):
Graph::minCost(G1)
```

# Graph::minCost

---

[1, 2]	5	[1, 2]	35	, 220,	1	12
[1, 3]	20	[1, 3]	120		2	5
[2, 3]	0	[2, 3]	0		3	2
[2, 4]	5	[2, 4]	20		4	1
[3, 4]	0	[3, 4]	0		5	0
[3, 5]	20	[3, 5]	40			
[4, 5]	5	[4, 5]	5			

All 25 units could be transported from vertex 1 to vertex 5, for a total cost of 220. The cost for each edge can be found in the first table, the accumulated costs in the second and the last table holds the dual prices. For example 6 units flow over edge [1, 3] since  $6 \cdot 20 = 120$  and 7 units flow over edge [1, 2] since  $7 \cdot 5 = 35$ .

**Parameters**     **G**

Graph

**Return Values**

Sequence, consisting of three tables and a number. The first table holds the amount flowing over the edge, the second the accumulated costs for each used edge and the number is the sum of all edge-costs for the flow. The last table holds the dual prices for each vertex.

**Algorithms**

The implemented algorithm is the relaxation algorithm due to Bertsekas (taken from Bertsekas, "Linear Network Optimization", MIT Press, Cambridge(Mass.)-London, 1991) which is known to be one of the fastest algorithms in practice.

**Purpose** Computes a minimal cut

**Syntax** `Graph::minCut(G, q, s)`

**Description** `Graph::minCut(G,q,s)` computes a minimal cut in `G` that separates `q` from `s`, i.e., a subset `T` of the set `S` of edges of `G` such that every path from `q` to `s` contains at least one edge in `T`. The cut is minimal with respect to the capacities of the edges.

`Graph::minCut(G,q,s)` returns a sequence consisting of the cut value (the sum of the edge weights of the cut edges) and a list with the edges of the cut.

Note that `q` is separated from `s`, not vice versa.

## Examples **Example 1**

In a complete graph, a vertex can be separated from another one only by cutting all edges starting at the first vertex:

```
G1 := Graph::createCompleteGraph(4):
Graph::minCut(G1, [1], [4])
```

```
3, [[1, 2], [1, 3], [1, 4]]
```

## **Example 2**

In the following example, the edge from vertex `q` to vertex `1` could have been used as well, but its edge capacity is higher than that of the edge used, so the minimality condition precludes this choice:

```
V := [1, 2, 3, q, s]:
Edge := [[q, 1], [1, 2], [1, 3], [2, 3], [3, s]]:
up := [5, 2, 6, 6, 1]:
G2 := Graph(V, Edge, EdgeWeights = up, Directed):
Graph::minCut(G2, [q], [s])
```

# Graph::minCut

---

1, [[3, s]]

There is no path from vertex  $s$  to vertex  $q$  (or any other vertex of the Graph), so no cut is necessary to separate  $s$  from  $q$ :

`Graph::minCut(G2, [s], [q])`

0, []

## Parameters

**q, s**

Vertices that have to be defined within G

**G**

Graph

## Return Values

Sequence, consisting of the “cut value” and a list of edges cut

## Purpose

Creates a MST

## Syntax

```
Graph::minimumSpanningTree(G, <SearchFor = Weights
| Costs>, <ReturnAsTable>)
```

## Description

`Graph::minimumSpanningTree(G)` creates a minimum spanning tree according to the weights of the edges and returns a Graph consisting only of them. The same result would be achieved using `Graph::minimumSpanningTree(G, SearchFor = Weights)`

`Graph::minimumSpanningTree(G, SearchFor = Costs)` creates a minimum spanning tree according to the costs of the edges and returns a Graph consisting only of them.

`Graph::minimumSpanningTree(G, ReturnAsTable)` creates a minimum spanning tree according to the weights of the edges and returns a list with two objects. The first is a table consisting of the used edges and their weights. The second object is a number containing the sum of all the edge weights.(The same result can be achieved using: `Graph::minimumSpanningTree(G, SearchFor=Weights, ReturnAsTable)`.)

`Graph::minimumSpanningTree(G, SearchFor=Costs, ReturnAsTable)` creates a minimum spanning tree according to the costs of the edges and returns a list with two objects. The first is a table consisting of the used edges and their costs. The second object is a number containing the sum of all the edge costs.

## Examples

### Example 1

The following graph will be used throughout all the following examples. MuPAD does not allow placement of any text at a specified coordinate. Thus the output of this description was not created with MuPAD. (Have a look at the edge  $[c, f]$ . This edge is responsible for the different outputs whether Costs or Weights was chosen.)

```
G := Graph([a, b, c, d, e, f, g, h, i],
 [[a, b], [a, h], [b, h], [b, c], [c, d], [d, f], [d,
```

# Graph::minimumSpanningTree

---

```
[f, e], [h, g], [g, f], [c, i], [h, i], [g, i], [c, f]]
EdgeWeights = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6,
EdgeCosts = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6, 1
```

We will plot this graph and all graphs derived from it using `Graph::plotGridGraph` with the following options:

```
plotOptions :=
 VerticesPerLine=7,
 VertexOrder = [
 None, b, None, c, None, d, None,
 a, None, i, None, None, None, e,
 None, h, None, g, None, f, None]:

plot(Graph::plotGridGraph(G, plotOptions))
```

Now we use this Graph to create a minimum spanning tree according to the weights of the edges and have a look which edges were used:

# Graph::minimumSpanningTree

```
Graph::minimumSpanningTree(G, SearchFor = Weights, ReturnAsTable)
Graph::minimumSpanningTree(G, ReturnAsTable)
```

[a, b]	4		[a, b]	4
[b, a]	4		[b, a]	4
[b, c]	8		[b, c]	8
[c, b]	8		[c, b]	8
[c, d]	7		[c, d]	7
[d, c]	7		[d, c]	7
[c, f]	4		[c, f]	4
[d, e]	9, 37	,	[d, e]	9, 37
[e, d]	9		[e, d]	9
[f, c]	4		[f, c]	4
[c, i]	2		[c, i]	2
[i, c]	2		[i, c]	2
[f, g]	2		[f, g]	2
[g, f]	2		[g, f]	2
[g, h]	1		[g, h]	1
[h, g]	1		[h, g]	1

Both calls return exactly the same tables. That was expected and just to show that it is of no importance if the additional SearchFor=Weights is omitted.

Now we want to get the minimum spanning tree returned as a Graph so we can have a look how it looks like

```
weightMST := Graph::minimumSpanningTree(G):
plot(Graph::plotGridGraph(weightMST, plotOptions, EdgeColor = RG
```

# Graph::minimumSpanningTree

---

There are two ways of displaying both graphs at the same time:

```
plot(
 Graph::plotGridGraph(G, plotOptions, EdgeColor = RGB::Black),
 Graph::plotGridGraph(weightMST, plotOptions, EdgeColor = RGB::Gre
)
```

# Graph::minimumSpanningTree

---

```
edgesWeightMST := Graph::getEdges(weightMST):
plot(Graph::plotGridGraph(G, plotOptions,
 EdgeColor = RGB::Black,
 SpecialEdges = edgesWeightMST,
 SpecialEdgeColor = RGB::Green))
```

# Graph::minimumSpanningTree

---

## Example 2

Maybe instead of the weights there is an interest in getting the MST for the costs of the edges.

```
G := Graph([a, b, c, d, e, f, g, h, i],
 [[a, b], [a, h], [b, h], [b, c], [c, d], [d, f], [d, e],
 [f, e], [h, g], [g, f], [c, i], [h, i], [g, i], [c, f]]
 EdgeWeights = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6,
 EdgeCosts = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6, 1
```

```
Graph::minimumSpanningTree(G, SearchFor = Costs, ReturnAsTable)
```

[a, b]	4
[b, a]	4
[b, c]	8
[c, b]	8
[c, d]	7
[d, c]	7
[d, e]	9
[e, d]	9, 39
[c, i]	2
[i, c]	2
[f, g]	2
[g, f]	2
[g, h]	1
[h, g]	1
[g, i]	6
[i, g]	6

Plotting this spanning tree is just as easy as above:

```
costMST := Graph::minimumSpanningTree(G, SearchFor = Costs):
plot(Graph::plotGridGraph(costMST, plotOptions, EdgeColor = RGB:
```

# Graph::minimumSpanningTree

---

To combine both spanning trees, we use different line widths, to avoid one graph being completely covered by the other:

```
plot(
 plot::Group2d(
 Graph::plotGridGraph(costMST, plotOptions, EdgeColor = RGB::Blue,
 LineWidth = 2.5
),
 plot::Group2d(
 Graph::plotGridGraph(G, plotOptions, EdgeColor = RGB::Black),
 Graph::plotGridGraph(weightMST, plotOptions, EdgeColor = RGB::Green,
 PointSize = 5,
 LineWidth = 1
)
)
)
```

# Graph::minimumSpanningTree

## Parameters

**G**

Graph

## Options

**SearchFor**

Can either be Costs or Weights. Default is Weights

**ReturnAsTable**

If omitted, a Graph is returned, otherwise a list containing a table and the sum of the edge weights/costs.

## Return Values

Graph consisting of the MST. Only if ReturnAsTable was specified, a list containing a table and a number are returned. The table holds the edges with either the weights or costs of each edge and the number is the sum of all edges.

# Graph

---

## Purpose

Creates a new Graph

## Syntax

```
Graph(V, E, <VertexWeights = vw>, <EdgeDescriptions
= ed>, <EdgeWeights = ew>, <EdgeCosts = ec>,
<Directed | Undirected>)
```

## Description

Graph(V, E) creates a Graph

Graph([v1, ..., vn], [e1, ..., em]) generates a new undirected graph with  $n$  vertices and  $m$  edges.

Graph([1,a,3], [[1,a],[1,3]], Directed) generates a new directed graph with the vertices 1, a, 3 and the edges [1,a], [1,3].

Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,2,3], EdgeWeights = [4,5]) generates a new directed graph where the vertices have the values a=1, b=2, 3=3 and the edges [a,b]=4, [b,3]=5.

Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,None,3], EdgeWeights = [4, None]) generates a new directed graph where the vertices have the values a=1, 3=3 and the edges [a,b]=4. The difference to the example directly above is that the keyword None can be used to not assign a value to a vertex or edge.

## Examples

### Example 1

An (undirected) graph with four vertices:

```
G1 := Graph([1,a,3], [[1,a],[1,3]]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 3, a]
Edges: [[1, 3], [1, a], [3, 1], [a, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, a], a = [1], 3 = [1]
```

```
Adjacency list (in): 1 = [3, a], a = [1], 3 = [1]
Graph is undirected.
```

## Example 2

The same graph but this time with parameter Directed:

```
G1 := Graph([1,a,3], [[1,a],[1,3]], Directed):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 3, a]
Edges: [[1, 3], [1, a]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, a], a = [], 3 = []
Adjacency list (in): 1 = [], a = [1], 3 = [1]
Graph is directed.
```

## Example 3

The circle graph with predefined vertices:

```
G3 := Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,2,3], Edg
Graph::printGraphInformation(G3)
```

```
Vertices: [3, a, b]
Edges: [[3, b], [a, b], [b, 3], [b, a]]
Vertex weights: a = 1, b = 2, 3 = 3 (other existing vertices hav
Edge descriptions: no edge descriptions.
Edge weights: [a, b] = 4, [b, 3] = 5, [b, a] = 4, [3, b] = 5 (ot
Edge costs: no edge costs.
Adjacency list (out): a = [b], b = [3, a], 3 = [b]
Adjacency list (in): a = [b], b = [3, a], 3 = [b]
```

# Graph

---

Graph is undirected.

## Example 4

The circle graph with predefined vertices:

```
G3 := Graph([a,b,3,7], [[a,b],[b,3],[3,7]],
VertexWeights = [1,2,3,4], EdgeWeights = [-1,-2,-5],
EdgeDescriptions = ["Small", None, "Smallest"]):
Graph::printGraphInformation(G3)
```

```
Vertices: [3, 7, a, b]
Edges: [[3, 7], [3, b], [7, 3], [a, b], [b, 3], [b, a]]
Vertex weights: a = 1, b = 2, 3 = 3, 7 = 4 (other existing vertices
Edge descriptions: [a, b] = "Small", [3, 7] = "Smallest", [b, a] =
Edge weights: [a, b] = -1, [b, 3] = -2, [3, 7] = -5, [b, a] = -1, [
o weight)
Edge costs: no edge costs.
Adjacency list (out): a = [b], b = [3, a], 3 = [7, b], 7 = [3]
Adjacency list (in): a = [b], b = [3, a], 3 = [7, b], 7 = [3]
Graph is undirected.
```

If you look at the edge descriptions, the keyword `None` can be used for every edge which is not supposed to have a description.

## Parameters

**V**

List of vertices

**E**

List of edges

**vw, ew, ec**

List of numbers

**ed**

List of strings

## **Options**

### **Directed**

The Graph is created as a directed graph.

### **Undirected**

The Graph is created as an undirected graph. Default.

# Graph::outDegree

**Purpose** Returns the outdegree of one or more vertices.

**Syntax** `Graph::outDegree(G, <Vertex>)`

**Description** `Graph::outDegree(G)` returns the number of edges leaving each vertex `Vertex` of the Graph `G`.

`Graph::outDegree(G, Vertex)` returns the outdegree of the vertex `Vertex` in the Graph `G`, i.e., the number of edges [`Vertex`, `u`].

`Graph::outDegree(G, [v1, v2, ..., vn])` returns a table in which the keys are `v1`, `v2`, ..., `vn` and the corresponding values are the outdegrees.

`Graph::outDegree(G)` returns a table in which each node of `G` is mapped to its outdegree. `Graph::outDegree(G)` is equivalent to `Graph::outDegree(G, Graph::getVertices(G))`.

## Examples

### Example 1

In a complete graph of  $n$  vertices, each vertex has outdegree  $n - 1$ :

```
G := Graph::createCompleteGraph(5):
Graph::outDegree(G, [2, 4, 5]), Graph::outDegree(G),
Graph::outDegree(G, Graph::getVertices(G))
```

	1	4	1	4	
2	4	2	4	2	4
4	4	3	4	3	4
5	4	4	4	4	4
	5	4	5	4	

The first table shows what happens, if some vertices are specified. The second and third table return all indegrees, but with two different calls (the second is redundant).

### Example 2

Remember that also only one vertex needs to be specified as a list !

```
G := Graph::createCompleteGraph(5):
Graph::outDegree(G, [2])
```

2|4

## Parameters

**G**

A Graph

## Options

**Vertex**

A list containing one or more vertices.

## Return Values

Table containing all the outdegrees of the specified vertices.

# Graph::plotBipartiteGraph

---

**Purpose** Plots a Graph in a bipartite layout

**Syntax** `Graph::plotBipartiteGraph(G, <PointSize = n>, <SpecialVertices = [v1, ..., vn]>, <SpecialEdges = [e1, ..., en]>, <EdgeColor = RGB>, <SpecialEdgeColor = RGB>, <SpecialVertexColor = RGB>, <Vertex1Color = RGB>, <Vertex2Color = RGB>)`

**Description** `Graph::plotBipartiteGraph(G)` returns a `plot::Group2d` object in which the vertices are ordered in two rows (from bottom to top). The first vertex in the left row is drawn in blue and the second (the first vertex in the right row) in green. All other vertices are drawn in red. The width of the points is predefined with 40.

**Examples** **Example 1**

A random graph is created and plotted (your output may differ due to random creation):

```
G1 := Graph::createRandomGraph(110, 10, Undirected):
plot(Graph::plotBipartiteGraph(G1)):
```

## Example 2

If some edges are to be emphasized they can be drawn in a special color:

```
G2 := Graph([1, 2, 3, 4, 5, 6],
 [[1, 2], [2, 3], [3, 4], [4, 5], [1, 6]]):
Graph::bipartite(G2, Lists)

[[2, 4, 6], [1, 3, 5]]

edges := [[6, 1], [1, 2]]:
plot(Graph::plotBipartiteGraph(G2, SpecialEdges = edges,
 SpecialEdgeColor = RGB::Blue))
```

# Graph::plotBipartiteGraph

---

## Parameters

**G**

Graph

**n**

a positive integer.

**[v<sub>1</sub>, ..., v<sub>n</sub>]**

a list of vertices.

**[e<sub>1</sub>, ..., e<sub>n</sub>]**

a list of edges.

## Options

**PointSize**

Defines the thickness in which the points are drawn. Default is 40.

**SpecialVertices**

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

## **SpecialEdges**

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

## **EdgeColor**

Defines a color with which to draw the edges. Default is `RGB::Red`.

## **SpecialEdgeColor**

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`.

## **VertexColor**

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They can be given different colors via `Vertex1Color` and `Vertex2Color`. Default is `RGB::Red`.

## **SpecialVertexColor**

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`.

## **Vertex1Color**

Defines a color with which to draw the first vertex with (the starting vertex at the bottom of the first set). Default is `RGB::Blue`.

## **Vertex2Color**

Defines a color with which to draw the second vertex with (the starting vertex at the bottom of the second set). Default is `RGB::Green`.

## **Return Values**

`plot::Group2d`

# Graph::plotCircleGraph

---

**Purpose** Plots a Graph in a circle layout

**Syntax** `Graph::plotCircleGraph(G, <PointSize = n>, <SpecialVertices = [v1, ..., vn]>, <SpecialEdges = [e1, ..., en]>, <EdgeColor = RGB>, <SpecialEdgeColor = RGB>, <SpecialVertexColor = RGB>, <Vertex1Color = RGB>, <Vertex2Color = RGB>)`

**Description** `Graph::plotCircleGraph(G)` returns a `plot::Group2d` object in which the vertices are ordered in a circle (rightmost position upwards). The first vertex is drawn in blue and the second in green. All other vertices are drawn in red. The edges are drawn in red. The width of the points is predefined with 40. If a vertex points to itself it will be drawn outside

## **Examples** **Example 1**

A random graph is created and plotted (your output may differ due random creation):

```
G1 := Graph::createRandomGraph(20, 10, Undirected):
plot(Graph::plotCircleGraph(G1))
```

Next, a complete graph will be plotted.

```
G1 := Graph::createCompleteGraph(20):
plot(Graph::plotCircleGraph(G1))
```

# Graph::plotCircleGraph

---

## Example 2

If some edges are to be emphasized they can be drawn in a special color:

```
G2 := Graph([1, 2, 3, 4, 5],
 [[1, 2], [2, 3], [3, 4], [4, 5],
 [1, 3], [1, 4], [1, 5]]):
edges := [[1, 3], [1, 4]]:
plot(Graph::plotCircleGraph(G2,
 SpecialEdges = edges, SpecialEdgeColor = RGB::Blue)
```

## Parameters

**G**

Graph

**n**

a positive integer.

**[v<sub>1</sub>, ..., v<sub>n</sub>]**

a list of vertices.

**[e<sub>1</sub>, ..., e<sub>n</sub>]**

a list of edges.

## Options

**PointSize**

Defines the thickness in which the points are drawn. Default is 40.

**SpecialVertices**

# Graph::plotCircleGraph

---

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

## **SpecialEdges**

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

## **EdgeColor**

Defines a color with which to draw the edges. Default is `RGB::Red`

## **SpecialEdgeColor**

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`

## **VertexColor**

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They must be specified via `Vertex1Color` and `Vertex2Color` to distinct them again. Default is `RGB::Red`

## **SpecialVertexColor**

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`

## **Vertex1Color**

Defines a color with which to draw the uppermost left (first) vertex with (the starting vertex). Default is `RGB::Blue`

## **Vertex2Color**

Defines a color with which to draw the second vertex with. Default is `RGB::Green`

## **Return Values**

`plot::Group2d`

## Purpose

Plots a Graph in a grid layout

## Syntax

```
Graph::plotGridGraph(G, <PointSize = n>, <VerticesPerLine = n>, <VertexOrder = [n1, ..., nm]>, <SpecialVertices = [v1, ..., vn]>, <SpecialEdges = [e1, ..., en]>, <EdgeColor = RGB>, <SpecialEdgeColor = RGB>, <SpecialVertexColor = RGB>, <Vertex1Color = RGB>, <Vertex2Color = RGB>)
```

## Description

`Graph::plotGridGraph(G)` returns a `plot::Scene` object in which the vertices are square ordered (topmost left to downmost right). The number of vertices per line is the floor of the squareroot of the number of the vertices. The first vertex is drawn in `RGB::Blue` and the second in `RGB::Green`. All other vertices are drawn in `RGB::Red`. The edges are drawn in `RGB::Red`. The width of the points is predefined with 40. If the last line contains only one vertex, it will be drawn centered in the middle of the line.

`Graph::plotGridGraph(G, VerticesPerLine=n)` returns a `plot::Scene` object like described above with one exception. In every line there are exactly `n` vertices. They appear in sorted order depending on their name. If the last row consists of only one vertex, this one will be centered.

`Graph::plotGridGraph(G, VerticesPerLine=[v1..vn])` returns a `plot::Scene` object like described above with one exception. In line 1 there are exactly `v1` vertices placed. In line 2 there are `v2` vertices and so on. The last line contains `vn` vertices. They appear in sorted order depending on their name. The sum of the numbers specified in `VerticesPerLine` must equal the number of vertices in the graph.

`Graph::plotGridGraph(G, VerticesPerLine=n, VertexOrder=[v1..vn])` returns a `plot::Scene` object like described above with one exception. In every line there are exactly `n` vertices. They appear in sorted order depending on the order that was specified in `VertexOrder`. `vi` can consist of any vertex defined as well as the substitute `None`. Nevertheless the number of vertices in `G` must not exceed the number of `VerticesPerLine`. If the last line holds only one vertex, it will be centered.

# Graph::plotGridGraph

---

## Examples

### Example 1

First, a small graph is created and plotted with the default values:

```
G := Graph([a, b, c, d], [[a, b], [b, c], [c, d], [d, a]]):
plot(Graph::plotGridGraph(G))
```

Now, we exchange the two vertices c and d. The order given above was [a, b, c, d]:

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c]))
```

If only one vertex is placed in the last line, it will be centered:

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c],
 VerticesPerLine = 3))
```

# Graph::plotGridGraph

---

The same result can be gained by defining the Vertices per line specifically (in this case the number of vertices must be no less than the number of vertices in the graph):

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c],
 VerticesPerLine = [3, 1]))
```

Now we get to the point, why the plot routine got the name Grid. The substitute `None` can be used whenever a place should be skipped. Think of some drawing paper with caskets. The layout is exactly the same. In this case it would consist of 3 caskets in each row. `None` leaves it blank, while a vertex from the Graph is drawn. Because the first casket is empty, the first color is omitted, too. The vertex `a` which is placed in the second casket is drawn as predefined in `Vertex2Color` (`RGB::Green`):

```
plot(Graph::plotGridGraph(G,
 VertexOrder = [None, a, None,
 b, None, c,
 None, d, None],
 VerticesPerLine = 3))
```

# Graph::plotGridGraph

---

## Example 2

With the knowledge obtained so far, it is possible to get deeper into the art of creating objects. One of the most useful outputs is that of a tree. Thus a Graph is created to be used for the tree output:

```
TreeGraph := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
 [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
 [d, h], [e, i], [e, j], [f, k], [g, l]], Directed):
```

Next we define a special vertex order, because the vertices are not drawn the way they were defined:

```
vOrder :=
[None, None, None, None, None, None, a, None, None, None, None,
 None, None, b, None, None, None, None, None, None, c, None,
 None, d, None, None, e, None, None, f, None, None, g,
 h, None, None, i, None, j, None, None, k, None, None,
```

Now it is time to have a look at how the tree looks:

```
plot(Graph::plotGridGraph(TreeGraph,
 VerticesPerLine = 12, VertexOrder = vOrder))
```

Now we want to see the path from vertex a to Vertexb. For this example it will be given explicitly. For bigger graphs one of the `shortestPath` procedures is recommended:

```
specialPath := [[a, c], [c, f], [f, k]]:
```

Finally we draw the path inside the Graph and have a good overview about the path it takes:

```
plot(Graph::plotGridGraph(TreeGraph,
 VerticesPerLine = 12, VertexOrder = vOrder,
 SpecialEdges = specialPath, SpecialEdgeColor = RGB::Blu
```

# Graph::plotGridGraph

## Example 3

To show what can be done with more detailed and complex examples a small outer face is being drawn (have a close look at the Vertices which are not drawn, because the color is set to RGB::White and thus equals the background-color). Additionally, the “eyes” have been colored differently, so the usage of `SpecialVertexColor` could be presented:

```
Smile := Graph([1,2,4,5,7,8,9,10,11,12,13,14,15,16,17,18,19,20,
 21,22,23,24,25,26,27,28,29,30,31,32,33,34,35,36],
 [[1,4],[2,5],[4,5],[7,4],[5,8],[7,10],[9,10],[10,14],[9,13],
 [13,19],[19,20],[20,14],[14,15],[15,16],[16,17],[17,11],
 [8,11],[11,12],[12,18],[18,22],[22,21],[21,17],[21,24],
 [24,28],[28,32],[32,36],[36,35],[35,34],[34,33],[33,29],
 [29,25],[25,23],[23,20],[26,30],[30,31],[31,27]]):
plot(
 Graph::plotGridGraph(Smile, VerticesPerLine = 10,
 VertexOrder = [
 None,None,None, 1,None,None, 2,None,None,None,
```

```
None, None, None, None, 4, 5, None, None, None, None,
None, None, None, 7, None, None, 8, None, None, None,
None, 9, 10, None, None, None, None, 11, 12, None,
13, None, None, 14, 15, 16, 17, None, None, 18,
None, 19, 20, None, None, None, None, 21, 22, None,
None, None, 23, None, None, None, None, 24, None, None,
None, None, 25, 26, None, None, 27, 28, None, None,
None, None, 29, None, 30, 31, None, 32, None, None,
None, None, None, 33, 34, 35, 36, None, None, None],
SpecialEdges = [[13,9],[9,10],[10,14],[14,20],[20,19],[19,14],
[14,15],[15,16],[16,17],[17,21],[21,22],[22,18],[18,12],
[11,17]],
SpecialVertices = [1,2,4,5,7,8,23,24,25,26,27,28,29,30,31,
32,33,34,35,36],
VertexColor = RGB::White,
SpecialVertexColor = RGB::Green, EdgeColor = RGB::Green,
SpecialEdgeColor = RGB::Black)
)
```

# Graph::plotGridGraph

---

## Example 4

The next example is a complete graph drawn with the vertices ordered in a square so that all vertices can be connected inside the square:

```
CG := Graph::createCompleteGraph(30):
plot(Graph::plotGridGraph(CG,
 VerticesPerLine = [8, 2, 2, 2, 2, 2, 2, 2, 8],
 Vertex1Color = RGB::Red, Vertex2Color = RGB::Red))
```

Using the default values in every line vertices are drawn and the graph looks not as “dense” as the above one:

```
plot(Graph::plotGridGraph(CG, Vertex1Color = RGB::Red,
 Vertex2Color = RGB::Red))
```

## Example 5

The last example shows a small kite inside a frame:

```
Shield := Graph([1, 2, 3, 4, 5, 6, 7, 8, 9],
 [[1, 2], [1, 8], [2, 9], [8, 9], [3, 5], [4, 5],
 [5, 6], [5, 7], [3, 6], [6, 7], [3, 4], [4, 7]]):
plot(Graph::plotGridGraph(Shield, Vertex1Color = RGB::White,
 Vertex2Color = RGB::White, VertexColor = RGB::White,

 [3, 6], [6, 7], [3, 4], [4, 7]],
SpecialEdgeColor = RGB::Blue))
```

## Parameters

**G**

Graph

**n**

a positive integer.

**[n<sub>1</sub>, ..., n<sub>m</sub>]**

a list of positive integers.

**[v<sub>1</sub>, ..., v<sub>n</sub>]**

a list of vertices.

**[e<sub>1</sub>, ..., e<sub>n</sub>]**

a list of edges.

## Options

**PointSize**

Defines the thickness in which the points are drawn. Default is 40.

**VerticesPerLine**

If specified as single number, this many vertices are placed in every row. If specified as list, the number of vertices per line are read out of the list. If the vertices are specified as list, the number of vertices must match either the number of vertices defined in the graph, or, if specified, the number defined in `VertexOrder`.

**VertexOrder**

Defines an order in which the vertices are to be placed. It starts in the upper left and ends in the lower right. The number of specified vertices must match the number of vertices defined in the graph or the sum of the vertices specified in `VerticesPerLine`.

**SpecialVertices**

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

**SpecialEdges**

# Graph::plotGridGraph

---

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

## **EdgeColor**

Defines a color with which to draw the edges. Default is `RGB::Red`

## **SpecialEdgeColor**

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`

## **VertexColor**

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They must be specified via `Vertex1Color` and `Vertex2Color` to distinct them again. Default is `RGB::Red`

## **SpecialVertexColor**

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`

## **Vertex1Color**

Defines a color with which to draw the uppermost left (first) vertex with (the starting vertex). If `VertexOrder` holds a `None` for this vertex, it will be skipped. Default is `RGB::Blue`

## **Vertex2Color**

Defines a color with which to draw the second vertex with. If `VertexOrder` holds a `None` for this vertex, it will be skipped. Default is `RGB::Green`

## **Return Values**

`Plot::Scene`.

# Graph::printEdgeCostInformation

---

**Purpose** Prints the edge costs of a graph

**Syntax** `Graph::printEdgeCostInformation(G)`

**Description** `Graph::printEdgeCostInformation` prints the edge costs of a graph.  
`Graph::printEdgeCostInformation(G)` prints the edge costs of the graph *G*

**Examples** **Example 1**

A circle graph is created and the edge costs of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printEdgeCostInformation(G)
```

```
No edge costs defined.
```

```
G := Graph::setEdgeCosts(G, [[1, 2], [2, 3], [3, 1]], [10, 20, 30])
Graph::printEdgeCostInformation(G)
```

```
Edge costs existing in the graph:
```

```

Edge [1, 2] has cost 10
Edge [2, 3] has cost 20
Edge [3, 1] has cost 30
```

**Parameters** **G**

Graph

**Return Values** Text containing information about the edge costs of a graph.

# Graph::printEdgeDescInformation

---

<b>Purpose</b>	Prints the edge descriptions of a graph
<b>Syntax</b>	<code>Graph::printEdgeDescInformation(G)</code>
<b>Description</b>	<p><code>Graph::printEdgeDescInformation</code> prints the edge descriptions of a graph.</p> <p><code>Graph::printEdgeDescInformation(G)</code> prints the edge descriptions of the graph <i>G</i></p>

## Examples

### Example 1

A circle graph is created and the edge descriptions of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printEdgeDescInformation(G)
```

```
No edge descriptions defined.
```

```
G := Graph::setEdgeDescriptions(G, [[1, 2], [2, 3], [3, 1]],
 ["Shortcut", "Highway", "Speedup"]):
Graph::printEdgeDescInformation(G)
```

```
Edge descriptions existing in the graph:
```

```

Edge [1, 2] = "Shortcut"
Edge [2, 3] = "Highway"
Edge [3, 1] = "Speedup"
```

## Parameters

**G**

Graph

# Graph::printEdgeDescInformation

---

## **Return Values**

Text containing information about the edge descriptions of a graph.

# Graph::printEdgeInformation

---

**Purpose** Prints the edges of a graph

**Syntax** `Graph::printEdgeInformation(G)`

**Description** `Graph::printEdgeInformation` prints the edges of a graph.  
`Graph::printEdgeInformation(G)` prints the edges used in the graph *G*.

**Examples**      **Example 1**

A circle graph is created and the edges of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printEdgeInformation(G)
```

```
Edges existing in the graph:
```

```

[1, 2], [2, 3], [3, 1]
```

**Example 2**

A complete graph is created and the edges of it printed to screen:

```
G := Graph::createCompleteGraph(3):
Graph::printEdgeInformation(G)
```

```
Edges existing in the graph:
```

```

[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]
```

**Parameters**      **G**

Graph

## **Return Values**

Text containing information about the edges of a graph.

# Graph::printEdgeWeightInformation

---

**Purpose** Prints the edge weights of a graph

**Syntax** Graph::printEdgeWeightInformation(G)

**Description** Graph::printEdgeWeightInformation prints the edge weights of a graph.

Graph::printEdgeWeightInformation(G) prints the edge weights of the graph  $G$

## Examples **Example 1**

A circle graph is created and the edge weights of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printEdgeWeightInformation(G)
```

```
No edge weights defined.
```

```
G := Graph::setEdgeWeights(G, [[1, 2], [2, 3], [3, 1]], [10, 20, 30])
Graph::printEdgeWeightInformation(G)
```

```
Edge weights existing in the graph:
```

```

Edge [1, 2] has weight 10
Edge [2, 3] has weight 20
Edge [3, 1] has weight 30
```

## Parameters **G**

Graph

# Graph::printEdgeWeightInformation

---

## **Return Values**

Text containing information about the edge weights of a graph.

# Graph::printGraphInformation

---

**Purpose** Prints the edges of a graph

**Syntax** Graph::printGraphInformation(G)

**Description** Graph::printGraphInformation prints a summary of various information about a graph.

Graph::printGraphInformation(G) prints a summary of the graph *G*

## Examples **Example 1**

A circle graph is created and a summary of it printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

## **Example 2**

A complete graph is created and a summary of it printed to screen:

```
G := Graph::createCompleteGraph(3):
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Graph is undirected.
```

## Parameters

**G**

Graph

## Return Values

Text containing information about the graph.

# Graph::printVertexInformation

---

<b>Purpose</b>	Prints vertex information of a graph
<b>Syntax</b>	<code>Graph::printVertexInformation(G)</code>
<b>Description</b>	<code>Graph::printVertexInformation</code> prints the edges of a graph. <code>Graph::printVertexInformation(G)</code> prints the edges of the graph <i>G</i>

## Examples

### Example 1

A circle graph is created and information of the vertices printed to screen:

```
G := Graph::createCircleGraph(3):
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
```

```

```

```
Vertex 1 has weight None
```

```
Vertex 2 has weight None
```

```
Vertex 3 has weight None
```

### Example 2

A complete graph is created and information of the vertices printed to screen:

```
G := Graph::createCompleteGraph(3):
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
```

```

```

```
Vertex 1 has weight None
```

```
Vertex 2 has weight None
```

```
Vertex 3 has weight None
```

# Graph::printVertexInformation

---

## Parameters

**G**

Graph

## Return Values

Text containing information about the vertices of a graph.

# Graph::removeEdge

---

**Purpose** Removes one or several edges from a graph

**Syntax** Graph::removeEdge(G, e)  
Graph::removeEdge(G, l)

**Description** Graph::removeEdge(G, [e1, ..., en]) removes edges e1...en from graph G.

Graph::removeEdge deletes one or several edges from a graph. An edge is represented by a list containing two vertices of the graph. A warning is printed if the specified edge is not contained in the graph.

Graph::removeEdge(G, e) removes the edge e from the graph G.

Graph::removeEdge(G, l) removes all edges in list l from graph G.

## Examples

### Example 1

Removing an edge from a cyclic graph results in a (degenerated) tree:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G1))
```

```
G2 := Graph::removeEdge(G1, [[5, 1]]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = []
Adjacency list (in): 1 = [], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G2))
```

# Graph::removeEdge

---

If more than one edge is to be removed they must also be specified in a list:

```
edges := [[2, 3], [4, 5]]:
G3 := Graph::removeEdge(G1, edges):
Graph::printGraphInformation(G3)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [3, 4], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [], 3 = [4], 4 = [], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [], 4 = [3], 5 = []
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G3))
```

## Parameters

**I**

A list of edges

**e**

An edge

**G**

A graph

## Return Values

Graph

# Graph::removeVertex

---

**Purpose** Removes one or several vertices from a graph

**Syntax** `Graph::removeVertex(G, v)`  
`Graph::removeVertex(G, l)`

**Description** `Graph::removeVertex(G, v)` removes vertex `v` from graph `G`.  
`Graph::removeVertex(G, [v1, ..., vn])` removes vertices `v1...vn` from graph `G`.  
`Graph::removeVertex` deletes one or several vertices from a graph. A warning is printed if the specified vertex is not contained in the graph.

---

**Note** If a vertex is connected to other vertices with edges, they will be removed from the graph, too!

---

`Graph::removeVertex(G, v)` removes the vertex `v` from the graph `G`.  
`Graph::removeVertex(G, l)` removes all vertices in list `l` from graph `G`.

## Examples

### Example 1

Removing a vertex from a cyclic graph removes also two edges:

```
G1 := Graph::createCircleGraph(5):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
```

Graph is directed.

```
plot(Graph::plotCircleGraph(G1))
```

```
G2 := Graph::removeVertex(G1, [1]):
Graph::printGraphInformation(G2)
```

```
Vertices: [2, 3, 4, 5]
Edges: [[2, 3], [3, 4], [4, 5]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 2 = [3], 3 = [4], 4 = [5], 5 = []
Adjacency list (in): 2 = [], 3 = [2], 4 = [3], 5 = [4]
Graph is directed.
```

# Graph::removeVertex

---

```
plot(Graph::plotCircleGraph(G2))
```

If more than one vertex is to be removed they must also be specified in a list:

```
vertices := [2, 4]:
G3 := Graph::removeVertex(G1, vertices):
Graph::printGraphInformation(G3)
```

```
Vertices: [1, 3, 5]
Edges: [[5, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
```

```
Adjacency list (out): 1 = [], 2 = [], 3 = [], 5 = [1]
Adjacency list (in): 1 = [5], 2 = [], 3 = [], 5 = []
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G3))
```

## Parameters

**I**

A list of vertices

**v**

A vertex

**G**

A graph

# Graph::removeVertex

---

**Return  
Values**

Graph

**Purpose** Computes the residual graph

**Syntax** `Graph::residualGraph(G, f, <Extended>)`

**Description** `Graph::residualGraph(G, flow)` computes the residual of the graph `G` with respect to the flow `flow`, meaning the graph that remains when the flow `flow` is “subtracted” from `G`.

`Graph::residualGraph` computes the residual graph with respect to a given flow. A flow in a `Graph` is a table `tbl`, where `tbl[[i,j]]` gives the number of units flowing from vertex `i` to vertex `j`.

If the optional argument `Extended` is given, then also those edges with a zero residual capacity are considered, otherwise these edges are omitted.

## Examples

### Example 1

In the following call, `G2` is the graph consisting of the remaining transport capacities after a given flow:

```
G1 := Graph::createCompleteGraph(3):
G2 := Graph::residualGraph(G1,
 table([1, 2] = 1, [2, 1] = 1/2,
 [1, 3] = 0, [3, 1] = 0.5,
 [2, 3] = 1, [3, 2] = 0)):
Graph::getEdgeWeights(G2)
```

[2, 1]	$\frac{1}{2}$
[1, 3]	1
[3, 1]	0.5
[3, 2]	1

# Graph::residualGraph

The algorithm detects the lack of edge weights and edge costs and sets all edge weights and costs to default values of 1.

## Example 2

The resulting graph depends on whether the option `Extended` is used:

```
V := [1, 2, 3, q, s]:
Edge := [[q, 1], [1, 2], [1, 3], [2, 3], [3, s]]:
up := [5, 4, 4, 2, 5]:
G := Graph(V,Edge,EdgeWeights = up, Directed):
flow := table([q, 1] = 5, [3, s] = 5, [1, 2] = 1,
 [1, 3] = 4, [2, 3] = 1):
G1 := Graph::residualGraph(G, flow):
Graph::printGraphInformation(G1);
```

```
Vertices: [1, 2, 3, q, s]
Edges: [[2, 1], [3, 1], [3, 2], [s, 3], [1, q], [1, 2], [2, 3]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = 3, [2, 3] = 1, [2, 1] = 1, [3, 1] = 4, [3, 2]
have no weight)
Edge costs: [1, 2] = 1, [2, 3] = 1, [2, 1] = -3, [3, 1] = 0, [3, 2]
have costs zero)
Adjacency list (out): 1 = [2, q], 2 = [1, 3], 3 = [1, 2], q = [], s
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [2, s], q = [1], s
Graph is directed.
```

Edge Weights contain the residual graph with all the flows. Edge Costs show the flow that was subtracted or added. For example edge [1, 2] had weight 4. After a flow of 3 was sent over it, the residual edge [2, 1] contains the flow of -3 and the residual edge [1, 2] contains the flow of 1. Since the negative flow of the reverted edge plus the flow of the edge in the residual graph have to sum up to the flow it shows that the flow is calculated correctly.  $(- (-3) + 1 = 4)$

```
G1 := Graph::residualGraph(G, flow, Extended):
Graph::printGraphInformation(G1);
```

```
Vertices: [1, 2, 3, q, s]
Edges: [[2, 1], [3, 1], [3, 2], [s, 3], [1, q], [1, 2], [1, 3],
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [q, 1] = 5, [1, 2] = 4, [1, 3] = 4, [2, 3] = 2, [3, 1]
= -5, [1, q] = -5 (other existing edges have no weight)
Edge costs: [1, 2] = 3, [1, 3] = 0, [2, 3] = 1, [3, s] = 0, [q, 1]
[1, q] = 5 (other existing edges have costs zero)
Adjacency list (out): 1 = [2, 3, q], 2 = [1, 3], 3 = [1, 2, s],
Adjacency list (in): 1 = [2, 3, q], 2 = [1, 3], 3 = [1, 2, s], q
Graph is directed.
```

## Parameters

### **G**

Graph

### **flow**

The predefined flow

## Options

### **Extended**

Include edges with zero capacities

## Return Values

Graph

# Graph::revert

---

**Purpose** Reverts the edges of a graph.

**Syntax** `Graph::revert(G)`

**Description** `Graph::revert(G)` returns a graph in which all edges  $[u, v]$  and their properties belong to edges  $[v, u]$ .

`Graph::revert` overloads the system function `revert`.

## Examples **Example 1**

First, a circle graph is defined with some additional settings:

```
G1 := Graph::createCircleGraph(3):
G1 := Graph::setEdgeWeights(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeCosts(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeDescriptions(G1, [[1, 2]], ["Shortcut"]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut"
Edge weights: [1, 2] = 20 (other existing edges have no weight)
Edge costs: [1, 2] = 20 (other existing edges have costs zero)
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

Now we revert the graph:

```
G2 := revert(G1):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 3], [2, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: [2, 1] = "Shortcut"
Edge weights: [2, 1] = 20 (other existing edges have no weight)
Edge costs: [2, 1] = 20 (other existing edges have costs zero)
Adjacency list (out): 1 = [3], 2 = [1], 3 = [2]
Adjacency list (in): 1 = [2], 2 = [3], 3 = [1]
Graph is directed.
```

## Parameters

**G**

A graph

## Return Values

Graph

# Graph::setEdgeCosts

---

## Purpose

Assigns edge costs to edges.

## Syntax

```
Graph::setEdgeCosts(G, Edge, EdgeCosts,
<OnlySpecifiedEdges>)
```

## Description

Graph::setEdgeCosts(G, Edges, EdgeCosts) returns a graph where Edges have the edge costs EdgeCosts.

---

**Note** If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeCosts(G, [[u,v]], [1])` is invoked, only the edge  $[u, v]$  gets 1. The edge  $[v, u]$  will not be changed.

---

---

**Note** The substitute `None` can be used when a specified edge should not get the assigned costs.

---

## Examples

### Example 1

First lets define a graph without edge costs:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeCosts(G1)
```

FAIL

FAIL was returned, because no edge costs werde defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeCosts(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

```
-----|
[1, 2] | 5
[3, 1] | $\frac{1}{2}$
```

The first output shows all the edges and the second one the assigned edge costs.

```
G1 := Graph::setEdgeCosts(G1, [[2, 3]], [infinity]):
Graph::getEdgeCosts(G1)
```

```
-----|
[1, 2] | 5
[3, 1] | $\frac{1}{2}$
[2, 3] | ∞
```

It is easy to see that only the edge cost of [2,3] was changed.

## Example 2

First lets define a graph without edge costs:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeCosts(G1)
```

```
FAIL
```

FAIL was returned, because no edge costs werde defined.

```
Graph::getEdges(G1);
```

## Graph::setEdgeCosts

---

```
G2 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeCosts(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]		5
[2, 1]		5
[1, 3]		$\frac{1}{2}$
[3, 1]		$\frac{1}{2}$

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge costs. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2],
 OnlySpecifiedEdges):
Graph::getEdgeCosts(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]		5
[3, 1]		$\frac{1}{2}$

It is easy to see that only the specified edge costs were changed and not the reverted edges, too.

## Example 3

There exist also the possibility to set the costs via a table instead of a list.

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):
```

```
G2 := Graph::setEdgeCosts(G2, [[1, 2], [3, 1]], tbl):
Graph::getEdgeCosts(G2)
```

[1, 2]	15
[2, 1]	15
[1, 3]	20
[3, 1]	20

And again, but this time only the specified edges:

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):
```

```
G2 := Graph::setEdgeCosts(G2, [[1, 2], [3, 1]], tbl,
 OnlySpecifiedEdges):
Graph::getEdgeCosts(G2)
```

[1, 2]	15
[3, 1]	20

## Parameters

### G

A graph

### Edge

# Graph::setEdgeCosts

---

A list of one or more edges

## **EdgeCosts**

A list of one or more numbers, or a table consisting of the edges with their costs.

## **Options**

### **OnlySpecifiedEdges**

Only the edges specified in Edge will be set.

## **Return Values**

New graph with the corrected edge costs.

**Purpose** Assigns edge Descriptions to edges.

**Syntax** `Graph::setEdgeDescriptions(G, Edge, EdgeDescriptions, <OnlySpecifiedEdges>)`

**Description** `Graph::setEdgeDescriptions(G, Edges, EdgeDescriptions)` returns a graph where Edges have the edge descriptions EdgeDescriptions.

---

**Note** If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeDescriptions(G, [[u,v]], [1])` is invoked, only the edge  $[u, v]$  gets 1. The edge  $[v, u]$  will not be changed.

---

---

**Note** The substitute `None` can be used when a specified edge should not get the assigned description.

---

## Examples

### Example 1

First lets define a graph without edge descriptions:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeDescriptions(G1)
```

FAIL

FAIL was returned, because no edge descriptions werde defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeDescriptions(G1, [[1, 2],[3, 1]],
 ["Route 66", "Speedway"]):
```

# Graph::setEdgeDescriptions

---

```
Graph::getEdgeDescriptions(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

```

[1, 2] | "Route 66"
[3, 1] | "Speedway"
```

The first output shows all the edges and the second one the assigned edge descriptions.

```
G1 := Graph::setEdgeDescriptions(G1, [[2, 3]], ["Shortcut"]):
Graph::getEdgeDescriptions(G1)
```

```

[1, 2] | "Route 66"
[3, 1] | "Speedway"
[2, 3] | "Shortcut"
```

It is easy to see that only the edge description of [2,3] was changed.

## Example 2

First lets define a graph without edge Descriptions:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeDescriptions(G1)
```

```
FAIL
```

FAIL was returned, because no edge descriptions werde defined.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],
```

# Graph::setEdgeDescriptions

```
Graph::getEdgeDescriptions(G2) ["Route 66", "Speedway"]):
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]	"Route 66"
[2, 1]	"Route 66"
[1, 3]	"Speedway"
[3, 1]	"Speedway"

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge Descriptions. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],
 ["Route 66", "Speedway"],
 OnlySpecifiedEdges):
Graph::getEdgeDescriptions(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"

It is easy to see that only the specified edge Descriptions were changed and not the reverted edges, too.

# Graph::setEdgeDescriptions

---

## Example 3

There exist also the possibility to set the Descriptions via a table instead of a list.

```
tbl := table([1, 2] = "Highway", [1, 3] = "Road to nowhere");
G2 := Graph::createCompleteGraph(3):
Graph::getEdgeDescriptions(G2):
```

```
G2 := Graph::setEdgeDescriptions(G2, [[1, 2], [3, 1]], tbl):
Graph::getEdgeDescriptions(G2)
```

```

[1, 2] | "Highway"
[2, 1] | "Highway"
[1, 3] | "Road to nowhere"
[3, 1] | "Road to nowhere"
```

And again, but this time only the specified edges:

```
tbl := table([1, 2] = "Highway", [1, 3] = "Road to nowhere");
G2 := Graph::createCompleteGraph(3):
Graph::getEdgeDescriptions(G2):
G2 := Graph::setEdgeDescriptions(G2, [[1, 2], [3, 1]], tbl,
 OnlySpecifiedEdges):
Graph::getEdgeDescriptions(G2)
```

```

[1, 2] | "Highway"
[3, 1] | "Road to nowhere"
```

## Parameters **G**

A graph

## Edge

A list of one or more edges

## **EdgeDescriptions**

A list of one or more numbers, or a table consisting of the edges with their descriptions.

## **Options**

### **OnlySpecifiedEdges**

Only the edges specified in Edge will be set.

## **Return Values**

New graph with the corrected edge Descriptions.

# Graph::setEdgeWeights

---

**Purpose** Assigns edge weights to edges.

**Syntax** `Graph::setEdgeWeights(G, Edge, EdgeWeights, <OnlySpecifiedEdges>)`

**Description** `Graph::setEdgeWeights(G, Edges, EdgeWeights)` returns a graph where Edges have the edge weights EdgeWeights.

---

**Note** If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeWeights(G, [[u,v]], [1])` is invoked, only the edge  $[u, v]$  gets 1. The edge  $[v, u]$  will not be changed.

---

---

**Note** The substitute `None` can be used when a specified edge should not get the assigned weights.

---

## Examples

### Example 1

How to set edge weights with a list:

```
G1 := Graph::createCircleGraph(3):
Graph::getEdgeWeights(G1)
```

FAIL

FAIL was returned, because no edge weights were defined.

```
Graph::getEdges(G1);
G1 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeWeights(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

[1, 2]	5
[3, 1]	$\frac{1}{2}$

The first output shows all the edges and the second one the assigned edge weights.

```
G1 := Graph::setEdgeWeights(G1, [[2, 3]], [infinity]):
Graph::getEdgeWeights(G1)
```

[1, 2]	5
[3, 1]	$\frac{1}{2}$
[2, 3]	$\infty$

It is easy to see that only the edge weight of [2, 3] was changed.

## Example 2

How to set edge weights with a table:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeWeights(G1)
```

FAIL

FAIL was returned, because no edge weights were defined.

```
Graph::getEdges(G1);
```

# Graph::setEdgeWeights

---

```
G2 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeWeights(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]		5
[2, 1]		5
[1, 3]		$\frac{1}{2}$
[3, 1]		$\frac{1}{2}$

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge weights. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2],
 OnlySpecifiedEdges):
Graph::getEdgeWeights(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]		5
[3, 1]		$\frac{1}{2}$

It is easy to see that only the specified edge Weights were changed and not the reverted edges, too.

## Example 3

There exist also the possibility to set the weights via a table instead of a list.

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):
```

```
G2 := Graph::setEdgeWeights(G2, [[1, 2], [3, 1]], tbl):
Graph::getEdgeWeights(G2)
```

[1, 2]		15
[2, 1]		15
[1, 3]		20
[3, 1]		20

And again, but this time only the specified edges:

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):
```

```
G2 := Graph::setEdgeWeights(G2, [[1, 2], [3, 1]], tbl,
 OnlySpecifiedEdges):
Graph::getEdgeWeights(G2)
```

[1, 2]		15
[3, 1]		20

## Parameters

### G

A graph

### Edge

# Graph::setEdgeWeights

---

A list of one or more edges

## **EdgeWeights**

A list of one or more numbers, or a table consisting of the edges with their weights.

## **Options**

### **OnlySpecifiedEdges**

Only the edges specified in Edge will be set.

## **Return Values**

New graph with the corrected edge weights.

## Purpose

Assigns vertex weights to vertices.

## Syntax

```
Graph::setVertexWeights(G, Vertex, VertexWeights)
```

## Description

`Graph::setVertexWeights(G, Vertex, VertexWeights)` returns a graph where the vertices in `Vertex` have the vertex weights `VertexWeights`.

---

**Note** The substitute `None` can be used when a specified edge should not get the assigned weights.

---

## Examples

### Example 1

How to set vertex weights with a list:

```
G1 := Graph::createCircleGraph(3):
Graph::getVertexWeights(G1)
```

FAIL

FAIL was returned, because no vertex weights were defined.

```
Graph::getVertices(G1);
G1 := Graph::setVertexWeights(G1, [1, 3], [5, 1/2]):
Graph::getVertexWeights(G1)
```

[1, 2, 3]

	5
1	
3	
	$\frac{1}{2}$

# Graph::setVertexWeights

---

The first output shows all vertices and the second the assigned vertex weights.

## Example 2

How to set vertex weights with a table:

```
G1 := Graph::createCompleteGraph(3):
Graph::getVertexWeights(G1)
```

FAIL

FAIL was returned, because no vertex weights were defined.

```
G2 := Graph::createCompleteGraph(3):
tbl := table(1 = 15, 3 = 20):
G2 := Graph::setVertexWeights(G2, [1, 3], tbl):
Graph::getVertexWeights(G2)
```

```
1 | 15
3 | 20
```

## Parameters

### G

A graph

### Vertex

A list of one or more vertices

### VertexWeights

A list of one or more numbers, or a table consisting of the vertices with their weights.

## Return Values

New graph with the corrected vertex weights.

## Purpose

Shortest paths from and to all vertices

## Syntax

```
Graph::shortestPathAllPairs(G, <SearchFor =
Weights | Costs>)
```

## Description

`Graph::shortestPathAllPairs(G)` returns a table with all paths between all vertices.

`Graph::shortestPathAllPairs(G, SearchFor=Costs)` returns a table with all paths according to the edge costs.

`Graph::shortestPathAllPairs(G, SearchFor=Weights)` returns a table with all paths according to the edge weights. (Default)

## Examples

### Example 1

A small graph to be used for the algorithms:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
 EdgeWeights = [2, 1, 3, 2],
 EdgeCosts = [1, 3, 1, 2],
 Directed):
```

Now the shortest path between all vertices is found according to the edge weights, because no specification was given and defaults are used.

```
Graph::shortestPathAllPairs(G)
```

# Graph::shortestPathAllPairs

a, a	0		
a, b	2		
b, a	$\infty$	a, b	a
a, c	1	b, a	$\infty$
b, b	0	a, c	a
c, a	$\infty$	c, a	$\infty$
a, d	3	a, d	c
b, c	3	b, c	b
c, b	$\infty$	c, b	$\infty$
d, a	$\infty$	d, a	$\infty$
b, d	5	b, d	c
c, c	0	d, b	$\infty$
d, b	$\infty$	c, d	c
c, d	2	d, c	$\infty$
d, c	$\infty$		
d, d	0		

The interpretation of the table is as follows:

The first table holds each path: (FromVertex, ToVertex) = weight/cost. The second table is a bit more tricky. The left hand side again is the path itself. On the right hand side though, the vertex that was found before the final vertex was reached is stated. If for example the path from a to d is to be found with all vertices that are used within this path it is done in the following way: First take the path itself (a, d). The predecessor is c. Now have a look for the path (a, c). It's predecessor is a. Since the predecessor equals the first vertex in the path to be found, the search is over and the path a -> c -> d is found. To search the graph for costs the option SearchFor=Costs has to be added.

**Graph::shortestPathAllPairs(G, SearchFor = Costs)**

<i>a, a</i>	0		
<i>a, b</i>	1		
<i>b, a</i>	$\infty$	<i>a, b</i>	<i>a</i>
<i>a, c</i>	2	<i>b, a</i>	$\infty$
<i>b, b</i>	0	<i>a, c</i>	<i>b</i>
<i>c, a</i>	$\infty$	<i>c, a</i>	$\infty$
<i>a, d</i>	4	<i>a, d</i>	<i>c</i>
<i>b, c</i>	1	<i>b, c</i>	<i>b</i>
<i>c, b</i>	$\infty$	<i>c, b</i>	$\infty$
<i>d, a</i>	$\infty$	<i>d, a</i>	$\infty$
<i>b, d</i>	3	<i>b, d</i>	<i>c</i>
<i>c, c</i>	0	<i>d, b</i>	$\infty$
<i>d, b</i>	$\infty$	<i>c, d</i>	<i>c</i>
<i>c, d</i>	2	<i>d, c</i>	$\infty$
<i>d, c</i>	$\infty$		
<i>d, d</i>	0		

## Example 2

Now the weights of the graph are changed, so that negative edge weights are assigned. You will see that this does not influence the correctness of the results the algorithm returns (like for example Dijkstra).

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
 EdgeWeights = [2, 1, 3, 2],
 EdgeCosts = [1, 3, 1, 2],
 Directed):
```

```
G := Graph::setEdgeWeights(G, Graph::getEdges(G), [2, 1, -3, 2])
```

```
Graph::shortestPathAllPairs(G)
```

# Graph::shortestPathAllPairs

---

<i>a, a</i>	0		
<i>a, b</i>	2		
<i>b, a</i>	$\infty$	<i>a, b</i>	<i>a</i>
<i>a, c</i>	-1	<i>b, a</i>	$\infty$
<i>b, b</i>	0	<i>a, c</i>	<i>b</i>
<i>c, a</i>	$\infty$	<i>c, a</i>	$\infty$
<i>a, d</i>	1	<i>a, d</i>	<i>c</i>
<i>b, c</i>	-3	<i>b, c</i>	<i>b</i>
<i>c, b</i>	$\infty$	<i>c, b</i>	$\infty$
<i>d, a</i>	$\infty$	<i>d, a</i>	$\infty$
<i>b, d</i>	-1	<i>b, d</i>	<i>c</i>
<i>c, c</i>	0	<i>d, b</i>	$\infty$
<i>d, b</i>	$\infty$	<i>c, d</i>	<i>c</i>
<i>c, d</i>	2	<i>d, c</i>	$\infty$
<i>d, c</i>	$\infty$		
<i>d, d</i>	0		

## Parameters **G**

Graph

## Options **SearchFor**

Defines whether the weights of the graph are considered or the costs. Default is Weights.

## Return Values

List consisting of two tables. The first table holds the sum of the path weights or costs and the second the predecessors for every path (to find the complete path).

## Algorithms

The algorithm is also known as Floyd-Warshall or Roy-Warshall algorithm. The idea behind it is to solve the problem by continuous matrix multiplication. The only difference is that Floyd uses the assignment  $a_{i,j} := \min(a_{i,j}, a_{i,k} + a_{k,j})$ .

# Graph::shortestPathSingleSource

---

**Purpose** Shortest paths from one single vertex

**Syntax** `Graph::shortestPathSingleSource(G, StartVertex, <EndVertex = v>, <SearchWith = Dijkstra | Bellman>, <SearchFor = Weights | Costs>, <ReturnAsGraph>)`

**Description** `Graph::shortestPathSingleSource(G, StartVertex=vertex)` gives the length of a shortest path from `StartVertex` to every other vertex in `G`.

`Graph::shortestPathSingleSource(G, StartVertex=sv)` returns a table with all paths from `sv` to any other.

`Graph::shortestPathSingleSource(G, StartVertex=sv, ReturnAsGraph)` returns a table with all paths from `sv` to any other because `EndVertex` has to be set in order to get a `Graph` as return value.

With `Graph::shortestPathSingleSource(G, StartVertex=sv, EndVertex=ev, SearchWith=Dijkstra, SearchFor=Costs)` returns a table from vertex `sv` to vertex `ev` according to Dijkstra which used the edge-costs for its algorithm.

---

**Note** Using Dijkstra for shortest path can be erroneous if the graph contains negative edges.

---

---

**Note** If `ReturnAsGraph` is stated and `EndVertex` omitted, a table is returned nevertheless.

---

## Examples

### Example 1

A small graph to be used for the algorithms:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
 EdgeWeights = [2, 1, 3, 2],
```

```
EdgeCosts = [1, 3, 1, 2], Directed):
```

Now the shortest path is found according to Bellman using edge weights, because no specification was given and defaults are used:

```
Graph::shortestPathSingleSource(G, StartVertex = [a])
```

a	0	b	a
b	2	c	a
c	1	d	c
d	3		

To search the graph with Bellman for costs the option SearchFor=Costs has to be added:

```
Graph::shortestPathSingleSource(G, StartVertex = [a],
 SearchFor=Costs)
```

a	0	b	a
b	1	c	b
c	2	d	c
d	4		

## Example 2

Now the weights of the graph are changed, so that negative edge weights are assigned. After this the procedure is called again with Bellman and afterwards with Dijkstra to compare the results:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
 EdgeWeights = [2, 1, 3, 2],
 EdgeCosts = [1, 3, 1, 2], Directed):
```

```
G := Graph::setEdgeWeights(G, Graph::getEdges(G),
 [2, 1, -3, 2]):
```

# Graph::shortestPathSingleSource

```
Graph::shortestPathSingleSource(G, StartVertex = [a],
 SearchWith = Bellman),
Graph::shortestPathSingleSource(G, StartVertex = [a],
 SearchWith = Dijkstra)
```

$$\left[ \begin{array}{c|c} a & 0 \\ b & 2 \\ c & -1 \\ d & 1 \end{array} , \begin{array}{c|c} b & a \\ c & b \\ d & c \end{array} \right], \left[ \begin{array}{c|c} a & 0 \\ b & 2 \\ c & -1 \\ d & 3 \end{array} , \begin{array}{c|c} b & a \\ c & b \\ d & c \end{array} \right]$$

This is a typical example where Dijkstra can make a mistake because he does not correct earlier solutions (a so called greedy strategy). Although vertex c gets the correct value -1, at the time d got the value 3, vertex c still held the value 1. This happens because Dijkstra first searches the best solutions (a->c = 1) then traverses further (c->d = 1 + 2 = 3). In spite of changing the value of vertex c the value for d is never to be changed again (because no other path ever reaches it again):

It might be interesting to see a shortest path inside the graph. Here are two steps that accomplish this task:

Fist step (creation of a shortest path graph [in this case with Dijkstra]):

```
dijk := Graph::shortestPathSingleSource(G, StartVertex = [a],
 EndVertex = [d],
 SearchWith = Dijkstra,
 ReturnAsGraph):
```

Second step (combination of the graphs using plotGridGraph):

```
plot(Graph::plotGridGraph(G, VerticesPerLine = 4,
 VertexOrder = [None, b, None, d, a, None, c, None],
 VertexColor = RGB::Red,
 SpecialEdges = Graph::getEdges(dijk),
 SpecialEdgeColor = RGB::Blue))
```

# Graph::shortestPathSingleSource

The same with Bellman to show the differences:

First step (creation of a shortest path graph [in this case with Dijkstra]):

```
bellm := Graph::shortestPathSingleSource(G, StartVertex = [a],
 EndVertex = [d],
 SearchWith = Bellman,
 ReturnAsGraph):
```

Second step (combination of the graphs using plotGridGraph):

```
plot(Graph::plotGridGraph(G, VerticesPerLine = 4,
 VertexOrder = [None, b, None, d, a, None, c, None],
 VertexColor = RGB::Red,
 SpecialEdges = Graph::getEdges(bellm),
 SpecialEdgeColor = RGB::Blue))
```

# Graph::shortestPathSingleSource

---

## Parameters

### **G**

Graph

### **vertex**

A vertex in G

## Options

### **EndVertex**

Specifies a single vertex to which the shortest path is to be found.

### **SearchWith**

Defines the algorithm to use. Dijkstra can be erroneous if the graph consists of negative edges. Default is Bellman

### **SearchFor**

Defines whether the weights of the graph are considered or the costs. Default is Weights.

## **ReturnAsGraph**

If stated and EndVertex is set, the path is returned as a Graph. If stated and EndVertex is not set, this option is omitted.

## **Return Values**

Either a list consisting of two tables or a Graph. The first table holds the weights or cost for each vertex and the second the predecessors for every vertex (to find the path)

## **Algorithms**

Both, Bellman and Dijkstra expect a Graph without negative circles. Only Dijkstra may return erroneous results when negative edges (either weights or costs) are specified.

The Bellman algorithm originated from: Ahuja, Magnanti, Orlin: Graph Flows, Prentice-Hall, 1993 Section 5.4

# Graph::stronglyConnectedComponents

---

**Purpose** Finds the strongly connected components

**Syntax** Graph::stronglyConnectedComponents(G)

**Description** Graph::stronglyConnectedComponents(G) finds the strongly connected components of G  
Graph::stronglyConnectedComponents returns all the strongly connected components of a graph. Single vertices form a component of themselves.

## **Examples** **Example 1**

Two obvious components pointing to a single vertex:

```
G1 := Graph([a, b, c, d, e, f, g],
 [[a, b], [b, g], [g, a], [b, c],
 [d, c], [e, d], [d, f], [f, e]], Directed):

plot(Graph::plotGridGraph(G1,
 VertexOrder = [a, None, None, None, e,
 None, b, c, d, None,
 g, None, None, None, f],
 VerticesPerLine=5))
```

# Graph::stronglyConnectedComponents

The graphical output reveals the two "big" components [a, b, g] and [d, e, f]. The single vertex [c] forms a component of itself:

```
G2 := Graph::stronglyConnectedComponents(G1)
```

```
[Graph(...), Graph(...), Graph(...)]
```

A list containing three Graphs is returned. Now we find out which vertices belong to each component:

```
Graph::getVertices(op(G2, 1))
```

```
[d, e, f]
```

```
Graph::getVertices(op(G2, 2))
```

# Graph::stronglyConnectedComponents

---

`[a, b, g]`

```
Graph::getVertices(op(G2, 3))
```

`[c]`

## Example 2

A complete graph is returned as a single component:

```
G3 := Graph::createCompleteGraph(5):
plot(Graph::plotCircleGraph(G3))
```

```
G4 := Graph::stronglyConnectedComponents(G3):
plot(Graph::plotCircleGraph(op(G4)))
```

# Graph::stronglyConnectedComponents

---

It was necessary to use `op(G4)`, because `G4` is a list containing a graph!

## Parameters

**G**

A graph

## Return Values

List of graphs containing the strongly connected components.

# Graph::topSort

---

**Purpose** Topological sorting of the vertices

**Syntax** Graph::topSort(G)

**Description** Graph::topSort(G) computes a topological sorting of the graph G, i.e., a numbering  $T$  of the vertices, such that  $T_i < T_j$  whenever there is an edge  $[i, j]$  in the graph. Single vertices are positioned at the beginning.

Graph::topSort returns a list containing two tables. The first table holds the ordering of the vertices. The second table shows the predecessors of each vertex. If several vertex  $u_i$  precede a vertex  $v$ , the first vertex in the ordering of  $u_i$  is the predecessor of  $v$ . If no predecessor exist, the value will be *infinity*.

---

**Note** If G contains any cycle then a topological sorting does not exist and the call of Graph::topSort results in an error.

---

## Examples

### Example 1

A "butterfly" graph that is decomposed in three strongly connected components:

```
G1 := Graph([a, b, c, d, e, f],
 [[a, b], [a, c], [a, d], [c, e], [d, e]],
 Directed):
Graph::topSort(G1)
```

1	f	a	a
2	a	b	a
3	b,	c	a
4	c	d	a
5	d	e	c
6	e	f	∞

The first table shows the ordering of the vertices. The left side holds the order for each vertex, whereas the right side holds the name of the vertex. The second table shows the predecessors of each vertex. If no predecessor exist, the right side holds *infinity*. Otherwise the right side holds the vertex that is the direct predecessor of the vertex on the left side. To see how the graph looks a graphical plotting helps:

```
plot(Graph::plotGridGraph(G1,
 VertexOrder = [None, b, f,
 a, c, None,
 None, None, e,
 None, d, None],
 VerticesPerLine=3))
```

## Parameters

**G**

A graph

# Graph::topSort

---

## **Return Values**

List containing two tables.

# groebner – Gröbner bases

---

groebner::dimension  
groebner::eliminate  
groebner::gbasis  
groebner::normalf  
groebner::spoly  
groebner::stronglyIndependentSets

# groebner::dimension

---

**Purpose** Dimension of the affine variety generated by polynomials

**Syntax** `groebner::dimension(polys, <order>)`

**Description** `groebner::dimension(polys)` computes the dimension of the affine variety generated by the polynomials in the set or list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type. In particular, do not mix polynomials created via `poly` and polynomial expressions!

## **Examples** **Example 1**

An example from the book of Cox, Little and O'Shea (see below):

```
groebner::dimension([y^2*z^3, x^5*z^4, x^2*y*z^2])
```

2

## **Parameters** **polys**

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions.

## **order**

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom: MonomOrdering`. The default ordering is `DegInvLexOrder`.

**Return Values** Nonnegative integer

## Algorithms

First, the Gröbner basis of the given polynomials with respect to the given monomial ordering is computed using `groebner::gbasis`. This Gröbner basis is then used to compute the dimension of the affine variety generated by the polynomials.

## References

The implemented algorithm is described in Cox, Little, O’Shea: “Ideals, Varieties and Algorithms”, Springer, 1992, Chapter 9.

## See Also

## MuPAD Functions

`groebner::gbasis` | `poly`

# groebner::eliminate

---

**Purpose** Eliminate variables

**Syntax** `groebner::eliminate(sys, vars)`

**Description** `groebner::eliminate(sys, vars)` returns a list of polynomial expressions obtained by eliminating the elements of `vars` from `sys`. In other words, the return value does not contain the variables in `vars`, every zero of the original system `sys` must be a zero of the return value, and every tuple of numbers that makes the return value zero can be extended to a solution of `sys`.

## Examples **Example 1**

Suppose that  $x^2 + y = 0$  and  $x + y = 0$ , what does this imply for  $y$ ?

```
groebner::eliminate({x^2 +y, y+x}, {x})
```

```
[y^2 + y]
```

We infer that for every pair  $(x, y)$  solving the system,  $y$  must satisfy  $y^2 + y = 0$ , that is,  $y = 0$  or  $y = -1$ . Indeed:

```
solve({x^2 +y, y+x}, {x, y})
```

```
{[x = 0, y = 0], [x = 1, y = -1]}
```

**Parameters** **sys**

A set or list of polynomial expressions. The coefficients in these polynomial expressions can be arbitrary arithmetical expressions.

**vars**

A set or list of identifiers

**Return Values**

List of polynomial expressions

**Algorithms**

`groebner::eliminate` proceeds by computing a lexical-order Gröbner basis. Hence the computation complexity grows fast when increasing the number of variables.

**See Also****MuPAD Functions**

`groebner::gbasis`

# groebner::gbasis

---

<b>Purpose</b>	Computation of a reduced Gröbner basis
<b>Syntax</b>	<code>groebner::gbasis(polys, &lt;order&gt;, options)</code>
<b>Description</b>	<p><code>groebner::gbasis(polys)</code> computes a reduced Gröbner basis of the ideal generated by the polynomials in the list <code>polys</code>.</p> <p>The rules laid down in the introduction to the <code>groebner</code> package concerning the polynomial types and the ordering apply.</p> <p>The polynomials in the list <code>polys</code> must all be of the same type. In particular, do not mix polynomials created via <code>poly</code> and polynomial expressions!</p> <p>The ordering strategy indicated by <code>Reorder</code> is used automatically when polynomial expressions are used.</p>

## Examples

### Example 1

We demonstrate the effect of various input formats. First, we use polynomial expressions to define the polynomial ideal. The Gröbner basis is returned as a list of polynomial expressions:

```
groebner::gbasis([x^2 - y^2, x^2 + y], LexOrder)
```

```
[x^2 + y, x^4 - x^2]
```

Next, the same polynomials are defined via `poly`. Note that `poly` fixes the ordering of the variables.

```
groebner::gbasis([poly(x^2 - y^2, [x, y]),
 poly(x^2 + y, [x, y])], LexOrder)
```

```
[poly(x^2 + y, [x, y]), poly(y^2 + y, [x, y])]
```

Changing the ordering of the variables in `poly` changes the lexicographical ordering. This results in a different basis:

```
groebner::gbasis([poly(x^2 - y^2, [y, x]),
 poly(x^2 + y, [y, x])], LexOrder)
```

$$\left[ \text{poly}(y + x^2, [y, x]), \text{poly}(x^4 - x^2, [y, x]) \right]$$

With `Reorder` the ordering of the variables may be changed internally:

```
groebner::gbasis([poly(x^2 - y^2, [x, y]),
 poly(x^2 + y, [x, y])], LexOrder, Reorder)
```

$$\left[ \text{poly}(y + x^2, [y, x]), \text{poly}(x^4 - x^2, [y, x]) \right]$$

## Example 2

Polynomials over arbitrary fields are allowed. In particular, you can use the field of rational functions in some given variable(s):

```
F := Dom::Fraction(Dom::DistributedPolynomial([y])):
F::Name := "Q(y)":
groebner::gbasis(
[poly(y*z^2 + 1, [x, z], F),
 poly((y^2 + 1)*x^2 - y - z^3, [x, z], F)])
```

$$\left[ \text{poly}\left(x^2 + \frac{z}{y + y^3} - \frac{y}{y^2 + 1}, [x, z], \text{Q}(y)\right), \text{poly}\left(z^2 + \frac{1}{y}, [x, z], \text{Q}(y)\right) \right]$$

```
delete F:
```

**Parameters**    `polys`

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions. If `polys` are polynomials over an arbitrary domain, then their coefficients must be domain elements and the domain must be a field.

## **order**

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

## **Options**

### **Factor**

With this option, `groebner::gbasis` returns a set of lists, such that each list is the Gröbner basis of an ideal. The union of these ideals is a superset of the ideal given as input, and a subset of the radical of that ideal. In other words, it has the same variety (only the multiplicity of points can change).

### **IgnoreSpecialCases**

With this option, `groebner::gbasis` handles all coefficients in all intermediate results as nonzero unless these coefficients are equal to zero for all parameter values. In other words, if the coefficients are rational functions of the free parameters, then results are correct on all of the parameter space except on an algebraic variety of lower dimension.

### **Reorder**

With this option `groebner::gbasis` internally may change the lexicographical ordering of variables to decrease running time.

With this option the variables are sorted internally such that they have a “heuristic optimal” ordering. Consequently, the ordering of the variables in the output polynomials may differ from their ordering in the input polynomials. For details on the ordering strategy, see W. Boege, R. Gebauer und H. Kredel: “Some Examples for Solving Systems of Algebraic Equations by

Calculating Groebner Bases” im J. Symbolic Comp. (1986) Vol. 1, 83-98.

Re-ordering is always applied when polynomial expressions are used for input.

## Monic

Option, specified as `Monic = N`

This option sets the normalizing routine to `N`. For every polynomial `f` in the polynomial ring, `N(f, o)` must return some associate of `f`, where `o` is the chosen order.

The method `N` should be chosen such that it produces simple output.

By default, `polylib::primpart` is used for polynomials with integer coefficients; other polynomials are divided by their leading coefficient.

## Order

Option, specified as `Order = order`

This option is equivalent to passing `order` as an argument.

## Return Values

List of polynomials. The output polynomials have the same type as the polynomials of the input list.

## Algorithms

In most cases, `groebner::gbasis` computes the basis via the Buchberger algorithm with the “sugar” selection strategy being used.

## References

For general information, see T. Becker and V. Weispfenning: “Gröbner Bases”, Springer (1993). For details on the sugar selection strategy, see A. Giovini, T. Mora, G. Niesi, L. Robbiano, C. Traverso: “One sugar cube, please — or Selection strategies in the Buchberger algorithm”, Proc. ISSAC '91, Bonn, 49-54 (1991).

# groebner::gbasis

---

## See Also

**MuPAD**      poly  
**Functions**

**Purpose** Complete reduction modulo a polynomial ideal

**Syntax** `groebner::normalf(p, polys, <order>)`

**Description** `groebner::normalf(p, polys)` computes a normal form of the polynomial `p` by complete reduction modulo all polynomials in the list `polys`.

The rules laid down in the introduction to the `groebner` package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type as `p`. In particular, do not mix polynomials created via `poly` and polynomial expressions.

## Examples **Example 1**

We consider the ideal generated by the following polynomials:

```
p1 := poly(x^2 - x + 2*y^2, [x,y]):
p2 := poly(x + 2*y - 1, [x,y]):
```

We compute the normal form of the following polynomial `p` modulo the ideal generated by `p1`, `p2` with respect to lexicographical ordering:

```
p := poly(x^2*y - 2*x*y + 1, [x,y]):
groebner::normalf(p, [p1, p2], LexOrder);
```

```
poly(-2 y^3 + 2 y^2 - y + 1, [x, y])
```

Note that `p1`, `p2` do not form a Gröbner basis. The corresponding Gröbner basis leads to a different normal form of `p`:

```
groebner::normalf(p, groebner::gbasis([p1, p2]), LexOrder)
```

# groebner::normalf

---

$$\text{poly}\left(-\frac{5y}{9} + 1, [x, y]\right)$$

delete p1, p2, p:

## Parameters

**p**

A polynomial or a polynomial expression. The coefficients in this polynomial and polynomial expression can be arbitrary arithmetical expressions.

**polys**

A list of polynomials of the same type as p. In particular, if p is a polynomial expression, polys must be a list of polynomial expressions.

**order**

One of the identifiers DegInvLexOrder, DegreeOrder, and LexOrder, or a user-defined term ordering of type Dom: MonomOrdering. The default ordering is DegInvLexOrder.

## Return Values

Polynomial of the same type as the input polynomials. If polynomial expressions are used as input, then a polynomial expression is returned.

## Algorithms

A polynomial  $g$  is a reduced form of a polynomial  $p$  modulo a list of polynomials  $p_1, \dots, p_n$ , if  $g \equiv p$  and none of the leading terms of the  $p_i$  divides the leading term of  $p$ , or if — for some  $i$  —  $g$  is a reduced form of  $p - qp_i$ , where  $q$  is the quotient of the leading monomial of  $p$  and the leading monomial of  $p_i$ . A reduced form always exists, but need not be unique. It is unique, if the  $p_i$  form a Gröbner basis.

In the implementation of `groebner::normalf`, reduction modulo some  $p_i$  of largest possible total degree is preferred, if reduction modulo several  $p_i$  is possible.

## MuPAD Functions

`groebner::gbasis` | `poly`

# groebner::spoly

---

**Purpose** The S-polynomial of two polynomials

**Syntax** `groebner::spoly(p1, p2, <order>)`

**Description** `groebner::spoly(p1, p2)` computes the S-polynomial of the polynomials p<sub>1</sub> and p<sub>2</sub>.

The rules laid down in the introduction to groebner concerning the polynomial types and the ordering apply.

The polynomials must be of the same type. In particular, do not mix polynomials created via `poly` and polynomial expressions!

## Examples **Example 1**

The polynomials

```
p1 := poly(x^2 - x + 2*y^2, [x, y]):
p2 := poly(x + 2*y - 1, [x, y]):
```

generate the following S-polynomial with respect to lexicographical ordering:

```
groebner::spoly(p1, p2, LexOrder)
```

```
poly(-2 x y + 2 y^2, [x, y])
```

```
delete p1, p2:
```

## Parameters **P<sub>1</sub>, P<sub>2</sub>**

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions.

**order**

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

### Return Values

Polynomial of the same type as the input polynomials. If polynomial expressions are used as input, then a polynomial expression is returned.

### Algorithms

The S-polynomial of two polynomials  $p_1, p_2$  is defined to be

$$\frac{\text{lcm}(\text{lterm}(p_1), \text{lterm}(p_2))}{\text{lmonomial}(p_1)} p_1 - \frac{\text{lcm}(\text{lterm}(p_1), \text{lterm}(p_2))}{\text{lmonomial}(p_2)} p_2$$

where `lterm` and `lmonomial` are used in the same sense as the MuPAD functions of the same name. This formula is constructed such that the leading terms of the two summands cancel.

`poly`

# groebner::stronglyIndependentSets

---

**Purpose** Strongly independent set of variables

**Syntax** `groebner::stronglyIndependentSets(G)`

**Description** `groebner::stronglyIndependentSets(G)` computes a strongly independent set of variables modulo the ideal generated by  $G$ .

A set of variables  $S$  is strongly independent modulo an ideal  $I$  if no leading term of an element of the Gröbner basis of  $I$  consists entirely of elements of  $S$ . A set is maximally strongly independent if no proper superset of it is strongly independent. Two maximally strongly independent set may be of different size.

`groebner::stronglyIndependentSets` accepts Gröbner bases in the format returned by `groebner::gbasis`.

## Examples

### Example 1

The following example has been given by Moeller and Mora in 1983.

```
G:=map([X0^8*X2, X0*X3, X1^8*X3, X1^7*X3^2, X1^6*X3^3,
 X1^5*X3^4, X1^4*X3^5, X1^3*X3^6, X1^2*X3^7, X1*X3^8],
 poly, [X3, X2, X1, X0]):
groebner::stronglyIndependentSets(G)
```

```
[2, {X0, X1}, {{X2, X3}, {X0, X1}, {X1, X2}}]
```

```
delete G:
```

**Parameters** **G**

The Gröbner basis of an ideal: a list.

## Return Values

List of the form  $[d, S, M]$ , where  $d$  is an integer equal to the dimension of the ideal generated by  $G$ ,  $S$  is the greatest strongly independent set of variables, and  $M$  is a set consisting of all maximal strongly independent sets of variables or a piecewise consisting of such lists.

`groebner::gbasis`

# groebner::stronglyIndependentSets

---

# import – Import Data

---

```
import::csv
import::readbitmap
import::readdata
import::readlisp
```

# import::csv

---

**Purpose** Read CSV data from an ASCII file

**Syntax** `import::csv(filename, <separator>, <NonNested>, <Trim>, <DecimalComma>)`  
`import::csv(n, <separator>, <NonNested>, <Trim>, <DecimalComma>)`

**Description** `import::csv` is used to read CSV (“Comma Separated Values” or “Character Separated Values”) data files produced by external programs, like Microsoft Excel<sup>®</sup>. CSV is an ASCII based tabular data file format, formally defined in RfC 4180, that has fields separated by the comma character.

---

**Note** Some localized versions of Microsoft Excel use semicolons instead of commas! Set the parameter `separator` to change the default separator.

---

`import::csv(filename)` reads the data in the file `filename`. File data separated by a comma are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::csv(filename, separator)` reads the data in the file `filename`. File data separated by the character `separator` are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::csv(filename, separator, NonNested)` reads the data in the file `filename` as a single data record. File data separated by the character `separator` are regarded as different data elements. The result is a plain non-nested list containing the data of all lines of the file.

In contrast to `finput`, the data must not be ended by a colon or semicolon. Data separated by `separator` are interpreted as single data items. The default separator is a comma.

Empty lines are ignored.

All data elements in the file that cannot be converted to valid MuPAD numbers are imported as MuPAD strings.

`import::csv` tries to convert a number contained in the CSV file to a valid MuPAD number. For example: 1,234.56 or 1 234.56 are converted to the MuPAD number 1234.56. Many countries use a comma to separate the integral and fractional part instead of the dot used in England and the US. For example: 1234,56 or 1.234,56 are converted to 1234.56. `import::csv` expects this number format if the option `DecimalComma` is given.

---

**Note** A comma as CSV separator doesn't make sense if the comma is used to separate thousands in a number or the decimal comma is used. In most cases, the CSV file uses a semicolon to separate data. So, a semicolon should be used as separator.

---

---

**Note** All numbers contained in the CSV file must use the same radix separator, mixed formats cannot be converted.

---

With `NonNested`, the result will be a list containing all data. Otherwise, the result is a list of list, each "inner" list representing a line of the CSV file.

With `Trim`, leading and trailing blanks in strings are removed.

If the file is specified by a string, the corresponding file is opened and closed, automatically. If the user has opened a text file in `Read` mode and passes the file descriptor to `import::readdata`, the file remains open and needs to be closed by the user.

Files compressed with `gzip` or in a compatible format, whose names end in ".gz", are automatically decompressed while being read by `import::csv`.

`import::csv(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the “working directory”.
- Last, the file name is concatenated to each directory given by the environment variable `LIBPATH`.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

A path separator (“/”) is inserted as necessary when concatenating a given path and `filename`.

If a file is specified by a file name, there is no need to open or close the file via `fopen` and `fclose`, respectively. This is done automatically by `import::readdata`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. Note that the file must have been opened in `Read` mode by `fopen`. If a file descriptor is used, the corresponding file is not closed automatically but must be closed by the user via `fclose`.

## Examples

### Example 1

We wish to read CSV data into a MuPAD session. Assume that the file “`datafile.csv`” contains the following two columns of ASCII data:

```
a ,12.5
a-b ,1234.56
```

`import::csv` returns the following list representing the data in the file:

```
data := import::csv("datafile.csv")
```

```
[["a ", 12.5], [" a-b ", 1234.56]]
```

```
data := import::csv("datafile.csv", Trim)
```

```
[["a", 12.5], ["a-b", 1234.56]]
```

```
data := import::csv("datafile.csv", NonNested)
```

```
["a ", 12.5, " a-b ", 1234.56]
```

## Example 2

Let us assume that the file “datafile.csv” contains the following ASCII data:

```
a ;12.5
a-b;1,234.56
a b; -12345.6789E-02
```

We specify the data separator ";" for reading the data:

```
import::csv("datafile.csv", ";")
```

```
[["a ", 12.5], ["a-b", 1234.56], ["a b", - 123.456789]]
```

## Example 3

Let us assume that the file “datafile.csv” contains the following ASCII data:

```
abc;12,5
a-b;1.234,56
a b; -12345.6789E-02
```

We specify the data separator ";" and the option `DecimalComma` for reading the data:

```
import::csv("datafile.csv", ";", DecimalComma)

[["a ", 12.5], ["a-b", 1234.56], ["a b", -123.456789]]
```

## Parameters

### filename

The file name: a non-empty character string

### n

A file descriptor provided by `fopen`: a positive integer

### separator

The separator between data elements: a character string of length 1 (a single character). The default separator is a comma (the single character string ",").

## Options

### NonNested

Return all file data as a single data record in a non-nested list. The data of all lines are ordered sequentially in this list.

### Trim

Leading and trailing blanks in strings are removed.

## **DecimalComma**

A decimal comma instead of a decimal point is used as the radix separator in the CSV file.

## **Return Values**

Nested list of lists. The sublists contain the data of the individual lines. With the option `NonNested`, a plain list containing all data elements from every line in the file.

## **See Also**

## **MuPAD Functions**

FILEPATH | fopen | import::readdata | LIBPATH | readbytes  
| READPATH

# import::readbitmap

---

**Purpose** Read bitmap data

**Syntax** `import::readbitmap(filename, <ReturnType = DOM_HFARRAY  
| DOM_ARRAY | DOM_LIST>)`

**Description** `import::readbitmap` is used for reading ASCII or binary data files storing bitmap images of pictures. The following standard graphical formats can be read: BMP, DCX, DDS, WAD, GIF, ICO, JPG, LIF, MDL, PCD, PCX, PIC, PIX, PNG, PNM, PSD, PSP, PXR, RAW, SGI, TGA, TIF, WAL, XPM. The format of the pixel data is determined automatically from the contents of the file. The return value [w, h, colordata] provides the pixel height h, the pixel width w, and the color data of the bitmap image.

Either the complete return value or just the third element, `colordata`, can be passed to the function `plot::Raster` to generate a plot object that can be used in a MuPAD graphics. E.g., the command

```
plot(plot::Raster(import::readbitmap("mypicture.jpeg")))
```

creates a MuPAD graphics of the bitmap stored in the JPG file "mypicture.jpeg".

---

**Note** Most of the standard graphical formats store the pixel data row by row in the usual reading order starting with the upper left corner of the image. The pixel data in the returned array `colordata` (if requesting `ReturnType = DOM_ARRAY`), however, are to be interpreted as follows:

`colordata[1, 1]` is the RGB color of the lower left corner.

`colordata[h, 1]` is the RGB color of the upper left corner.

`colordata[1, w]` is the RGB color of the lower right corner.

`colordata[h, w]` is the RGB color of the upper right corner.

The interpretation of the other return types is analogous, see below for details on the return types.

---

This is consistent with the interpretation of a color array by `plot::Raster`.

`import::readbitmap(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the “working directory.”
- Last, the file name is concatenated to each directory given by the environment variable `LIBPATH`.

If a file can be opened with one of this names, then the file is read.

# import::readbitmap

---

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

A path separator (“/”) is inserted as necessary when concatenating a given path and filename.

`import::readbitmap` does not accept file handles returned by `fopen`. Nor can it handle files which have been compressed by `gzip`, but since most bitmap formats employ high quality compression in any case, there is little reason to try compressing them again in any case.

## Examples

### Example 1

We import a PGM (portable graymap) picture:

```
[w, h, Norton] := import::readbitmap("Norton.pgm");
```

The bitmap image is to be embedded in a MuPAD graphics. We use the width `w` and the height `h` to place the bitmap in a rectangle whose sides have the same ratio as the original bitmap. With `Scaling = Constrained` we make sure that this aspect ratio is also used in the final graphics:

```
xmin := 2: xmax := xmin + w/100:
ymin := 0.5: ymax := ymin + h/100:
plot(plot::Function2d(x*sin(PI/x), x = -1..4.5, AdaptiveMesh = 2),
 plot::Raster(Norton, x = xmin ..xmax, y = ymin .. ymax),
 Scaling = Constrained, Footer = "Work And Play");
```

## Parameters

### filename

The file name: a non-empty character string

## Options

### ReturnType

Option, specified as `ReturnType = DOM_HFARRAY | DOM_ARRAY | DOM_LIST`

Set the type of the actual color data returned as `colordata`.

If set to `DOM_LIST`, `colordata` is a nested list, the outermost list containing `h` lists, each of which represents one row of image data and contains `w` lists of three floating-point numbers, each of which represents an “RGB Colors” color.

If set to `DOM_ARRAY`, `colordata` is an array containing lists with color information, as in `array(2, 1..h, 1..w, [color1, color2, ] )`. The interpretation is analogous to the nested lists described above.

# import::readbitmap

---

If set to `DOM_HFARRAY`, which is the default setting, `colordata` is a `DOM_HFARRAY` of dimensions `hfarray(3, 1..h, 1..w, 1..3, [actual data])`. The interpretation of these floating-point values is as described above for the `DOM_LIST` case.

## Return Values

`list[w, h, colordata]`. The integer `w` is the pixel width of the bitmap. The integer `h` is the pixel height of the bitmap. `colordata` provides the RGB colors of the bitmap. Its type depends on the setting of the option `ReturnType`.

### MuPAD Functions

`import::readdata` | `LIBPATH` | `readbytes` | `READPATH`

### MuPAD Graphical Primitives

`plot::Raster`

**Purpose** Read data from an ASCII file

**Syntax** `import::readdata(filename | n, <separator>, <NonNested>)`

**Description** `import::readdata(filename)` reads the data in the file `filename`. File data separated by whitespace are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::readdata(filename, separator)` reads the data in the file `filename`. File data separated by the character `separator` are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::readdata(filename, separator, NonNested)` reads the data in the file `filename` as a single data record. File data separated by the character `separator` are regarded as different data elements. The result is a plain non-nested list containing the data of all lines of the file.

`import::readdata(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the “working directory.”
- Last, the file name is concatenated to each directory given by the environment variable `LIBPATH`.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

## import::readdata

---

A path separator (“/”) is inserted as necessary when concatenating a given path and filename.

If a file is specified by a file name, there is no need to open or close the file via `fopen` and `fclose`, respectively. This is done automatically by `import::readdata`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. Note that the file must have been opened in `Read` mode by `fopen`. If a file descriptor is used, the corresponding file is not closed automatically but must be closed by the user via `fclose`.

Files compressed by `gzip` or a compatible program (having a name ending in “.gz”) are decompressed automatically upon reading.

All data elements in the file are interpreted as MuPAD objects. If a data element cannot be interpreted as a MuPAD object, it is imported as a MuPAD string. Otherwise, the corresponding MuPAD object is inserted into the list returned by `import::readdata`.

---

**Note** Note that the MuPAD objects corresponding to the data elements are evaluated after reading. E.g., the data element “sin(0)” in the file is evaluated and imported as the MuPAD integer 0. Beware: the characters “;” and “:” have a specific meaning if not specified as separators in `import::readdata`: they separate MuPAD commands. Hence, if a read data element contains one of this characters, MuPAD interprets this data element as a sequence of statements and, upon evaluation, returns the value of the *last* statement as the MuPAD object corresponding to the data element. Cf. “Example 3” on page 12-17.

---

In contrast to `finput`, the data elements in the file do not have to be ended by a colon or a semicolon.

Empty lines in the file are ignored.

## Examples

### Example 1

We wish to read statistical data into a MuPAD session to test the correlation of two data samples. Assume that the file “datafile” contains the following two columns of ASCII data (each column representing a data sample):

```
0.12 0.2534
2.324 5.72
1.02 2.2232
4.02 7.321
7.4 14.9
-7.4 -15.1
```

`import::readdata` returns the following list representing the data in the file:

```
data := import::readdata("datafile")
```

```
[[0.12, 0.2534], [2.324, 5.72], [1.02, 2.2232], [4.02, 7.321], [7.4, 14.9], [-7.4, -15.1]]
```

The data structure `stats::sample` converts this nested list into two data columns:

```
s := stats::sample(data)
```

```
0.12 0.2534
2.324 5.72
1.02 2.2232
4.02 7.321
7.4 14.9
-7.4 -15.1
```

# import::readdata

---

The following computation shows that there is a very strong correlation between the data in the first column and the data in the second column:

```
stats::correlation(s, 1, 2)
```

```
0.9982703003
```

If the data in the file are supposed to represent a single sample (data record), we may ignore the fact that the numbers are arranged on several lines. With `NonNested`, the data are read as a single sample:

```
data := import::readdata("datafile", NonNested)
```

```
[0.12, 0.2534, 2.324, 5.72, 1.02, 2.2232, 4.02, 7.321, 7.4, 14.9, -7.4, -15.1]
```

Mean and standard deviation of the data are:

```
stats::mean(data), stats::stdev(data)
```

```
1.900133333, 7.568789783
```

```
delete data, s:
```

## Example 2

Let us assume that the file “datafile” contains the following ASCII data:

```
1 | 2 | 3
4 | 5 | 6.65786
7 | 8 | 9 | 5 | "ahfjd" | ab100|-23
```

We specify the data separator " | " for reading the data:

```
import::readdata("datafile", "|")

[[1, 2, 3], [4, 5, 6.65786], [7, 8, 9, 5, "ahfjd", ab100, -23]]
```

Note that whitespace inside the data elements as well as the empty line in the file are ignored.

### Example 3

We first create the ASCII data files that will be used in this example.

We recall that  $x$  degrees Celsius are  $\frac{9x}{5} + 32$  degrees Fahrenheit. First, two data files are created containing the matching temperatures from -5 degrees Celsius to 30 degrees Celsius in steps of 5 degrees Celsius:

```
n1 := fopen(Text, "data1", Write):
n2 := fopen(Text, "data2", Write):
for celsius from -5 to 20 step 5 do
 fahrenheit := 9/5*celsius + 32:
 fprintf(Unquoted, n1, celsius, " ", fahrenheit):
 fprintf(n2, celsius, fahrenheit):
end_for:
fclose(n1):
fclose(n2):
```

The file "data1" now contains the following data:

```
-5 23
0 32
5 41
10 50
15 59
20 68
```

# import::readdata

---

The file “data2” contains the following data:

```
-5:23:
0:32:
5:41:
10:50:
15:59:
20:68:
```

Now, we import the data:

```
import::readdata("data1")
```

```
[[-5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]
```

Reading data from the file “data2” yields an unexpected result:

```
import::readdata("data2")
```

```
[[23], [32], [41], [50], [59], [68]]
```

What went wrong? Remember that the default data separator is whitespace. Consequently, MuPAD reads the expression `-5:23:` as the only data element in the first line. When MuPAD evaluates this data element, it interprets it as a sequence of two MuPAD statements. The result of the statement sequence is the result of the last of the two statements, i.e., the number 23. This is the first datum in the resulting list. For getting the data as desired, an appropriate separator must be specified. The file “data2” should be read as follows:

```
import::readdata("data2", ":")
```

```
[[-5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]
```

We use the option `NonNested` to get a plain list containing all data elements without putting each record (line) in a sublist of its own:

```
import::readdata("data2", ":", NonNested)
```

```
[-5, 23, 0, 32, 5, 41, 10, 50, 15, 59, 20, 68]
```

```
delete n1, n2:
```

## Example 4

Here we can see that the data are evaluated after reading. First, we create the data file:

```
n1 := fopen(Text, "data3", Write) :
fprint(Unquoted, n1, a, " 12 ", b):
fclose(n1):
```

Now, the data are read:

```
import::readdata("data3")
```

```
[[a, 12, b]]
```

If `a` and `b` have values, we get:

```
a := 3: b := 34: import::readdata("data3")
```

```
[[3, 12, 34]]
```

# import::readdata

---

```
delete n1, a, b:
```

## Example 5

First, we create a data file with random floating-point data that is separated by blank characters:

```
n := fopen(Text, "data4", Write):
for i from 1 to 3 do
 fprintf(Unquoted, n, (frandom(), " ") $ j = 1..4);
end_for;
fclose(n):
```

This file is reopened for reading with `fopen`:

```
n := fopen(Text, "data4", Read)
```

```
64
```

The file descriptor `n` returned by `fopen` can be passed to `import::readdata`:

```
import::readdata(n)
```

```
[[0.2703567032, 0.8142678572, 0.1145977439, 0.247668289],
 [0.436855213, 0.7507294917, 0.5143284818, 0.47002619],
 [0.06956333824, 0.5063265159, 0.4145331467, 0.365909575]]
```

Note, however, that the file was opened explicitly by the user with `fopen` and is not closed automatically by `import::readdata`. Consequently, the user is supposed to close the file explicitly via `fclose`:

```
fclose(n):
delete i, n:
```

## Parameters

### **filename**

The file name: a non-empty character string

### **n**

A file descriptor provided by `fopen`: a positive integer

### **separator**

The separator between data elements: a character string of length 1 (a single character). The default separator is whitespace.

## Options

### **NonNested**

Return all file data as a single data record in a non-nested list. The data of all lines are ordered sequentially in this list.

## Return Values

Nested list of lists. The sublists contain the data of the individual lines. With the option `NonNested`, a plain list containing all data elements from every line in the file.

## See Also

## MuPAD Functions

`finput` | `fopen` | `fread` | `ftextinput` | `import::csv` | `import::readbitmap` | `pathname` | `read`

# import::readlisp

---

**Purpose** Parse Lisp-formatted string

**Syntax** `import::readlisp(s)`

**Description** `import::readlisp(s)` parses the Lisp-formatted string `s` and returns the corresponding MuPAD expression.

`import::readlisp` returns the constructed MuPAD expression as an unevaluated call. So the result of `import::readlisp` is in every case of type `DOM_EXPR`.

If the parsed string `s` contains only white spaces, then the unevaluated `null()` expression is returned.

## Examples

### Example 1

A first example:

```
import::readlisp("(INTEGRATE (EXPT X -1) X)")
```

$$\int \frac{1}{X} dx$$

```
import::readlisp("(EXP 2.0)")
```

$$e^{2.0}$$

### Example 2

In “Example 1” on page 12-22 above we can see that the corresponding MuPAD expression is not evaluated. Let us have a closer look at this behavior:

```
domtype(import::readlisp("(INTEGRATE (EXPT X -1) X))),
eval(import::readlisp("(INTEGRATE (EXPT X -1) X))),
domtype(import::readlisp("(EXP 2.0))),
```

```
eval(import::readlisp("(EXP 2.0)"))
```

```
DOM_EXPR, ln(X), DOM_EXPR, 7.389056099
```

### Example 3

Another example demonstrating that `import::readlisp` returns an unevaluated call:

```
x := 2: import::readlisp>(* x (/ 2 y))
```

```
 $x \frac{2}{y}$
```

```
eval(import::readlisp>(* x (/ 2 y)))
```

```
 $\frac{4}{y}$
```

### Example 4

An empty string is converted into an unevaluated call of `null()`:

```
type(import::readlisp(""))
```

```
"null"
```

We try to convert an illegal Lisp string:

```
import::readlisp>(* 2(EXP 3))
```

```
Error: The closing parenthesis is missing. [import::parseLambda]
```

# import::readlisp

---

## Parameters

**s**

A string

## Return Values

MuPAD expression of type DOM\_EXPR

# intlib – Integration Utilities

---

intlib::byparts  
intlib::changevar  
intlib::intOverSet  
intlib::printWarnings

# intlib::byparts

---

**Purpose** Integration by parts

**Syntax** `intlib::byparts(integral, du)`

**Description** `intlib::byparts(integral, du)` performs on `integral` the integration by parts, where `du` is the part to be integrated and returns an expression containing the unevaluated partial integral.

Mathematically, the rule of integration by parts is formally defined for indefinite integrals as

$$\int u'(x) v(x) dx = u(x) v(x) - \int u(x) v'(x) dx$$

and for definite integrals as

$$\int_a^b u'(x) v(x) dx = u(b) v(b) - u(a) v(a) - \int_a^b u(x) v'(x) dx$$

`intlib::byparts` works for indefinite as well as for definite integrals.

If MuPAD cannot solve the integral for `du` in case of definite integration, the function call is returned unevaluated.

The first argument should contain a symbolic integral of type "int". Such an expression can be obtained with `hold` or `freeze` (cf. "Example 1" on page 13-3).

The second argument `du` should typically be a partial expression of the integrand in `integral`.

**Examples****Example 1**

As a first example we apply the rule of integration by parts to the integral  $\int_a^b x e^x dx$ . By using the function hold we ensure that the first argument is of type "int":

```
intlib::byparts(hold(int)(x*exp(x), x = a..b), exp(x))
```

$$b e^b - a e^a - \int_a^b e^x dx$$

In this case the ansatz is chosen as  $u'(x) = e^x$  and thus  $v(x) = x$ .

**Example 2**

In the following we give a more advanced example using the method of integration by parts for solving the integral  $\int e^{ax} \sin(bx) dx$ . For this we have to prevent that the integrator already evaluates the integrals. Thus we first inactivate the requested integral with the function freeze

```
F := freeze(int)(exp(a*x)*sin(b*x), x)
```

$$\int e^{ax} \sin(bx) dx$$

and apply afterwards partial integration with  $u'(x) = e^{ax}$ :

```
F1 := intlib::byparts(F, exp(a*x))
```

$$\frac{e^{ax} \sin(bx)}{a} - \int \frac{b e^{ax} \cos(bx)}{a} dx$$

This result contains another symbolic integral, which MuPAD can solve directly:

```
eval(F1)
```

$$\frac{e^{a x} \sin(b x)}{a} - \frac{b e^{a x} (a \cos(b x) + b \sin(b x))}{a (a^2 + b^2)}$$

### Example 3

Here we demonstrate the difference between indefinite and definite integration by parts. If in the indefinite case the partial part cannot be solved, simply the unevaluated integral is plugged into the integration rule:

```
intlib::byparts(hold(int)(x*f(x), x), f(x))
```

$$x \int f(x) dx - \int \int f(x) dx dx$$

This is no longer true for the definite case:

```
intlib::printWarnings(TRUE):
intlib::byparts(hold(int)(x*f(x), x=a..b), f(x))
```

```
Warning: No closed form for 'int(f(x), x)' is found. [intlib::byparts]
```

$$\text{intlib::byparts}\left(\int_a^b x f(x) dx, f(x)\right)$$

## Parameters

### **integral**

Integral: an arithmetical expression containing a symbolic "int" call of the form `int(du*v, x)` or `int(du*v, x = a..b)`

### **du**

The part to be integrated: an arithmetical expression

## Return Values

Arithmetical expression.

## See Also

## MuPAD Functions

`subs` | `intlib::changevar`

# intlib::changevar

---

**Purpose** Change of variable

**Syntax** `intlib::changevar(integral, eq, <var>)`

**Description** `intlib::changevar(integral, eq)` performs a change of variable for indefinite and definite integrals.

Mathematically, the substitution rule is formally defined for indefinite integrals as

$$\int f(g(x)) g'(x) dx = \left( \int f(t) dt \right) \Big|_{t=g(x)}$$

and for definite integrals as

$$\int_a^b f(g(x)) g'(x) dx = \int_{g(a)}^{g(b)} f(t) dt$$

`intlib::changevar(integral, eq)` performs in `integral` the change of variable defined by `eq` and returns an unevaluated new integral. You can use the `eval` command to find the closed form of this new integral providing that the closed form exists.

`intlib::changevar` works for indefinite as well as for definite integrals.

The first argument should contain a symbolic integral of type "int". Such an expression can be obtained with `hold` or `freeze`. See "Example 1" on page 13-7.

If more than two variables occur in `eq`, the new variable must be given as third argument.

If MuPAD cannot solve the given equation `eq` an error will occur.

## Examples

### Example 1

As a first example we perform a change of variable for the integral

$\int_a^b f(x + c) dx$ . By using the hold function we ensure that the first argument is of type "int":

```
intlib::changevar(hold(int)(f(x + c), x = a..b),
 t = x + c, t)
```

$$\int_{a+c}^{b+c} f(t) dt$$

Note that in this case the substitution equation has two further variables besides  $x$ . Thus it is necessary to specify the new integration variable as third argument.

### Example 2

In the following example we use the change of variable method for solving the integral  $\int \cos(\ln(x)) dx$ . First we perform the transformation  $t = \ln(x)$ :

```
f1 := intlib::changevar(hold(int)(cos(ln(x)), x),
 t = ln(x), t)
```

$$\int e^t \cos(t) dt$$

Now we can evaluate the integral with the MuPAD integrator:

```
f2:=eval(f1)
```

# intlib::changevar

---

$$\frac{e^t (\cos(t) + \sin(t))}{2}$$

Finally we change the variable  $t$  back to  $x$  and get the result:

```
F := simplify(f2 | t = ln(x))
```

$$\frac{x (\cos(\ln(x)) + \sin(\ln(x)))}{2}$$

We can also verify the solution of the integral:

```
simplify(diff(F,x) - cos(ln(x)))
```

```
0
```

## Parameters

### **integral**

The integral: an arithmetical expression containing a symbolic "int" call

### **eq**

Equation defining the new integration variable in terms of the old one: an equation

### **var**

The new integration variable: an identifier

## Return Values

Arithmetical expression.

## See Also

### MuPAD Functions

subs | intlib::byparts

# intlib::intOverSet

---

**Purpose** Integration over a set

**Syntax** `intlib::intOverSet(f, x, S)`

**Description** `intlib::intOverSet(f, x, S)` computes the integral

$\int_{-\infty}^{\infty} f(x) i_S(x) dx$  where  $i_S(x)$  is the indicator function of the set  $S$ .

If  $S$  is an interval  $(a, b)$  with  $a \leq b$ , the call is equivalent to `int(f, x=a..b)`. However, by definition, interchanging the borders to `int(f, x=b..a)` just reverses the sign of the latter while  $(b, a)$  is empty and any integral over the empty set is zero.

The function may return unevaluated if the integral could not be computed.

## Examples

### Example 1

For intervals, calling `intlib::intOverSet` is just equivalent to calling definite integration:

```
int(1/x, x=1..2), intlib::intOverSet(1/x, x, Dom::Interval(1, 2))
```

```
ln(2), ln(2)
```

If the lower border is greater than the upper, this does not hold anymore:

```
int(1/x, x=2..1), intlib::intOverSet(1/x, x, Dom::Interval(2, 1))
```

```
-ln(2), 0
```

### Example 2

In more complex cases, the function returns unevaluated:

```
intlib::intOverSet(1/x^2, x, solve(t > sin(t), t))
```

$$\int_{x \in \text{solve}(\sin(t) < t, t)} \frac{1}{x^2} dx$$

<b>Parameters</b>	<b>f</b> Arithmetical expression
	<b>x</b> Identifier
	<b>S</b> Set-theoretic expression

**Return Values** Arithmetical expression.

**See Also**

**MuPAD Functions** `int`

# intlib::printWarnings

---

**Purpose** Enable or disable warnings

**Syntax** `intlib::printWarnings(TRUE)`  
`intlib::printWarnings(FALSE)`  
`intlib::printWarnings()`

**Description** `intlib::printWarnings` lets you enable or disable warnings. By default, MuPAD does not display warnings during integration. To enable warnings, use the `intlib::printWarnings(TRUE)` function call. If later you want to disable warnings, use the `intlib::printWarnings(FALSE)` function call. See “Example 1” on page 13-12.

The `intlib::printWarnings()` function call shows whether warnings are enabled or disabled. See “Example 1” on page 13-12.

The output of `intlib::printWarnings` displays the previous setting. You can save this previous setting and switch to a new setting in a single function call. See “Example 2” on page 13-13.

## Examples **Example 1**

Enable the warnings by setting the value of `intlib::printWarnings` to `TRUE`:

```
intlib::printWarnings(TRUE):
```

Compute the integral of  $|x|$  under the assumption that  $x$  is an integer. MuPAD cannot integrate the expression over a discrete subset of the real numbers. The system issues a warning and integrates over the set  $\mathbb{R}$  of real numbers:

```
int(abs(x), x) assuming x in Z_
```

```
Warning: Cannot integrate when 'x' has property 'Z_'. The assumption
```

$$\frac{x^2 \operatorname{sign}(x)}{2}$$

If you evaluate the same integral again, MuPAD does not recalculate the integral. The system remembers the previous result and returns it, skipping the warning:

```
int(abs(x), x) assuming x in Z_
```

$$\frac{x^2 \operatorname{sign}(x)}{2}$$

To check whether the warnings are enabled or disabled, use the `intlib::printWarnings()` function call:

```
intlib::printWarnings()
```

TRUE

Disable the warnings for further computations:

```
intlib::printWarnings(FALSE):
```

## Example 2

Enable the warnings and save the previous setting in a single function call:

```
old := intlib::printWarnings(TRUE):
```

Assume that  $x$  is positive. Then, integrate  $x$  over the interval  $[-2, 1]$ . In this case, the system issues a warning, temporarily disregards the assumption  $x > 0$ , and integrates over the interval  $[-2, 1]$ :

# intlib::printWarnings

---

```
assume(x > 0):
int(x, x = -2..1)
```

Warning: The assumption that 'x' has property '[-2, 1]' instead of

$-\frac{3}{2}$

Restore the setting of intlib::printWarnings:

```
intlib::printWarnings(old):
```

The warnings are disabled now:

```
intlib::printWarnings()
```

FALSE

For further computations, clear the assumption on the variable x:

```
unassume(x):
```

Previously set value TRUE or FALSE

## Return Values

# linalg::addCol

---

**Purpose** Linear combination of matrix columns

**Syntax** `linalg::addCol(A, c1, c2, s1)`  
`linalg::addCol(A, c1, c2, s1, s2)`

**Description** `linalg::addCol(A, c1, c2, s1)` adds  $s_1$  times column  $c_1$  to column  $c_2$  in the matrix  $A$ .

`linalg::addCol(A, c1, c2, s)` returns a copy of the matrix  $A$  in which column  $c_2$  of  $A$  is replaced by  $s \cdot \text{col}(A, c_1) + \text{col}(A, c_2)$ .

`linalg::addCol(A, c1, c2, s1, s2)` returns a copy of the matrix  $A$  in which column  $c_2$  of  $A$  is replaced by  $s_1 \cdot \text{col}(A, c_1) + s_2 \cdot \text{col}(A, c_2)$ .

## Examples **Example 1**

The following defines a 3 3 matrix over the integers:

```
A := Dom::Matrix(Dom::Integer)(
 [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

We replace the 2nd column by  $-\text{col}(A, 1) + \text{col}(A, 2)$ , i.e., we subtract the first column from the second:

```
linalg::addCol(A, 1, 2, -1)
```

$$\begin{pmatrix} 1 & 1 & 3 \\ 4 & 1 & 6 \\ 7 & 1 & 9 \end{pmatrix}$$

**Example 2**

The following defines a 2 3 matrix over the reals:

```
B := Dom::Matrix(Dom::Real)(
 [[sin(2), 0, 1], [1, PI, 0]]
)
```

$$\begin{pmatrix} \sin(2) & 0 & 1 \\ 1 & \pi & 0 \end{pmatrix}$$

If  $s$  is an expression that does not represent a real number then an error message is reported. The following tries to replace the 1st column by  $xcol(B, 3) + col(B, 1)$ , where  $x$  is an identifier which cannot be converted to the component ring `Dom::Real` of  $B$ :

```
delete x: linalg::addCol(B, 3, 1, x)
```

```
Error: Cannot convert 'x'. [linalg::addCol]
```

**Example 3**

If symbolic expressions are involved, then one may define matrices over a component ring created by `Dom::ExpressionField`. The following example defines a matrix over this default component ring:

```
delete a11, a12, a21, a22, x:
C := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

We retry the input from the previous example:

# linalg::addCol

---

```
linalg::addCol(C, 2, 1, x)
```

$$\begin{pmatrix} a_{11} + a_{12} x & a_{12} \\ a_{21} + a_{22} x & a_{22} \end{pmatrix}$$

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**$c_1, c_2$**

The column indices: positive integers less or equal to  $n$

**$s_1, s_2$**

Expressions that can be converted to the component ring of A

## Return Values

Matrix of the same domain type as A.

## See Also

### MuPAD Domains

`Dom::Matrix`

### MuPAD Functions

`linalg::addRow` | `linalg::col` | `linalg::multCol` |  
`linalg::multRow`

## Purpose

Linear combination of matrix rows

## Syntax

```
linalg::addRow(A, r1, r2, s)
linalg::addRow(A, r1, r2, s1, s2)
```

## Description

`linalg::addRow(A, r1, r2, s1)` adds  $s_1$  times row  $r_1$  to row  $r_2$ , in the matrix  $A$ .

`linalg::addRow(A, r1, r2, s)` returns a copy of the matrix  $A$  in which row  $r_2$  of  $A$  is replaced by  $s \text{row}(A, r_1) + \text{row}(A, r_2)$ .

`linalg::addRow(A, r1, r2, s1, s2)` returns a copy of the matrix  $A$  in which row  $r_2$  of  $A$  is replaced by  $s_1 \text{row}(A, r_1) + s_2 \text{row}(A, r_2)$ .

## Examples

### Example 1

The following defines a 3 3 matrix over the integers:

```
A := Dom::Matrix(Dom::Integer)(
 [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

We replace the 2nd row by  $-\text{row}(A, 1) + \text{row}(A, 2)$ , i.e., we subtract the first row from the second:

```
linalg::addRow(A, 1, 2, -1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 3 & 3 & 3 \\ 7 & 8 & 9 \end{pmatrix}$$

# linalg::addRow

---

## Example 2

The following defines a 2 3 matrix over the reals:

```
B := Dom::Matrix(Dom::Real)(
 [[sin(2), 0, 1], [1, PI, 0]]
)
```

$$\begin{pmatrix} \sin(2) & 0 & 1 \\ 1 & \pi & 0 \end{pmatrix}$$

If  $s$  is an expression that does not represent a real number then an error message is reported. The following tries to replace the 1st row by  $xrow(B, 2) + row(B, 1)$ , where  $x$  is an identifier which cannot be converted to the component ring `Dom::Real` of  $B$ :

```
delete x: linalg::addRow(B, 2, 1, x)
```

```
Error: Cannot convert 'x'. [linalg::addRow]
```

## Example 3

If symbolic expressions are involved, then one may define matrices over the component ring created by `Dom::ExpressionField`. The following example defines a matrix over this default component ring:

```
delete a11, a12, a21, a22, x:
C := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

We retry the input from the previous example:

```
linalg::addRow(C, 2, 1, x)
```

$$\begin{pmatrix} a_{11} + a_{21} x & a_{12} + a_{22} x \\ a_{21} & a_{22} \end{pmatrix}$$

## Parameters

**A**

An  $m \times n$  matrix of a domain of category `Cat::Matrix`

**r<sub>1</sub>, r<sub>2</sub>**

The row indices: positive integers less or equal to  $m$

**s, s<sub>1</sub>, s<sub>2</sub>**

Expressions that can be converted to the component ring of A

## Return Values

Matrix of the same domain type as A.

## See Also

## MuPAD Functions

`linalg::addCol` | `linalg::row` | `linalg::multCol` |  
`linalg::multRow`

# linalg::adjoint

---

**Purpose** Adjoint of a matrix

**Syntax** `linalg::adjoint(A)`

**Description** `linalg::adjoint(A)` computes the adjoint  $Adj(A)$  of the  $n \times n$  matrix  $A$ . The adjoint matrix satisfies the equation  $A Adj(A) = \det A I_n$ , where  $I_n$  is the  $n \times n$  identity matrix.

The component ring of  $A$  must be of category `Cat::CommutativeRing`.

## Examples **Example 1**

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[0, 2, 1], [2, 1, 0], [1, 0, 2]])
```

$$\begin{pmatrix} 0 & 2 & 1 \\ 2 & 1 & 0 \\ 1 & 0 & 2 \end{pmatrix}$$

Then the adjoint matrix of  $A$  is given by:

```
Ad := linalg::adjoint(A)
```

$$\begin{pmatrix} 2 & -4 & -1 \\ -4 & -1 & 2 \\ -1 & 2 & -4 \end{pmatrix}$$

We check the property of the adjoint matrix  $Ad$  mentioned above:

```
A * Ad = linalg::det(A)*MatQ::identity(3)
```

$$\begin{pmatrix} -9 & 0 & 0 \\ 0 & -9 & 0 \\ 0 & 0 & -9 \end{pmatrix} = \begin{pmatrix} -9 & 0 & 0 \\ 0 & -9 & 0 \\ 0 & 0 & -9 \end{pmatrix}$$

**Parameters****A**A square matrix of a domain of category `Cat::Matrix`**Return Values**

Matrix of the same domain type as A.

**Algorithms**

The adjoint of a square matrix  $A$  is the matrix whose  $(i, j)$ -th entry is the  $(j, i)$ -th cofactor of  $A$ .

The  $(j, i)$ -th *cofactor* of  $A$  is defined by  $a'_{ji} = (-1)^{i+j} \det(A_{ij})$ , where  $A_{ij}$  is the submatrix of  $A$  obtained from  $A$  by deleting the  $i$ -th row and  $j$ -th column.

**See Also****MuPAD Functions**`linalg::det`

# linalg::angle

---

**Purpose** Angle between two vectors

**Syntax** `linalg::angle(u, v)`

**Description** `linalg::angle(u,v)` computes the angle  $\varphi$  between the two vectors  $u$  and  $v$ , defined by

$$\varphi = \arccos\left(\frac{\langle \vec{u}, \vec{v} \rangle}{\|\vec{u}\|_2 \|\vec{v}\|_2}\right),$$

where  $\langle \vec{u}, \vec{v} \rangle$  denotes the scalar product of two vectors given by `linalg::scalarProduct`, and  $\|\cdot\|_2$  the 2-norm of a vector, i.e.,

$$\|\vec{u}\|_2 = \sqrt{\langle \vec{u}, \vec{u} \rangle}.$$

`linalg::angle` does not check if the computation is defined in the corresponding component ring. This can lead to an error message, as shown in “Example 2” on page 14-13.

The following relationship between the angle between  $\vec{u}$  and  $\vec{v}$  and the angle between  $\vec{u}$  and  $-\vec{v}$  holds:  $\varphi(\vec{u}, -\vec{v}) = \pi - \varphi(\vec{u}, \vec{v})$ .

An error message is returned if the vectors are not defined over the same component ring.

## Examples

### Example 1

We compute the angle between the two vectors  $\begin{pmatrix} 2 \\ 5 \end{pmatrix}$  and  $\begin{pmatrix} -3 \\ 3 \end{pmatrix}$ :

```
phi := linalg::angle(
 matrix([2, 5]), matrix([-3, 3])
)
```

$$\arccos\left(\frac{\sqrt{18}\sqrt{29}}{58}\right)$$

We use the function `float` to get a floating-point approximation of this number:

```
float(phi)
```

```
1.165904541
```

We give two further examples:

```
linalg::angle(
 matrix([1, -1]), matrix([1, 1])
)
```

```
 $\frac{\pi}{2}$
```

```
linalg::angle(
 matrix([1, 1]), matrix([-1, -1])
)
```

```
 π
```

## Example 2

`linalg::angle` does not check whether the term  $\frac{\langle \vec{u}, \vec{v} \rangle}{\|\vec{u}\|_2 \|\vec{v}\|_2}$  is defined in the corresponding component ring.

As an example, we try to compute the angle between two vectors with components in  $\mathbb{Z}$ :

# linalg::angle

---

```
MatZ7 := Dom::Matrix(Dom::IntegerMod(7))
```

```
Dom::Matrix(Dom::IntegerMod(7))
```

The following call leads to an error because the 2-norm cannot be computed:

```
linalg::angle(MatZ7([1, 1]), MatZ7([-1, -1]))
```

```
Error: An integer exponent is expected. [(Dom::IntegerMod(7))::_pow
```

Note that the domain `Dom::IntegerMod(7)` does not implement the square root of an element, therefore in MuPAD you cannot compute the angle of any two vectors over  $\mathbb{Z}_7$ .

## Parameters

**u, v**

Vectors of the same dimension; a vector is a  $n \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`

## Return Values

Arithmetical expression.

## See Also

## MuPAD Functions

`arccos` | `linalg::scalarProduct` | `linalg::vecdim`

**Purpose** Basis for a vector space

**Syntax** `linalg::basis(S)`

**Description** `linalg::basis(S)` returns a basis for the vector space spanned by the vectors in the set or list  $S$ .

`linalg::basis(S)` removes those vectors in  $S$  that are linearly dependent on other vectors in  $S$ . The result is a basis for the vector space spanned by the vectors in  $S$ .

For an ordered basis of vectors,  $S$  should be a list of vectors.

The vectors in  $S$  must be defined over the same component ring.

The component ring of the vectors in  $S$  must be a field, i.e., it must be of category `Cat::Field`.

## Examples **Example 1**

We define the domain of matrices over :

```
MatQ := Dom::Matrix(Dom::Rational):
```

and compute a basis for the vector space spanned by the vectors  $\begin{pmatrix} 3 \\ -2 \end{pmatrix}$ ,

$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$  and  $\begin{pmatrix} 5 \\ -3 \end{pmatrix}$ :

```
v1 := MatQ([3, -2]):
```

```
v2 := MatQ([1, 0]):
```

```
v3 := MatQ([5, -3]):
```

```
linalg::basis([v1, v2, v3])
```

$$\left[ \begin{pmatrix} 3 \\ -2 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \end{pmatrix} \right]$$

# linalg::basis

---

If not a list but a set of vectors is given, then the basis returned may not consist of the same vectors as above. The order of the vectors in the set depends on the internal order (see `sysorder` and `DOM_SET`), i.e., the order of the vectors appears to be random:

```
b := linalg::basis({v1, v2, v3}):
op(b, 1)
```

$$\begin{pmatrix} 3 \\ -2 \end{pmatrix}$$

## Parameters **s**

A set or list of  $n$ -dimensional vectors; a vector is a  $n \ 1$  or  $1 \ n$  matrix of a domain of category `Cat::Matrix`

## Return Values

Set or a list of vectors, respectively.

## See Also

## MuPAD Functions

`linalg::intBasis` | `linalg::sumBasis` | `l1l1nt`

**Purpose** Characteristic matrix

**Syntax** `linalg::charmat(A, x)`

**Description** `linalg::charmat(A, x)` returns the characteristic matrix  $xI_n - A$  of the  $n \times n$  matrix  $A$ , where  $I_n$  denotes the  $n \times n$  identity matrix.

The component ring of  $A$  must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

The characteristic matrix  $M = xI_n - A$  of  $A$  can be evaluated at a point  $x = u$  via `evalp(M, x = u)`. See “Example 2” on page 14-18.

**Examples**      **Example 1**

We define a matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

and compute the characteristic matrix of  $A$  in the variable  $x$ :

```
MA := linalg::charmat(A, x)
```

$$\begin{pmatrix} x-1 & -2 \\ -3 & x-4 \end{pmatrix}$$

The determinant of the matrix  $MA$  is a polynomial in  $x$ , the characteristic polynomial of the matrix  $A$ :

```
pA := linalg::det(MA)
```

# linalg::charmat

---

$$x^2 - 5x - 2$$

`domtype(pA)`

`Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)`

Of course, we can compute the characteristic polynomial of  $A$  directly via `linalg::charpoly`:

`linalg::charpoly(A, x)`

$$x^2 - 5x - 2$$

The result is of the same domain type as the polynomial  $pA$ .

## Example 2

We define a matrix over the complex numbers:

`B := Dom::Matrix(Dom::Complex)([[1 + I, 1], [1, 1 - I]])`

$$\begin{pmatrix} 1+i & 1 \\ 1 & 1-i \end{pmatrix}$$

The characteristic matrix of  $B$  in the variable  $z$  is:

`MB := linalg::charmat(B, z)`

$$\begin{pmatrix} z-1-i & -1 \\ -1 & z-1+i \end{pmatrix}$$

We evaluate MB at  $z = i$  and get the matrix:

```
evalp(MB, z = I)
```

$$\begin{pmatrix} -1 & -1 \\ -1 & -1 + 2i \end{pmatrix}$$

Note that this is a matrix of the domain type  
Dom::Matrix(Dom::Complex):

```
domtype(%)
```

```
Dom::Matrix(Dom::Complex)
```

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

**x**

An identifier

## Return Values

Matrix of the domain

`Dom::Matrix(Dom::DistributedPolynomial([x], R))` or of  
`Dom::DenseMatrix(Dom::DistributedPolynomial([x], R))`,  
where R is the component ring of A.

## See Also

## MuPAD Functions

`linalg::charpoly`

# linalg::charpoly

---

**Purpose** Characteristic polynomial of a matrix

**Syntax** `linalg::charpoly(A, x)`

**Description** `linalg::charpoly(A, x)` computes the characteristic polynomial of the matrix  $A$ . The characteristic polynomial of a  $n \times n$  matrix is defined by  $p_A(x) := \det(x I_n - A)$ , where  $I_n$  denotes the  $n \times n$  identity matrix. The component ring of  $A$  must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

## Examples **Example 1**

We define a matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Then the characteristic polynomial  $p_A(x)$  is given by:

```
linalg::charpoly(A, x)
```

$$x^2 - 5x - 2$$

It is of the domain type:

```
domtype(%)
```

```
Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)
```

## Example 2

We define a matrix over  $\mathbb{7}$ :

```
B := Dom::Matrix(Dom::IntegerMod(7))([[1, 2], [3, 0]])
```

$$\begin{pmatrix} 1 \bmod 7 & 2 \bmod 7 \\ 3 \bmod 7 & 0 \bmod 7 \end{pmatrix}$$

The characteristic polynomial  $p_B(x)$  of B is given by:

```
p := linalg::charpoly(B, x)
```

$$(1 \bmod 7) x^2 + (6 \bmod 7) x + (1 \bmod 7)$$

We compute the zeros of  $p_B(x)$ , i.e., the eigenvalues of the matrix B:

```
solve(p)
```

$$\{[x = 3 \bmod 7], [x = 5 \bmod 7]\}$$

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

**x**

An identifier

## Return Values

Polynomial of the domain `Dom::DistributedPolynomial([x],R)`, where R is the component ring of A.

## Algorithms

`linalg::charpoly` implements Hessenberg's algorithm to compute the characteristic polynomial of a square matrix A. See: Henri Cohen: *A Course in Computational Algebraic Number Theory*, GTM 138, Springer Verlag.

# **linalg::charpoly**

---

This algorithm works for any field and requires only  $O(n^3)$  field operations, in contrast to  $O(n^4)$  when computing the determinant of the characteristic matrix of  $A$ .

Since the size of the components of  $A$  in intermediate computations of Hessenberg's algorithm can swell extremely, it is only applied for matrices over `Dom::Float` and `Dom::IntegerMod`.

For any other component ring, the characteristic polynomial is computed using the Berkowitz algorithm.

## **See Also**

## **MuPAD Functions**

`linalg::charmat` | `linalg::det` | `linalg::hessenberg` |  
`linalg::minpoly`

**Purpose** Extract columns of a matrix

**Syntax**  
`linalg::col(A, c)`  
`linalg::col(A, c1 .. c2)`  
`linalg::col(A, list)`

**Description** `linalg::col(A, c)` extracts the  $c$ -th column vector of the matrix  $A$ .  
`linalg::col(A, c1.. c2)` returns a list of column vectors whose indices are in the range  $c_1.. c_2$ . If  $c_2 < c_1$  then the empty list `[]` is returned.  
`linalg::col(A, list)` returns a list of column vectors whose indices are contained in `list` (in the same order).

**Examples**      **Example 1**

We define a matrix over :

```
A := Dom::Matrix(Dom::Rational)(
 [[1, 1/5, 2], [-3/2, 0, 5]]
)
```

$$\begin{pmatrix} 1 & \frac{1}{5} & 2 \\ -\frac{3}{2} & 0 & 5 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::col`:

```
linalg::col(A, 2)
```

$$\begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}$$

```
linalg::col(A, [2, 1, 3])
```

# linalg::col

---

$$\left[ \begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}, \begin{pmatrix} 1 \\ -\frac{3}{2} \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \end{pmatrix} \right]$$

`linalg::col(A, 2..3)`

$$\left[ \begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \end{pmatrix} \right]$$

## Parameters

**A**

An  $m \times n$  matrix of a domain of category `Cat::Matrix`

**c**

The column index: a positive integer less or equal to  $n$

**c<sub>1</sub> .. c<sub>2</sub>**

A range of column indices (positive integers less or equal to  $n$ )

**list**

A list of column indices (positive integers less or equal to  $n$ )

## Return Values

Single column vector or a list of column vectors; a column vector is an  $m \times 1$  matrix of category `Cat::Matrix(R)`, where  $R$  is the component ring of  $A$ .

## See Also

`linalg::row` | `linalg::delCol` | `linalg::delRow` |  
`linalg::setCol` | `linalg::setRow`

<b>Purpose</b>	Companion matrix of a univariate polynomial
<b>Syntax</b>	<code>linalg::companion(p, &lt;x&gt;)</code>
<b>Description</b>	<p><code>linalg::companion(p)</code> returns the companion matrix associated with the polynomial <math>p</math>.</p> <p><math>p</math> must be monic and of degree one at least.</p> <p>If <math>p</math> is a polynomial, i.e., an object of type <code>DOM_POLY</code>, then specifying <math>x</math> has no effect.</p> <p>If <math>p</math> is a polynomial, then the component ring of the returned matrix is the coefficient ring of <math>p</math>, except in two cases for built-in coefficient rings: if the coefficient ring of <math>p</math> is <code>Expr</code> then the domain <code>Dom::ExpressionField()</code> is the component ring of the companion matrix. If it is <code>IntMod(m)</code> then the companion matrix is defined over the ring <code>Dom::IntegerMod(m)</code> (see “Example 2” on page 14-26).</p> <p>If <math>p</math> is a polynomial expression, then the companion matrix is defined over <code>Dom::ExpressionField()</code>.</p> <p>If <math>p</math> is a polynomial expression containing several symbolic indeterminates then <math>x</math> must be specified and distinguishes the indeterminate <math>x</math> from the other symbolic parameters.</p>

## Examples

### Example 1

We start with the following polynomial expression:

```
delete a_0, a_1, a_2, a_3:
p := x^4 + a_3*x^3 + a_2*x^2 + a_1*x + a_0
```

$$X^4 + a_3 X^3 + a_2 X^2 + a_1 X + a_0$$

To compute the companion matrix of  $p$  with respect to  $x$  we must specify the second parameter  $x$ , because the expression  $p$  contains the indeterminates  $a_0, a_1, a_2, a_3$  and  $x$ :

# linalg::companion

---

```
linalg::companion(p)
```

```
Error: The polynomial expression is multivariate. Specify the indet
```

```
linalg::companion(p, x)
```

$$\begin{pmatrix} 0 & 0 & 0 & -a_0 \\ 1 & 0 & 0 & -a_1 \\ 0 & 1 & 0 & -a_2 \\ 0 & 0 & 1 & -a_3 \end{pmatrix}$$

Of course, we can compute the companion matrix of  $p$  with respect to  $a_0$  as well:

```
linalg::companion(p, a_0)
```

$$(-X^4 - a_3 X^3 - a_2 X^2 - a_1 X)$$

The following fails with an error message, because the polynomial  $p$  is not monic with respect to  $a_1$ :

```
linalg::companion(p, a_1)
```

```
Error: Polynomial is not monic. [linalg::companion]
```

## Example 2

If we enter a polynomial over the built-in coefficient domain Expr, then the companion matrix is defined over the standard component ring for matrices (the domain Dom::ExpressionField()):

```
C := linalg::companion(poly(x^2 + 10*x + PI, [x]))
```

$$\begin{pmatrix} 0 & -\pi \\ 1 & -10 \end{pmatrix}$$

```
domtype(C)
```

```
Dom::Matrix()
```

If we define a polynomial over the build-in coefficient domain `IntMod(m)`, then the companion matrix is defined over the corresponding component ring `Dom::IntegerMod(m)`, as shown in the next example:

```
p := poly(x^2 + 10*x + 7, [x], IntMod(3))
```

```
poly(x2 + x + 1, [x], IntMod(3))
```

```
C := linalg::companion(p)
```

$$\begin{pmatrix} 0 \bmod 3 & 2 \bmod 3 \\ 1 \bmod 3 & 2 \bmod 3 \end{pmatrix}$$

```
domtype(C)
```

```
Dom::Matrix(Dom::IntegerMod(3))
```

## Parameters

**p**

An univariate polynomial, or a polynomial expression

# linalg::companion

---

**x**

An identifier

## Return Values

Matrix of the domain `Dom::Matrix(R)`.

## Algorithms

The companion matrix of the polynomial  $x^n + a_{n-1}x^{n-1} + \dots + a_1x + a_0$  is the matrix:

$$C = \begin{pmatrix} 0 & \cdot & \cdot & \cdot & 0 & -a_0 \\ 1 & \cdot & & & & -a_1 \\ & \cdot & \cdot & & & \cdot \\ & & \cdot & \cdot & & \cdot \\ & & & \cdot & 0 & -a_{n-1} \\ & & & & 1 & -a_n \end{pmatrix}$$

The companion matrix of a univariate polynomial  $p$  of degree  $n$  is an  $n \times n$  matrix  $C$  with  $p_C = p$ , where  $p_C$  is the characteristic polynomial of  $C$ .

**Purpose** Join matrices horizontally

**Syntax** `linalg::concatMatrix(A, B1, <B2, >)`

**Description** `linalg::concatMatrix(A, B1, B2, dots )` returns the matrix formed by joining the matrices  $A, B_1, B_2, \dots$  horizontally.

The matrices  $B_1, B_2, \dots$  are converted into the matrix domain `Dom::Matrix(R)`, where  $R$  is the component ring of  $A$ .

An error message is raised if one of these conversions fails, or if the matrices do not have the same number of rows as the matrix  $A$ .

A short form of `linalg::concatMatrix` is available through the dot operator `.`, i.e., instead of `linalg::concatMatrix(A, B)` one may use the short form `A . B`.

## Examples **Example 1**

We define the matrix:

```
A := matrix([[sin(x), x], [-x, cos(x)]])
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \end{pmatrix}$$

and append the 2 2 identity matrix to the right of A:

```
I2 := matrix::identity(2):
linalg::concatMatrix(A, I2)
```

$$\begin{pmatrix} \sin(x) & x & 1 & 0 \\ -x & \cos(x) & 0 & 1 \end{pmatrix}$$

The short form for this operation is:

# linalg::concatMatrix

---

`A . I2`

$$\begin{pmatrix} \sin(x) & x & 1 & 0 \\ -x & \cos(x) & 0 & 1 \end{pmatrix}$$

## Example 2

We define a matrix from the ring of 2 2 square matrices:

```
SqMatQ := Dom::SquareMatrix(2, Dom::Rational):
A := SqMatQ([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Note the following operation:

```
AA := A . A
```

$$\begin{pmatrix} 1 & 2 & 1 & 2 \\ 3 & 4 & 3 & 4 \end{pmatrix}$$

returns a matrix of a different domain type as the input matrix:

```
domtype(AA)
```

```
Dom::Matrix(Dom::Rational)
```

## Parameters

`A, B1, B2, ...`

Matrices of a domain of category `Cat::Matrix`

## Return Values

Matrix of the domain type `Dom::Matrix(R)`, where R is the component ring of A.

## See Also

### MuPAD Functions

`linalg::stackMatrix`

# linalg::cond

---

**Purpose** Condition number of a matrix

**Syntax** `linalg::cond(M, <1 | 2 | Spectral | Infinity | Frobenius>)`

**Description** `linalg::cond(M)` computes the condition number of a matrix, defined by  $\|M\|_{\infty} \|\frac{1}{M}\|_{\infty}$ . By default the matrix norm Infinity is used by `linalg::cond`.

`linalg::cond(M)` is the short form of `linalg::cond(M, Infinity)`.

`linalg::cond(M, k)` computes the condition number of the matrix M, defined by  $\|M\|_k \|\frac{1}{M}\|_k$ .

For further details see the help page of `norm`.

## Examples

### Example 1

We define the 3 3 matrix A.

```
A := matrix(3,3, [[1,0,3],[-4,2,0],[0,3,-2]])
```

$$\begin{pmatrix} 1 & 0 & 3 \\ -4 & 2 & 0 \\ 0 & 3 & -2 \end{pmatrix}$$

Now we calculate the condition number of A for some matrix norms.

```
linalg::cond(A)
```

$$\frac{33}{10}$$

```
linalg::cond(A, Infinity)
```

$$\frac{33}{10}$$

```
linalg::cond(A, 1)
```

3

```
linalg::cond(A, Frobenius)
```

$$\frac{\sqrt{2} \sqrt{43} \sqrt{251}}{40}$$

The result for the spectral norm is too complex, so we want the floating valuation. The tiny imaginary part is a rounding artifact:

```
linalg::cond(A, 2);
float(%)
```

$$\sqrt{\frac{343}{9 \left( \frac{3970}{27} + \frac{\sqrt{27} \sqrt{910841} i}{27} \right)^{1/3} + \left( \frac{3970}{27} + \frac{\sqrt{27} \sqrt{910841} i}{27} \right)^{1/3} + \frac{43}{3}}}$$

$$\text{sqrt} \left( \frac{11401}{5760000 \left( \frac{705851}{13824000000} + \frac{\sqrt{910841} \sqrt{176947200000000} i}{17694720000000} \right)^{1/3} + \left( \frac{705851}{13824000000} + \frac{\sqrt{910841} \sqrt{176947200000000} i}{17694720000000} \right)^{1/3} + \frac{251}{2400} \right)$$

$$2.223147175 + 1.386849201 \cdot 10^{-18} i$$

# linalg::cond

---

If  $A$  contains at least one floating-point number, the result will be computed numerically.

```
B := A:
B[1,1] := float(B[1,1]):
linalg::cond(B, 2)
```

```
2.223147175
```

## Example 2

We define the 2 2 matrix  $C$ .

```
C := matrix([[1,-2],[3,-4]])
```

$$\begin{pmatrix} 1 & -2 \\ 3 & -4 \end{pmatrix}$$

Now we calculate the condition number of  $C$  for some matrix norms.

```
linalg::cond(C,1)
```

```
21
```

```
linalg::cond(C,Infinity)
```

```
21
```

```
linalg::cond(C,Frobenius); Simplify(%);
```

$$\frac{\sqrt{2} \sqrt{15} \sqrt{30}}{2}$$

15

**Example 3**

Hilbert matrices are very ill-conditioned:

```
linalg::cond(linalg::hilbert(3))
```

748

```
linalg::cond(linalg::hilbert(5))
```

943656

```
linalg::cond(linalg::hilbert(7))
```

$$\frac{1970389773}{2}$$

**Parameters****M**

Square matrix of domain type `Dom::Matrix`

**Options****Frobenius, Infinity, Spectral**

The index of the matrix norm.

**Return Values**

Arithmetical expression.

# **linalg::cond**

---

## **See Also**

## **MuPAD Functions**

norm

**Purpose** Cross product of three-dimensional vectors

**Syntax** `linalg::crossProduct(u, v)`

**Description** `linalg::crossProduct(u, v)` computes the cross product of the three-dimensional vectors  $\vec{u}$  and  $\vec{v}$ . This is the vector

$$\vec{u} \times \vec{v} = \begin{pmatrix} u_2 v_3 - u_3 v_2 \\ u_3 v_1 - u_1 v_3 \\ u_1 v_2 - u_2 v_1 \end{pmatrix}$$

The vectors must be defined over the same component ring.

## Examples **Example 1**

We define two vectors:

```
a := matrix([[1, 2, 3]]);
b := matrix([[-1, 0, 1]])
```

```
(1 2 3)
```

```
(-1 0 1)
```

The cross product of these two vectors is a vector  $\vec{c}$  which is orthogonal to  $\vec{a}$  and  $\vec{b}$ :

```
c := linalg::crossProduct(a, b)
```

```
(2 -4 2)
```

# **linalg::crossProduct**

---

```
linalg::scalarProduct(a, c), linalg::scalarProduct(b, c)
```

```
0, 0
```

## **Parameters**

**u, v**

3-dimensional vectors, i.e., either two  $3 \times 1$  or two  $1 \times 3$  matrices of a domain of category `Cat::Matrix`

## **Return Values**

Vector of the same domain type as u.

## **See Also**

## **MuPAD Functions**

`linalg::scalarProduct`

**Purpose** Curl of a vector field

**Syntax** `linalg::curl(v, x)`  
`linalg::curl(v, x, ogCoord, <c>)`

**Description** `linalg::curl(v, x)` computes the curl of the three-dimensional vector field  $\vec{v}$  with respect to the three-dimensional vector  $\vec{x}$  in Cartesian coordinates. This is the vector field

$$\text{curl}(\vec{v}) = \begin{pmatrix} \frac{\partial}{\partial x_2} V_3 - \frac{\partial}{\partial x_3} V_2 \\ \frac{\partial}{\partial x_3} V_1 - \frac{\partial}{\partial x_1} V_3 \\ \frac{\partial}{\partial x_1} V_2 - \frac{\partial}{\partial x_2} V_1 \end{pmatrix}$$

`linalg::curl` and `curl` are equivalent. See details and examples on the `curl` help page.

**Parameters**

**v**

A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3 1 or 1 3 matrix of a domain of category `Cat::Matrix`)

**x**

A list of three (indexed) identifiers

**ogCoord**

The name of a 3 dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic expressions representing the “scale parameters” of an orthogonal coordinate system.

**c**

# **linalg::curl**

---

The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is  $c = 1$ .

## **Return Values**

Column vector.

**Purpose** Delete matrix columns

**Syntax** `linalg::delCol(A, c)`  
`linalg::delCol(A, c1 .. c2)`  
`linalg::delCol(A, list)`

**Description** `linalg::delCol(A, c)` returns a copy of the matrix  $A$  in which the column with index  $c$  is deleted.

`linalg::delCol(A, c1 .. c2)` deletes those columns whose indices are in the range  $c_1 .. c_2$ . If  $c_2 < c_1$  then the input matrix  $A$  is returned.

`linalg::delCol(A, list)` deletes those columns whose indices are contained in `list`.

If all columns are deleted then `NIL` is returned.

## Examples **Example 1**

We define the following matrix:

```
A := matrix([[1, 2, 3, 4], [5, 6, 7, 8]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{pmatrix}$$

and demonstrate the three different input formats for `linalg::delCol`:

```
linalg::delCol(A, 2)
```

$$\begin{pmatrix} 1 & 3 & 4 \\ 5 & 7 & 8 \end{pmatrix}$$

```
linalg::delCol(A, [1, 3])
```

# linalg::delCol

---

$$\begin{pmatrix} 2 & 4 \\ 6 & 8 \end{pmatrix}$$

```
linalg::delCol(A, 2..4)
```

$$\begin{pmatrix} 1 \\ 5 \end{pmatrix}$$

## Example 2

We compute the inverse of the 2 2 matrix:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[3, 2], [5, -4]])
```

$$\begin{pmatrix} 3 & 2 \\ 5 & -4 \end{pmatrix}$$

by appending the 2 2 identity matrix to the right side of  $A$  and applying the Gauss-Jordan algorithm provided by the function `linalg::gaussJordan`:

```
B := linalg::gaussJordan(A . MatQ::identity(2))
```

$$\begin{pmatrix} 1 & 0 & \frac{2}{11} & \frac{1}{11} \\ 0 & 1 & \frac{5}{22} & -\frac{3}{22} \end{pmatrix}$$

We get the inverse of  $A$  by deleting the first two columns of the matrix  $B$ :

```
AI := linalg::delCol(B, 1..2)
```

$$\begin{pmatrix} \frac{2}{11} & \frac{1}{11} \\ \frac{5}{22} & -\frac{3}{22} \end{pmatrix}$$

Finally, we check the result:

$$A * AI, AI * A$$

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Note: The inverse of A can be computed directly by entering 1/A.

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**c**

The column index: a positive integer less or equal to  $n$

**c<sub>1</sub> .. c<sub>2</sub>**

A range of column indices (positive integers less or equal to  $n$ )

**list**

A list of column indices (positive integers less or equal to  $n$ )

## Return Values

Matrix of a domain of category `Cat::Matrix(R)`, where R is the component ring of A, or NIL.

## See Also

## MuPAD Functions

`linalg::col` | `linalg::delRow` | `linalg::row`

# linalg::delCol

---

## Concepts

- “Swap and Delete Rows and Columns”

**Purpose** Delete matrix rows

**Syntax** `linalg::delRow(A, r)`  
`linalg::delRow(A, r1 .. r2)`  
`linalg::delRow(A, list)`

**Description** `linalg::delRow(A, r)` returns a copy of the matrix  $A$  in which the row with index  $r$  is deleted.

`linalg::delRow(A, r1 .. r2)` deletes those rows whose indices are in the range  $r_1 .. r_2$ . If  $r_2 < r_1$  then the input matrix  $A$  is returned.

`linalg::delRow(A, list)` deletes those rows whose indices are contained in `list`.

If all rows are deleted then NIL is returned.

## Examples **Example 1**

We define the following matrix:

```
A := matrix([[1, 2], [3, 4], [5, 6], [7, 8]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 5 & 6 \\ 7 & 8 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::delRow`:

```
linalg::delRow(A, 2)
```

$$\begin{pmatrix} 1 & 2 \\ 5 & 6 \\ 7 & 8 \end{pmatrix}$$

```
linalg::delRow(A, [1, 4])
```

# linalg::delRow

---

$$\begin{pmatrix} 3 & 4 \\ 5 & 6 \end{pmatrix}$$

```
linalg::delRow(A, 2..4)
```

$$(1 \ 2)$$

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**r**

The row index: a positive integer less or equal to  $m$

**r<sub>1</sub> .. r<sub>2</sub>**

A range of row indices (positive integers less or equal to  $m$ )

**list**

A list of row indices (positive integers less or equal to  $m$ )

## Return Values

Matrix of a domain of category `Cat::Matrix(R)`, where  $R$  is the component ring of  $A$  or `NIL`.

## See Also

## MuPAD Functions

`linalg::col` | `linalg::delCol` | `linalg::row`

## Concepts

- “Swap and Delete Rows and Columns”

**Purpose** Determinant of a matrix

**Syntax** `linalg::det(A, options)`

**Description** `linalg::det(A)` computes the determinant of the square matrix  $A$ .

A floating-point approximation of the determinant is computed with `numeric::det`, if  $A$  is defined over the component ring `Dom::Float`. In this case, it is recommended to call `numeric::det` directly for a better efficiency.

The component ring of  $A$  must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

The `MinorExpansion` option is useful for small matrices (typically, matrices of dimension up to 10) containing many symbolic entries. By default, `linalg::det` tries to recognize matrices that can benefit from using `MinorExpansion`, and uses this option when computing their determinants. Nevertheless, `linalg::det` does not always recognize these matrices. Also, identifying that a matrix is small enough and contains many symbolic entries takes time. To improve performance, use the `MinorExpansion` option explicitly.

By default, `linalg::det` calls `normal` before returning results. This additional internal call ensures that the final result is normalized. This call can be computationally expensive. It also affects the result returned by `linalg::det` only if a matrix contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

To avoid this additional call, specify `Normal = FALSE`. In this case, `linalg::det` also can return normalized results, but does not guarantee such normalization. See “Example 2” on page 14-48 and “Example 3” on page 14-48.

## Examples **Example 1**

Compute the determinant of the following matrix:

```
A := matrix([[a11, a12], [a21, a22]])
```

# linalg::det

---

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

`linalg::det` returns the well-known formula for the determinant of an arbitrary 2 2 matrix:

```
linalg::det(A)
```

$$a_{11} a_{22} - a_{12} a_{21}$$

## Example 2

If you use the `Normal` option, `linalg::det` calls the `normal` function for final results. This call ensures that `linalg::det` returns results in normalized form:

```
linalg::det(matrix([[x, x^2], [x/(x + 2), 1/x]]))
```

$$\frac{-x^3 + x + 2}{x + 2}$$

If you specify `Normal = FALSE`, `linalg::det` does not call `normal` for the final result:

```
linalg::det(matrix([[x, x^2], [x/(x + 2), 1/x]]), Normal = FALSE)
```

$$1 - \frac{x^3}{x + 2}$$

## Example 3

Using `Normal` can significantly decrease the performance of `linalg::det`. For example, computing the determinant of this matrix takes a long time:

```
n := 5:
det5 := linalg::det(matrix([[x[i*j]^(i + j) + x[i+j]^j)/(i + j)]))
```

For better performance, specify `Normal = FALSE`:

```
n := 5:
det5 := linalg::det(matrix([[x[i*j]^(i + j) + x[i+j]^j)/(i + j)]))
```

## Parameters

### A

Square matrix of a domain of category `Cat::Matrix`

## Options

### MinorExpansion

Compute the determinant by a recursive minor expansion along the first column.

### Normal

Option, specified as `Normal = b`

Return normalized results. The value `b` must be `TRUE` or `FALSE`. By default, `Normal = TRUE`, meaning that `linalg::det` guarantees normalization of the returned results. Normalizing results can be computationally expensive.

## Return Values

Element of the component ring of `A`.

## Algorithms

For an  $n \times n$  matrix  $A = (a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq n}$  over a commutative ring its determinant is defined as:

$$\det A := \sum_{\sigma \in S_n} \text{sign}(\sigma) \left( \prod_{j=1}^n a_{\sigma(j), j} \right)$$

( $S_n$  is the symmetric group of all permutations of  $\{1, \dots, n\}$ .)

# **linalg::det**

---

For a component ring of  $A$  that is an integral domain (i.e., a domain of category `Cat::IntegralDomain`) and not defined over the domain `Dom::Float`, Gaussian elimination is used to compute the determinant of  $A$ .

For any other commutative ring that is not an integral domain, a modification of the Berkowitz algorithm is used.

## **See Also**

## **MuPAD Functions**

`linalg::gaussElim` | `linalg::permanent` | `linalg::rank` | `numeric::det`

**Purpose** Divergence of a vector field

**Syntax** `linalg::divergence(v, x)`  
`linalg::divergence(v, x, ogCoord, <c>)`

**Description** `linalg::divergence(v, x)` computes the divergence of the vector field  $\vec{v}$  with respect to  $\vec{x}$  in Cartesian coordinates. This is the sum

$$\operatorname{div}(\vec{v}) = \sum_{i=1}^n \frac{\partial}{\partial x_i} v_i.$$

`linalg::divergence` and `divergence` are equivalent. See details and examples on the `divergence` help page.

**Parameters** **v**

A list of arithmetical expressions, or a vector (i.e., an  $n \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`)

**x**

A list of (indexed) identifiers

**ogCoord**

The name of a 3 dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic expressions representing the “scale parameters” of an orthogonal coordinate system.

**c**

The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is `c = 1`.

**Return Values**

Arithmetical expression, or an element of the component ring of `v`.

# linalg::eigenvalues

---

**Purpose** Eigenvalues of a matrix

**Syntax** `linalg::eigenvalues(A, <Multiple>)`

**Description** `linalg::eigenvalues(A)` returns a list of the eigenvalues of the matrix  $A$ .

A floating-point approximation of the eigenvalues is computed with `numeric::eigenvalues`, if the matrix  $A$  is defined over the component ring `Dom::Float` (see “Example 1” on page 14-52). In this case it is recommended to call `numeric::eigenvalues` directly for a better efficiency.

The eigenvalues are obtained by computing the zeros of the characteristic polynomial of  $A$ . The solver `solve` must be able to compute the roots of the characteristic polynomial over the component ring of  $A$ .

## Examples

### Example 1

We compute the eigenvalues of the matrix

$$A = \begin{pmatrix} 1 & 4 & 2 \\ 1 & 4 & 2 \\ 2 & 5 & 3 \end{pmatrix} :$$

```
A := matrix([[1, 4, 2], [1, 4, 2], [2, 5, 3]]):
linalg::eigenvalues(A)
```

```
{0, 4 - $\sqrt{15}$, $\sqrt{15} + 4$ }
```

If we consider the matrix over the domain `Dom::Float`, then the call of `linalg::eigenvalues(A)` results in a numerical computation of the eigenvalues of  $A$  via `numeric::eigenvalues`:

```
B := Dom::Matrix(Dom::Float)(A):
linalg::eigenvalues(B)
```

```
{ -1.370431546 10-15, 0.1270166538, 7.872983346 }
```

## Example 2

With the option `Multiple` we get the information about the algebraic multiplicity of each eigenvalue:

```
C := Dom::Matrix(Dom::Rational)(4, 4, [[-3], [0, 6]])
```

```
(-3 0 0 0)
 (0 6 0 0)
 (0 0 0 0)
 (0 0 0 0)
```

```
linalg::eigenvalues(C, Multiple)
```

```
[[-3, 1], [0, 2], [6, 1]]
```

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

## Options

**Multiple**

Returns a list of sublists, where each sublist contains an eigenvalue of `A` and its algebraic multiplicity. Note that due to rounding errors, this may lead to wrong results in cases where multiple eigenvalues exist and `numeric::eigenvalues` is used.

## Return Values

Set of the eigenvalues of `A`, or a list of inner lists when the option `Multiple` is given (see below).

# **linalg::eigenvalues**

---

## linalg::eigenvectors

---

$$A = \begin{pmatrix} 1 & -3 & 3 \\ 6 & -10 & 6 \\ 6 & 6 & 4 \end{pmatrix} :$$

```
A := Dom::Matrix(Dom::Rational)(
 [[1, -3, 3], [6, -10, 6], [6, 6, 4]]
):
Ev:= linalg::eigenvectors(A)
```

$$\left[ \left[ -11, 1, \left[ \begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix} \right] \right], \left[ -2, 1, \left[ \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \right] \right], \left[ 8, 1, \left[ \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix} \right] \right] \right]$$

The matrix A is diagonalizable. Hence, we extract the eigenvectors and combine them to a matrix P such that  $P^{-1} * A * P$  is the diagonal matrix whose diagonal entries are given by the corresponding eigenvalues:

```
Eigenvectors:= Ev[1][3][1], Ev[2][3][1], Ev[3][3][1]
```

$$\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix}$$

```
P:= Eigenvectors[1].Eigenvectors[2].Eigenvectors[3]
```

$$\begin{pmatrix} -\frac{7}{10} & -1 & \frac{1}{4} \\ -\frac{9}{5} & 0 & \frac{5}{12} \\ 1 & 1 & 1 \end{pmatrix}$$

`P^-1 * A * P`

$$\begin{pmatrix} -11 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & 8 \end{pmatrix}$$

A more skillful way of extracting the above eigenvectors from the output generated by `linalg::eigenvectors` is the following:

`map(Ev, op@op, 3)`

$$\left[ \begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix} \right]$$

If we consider the matrix `A` over the domain `Dom::Float`, the call of `linalg::eigenvectors(A)` results in a numerical computation of the eigenvalues and the eigenvectors of `A` via the function `numeric::eigenvectors`:

```
B := Dom::Matrix(Dom::Float)(A):
linalg::eigenvectors(B)
```

# linalg::eigenvectors

---

```
[[[8.0, 1, [[[0.2248595067], [0.3747658445], [0.8994380268]]]], [-2.0, 1, [[[0.7071067812], [0.0], [-0.7071067812]]]], [-11.0, 1, [[[0.32186034], [0.82764088], [-0.45980048]]]]
```

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

## Return Values

List of sublists, where each sublist consists of an eigenvalue  $\lambda$  of **A**, its algebraic multiplicity and a basis for the eigenspace of  $\lambda$ . If a basis of an eigenspace cannot be computed, `FAIL` is returned.

- “Compute Eigenvalues and Eigenvectors Numerically”

**Purpose** Construct a matrix from equations

**Syntax** `linalg::expr2Matrix(eqns, <vars, R>, <Include>)`

**Description** `linalg::expr2Matrix(eqns, vars)` constructs the extended coefficient matrix  $(A, \bar{b})$  of the system of  $m$  linear equations in eqns with respect to the  $n$  indeterminates in vars. The vector  $\bar{b}$  is the right-hand side of this system.

`linalg::expr2Matrix` returns the extended coefficient matrix  $M = (A, \bar{b})$ . The right-hand side vector  $\bar{b}$  can be extracted from the matrix  $M$  by `linalg::col(M, n + 1)`.

The coefficient matrix  $A$  can be extracted by `linalg::delCol(M, n + 1)`.

Arithmetical expressions in eqns are considered as equations with right hand-sides zero.

If no variables are given, then the indeterminates of the equations are determined with the function `indets` and the option `PolyExpr`, i.e., the left-hand sides of the equations are considered as polynomial expressions.

If no component ring  $R$  is given then the standard domain `Dom::ExpressionField()` is chosen as the component ring of the extended coefficient matrix.

The coefficients of the linear equations are converted into elements of the component ring  $R$ . An error message is returned if this is not possible.

## Examples

### Example 1

The extended coefficient matrix of the system  $x + y + z = 1$ ,  $2y - z + 5 = 0$  of linear equations in the variables  $x, y, z$  is the following 2 4 matrix:

```
delete x, y, z:
```

# `linalg::expr2Matrix`

---

```
Ab := linalg::expr2Matrix(
 [x + y + z = 1, 2*y - z + 5], [x, y, z], Dom::Real
)
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 2 & -1 & -5 \end{pmatrix}$$

We use `linalg::matlinsolve` to compute the general solution of this system:

```
linalg::matlinsolve(Ab)
```

$$\left[ \left( \begin{array}{c} \frac{7}{2} \\ -\frac{5}{2} \\ 0 \end{array} \right), \left[ \left( \begin{array}{c} -\frac{3}{2} \\ \frac{1}{2} \\ 1 \end{array} \right) \right] \right]$$

The coefficient matrix or the right-hand side vector can be extracted from the matrix `Ab` in the following way:

```
A := linalg::delCol(Ab, 4); b := linalg::col(Ab, 4)
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 2 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 1 \\ -5 \end{pmatrix}$$

## Example 2

The following two inputs lead to different linear systems:

```
delete x, y, z:
```

```
linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5 = x]),
linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5 = x], [x, y])
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ -1 & 2 & -1 & -5 \end{pmatrix}, \begin{pmatrix} 1 & 1 & 1-z \\ -1 & 2 & z-5 \end{pmatrix}$$

### Example 3

Note the difference between calling `linalg::expr2Matrix` with and without option `Include`:

```
delete x, y:
linalg::expr2Matrix([x + y = 1, 2*x - y = 3], [x, y])
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 2 & -1 & 3 \end{pmatrix}$$

```
linalg::expr2Matrix([x + y = 1, 2*x - y = 3], [x, y], Include)
```

$$\begin{pmatrix} 1 & 1 & -1 \\ 2 & -1 & -3 \end{pmatrix}$$

## Parameters

### eqns

The system of linear equations, i.e. a set or list of expressions of type `"_equal"`

### vars

A set or list of indeterminates

### R

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`

# linalg::expr2Matrix

---

## Options

### Include

Appends the negative of the right-hand side vector  $\vec{b}$  to the coefficient matrix  $A$  of the given system of linear equations. The result is the  $m (n + 1)$  matrix  $(A, -\vec{b})$ .

## Return Values

$m (n + 1)$  matrix of the domain  $\text{Dom}::\text{Matrix}(\mathbb{R})$ .

## See Also

## MuPAD Functions

`linalg::matlinsolve` | `linsolve` | `indets`

## Purpose

The Cholesky decomposition of a matrix

## Syntax

```
linalg::factorCholesky(A, <NoCheck>, <Real>)
```

## Description

`linalg::factorCholesky(A)` computes the Cholesky factorization of a Hermitian positive definite matrix  $A$  and returns a lower triangular matrix  $L$ , such that  $LL^H = A$ . Here,  $L^H$  is the Hermitian conjugate of  $L$  (the complex conjugate of the transpose).

The component ring of  $A$  must be a field (a domain of category `Cat::Field`).

If  $A$  is not a Hermitian positive definite matrix, then `linalg::factorCholesky` throws an error. If you use `NoCheck`, `linalg::factorCholesky` does not check whether the matrix is Hermitian positive definite. See “Example 2” on page 14-64.

If you use `Real`, then `linalg::factorCholesky` assumes that  $A$  is real and symmetric and, therefore, does not apply complex conjugate in the course of the algorithm.

`linalg::factorCholesky` returns `FAIL` if it fails to compute the matrix  $L$  over the component ring of  $A$ . (The algorithm requires the computation of square roots of some elements in  $L$ ).

## Environment Interactions

Properties of identifiers are taken into account.

## Examples

### Example 1

Define matrix  $S$  as follows:

```
S := Dom::Matrix(Dom::Rational)(
 [[4, -2, 4, 2], [-2, 10, -2, -7], [4, -2, 8, 4], [2, -7, 4, 7]]
)
```

# linalg::factorCholesky

---

$$\begin{pmatrix} 4 & -2 & 4 & 2 \\ -2 & 10 & -2 & -7 \\ 4 & -2 & 8 & 4 \\ 2 & -7 & 4 & 7 \end{pmatrix}$$

Compute the Cholesky factorization of S:

```
L := linalg::factorCholesky(S)
```

$$\begin{pmatrix} 2 & 0 & 0 & 0 \\ -1 & 3 & 0 & 0 \\ 2 & 0 & 2 & 0 \\ 1 & -2 & 1 & 1 \end{pmatrix}$$

Verify the result:

```
is(L * htranspose(L) = S)
```

```
TRUE
```

## Example 2

Define matrix H as follows:

```
H := matrix([[a, b], [b, a]])
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

`linalg::factorCholesky` cannot compute the Cholesky factorization because it cannot prove that H is a Hermitian matrix:

```
linalg::factorCholesky(H)
```

```
Error: A Hermitian matrix is expected. [linalg::factorCholesky]
```

If you assume that  $a$  and  $b$  are real, then matrix  $H$  is Hermitian. Still, `linalg::factorCholesky` cannot compute the Cholesky factorization:

```
linalg::factorCholesky(H) assuming a in R_ and b in R_
```

```
Error: Cannot check whether the matrix component is positive. [linalg::factorCholesky]
```

Use the `NoCheck` option to skip checking whether this matrix is Hermitian positive definite. Now, `linalg::factorCholesky` computes the factorization:

```
L := linalg::factorCholesky(H, NoCheck)
```

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \frac{\sqrt{a|a|-|b|^2}}{\sqrt{|a|}} \end{pmatrix}$$

This result is not generally valid:

```
L*htranspose(L) = H
```

# linalg::factorCholesky

---

$$\begin{pmatrix} \sqrt{a} & \sqrt{a} \\ \frac{b\sqrt{a}}{\sqrt{a}} & \frac{\sqrt{a}b}{\sqrt{a}} + \frac{\sqrt{a|a|-|b|^2}}{|a|} \sqrt{a|a|-|b|^2} \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

It is valid for  $0 < a < b$ :

`simplify(L*Htranspose(L) = H)` assuming  $0 < b < a$

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

### Example 3

Compute the Cholesky factorization of matrix H using NoCheck to skip checking whether it is Hermitian positive definite. By default, `linalg::factorCholesky` computes a Hermitian factorization  $A = LL^H$ . Thus, the result contains complex conjugates (implied by  $|a| = a\bar{a}$ ).

```
H := matrix([[a, b], [b, a]]):
L := linalg::factorCholesky(H, NoCheck)
```

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \frac{\sqrt{a|a|-|b|^2}}{\sqrt{|a|}} \end{pmatrix}$$

To avoid complex conjugates in the result, use `Real`:

```
L := linalg::factorCholesky(H, NoCheck, Real)
```

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \sqrt{\frac{a^2 - b^2}{a}} \end{pmatrix}$$

With this option, `linalg::factorCholesky` computes a symmetric factorization  $A = LL^t$  instead of a Hermitian factorization  $A = LL^H$ :

```
simplify(L*transpose(L) = H)
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

## Parameters

**A**

Square matrix of a domain of category `Cat::Matrix`.

## Options

**NoCheck**

Skip checking whether  $A$  is Hermitian positive definite. When you use this option, the identity  $LL^H = A$  is guaranteed to hold only if  $A$  is a Hermitian positive definite matrix.

**Real**

Compute the Cholesky factorization assuming that matrix  $A$  is symmetric and all its symbolic parameters are real. In this case, the transpose of the matrix is its Hermitian transpose. Use this option if  $A$  contains symbolic parameters, and you want to avoid complex conjugates. When using this option, the identity  $LL^T = A$  is guaranteed to hold.

## Return Values

Matrix of the same domain type as  $A$ , or the value `FAIL`.

# linalg::factorCholesky

---

## Algorithms

The Cholesky factorization of a Hermitian positive definite  $n \times n$  matrix  $A$  is a decomposition of  $A$  in a product  $LL^H = A$ , such that  $L$  is a lower triangular matrix with positive entries on the main diagonal.  $L$  is called the “Cholesky factor” of  $A$ .

If  $L = (l_{i,j})$ , where  $1 \leq i \leq n$ ,  $1 \leq j \leq n$ , is the Cholesky factor of  $A$ , then

$$\det A = \left( \prod_{i=1}^n l_{ii} \right)^2.$$

### Related Examples

- “Compute Cholesky Factorization”

**Purpose** LU-decomposition of a matrix

**Syntax** `linalg::factorLU(A)`

**Description** `linalg::factorLU(A)` computes an LU-decomposition of an  $m \times n$  matrix  $A$ , i.e., a decomposition of the  $A$  into an  $m \times m$  lower triangular matrix  $L$  and an  $m \times n$  upper triangular matrix  $U$  such that  $PA = LU$ , where  $P$  is a permutation matrix.

The diagonal entries of the lower triangular matrix  $L$  are equal to one (*Doolittle*-decomposition). The diagonal entries of  $U$  are the pivot elements used during the computation.

The matrices  $L$  and  $U$  are unique.

`pivindex` is a list  $[r_1, r_2, \dots]$  representing the row exchanges of  $A$  in the pivoting steps, i.e.,  $B = PA = LU$ , where  $b_{ij} = a_{r_i, j}$ .

A floating-point approximation of the decomposition is computed using `numeric::factorLU`, if the matrix  $A$  is defined over the component ring `Dom::Float`. In this case it is recommended to call `numeric::factorLU` directly for a better efficiency.

The algorithm also works for singular  $A$ . In this case either  $L$  or  $U$  is singular.

$L$  and  $U$  are nonsingular if and only if  $A$  is nonsingular.

The component ring of the matrix  $A$  must be a field, i.e., a domain of category `Cat::Field`.

## Examples **Example 1**

We compute an LU-decomposition of the real matrix:

```
A := Dom::Matrix(Dom::Real)(
 [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)
```

# linalg::factorLU

---

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[ \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 0 & \frac{2}{5} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 & -1 \\ 0 & \frac{5}{2} & -\frac{1}{2} \\ 0 & 0 & -\frac{4}{5} \end{pmatrix}, [1, 2, 3] \right]$$

The lower triangular matrix  $L$  is the first element and the upper triangular matrix  $U$  is the second element of the list LU. The product of these two matrices is equal to the input matrix A:

```
L * U
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

## Example 2

An LU-decomposition of the 3 2 matrix:

```
A := Dom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

gives a 3 3 lower triangular matrix and a 3 2 upper triangular matrix:

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[ \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 1 & \frac{12}{7} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 \\ 0 & \frac{7}{2} \\ 0 & 0 \end{pmatrix}, [1, 2, 3] \right]$$

```
L * U
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

### Example 3

To compute the LU-decomposition of the matrix:

```
A := matrix([[1, 2, -1], [0, 0, 3], [0, 2, -1]])
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 0 & 0 & 3 \\ 0 & 2 & -1 \end{pmatrix}$$

one row interchange is needed, and we therefore get a non-trivial permutation list:

```
[L, U, pivlist] := linalg::factorLU(A)
```

# linalg::factorLU

---

$$\left[ \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 2 & -1 \\ 0 & 2 & -1 \\ 0 & 0 & 3 \end{pmatrix}, [1, 3, 2] \right]$$

The corresponding permutation matrix is the following:

```
P := linalg::swapRow(matrix::identity(3), 3, 2)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

Hence, we have a decomposition of  $A$  into the product of the three matrices  $\frac{1}{P}$ ,  $L$  and  $U$  as follows:

```
P^(-1) * L * U
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 0 & 0 & 3 \\ 0 & 2 & -1 \end{pmatrix}$$

## Example 4

You may compute an LU-decomposition of a matrix with symbolic components, such as:

```
delete a, b, c, d:
A := matrix([[a, b], [c, d]])
```

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

The diagonal entries of the matrix  $U$  are the pivot elements used during the computation. They must be non-zero, if the inverse of  $U$  is needed:

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[ \left( \begin{array}{cc} 1 & 0 \\ \frac{c}{a} & 1 \end{array} \right), \left( \begin{array}{cc} a & b \\ 0 & d - \frac{bc}{a} \end{array} \right), [1, 2] \right]$$

For example, if we use this decomposition to solve the linear system  $A \vec{x} = \vec{b}$  for arbitrary vectors  $\vec{b} = (b_1, b_2)^t$ , then the following result is only correct for  $a \neq 0$  and  $d - \frac{bc}{a} \neq 0$ :

```
delete b1, b2;
linalg::matlinsolveLU(L, U, matrix([b1, b2]))
```

$$\begin{pmatrix} \frac{b_1 - \frac{b(a b_2 - b_1 c)}{a d - b c}}{a} \\ \frac{a b_2 - b_1 c}{a d - b c} \end{pmatrix}$$

## Parameters

**A**

A matrix of a domain of category `Cat::Matrix`

## Return Values

List `[L, U, pivindex]` with the two matrices  $L$  and  $U$  of the domain `Dom::Matrix(R)` and a list `pivindex` of positive integers.  $R$  is the component ring of  $A$ .

## Algorithms

The following algorithm for solving the system  $A \vec{x} = \vec{b}$  with a nonsingular matrix  $A$  uses LU-decomposition:

# linalg::factorLU

---

**1** Compute a LU-decomposition of  $A$ :  $A = LU$ .

**2** Solve  $\vec{y} = \frac{\vec{b}}{L}$  by forward substitution.

**3** Solve  $\vec{x} = \frac{\vec{y}}{R}$  by backward substitution.

The LU-decomposition of a matrix  $A$  is useful for solving several systems of linear equations  $A \vec{x} = \vec{b}$  with the same coefficient matrix  $A$  and several right-hand side vectors  $\vec{b}$ , because then step one of the algorithm above needs to be done only once.

`linalg::factorQR` | `linalg::factorCholesky` |  
`linalg::inverseLU` | `linalg::matlinsolveLU` | `lllint` |  
`numeric::factorLU`

### Related Examples

- “Compute LU Factorization”

**Purpose** QR-decomposition of a matrix

**Syntax** `linalg::factorQR(A)`

**Description** `linalg::factorQR(A)` computes an QR-decomposition of an  $m \times n$  matrix  $A$ , i.e., a decomposition of  $A$  into an  $m \times m$  unitary matrix  $Q$  and an  $m \times n$  upper triangular matrix  $R$  such that  $QR = A$ .

`linalg::factorQR` uses Gram-Schmidt orthonormalization to compute the decomposition.

For a singular or non-square matrix  $A$  the QR-decomposition of  $A$  is not unique.

The columns of  $Q$  form an orthonormal basis with respect to the scalar product of two vectors, defined by `linalg::scalarProduct`, and the 2-norm of two vectors (see the method "norm" of the domain constructor `Dom::Matrix`).

If the component ring of  $A$  does not define the method "conjugate", then the factor  $Q$  is orthogonal instead of unitary.

If the columns of  $A$  cannot be orthonormalized then FAIL is returned.

If  $A$  is a matrix over the domain `Dom::Float` and the computations are based on the standard scalar product, then the use of the corresponding function from the numeric library (`numeric::factorQR`) is recommended.

Even if  $A$  is defined over the real or the complex numbers the call of `numeric::factorQR` with the option `Symbolic` is recommended for better efficiency.

The component ring of the matrix  $A$  must be a field, i.e., a domain of category `Cat::Field`.

## Examples **Example 1**

We compute the QR-decomposition of a real matrix:

```
A := Dom::Matrix(Dom::Real)(
```

# linalg::factorQR

```
) [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

```
QR := linalg::factorQR(A)
```

$$\left[ \begin{pmatrix} \frac{2\sqrt{5}}{5} & -\frac{\sqrt{6}}{6} & -\frac{\sqrt{2}\sqrt{15}}{30} \\ \frac{\sqrt{5}}{5} & \frac{\sqrt{6}}{3} & \frac{\sqrt{2}\sqrt{15}}{15} \\ 0 & \frac{\sqrt{6}}{6} & -\frac{\sqrt{2}\sqrt{15}}{6} \end{pmatrix}, \begin{pmatrix} \sqrt{5} & -\sqrt{5} & -\frac{3\sqrt{5}}{5} \\ 0 & \sqrt{6} & -\frac{\sqrt{6}}{3} \\ 0 & 0 & \frac{2\sqrt{2}\sqrt{15}}{15} \end{pmatrix} \right]$$

The orthogonal matrix  $Q$  is the first element and the upper triangular matrix  $R$  is the second element of the list  $QR$ . The product of these two matrices is equal to the input matrix  $A$ :

```
QR[1] * QR[2]
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

## Example 2

The QR-decomposition of the 3 2 matrix:

```
B := Dom::Matrix(Dom::Real)(
 [[2, -3], [1, 2], [2, 3]]
)
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

yields a 3 3 orthogonal matrix and a 3 2 upper triangular matrix:

```
QR := linalg::factorQR(B)
```

$$\left[ \begin{pmatrix} \frac{2}{3} & -\frac{31\sqrt{194}}{582} & \frac{\sqrt{194}}{194} \\ \frac{1}{3} & \frac{8\sqrt{194}}{291} & \frac{6\sqrt{194}}{97} \\ \frac{2}{3} & \frac{23\sqrt{194}}{582} & -\frac{7\sqrt{194}}{194} \end{pmatrix}, \begin{pmatrix} 3 & \frac{2}{3} \\ 0 & \frac{\sqrt{194}}{3} \\ 0 & 0 \end{pmatrix} \right]$$

```
QR[1] * QR[2]
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

For this example we may call `numeric::factorQR(B, Symbolic)` instead, which in general is faster than `linalg::factorQR`:

```
QR := numeric::factorQR(B, Symbolic)
```

$$\left[ \begin{pmatrix} \frac{2}{3} & -\frac{31\sqrt{194}}{582} & \frac{\sqrt{194}}{194} \\ \frac{1}{3} & \frac{8\sqrt{194}}{291} & \frac{6\sqrt{194}}{97} \\ \frac{2}{3} & \frac{23\sqrt{194}}{582} & -\frac{7\sqrt{194}}{194} \end{pmatrix}, \begin{pmatrix} 3 & \frac{2}{3} \\ 0 & \frac{\sqrt{194}}{3} \\ 0 & 0 \end{pmatrix} \right]$$

# linalg::factorQR

---

## Parameters

**A**

A matrix of a domain of category `Cat::Matrix`

## Return Values

List [Q, R] of the two matrices  $Q$  and  $R$  (of the same domain type as  $A$ ), or the value FAIL.

## Algorithms

The QR-decomposition can be used to generate a least square solution to an overdetermined system of linear equations. If  $A \vec{x} = \vec{b}$ , then  $R \vec{x} = Q^t \vec{b}$  can be solved via backward substitution.

### Related Examples

- “Compute QR Factorization”

**Purpose** Frobenius form of a matrix

**Syntax** `linalg::frobeniusForm(A, <All>)`

**Description** `linalg::frobeniusForm(A)` returns the Frobenius form of the matrix  $A$ , also called the Rational Canonical form of  $A$ .

`linalg::frobeniusForm(A, All)` computes the Frobenius form  $R$  of  $A$  and a transformation matrix  $P$  such that  $PRP^{-1}$ .

The Frobenius form as computed by `linalg::frobeniusForm` is unique (see below).

The component ring of  $A$  must be a field, i.e., a domain of category `Cat::Field`.

## Examples **Example 1**

The Frobenius form of the following matrix over :

```
A := Dom::Matrix(Dom::Complex)(
 [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

is the matrix:

```
R := linalg::frobeniusForm(A)
```

$$\begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 18 \\ 0 & 1 & 15 \end{pmatrix}$$

# linalg::frobeniusForm

---

The transformation matrix  $P$  can be selected from the list  $[R, P]$ , which is the result of `linalg::frobeniusForm` with option `All`:

```
P := linalg::frobeniusForm(A, All)[2]
```

$$\begin{pmatrix} 1 & 1 & 30 \\ 0 & 4 & 66 \\ 0 & 7 & 102 \end{pmatrix}$$

We check the result:

```
P * R * P^(-1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

## Options

**All**

Returns the list  $[R, P]$  with the Frobenius form  $R$  of  $A$  and a transformation matrix  $P$  such that  $A = PRP^{-1}$ .

## Return Values

Matrix of the same domain type as  $A$ , or the list  $[R, P]$  when the option `All` is given.

## Algorithms

The Frobenius form of a square matrix  $A$  is the matrix

$$R = \begin{pmatrix} R_1 & & & \\ & \cdot & & \\ & & \cdot & \\ & & & R_r \end{pmatrix},$$

where  $R_1, \dots, R_r$  are known as companion matrices and have the form:

$$R_i = \begin{pmatrix} 0 & \cdot & \cdot & \cdot & 0 & -a_0 \\ 1 & \cdot & & & & -a_1 \\ & \cdot & \cdot & & & \cdot \\ & & \cdot & \cdot & & \cdot \\ & & & \cdot & 0 & \cdot \\ & & & & 1 & -a_{n_i-1} \end{pmatrix}, i = 1, \dots, r$$

In the last column of the companion matrix  $R_i$ , you see the coefficients of its minimal polynomial in ascending order, i.e., the polynomial  $m_i := X^{n_i} + a_{n_i-1}X^{n_i-1} + \dots + a_1X + a_0$  is the minimal polynomial of the matrix  $R_i$ .

For these polynomials the following holds:  $m_{i+1}$  divides  $m_i$  for  $i = 1, \dots, r - 1$ , and the product of all  $m_i$  for  $i = 1, \dots, r$  gives a factorization of the characteristic polynomial of the matrix  $A$ . The Frobenius form defined in this way is unique.

# **linalg::frobeniusForm**

---

## **See Also**

## **MuPAD Functions**

`linalg::jordanForm` | `linalg::hermiteForm` |  
`linalg::smithForm` | `linalg::minpoly`

## Purpose

Gaussian elimination

## Syntax

`linalg::gaussElim(A, <All>)`

## Description

`linalg::gaussElim(A)` performs Gaussian elimination on the matrix  $A$  to reduce  $A$  to a similar matrix in upper row echelon form.

A row echelon form of  $A$  returned by `linalg::gaussElim` is not unique. See `linalg::gaussJordan` for computing the *reduced* row echelon form.

The component ring  $R$  of  $A$  must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If  $R$  is a field, i.e., a domain of category `Cat::Field`, ordinary Gaussian elimination is used. Otherwise, `linalg::gaussElim` applies fraction-free Gaussian elimination to  $A$ .

`linalg::gaussElim` serves as an interface function for the method "gaussElim" of the matrix domain of  $A$ , i.e., one may call `A::dom::gaussElim(A)` directly instead of `linalg::gaussElim(A, All)`

Refer to the help page of `Dom::Matrix` for details about the computation strategy of `linalg::gaussElim`.

## Examples

### Example 1

We apply Gaussian elimination to the following matrix:

```
A := Dom::Matrix(Dom::Rational)(
 [[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

which reduces  $A$  to the following row echelon form:

# linalg::gaussElim

---

```
linalg::gaussElim(A)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 0 & 2 & 4 & 4 \\ 0 & 0 & -1 & -1 \end{pmatrix}$$

## Example 2

We apply Gaussian elimination to the matrix:

```
B := Dom::Matrix(Dom::Integer)(
 [[1, 2, -1], [1, 0, 1], [2, -1, 4]]
)
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 1 & 0 & 1 \\ 2 & -1 & 4 \end{pmatrix}$$

and get the following result:

```
linalg::gaussElim(B, All)
```

$$\left[ \begin{pmatrix} 1 & 2 & -1 \\ 0 & -2 & 2 \\ 0 & 0 & -2 \end{pmatrix}, 3, -2, \{1, 2, 3\} \right]$$

We see that  $\text{rank}(B) = 3$  and  $\det B = -2$ .

## Parameters **A**

A matrix of a domain of category `Cat::Matrix`

**Options****All**

Returns a list  $[T, \text{rank}(A), \det A, \{j_1, \dots, j_r\}]$  where  $T$  is a row echelon form of  $A$  and  $\{j_1, \dots, j_r\}$  is the set of characteristic column indices of  $T$ .

If  $A$  is not square, then the value FAIL is given instead of  $\det A$ .

**Return Values**

a matrix of the same domain type as  $A$ , or the list  $[T, \text{rank}(A), \det(A), \{j_1, \dots, j_r\}]$  when the option All is given (see below).

**Algorithms**

Let  $T = (t_{i,j})_{1 \leq i \leq m, 1 \leq j \leq n}$  be an  $m \times n$  matrix. Then  $T$  is a matrix in an upper *row echelon form*, if  $r \in \{0, 1, \dots, n\}$  and indices  $j_1, j_2, \dots, j_r \in \{1, \dots, n\}$  exist with:

- 1**  $j_1 < j_2 < \dots < j_r$ .
- 2** For each  $i \in \{1, \dots, r\}$ :  $t_{i,1} = t_{i,2} = \dots = t_{i,j_i-1} = 0$ .
- 3** For each  $i \in \{r+1, \dots, m\}$ :  $t_{i,j} = 0$  for each  $j \in \{1, \dots, n\}$ .

The indices  $j_1, j_2, \dots, j_r$  are the *characteristic column indices* of the matrix  $T$ .

**See Also****MuPAD Functions**

`linalg::gaussJordan` | `l11int`

# linalg::gaussJordan

---

**Purpose** Gauss-Jordan elimination

**Syntax** `linalg::gaussJordan(A, <All>)`

**Description** `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on the matrix  $A$ , i.e., it returns the reduced row echelon form of  $A$ .

The component ring  $R$  of  $A$  must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If  $R$  is a field, i.e., a domain of category `Cat::Field`, then the leading entries of the matrix  $T$  in reduced row echelon form are equal to one.

If  $R$  is a ring providing the method "gcd", then the components of each row of  $T$  do not have a non-trivial common divisor.

If the component ring of  $A$  is a field, then the reduced row echelon form is unique.

## Examples

### Example 1

We apply Gauss-Jordan elimination to the following matrix:

```
A := Dom::Matrix(Dom::Rational)(
 [[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -5 & 0 & 3 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

```
linalg::gaussJordan(A, All)
```

$$\left[ \begin{pmatrix} 1 & 0 & 0 & \frac{1}{2} \\ 0 & 1 & 0 & \frac{1}{2} \\ 0 & 0 & 1 & \frac{5}{6} \end{pmatrix}, 3, \text{FAIL}, \{1, 2, 3\} \right]$$

We see that  $\text{rank}(B) = 3$ . Because the determinant of a matrix is only defined for square matrices, the third element of the returned list is the value FAIL.

## Example 2

If we consider the matrix from “Example 1” on page 14-86 as an integer matrix and apply the Gauss-Jordan elimination we get the following matrix:

```
B := Dom::Matrix(Dom::Integer)(
 [[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]]
):
linalg::gaussJordan(B)
```

$$\begin{pmatrix} 2 & 0 & 0 & 1 \\ 0 & -2 & 0 & -1 \\ 0 & 0 & -6 & -5 \end{pmatrix}$$

## Parameters

**A**

A matrix of a domain of category `Cat::Matrix`

## Options

**All**

Returns a list  $[T, \text{rank}(A), \det A, \{j_1, \dots, j_r\}]$  where  $T$  is the reduced row echelon form of  $A$  and  $\{j_1, \dots, j_r\}$  is the set of characteristic column indices of  $T$ .

If  $A$  is not square, then the value FAIL is given instead of  $\det A$ .

# linalg::gaussJordan

---

## Return Values

a matrix of the same domain type as A, or the list [T, rank(A), det(A), {j\_1, dots, j\_r}] when the option All is given (see below).

## Algorithms

Let  $T = (t_{i,j})_{1 \leq i \leq m, 1 \leq j \leq n}$  be an  $m \times n$  matrix. Then  $T$  is a matrix in *reduced row echelon form*, if  $r \in \{0, 1, \dots, n\}$  and indices  $j_1, j_2, \dots, j_r \in \{1, \dots, n\}$  exist with:

**1**  $j_1 < j_2 < \dots < j_r$ .

**2** For each  $i \in \{1, \dots, r\}$ :  $t_{i,1} = t_{i,2} = \dots = t_{i,j_i-1} = 0$ . In addition, if A is defined over a field:  $t_{i,j_i} = 1$ .

**3** For each  $i \in \{r+1, \dots, m\}$ :  $t_{i,j} = 0$  for each  $j \in \{1, \dots, n\}$ .

**4** For each  $i \in \{1, \dots, r\}$ :  $t_{k,j_i} = 0$  for each  $k \in \{1, \dots, i-1\}$ .

The indices  $j_1, j_2, \dots, j_r$  are the *characteristic column indices* of the matrix  $T$ .

# linalg::grad

---

**Purpose** Vector gradient

**Syntax** `linalg::grad(f, x)`  
`linalg::grad(f, x, ogCoord, <c>)`

**Description** `linalg::grad(f, x)` computes the vector gradient of the scalar function  $f(\vec{X})$  with respect to  $\vec{X}$  in Cartesian coordinates. This is the vector  $\text{grad}(f) = \left( \frac{\partial}{\partial x_1} f, \dots, \frac{\partial}{\partial x_n} f \right)$ . `linalg::gradient` and `linalg::grad` are equivalent.

In the case of three dimensions, `linalg::grad(f, x, ogCoord)` computes the gradient of  $f$  with respect to  $x$  in the orthogonally curvilinear coordinate system specified by `ogCoord`. The scaling factors of the specified coordinate system must be the value of the index `ogCoord` of the table `linalg::ogCoordTab` (see “Example 2” on page 14-90).

If `ogCoord` is an identifier then the scaling factors must be defined under the name of the identifier as an entry of the table `linalg::ogCoordTab`.

## Examples

### Example 1

We compute the vector gradient of the scalar function  $f(x, y) = x^2 + y$  in Cartesian coordinates:

```
delete x, y;
linalg::gradient(x^2 + y, [x, y])
```

$$\begin{pmatrix} 2x \\ 1 \end{pmatrix}$$

### Example 2

We compute the gradient of the function  $f(r, \varphi, z) = r \cos(\varphi) z$  ( $0 \leq \varphi \leq \pi$ ) in cylindrical coordinates:

```
delete r, z, phi:
linalg::gradient(r*cos(phi)*z, [r, phi, z], Cylindrical)
```

$$\begin{pmatrix} z \cos(\phi) \\ -z \sin(\phi) \\ r \cos(\phi) \end{pmatrix}$$

### Example 3

We want to compute the gradient of the function  $f(r, \phi, \theta) = r \sin(\phi) \cos(\theta)$  in spherical coordinates given by

$$\vec{X} = \begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \begin{pmatrix} r \cos(\phi) \sin(\theta) \\ r \sin(\phi) \sin(\theta) \\ r \cos(\theta) \end{pmatrix}$$

with  $0 \leq \phi \leq 2\pi$ ,  $0 \leq \theta \leq \pi$ .

The vectors

$$\vec{e}_r = \frac{\frac{\partial}{\partial r} \vec{X}}{\left| \frac{\partial}{\partial r} \vec{X} \right|} = \begin{pmatrix} \cos(\phi) \sin(\theta) \\ \sin(\phi) \sin(\theta) \\ \cos(\theta) \end{pmatrix}, \quad \vec{e}_\phi = \frac{\frac{\partial}{\partial \phi} \vec{X}}{\left| \frac{\partial}{\partial \phi} \vec{X} \right|} = \begin{pmatrix} -\sin(\phi) \\ \cos(\phi) \\ 0 \end{pmatrix}, \quad \vec{e}_\theta = \frac{\frac{\partial}{\partial \theta} \vec{X}}{\left| \frac{\partial}{\partial \theta} \vec{X} \right|} = \begin{pmatrix} \cos(\phi) \cos(\theta) \\ \sin(\phi) \cos(\theta) \\ -\sin(\theta) \end{pmatrix}$$

form an orthogonal system in spherical coordinates.

The scaling factors of the corresponding coordinate transformation (see `linalg::ogCoordTab`) are:

$g_1 = |\vec{e}_r| = 1$ ,  $g_2 = |\vec{e}_\phi| = r \sin(\theta)$ ,  $g_3 = |\vec{e}_\theta| = r$ , which we use in the following example to compute the gradient of the function  $f$  in spherical coordinates:

```
delete r, phi, Theta:
```

# linalg::grad

---

```
linalg::gradient(r*sin(phi)*cos(Theta), [r, phi, Theta], [1, r*sin(phi),
```

$$\begin{pmatrix} \cos(\Theta) \sin(\phi) \\ \frac{\cos(\Theta) \cos(\phi)}{\sin(\Theta)} \\ -\sin(\Theta) \sin(\phi) \end{pmatrix}$$

Note that the spherical coordinates are already defined in `linalg::ogCoordTab`, i.e., the last result can also be achieved with the input `linalg::gradient(r*sin(phi)*cos(Theta), [r, phi, Theta], Spherical)`:

```
linalg::gradient(r*sin(phi)*cos(Theta), [r, phi, Theta], Spherical)
```

$$\begin{pmatrix} \cos(\Theta) \sin(\phi) \\ \frac{\cos(\Theta) \cos(\phi)}{\sin(\Theta)} \\ -\sin(\Theta) \sin(\phi) \end{pmatrix}$$

## Parameters

**f**

An arithmetical expression in the variables given in **x**

**x**

A list of (indexed) identifiers

**ogCoord**

The name of a 3 dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic expressions representing the “scale parameters” of an orthogonal coordinate system.

## **c**

The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is  $c = 1$ .

## **Return Values**

Column vector of the domain `Dom::Matrix()`.

## **See Also**

`linalg::laplacian` | `linalg::ogCoordTab` | `linalg::potential`  
| `linalg::vectorPotential`

# linalg::hermiteForm

---

**Purpose** Hermite normal form of a matrix

**Syntax** `linalg::hermiteForm(A, <All>)`

**Description** `linalg::hermiteForm(A)` computes the Hermite normal form of a non-singular integer square matrix  $A$ . This is an upper-triangular matrix  $H$  such that  $H_{jj} \geq 0$  and  $-\frac{H_{ij}}{2} < H_{ij} \leq \frac{H_{ij}}{2}$  for  $j > i$ . In the case,  $A$  is not a square matrix or a singular matrix, the matrix  $H$  is simply an upper-triangular matrix.

If the matrix  $A$  is not of the domain `Dom::Matrix(Dom::Integer)` then  $A$  is converted into a matrix of this domain for intermediate computations.

If this conversion fails, then an error message is returned.

`linalg::hermiteForm(A, All)` computes a transformation matrix  $U$  and a matrix  $H$  such that  $H = UA$ .

## Examples

### Example 1

We compute the Hermite normal form of the matrix:

```
A := Dom::Matrix(Dom::Rational)(
 [[9, -36, 30], [-36, 192, -180], [30, -180, 180]]
)
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

```
linalg::hermiteForm(A)
```

$$\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

We may also compute the transformation matrix by giving the option `All`:

```
linalg::hermiteForm(A, All)
```

$$\left[ \left( \begin{array}{ccc} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{array} \right), \left( \begin{array}{ccc} 13 & 9 & 7 \\ 6 & 4 & 3 \\ 20 & 15 & 12 \end{array} \right) \right]$$

Let us check the result:

```
U := linalg::hermiteForm(A, All)[2]:
```

```
U * A
```

$$\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

## Parameters

**A**

An integer matrix of category `Cat::Matrix`

## Options

**All**

Returns the list `[H, U]` with the hermite normal form  $H$  of  $A$  and the corresponding transformation matrix  $U$

## Return Values

Either a matrix of the same domain type as  $A$  or the list `[H, U]` when the option `All` is given.

## Algorithms

Let  $A$  be an  $n \times n$  matrix with coefficients in  $\mathbb{Z}$ . Then there exists an  $n \times n$  matrix  $H = (h_{ij})$  in Hermite normal form such that  $H = AU$  with  $|U| = \pm 1$ .

# **linalg::hermiteForm**

---

Note that  $H$  is unique, if  $A$  has full row rank. The matrix  $U$  is not unique.  $U$  may be computed by using the option `All`.

If  $A$  is a square matrix, then the product of the diagonal elements of its Hermite normal form is, up to the sign, the determinant of  $A$ .

## **See Also**

### **MuPAD Functions**

`linalg::frobeniusForm` | `linalg::jordanForm` |  
`linalg::smithForm` | `lllint`

**Purpose** Hessenberg matrix

**Syntax** `linalg::hessenberg(A, <All>)`

**Description** `linalg::hessenberg(A)` returns an (upper) Hessenberg matrix  $H$ .  
`linalg::hessenberg` uses Gaussian elimination without pivoting. There is no special implementation for matrices with floating-point components.

The component ring of  $A$  must be a field, i.e., a domain of category `Cat::Field`.

## Examples **Example 1**

Consider the matrix:

```
A := Dom::Matrix(Dom::Rational)(
 [[0, 1, 0, -1], [-4/3, 2/3, 5/3, -1/3],
 [-1, 2, 0, 0], [-5/3, 4/3, 1/3, 1/3]]
)
```

$$\begin{pmatrix} 0 & 1 & 0 & -1 \\ -\frac{4}{3} & \frac{2}{3} & \frac{5}{3} & -\frac{1}{3} \\ -1 & 2 & 0 & 0 \\ -\frac{5}{3} & \frac{4}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix}$$

The following Hessenberg matrix is similar to  $A$ :

```
H := linalg::hessenberg(A)
```

# linalg::hessenberg

---

$$\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}$$

If the corresponding transformation matrix is needed as well, call `linalg::hessenberg` with option `All`:

```
[H, P] := linalg::hessenberg(A, All)
```

$$\left[ \begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & -\frac{3}{4} & 1 & 0 \\ 0 & -\frac{8}{7} & -\frac{1}{7} & 1 \end{pmatrix} \right]$$

Then  $P$  is a nonsingular matrix such that the product  $PAP^{-1}$  is equal to  $H$ :

```
P * A * P^(-1)
```

$$\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}$$

<b>Parameters</b>	<b>A</b> A square matrix of a domain of category <code>Cat::Matrix</code>
<b>Options</b>	<b>All</b> Returns the list [H, P] with a Hessenberg matrix $H$ similar to $A$ and the corresponding nonsingular transformation matrix $P$ such that $H = PAP^{-1}$ .
<b>Return Values</b>	Matrix of the same domain type as $A$ , or the list [H, P] when the option <code>All</code> is given.
<b>Algorithms</b>	An $n \times n$ matrix $A = (a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq n}$ is called an (upper) <i>Hessenberg matrix</i> , if the following holds: $a_{i,j} = 0$ for all $i, j \in \{1, \dots, n\}$ with $i > j$ . For each square matrix $A$ over a field there exists a Hessenberg matrix similar to $A$ . In general, the upper Hessenberg matrix is not unique.

# linalg::hessian

---

**Purpose** Hessian matrix of a scalar function

**Syntax** `linalg::hessian(f, x)`

**Description** `linalg::hessian(f, x)` computes the Hesse matrix (the Hessian) of the scalar function  $f(\vec{X})$  in Cartesian coordinates, i.e., the square matrix of second partial derivatives of  $f(\vec{X})$ .

## Examples **Example 1**

The Hessian of the function  $f(x, y, z) = xy + 2xz$  is the following matrix:

```
delete x, y, z:
linalg::hessian(x*y + 2*z*x, [x, y, z])
```

$$\begin{pmatrix} 0 & 1 & 2 \\ 1 & 0 & 0 \\ 2 & 0 & 0 \end{pmatrix}$$

**Parameters** **f**  
An arithmetical expression (the scalar function)

**x**  
A list of (indexed) identifiers

**Return Values** Matrix of the domain `Dom::Matrix()`.

**Algorithms**

For a function  $f: X \rightarrow \mathbb{R}$ ,  $X$  a subset of  $\mathbb{R}^p$ , the  $p \times p$  matrix

$$H_f(\vec{X}) = \begin{pmatrix} \frac{\partial^2}{\partial x_1^2} f & \frac{\partial}{\partial x_1} \frac{\partial}{\partial x_2} f & \dots & \frac{\partial}{\partial x_1} \frac{\partial}{\partial x_p} f \\ \frac{\partial}{\partial x_2} \frac{\partial}{\partial x_1} f & \frac{\partial^2}{\partial x_2^2} f & \dots & \frac{\partial}{\partial x_2} \frac{\partial}{\partial x_p} f \\ \cdot & \cdot & \cdot & \cdot \\ \frac{\partial}{\partial x_p} \frac{\partial}{\partial x_1} f & \frac{\partial}{\partial x_p} \frac{\partial}{\partial x_2} f & \dots & \frac{\partial^2}{\partial x_p^2} f \end{pmatrix}$$

is called the *Hesse matrix* of  $f$ .

---

**Purpose** Hilbert matrix

**Syntax** `linalg::hilbert(n, <R>)`

**Description** `linalg::hilbert(n)` returns the  $n \times n$  Hilbert matrix  $H = (h_{i,j})_{1 \leq i \leq n, 1$

$\leq j \leq n$  defined by  $h_{i,j} = \frac{1}{(i+j-1)}$ .

The entries of Hilbert matrices are rational numbers. Note, however, that the returned matrix is not defined over the component domain `Dom::Rational`, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

Use `linalg::hilbert(n, Dom::Rational)` to define the  $n \times n$  Hilbert matrix over the field of rational numbers.

## Examples

### Example 1

We construct the  $3 \times 3$  Hilbert matrix:

```
H := linalg::hilbert(3)
```

$$\begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the Hilbert matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
H := linalg::hilbert(3, Dom::Float)
```

$$\begin{pmatrix} 1.0 & 0.5 & 0.3333333333 \\ 0.5 & 0.3333333333 & 0.25 \\ 0.3333333333 & 0.25 & 0.2 \end{pmatrix}$$

```
domtype(H)
```

```
Dom::Matrix(Dom::Float)
```

## Parameters

**n**

The dimension of the matrix: a positive integer

**R**

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

## Return Values

$n \times n$  matrix of the domain `Dom::Matrix(R)`.

## Algorithms

Hilbert matrices are symmetric and positive definite.

Hilbert matrices of large dimension are notoriously ill-conditioned challenging any numerical inversion scheme. However, their inverse can also be computed by a closed formula (see `linalg::invhilbert`).

`linalg::vandermondeSolve`

# linalg::htranspose

---

**Purpose** Hermitian transpose of a matrix

**Syntax** `linalg::htranspose(M)`

**Description** `linalg::htranspose(M)` computes the Hermitian transpose of the matrix  $M$ .

The Hermitian transpose of  $M$  is computed. The result is an  $n \ m$  matrix.

The  $[i, j]$ th element of the result is equal to the conjugate of the  $[j, i]$ th element of  $M$ .

## Examples

### Example 1

We define a 3 4 matrix:

```
A := matrix([[1, 2, 3, 4], [-I, 0, 1+I, 0], [3, 5, 6, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -i & 0 & 1+i & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Then the Hermitian transpose of A is the 4 3 matrix:

```
linalg::htranspose(A)
```

$$\begin{pmatrix} 1 & i & 3 \\ 2 & 0 & 5 \\ 3 & 1-i & 6 \\ 4 & 0 & 9 \end{pmatrix}$$

**Parameters** **M**

$m \ n$  matrix of domain `Dom::Matrix`

**Return Values**  $n \times m$  matrix of domain `Dom::Matrix`.

**Overloaded By** `M`

**Algorithms** Let  $A = (a_{i,j})_{1 \leq i \leq m, 1 \leq j \leq n}$  be an  $m \times n$  matrix. Then the Hermitian transpose of  $A$  is the  $n \times m$  matrix:

$$A^t = \begin{pmatrix} \overline{a_{1,1}} & \overline{a_{1,2}} & \cdots & \overline{a_{m,1}} \\ \overline{a_{1,2}} & \overline{a_{2,2}} & \cdots & \overline{a_{m,2}} \\ \vdots & \vdots & \ddots & \vdots \\ \overline{a_{1,n}} & \overline{a_{2,n}} & \cdots & \overline{a_{m,n}} \end{pmatrix}$$

**See Also**

**MuPAD Functions** `conjugate` | `linalg::transpose`

# linalg::intBasis

---

**Purpose** Basis for the intersection of vector spaces

**Syntax** `linalg::intBasis(S1, S2, ...)`

**Description** `linalg::intBasis(S1, S2, ...)` returns a basis for the intersection of the vector spaces spanned by the vectors in S<sub>1</sub>, S<sub>2</sub>, ....

The domain type of the vectors of the returned set is the domain type of the first parameter S<sub>1</sub>.

A basis for the zero-dimensional space is the empty set or empty list, respectively.

The given vectors must be defined over the same component ring which must be a field, i.e., a domain of category `Cat::Field`.

## Examples

### Example 1

We define three vectors  $\vec{v}_1, \vec{v}_2, \vec{v}_3$  in  $\mathbb{R}^2$ :

```
MatQ := Dom::Matrix(Dom::Rational):
v1 := MatQ([[3, -2]]); v2 := MatQ([[1, 0]]); v3 := MatQ([[5, -3]])
```

$\begin{pmatrix} 3 & -2 \end{pmatrix}$

$\begin{pmatrix} 1 & 0 \end{pmatrix}$

$\begin{pmatrix} 5 & -3 \end{pmatrix}$

A basis for the vector space  $V_1 \cap V_2 \cap V_3$  with

- $V_1$  generated by  $\vec{v}_1, \vec{v}_2, \vec{v}_3$
- $V_2$  generated by  $\vec{v}_1, \vec{v}_3$

- $V_3$  generated by  $\vec{v}_1 + \vec{v}_2, \vec{v}_2, \vec{v}_1 + \vec{v}_3$

is:

```
linalg::intBasis([v1, v2, v3], [v1, v3], [v1 + v2, v2, v1 + v3])

[(4 -2), (1 0)]
```

## Example 2

The intersection of the two vector spaces spanned by the vectors in  $S_1$  and  $S_2$ , respectively:

```
S1 := {matrix([[1, 0, 1, 0]]), matrix([[0, 1, 0, 1]])};
S2 := {matrix([[1, 2, 1, 1]]), matrix([[-1, -2, 1, 0]])}
```

```
{(0 1 0 1), (1 0 1 0)}
```

```
{(-1 -2 1 0), (1 2 1 1)}
```

is the zero-dimensional space:

```
linalg::intBasis(S1, S2)
```

```
∅
```

## Parameters

$S_1, S_2, \dots$

Either sets or lists of  $n$ -dimensional vectors (a vector is an  $n \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`)

## Return Values

Set or a list of vectors, according to the domain type of the parameter  $S_1$ .

# **linalg::intBasis**

---

## **See Also**

## **MuPAD Functions**

`linalg::basis` | `linalg::sumBasis`

## Purpose

Computing the inverse of a matrix using LU-decomposition

## Syntax

```
linalg::inverseLU(A)
linalg::inverseLU(L, U, pivindex)
```

## Description

`linalg::inverseLU(A)` computes the inverse  $\frac{1}{A}$  of the square matrix  $A$  using LU-decomposition.

`linalg::inverseLU(L, U, pivindex)` computes the inverse of the matrix  $A = P^{-1}LU$  where  $L$ ,  $U$  and `pivindex` are the result of an LU-decomposition of the (nonsingular) Matrix  $A$ , as computed by `linalg::factorLU`.

The matrix  $A$  must be nonsingular.

`pivindex` is a list `[r[1], r[2], ...]` representing a permutation matrix  $P$  such that  $B = PA = LU$ , where  $b_{ij} = a_{r_i, j}$ .

It is not checked whether `pivindex` has such a form.

The component ring of the input matrices must be a field, i.e., a domain of category `Cat::Field`.

## Examples

### Example 1

We compute the inverse of the matrix:

```
A := Dom::Matrix(Dom::Real)(
 [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

using LU-decomposition:

# linalg::inverseLU

---

```
Ai := linalg::inverseLU(A)
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

We check the result:

```
A * Ai, Ai * A
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We can also compute the inverse of  $A$  in the usual way:

```
1/A
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

`linalg::inverseLU` should be used for efficiency reasons in the case where an LU decomposition of a matrix already is computed, as the next example illustrates.

## Example 2

If we already have an LU decomposition of a (nonsingular) matrix, we can compute the inverse of the matrix  $A = P^{-1}LU$  as follows:

```
LU := linalg::factorLU(linalg::hilbert(3))
```

$$\left[ \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ \frac{1}{3} & 1 & 1 \end{pmatrix}, \begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ 0 & \frac{1}{12} & \frac{1}{12} \\ 0 & 0 & \frac{1}{180} \end{pmatrix}, [1, 2, 3] \right]$$

```
linalg::inverseLU(op(LU))
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

`linalg::inverseLU` then only needs to perform forward and backward substitution to compute the inverse matrix (see also `linalg::matlinsolveLU`).

## Parameters

### **A, L, U**

A square matrix of a domain of category `Cat::Matrix`

### **pivindex**

A list of positive integers

## Return Values

Matrix of the same domain type as A or L, respectively.

## See Also

## MuPAD Functions

`_invert` | `linalg::factorLU` | `linalg::matlinsolveLU`

# linalg::invhilbert

---

**Purpose** Inverse of a Hilbert matrix

**Syntax** `linalg::invhilbert(n, <R>)`

**Description** `linalg::invhilbert(n)` returns the inverse of the  $n \times n$  Hilbert matrix  $H$ . The  $n \times n$  Hilbert matrix  $H = (h_{i,j})_{1 \leq i \leq n, 1 \leq j \leq n}$  is defined by

$$h_{i,j} = \frac{1}{(i+j-1)}.$$

`linalg::invhilbert` uses an explicit formula for the inverse.

Note that the entries of the inverse of a Hilbert matrix are integers. But the returned matrix is defined over the standard component domain `Dom::ExpressionField()` so that no conversion is necessary when working with other functions that expect or return matrices over that component domain.

`linalg::invhilbert(n, Dom::Integer)` returns the inverse of the  $n \times n$  Hilbert matrix defined over the integers.

## Examples

### Example 1

We compute the inverse of the  $3 \times 3$  Hilbert matrix:

```
A := linalg::invhilbert(3)
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted into the desired domain afterwards (see `coerce`, for example).

Alternatively, one can specify the component ring when calling `linalg::invhilbert`, for example the domain `Dom::Float`:

```
A := linalg::invhilbert(3, Dom::Float)
```

$$\begin{pmatrix} 9.0 & -36.0 & 30.0 \\ -36.0 & 192.0 & -180.0 \\ 30.0 & -180.0 & 180.0 \end{pmatrix}$$

```
domtype(A)
```

```
Dom::Matrix(Dom::Float)
```

## Parameters

**n**

The dimension of the matrix: a positive integer

**R**

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

## Return Values

$n \times n$  matrix of the domain `Dom::Matrix(R)`.

## Algorithms

Hilbert matrices of large dimension are notoriously ill-conditioned, challenging any numerical inversion scheme.

`linalg::invhilbert` uses the formula

$$\left(\frac{1}{H}\right)_{i,j} = \frac{(-1)^{i+j} (c_i c_j)}{i+j-1}$$

where

# **linalg::invhilbert**

---

$$c_i = \frac{(n + i - 1)!}{(n - i)! ((i - 1)!)^2}$$

for the inverse of the  $n \times n$  Hilbert matrix  $H$ . All entries of  $\frac{1}{H}$  are integers.

`linalg::hilbert` | `linalg::invpascal` |  
`linalg::invvandermonde` | `linalg::pascal` | `linalg::toeplitz`  
| `linalg::toeplitzSolve` | `linalg::vandermonde` |  
`linalg::vandermondeSolve`

**Purpose** Inverse of a Pascal matrix

**Syntax** `linalg::invpascal(n, <R>)`

**Description** `linalg::invpascal(n)` returns the inverse of the  $n \times n$  Pascal matrix. The entries of inverse Pascal matrices are integer numbers. Note, however, that the returned matrix is not defined over the component domain `Dom::Integer`, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

The runtime to compute the inverse  $n \times n$  Pascal matrix via `linalg::invpascal` is  $O(n^2)$ . This is much faster than inverting the Pascal matrix by a generic inversion algorithm.

The Pascal matrices are provided by `linalg::pascal`.

## Examples **Example 1**

We construct the inverse  $3 \times 3$  Pascal matrix:

```
linalg::invpascal(3)
```

$$\begin{pmatrix} 3 & -3 & 1 \\ -3 & 5 & -2 \\ 1 & -2 & 1 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the inverse Pascal matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

# linalg::invpascal

---

```
linalg::invpascal(3, Dom::Float)
```

$$\begin{pmatrix} 3.0 & -3.0 & 1.0 \\ -3.0 & 5.0 & -2.0 \\ 1.0 & -2.0 & 1.0 \end{pmatrix}$$

```
domtype(%)
```

```
Dom::Matrix(Dom::Float)
```

## Parameters

**n**

The dimension of the matrix: a positive integer

**R**

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

## Return Values

$n \times n$  matrix of the domain `Dom::Matrix(R)`.

## Algorithms

Pascal matrices and their inverses are symmetric and positive definite.

The determinant of a Pascal matrix and its inverse is 1.

The inverse of a Pascal matrix has integer entries.

If  $\lambda$  is an eigenvalue of a Pascal matrix/inverse Pascal matrix, then  $\frac{1}{\lambda}$  is also an eigenvalue of the matrix.

The entries  $Q_{ij}$  of the inverse  $n \times n$  Pascal matrix  $Q$  satisfy the linear relation

$$Q_{i,j} = Q_{i,j+1} + Q_{i+1,j} + (-1)^{i+j} \binom{n}{i} \binom{n}{j} .$$

This relation is used by `linalg::invpascal` to compute the matrix.

# linalg::isHermitian

---

**Purpose** Checks whether a matrix is Hermitian

**Syntax** `linalg::isHermitian(A)`

**Description** `linalg::isHermitian(A)` determines whether the matrix  $A$  is Hermitian, i.e., whether  $A = \overline{A}^t$ , where  $\overline{A}$  denotes the conjugate matrix.

If the component ring of the matrix  $A$  does not provide the method "conjugate", then  $A$  is tested for symmetry, i.e., `linalg::isHermitian` returns `TRUE` if and only if  $A$  satisfies the equation  $A = A^t$ .

## Examples **Example 1**

Here is an example of a Hermitian matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, I], [-I, 1]])
```

$$\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix}$$

```
linalg::isHermitian(A)
```

```
TRUE
```

The following matrix is not Hermitian:

```
B := Dom::Matrix(Dom::Complex)([[1, -I], [-I, 1]])
```

$$\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}$$

```
linalg::isHermitian(B)
```

FALSE

The reason is the following:

```
linalg::transpose(conjugate(B)) <> B
```

$$\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \neq \begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}$$

## Example 2

Here is an example of a symmetric matrix over the integers:

```
C := Dom::Matrix(Dom::Integer)([[1, 2], [2, -1]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & -1 \end{pmatrix}$$

```
linalg::isHermitian(C)
```

TRUE

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

## Return Values

Either TRUE or FALSE.

# **linalg::isHermitian**

---

## **See Also**

## **MuPAD Functions**

`linalg::isPosDef`

**Purpose** Test a matrix for positive definiteness

**Syntax** `linalg::isPosDef(A)`

**Description** `linalg::isPosDef(A)` checks whether the matrix  $A$  is positive definite, so that  $\vec{x}^t A \vec{x} > 0$  for arbitrary vectors  $\vec{x} \neq \vec{0}$ .

The component ring of  $A$  must be a field, i.e., a domain of category `Cat::Field`.

An error message is returned, if a result of an intermediate computation cannot be checked for being positive (which could happen, for example, if components of  $A$  are symbolic).

**Environment Interactions** Properties of identifiers are taken into account.

**Examples** **Example 1**

Here is an example of a positive definite matrix:

```
MatR := Dom::Matrix(Dom::Real) :
A := MatR([[14, 6, 9], [6, 17, -4], [9, -4, 13]])
```

$$\begin{pmatrix} 14 & 6 & 9 \\ 6 & 17 & -4 \\ 9 & -4 & 13 \end{pmatrix}$$

```
linalg::isPosDef(A)
```

```
TRUE
```

The following matrix is not positive definite:

# linalg::isPosDef

---

```
B := MatR([[1, 2, 3], [2, 3, 4], [5, 6, 7]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 4 \\ 5 & 6 & 7 \end{pmatrix}$$

```
linalg::isPosDef(B)
```

```
FALSE
```

## Example 2

`linalg::isPosDef` in general does not work for matrices with symbolic entries. It may respond with an error message (because the system in general cannot decide whether a symbolic component is positive), such as for the following matrix:

```
delete a, b:
C := matrix([[a, b], [b, a]])
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

```
linalg::isPosDef(C)
```

```
Error: Cannot check whether the matrix component is positive. [linalg::isPosDef]
```

However, properties of identifiers are taken into account, so that, for example, `linalg::isPosDef` is able to perform the test correctly for the following matrix:

```
assume(a > 1): C := matrix([[a, 1], [1, a]]):
```

`linalg::isPosDef(C)`

TRUE

Note that such computations depend on the power of the underlying property mechanism implemented in the property library.

## **Parameters**

**A**

A matrix of a domain of category `Cat::Matrix`

## **Return Values**

Either TRUE or FALSE.

## **See Also**

## **MuPAD Functions**

`linalg::factorCholesky` | `linalg::isHermitian`

# linalg::isUnitary

---

**Purpose** Test whether a matrix is unitary

**Syntax** `linalg::isUnitary(A)`

**Description** `linalg::isUnitary` tests whether the matrix  $A$  is a unitary matrix. An  $n \times n$  matrix  $A$  is unitary, if  $A \overline{A}^t = I_n$ , where  $I_n$  is the  $n \times n$  identity matrix.

The square matrix  $A$  is a unitary matrix, if and only if the columns of  $A$  form an orthonormal basis with respect to the scalar product `linalg::scalarProduct` of two vectors.

The correctness of the result `FALSE` of `linalg::isUnitary` can only be guaranteed if the elements of the component ring  $R$  of the matrix  $A$  are canonically represented, i.e., if each element of  $R$  has only one unique representation.

The axiom `Ax::canonicalRep` states that a domain has this property. Hence, `linalg::isUnitary` returns `FALSE` or `UNKNOWN`, respectively, depending on whether the component ring of  $A$  has the axiom `Ax::canonicalRep`.

If the component ring of  $A$  does not define the method "conjugate" then it is checked whether  $A$  is an orthogonal matrix such that  $AA^t = E_n$ , where  $E_n$  is the  $n \times n$  identity matrix.

## Examples

### Example 1

The following matrix is unitary:

```
A := 1/sqrt(5) * matrix([[1, 2], [2, -1]])
```

$$\begin{pmatrix} \frac{\sqrt{5}}{5} & \frac{2\sqrt{5}}{5} \\ \frac{2\sqrt{5}}{5} & -\frac{\sqrt{5}}{5} \end{pmatrix}$$

```
linalg::isUnitary(A)
```

TRUE

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

## Return Values

Either TRUE, FALSE, or UNKNOWN.

## See Also

## MuPAD Functions

`linalg::orthog` | `linalg::scalarProduct`

# linalg::jacobian

---

**Purpose** Jacobian matrix of a vector function

**Syntax** `linalg::jacobian(v, x)`

**Description** `linalg::jacobian(v, x)` computes the Jacobian matrix of the vector function  $\vec{v}$  with respect to  $\vec{x}$ .

If  $v$  is a vector then the component ring of  $v$  must be a field (i.e., a domain of category `Cat::Field`) for which differentiation with respect to  $x$  is defined.

If  $v$  is given as a list of arithmetical expressions, then `linalg::jacobian` returns a matrix with the standard component ring `Dom::ExpressionField()`.

## Examples **Example 1**

The Jacobian matrix of the vector function  $\vec{v} = \begin{pmatrix} x^3 \\ xz \\ y+z \end{pmatrix}$  is:

```
delete x, y, z:
linalg::jacobian([x^3, x*z, y+z], [x, y, z])
```

$$\begin{pmatrix} 3x^2 & 0 & 0 \\ z & 0 & x \\ 0 & 1 & 1 \end{pmatrix}$$

## Parameters **v**

A list of arithmetical expressions, or a vector (i.e., an  $n \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`)

## **x**

A list of (indexed) identifiers

**Return Values**

Matrix of the domain `Dom::Matrix(R)`, where `R` is the component ring of `v` or the domain `Dom::ExpressionField()`.

**Algorithms**

For a vector function  $\vec{v}: G \rightarrow R^m$ , where  $G$  is a subset of  $\mathbb{R}^n$  the matrix

$$H_f(\vec{X}) = \begin{pmatrix} \frac{\partial}{\partial x_1} V_1 & \frac{\partial}{\partial x_2} V_1 & \dots & \frac{\partial}{\partial x_n} V_1 \\ \frac{\partial}{\partial x_1} V_2 & \frac{\partial}{\partial x_2} V_2 & \dots & \frac{\partial}{\partial x_n} V_2 \\ \vdots & \vdots & & \vdots \\ \frac{\partial}{\partial x_1} V_m & \frac{\partial}{\partial x_2} V_m & \dots & \frac{\partial}{\partial x_n} V_m \end{pmatrix}$$

is the *Jacobian matrix* of  $\vec{v}$ .

**See Also****MuPAD Functions**

`linalg::hessian` | `linalg::gradient`

# linalg::jordanForm

---

**Purpose** Jordan normal form of a matrix

**Syntax** `linalg::jordanForm(A, <All>)`

**Description** `linalg::jordanForm(A)` returns the Jordan normal form  $J$  of the matrix  $A$ .

`linalg::jordanForm` computes a nonsingular transformation matrix  $P$  and a matrix  $J$  such that  $A = PJP^{-1}$  with  $J = \text{diag}(J_1, \dots, J_r)$  and Jordan matrices  $J_1, \dots, J_r$ .

The Jordan normal form of a square matrix  $A$  over a field  $F$  exists if the characteristic polynomial of  $A$  splits over  $F$  into linear factors. If this is not the case for the matrix  $A$ , then `linalg::jordanForm` returns FAIL.

The Jordan normal form is unique up to permutations of the Jordan matrices  $J_1, \dots, J_r$ .

The implemented method computes the eigenvalues of  $A$ . It returns FAIL if this is not possible (see `linalg::eigenvalues`).

The component ring of  $A$  must be a field, i.e., a domain of category `Cat::Field`.

## Examples

### Example 1

The Jordan normal form of the matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, 2], [4, 5]])
```

$$\begin{pmatrix} 1 & 2 \\ 4 & 5 \end{pmatrix}$$

is the following matrix:

```
J := linalg::jordanForm(A)
```

$$\begin{pmatrix} -2\sqrt{3}+3 & 0 \\ 0 & 2\sqrt{3}+3 \end{pmatrix}$$

The corresponding transformation matrix  $P$  can be obtained from the result  $[J, P]$  of `linalg::jordanForm` with the option `All`:

```
P := linalg::jordanForm(A, All)[2]
```

$$\begin{pmatrix} -\frac{\sqrt{3}}{2} - \frac{1}{2} & \frac{\sqrt{3}}{2} - \frac{1}{2} \\ 1 & 1 \end{pmatrix}$$

We check the result:

```
map(P * J * P^(-1), radsimp)
```

$$\begin{pmatrix} 1 & 2 \\ 4 & 5 \end{pmatrix}$$

To get this result we must apply the function `radsimp` to each component of the matrix that is returned by the matrix product  $PJP^{-1}$ .

## Parameters

### A

A square matrix of a domain of category `Cat::Matrix`

## Options

### All

Returns the list  $[J, P]$  with the Jordan normal form  $J$  of  $A$  and the corresponding transformation matrix  $P$  such that  $A = PJP^{-1}$ .

## Return Values

Either a matrix of the same domain type as  $A$ , the list  $[J, P]$  when the option `All` is given, or the value `FAIL`.

# `linalg::jordanForm`

---

## See Also

## MuPAD Functions

`linalg::eigenvalues` | `linalg::frobeniusForm` |  
`linalg::smithForm` | `linalg::hermiteForm`

**Purpose** Kronecker product of matrices

**Syntax** `linalg::kroneckerProduct(A, <B, >)`

**Description** `linalg::kroneckerProduct(A, B)` computes the Kronecker product of two matrices A and B.

The Kronecker product (direct matrix product) of an  $m \times n$  matrix A and a  $p \times q$  matrix B is the  $(mp) \times (nq)$  matrix  $A \otimes B$  given in block form as

$$A \otimes B = \begin{pmatrix} a_{1,1} B & \dots & a_{1,n} B \\ \cdot & & \cdot \\ \cdot & & \cdot \\ \cdot & & \cdot \\ a_{m,1} B & \dots & a_{m,n} B \end{pmatrix}$$

Componentwise:  $(A \otimes B)_{I,J} = A_{i,j} B_{k,l}$  with  $I = p(i - 1) + k$ ,  $J = q(j - 1) + l$ .

If A and B are matrices of the same matrix domain with the same component ring, the result is a matrix of the same type as A and B. If the domains or the component rings of A and B differ, `linalg::kroneckerProduct` tries to convert B into the domain type of A by `A::dom::coerce`. If this fails, conversion of A to the domain type of B is attempted. If no conversion is possible, an error is raised.

---

**Note** Note that the Kronecker product is only implemented for matrices over the domains `Dom::Matrix`, `Dom::SquareMatrix` or `Dom::MatrixGroup`. In particular, this includes matrices created by `matrix`.

---

# linalg::kroneckerProduct

---

A call with more than two arguments produces  
`linalg::kroneckerProduct(A, B, C) =`  
`linalg::kroneckerProduct(linalg::kroneckerProduct(A, B),`  
`C) etc.`

A call with only one argument is possible. It returns the input matrix.

## Examples

### Example 1

We consider two matrices A and B with symbolic components:

```
A:= matrix([[a11, a12], [a21, a22]]);
B:= matrix([[b11, b12, b13], [b21, b22, b23]]);
```

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

$$\begin{pmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \end{pmatrix}$$

The Kronecker product of A and B is computed by multiplying the matrix B with each of the components of the matrix A. The resulting block matrix is returned as a matrix of larger dimension:

```
linalg::kroneckerProduct(A, B);
```

$$\begin{pmatrix} a_{11} b_{11} & a_{11} b_{12} & a_{11} b_{13} & a_{12} b_{11} & a_{12} b_{12} & a_{12} b_{13} \\ a_{11} b_{21} & a_{11} b_{22} & a_{11} b_{23} & a_{12} b_{21} & a_{12} b_{22} & a_{12} b_{23} \\ a_{21} b_{11} & a_{21} b_{12} & a_{21} b_{13} & a_{22} b_{11} & a_{22} b_{12} & a_{22} b_{13} \\ a_{21} b_{21} & a_{21} b_{22} & a_{21} b_{23} & a_{22} b_{21} & a_{22} b_{22} & a_{22} b_{23} \end{pmatrix}$$

```
delete A, B;
```

## Example 2

An  $n \times n$  matrix  $H$  with components in  $\{-1, 1\}$  is called a *Hadamard matrix* if  $H$  multiplied with its transpose equals  $n$  times the  $n \times n$  identity matrix. The matrix  $H$  defined below is a Hadamard matrix:

```
H:= matrix([[1, 1], [1, -1]]);
H * linalg::transpose(H) = 2 * matrix::identity(2);
```

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}$$

Hadamard matrices play a role in the field of error correcting codes. A basic property of this type of matrices is that the Kronecker product of two Hadamard matrices is again a Hadamard matrix. We verify this statement for the matrix  $H$ :

```
H2:= linalg::kroneckerProduct(H, H);
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}$$

Indeed, the matrix  $H2$  is again a Hadamard matrix:

```
H2 * linalg::transpose(H2) = 4 * matrix::identity(4);
```

# linalg::kroneckerProduct

---

$$\begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 4 \end{pmatrix} = \begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 4 \end{pmatrix}$$

delete H, H2:

## Parameters

**A, B, ...**

Matrices of the domains `Dom::Matrix`, `Dom::SquareMatrix` or `Dom::MatrixGroup`

## Return Values

Matrix of the same type as A or B.

## Purpose

The Laplacian

## Syntax

```
linalg::laplacian(f, [x1, x2, ...])
linalg::laplacian(f, [x1, x2, ...], ogCoord, <c>)
```

## Description

`linalg::laplacian(f, [ x1, x2, ...])` computes the Laplacian

$$\Delta f = \sum_i \frac{\partial^2}{\partial x_i^2} f \text{ of the function } f.$$

`linalg::laplacian` and `laplacian` are equivalent. See details and examples on the `laplacian` help page.

## Parameters

**f**

An arithmetical expression in the variables  $x_1, x_2$  etc.

**x<sub>1</sub>, x<sub>2</sub>, ...**

identifiers or indexed identifiers

**ogCoord**

The name of a 3 dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic expressions representing the “scale parameters” of an orthogonal coordinate system.

**c**

The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is  $c = 1$ .

## Return Values

Arithmetical expression.

# linalg::matdim

---

**Purpose** Dimension of a matrix

**Syntax** `linalg::matdim(A)`

**Description** `linalg::matdim(A)` returns the dimension of the matrix  $A$ , i.e., the number of rows and columns of  $A$ .

`linalg::matdim` is an interface function for the method "matdim" of the matrix domain of  $A$ , i.e., instead of `linalg::matdim(A)` one may call `A::dom::matdim(A)` directly.

## Examples

### Example 1

The dimension of the matrix:

```
A := matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

can be determined by:

```
linalg::matdim(A)
```

```
[3, 4]
```

**Parameters** **A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**Return Values**

List  $[m, n]$ , where  $m$  is the number of rows and  $n$  is the number of columns of  $A$ .

## **See Also**

## **MuPAD Functions**

`linalg::vecdim` | `linalg::ncols` | `linalg::nrows`

## **Related Examples**

- “Compute Dimensions of a Matrix”

# linalg::matlinsolve

---

**Purpose** Solving systems of linear equations

**Syntax** `linalg::matlinsolve(A, b, <list>, options)`  
`linalg::matlinsolve(A, B, options)`  
`linalg::matlinsolve(A, options)`

**Description** `linalg::matlinsolve(A, b)` computes the general solution of the equation  $A \vec{x} = \vec{b}$ .

`linalg::matlinsolve(A, b)` returns the solution vector  $\vec{x}$  of the system  $A \vec{x} = \vec{b}$  if it is a unique solution.

`linalg::matlinsolve(A, b)` returns a list  $[\vec{w}, [\vec{v}_1, \dots, \vec{v}_r]]$  if the system  $A \vec{x} = \vec{b}$  has more than one solution, where  $\vec{w}$  is one particular solution, i.e.,  $A \vec{w} = \vec{b}$  and  $\vec{v}_1, \dots, \vec{v}_r$  form a basis of the kernel of A, i.e., the solution space of the homogenous system  $A \vec{x} = (\vec{0})$ .

Each solution  $\vec{x}$  has the form  $\vec{x}_s + s_1 \vec{v}_1 + \dots + s_r \vec{v}_r (r \leq n)$  with certain scalars  $s_1, \dots, s_r$ .

A list of  $n$  scalars  $[s_1, \dots, s_n]$  may be passed as the additional parameter `list`. This extracts the solution  $\vec{x}_s + s_{i_1} \vec{v}_1 + \dots + s_{i_r} \vec{v}_r$  with  $\{i_1, \dots, i_r\} = \{1, \dots, n\} \setminus \{j_1, \dots, j_l\}$  from the solution space of the system  $A \vec{x} = \vec{b}$ , where  $j_1, \dots, j_l$  are the characteristic column indices of A (see `linalg::gaussJordan`).

The entries of `list` are converted to elements of the component ring of A (an error message is returned if this is not possible).

---

**Note** This option should only be used for exact and symbolic computations. In the case that A or b contains floating-point entries, it should not be used.

---

If the system  $A \vec{x} = \vec{b}$  has no solution, then the empty list `[]` is returned.

`linalg::matlinsolve(A)` solves the matrix equation  $C \vec{x} = \vec{b}$ , where  $\vec{b}$  is the last column of  $A$  and  $C$  is  $A$  with the last column deleted.

`linalg::matlinsolve(A, B)` returns the solution  $X$  of the matrix equation  $AX = B$ , if it has exactly one solution. Otherwise the empty list `[]` is returned.

The vector  $\mathbf{b}$  and the matrix  $B$  respectively, are converted into the domain `Dom::Matrix(R)`, where  $R$  is the component ring of  $A$ . Solution vectors also belong to this domain.

The component ring of  $A$  must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

`linalg::matlinsolve` can compute the general solution for systems with more than one solution only over fields, i.e., component rings of category `Cat::Field`. If in this case the component ring of  $A$  does not have a canonical representation of the zero element, then it may happen that `linalg::matlinsolve` does not find a basis for the null space. In such a case, a wrong result is returned.

`linalg::matlinsolve` does exploit a sparse structure of  $A$ . (A matrix is *sparse* if it has many zero components). See “Example 5” on page 14-145.

Use the function `numeric::matlinsolve` to solve a linear system numerically.

## Examples

### Example 1

Solve the linear system:

$$\begin{pmatrix} 1 & 2 \\ -1 & 2 \end{pmatrix} \vec{x} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

over the reals. First, enter the coefficient matrix and the right side:

# linalg::matlinsolve

---

```
MatR := Dom::Matrix(Dom::Real):
A := MatR([[1, 2], [-1, 2]]); b := MatR([1, -1])
```

$$\begin{pmatrix} 1 & 2 \\ -1 & 2 \end{pmatrix}$$

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Next, call `linalg::matlinsolve` to solve the system:

```
x := linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

The system has exactly one solution. The vector  $x$  satisfies the matrix equation given above:

```
A * x
```

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

## Example 2

The system:

$$\begin{pmatrix} 1 & 2 \\ -1 & -2 \end{pmatrix} \vec{x} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

does not have a solution over  $\mathbb{R}$  (in fact, over no component domain):

```
MatR := Dom::Matrix(Dom::Real):
A := MatR([[1, 2], [-1, -2]]): b := MatR([1, 0]):
linalg::matlinsolve(A, b)
```

[]

### Example 3

Solve the linear system:

$$\begin{pmatrix} 1 & 1 & -4 & -7 & -6 \\ 1 & -3 & -5 & -7 & -7 \end{pmatrix} \vec{x} = \begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

over the rational numbers. First, enter the coefficient matrix and the right side:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[1, 1, -4, -7, -6], [0, 1, -3, -5, -7]]):
b := MatQ([30, 17])
```

$$\begin{pmatrix} 1 & 1 & -4 & -7 & -6 \\ 0 & 1 & -3 & -5 & -7 \end{pmatrix}$$

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

Next, call `linalg::matlinsolve` to solve the system:

```
sol:= linalg::matlinsolve(A, b)
```

# linalg::matlinsolve

---

$$\left[ \begin{pmatrix} 13 \\ 17 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \left[ \begin{pmatrix} 1 \\ 3 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \\ 0 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 7 \\ 0 \\ 0 \\ 1 \end{pmatrix} \right] \right]$$

The result is to be interpreted as follows: The first vector of the list `sol` is a particular solution of the linear system:

$$A * \text{sol}[1]$$

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

The second entry of the list contains a basis for the null space of  $A$ , i.e., the solution space of the corresponding homogenous system  $A \vec{x} = \vec{0}$  (the kernel of  $A$ ). The basis returned is given as a list of vectors.

The following input checks this fact by computing the product  $A \vec{x}$  for each vector  $\vec{x}$  of the list `sol[2]`:

$$\text{map}(\text{sol}[2], x \rightarrow A * x)$$

$$\left[ \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \end{pmatrix} \right]$$

Any solution of the linear system can be represented as a sum of a particular solution (here: `sol[1]`) and a linear combination of the basis vectors of the kernel of  $A$ . Hence the input system has an infinite number of solutions.

For example, another solution of the system is given by:

$$x := \text{sol}[1] + 1*\text{sol}[2][1] + 1/2*\text{sol}[2][2] - 2*\text{sol}[2][3]$$

$$\begin{pmatrix} 17 \\ \frac{17}{2} \\ 1 \\ \frac{1}{2} \\ -2 \end{pmatrix}$$

`A * x`

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

If you identify the columns of the coefficient matrix  $A$  of the linear system with the variables  $x_1, x_2, x_3, x_4, x_5$ , then you see from the general solution that the variables  $x_3, x_4, x_5$  act as free parameters. They can be assigned arbitrary rational values to obtain a unique solution.

By giving a list of values for these variables as a third parameter to `linalg::matlinsolve`, you can select a certain vector from the set of all solutions of the linear system. For example, to select the same vector  $x$  as chosen in the previous input, enter:

```
linalg::matlinsolve(A, b, [0, 0, 1, 1/2, -2])
```

$$\begin{pmatrix} 17 \\ \frac{17}{2} \\ 1 \\ \frac{1}{2} \\ -2 \end{pmatrix}$$

# linalg::matlinsolve

---

If you are only interested in a particular solution and do not need the general solution of the linear system, enter:

```
linalg::matlinsolve(A, b, Special)
```

$$\begin{pmatrix} 13 \\ 17 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

This call suppresses the computation of the kernel of  $A$ .

## Example 4

If the linear system is given in the form of equations the function `linalg::expr2Matrix` can be used to form the corresponding matrix equation:

```
delete x, y, z:
Ab := linalg::expr2Matrix(
 [x + y + z = 6, 2*x + y + 2*z = 10, x + 3*y + z = 10]
)
```

$$\begin{pmatrix} 1 & 1 & 1 & 6 \\ 2 & 1 & 2 & 10 \\ 1 & 3 & 1 & 10 \end{pmatrix}$$

The result here is the extended coefficient matrix of the input system, that is, the right side vector  $\vec{b}$  is the 4th column vector of the matrix  $Ab$ . Since you did not specify a component ring for this matrix, the standard component ring for matrices, the domain `Dom::ExpressionField()`, was chosen.

To solve the linear system, call:

```
linalg::matlinsolve(Ab)
```

$$\left[ \begin{pmatrix} 4 \\ 2 \\ 0 \end{pmatrix}, \left[ \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \right] \right]$$

The system has an infinite number of solutions. The third variable  $z$  acts as a free parameter and therefore can have any (complex) value.

To get the general solution in parameter form, you can use parameters for the variables  $x, y, z$  of the input system:

```
delete u, v, w:
sol := linalg::matlinsolve(Ab, [u, v, w])
```

$$\begin{pmatrix} 4 - w \\ 2 \\ w \end{pmatrix}$$

This is possible here because you perform the matrix computations over `Dom::ExpressionField()` which lets you compute with symbolical (arithmetical) expressions.

To select a certain vector from the set of solutions, for example, the solution for  $w = 1$ , enter:

```
x := subs(sol, w = 1)
```

$$\begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}$$

## Example 5

Consider a system of linear equations with a sparse structure, that is, the coefficient matrix has many zero components:

```
eqs := {x1 + x5 = 0, x2 - x4 = 1, x3 + 2*x5 = 2, x4 - x5 = -1}:
```

## `linalg::matlinsolve`

---

```
Ab := linalg::expr2Matrix(eqs, [x1, x2, x3, x4, x5])
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & -1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 2 & 2 \\ 0 & 0 & 0 & 1 & -1 & -1 \end{pmatrix}$$

`linalg::matlinsolve` exploits the sparsity of the coefficient matrix if it is passed as a matrix of type `Dom::Matrix`. Alternatively, you can use the function `linsolve` which allows sparse input and output via symbolic equations:

```
linsolve(eqs)
```

$$[x1 = -x5, x2 = x5, x3 = 2 - 2x5, x4 = x5 - 1]$$

You also can use the function `numeric::matlinsolve` with the option `Symbolic` instead of `linalg::matlinsolve`:

```
A := linalg::delCol(Ab, 6):
b := linalg::col(Ab, 6):
numeric::matlinsolve(A, b, Symbolic)
```

$$\left[ \begin{pmatrix} 0 \\ 0 \\ 2 \\ -1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \\ -2 \\ 1 \\ 1 \end{pmatrix} \right]$$

Note that the function `numeric::matlinsolve` always works over a subfield of the complex numbers and does not let you specify the domain of computation. Without the option `Symbolic`, `numeric::matlinsolve` converts input data to floating-point numbers.

## Example 6

Check whether the matrix equation

$$\begin{pmatrix} 1 & 2 \\ -2 & 3 \end{pmatrix} \vec{X} = \begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

has a unique solution over the integers.

Start by entering the coefficient matrix and the right side matrix:

```
MatZ := Dom::Matrix(Dom::Integer):
A := MatZ([[1, 2], [-2, 3]]); B := MatZ([[4, 2], [6, 3]])
```

$$\begin{pmatrix} 1 & 2 \\ -2 & 3 \end{pmatrix}$$

$$\begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

Next, solve the matrix equation:

```
X := linalg::matlinsolve(A, B)
```

$$\begin{pmatrix} 0 & 0 \\ 2 & 1 \end{pmatrix}$$

The equation indeed has a unique solution (otherwise the answer of `linalg::matlinsolve` would be the empty list []). Check the result:

```
A * X
```

$$\begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

# linalg::matlinsolve

---

## Example 7

If you use the Normal option, `linalg::matlinsolve` calls the normal function for final results. This call ensures that `linalg::matlinsolve` returns results in normalized form:

```
A := matrix([[1, s], [t, -1]]):
b := matrix([s + 1, t - 1]):
x := linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

If you specify `Normal = FALSE`, `linalg::matlinsolve` does not call normal for the final result:

```
x := linalg::matlinsolve(A, b, Normal = FALSE)
```

$$\begin{pmatrix} s - \frac{s(t(s+1)-t+1)}{st+1} + 1 \\ \frac{t(s+1)-t+1}{st+1} \end{pmatrix}$$

## Example 8

Solve this system:

```
A := matrix([[1, s], [1, t]]):
b := matrix([1, 1]):

linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

Note that more solutions exist for  $t = s$ . `linalg::matlinsolve` omits these solutions because it makes some additional assumptions on symbolic parameters of this system. To see the assumptions that `linalg::matlinsolve` made while solving this system, use the `ShowAssumptions` option:

```
linalg::matlinsolve(A, b, ShowAssumptions)
```

```

$$\left[\left(\begin{matrix} 1 \\ 0 \end{matrix}\right), [], [], [t - s \neq 0]\right]$$

```

## Parameters

**A**

$m \ n$  matrix of a domain of category `Cat::Matrix`

**B**

$m \ k$  matrix of a domain of category `Cat::Matrix`

**b**

$m$ -dimensional column vector, i.e., a  $m \ 1$  matrix of a domain of category `Cat::Matrix`

**list**

List of  $n$  elements of the component ring of A

## Options

**Normal**

Option, specified as `Normal = b`

Return normalized results. The value `b` must be `TRUE` or `FALSE`. By default, `Normal = TRUE`, meaning that `linalg::matlinsolve` guarantees normalization of the returned results. Normalizing results can be computationally expensive.

By default, `linalg::matlinsolve` calls `normal` before returning results. This additional internal call ensures that the final result is normalized. This call can be computationally expensive. This

option affects the output only if the solution contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`).

To avoid this additional call, specify `Normal = FALSE`. In this case, `linalg::matlinsolve` also can return normalized results, but does not guarantee such normalization. See “Example 7” on page 14-148.

## ShowAssumptions

Return information about internal assumptions that `linalg::matlinsolve` made on symbolic parameters in eqs.

With `ShowAssumptions`, `linalg::matlinsolve` returns a list [`S`, `KernelBasis`, `Constraints`, `Pivots`]. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `b` (or `B`). Internally, these were assumed to hold true when solving the system. See “Example 8” on page 14-148.

When Gaussian elimination produces an equation  $0 = c$  with nonzero `c`, `linalg::matlinsolve` without `ShowAssumptions` returns `[]`. If `c` involves symbolic parameters, try using `linalg::matlinsolve` with `ShowAssumptions` to solve such systems. If the system is solvable, you will get the solution. In this case, an equation  $0 = c$  is returned in the `Constraints` list. If the system is not solvable, `linalg::matlinsolve` with `ShowAssumptions` returns `[[], [], [], []]`.

## Special

Only one particular solution  $w$  of the system  $A \vec{x} = \vec{b}$  is returned. This suppresses the computation of a basis for the kernel of `A`.

## Unique

Checks whether the system has a unique solution and returns it. The return value `NIL` means that the system has more than one solution.

## Return Values

Without `ShowAssumptions`, `linalg::matlinsolve` can return a vector or a list `[S, KernelBasis]` (possibly empty), where `S` is a solution vector and `KernelBasis` is a list of basis vectors for the kernel of `A`. It also can return a matrix or the value `NIL`.

The matrix and the vectors, respectively, are of the domain type `Dom::Matrix(R)`, where `R` is the component ring of `A`.

With `ShowAssumptions`, `linalg::matlinsolve` returns a list `[S, KernelBasis, Constraints, Pivots]`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `b` (or `B`). Internally, these were assumed to hold true when solving the system. If the system is not solvable, `linalg::matlinsolve` with `ShowAssumptions` returns `[[], [], [], []]`.

## Algorithms

Let  $A$  be an  $m \times n$  matrix with components from a field  $F$  and  $\vec{b}$  an  $m$ -dimensional vector over  $F$ . Let  $(A, \vec{b})$  be the extended coefficient matrix of the linear system  $A \vec{x} = \vec{b}$ .

Then the following holds:

- The linear system  $A \vec{x} = \vec{b}$  has a solution, if and only if  $\text{rank}(A, \vec{b}) = \text{rank}(A)$ .
- It has exactly one solution, if and only if  $\text{rank}(A, \vec{b}) = \text{rank}(A) = n$ .
- If  $\vec{x}_s$  is a solution of the system  $A \vec{x} = \vec{b}$  and  $\{\vec{v}_1, \dots, \vec{v}_r\}$  a basis of the kernel of  $A$ , then

$$L(A, \vec{b}) = \{\vec{w} + \lambda_1 \vec{v}_1 + \lambda_2 \vec{v}_2 + \dots + \lambda_r \vec{v}_r \mid \lambda_1, \dots, \lambda_r \in K\}$$

# linalg::matlinsolve

---

is the set of all solutions of the linear system  $A \vec{x} = \vec{b}$ , the *general solution* of the (inhomogeneous) linear system.

The *kernel of the matrix*  $A$  is defined as:

$$\ker(A) = \{ \vec{w} \mid A \vec{w} = \vec{0} \}$$

The kernel of  $A$  is a vector space over  $F$  of dimension  $n - \text{rank}(A)$ .

## See Also

## MuPAD Functions

`linsolve` | `linalg::expr2Matrix` | `linalg::nullspace`  
| `linalg::matlinsolveLU` | `linalg::wiedemann` |  
`numeric::matlinsolve`

## Concepts

- “Solve Algebraic Systems”

## Purpose

Solving the linear system given by an LU decomposition

## Syntax

```
linalg::matlinsolveLU(L, U, b)
linalg::matlinsolveLU(L, U, B)
```

## Description

`linalg::matlinsolveLU(L, U, b)` solves the linear system

$L U \vec{x} = \vec{b}$ , where the matrices  $L$  and  $U$  form an LU-decomposition, as computed by `linalg::factorLU`.

If the third parameter is an  $n \times k$  matrix  $B$  then the result is an  $n \times k$  matrix  $X$  satisfying the matrix equation  $LUX = B$ .

The system to be solved always has a unique solution.

The diagonal entries of the lower diagonal matrix  $L$  must be equal to one (*Doolittle*-decomposition, see `linalg::factorLU`).

`linalg::matlinsolveLU` expects  $L$  and  $U$  to be nonsingular.

`linalg::matlinsolveLU` does not check on any of the required properties of  $L$  and  $U$ .

The component ring of the matrices  $L$  and  $U$  must be a field, i.e., a domain of category `Cat::Field`.

The parameters must be defined over the same component ring.

## Examples

### Example 1

We solve the system

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ & 1 & -1 \end{pmatrix} X = \begin{pmatrix} 1 & & \\ & 1 & \\ & & 1 \end{pmatrix} :$$

```
MatR := Dom::Matrix(Dom::Real):
A := MatR([[2, -3, -1], [1, 1, -1], [0, 1, -1]]);
I3 := MatR::identity(3)
```

# linalg::matlinsolveLU

---

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We start by computing an LU-decomposition of  $A$ :

```
LU := linalg::factorLU(A)
```

$$\left[ \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 0 & \frac{2}{5} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 & -1 \\ 0 & \frac{5}{2} & -\frac{1}{2} \\ 0 & 0 & -\frac{4}{5} \end{pmatrix}, [1, 2, 3] \right]$$

Now we solve the system  $AX = I_3$ , which gives us the inverse of  $A$ :

```
Ai := linalg::matlinsolveLU(LU[1], LU[2], I3)
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

```
A * Ai, Ai * A
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

## Parameters

**L**

An  $n \times n$  lower triangular matrix of a domain of category `Cat::Matrix`

**U**

An  $n \times n$  upper triangular form matrix of the same domain as L

**B**

An  $n \times k$  matrix of a domain of category `Cat::Matrix`

**b**

An  $n$ -dimensional column vector, i.e., an  $n \times 1$  matrix of a domain of category `Cat::Matrix`

## Return Values

$n$ -dimensional solution vector or  $n \times k$  dimensional solution matrix, respectively, of the domain type `Dom::Matrix(R)`, where R is the component ring of A.

## See Also

## MuPAD Functions

`linalg::factorLU` | `linalg::inverseLU` | `linalg::matlinsolve`

# linalg::minpoly

---

**Purpose** Minimal polynomial of a matrix

**Syntax** `linalg::minpoly(A, x)`

**Description** `linalg::minpoly(A, x)` computes the minimal polynomial of the square matrix  $A$  in  $x$ , i.e., the monic polynomial of lowest degree annihilating the matrix  $A$ .

The minimal polynomial of  $A$  divides the characteristic polynomial of  $A$ , by Cayley-Hamilton theorem.

If the matrix is defined over `Dom::Float`, then due to numerical errors the computed polynomial can have a degree higher than the dimension of the matrix. In such cases, `linalg::minpoly` returns the value `FAIL`. See “Example 3” on page 14-158.

The component ring of  $A$  must be a field, i.e., a domain of category `Cat::Field`.

## Examples

### Example 1

We define the following matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)(
 [[0, 2, 0], [0, 0, 2], [2, 0, 0]]
)
```

$$\begin{pmatrix} 0 & 2 & 0 \\ 0 & 0 & 2 \\ 2 & 0 & 0 \end{pmatrix}$$

The minimal polynomial of the matrix  $A$  in the variable  $x$  is then given by:

```
delete x: linalg::minpoly(A, x)
```

$$x^3 - 8$$

In this case, the minimal polynomial is in fact equal to the characteristic polynomial of  $A$ :

```
linalg::charpoly(A, x)
```

$$x^3 - 8$$

## Example 2

The minimal polynomial of the matrix:

```
B := matrix([[0, 1, 0], [0, 0, 0], [0, 0, 0]])
```

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

is a polynomial of degree 2:

```
m := linalg::minpoly(B, x)
```

$$x^2$$

The characteristic polynomial of  $B$  has degree 3 and is divided by the minimal polynomial of  $B$ :

```
p := linalg::charpoly(B, x)
```

$$x^3$$

```
p / m
```

```
x
```

### Example 3

For the following example, MuPAD is not able to compute the minimal polynomial, and thus FAIL is returned:

```
C := Dom::Matrix(Dom::Float)([
 [7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0],
 [1, 2, 3, 0, 0], [1, 2, 3, 4, 7]
])
```

```
(7.0 0.0 0.0 0.0 0.0
 1.0 0.0 0.0 0.0 0.0
 1.0 2.0 0.0 0.0 0.0
 1.0 2.0 3.0 0.0 0.0
 1.0 2.0 3.0 4.0 7.0)
```

```
delete x: linalg::minpoly(C, x)
```

```
Warning: Cannot compute the minimal polynomial. [linalg::minpoly]
```

```
FAIL
```

In fact, for this example MuPAD is not able to check for zero equivalence during Gaussian elimination and therefore chose a wrong pivot element.

If you perform the computation over the coefficient domain `Dom::ExpressionField(normal)` instead, then in most cases the minimal polynomial can be computed:

```
C := matrix([
```

```
[7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0],
[1, 2, 3, 0, 0], [1, 2, 3, 4, 7]
])
```

$$\begin{pmatrix} 7 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 2 & 0 & 0 & 0 \\ 1 & 2 & 3 & 0 & 0 \\ 1 & 2 & 3 & 4 & 7 \end{pmatrix}$$

```
linalg::minpoly(C, x)
```

$$x^5 - 14x^4 + 49x^3$$

However, in general this problem regarding zero recognition cannot be avoided.

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

**x**

An indeterminate

## Return Values

Polynomial of the domain `Dom::DistributedPolynomial([x],R)`, where `R` is the component ring of `A`, or the value `FAIL`.

## See Also

## MuPAD Functions

`linalg::charpoly` | `linalg::frobeniusForm`

# linalg::multCol

---

**Purpose** Multiply columns with a scalar

**Syntax** `linalg::multCol(A, c, s)`  
`linalg::multCol(A, c1 .. c2, s)`  
`linalg::multCol(A, list, s)`

**Description** `linalg::multCol(A, c, s)` returns a copy of the matrix  $A$  resulting from  $A$  by multiplying the  $c$ -th column of  $A$  with the scalar  $s$ .

`linalg::multCol(A, c1 .. c2, s)` returns a copy of the matrix  $A$  obtained from  $A$  by multiplying those columns whose indices are in the range  $c_1 .. c_2$  with the scalar  $s$ .

`linalg::multCol(A, list, s)` returns a copy of the matrix  $A$  obtained from matrix  $A$  by multiplying those columns whose indices are contained in `list` with the scalar  $s$ .

The scalar  $s$  is converted into an element of the component ring of the matrix  $A$ . An error message is returned if the conversion fails.

## Examples

### Example 1

We define the following matrix:

```
A := matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::multCol`:

```
linalg::multCol(A, 2, -1)
```

$$\begin{pmatrix} 1 & -2 & 3 \\ 4 & -5 & 6 \\ 7 & -8 & 9 \end{pmatrix}$$

```
linalg::multCol(A, 1..2, 2)
```

$$\begin{pmatrix} 2 & 4 & 3 \\ 8 & 10 & 6 \\ 14 & 16 & 9 \end{pmatrix}$$

```
linalg::multCol(A, [3, 1], 0)
```

$$\begin{pmatrix} 0 & 2 & 0 \\ 0 & 5 & 0 \\ 0 & 8 & 0 \end{pmatrix}$$

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**c**

The column index: a positive integer less or equal to  $n$

**c<sub>1</sub> .. c<sub>2</sub>**

A range of column indices (positive integers less or equal to  $n$ )

**list**

A list of column indices (positive integers less or equal to  $n$ )

## Return Values

Matrix of the same domain type as  $A$ .

# **linalg::multCol**

---

## **See Also**

## **MuPAD Functions**

`linalg::addCol` | `linalg::addRow` | `linalg::multRow`

**Purpose** Multiply rows with a scalar

**Syntax**

```
linalg::multRow(A, r, s)
linalg::multRow(A, r1 .. r2, s)
linalg::multRow(A, list, s)
```

**Description** `linalg::multRow(A, r, s)` returns a copy of the matrix  $A$  resulting from  $A$  by multiplying the  $r$ -th row of  $A$  with the scalar  $s$ .

`linalg::multRow(A, r1.. r2, s)` returns a copy of the matrix  $A$  obtained from  $A$  by multiplying those rows whose indices are in the range  $r_1.. r_2$  with the scalar  $s$ .

`linalg::multRow(A, list, s)` returns a copy of the matrix  $A$  obtained from matrix  $A$  by multiplying those rows whose indices are contained in `list` with the scalar  $s$ .

The scalar  $s$  is converted into an element of the component ring of the matrix  $A$ . An error message is returned if the conversion fails.

**Examples**      **Example 1**

We define the following matrix:

```
A := matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::multRow`:

```
linalg::multRow(A, 2, -1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ -4 & -5 & -6 \\ 7 & 8 & 9 \end{pmatrix}$$

# linalg::multRow

---

```
linalg::multRow(A, 1..2, 2)
```

$$\begin{pmatrix} 2 & 4 & 6 \\ 8 & 10 & 12 \\ 7 & 8 & 9 \end{pmatrix}$$

```
linalg::multRow(A, [3, 1], 0)
```

$$\begin{pmatrix} 0 & 0 & 0 \\ 4 & 5 & 6 \\ 0 & 0 & 0 \end{pmatrix}$$

## Parameters

**A**

An  $m \times n$  matrix of a domain of category `Cat::Matrix`

**r**

The row index: a positive integer less or equal to  $m$

**r<sub>1</sub> .. r<sub>2</sub>**

A range of row indices (positive integers less or equal to  $m$ )

**list**

A list of row indices (positive integers less or equal to  $m$ )

## Return Values

Matrix of the same domain type as A.

# linalg::nonZeros

---

**Purpose** Number of non-zero elements of a matrix

**Syntax** `linalg::nonZeros(A)`

**Description** `linalg::nonZeros(A)` returns the number of non-zero components of the matrix  $A$ .

## Examples **Example 1**

The matrix

```
MZ7 := Dom::Matrix(Dom::IntegerMod(7)):
A := MZ7([[18, -1], [4, 81]])
```

$$\begin{pmatrix} 4 \bmod 7 & 6 \bmod 7 \\ 4 \bmod 7 & 4 \bmod 7 \end{pmatrix}$$

has four non-zero entries:

```
linalg::nonZeros(A)
```

4

The matrix:

```
B := MZ7([[21, 2], [-1, 14]])
```

$$\begin{pmatrix} 0 \bmod 7 & 2 \bmod 7 \\ 6 \bmod 7 & 0 \bmod 7 \end{pmatrix}$$

has only two non-zero entries:

`linalg::nonZeros(B)`

2

## Parameters

**A**

A matrix of a domain of category `Cat::Matrix`

## Return Values

Nonnegative integer

# linalg::normalize

---

**Purpose** Normalize a vector

**Syntax** `linalg::normalize(v)`

**Description** `linalg::normalize(v)` normalizes the vector  $\vec{v}$  with respect to the 2-norm ( $\|\vec{v}\|_2 = \sqrt{\langle \vec{v}, \vec{v} \rangle}$ ).

The result of `linalg::normalize(v)` is a vector that has norm 1 and the same direction as  $v$ .

The scalar product  $\langle \vec{v}, \vec{v} \rangle$  for a vector  $\vec{v}$  is implemented by the function `linalg::scalarProduct`.

The norm of a vector is computed with the function `norm`, which is overloaded for vectors. See the method "norm" of the domain constructor `Dom::Matrix` for details.

If the norm is an object that cannot be converted into an element of the component ring of  $v$ , then an error occurs (see "Example 2" on page 14-169).

## Examples

### Example 1

We define the following vector:

```
u := matrix([[1, 2]])
```

```
(1 2)
```

Then the vector of norm 1 with the same direction as  $u$  is given by:

```
linalg::normalize(u)
```

```
($\frac{\sqrt{5}}{5}$ $\frac{2\sqrt{5}}{5}$)
```

## Example 2

The following computation fails because the vector (1, 2) cannot be normalized over the rationals:

```
v := Dom::Matrix(Dom::Rational)([[1, 2]]):
linalg::normalize(v)
```

Error: Cannot normalize the given vector over its component ring

If we define v over the real numbers, then we get the normalized vector of v as follows:

```
w := Dom::Matrix(Dom::Real)(v): linalg::normalize(w)
```

$$\left( \frac{\sqrt{5}}{5} \quad \frac{2\sqrt{5}}{5} \right)$$

### Parameters

**v**

A vector, i.e., an  $n \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`

### Return Values

Vector of the same domain type as v.

### See Also

### MuPAD Functions

`norm` | `linalg::scalarProduct`

# linalg::nrows

---

**Purpose** Number of rows of a matrix

**Syntax** `linalg::nrows(A)`

**Description** `linalg::nrows(A)` returns the number of rows of the matrix  $A$ .

**Examples** **Example 1**

The matrix:

```
A := matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

has three rows:

```
linalg::nrows(A)
```

3

**Parameters** **A**

A matrix of a domain of category `Cat::Matrix`

**Return Values** Positive integer.

**See Also**

**MuPAD Functions** `linalg::matdim` | `linalg::ncols` | `linalg::vecdim`

**Purpose** Basis for the null space of a matrix

**Syntax** `linalg::nullspace(A)`

**Description** `linalg::nullspace(A)` returns a basis for the null space of the matrix  $A$ , i.e., a list  $B$  of linearly independent vectors such that  $A \vec{x} = \vec{0}$  if and only if  $\vec{x}$  is a linear combination of the vectors in  $B$ .

The component ring of the matrix  $A$  must be a field, i.e., a domain of category `Cat::Field`.

If the component ring of  $A$  does not have a canonical representation of the zero element, it can happen that `linalg::nullspace` does not find a basis for the null space. In such a case, a wrong result is returned.

## Examples **Example 1**

The kernel of the matrix:

```
A := Dom::Matrix(Dom::Real)(
 [[3^(1/2)*2 - 2, 2], [4, 3^(1/2)*2 + 2]]
)
```

$$\begin{pmatrix} 2\sqrt{3}-2 & 2 \\ 4 & 2\sqrt{3}+2 \end{pmatrix}$$

is one-dimensional, and a basis is  $\left\{ \begin{pmatrix} -\frac{1}{\sqrt{3}-1} \\ 1 \end{pmatrix} \right\}$ :

```
linalg::nullspace(A)
```

# **linalg::nullspace**

---

$$\left[ \begin{pmatrix} -\frac{1}{\sqrt{3}-1} \\ 1 \end{pmatrix} \right]$$

## **Parameters**

**A**

A matrix of a domain of category `Cat::Matrix`

## **Return Values**

List of (column) vectors of the domain `Dom::Matrix(R)`, where R is the component ring of A.

## **See Also**

## **MuPAD Functions**

`linalg::basis` | `linalg::matlinsolve` | `linsolve` | `numeric::matlinsolve`

## **Related Examples**

- “Compute Bases for Null Spaces of Matrices”

**Purpose** Table of orthogonal coordinate transformations

**Syntax**

```

linalg::ogCoordTab[ogName](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
 Transformation](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
 InverseTransformation](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
 UnitVectors](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
 Scales](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName, Ranges](<c>)
linalg::ogCoordTab[ogName , Dimension]

```

**Description** `linalg::ogCoordTab` is a table of predefined orthogonal coordinate transformations in  $\mathbb{R}^3$ .

The entry associated with `ogName` defines a coordinate transformation  $\vec{X} = \vec{X}(\vec{u})$  which maps the orthogonal parameters  $\vec{u} = (u_1, u_2, u_3)$  to a vector  $\vec{X} = (X_1, X_2, X_3)$  in cartesian coordinates.

The coordinate systems `EllipticCylindrical` and `Torus` are defined with a constant parameter `c` which has to be passed as an additional argument. See “Example 2” on page 14-178.

The following coordinate transformations are stored in `linalg::ogCoordTab`. They are invertible for the indicated parameter values:

- Cartesian:

$$u_1, u_2, u_3 :$$

$$X_1 = u_1, X_2 = u_2, X_3 = u_3$$

# linalg::ogCoordTab

---

- Spherical:

$$0 < u_1 < \infty, 0 \leq u_2 < 2\pi, 0 \leq u_3 < \pi:$$

$$X_1 = u_1 \cos(u_2) \sin(u_3), X_2 = u_1 \sin(u_2) \sin(u_3), X_3 = u_1 \cos(u_3)$$

- Cylindrical:

$$0 < u_1 < \infty, 0 \leq u_2 < 2\pi, u_3 :$$

$$X_1 = u_1 \cos(u_2), X_2 = u_1 \sin(u_2), X_3 = u_3$$

- EllipticCylindrical:

$$0 < u_1 < \infty, 0 \leq u_2 < 2\pi, u_3 \quad (\text{with a real constant } c):$$

$$X_1 = c \cos(u_1) \cos(u_2), X_2 = c \sinh(u_1) \sin(u_2), X_3 = u_3$$

- ParabolicCylindrical:

$$0 < u_1 < \infty, u_2, u_3 :$$

$$X_1 = \frac{(u_1^2 - u_2^2)}{2}, X_2 = u_1 u_2, X_3 = u_3$$

- RotationParabolic:

$$0 < u_1 < \infty, 0 < u_2 < \infty, 0 \leq u_3 < 2\pi:$$

$$X_1 = u_1 u_2 \cos(u_3), X_2 = u_1 u_2 \sin(u_3), X_3 = \frac{(u_1^2 - u_2^2)}{2}$$

- Torus:

$$0 < u_1 < c, 0 \leq u_2 < 2\pi, 0 \leq u_3 < 2\pi \text{ (with a positive constant } c\text{):}$$

$$X_1 = (c - u_1 \cos(u_2)) \cos(u_3), X_2 = (c - u_1 \cos(u_2)) \sin(u_3), X_3 = u_1 \sin(u_2)$$

`linalg::ogCoordTab` is used by functions such as `linalg::curl`, `linalg::divergence`, `linalg::gradient`, and `linalg::laplacian` to perform computations in non-cartesian coordinates.

## Examples

### Example 1

The following call returns the cartesian vector  $\vec{X} = [X, Y, Z]$  in terms of spherical coordinates  $\vec{u} = [u_1, u_2, u_3]$ :

```
linalg::ogCoordTab[Spherical, Transformation](u1, u2, u3)

[u1 cos(u2) sin(u3), u1 sin(u2) sin(u3), u1 cos(u3)]
```

The spherical coordinates expressed by the cartesian coordinates:

```
linalg::ogCoordTab[Spherical, InverseTransformation](x, y, z)
```

# linalg::ogCoordTab

$$\left[ \sqrt{x^2 + y^2 + z^2}, \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right) + \text{sign}(y) (\text{sign}(y) - 1) \left(\pi - \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right)\right), \arccos\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right) \right]$$

Note the `sign(y)` in the expression for  $u_2$ . This ensures that the correct angle is returned for any value of  $y$ :

```
assume(y > 0):
linalg::ogCoordTab[Spherical, InverseTransformation](x, y, z)
```

$$\left[ \sqrt{x^2 + y^2 + z^2}, \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right), \arccos\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right) \right]$$

```
linalg::ogCoordTab[Spherical, InverseTransformation](1, 1, 0),
linalg::ogCoordTab[Spherical, InverseTransformation](-1, 0, 1),
linalg::ogCoordTab[Spherical, InverseTransformation](1, 0, 2),
linalg::ogCoordTab[Spherical, InverseTransformation](1, -1, 3)
```

$$\left[ \sqrt{2}, \frac{\pi}{4}, \frac{\pi}{2} \right], \left[ \sqrt{2}, \pi, \frac{\pi}{4} \right], \left[ \sqrt{5}, 0, \arccos\left(\frac{2\sqrt{5}}{5}\right) \right], \left[ \sqrt{11}, \frac{7\pi}{4}, \arccos\left(\frac{3\sqrt{11}}{11}\right) \right]$$

These parameter values are from the following ranges:

```
linalg::ogCoordTab[Spherical, Ranges]()
```

$$[0.. \infty, 0..2\pi, 0..\pi]$$

The following orthonormal vectors are tangent to the spherical parameter lines:

```
linalg::ogCoordTab[Spherical, UnitVectors](u1, u2, u3)
```

```
[[cos(u2) sin(u3), sin(u2) sin(u3), cos(u3)], [- sin(u2), cos(u2), 0], [cos(u2) cos(u3), cos(u3) s
```

The 'scaling factors' are:

```
linalg::ogCoordTab[Spherical,Scales](u1, u2, u3)
```

```
[1, u1 sin(u3), u1]
```

There is the following relationship between the Jacobian of the transformation  $\vec{u} \rightarrow \vec{X}$  from the orthogonal coordinates to the cartesian coordinates:

```
xyz:= linalg::ogCoordTab[Spherical,Transformation](u1, u2, u3):
unitvectors:= linalg::ogCoordTab[Spherical, UnitVectors](u1, u2,
scales:= linalg::ogCoordTab[Spherical, Scales](u1, u2, u3):
```

```
linalg::transpose(linalg::jacobian(xyz, [u1, u2, u3])) =
 matrix(3, 3, scales, Diagonal)* matrix(unitvectors)
```

$$\begin{pmatrix} \cos(u2) \sin(u3) & \sin(u2) \sin(u3) & \cos(u3) \\ - u1 \sin(u2) \sin(u3) & u1 \cos(u2) \sin(u3) & 0 \\ u1 \cos(u2) \cos(u3) & u1 \cos(u3) \sin(u2) & - u1 \sin(u3) \end{pmatrix} =$$

$$\begin{pmatrix} \cos(u2) \sin(u3) & \sin(u2) \sin(u3) & \cos(u3) \\ - u1 \sin(u2) \sin(u3) & u1 \cos(u2) \sin(u3) & 0 \\ u1 \cos(u2) \cos(u3) & u1 \cos(u3) \sin(u2) & - u1 \sin(u3) \end{pmatrix}$$

```
delete y, xyz, unitvectors, scales:
```

## Example 2

The following call returns the cartesian vector  $\vec{x} = [x, y, z]$  in terms of elliptic cylindrical coordinates  $\vec{u} = [u, v, w]$  involving a parameter  $c$ :

```
linalg::ogCoordTab[EllipticCylindrical, Transformation](u, v, z, c)
```

$$[c \cosh(u) \cos(v), c \sinh(u) \sin(v), z]$$

We compute the gradient of the function  $f(u, v, w) = x(u, v, w)$  in elliptic cylindrical coordinates  $\vec{u} = [u, v, w]$ .

```
f := (c*cos(v)*cosh(u))^2:
```

For computing the components of the gradient with respect to an orthogonal system, it is sufficient to know the 'scale parameters':

```
linalg::ogCoordTab[EllipticCylindrical, Scales](u, v, w, c)
```

$$\left[ c \sqrt{\cosh(u)^2 - \cos(v)^2}, c \sqrt{\cosh(u)^2 - \cos(v)^2}, 1 \right]$$

```
gradf := linalg::gradient(f, [u, v, w], %)
```

$$\begin{pmatrix} \frac{2 c \cosh(u) \cos(v)^2 \sinh(u)}{\sqrt{\cosh(u)^2 - \cos(v)^2}} \\ - \frac{2 c \cosh(u)^2 \cos(v) \sin(v)}{\sqrt{\cosh(u)^2 - \cos(v)^2}} \\ 0 \end{pmatrix}$$

These are the coefficients of the gradient with respect to the orthonormal basis  $\vec{e}_u, \vec{e}_v, \vec{e}_w$  returned via the option UnitVectors:

```
[e_u, e_v, e_w] :=
linalg::ogCoordTab[EllipticCylindrical, UnitVectors](u, v, w, c)
```

$$\left[ \left[ \frac{\cos(v) \sinh(u)}{\sqrt{\cosh(u)^2 - \cos(v)^2}}, \frac{\cosh(u) \sin(v)}{\sqrt{\cosh(u)^2 - \cos(v)^2}}, 0 \right], \left[ -\frac{\cosh(u) \sin(v)}{\sqrt{\cosh(u)^2 - \cos(v)^2}}, \frac{\cos(v) \sinh(u)}{\sqrt{\cosh(u)^2 - \cos(v)^2}} \right] \right]$$

We convert the lists e\_u, e\_v, e\_w into column vectors via matrix. Thus, in the standard basis of  $\mathbb{R}^3$ , the gradient vector field is:

```
G := gradf[1]*matrix(e_u)
 + gradf[2]*matrix(e_v)
 + gradf[3]*matrix(e_w)
```

$$\begin{pmatrix} \frac{2c \cosh(u) \cos(v)^3 \sinh(u)^2}{\cosh(u)^2 - \cos(v)^2} + \frac{2c \cosh(u)^3 \cos(v) \sin(v)^2}{\cosh(u)^2 - \cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} \frac{2c \cosh(u) \cos(v)^3 \sinh(u)^2}{\cosh(u)^2 - \cos(v)^2} + \frac{2c \cosh(u)^3 \cos(v) \sin(v)^2}{\cosh(u)^2 - \cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

# linalg::ogCoordTab

---

$$\begin{pmatrix} \frac{2 c \cosh(u) \cos(v)^3 \sinh(u)^2}{\cosh(u)^2 - \cos(v)^2} + \frac{2 c \cosh(u)^3 \cos(v) \sin(v)^2}{\cosh(u)^2 - \cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

We simplify this expression using the identities  $\sin^2(v) = 1 - \cos^2(v)$ ,  $\sinh^2(u) = \cosh^2(u) - 1$ :

```
normal(subs(G, sin(v)^2 = 1 - cos(v)^2,
sinh(u)^2 = cosh(u)^2 - 1))
```

$$\begin{pmatrix} 2 c \cosh(u) \cos(v) \\ 0 \\ 0 \end{pmatrix}$$

This is the gradient of the function  $f(x, y, z) = x^2$  with  $x$  expressed by elliptic cylindrical coordinates:

```
G := linalg::gradient(x^2, [x, y, z])
```

$$\begin{pmatrix} 2 x \\ 0 \\ 0 \end{pmatrix}$$

```
[x, y, z] :=
linalg::ogCoordTab[EllipticCylindrical, Transformation](u, v, w, c)
```

```
[c cosh(u) cos(v), c sinh(u) sin(v), w]
```

```
map(G, eval)
```

$$\begin{pmatrix} 2 c \cosh(u) \cos(v) \\ 0 \\ 0 \end{pmatrix}$$

delete f, gradf, e\_u, e\_v, e\_w, G, x, y, z:

## Parameters

### ogName

The name of a predefined coordinate system. The following 3 dimensional coordinate systems are available: Cartesian, Spherical, Cylindrical, EllipticCylindrical, ParabolicCylindrical, RotationParabolic, Torus.

### $u_1, u_2, u_3$

The coordinates of the orthogonal system: identifiers, indexed identifiers, or arithmetical expressions.

### $x_1, x_2, x_3$

Cartesian coordinates: identifiers, indexed identifiers, or arithmetical expressions.

### c

An arithmetical expression. The default value is  $c = 1$ .

## Options

### Transformation

`linalg::ogCoordTab [ogName, Transformation](  $u_1, u_2, u_3$  c )` returns a list of arithmetical expressions [  $x_1( u_1, u_2, u_3)$ ,  $x_2( u_1, u_2, u_3)$ ,  $x_3( u_1, u_2, u_3)$  ] defining the transformation from the orthogonal coordinates  $u_i$  to the cartesian coordinates  $x_j$ . The transformation is invertible if the coordinates  $u_i$  are from the range  $a_i < u_i < b_i$  where [a1..b1, a2..b2, a3..b3] = `linalg::ogCoordTab [ogName, Ranges]( c )`.

### InverseTransformation

# linalg::ogCoordTab

`linalg::ogCoordTab [ogName, InverseTransformation](  
x1, x2, x3 c )` returns a list of arithmetical expressions [ `u1(  
x1, x2, x3)`, `u2( x1, x2, x3)`, `u3( x1, x2, x3)`] defining the  
inverse transformation. The inverse transformation produces  
parameter values  $u_i$  in the range  $a_i \leq u_i \leq b_i$  given by [a1..b1,  
a2..b2, a3..b3] = `linalg::ogCoordTab [ogName, Ranges](  
c )`.

## UnitVectors

`linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3 c  
)` returns a list of orthonormal vectors [ $\vec{e}_1$ ,  $\vec{e}_2$ ,  $\vec{e}_3$ ], where each  
vector is represented by a list of three arithmetical expressions.

These vectors  $\vec{e}_i = \frac{1}{s_i} \frac{\partial \vec{X}}{\partial u_i}$  with  $s_i = \left| \frac{\partial \vec{X}}{\partial u_i} \right|$  are the unit  
vectors tangent to the parameter lines  $u_i$ .

## Scales

`linalg::ogCoordTab [ogName, Scales]( u1, u2, u3 c  
)` returns a list [ `s1`, `s2`, `s3`] of “scaling factors” of the  
transformation  $\vec{u} \rightarrow \vec{X}$ . The “scales” are the Euclidean lengths

$s_i = \left| \frac{\partial \vec{X}}{\partial u_i} \right|$  of the vectors  $\frac{\partial \vec{X}}{\partial u_i}$  tangent to the parameter  
lines  $u_i$ .

## Return Values

Most of the entries in `linalg::ogCoordTab` are functions:

`linalg::ogCoordTab [ogName, Transformation]( u1, u2, u3, c  
)` returns a list of arithmetical expressions [ `x1( u1, u2, u3)`, `x2(  
u1, u2, u3)`, `x3( u1, u2, u3)`] defining the transformation from the  
orthogonal coordinates  $u_i$  to the cartesian coordinates  $x_j$ .

`linalg::ogCoordTab [ogName, InverseTransformation]( x1,  
x2, x3, c )` returns a list of arithmetical expressions [ `u1( x1,  
x2, x3)`, `u2( x1, x2, x3)`, `u3( x1, x2, x3)`] defining the inverse  
transformation.

`linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3, c )` returns a list of orthogonal unit “vectors.” The “vectors” are given as lists of arithmetical expressions.

`linalg::ogCoordTab [ogName, Scales]( u1, u2, u3, c )` returns a list of arithmetical expressions.

`linalg::ogCoordTab [ogName, Ranges]( c )` returns a list of ranges [ a<sub>1</sub>.. b<sub>1</sub>, a<sub>2</sub>.. b<sub>2</sub>, a<sub>3</sub>.. b<sub>3</sub>]. The transformation is invertible for parameter values  $a_i < u_i < b_i$ .

`linalg::ogCoordTab [ogName, Dimension]` yields the dimension of the space parametrized by the orthogonal coordinates. Presently, all predefined systems parametrize <sup>3</sup>, i.e., the dimension is 3 in all cases.

The call `linalg::ogCoordTab [ogName]( u1, u2, u3, c )` is identical to the call `linalg::ogCoordTab [ogName, UnitVectors]( u1, u2, u3, c )`.

## MuPAD Functions

`linalg::curl` | `linalg::divergence` | `linalg::gradient` |  
`linalg::hessian` | `linalg::jacobian` | `linalg::laplacian`

# linalg::orthog

---

**Purpose** Orthogonalization of vectors

**Syntax** `linalg::orthog(S, <Real>)`

**Description** `linalg::orthog(S)` orthogonalizes the vectors in  $S$  using the Gram-Schmidt orthogonalization algorithm.

The vectors in  $S$  are orthogonalized with respect to the scalar product `linalg::scalarProduct`.

If  $O$  is the returned set, then the vectors of  $O$  span the same subspace as the vectors in  $S$ , and they are pairwise orthogonal, i.e.:  $\vec{v} \vec{w} = 0$  for all  $\vec{v}, \vec{w} \in O$  with  $\vec{v} \neq \vec{w}$ .

The vectors returned are not normalized. To normalize them use `map(O, linalg::normalize)`.

For an ordered set of orthogonal vectors,  $S$  should be a list.

The vectors in  $S$  must be defined over the same component ring.

The component ring of the vectors in  $S$  must be a field, i.e., a domain of category `Cat::Field`.

If you use the `Real` option, `linalg::orthog` computes an orthogonal basis using a real scalar product in the orthogonalization process.

## Examples

### Example 1

The following list of vectors is a basis of the vector space <sup>3</sup>:

```
MatR := Dom::Matrix(Dom::Real):
S := [MatR([2, 1, 0]), MatR([-3, 1, 1]), MatR([-1, -1, -1])]
```

$$\left[ \begin{pmatrix} 2 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -3 \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ -1 \\ -1 \end{pmatrix} \right]$$

The Gram-Schmidt algorithm then returns an orthogonal basis for  $S$ . We get an orthonormal basis with the following input:

```
ON:= linalg::orthog(S)
```

$$\left[ \begin{pmatrix} 2 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 2 \\ 1 \end{pmatrix}, \begin{pmatrix} -\frac{2}{15} \\ \frac{4}{15} \\ -\frac{2}{3} \end{pmatrix} \right]$$

The vectors can be normalized using `linalg::normalize`:

```
map(ON, linalg::normalize)
```

$$\left[ \begin{pmatrix} \frac{2\sqrt{5}}{5} \\ \frac{\sqrt{5}}{5} \\ 0 \end{pmatrix}, \begin{pmatrix} -\frac{\sqrt{6}}{6} \\ \frac{\sqrt{6}}{3} \\ \frac{\sqrt{6}}{6} \end{pmatrix}, \begin{pmatrix} -\frac{\sqrt{2}\sqrt{15}}{30} \\ \frac{\sqrt{2}\sqrt{15}}{15} \\ -\frac{\sqrt{2}\sqrt{15}}{6} \end{pmatrix} \right]$$

We may also build a matrix from the vectors in  $S$  and apply `linalg::orthog` to this matrix. The result is the matrix whose columns are given by the above elements of the list `ON`:

```
A:= S[1].S[2].S[3]
```

$$\begin{pmatrix} 2 & -1 & -\frac{2}{15} \\ 1 & 2 & \frac{4}{15} \\ 0 & 1 & -\frac{2}{3} \end{pmatrix}$$

```
linalg::orthog(A)
```

## linalg::orthog

---

$$\begin{pmatrix} 2 & -1 & -\frac{2}{15} \\ 1 & 2 & \frac{4}{15} \\ 0 & 1 & -\frac{2}{3} \end{pmatrix}$$

### Example 2

The orthogonalization of the vectors:

```
T := {matrix([[-2, 5, 3]]), matrix([[0, 2, 1]])}
 {(0 2 1), (-2 5 3)}
```

gives:

```
linalg::orthog(T)
 {(0 2 1), (-2 -1/5 2/5)}
```

### Example 3

The result of `linalg::orthog` is a list or set of linearly independent vectors, even if the input contains linearly dependent vectors:

```
MatQ := Dom::Matrix(Dom::Rational):
S := [MatQ([2, 1]), MatQ([3, 4]), MatQ([-1, 1])]
```

$$\left[ \begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 3 \\ 4 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix} \right]$$

```
linalg::orthog(S)
```

$$\left[ \begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 2 \end{pmatrix} \right]$$

**Example 4**

Compute an orthogonal basis of this matrix:

```
A := matrix([[a, 1], [1, a]]):
linalg::orthog(A)
```

$$\begin{pmatrix} a - \frac{a^2 - 1}{a \bar{a} + 1} \\ 1 - \frac{\bar{a} - a^2 \bar{a}}{a \bar{a} + 1} \end{pmatrix}$$

To avoid complex conjugates, use the `Real` option:

```
linalg::orthog(A, Real)
```

$$\begin{pmatrix} a - \frac{a^2 - 1}{a^2 + 1} \\ 1 - \frac{a(a^2 - 1)}{a^2 + 1} \end{pmatrix}$$

**Parameters** **s**

A set or list of vectors of the same dimension (a vector is an  $n \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`) or a matrix

# **linalg::orthog**

---

## **Options**

### **Real**

Avoid using a complex scalar product in the orthogonalization process.

## **Return Values**

Set or a list of vectors, respectively.

## **See Also**

## **MuPAD Functions**

`linalg::factorQR` | `linalg::isUnitary` | `linalg::normalize` | `linalg::scalarProduct` | `l1l1int` | `norm`

<b>Purpose</b>	Pascal matrix
<b>Syntax</b>	<code>linalg::pascal(n, &lt;R&gt;)</code>
<b>Description</b>	<p><code>linalg::pascal(n)</code> returns the <math>n \times n</math> Pascal matrix <math>P</math> given by</p> $P_{i,j} = \binom{i+j-2}{i-1}, 1 \leq i, j \leq n.$ <p>The entries of Pascal matrices are integer numbers. Note, however, that the returned matrix is not defined over the component domain <code>Dom::Integer</code>, but over the standard component domain <code>Dom::ExpressionField()</code>. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.</p> <p>Use <code>linalg::pascal(n, Dom::Integer)</code> to define the <math>n \times n</math> Pascal matrix over the ring of integer numbers.</p> <p>Inverse Pascal matrices are provided by <code>linalg::invpascal</code>.</p>

**Examples****Example 1**

We construct the  $3 \times 3$  Pascal matrix:

```
linalg::pascal(3)
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 3 & 6 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the Pascal matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

# linalg::pascal

---

```
linalg::pascal(3, Dom::Float)
```

$$\begin{pmatrix} 1.0 & 1.0 & 1.0 \\ 1.0 & 2.0 & 3.0 \\ 1.0 & 3.0 & 6.0 \end{pmatrix}$$

```
domtype(%)
```

```
Dom::Matrix(Dom::Float)
```

## Example 2

The Cholesky factor of a Pascal matrix consists of the elements of Pascal's triangle:

```
linalg::factorCholesky(linalg::pascal(4))
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 2 & 1 & 0 \\ 1 & 3 & 3 & 1 \end{pmatrix}$$

## Parameters

**n**

The dimension of the matrix: a positive integer

**R**

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

## Return Values

$n \times n$  matrix of the domain `Dom::Matrix(R)`.

## Algorithms

Pascal matrices are symmetric and positive definite.

The determinant of a Pascal matrix is 1.

The inverse of a Pascal matrix has integer entries.

If  $\lambda$  is an eigenvalue of a Pascal matrix, then  $\frac{1}{\lambda}$  is also an eigenvalue of the matrix.

## See Also

`linalg::vandermondeSolve`

# linalg::permanent

---

**Purpose** Permanent of a matrix

**Syntax** `linalg::permanent(A)`

**Description** `linalg::permanent(A)` computes the permanent of the square matrix  $A$ .

The component ring of the matrix  $A$  must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

## Examples

### Example 1

We compute the permanent of the following matrix:

```
delete a11, a12, a21, a22:
A := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

which gives us the general formula for the permanent of an arbitrary  $2 \times 2$  matrix:

```
linalg::permanent(A)
```

$$a_{11} a_{22} + a_{12} a_{21}$$

### Example 2

The permanent of a matrix can be computed over arbitrary commutative rings. Let us create a random matrix defined over the ring  $\mathbb{Z}_6$ , the integers modulo 6:

```
B := linalg::randomMatrix(5, 5, Dom::IntegerMod(6))
```

$$\begin{pmatrix} 3 \bmod 6 & 2 \bmod 6 & 3 \bmod 6 & 5 \bmod 6 & 4 \bmod 6 \\ 2 \bmod 6 & 5 \bmod 6 & 2 \bmod 6 & 1 \bmod 6 & 1 \bmod 6 \\ 1 \bmod 6 & 3 \bmod 6 & 3 \bmod 6 & 2 \bmod 6 & 2 \bmod 6 \\ 1 \bmod 6 & 0 \bmod 6 & 3 \bmod 6 & 3 \bmod 6 & 5 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 1 \bmod 6 & 3 \bmod 6 \end{pmatrix}$$

The permanent of this matrix is:

```
linalg::permanent(B)
```

4 mod 6

Its determinant is:

```
linalg::det(B)
```

0 mod 6

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

## Return Values

Element of the component ring of A.

## Algorithms

The permanent of an  $n \times n$  matrix  $A = (a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq n}$  is defined similarly as the determinant of A, only the signs of the permutations do not enter the definition:

# linalg::permanent

---

$$\text{perm}(A) := \sum_{\sigma \in S_n} \prod_{j=1}^n a_{\sigma(j), j}$$

( $S_n$  is the symmetric group of all permutations of  $\{1, \dots, n\}$ .)

In contrast to the computation of the determinant, the computation of the permanent takes time  $O(n^2 2^n)$ .

## See Also

## MuPAD Functions

`linalg::det`

<b>Purpose</b>	The (scalar) potential of a gradient field
<b>Syntax</b>	<code>linalg::potential(f, [x<sub>1</sub>, x<sub>2</sub>, ...], &lt;[y<sub>1</sub>, y<sub>2</sub>, ...]&gt;, &lt;Test&gt;)</code>
<b>Description</b>	<p><code>linalg::potential(f, x)</code> determines whether the vector field <math>\vec{f} = \vec{f}(\vec{x})</math> is a gradient field <math>\vec{f}(\vec{x}) = \text{grad}(p(\vec{x}))</math> of some scalar potential <math>p</math> with respect to the variables <math>\vec{x}</math>, and computes that potential if it exists.</p> <p><code>linalg::potential</code> and <code>potential</code> are equivalent. See details and examples on the <code>potential</code> help page.</p>
<b>Parameters</b>	<p><b>f</b></p> <p>The vector field: a list of arithmetical expressions, or a vector of such expressions. A vector is an <math>n \times 1</math> or <math>1 \times n</math> matrix of a domain of category <code>Cat::Matrix</code>.</p> <p><b>x<sub>1</sub>, x<sub>2</sub>, ...</b></p> <p>The variables: identifiers or indexed identifiers</p> <p><b>y<sub>1</sub>, y<sub>2</sub>, ...</b></p> <p>The components of the “base point:” arithmetical expressions. If a base point <math>\vec{y}</math> is specified, the returned potential <math>p</math> satisfies <math>p(\vec{y}) = 0</math>.</p>
<b>Options</b>	<p><b>Test</b></p> <p><code>linalg::potential</code> only checks whether the vector field has a potential and returns TRUE or FALSE, respectively.</p>
<b>Return Values</b>	Arithmetical expression or a Boolean value.

# linalg::pseudoInverse

---

**Purpose** Moore-Penrose inverse of a matrix

**Syntax** `linalg::pseudoInverse(A)`

**Description** `linalg::pseudoInverse(A)` computes the Moore-Penrose inverse of  $A$ . If the Moore-Penrose inverse of  $A$  does not exist, then FAIL is returned. The component ring of the matrix  $A$  must be a field, i.e., a domain of category `Cat::Field`.

## Examples **Example 1**

The Moore-Penrose inverse of the 2 3 matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, I, 3], [1, 3, 2]])
```

$$\begin{pmatrix} 1 & i & 3 \\ 1 & 3 & 2 \end{pmatrix}$$

is the 3 2 matrix:

```
Astar := linalg::pseudoInverse(A)
```

$$\begin{pmatrix} \frac{7}{96} + \frac{1}{32} i & \frac{1}{24} - \frac{1}{32} i \\ -\frac{7}{32} - \frac{5}{96} i & \frac{5}{16} + \frac{7}{96} i \\ \frac{7}{24} + \frac{1}{16} i & \frac{1}{96} - \frac{3}{32} i \end{pmatrix}$$

Note that in this example, only:

```
A * Astar
```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

yields the identity matrix, but not (see “Backgrounds” below):

$A^* * A$

$$\begin{pmatrix} \frac{11}{96} & \frac{3}{32} - \frac{1}{48}i & \frac{29}{96} + \frac{1}{32}i \\ \frac{3}{32} + \frac{1}{48}i & \frac{95}{96} & -\frac{1}{32} - \frac{1}{96}i \\ \frac{29}{96} - \frac{1}{32}i & -\frac{1}{32} + \frac{1}{96}i & \frac{43}{48} \end{pmatrix}$$

## Parameters

**A**

A matrix of category `Cat::Matrix`

## Return Values

Matrix of the same domain type as A, or the value FAIL.

## Algorithms

For an invertible matrix  $A$ , the Moore-Penrose inverse  $A^*$  of  $A$  coincides with the inverse of  $A$ . In general, only  $AA^*A = A$  and  $A^*AA^* = A^*$  holds.

If  $A$  is of dimension  $m \times n$ , then  $A^*$  is of dimension  $n \times m$ .

The computation of the Moore-Penrose inverse requires the existence of a scalar product on the vector space  $K^n$ , where  $K$  is the coefficient field of the matrix  $A$ . This is only the case for some fields  $K$  in theory, but `linalg::scalarProduct` works also for vectors over other fields (e.g. finite fields). The computation of a Moore-Penrose inverse may fail in such cases.

# linalg::pseudoinverse

---

## See Also

**MuPAD** `_invert`  
**Functions**

**Purpose** Generate a random matrix

**Syntax** `linalg::randomMatrix(m, n, <R>, <bound>, <Diagonal | Unimodular>)`

**Description** The call `linalg::randomMatrix(m, n)` returns a random  $m \times n$  matrix over the default component ring for matrices, i.e., over the domain `Dom::ExpressionField()`.

The matrix components are generated by the method "random" of the domain R (see "Example 2" on page 14-200).

The parameter `bound` is given as a parameter to the method "random" of the domain R in order to bound the size of the components of the random matrix. The correct type of `bound` is determined by the method "random". The parameter has no effect if the slot "random" does not have a size argument.

## Examples **Example 1**

We create a random square matrix over the integers. Because the matrix is random the created matrix can vary:

```
linalg::randomMatrix(2, 2, Dom::Integer)
```

$$\begin{pmatrix} 824 & -65 \\ -814 & -741 \end{pmatrix}$$

If you want to bound the size of its components, say between -2 and 2, enter:

```
linalg::randomMatrix(2, 2, Dom::Integer, -2..2)
```

# linalg::randomMatrix

---

$$\begin{pmatrix} -1 & 1 \\ -2 & 1 \end{pmatrix}$$

## Example 2

The following input creates a random vector over the component ring `Dom::FloatIV` of floating-point intervals. Because the vector is random the created vector can vary:

```
v := linalg::randomMatrix(1, 4, Dom::FloatIV)
```

```
[[0.2703581654 ... 0.831037179, 0.1531565158 ... 0.9948127811, 0.1801642274 ...
0.2662729024, 0.4520830547 ... 0.6787819565]]
```

```
domtype(v)
```

```
Dom::Matrix(Dom::FloatIV)
```

The components of this matrix are random floating-point intervals created by the "random" method of the domain constructor `Dom::FloatIV`.

## Example 3

To create a random diagonal matrix over the rationals we enter, for example:

```
linalg::randomMatrix(3, 3, Dom::Rational, Diagonal)
```

$$\begin{pmatrix} \frac{229}{220} & 0 & 0 \\ 0 & -\frac{535}{617} & 0 \\ 0 & 0 & -\frac{245}{597} \end{pmatrix}$$

## Example 4

The following command creates a random unimodular matrix over the integers so that its determinant is either 1 or -1:

```
A := linalg::randomMatrix(3, 3, Dom::Integer, Unimodular)
```

$$\begin{pmatrix} -1 & -8 & 4 \\ 4 & 0 & -5 \\ -3 & 5 & 2 \end{pmatrix}$$

```
linalg::det(A)
```

-1

We can bound the size of the components. The following input returns a unimodular matrix  $A = (a_{ij})$  with  $|a_{ij}| \leq 2$  for  $i, j = 1, 2, 3$ :

```
A := linalg::randomMatrix(3, 3, 2, Unimodular)
```

$$\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 2 \\ 1 & 0 & 1 \end{pmatrix}$$

# linalg::randomMatrix

---

Since we did not specify the component ring, the matrix is defined over the standard component ring for matrices (the domain `Dom::ExpressionField()`):

`domtype(A)`

`Dom::Matrix()`

## Parameters

**`m, n`**

Positive integers

**`R`**

The component ring, i.e., a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

**`bound`**

An arithmetical expression

## Options

**`Diagonal`**

Creates a random  $m \ n$  diagonal matrix over  $R$ .

**`Unimodular`**

Creates a random  $m \ m$  unimodular matrix over  $R$ , so that its determinant is a unit in  $R$ .

---

**Note** Note that this option is only available for square matrices.

---

The norm of each component of the matrix returned does not exceed `bound`, which must be a positive integer, if specified. The default value of `bound` is 10.

**Return Values**

Matrix of the domain `Dom::Matrix(R)`.

**References**

For generating random unimodular matrices, see Jürgen Hansen: *Generating Problems in Linear Algebra*, MapleTech, Volume 1, No.2, 1994.

`random`

# linalg::rank

---

**Purpose** Rank of a matrix

**Syntax** `linalg::rank(A)`  
`linalg::rank(S)`

**Description** `linalg::rank(A)` computes the rank of the matrix  $A$ .  
`linalg::rank(S)` computes the rank of the matrix whose columns are the vectors in  $S$ .  
The row rank of a matrix is the maximal number of linearly independent row vectors of that matrix. The column rank of a matrix is the maximal number of linearly independent column vectors of that matrix. For each matrix, its row rank is equal to its column rank. This number is called the rank of a matrix.  
The component ring of  $A$  or of the vectors given in  $S$  must be an integral domain (a domain of category `Cat::IntegralDomain`).  
`linalg::rank` replaces symbolic elements of a matrix by random integer numbers between 1 and  $10^{10}$ . Then the function computes the rank of the resulting numeric matrix by Gaussian elimination (see `linalg::gaussElim`). This approach introduces a tiny chance of getting a wrong result.

---

**Note** `linalg::rank` does not simplify special functions and algebraic numbers. For some matrices, this approach leads to wrong results. See “Example 3” on page 14-205.

---

## Examples **Example 1**

Define the following matrix  $A$  over :

```
MatZ := Dom::Matrix(Dom::Integer):
A := MatZ([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Compute the rank of the matrix A:

```
linalg::rank(A)
```

3

### Example 2

Use the three vectors  $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$ ,  $\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$ ,  $\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$  to define the columns of the matrix A. Compute the rank of A:

```
MatZ := Dom::Matrix(Dom::Integer):
S:= { MatZ([0,1,1]), MatZ([0,1,0]), MatZ([0,0,1]) }:
linalg::rank(S)
```

2

### Example 3

The `linalg::rank` function does not use any simplification rules for special functions, algebraic numbers (radicals), and so on. If `linalg::rank` computes intermediate expressions that can be simplified to zero, the function can return incorrect results. For example, create the following matrices:

```
A := matrix([[exp(x + y), exp(x)], [exp(y), 1]]);
B := matrix([[sin(x)^2 + cos(x)^2, 1], [1, 1]]);
C := matrix([[sqrt(6), sqrt(2)], [sqrt(3), 1]])
```

# linalg::rank

---

$$\begin{pmatrix} e^{x+y} & e^x \\ e^y & 1 \end{pmatrix}$$

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & 1 \\ 1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \sqrt{6} & \sqrt{2} \\ \sqrt{3} & 1 \end{pmatrix}$$

There is only one independent row in each of these matrices. The rank of the matrices A, B, and C is 1. The `linalg::rank` function returns 2 because it does not simplify the expressions  $e^{x+y} - e^x e^y$ ,  $\sin^2 + \cos^2 - 1$ , and  $\sqrt{2} \sqrt{3} - \sqrt{6}$ :

```
linalg::rank(A), linalg::rank(B), linalg::rank(C)
```

```
2, 2, 2
```

## Parameters

### A

A matrix of a domain of category `Cat::Matrix`

### S

A list or set of column vectors of the same dimension (a column vector is an  $n \times 1$  matrix of a domain of category `Cat::Matrix`)

## Return Values

Nonnegative integer

## **See Also**

## **MuPAD Functions**

`linalg::det` | `linalg::gaussElim`

## **Related Examples**

- “Compute Rank of a Matrix”

# linalg::row

---

**Purpose** Extract rows of a matrix

**Syntax** `linalg::row(A, r)`  
`linalg::row(A, r1 .. r2)`  
`linalg::row(A, list)`

**Description** `linalg::row(A, r)` extracts the  $r$ -th row vector of the matrix  $A$ .  
`linalg::row(A, r1 .. r2)` returns a list of row vectors whose indices are in the range  $r_1 .. r_2$ . If  $r_2 < r_1$  then the empty list `[]` is returned.  
`linalg::row(A, list)` returns a list of row vectors whose indices are contained in `list` (in the same order).

## Examples **Example 1**

We define a matrix over :

```
A := Dom::Matrix(Dom::Rational)(
 [[1, 1/5], [-3/2, 5], [2, -3]]
)
```

$$\begin{pmatrix} 1 & \frac{1}{5} \\ -\frac{3}{2} & 5 \\ 2 & -3 \end{pmatrix}$$

and illustrate the three different input formats for the function `linalg::row`:

```
linalg::row(A, 2)
```

$$\left(-\frac{3}{2} \ 5\right)$$

```
linalg::row(A, [2, 1, 3])
```

```

$$\left[\left(-\frac{3}{2} \ 5 \right), \left(1 \ \frac{1}{5} \right), (2 \ -3) \right]$$

```

```
linalg::row(A, 2..3)
```

```

$$\left[\left(-\frac{3}{2} \ 5 \right), (2 \ -3) \right]$$

```

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**r**

The row index: a positive integer less or equal to  $m$

**r<sub>1</sub> .. r<sub>2</sub>**

A range of row indices (positive integers less or equal to  $m$ )

**list**

A list of row indices (positive integers less or equal to  $m$ )

## Return Values

Single row vector or a list of row vectors; a row vector is a  $1 \ n$  matrix of category `Cat::Matrix(R)`, where  $R$  is the component ring of  $A$ .

`linalg::setCol` | `linalg::setRow`

# linalg::scalarProduct

---

**Purpose** Scalar product of vectors

**Syntax** `linalg::scalarProduct(u, v, <Real>)`

**Description** `linalg::scalarProduct(u, v)` computes the scalar product of the vectors  $\vec{u} = (u_1, \dots, u_n)$  and  $\vec{v} = (v_1, \dots, v_n)$  with respect to the standard basis, i.e., the sum  $u_1 \overline{v_1} + \dots + u_n \overline{v_n}$ .

The scalar product is also called “inner product” or “dot product”.

If the component ring of the vectors `u` and `v` does not define the entry "conjugate" or if the option `Real` is specified, then `linalg::scalarProduct` uses the definition  $u_1 v_1 + \dots + u_n v_n$  of the scalar product.

The vectors `u` and `v` must be defined over the same component ring.

`linalg::scalarProduct` can be redefined to a different scalar product. This also affects the behaviour of functions such as `linalg::angle`, `linalg::factorQR`, `linalg::isUnitary`, `norm` (for vectors and matrices), `linalg::orthog` and `linalg::pseudoInverse` depend on the definition of `linalg::scalarProduct`. See “Example 3” on page 14-211.

**Environment Interactions** Properties of identifiers are taken into account.

**Examples** **Example 1**

We compute the scalar product of the vectors  $(i, 1)$  and  $(1, -i)$ :

```
MatC := Dom::Matrix(Dom::Complex):
u := MatC([I, 1]): v := MatC([1, -I]):
linalg::scalarProduct(u, v)
```

```
2i
```

## Example 2

We compute the scalar product of the vectors  $\vec{u} = (u_1, u_2)$  and  $\vec{v} = (v_1, v_2)$  with the symbolic entries  $u_1, u_2, v_1, v_2$  over the standard component ring for matrices:

```
delete u1, u2, v1, v2:
u := matrix([u1, u2]): v := matrix([v1, v2]):
linalg::scalarProduct(u, v)
```

$$u_1 \vec{v}_1 + u_2 \vec{v}_2$$

You can use `assume` to tell the system that the symbolic components are to represent real numbers:

```
assume([u1, u2, v1, v2], Type::Real):
```

Then the scalar product of  $\vec{u}$  and  $\vec{v}$  simplifies to:

```
linalg::scalarProduct(u, v)
```

$$u_1 v_1 + u_2 v_2$$

Alternatively, the option `Real` can be specified:

```
unassume(u1, u2, v1, v2):
linalg::scalarProduct(u, v, Real)
```

$$u_1 v_1 + u_2 v_2$$

## Example 3

One particular scalar product in the real vector space of continuous functions on the interval  $[0, 1]$  is defined by

## linalg::scalarProduct

---

$$(f, g) = \int_0^1 f(t) g(t) dt$$

To compute an orthogonal basis corresponding to the polynomial basis  $1, t, t^2, t^3, \dots$  with respect to this scalar product, we replace the standard scalar product by the following procedure:

```
standardScalarProduct := linalg::scalarProduct:
unprotect(linalg):
linalg::scalarProduct := proc(u, v)
 local F, f, t;
begin
 // (0)
 f := expr(u[1] * v[1]);

 // (1)
 t := indets(f);
 if t = {} then t := genident("t") else t := op(t, 1) end_if;

 // (2)
 F := int(f, t = 0..1);

 // (3)
 u::dom::coeffRing::coerce(F)
end:
```

We start with step (0) to convert  $f(t)g(t)$  to an expression of a basic domain type, such that the system function `int` in step (2) can handle its input (this is not necessary if the elements of the component ring of the vectors are already represented by elements of basic domains).

Step (1) extracts the indeterminate of the polynomials, step (2) computes the scalar product as defined above and step (3) converts the result back to an element of the component ring of vectors  $u$  and  $v$ .

Note that we need to unprotect the write protected identifier `linalg`, otherwise the assignment would lead to an error message.

We next create the matrix which consists of the first five of the above polynomials:

```
P := matrix([[1, t, t^2, t^3, t^4]])
```

$$\begin{pmatrix} 1 & t & t^2 & t^3 & t^4 \end{pmatrix}$$

If we now perform the Gram-Schmidt orthogonalization procedure on the columns of `P` with the function `linalg::orthog`, we get:

```
S := linalg::orthog(linalg::col(P, 1..4))
```

$$\left[ \left( 1 \right), \left( t - \frac{1}{2} \right), \left( t^2 - t + \frac{1}{6} \right), \left( t^3 - \frac{3t^2}{2} + \frac{3t}{5} - \frac{1}{20} \right) \right]$$

Each vector in `S` is orthogonal to the other vectors in `S` with respect to the modified scalar product. We check this for the first vector:

```
linalg::scalarProduct(S[1], S[j]) $ j = 2..nops(S)
```

$$0, 0, 0$$

Finally, we undo the redefinition of the scalar product, so as not to run into trouble with subsequent computations:

```
linalg::scalarProduct := standardScalarProduct:
protect(linalg, Error):
```

## Parameters

`u, v`

# **linalg::scalarProduct**

---

Vectors of the same dimension (a vector is an  $n \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`)

## **Options**

### **Real**

Use  $u_1v_1 + \dots + u_nv_n$  as the definition of the scalar product, i.e., suppress the use of conjugate.

## **Return Values**

Element of the component ring of  $u$  and  $v$ .

## **See Also**

## **MuPAD Functions**

`linalg::angle` | `linalg::crossProduct` | `linalg::isUnitary` | `linalg::factorQR` | `linalg::orthog` | `norm`

**Purpose** Change a column of a matrix

**Syntax** `linalg::setCol(A, p, c)`

**Description** `linalg::setCol(A, p, c)` returns a copy of matrix  $A$  with the  $p$ -th column replaced by the column vector  $\vec{c}$ .

If  $c$  is a list with at most  $m$  elements, then  $c$  is converted into a column vector. An error message is returned if the conversion is not possible (e.g., if an element of the list cannot be converted into an object of the component ring of  $A$ ; see “Example 2” on page 14-215).

## Examples **Example 1**

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[1, 2], [3, 2]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$$

and replace the 2nd column by the 2 1 zero vector:

```
linalg::setCol(A, 2, MatQ([0, 0]))
```

$$\begin{pmatrix} 1 & 0 \\ 3 & 0 \end{pmatrix}$$

## **Example 2**

We create the 2 2 zero matrix over  $\mathbb{6}$ :

```
B := Dom::Matrix(Dom::IntegerMod(6))(2, 2)
```

# linalg::setCol

---

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 \end{pmatrix}$$

and replace the 2nd column by the vector  $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$ . We give the column vector in form of a list. Its elements are converted implicitly into objects of the component ring of B:

```
linalg::setCol(B, 2, [1, -1])
```

$$\begin{pmatrix} 0 \bmod 6 & 1 \bmod 6 \\ 0 \bmod 6 & 5 \bmod 6 \end{pmatrix}$$

The following input leads to an error message because the number 1/3 can not be converted into an object of type `Dom::IntegerMod(6)`:

```
linalg::setCol(B, 1, [1/3, 0])
```

```
Error: The column vector is invalid. [linalg::setCol]
```

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**c**

A column vector, or a list that can be converted into a column vector of the domain `Dom::Matrix(R)`, where R is the component ring of A (a column vector is an  $m \ 1$  matrix)

## Return Values

Matrix of the same domain type as A.

## **See Also**

### **MuPAD Functions**

`linalg::col` | `linalg::delCol` | `linalg::delRow` | `linalg::row`  
| `linalg::setRow`

# linalg::setRow

---

**Purpose** Change a row of a matrix

**Syntax** `linalg::setRow(A, p, r)`

**Description** `linalg::setRow(A, p, r)` returns a copy of the matrix  $A$  with the  $p$ -th row replaced by the row vector  $\vec{r}$ .

If  $r$  is a list with at most  $n$  elements, then  $r$  is converted into a row vector. An error message is returned if the conversion is not possible (e.g., if an element of the list cannot be converted into an object of the component ring of  $A$ ; see “Example 2” on page 14-218).

## Examples **Example 1**

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[1, 2], [3, 2]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$$

and replace the 2nd row by the 1 2 zero vector:

```
linalg::setRow(A, 2, MatQ(1, 2, [0, 0]))
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

## **Example 2**

We create the 2 4 zero matrix over  $\mathbb{Z}_6$ :

```
B := Dom::Matrix(Dom::IntegerMod(6))(2, 4)
```

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \end{pmatrix}$$

and replace the 2nd row by the vector (1, -1, 1, -1). We give the row vector in form of a list. Its elements are converted implicitly into objects of the component ring of B:

```
linalg::setRow(B, 2, [1, -1, 1, -1])
```

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \\ 1 \bmod 6 & 5 \bmod 6 & 1 \bmod 6 & 5 \bmod 6 \end{pmatrix}$$

The following input leads to an error message because the number  $\frac{1}{3}$  can not be converted into an object of type `Dom::IntegerMod(6)`:

```
linalg::setRow(B, 1, [1/3, 0, 1, 0])
```

```
Error: The row vector is invalid. [linalg::setRow]
```

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**r**

A row vector or a list that can be converted into a row vector the domain `Dom::Matrix(R)`, where `R` is the component ring of `A` (a row vector is a  $1 \ n$  matrix)

## Return Values

Matrix of the same domain type as `A`.

# **linalg::setRow**

---

## **See Also**

## **MuPAD Functions**

`linalg::col` | `linalg::delCol` | `linalg::delRow` | `linalg::row`  
| `linalg::setCol`

**Purpose** Smith canonical form of a matrix

**Syntax** `linalg::smithForm(A)`

**Description** `linalg::smithForm(A)` computes the Smith canonical form of the  $n$ -dimensional square matrix  $A$ , i.e., an  $n \times n$  diagonal matrix  $S$  such that  $S_{i-1, i-1}$  divides  $S_{i, i}$  for  $i = 2, \dots, n$ .

The Smith canonical form of a matrix  $A$  is unique.

The component ring of  $A$  must be a Euclidean ring, i.e., a domain of category `Cat::EuclideanDomain`.

**Examples**      **Example 1**

We define a matrix over the integers:

```
MatZ := Dom::Matrix(Dom::Integer):
A := MatZ([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

The Smith canonical form of  $A$  is then given by:

```
linalg::smithForm(A)
```

$$\begin{pmatrix} 3 & 0 & 0 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

**Example 2**

We compute the Smith canonical form of a matrix over a ring of polynomials:

# linalg::smithForm

---

```
MatPoly := Dom::Matrix(Dom::DistributedPolynomial([x], Dom::Rational)
B := MatPoly(
 [[-(x - 3)^2*(x - 2), (x - 3)*(x - 2)*(x - 4)],
 [(x - 3)*(x - 2)*(x - 4), -(x - 3)^2*(x - 4)]]
)
```

$$\begin{pmatrix} -x^3 + 8x^2 - 21x + 18 & x^3 - 9x^2 + 26x - 24 \\ x^3 - 9x^2 + 26x - 24 & -x^3 + 10x^2 - 33x + 36 \end{pmatrix}$$

The Smith canonical form of the matrix B is the following matrix:

```
linalg::smithForm(B)
```

$$\begin{pmatrix} x - 3 & 0 \\ 0 & x^3 - 9x^2 + 26x - 24 \end{pmatrix}$$

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

## Return Values

Matrix of the same domain type as A.

## Algorithms

An  $n \times n$  matrix  $S = (s_{ij})$  with coefficients in a Euclidean ring is said to be in Smith canonical form if  $S$  is a diagonal matrix (with nonnegative coefficients in case of the ring) such that  $s_{i,i}$  divides  $s_{i+1,i+1}$  for all  $i < n$ .

## See Also

### MuPAD Functions

`linalg::frobeniusForm` | `linalg::hermiteForm` |  
`linalg::jordanForm`

**Purpose** Square root of a matrix

**Syntax** `linalg::sqrtMatrix(A, <sqrtfunc>)`

**Description** `linalg::sqrtMatrix(A)` returns the square root of the matrix  $A$ .

The matrix  $A$  must have a Jordan canonical form (see also `linalg::jordanForm` for the computation of the Jordan canonical form in MuPAD). Furthermore,  $A$  must not have eigenvalue 0 of geometric multiplicity higher than 1 (in this situation the square root of  $A$  cannot be computed).

**Examples**      **Example 1**

A square root of a diagonal matrix is given by the diagonal matrix, whose diagonal entries are just the square roots of the original matrix.

We compute the square root of the matrix

$$A = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -1 \end{pmatrix} :$$

```
A := matrix([[4, 0, 0], [0, 2, 0], [0, 0, -1]]):
S := linalg::sqrtMatrix(A)
```

$$\begin{pmatrix} 2 & 0 & 0 \\ 0 & \sqrt{2} & 0 \\ 0 & 0 & i \end{pmatrix}$$

We can easily check the correctness of the result:

```
S^2
```

# linalg::sqrtMatrix

---

$$\begin{pmatrix} 4 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -1 \end{pmatrix}$$

## Example 2

We compute the square root of the matrix

$$A = \begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix} :$$

```
A := matrix([[2, -2, 0], [-1, 3, 0], [-1/3, 5/3, 2]]):
S := linalg::sqrtMatrix(A)
```

$$\begin{pmatrix} \frac{4}{3} & -\frac{2}{3} & 0 \\ -\frac{1}{3} & \frac{5}{3} & 0 \\ \frac{2\sqrt{2}}{3} - 1 & 1 - \frac{\sqrt{2}}{3} & \sqrt{2} \end{pmatrix}$$

If we compute the square of the matrix S and simplify the result, we obtain the matrix A:

```
simplify(S^2)
```

$$\begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix}$$

Using the function  $x \rightarrow -\sqrt{x}$  as second argument for the computation of the square root of the matrix  $A$ , we obtain a different matrix, whose components are just the negative components of the original square root computed above:

```
S:= linalg::sqrtMatrix(A, x -> -sqrt(x));
S, simplify(S^2);
```

$$\begin{pmatrix} -\frac{4}{3} & \frac{2}{3} & 0 \\ \frac{1}{3} & -\frac{5}{3} & 0 \\ 1 - \frac{2\sqrt{2}}{3} & \frac{\sqrt{2}}{3} - 1 & -\sqrt{2} \end{pmatrix}, \begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix}$$

## Parameters

**A**

A square matrix of a domain of category `Cat::Matrix`

**sqrtfunc**

A function satisfying  $\text{sqrtfunc}(a)^2 = a$  for every element  $a$  of the coefficient ring of  $A$  (i.e. the square root function of the coefficient domain of  $A$ ).

## Return Values

Matrix  $B$  with  $B^2 = A$  such that the eigenvalues of  $B$  are the square roots of the eigenvalues of  $A$  or FAIL if the square root of the matrix does not exist

## See Also

## MuPAD Functions

`linalg::eigenvalues` | `linalg::eigenvectors`  
| `linalg::jordanForm` | `numeric::eigenvalues` |  
`numeric::eigenvectors` | `solve`

# linalg::stackMatrix

---

**Purpose** Join matrices vertically

**Syntax** `linalg::stackMatrix(A, <B1, B2, >)`

**Description** `linalg::stackMatrix(A, B1, B2, ...)` returns the matrix formed by joining the matrices A, B<sub>1</sub>, B<sub>2</sub>, ... vertically.

The matrices B<sub>1</sub>, B<sub>2</sub>, ... are converted into the matrix domain `Dom::Matrix(R)`, where R is the component ring of A.

An error message is raised if one of these conversions fails, or if the matrices do not have the same number of columns as the matrix A.

## Examples

### Example 1

We define a matrix:

```
A:= matrix([[sin(x),x], [-x,cos(x)]])
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \end{pmatrix}$$

and append the 2 2 identity matrix to the lower end of the matrix A:

```
linalg::stackMatrix(A, matrix::identity(2))
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \\ 1 & 0 \\ 0 & 1 \end{pmatrix}$$

### Example 2

We define a matrix from the ring of 2 2 square matrices:

```
SqMatQ := Dom::SquareMatrix(2,Dom::Rational):
```

```
A := SqMatQ([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Note that the following operation:

```
AA := linalg::stackMatrix(A, A)
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 1 & 2 \\ 3 & 4 \end{pmatrix}$$

returns a matrix of a different domain type as the input matrix:

```
domtype(AA)
```

```
Dom::Matrix(Dom::Rational)
```

## Parameters

**A**, **<B<sub>1</sub>, B<sub>2</sub>, ...>**

Matrices of a domain of category `Cat::Matrix`

## Return Values

Matrix of the domain type `Dom::Matrix(R)`, where R is the component ring of A.

## See Also

## MuPAD Functions

`linalg::concatMatrix`

# linalg::submatrix

---

**Purpose** Extract a submatrix or a subvector from a matrix or a vector, respectively

**Syntax**

```
linalg::submatrix(A, r1 .. r2, c1 .. c2)
linalg::submatrix(A, rlist, clist)
linalg::submatrix(v, i1 .. i2)
linalg::submatrix(v, list)
```

**Description** `linalg::submatrix(A, r1.. r2, c1.. c2)` returns a copy of the submatrix of the matrix  $A$  obtained by selecting the rows  $r_1, r_1 + 1, \dots, r_2$  and the columns  $c_1, c_1 + 1, \dots, c_2$ .

`linalg::submatrix(v, i1.. i2)` returns a copy of the subvector of the vector  $\vec{v}$  obtained by selecting the components with indices  $i_1, i_1 + 1, \dots, i_2$ .

The index notation  $A[ r_1.. r_2, c_1.. c_2 ]$  and  $v[ i_1.. i_2 ]$ , respectively, can be used instead of `linalg::submatrix(A, r1.. r2, c1.. c2)` and `linalg::submatrix(v, i1.. i2)`.

`linalg::submatrix(A, rlist, clist)` returns the submatrix of the matrix  $A$  whose  $(i, j)$ -th component is  $a_{rlist_i, clist_j}$ .

`linalg::submatrix(v, list)` returns the subvector of the vector  $v$  whose  $i$ -th component is  $v_{list_i}$ .

If  $v$  is a row vector or a column vector, then `linalg::submatrix(v, 1..1, i1.. i2)` and `linalg::submatrix(v, i1.. i2, 1..1)`, respectively, are valid inputs, and they both are equivalent to the call `linalg::submatrix(v, i1.. i2)`.

## Examples **Example 1**

We define the following matrix:

```
A := matrix([[1, x], [0, x^2, 1]])
```

$$\begin{pmatrix} 1 & x & 0 \\ 0 & x^2 & 1 \end{pmatrix}$$

The submatrix  $(a_{1,j})_{1 \leq j \leq 2}$  of A is given by:

```
linalg::submatrix(A, 1..1, 1..2)
```

$$(1 \ x)$$

Equivalent to the use of the index operator we obtain:

```
A[1..1, 1..2]
```

$$(1 \ x)$$

We extract the first and the third column of A and get the 2 2 identity matrix:

```
linalg::submatrix(A, [1, 2], [1, 3])
```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

## Example 2

Vector components can be accessed by a single index or a range of indices. For example, to extract the first two components of the following vector:

```
v := matrix([1, 2, 3])
```

# linalg::submatrix

---

$$\begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}$$

just enter the command:

```
v[1..2]
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

Of course, the same subvector can be extracted with the command `linalg::submatrix(v, 1..2)`.

The following input returns the vector comprising the first and the third component of `v`:

```
linalg::submatrix(v, [1, 3])
```

$$\begin{pmatrix} 1 \\ 3 \end{pmatrix}$$

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**v**

A vector with  $k$  components, i.e., a  $k \ 1$  or  $1 \ k$  matrix of a domain of category `Cat::Matrix`

**r<sub>1</sub> .. r<sub>2</sub>, c<sub>1</sub> .. c<sub>2</sub>**

Ranges of row/column indices: positive integers less or equal to  $m$  and  $n$ , respectively

**rlist, clist**

Lists of row/column indices: positive integers less or equal to  $m$  and  $n$ , respectively

**$i_1 \dots i_2$**

A range of vector indices: positive integers less or equal to  $k$

**list**

A list of vector indices: positive integers less or equal to  $k$

## **Return Values**

Matrix of the same domain type as  $A$  or a vector of the same domain type as  $v$ , respectively.

## **See Also**

## **MuPAD Functions**

`linalg::col` | `linalg::row` | `linalg::substitute`

# linalg::substitute

---

**Purpose** Replace a part of a matrix by another matrix

**Syntax** `linalg::substitute(B, A, m, n)`

**Description** `linalg::substitute(B, A, m, n)` returns a copy of the matrix B, where entries starting at position  $[m, n]$  are replaced by the entries of the matrix A, i.e.,  $B_{mn}$  is  $A_{11}$ .

If the matrices are defined over different component domains, then the entries of A are converted into elements of the component domain of the matrix B. If one of these conversions fails, then an error message is returned.

## Examples

### Example 1

We define the following matrix:

```
B := matrix(
 [[1, 2, 3, 4], [5, 6, 7, 8],
 [9, 10, 11, 12], [13, 14, 15, 16]]
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix}$$

and copy the 2 2 zero matrix into the matrix B, beginning at position [3, 3]:

```
A := matrix(2, 2):
linalg::substitute(B, A, 3, 3)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 0 & 0 \\ 13 & 14 & 0 & 0 \end{pmatrix}$$

Matrix entries out of range are ignored:

```
linalg::substitute(B, A, 4, 4)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 0 \end{pmatrix}$$

## Parameters

**A, B**

Matrices of a domain of category `Cat::Matrix`

**m, n**

Positive integers

## Return Values

Matrix of the same domain type as B.

## See Also

## MuPAD Functions

`linalg::submatrix` | `linalg::concatMatrix` | `linalg::setCol` | `linalg::setRow` | `linalg::stackMatrix`

# linalg::sumBasis

---

**Purpose** Basis for the sum of vector spaces

**Syntax** `linalg::sumBasis(S1, S2, ...)`

**Description** `linalg::sumBasis(S1, S2, ...)` returns a basis of the vector space  $V_1 + V_2 + \dots$ , where  $V_i$  denotes the vector space spanned by the vectors in  $S_i$ .

To obtain an ordered basis,  $S_1, S_2, \dots$  should be given as lists of vectors.

A basis of the zero-dimensional space is the empty set or list, respectively.

The given vectors must be defined over the same component ring, which must be a field, i.e., a domain of category `Cat::Field`.

## Examples

### Example 1

We define three vectors  $\vec{v}_1, \vec{v}_2, \vec{v}_3$  over :

```
MatQ := Dom::Matrix(Dom::Rational):
v1 := MatQ([[3, -2]]); v2 := MatQ([[1, 0]]); v3 := MatQ([[5, -3]])
```

$(3 \ -2)$

$(1 \ 0)$

$(5 \ -3)$

A basis of the vector space  $V_1 + V_2 + V_3$  with

- $V_1$  generated by  $\vec{v}_1, \vec{v}_2, \vec{v}_3$
- $V_2$  generated by  $\vec{v}_1, \vec{v}_3$

- $V_3$  generated by  $\vec{v}_1 + \vec{v}_2$ ,  $\vec{v}_2$ ,  $\vec{v}_1 + \vec{v}_3$

is:

```
linalg::sumBasis([v1, v2, v3], [v1, v3], [v1 + v2, v2, v1 + v3])
```

```
[(3 -2), (1 0)]
```

## Example 2

The following set of two vectors:

```
MatQ := Dom::Matrix(Dom::Rational):
S1 := {MatQ([1, 2, 3]), MatQ([-1, 0, 2])}
```

$$\left\{ \begin{pmatrix} -1 \\ 0 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} \right\}$$

is a basis of a two-dimensional subspace of  $\mathbb{R}^3$ :

```
linalg::rank(S1)
```

```
2
```

The same holds for the following set:

```
S2 := {MatQ([0, 2, 3]), MatQ([2, 4, 6])};
linalg::rank(S2)
```

$$\left\{ \begin{pmatrix} 0 \\ 2 \\ 3 \end{pmatrix}, \begin{pmatrix} 2 \\ 4 \\ 6 \end{pmatrix} \right\}$$

# linalg::sumBasis

---

2

The sum of the corresponding two subspaces is the vector space <sup>3</sup>:

`Q3 := linalg::sumBasis(S1, S2)`

$$\left\{ \begin{pmatrix} -1 \\ 0 \\ 2 \end{pmatrix}, \begin{pmatrix} 0 \\ 2 \\ 3 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} \right\}$$

## Parameters

$S_1, S_2, \dots$

A set or list of vectors of the same dimension (a vector is a  $n \times 1$  or  $1 \times n$  matrix of a domain of category `Cat::Matrix`)

## Return Values

Set or a list of vectors, according to the domain type of the parameter  $S_1$ .

## See Also

## MuPAD Functions

`linalg::basis` | `linalg::intBasis` | `linalg::rank`

**Purpose** Swap two columns in a matrix

**Syntax** `linalg::swapCol(A, c1, c2)`  
`linalg::swapCol(A, c1, c2, r1 .. r2)`

**Description** `linalg::swapCol(A, c1, c2)` returns a copy of the matrix *A* with the columns with indices *c<sub>1</sub>* and *c<sub>2</sub>* interchanged.

The effect of `linalg::swapCol(A, c1, c2, r1.. r2)` is that only the components from row *r<sub>1</sub>* to row *r<sub>2</sub>* of column *c<sub>1</sub>* are interchanged with the corresponding components of column *c<sub>2</sub>*.

## Examples **Example 1**

We consider the following matrix:

```
A := matrix(3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The following command interchanges the first and the second column of *A*. The result is the following matrix:

```
linalg::swapCol(A, 1, 2)
```

$$\begin{pmatrix} 2 & 1 & 3 \\ 5 & 4 & 6 \\ 8 & 7 & 9 \end{pmatrix}$$

If only the components in the first two rows should be affected, we enter:

```
linalg::swapCol(A, 1, 2, 1..2)
```

# linalg::swapCol

---

$$\begin{pmatrix} 2 & 1 & 3 \\ 5 & 4 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The third row remains unchanged.

## Parameters

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**$c_1, c_2$**

The column indices: positive integers less or equal to  $n$

**$r_1 \dots r_2$**

A range of row indices (positive integers less or equal to  $m$ )

## Return Values

Matrix of the same domain type as A.

## See Also

## MuPAD Functions

`linalg::col` | `linalg::delCol` | `linalg::delRow` | `linalg::row`  
| `linalg::setCol` | `linalg::setRow` | `linalg::swapRow`

## Concepts

- “Swap and Delete Rows and Columns”

**Purpose** Swap two rows in a matrix

**Syntax** `linalg::swapRow(A, r1, r2)`  
`linalg::swapRow(A, r1, r2, c1 .. c2)`

**Description** `linalg::swapRow(A, r1, r2)` returns a copy of the matrix  $A$  with the rows with indices  $r_1$  and  $r_2$  interchanged.

The effect of `linalg::swapRow(A, r1, r2, c1.. c2)` is that only the components from column  $c_1$  to column  $c_2$  of row  $r_1$  are interchanged with the corresponding components of row  $r_2$ .

## Examples **Example 1**

We consider the following matrix:

```
A := matrix(3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The following command interchanges the first and the second row of  $A$ . The result is the following matrix:

```
linalg::swapRow(A, 1, 2)
```

$$\begin{pmatrix} 4 & 5 & 6 \\ 1 & 2 & 3 \\ 7 & 8 & 9 \end{pmatrix}$$

If only the components in the first two columns should be affected, we enter:

```
linalg::swapRow(A, 1, 2, 1..2)
```

# **linalg::swapRow**

---

$$\begin{pmatrix} 4 & 5 & 3 \\ 1 & 2 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The third column remains unchanged.

## **Parameters**

**A**

An  $m \ n$  matrix of a domain of category `Cat::Matrix`

**r<sub>1</sub>, r<sub>2</sub>**

The row indices: positive integers less or equal to  $m$

**c<sub>1</sub> .. c<sub>2</sub>**

A range of column indices (positive integers less or equal to  $n$ )

## **Return Values**

Matrix of the same domain type as A.

## **See Also**

## **MuPAD Functions**

`linalg::col` | `linalg::delCol` | `linalg::delRow` | `linalg::row`  
| `linalg::setCol` | `linalg::setRow` | `linalg::swapCol`

## **Concepts**

- “Swap and Delete Rows and Columns”

**Purpose** Sylvester matrix of two polynomials

**Syntax** `linalg::sylvester(p, q)`  
`linalg::sylvester(f, g, x)`

**Description** `linalg::sylvester(p, q)` returns the Sylvester matrix of the two polynomials  $p$  and  $q$ .

If no variable is specified, then the polynomials  $p$  and  $q$  must be either of the domain `DOM_POLY` or from a domain of category `Cat::Polynomial`. Polynomial expressions are not allowed.

If the polynomials  $p$  and  $q$  are of the domain `DOM_POLY`, then they must be univariate polynomials. The component ring of the Sylvester matrix is the common coefficient ring  $R$  of  $p$  and  $q$ , except in the following two cases for built-in coefficient rings: If  $R$  is `Expr` then the domain `Dom::ExpressionField()` is the component ring of the Sylvester matrix. If  $R$  is `IntMod(m)`, then the Sylvester matrix is defined over the ring `Dom::IntegerMod(m)` (see “Example 2” on page 14-242).

Otherwise, if the polynomials  $p$  and  $q$  are from a domain of category `Cat::Polynomial`, then the Sylvester matrix is computed with respect to the main variable of  $p$  and  $q$  (see the method “`mainvar`” of the category `Cat::Polynomial`). In the case of univariate polynomials the Sylvester matrix is defined over the common coefficient ring of  $p$  and  $q$ . In the case of multivariate polynomials, the Sylvester matrix is defined over the component ring `Dom::DistributedPolynomial(ind, R)`, where `ind` is the list of all variables of  $p$  and  $q$  except  $x$ , and  $R$  is the common coefficient ring of the polynomials.

If  $f$  and  $g$  are polynomial expressions or multivariate polynomials of type `DOM_POLY`, then you must specify the variable  $x$ .

In the case of polynomial expressions, the component ring of the Sylvester matrix is the domain `Dom::ExpressionField()` (see “Example 3” on page 14-243).

In the case of multivariate polynomials the Sylvester matrix is defined over the component ring `Dom::DistributedPolynomial(ind, R)`, where `ind` is the list of all variables of  $f$  and  $g$  except  $x$ , and  $R$  is the

# linalg::sylvester

---

common coefficient ring of the polynomials (see “Example 4” on page 14-244).

At least one of the input polynomials must have positive degree with respect to the main variable or  $x$ , respectively, but it is not necessary that both of them have positive degree.

## Examples

### Example 1

The Sylvester matrix of the two polynomials  $p = x^2 + 2x - 1$  and  $q = x^4 + 1$  over  $\mathbb{Z}$  is the following 6x6 matrix:

```
delete x: Z := Dom::Integer:
S := linalg::sylvester(poly(x^2 + 2*x - 1, Z), poly(x^4 + 1, Z))
```

$$\begin{pmatrix} 1 & 2 & -1 & 0 & 0 & 0 \\ 0 & 1 & 2 & -1 & 0 & 0 \\ 0 & 0 & 1 & 2 & -1 & 0 \\ 0 & 0 & 0 & 1 & 2 & -1 \\ 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix}$$

### Example 2

If the polynomials have the built-in coefficient ring  $\text{IntMod}(m)$ , then the Sylvester matrix is defined over the domain  $\text{Dom}::\text{IntegerMod}(m)$ :

```
delete x:
S:= linalg::sylvester(
 poly(x + 1, IntMod(7)), poly(x^2 - 2*x + 2, IntMod(7))
)
```

$$\begin{pmatrix} 1 \bmod 7 & 1 \bmod 7 & 0 \bmod 7 \\ 0 \bmod 7 & 1 \bmod 7 & 1 \bmod 7 \\ 1 \bmod 7 & 5 \bmod 7 & 2 \bmod 7 \end{pmatrix}$$

```
domtype(S)
```

```
Dom::Matrix(Dom::IntegerMod(7))
```

### Example 3

The Sylvester matrix of the following two polynomial expressions with respect to the variable x is:

```
delete x, y:
S := linalg::sylvester(x + y^2, 2*x^3 - 1, x)
```

$$\begin{pmatrix} 1 & y^2 & 0 & 0 \\ 0 & 1 & y^2 & 0 \\ 0 & 0 & 1 & y^2 \\ 2 & 0 & 0 & -1 \end{pmatrix}$$

```
domtype(S)
```

```
Dom::Matrix()
```

The Sylvester matrix of these two polynomials with respect to y is the following 2 2 matrix:

```
linalg::sylvester(x + y^2, 2*x^3 - 1, y)
```

$$\begin{pmatrix} 2x^3 - 1 & 0 \\ 0 & 2x^3 - 1 \end{pmatrix}$$

# linalg::sylvester

---

## Example 4

Here is an example for computing the Sylvester matrix of multivariate polynomials:

```
delete x, y: Q := Dom::Rational:
T := linalg::sylvester(poly(x^2 - x + y, Q), poly(x + 2, Q), x)
```

$$\begin{pmatrix} 1 & -1 & y \\ 1 & 2 & 0 \\ 0 & 1 & 2 \end{pmatrix}$$

```
domtype(T)
```

```
Dom::Matrix(Dom::DistributedPolynomial([y], Dom::Rational, LexOrder))
```

The Sylvester matrix of these two multivariate polynomials with respect to  $y$  is:

```
linalg::sylvester(poly(x^2 - x + y, Q), poly(x + 2, Q), y)
```

$$(x + 2)$$

## Parameters

**p, q**

Polynomials

**f, g**

Polynomials or polynomial expressions of positive degree

**x**

A variable

## **Return Values**

Matrix of the domain `Dom::Matrix(R)`, where `R` is the coefficient domain of the polynomials (see below).

## **See Also**

## **MuPAD Functions**

`polylib::discrim` | `polylib::resultant`

# linalg::tr

---

**Purpose** Trace of a matrix

**Syntax** `linalg::tr(A)`

**Description** `linalg::tr(A)` returns the trace of the square matrix  $A$ , i.e., the sum of the diagonal elements of  $A$ .

**Examples** **Example 1**

We compute the trace of the following matrix:

```
A := Dom::Matrix(Dom::Integer)
 (3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

```
linalg::tr(A)
```

```
15
```

**Parameters** **A**

A square matrix of a domain of category `Cat::Matrix`

**Return Values** Element of the component ring of  $A$ .

**See Also**

**MuPAD Functions** `linalg::det`

**Concepts**

- “Compute Determinants and Traces of Square Matrices”

# linalg::toeplitz

**Purpose** Toeplitz matrix

**Syntax**  
`linalg::toeplitz(m, n, [t-k, ..., tk], <R>)`  
`linalg::toeplitz(n, [t-k, ..., tk], <R>)`  
`linalg::toeplitz(c, r)`  
`linalg::toeplitz(r)`

**Description** `linalg::toeplitz(m, n, [t-k, ..., t-1, t0, t1, ..., tk])` returns the  $m \times n$  Toeplitz matrix

$$\begin{pmatrix} t_0 & t_1 & t_2 & \cdot & \cdot & \cdot & \cdot & \cdot & t_k \\ t_{-1} & t_0 & t_1 & t_2 & \cdot & \cdot & \cdot & \cdot & t_{k-1} \\ t_{-2} & t_{-1} & t_0 & t_1 & t_2 & \cdot & \cdot & \cdot & t_{k-2} \\ \vdots & & \cdot & \vdots & \vdots & \cdot & \cdot & \cdot & \vdots \\ \vdots & & & \vdots & \vdots & \cdot & \cdot & \cdot & \vdots \\ \cdot & & & & \cdot & t_0 & t_1 & t_2 & \\ \cdot & & & & \cdot & t_{-1} & t_0 & t_1 & \\ t_{-k} & \cdot & \cdot & \cdot & \cdot & \cdot & t_{-2} & t_{-1} & t_0 \end{pmatrix}$$

`linalg::toeplitz(n, [t-k, ..., tk])` returns the square Toeplitz matrix of dimension  $n \times n$ .

A number of entries  $[t_{-k}, \dots, t_k]$  must be an odd number  $2k + 1$ . There must be at least  $k$  diagonal bands above the diagonal and  $k$  diagonal bands below the diagonal:  $k$  must satisfy  $k \leq \min(m, n) - 1$ . Entries with matrix indices  $(i, j)$  satisfying  $|i - j| > k$  are set to 0.

Toeplitz matrices of dimension  $n \times n$  can be inverted with  $O(n^2)$  operations. See `linalg::toeplitzSolve`.

`linalg::toeplitz(c, r)` generates a nonsymmetric Toeplitz matrix having  $c$  as its first column and  $r$  as its first row. If the first elements of  $c$  and  $r$  differ, `toeplitz` issues a warning and uses the first element of the column.

`linalg::toeplitz(r)` generates a symmetric Toeplitz matrix if  $r$  is real. If  $r$  is complex, but its first element is real, then this syntax generates the Hermitian Toeplitz matrix formed from  $r$ . If the first

element of  $r$  is complex, then the resulting matrix is Hermitian off the main diagonal, meaning that  $T_{ij} = \text{conjugate}(T_{ji})$  for  $i \neq j$ .

When you use matrices in MuPAD computations, both computational efficiency and memory use can depend on whether the matrix is sparse or dense. The first two syntaxes are optimized for generating sparse matrices and, therefore, these syntaxes are preferable. For details about improving performance when working with matrices, see “Use Sparse and Dense Matrices”.

## Examples

### Example 1

Construct a 4 4 Toeplitz matrix with three bands:

```
linalg::toeplitz(4, [-1, 2, 1])
```

$$\begin{pmatrix} 2 & 1 & 0 & 0 \\ -1 & 2 & 1 & 0 \\ 0 & -1 & 2 & 1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

Construct a 3 5 Toeplitz matrix with symbolic entries:

```
linalg::toeplitz(3, 5, [a, b, c])
```

$$\begin{pmatrix} b & c & 0 & 0 & 0 \\ a & b & c & 0 & 0 \\ 0 & a & b & c & 0 \end{pmatrix}$$

### Example 2

Construct a Toeplitz matrix by using a vector to specify its first row. For a real vector, the resulting matrix is symmetric:

```
r := matrix([1, 2, 3]):
linalg::toeplitz(r)
```

## linalg::toeplitz

---

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 2 \\ 3 & 2 & 1 \end{pmatrix}$$

For a complex vector, the resulting matrix is Hermitian off the main diagonal:

```
r := matrix([1 + I, 2 + I, 3 + I]):
T := linalg::toeplitz(r);
htranspose(T)
```

$$\begin{pmatrix} 1+i & 2+i & 3+i \\ 2-i & 1+i & 2+i \\ 3-i & 2-i & 1+i \end{pmatrix}$$

$$\begin{pmatrix} 1-i & 2+i & 3+i \\ 2-i & 1-i & 2+i \\ 3-i & 2-i & 1-i \end{pmatrix}$$

### Example 3

Construct a Toeplitz matrix by using two vectors to specify its first column and first row:

```
c := matrix([1, a/2, b/2]):
r := [1, a, b]:
linalg::toeplitz(c, r)
```

$$\begin{pmatrix} 1 & \frac{a}{2} & \frac{b}{2} \\ a & 1 & \frac{a}{2} \\ b & a & 1 \end{pmatrix}$$

If the first elements of the vectors differ, `linalg::toeplitz` issues a warning and uses the first element of the column:

```
c := matrix([1, a/2, b/2]):
r := [2, a, b]:
linalg::toeplitz(c, r)
```

Warning: First element of input column does not match first element

$$\begin{pmatrix} 2 & \frac{a}{2} & \frac{b}{2} \\ a & 2 & \frac{a}{2} \\ b & a & 2 \end{pmatrix}$$

## Parameters

**m, n**

Row and column dimensions of the matrix: positive integers.

**t<sub>1,k</sub>, ..., t<sub>k</sub>**

Arithmetical expressions or elements of the component ring R.

**R**

Component ring: a domain of category `Cat::Rng`. The default ring is `Dom::ExpressionField()`.

**c**

Vector specifying the first column of a Toeplitz matrix.

**r**

Vector specifying the first row of a Toeplitz matrix.

## Return Values

Matrix of the domain `Dom::Matrix(R)`.

# **linalg::toeplitz**

---

## **See Also**

## **MuPAD Functions**

`linalg::hilbert` | `linalg::invhilbert` | `linalg::invpascal`  
| `linalg::invvandermonde` | `linalg::pascal` |  
`linalg::toeplitzSolve` | `linalg::vandermonde` |  
`linalg::vandermondeSolve`

**Purpose** Solve a linear Toeplitz system

**Syntax** `linalg::toeplitzSolve(t, y)`

**Description** `linalg::toeplitzSolve(t, y)` returns the solution  $\vec{X}$  of the linear Toeplitz system  $\sum_{j=1}^n t_{i-j} X_j = y_i$  with  $i = 1, \dots, n$ .

`linalg::toeplitzSolve(t, y)` with  $t = [t_k, \dots, t_0, \dots, t_{-k}]$  and  $y = [y_1, \dots, y_n]$  solves the  $n \times n$  Toeplitz system

$$\begin{pmatrix} t_0 & t_{-1} & \cdot & \cdot & \cdot & t_{-k} \\ t_1 & t_0 & t_{-1} & \cdot & \cdot & t_{-k} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} \\ & t_k & t_{k-1} & \cdot & \cdot & t_{-k} \\ & & t_k & t_{k-1} & \cdot & t_{-k} & \cdot & \cdot \\ & & & \vdots & \vdots & \vdots & \vdots & \cdot & \cdot \\ & & & & \vdots & \vdots & \vdots & \vdots & \cdot & \cdot \end{pmatrix} \begin{pmatrix} X_1 \\ X_2 \\ \vdots \\ X_n \end{pmatrix} = \begin{pmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_n \end{pmatrix}$$

with  $2k + 1$  bands.

`linalg::toeplitzSolve` implements the Levinson algorithm. It uses  $O(n^2)$  elementary operations to solve the Toeplitz system. The memory requirements are  $O(n)$ . For dense Toeplitz systems, it is faster than the general solver `solve` and the linear solvers `linsolve`, `numeric::linsolve`, `linalg::matlinsolve` and `numeric::matlinsolve`.

# linalg::toeplitzSolve

---

---

**Note** Note that the Levinson algorithm requires that all principal minors

$$t_0, \begin{pmatrix} t_0 & t_{-1} \\ t_1 & t_0 \end{pmatrix}, \begin{pmatrix} t_0 & t_{-1} & t_{-2} \\ t_1 & t_0 & t_{-1} \\ t_2 & t_1 & t_0 \end{pmatrix}, \text{ etc}$$

are non-singular.

---

If `linalg::toeplitzSolve` does not manage to find the solution due to this limitation, or if the system is very sparse with  $k$  smaller than  $\sqrt{n}$ , we recommend to generate the corresponding Toeplitz matrix via `linalg::toeplitz` and compute the solution via `linalg::matlinsolve` or `numeric::matlinsolve`, respectively. Cf. “Example 2” on page 14-255

`linalg::toeplitzSolve` can solve Toeplitz systems over arbitrary coefficient rings. Just make sure that both the Toeplitz entries  $t$  as well as the components of the ‘right hand side’  $y$  are elements of the desired coefficient ring. Cf. “Example 3” on page 14-256.

## Examples

### Example 1

The Toeplitz entries  $t$  and the right hand side  $y$  of the linear system are entered as row vectors:

```
t := matrix([4, 2, 1, 3, 5]):
y := matrix([y1, y2, y3]):
```

The solution of the Toeplitz system is returned as a vector of the same type as the input vector  $y$ :

```
x := linalg::toeplitzSolve(t, y): x, domtype(x)
```

$$\begin{pmatrix} \frac{7 y_2}{25} - \frac{y_1}{5} + \frac{4 y_3}{25} \\ \frac{2 y_1}{5} - \frac{19 y_2}{25} + \frac{7 y_3}{25} \\ \frac{2 y_2}{5} - \frac{y_3}{5} \end{pmatrix}, \text{Dom::Matrix()}$$

If the input vector is a list, the output is a list, too:

```
x := linalg::toeplitzSolve(t, [y1, y2, y3]): x, domtype(x)
```

$$\left[ \frac{7 y_2}{25} - \frac{y_1}{5} + \frac{4 y_3}{25}, \frac{2 y_1}{5} - \frac{19 y_2}{25} + \frac{7 y_3}{25}, \frac{2 y_2}{5} - \frac{y_3}{5} \right], \text{DOM\_LIST}$$

```
delete t, y, x:
```

## Example 2

The Levinson algorithm cannot solve the following Toeplitz system because the first principal minor of the Toeplitz matrix (the central element of the Toeplitz entries) vanishes:

```
linalg::toeplitzSolve([1, 0, 1], [y1, y2, y3, y4])
```

FAIL

This does not necessarily imply that the Toeplitz system is not solvable. We generate the corresponding Toeplitz matrix and use a generic linear solver such as `linalg::matlinsolve`:

```
T := linalg::toeplitz(4, 4, [1, 0, 1])
```

# linalg::toeplitzSolve

---

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

```
linalg::matlinsolve(T, matrix([y1, y2, y3, y4]))
```

$$\begin{pmatrix} y2 - y4 \\ y1 \\ y4 \\ y3 - y1 \end{pmatrix}$$

### Example 3

We solve a Toeplitz system over the field  $\mathbb{Z}_7$  (the integers modulo 7) represented by the domain `Dom::IntegerMod(7)`:

```
R := Dom::IntegerMod(7):
t := [R(5), R(3), R(2), R(5), R(1)]:
y := [R(1), R(2), R(3)]:
linalg::toeplitzSolve(t, y)
```

```
[1 mod 7, 5 mod 7, 2 mod 7]
```

```
delete R, t, y:
```

### Parameters

**t**

A vector or a list with  $2k + 1$  elements. (A vector is a  $(2k + 1) \times 1$  or a  $1 \times (2k + 1)$  matrix of category `Cat::Matrix`).

**y**

A vector or a list with  $n$  elements

## **Return Values**

Vector or list with  $n$  elements of the same domain type as the elements of  $y$ . FAIL is returned if the algorithm does not succeed in finding a solution.

## **See Also**

## **MuPAD Functions**

`linalg::hilbert` | `linalg::invhilbert` | `linalg::invpascal`  
| `linalg::invvandermonde` | `linalg::matlinsolve`  
| `linalg::pascal` | `linalg::vandermonde` |  
`linalg::vandermondeSolve` | `linalg::toeplitz` | `linsolve` |  
`numeric::linsolve` | `numeric::matlinsolve` | `solve`

# linalg::transpose

---

**Purpose** Transpose of a matrix

**Syntax** `linalg::transpose(A)`

**Description** `linalg::transpose(A)` returns the transpose  $A^t$  of the matrix  $A$ .  
`linalg::transpose` is an interface function for the method "transpose" of the matrix domain of  $A$ , i.e., instead of `linalg::transpose(A)` one may call `A::dom::transpose(A)` directly.

## Examples **Example 1**

We define a 3 4 matrix:

```
A := matrix([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Then the transpose of  $A$  is the 4 3 matrix:

```
linalg::transpose(A)
```

$$\begin{pmatrix} 1 & -1 & 3 \\ 2 & 0 & 5 \\ 3 & 1 & 6 \\ 4 & 0 & 9 \end{pmatrix}$$

**Parameters** **A**

A matrix of a domain of category `Cat::Matrix`

**Return Values** Matrix of the same domain type as  $A$ .

## Algorithms

Let  $A = (a_{i,j})_{1 \leq i \leq m, 1 \leq j \leq n}$  be an  $m \ n$  matrix. Then the transpose of  $A$  is the  $n \ m$  matrix:

$$A^t = \begin{pmatrix} a_{1,1} & a_{1,2} & \cdots & a_{m,1} \\ a_{1,2} & a_{2,2} & \cdots & a_{m,2} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1,n} & a_{1,n} & \cdots & a_{m,n} \end{pmatrix}$$

# linalg::vandermonde

---

**Purpose** Vandermonde matrices and their inverses

**Syntax** `linalg::vandermonde([v1, v2, ...], <R>)`

**Description** `linalg::vandermonde([v1, v2, ..., vn], R)` returns the  $n \times n$  Vandermonde matrix  $V$  with entries  $V_{ij} = v_i^{j-1}$ .

Use `linalg::vandermonde([v1, ..., vn], R)` to define the  $n \times n$  Vandermonde matrix over the field  $R$ . Note that the Vandermonde nodes  $v_i$  must be elements of  $R$  or must be convertible to elements of  $R$ . The same holds true for the inverse Vandermonde matrix.

Vandermonde matrices of dimension  $n \times n$  can be inverted with  $O(n^2)$  operations. Linear equations with a Vandermonde coefficient matrix can be solved via `linalg::vandermondeSolve`.

## Examples

### Example 1

We construct a  $3 \times 3$  Vandermonde matrix:

```
V := linalg::vandermonde([v1, v2, v3])
```

$$\begin{pmatrix} 1 & v_1 & v_1^2 \\ 1 & v_2 & v_2^2 \\ 1 & v_3 & v_3^2 \end{pmatrix}$$

The inverse of this matrix is:

```
linalg::invvandermonde([v1, v2, v3])
```

$$\begin{pmatrix} \frac{v_2 v_3}{(v_1 - v_2)(v_1 - v_3)} & - \frac{v_1 v_3}{(v_1 - v_2)(v_2 - v_3)} & \frac{v_1 v_2}{(v_1 - v_3)(v_2 - v_3)} \\ - \frac{v_2 + v_3}{(v_1 - v_2)(v_1 - v_3)} & \frac{v_1 + v_3}{(v_1 - v_2)(v_2 - v_3)} & - \frac{v_1 + v_2}{(v_1 - v_3)(v_2 - v_3)} \\ \frac{1}{(v_1 - v_2)(v_1 - v_3)} & - \frac{1}{(v_1 - v_2)(v_2 - v_3)} & \frac{1}{(v_1 - v_3)(v_2 - v_3)} \end{pmatrix}$$

V and its inverse are matrices of the domain `Dom::Matrix()`. One can specify a special component ring for the matrices, provided the nodes can be converted to elements of the ring. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
V := linalg::vandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} 1.0 & 2.0 & 4.0 \\ 1.0 & 3.141592654 & 9.869604401 \\ 1.0 & 0.3333333333 & 0.1111111111 \end{pmatrix}$$

```
domtype(V)
```

```
Dom::Matrix(Dom::Float)
```

It is faster to compute the inverse via `linalg::invvandermonde` than inverting the Vandermonde matrix by a generic inversion algorithm (as implemented by `V^(-1)`):

```
V^(-1) = linalg::invvandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix} = \begin{pmatrix} -0.5503876788 & 0.2079506905 \\ 1.826356876 & -0.7278274166 \\ -0.5255815182 & 0.3119260357 \end{pmatrix}$$

# `linalg::vandermonde`

---

`delete V:`

## Parameters

$v_1, v_2, \dots$

The Vandermonde nodes: arithmetical expressions

**R**

The component ring: a domain of category `Cat::Rng`; default:  
`Dom::ExpressionField()`

## Return Values

$n \times n$  matrix of the domain `Dom::Matrix(R)`.

## Algorithms

Vandermonde matrices are notoriously ill-conditioned. The inverses of large floating-point Vandermonde matrices are subject to severe round-off effects.

## See Also

## MuPAD Functions

`linalg::invhilbert` | `linalg::invpascal` | `linalg::pascal`  
| `linalg::toeplitz` | `linalg::toeplitzSolve` |  
`linalg::vandermondeSolve`

## Purpose

Vandermonde matrices and their inverses

## Syntax

```
linalg::invvandermonde([v1, v2, ...], <R>)
```

## Description

`linalg::invvandermonde(v1, v2, ..., vn)` returns the inverse of the Vandermonde matrix with nodes  $v_i$ .

Use `linalg::vandermonde([v1, ..., vn], R)` to define the  $n \times n$  Vandermonde matrix over the field  $R$ . Note that the Vandermonde nodes  $v_i$  must be elements of  $R$  or must be convertible to elements of  $R$ . The same holds true for the inverse Vandermonde matrix.

Vandermonde matrices of dimension  $n \times n$  can be inverted with  $O(n^2)$  operations. Linear equations with a Vandermonde coefficient matrix can be solved via `linalg::vandermondeSolve`.

## Examples

### Example 1

We construct a  $3 \times 3$  Vandermonde matrix:

```
V := linalg::vandermonde([v1, v2, v3])
```

$$\begin{pmatrix} 1 & v_1 & v_1^2 \\ 1 & v_2 & v_2^2 \\ 1 & v_3 & v_3^2 \end{pmatrix}$$

The inverse of this matrix is:

```
linalg::invvandermonde([v1, v2, v3])
```

# linalg::invvandermonde

$$\begin{pmatrix} \frac{v_2 v_3}{(v_1 - v_2)(v_1 - v_3)} & -\frac{v_1 v_3}{(v_1 - v_2)(v_2 - v_3)} & \frac{v_1 v_2}{(v_1 - v_3)(v_2 - v_3)} \\ -\frac{v_2 + v_3}{(v_1 - v_2)(v_1 - v_3)} & \frac{v_1 + v_3}{(v_1 - v_2)(v_2 - v_3)} & -\frac{v_1 + v_2}{(v_1 - v_3)(v_2 - v_3)} \\ \frac{1}{(v_1 - v_2)(v_1 - v_3)} & -\frac{1}{(v_1 - v_2)(v_2 - v_3)} & \frac{1}{(v_1 - v_3)(v_2 - v_3)} \end{pmatrix}$$

V and its inverse are matrices of the domain `Dom::Matrix()`. One can specify a special component ring for the matrices, provided the nodes can be converted to elements of the ring. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
V := linalg::vandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} 1.0 & 2.0 & 4.0 \\ 1.0 & 3.141592654 & 9.869604401 \\ 1.0 & 0.3333333333 & 0.1111111111 \end{pmatrix}$$

```
domtype(V)
```

```
Dom::Matrix(Dom::Float)
```

It is faster to compute the inverse via `linalg::invvandermonde` than inverting the Vandermonde matrix by a generic inversion algorithm (as implemented by `V^(-1)`):

```
V^(-1) = linalg::invvandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix} = \begin{pmatrix} -0.5503876788 & 0.2079506905 & 1 \\ 1.826356876 & -0.7278274166 & - \\ -0.5255815182 & 0.3119260357 & 0 \end{pmatrix}$$

**delete V:**

## **Parameters**

$v_1, v_2, \dots$

The Vandermonde nodes: arithmetical expressions

**R**

The component ring: a domain of category `Cat::Rng`; default:  
`Dom::ExpressionField()`

## **Return Values**

$n \times n$  matrix of the domain `Dom::Matrix(R)`.

## **Algorithms**

Vandermonde matrices are notoriously ill-conditioned. The inverses of large floating-point Vandermonde matrices are subject to severe round-off effects.

## **See Also**

## **MuPAD Functions**

`linalg::vandermonde` | `linalg::hilbert` | `linalg::invhilbert` | `linalg::invpascal` | `linalg::pascal` | `linalg::toeplitz` | `linalg::toeplitzSolve` | `linalg::vandermondeSolve`

# linalg::vandermondeSolve

---

**Purpose** Solve a linear Vandermonde system

**Syntax** `linalg::vandermondeSolve(v, y, <Transposed>)`

**Description** `linalg::vandermondeSolve(v, y)` returns the solution  $\vec{X}$  of the linear

Vandermonde system  $\sum_{j=1}^n v_i^{j-1} x_j = y_i$  with  $i = 1, \dots, n$ .

`linalg::vandermondeSolve` uses  $O(n^2)$  elementary operations to solve the Vandermonde system. It is faster than the general solver `solve` and the linear solvers `linsolve`, `numeric::linsolve`, `linalg::matlinsolve` and `numeric::matlinsolve`.

The solution  $\vec{X} = (X_1, \dots, X_n)$  returned by `linalg::vandermondeSolve([v[i] $ i=1..n], [y[i] $ i=1..n])` yields the coefficients of the polynomial  $p(v) = x_1 + x_2v + \dots + x_nv^{n-1}$  interpolating the data table  $(v_1, y_1), \dots, (v_n, y_n)$ , i.e.,

$$p(v_1) = y_1, \dots, p(v_n) = y_n$$

See “Example 1” on page 14-266.

## Examples

### Example 1

The Vandermonde points  $v$  and the right hand side  $y$  of the linear system are entered as vectors:

```
delete y0, y1, y2:
v := matrix([[0, 1, 2]]);
y := matrix([[y0, y1, y2]])
```

```
(0 1 2)
```

```
(y0 y1 y2)
```

The solution vector is:

```
x := linalg::vandermondeSolve(v, y)
```

$$\left( y_0 \quad 2 y_1 - \frac{3 y_0}{2} - \frac{y_2}{2} \quad \frac{y_0}{2} - y_1 + \frac{y_2}{2} \right)$$

The solution yields the coefficients of the interpolating polynomial:

```
P := v -> _plus(x[i+1]*v^i $ i=0..2):
```

through the points  $(0, y_0)$ ,  $(1, y_1)$ ,  $(2, y_2)$ :

```
P(v[1]), P(v[2]), P(v[3])
```

```
y0, y1, y2
```

With the optional argument `Transposed`, the linear system with the transposed Vandermonde matrix corresponding to `v` is solved:

```
linalg::vandermondeSolve(v, y, Transposed)
```

$$\left( y_0 - \frac{3 y_1}{2} + \frac{y_2}{2} \quad 2 y_1 - y_2 \quad \frac{y_2}{2} - \frac{y_1}{2} \right)$$

```
delete v, y, x, P:
```

## Example 2

The Vandermonde points `v` and the right hand side `y` of the linear system are entered as 2 1 matrices:

```
Mat := Dom::Matrix(Dom::ExpressionField(normal)):
```

```
delete v1, v2, y1, y2:
```

# linalg::vandermondeSolve

---

```
v := Mat([v1, v2]):
y := Mat([y1, y2]):
```

We define the vectors over the domain `Dom::ExpressionField(normal)` in order to simplify intermediate computations.

Next, we compute the solution of the corresponding Vandermonde system:

```
x := linalg::vandermondeSolve(v, y)
```

$$\begin{pmatrix} \frac{v1 y2 - v2 y1}{v1 - v2} \\ \frac{y1 - y2}{v1 - v2} \end{pmatrix}$$

We construct the Vandermonde matrix `V` and verify the result:

```
V := Mat([[1, v[1]], [1, v[2]]])
```

$$\begin{pmatrix} 1 & v1 \\ 1 & v2 \end{pmatrix}$$

```
V * x
```

$$\begin{pmatrix} y1 \\ y2 \end{pmatrix}$$

```
delete Mat, v, y, x, V:
```

### Example 3

We solve a Vandermonde system over the field  $\mathbb{Z}_7$  (the integers modulo 7) represented by the domain `Dom::IntegerMod(7)`:

```
MatZ7 := Dom::Matrix(Dom::IntegerMod(7)):
v := MatZ7([1, 2, 3]): y := MatZ7([0, 1, 2]):

linalg::vandermondeSolve(v, y)
```

$$\begin{pmatrix} 6 \bmod 7 \\ 1 \bmod 7 \\ 0 \bmod 7 \end{pmatrix}$$

```
delete MatZ7, v, y:
```

## Parameters

**v**

A vector with distinct elements (a vector is an  $n \times 1$  or  $1 \times n$  matrix of category `Cat::Matrix`). Alternatively, a list with  $n$  distinct elements is also accepted.

**y**

A vector of the same dimension and domain type as `v`. Alternatively, a list with  $n$  elements is also accepted.

## Options

**Transposed**

Returns the solution  $\vec{x}$  of the transposed system

$$\sum_{j=1}^n v_j^{i-1} x_j = y_i \text{ with } i = 1, \dots, n.$$

## Return Values

Vector of the same domain type as `y`.

# linalg::vandermondeSolve

---

## Algorithms

The Vandermonde matrix

$$V = \begin{pmatrix} 1 & v_1 & v_1^2 & \dots & v_1^{n-1} \\ 1 & v_2 & v_2^2 & \dots & v_2^{n-1} \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ 1 & v_n & v_n^2 & \dots & v_n^{n-1} \end{pmatrix}$$

generated by  $v = [v_1, \dots, v_n]$  is invertible if and only if the  $v_i$  are distinct.

The vector  $\vec{x}$  returned by `linalg::vandermondeSolve(x, y)` is the unique solution of  $V \vec{x} = \vec{y}$ .

The vector  $x$  returned by `linalg::vandermondeSolve(x, y, Transposed)` is the unique solution of  $V^t \vec{x} = \vec{y}$ .

## See Also

## MuPAD Functions

`interpolate` | `linalg::invhilbert` | `linalg::invpascal`  
| `linalg::invvandermonde` | `linalg::matlinsolve` |  
`linalg::pascal` | `linalg::toeplitz` | `linalg::toeplitzSolve` |  
`linalg::vandermonde` | `linalg::vandermondeSolve` | `linsolve` |  
`numeric::linsolve` | `numeric::matlinsolve` | `solve`

**Purpose** Number of components of a vector

**Syntax** `linalg::vecdim(v)`

**Description** `linalg::vecdim(v)` returns the number of elements of the vector  $\vec{v}$ .

**Examples** **Example 1**

We define a column vector with two elements and a row vector with four elements:

```
v1 := matrix([1, 0]); v2 := matrix([[1, 2, 3, 4]])
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$
$$(1\ 2\ 3\ 4)$$

`linalg::vecdim` gives us the number of elements, i.e., the dimension of these vectors:

```
linalg::vecdim(v1), linalg::vecdim(v2)
```

$$2, 4$$

In contrast, the function `linalg::matdim` returns the number of rows and columns of these vectors:

```
linalg::matdim(v1), linalg::matdim(v2)
```

$$[2, 1], [1, 4]$$

# **linalg::vecdim**

---

## **Parameters**    **v**

A vector, i.e., an  $n \times 1$  or  $1 \times n$  matrix of a domain of category  
`Cat::Matrix`

**Return Values**    Positive integer.

## **See Also**

**MuPAD Functions**    `linalg::matdim` | `linalg::ncols` | `linalg::nrows`

**Purpose** Type specifier for vectors

**Syntax** `linalg::vectorOf(R)`  
`linalg::vectorOf(R, n)`

**Description** `linalg::vectorOf(R)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with component ring `R` and number of rows or number of columns equal to one.

`linalg::vectorOf(R,n)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with component ring `R` and number of rows equal to `n` and number of columns equal to one, or vice versa.

`linalg::vectorOf(Type::AnyType,n)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with an arbitrary component ring `R` and number of rows equal to `n` and number of columns equal to one, or vice versa.

## Examples **Example 1**

`linalg::vectorOf` can be used together with `testtype` to check whether a MuPAD object is a vector:

```
MatZ := Dom::Matrix(Dom::Integer):
v := MatZ([1, 0, -1])
```

$$\begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$$

The following yields `FALSE` because `v` is 3-dimensional vector:

```
testtype(v, linalg::vectorOf(Dom::Integer, 4))
```

```
FALSE
```

# linalg::vectorOf

---

The following yields FALSE because `v` is defined over the integers:

```
testtype(v, linalg::vectorOf(Dom::Rational))
```

```
FALSE
```

Of course, `v` can be converted into a vector over the rationals, as shown by the following call:

```
bool(coerce(v, Dom::Matrix(Dom::Rational)) <> FAIL)
```

```
TRUE
```

This shows that `testtype` in conjunction with `linalg::vectorOf(R)` does not check whether an object can be converted into a vector over the specified component ring `R`. It checks only if the object is a vector whose component ring is `R`.

The following test returns TRUE because `v` is a 3-dimensional vector:

```
testtype(v, linalg::vectorOf(Type::AnyType, 3))
```

```
TRUE
```

## Example 2

`linalg::vectorOf` can also be used for checking parameters of procedures. The following procedure computes the orthogonal complement of a 2-dimensional vector:

```
orth := proc(v:linalg::vectorOf(Type::AnyType, 2))
begin
 [v[1], v[2]] := [-v[2],v[1]];
 return(v)
end:
```

```
u := matrix([[1, 2]]); u_ := orth(u)
```

```
(1 2)
```

```
(-2 1)
```

Calling the procedure `orth` with an invalid parameter leads to an error message:

```
orth([1, 2])
```

```
Error: The type of argument number 1 must be 'slot(Type, vectorOf)'
Evaluating: orth
```

## Parameters

**R**

The component ring: a library domain

**n**

A positive integer

## Return Values

Type expression of the domain type `Type`.

## MuPAD Functions

`testtype`

# linalg::vectorPotential

---

<b>Purpose</b>	Vector potential of a three-dimensional vector field
<b>Syntax</b>	<code>linalg::vectorPotential(j, [x<sub>1</sub>, x<sub>2</sub>, x<sub>3</sub>], &lt;Test&gt;)</code>
<b>Description</b>	<code>linalg::vectorPotential(j, x)</code> returns the vector potential of the vector field $\vec{j}(\vec{x})$ with respect to $\vec{x}$ . This is a vector field $\vec{v}$ with $\text{curl}_{\vec{v}}(\vec{x}) = \vec{j}$ . <code>linalg::vectorPotential</code> and <code>vectorPotential</code> are equivalent. See details and examples on the <code>vectorPotential</code> help page.
<b>Parameters</b>	<b>j</b> A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3 1 or 1 3 matrix of a domain of category <code>Cat::Matrix</code> ) <b>x<sub>1</sub>, x<sub>2</sub>, x<sub>3</sub></b> (indexed) identifiers
<b>Options</b>	<b>Test</b> <code>linalg::vectorPotential</code> only checks whether the vector field <code>j</code> has a vector potential and returns <code>TRUE</code> or <code>FALSE</code> , respectively.
<b>Return Values</b>	Vector with three components, i.e., an 3 1 or 1 <i>n</i> matrix of a domain of category <code>Cat::Matrix</code> , or a boolean value.

**Purpose** Solving linear systems by Wiedemann's algorithm

**Syntax** `linalg:wiedemann(A, b, <mult>, <prob>)`

**Description** `linalg:wiedemann(A, b, mult, ...)` tries to find a vector  $\vec{x}$  that satisfies the equation  $A \vec{x} = \vec{b}$  by using Wiedemann's algorithm. The parameter `mult` must be a function such that the result of `mult(A,y)` equals  $A \vec{y}$  for every  $n$ -dimensional column vector  $\vec{y}$ . The parameter `y` is of the same domain type as `A`. The argument `mult` does not need to handle other types of parameters, nor does it need to handle other matrices than `A`.

`linalg:wiedemann` uses a probabilistic algorithm. For a deterministic variant enter `FALSE` for the optional parameter `prob`.

If the system  $A \vec{x} = \vec{b}$  does not have a solution, then `linalg:wiedemann` returns `FAIL`.

If the system  $A \vec{x} = \vec{b}$  has more than one solution, then a random one is returned.

Due to the probabilistic nature of Wiedemann's algorithm, the computation may fail with small probability. In this case `FAIL` is returned. If the deterministic variant is chosen, then the algorithm may be slower for a small number of matrices.

The vector `b` must be defined over the component ring of `A`.

The coefficient ring of `A` must be a field, i.e., a domain of category `Cat::Field`.

It is recommended to use `linalg:wiedemann` only if `mult` uses significantly less than  $O(n^2)$  field operations.

**Examples**      **Example 1**

We define a matrix and a column vector over the finite field with 29 elements:

```
MatZ29 := Dom::Matrix(Dom::IntegerMod(29)):
A := MatZ29([[1, 2, 3], [4, 7, 8], [9, 12, 17]]);
b := MatZ29([1, 2, 3])
```

$$\begin{pmatrix} 1 \bmod 29 & 2 \bmod 29 & 3 \bmod 29 \\ 4 \bmod 29 & 7 \bmod 29 & 8 \bmod 29 \\ 9 \bmod 29 & 12 \bmod 29 & 17 \bmod 29 \end{pmatrix}$$

$$\begin{pmatrix} 1 \bmod 29 \\ 2 \bmod 29 \\ 3 \bmod 29 \end{pmatrix}$$

Since A does not have a special form that would allow a fast matrix-vector multiplication, we simply use `_mult`. Wiedemann's algorithm works in this case, although it is less efficient than Gaussian elimination:

```
linalg:wiedemann(A, b, _mult)
```

$$\left[ \begin{pmatrix} 24 \bmod 29 \\ 21 \bmod 29 \\ 17 \bmod 29 \end{pmatrix}, \text{TRUE} \right]$$

## Example 2

Now let us define another matrix that has a special form:

```
MatZ29 := Dom::Matrix(Dom::IntegerMod(29)):
A := MatZ29([[1, 0, 0], [0, 1, 2], [0, 0, 1]]);
b := MatZ29(3, 1, [1, 2, 3]):
```

$$\begin{pmatrix} 1 \bmod 29 & 0 \bmod 29 & 0 \bmod 29 \\ 0 \bmod 29 & 1 \bmod 29 & 2 \bmod 29 \\ 0 \bmod 29 & 0 \bmod 29 & 1 \bmod 29 \end{pmatrix}$$

For this particular matrix, it is easy to define an efficient multiplication method:

```
mult := proc(dummy, y)
begin
 y[2]:=y[2]+2*y[3];
 y
end:
linalg:wiedemann(A, b, mult)
```

$$\left[ \begin{pmatrix} 1 \bmod 29 \\ 25 \bmod 29 \\ 3 \bmod 29 \end{pmatrix}, \text{TRUE} \right]$$

## Parameters

**A**

An  $n \times n$  matrix of a domain of category `Cat::Matrix`

**b**

An  $n$ -dimensional column vector, i.e., an  $n \times 1$  matrix of a domain of category `Cat::Matrix`

**mult**

A matrix-vector multiplication method: function or functional expression; default: `_mult`

**prob**

TRUE or FALSE (default: TRUE)

## Return Values

Either the list  $[x, \text{TRUE}]$  if a solution for the system  $A \vec{x} = \vec{b}$  has been found, or the list  $[x, \text{FALSE}]$  if a non-zero solution for the corresponding homogeneous system  $A \vec{x} = \vec{0}$  has been found, or the value FAIL (see below).

## Algorithms

The expected running time for the probabilistic algorithm is  $O(n^2 + nM)$ , and the running time for the deterministic variant is  $O(n^2M)$  in the worst case, but only  $O(n^2 + nM)$  on average. Here,  $M$  is the number of field operations that the matrix-vector multiplication routine `mult` uses.

The basic idea of the algorithm is to solve a linear system  $A \vec{x} = \vec{b}$  by finding the minimal polynomial  $f(y)$  that solves  $f(A) \vec{b} = \vec{0}$ . If the constant coefficient  $c = f(0)$  is non-zero and  $g(y) := f(y) - c$ , the equality  $g(A) \vec{b} = -c \vec{b}$  implies that  $\vec{x} = -\frac{1}{c} \left(\frac{g}{y}\right)(A)$  is the solution.

The polynomial  $f$  is found by looking for the minimal polynomial  $h$  satisfying  $\vec{u} h(A) \vec{b} = \vec{0}$  for some randomly chosen row vector  $\vec{u}$ . This may yield  $h \neq f$  in unlucky cases, but in general the probability for this is small.

linopt::Transparent::suggest
linopt::Transparent::userstep
```

# linopt::corners

---

**Purpose** Return the feasible corners of a linear program

**Syntax**

```
linopt::corners([constr, obj], vars, <All>, <Logic>)
linopt::corners([constr, obj, <NonNegative>, <seti>],
vars, <All>, <Logic>)
linopt::corners([constr, obj, <NonNegative>, <All>],
vars, <All>, <Logic>)
linopt::corners([constr, obj, <setn>, <seti>],
vars, <All>, <Logic>)
linopt::corners([constr, obj, <setn>, <All>],
vars, <All>, <Logic>)
```

**Description** `linopt::corners([constr, obj], vars)` returns all valid corners of the linear program.

`linopt::corners([constr, obj], vars, All)` returns all corners of the linear program.

`[constr, obj]` is a linear program of the same structure like in `linopt::maximize`. The second parameter `vars` specifies the order in which the components of the corners found are printed; if e.g. `{x=1, y=2}` is a corner and `[x,y]` was entered, `[1,2]` will be returned.

As options, for finding the corners, one may use `All` and/or `Logic`. `All` causes the output of non-feasible corners, too, `Logic` allows the algorithm to search for corners in planes like `x=0`, too, although `x ≥ 0` is not part of the input. This guarantees that for all non-empty feasible regions a corner will be found.

As the result of `linopt::corners` a triple consisting of the set of corners, the maximal objective function value found and the corner associated to it is returned. If there is no feasible corner found, only the empty set is returned.

## Examples

### Example 1

We compute all valid corners of a small linear program:

```
k := [{4 <= 2*x + 2*y, -2 <= 4*y - 2*x, -8 <= y - 2*x,
```

```

 y - 2*x <= -2, y <= 6}, x + y):
linopt::corners(k, [x, y])

```

```

[[{[4/3, 2/3], [5/3, 1/3], [4, 6], [5, 2], [7, 6]}, 13, [7, 6]]

```

Now we compute all corners, also the ones which are not valid. We see that we now get e.g. also the corner which is given by the cut of  $-2x + 4y = 2$  and  $-2x + y \leq -2$ . Here we see that the invalid corner (13,6) has the maximal objective function value 19:

```

k := [{4 <= 2*x + 2*y, -2 <= 4*y - 2*x, -8 <= y - 2*x,
 y - 2*x <= -2, y <= 6}, x + y]:
linopt::corners(k, [x, y], All)

```

```

[[-4, 6], [1, 0], [4/3, 2/3], [5/3, 1/3], [10/3, -4/3], [4, 6], [5, 2], [7, 6], [13, 6]}, 19, [13, 6]]

```

```
delete k:
```

## Example 2

As one can see the linear program given by the constraints  $x + y \geq -1$  and  $x + y \leq 3$  and the linear objective function  $x + 2y$  has no corners:

```

l := [{-1 <= x + y, x + y <= 3}, x + 2*y]:
linopt::corners(l, [x,y]), linopt::corners(l, [x,y], All)

```

```
∅, ∅
```

If one also assumes a cut with a coordinate plane as a corner, some corners exist. One can use `linopt::plot_data` to visualize this problem:

```
linopt::corners(l, [x,y], Logic)
```

# linopt::corners

---

```
[{-1, 0], [0, 0], [0, -1], [0, 3], [3, 0]}, 6, [0, 3]]
```

```
delete 1:
```

## Parameters

### **constr**

A set or list of linear constraints

### **obj**

A linear expression

### **seti**

A set which contains identifiers interpreted as indeterminants

### **setn**

A set which contains identifiers interpreted as indeterminants

### **vars**

A list containing the variables of the linear program described by `constr` and `obj` and the existing options

## Options

### **All**

This option can appear at two different places in the call of `linopt::corners`. If it is part of the linear program it means that all variables are constrained to be integers. If it appears as the third or fourth argument of the call it means that all corners, not only the valid ones should be computed by `linopt::corners`.

### **NonNegative**

All variables are constrained to be nonnegative

### **Logic**

This allows the algorithm to search for corners in planes like  $x=0$  too, although  $x \geq 0$  is not part of the linear program.

## Return Values

Set or a list with 3 elements.

## See Also

## MuPAD Functions

`linopt::maximize` | `linopt::minimize` | `linopt::plot_data`

# linopt::maximize

---

**Purpose** Maximize a linear or mixed-integer program

**Syntax**

```
linopt::maximize([constr, obj], <DualPrices>)
linopt::maximize([constr, obj, <NonNegative>, <seti>])
linopt::maximize([constr, obj, <NonNegative>, <All>])
linopt::maximize([constr, obj, <setn>, <seti>])
linopt::maximize([constr, obj, <setn>, <All>])
linopt::maximize([constr, obj, <NonNegative>], DualPrices)
linopt::maximize([constr, obj, <set>], DualPrices)
```

**Description** `linopt::maximize([constr, obj])` returns the solution of the linear or mixed-integer program given by the constraints `constr` and the linear objective function `obj` which should be maximized.

The expression `obj` is the linear objective function to be maximized subject to the linear constraints `constr`. The function `linopt::maximize` returns a triple consisting of the state of the output, `OPTIMAL`, `EMPTY` or `UNBOUNDED`, a set of equations which describes the optimal solution of the specified linear program, which is empty or depends on a free variable  $\Phi$  subject to the state, and finally the maximal objective function value, which can be either a number, `-infinity` or a linear function in  $\Phi$ .

The states `OPTIMAL`, `EMPTY` or `UNBOUNDED` have the following meanings. `OPTIMAL` means an optimal solution for the linear program was found. If the state is `EMPTY` no optimal solution was found and if it is `UNBOUNDED` then the solution has no upper bound.

If the option `NonNegative` is used all variables are constrained to be nonnegative. If instead of `NonNegative` a set `setn` is given then only the variables from `setn` are constrained to be nonnegative.

If the option `All` is used all variables are constrained to be integers. If instead of `All` a set `seti` is given, then only the variables from `seti` are constrained to be integers.

As a second parameter for `linopt::maximize` the option `DualPrices` is provided for the linear case (the first parameter therefore must not have more than three elements). This option causes the output of the

dual-prices in addition to the solution-triplet. In this case the result of `linopt::maximize` is a sequence of a list containing the solution-triplet and a set containing the dual prices. See “Example 4” on page 15-8.

## Examples

### Example 1

We try to solve the linear program

$$\begin{aligned}2 c_1 &\leq 1 \\2 c_2 &\leq 1\end{aligned}$$

with the linear objective function  $c_1 + 2c_2$ :

```
linopt::maximize([{2*c1 <= 1, 2*c2 <= 1}, c1 + 2*c2])
```

```
[OPTIMAL, {c1 = 1/2, c2 = 1/2}, 3/2]
```

### Example 2

Now let's have a look at the linear program

$$\begin{aligned}3 x + 4 y - 3 z &\leq 23 \\5 x - 4 y - 3 z &\leq 10 \\7 x + 4 y + 11 z &\leq 30\end{aligned}$$

with the linear objective function  $-x + y + 2z$ . If we make no restriction to the variables the result is unbounded:

```
c := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
 7*x + 4*y + 11*z <= 30}, -x + y + 2*z]:
linopt::maximize(c)
```

# linopt::maximize

---

$$\left[ \text{UNBOUNDED}, \left\{ x = -\text{PHI1}, y = 0, z = \frac{7 \text{PHI1}}{11} + \frac{30}{11} \right\}, \frac{25 \text{PHI1}}{11} + \frac{60}{11} \right]$$

But if all variables are constrained to be nonnegative, we get a result. That's also the case if only x and y are constrained to be nonnegative:

```
linopt::maximize(append(c, NonNegative));
linopt::maximize(append(c, {x, y}))
```

$$\left[ \text{OPTIMAL}, \left\{ x = 0, y = \frac{49}{8}, z = \frac{1}{2} \right\}, \frac{57}{8} \right]$$

$$\left[ \text{OPTIMAL}, \left\{ x = 0, y = \frac{49}{8}, z = \frac{1}{2} \right\}, \frac{57}{8} \right]$$

```
delete c:
```

### Example 3

The following linear program do not have a solution:

```
linopt::maximize([x <= -1, x >= 0], x)
```

$$[\text{EMPTY}, \emptyset, -\infty]$$

### Example 4

The output of the dual prices can be enforced with the option DualPrices:

```
linopt::maximize([2*c1 <= 1, 2*c2 <= 1], c1 + 2*c2),
 DualPrices)
```

```
[OPTIMAL, {c1 = 1/2, c2 = 1/2}, 3/2], {[c1 ≤ 1/2, 1], [c2 ≤ 1/2, 2]}
```

## Example 5

We have a look at the knapsack problem with  $x_1, x_2, x_3, x_4 \in \{0, 1\}$ :

```
c := {20*x1 + 15*x2 + 20*x3 + 5*x4 <= 25}:
c := c union {x1 <= 1, x2 <= 1, x3 <= 1, x4 <= 1}:
f := 10*x1 + 15*x2 + 16*x3 + x4:
linopt::maximize([c, f, NonNegative, All])
```

```
[OPTIMAL, {x1 = 0, x2 = 0, x3 = 1, x4 = 1}, 17]
```

```
delete c, f:
```

## Parameters

### constr

A set or list of linear constraints

### obj

A linear expression

### seti

A set which contains identifiers interpreted as indeterminates

### setn

A set which contains identifiers interpreted as indeterminates

## Options

### All

All variables are constrained to be integers

### NonNegative

All variables are constrained to be nonnegative

### DualPrices

# linopt::maximize

---

This option is only available in the linear case. It causes the output of the dual-prices in addition to the solution-triple.

## Return Values

List or a sequence of a list and a set containing the solution of the linear or mixed-integer program.

linopt::minimize([constr, obj, <set>], DualPrices)
```

## Description

`linopt::minimize([constr, obj])` returns the solution of the linear or mixed-integer program given by the constraints `constr` and the linear objective function `obj` which should be minimized.

The expression `obj` is the linear objective function to be minimized subject to the linear constraints `constr`. The function `linopt::minimize` returns a triple consisting of the state of the output, `OPTIMAL`, `EMPTY` or `UNBOUNDED`, a set of equations which describes the optimal solution of the specified linear program, which is empty or depends on a free variable  $\Phi$  subject to the state, and finally the minimal objective function value, which can be either a number, infinity or a linear function in  $\Phi$ .

The states `OPTIMAL`, `EMPTY` or `UNBOUNDED` have the following meanings. `OPTIMAL` means an optimal solution for the linear program was found. If the state is `EMPTY` no optimal solution was found and if it is `UNBOUNDED` then the solution has no upper bound.

If the option `NonNegative` is used all variables are constrained to be nonnegative. If instead of `NonNegative` a set `setn` is given then only the variables from `setn` are constrained to be nonnegative.

If the option `All` is used all variables are constrained to be integers. If instead of `All` a set `seti` is given, then only the variables from `seti` are constrained to be integers.

As a second parameter for `linopt::minimize` the option `DualPrices` is provided for the linear case (the first parameter therefore must not have more than three elements). This option causes the output of the

# linopt::minimize

---

dual-prices in addition to the solution-triplet. In this case the result of `linopt::minimize` is a sequence of a list containing the solution-triplet and a set containing the dual prices. See “Example 4” on page 15-13.

## Examples

### Example 1

We try to solve the linear program

$$\begin{aligned}c_1 + c_2 &\leq 3 \\c_2 &\leq 9\end{aligned}$$

with the linear objective function  $-c_1 - c_2$ :

```
linopt::minimize([c1 + c2 <= 3, c2 <= 9], -c1 - c2)
```

```
[OPTIMAL, {c1 = 0, c2 = 3}, -3]
```

### Example 2

Now let's have a look at the linear program

$$\begin{aligned}3x + 4y - 3z &\leq 23 \\5x - 4y - 3z &\leq 10 \\7x + 4y + 11z &\leq 30\end{aligned}$$

with the linear objective function  $-x + y + 2z$ . If we make no restriction to the variables the result is unbounded:

```
c := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
 7*x + 4*y + 11*z <= 30}, -x + y + 2*z]:
linopt::minimize(c)
```

```
[UNBOUNDED, {y = -PHI1, x = -4 PHI1 - 13/2, z = -16 PHI1/3 - 85/8}, -23 PHI1/3 - 131/8]
```

But if all variables are constrained to be nonnegative, we get a result. That's also the case if only x and y are constrained to be nonnegative:

```
linopt::minimize(append(c, NonNegative));
linopt::minimize(append(c, {x, y}))
```

```
[OPTIMAL, {x = 2, y = 0, z = 0}, -2]
```

```
[OPTIMAL, {x = 0, y = 13/8, z = -11/2}, -75/8]
```

```
delete c:
```

### Example 3

The following linear program does not have a solution:

```
linopt::minimize([x <= -1, x >= 0], x)
```

```
[EMPTY, {}, ∞]
```

### Example 4

The output of the dual prices can be enforced with the option DualPrices:

```
linopt::minimize([c1 + c2 <= 3, c2 <= 9], -c1 - c2,
 DualPrices)
```

```
[OPTIMAL, {c1 = 0, c2 = 3}, -3], {[c1 + c2 ≤ 3, 1], [c2 ≤ 9, 0]}
```

# linopt::minimize

---

## Parameters

### **constr**

A set or list of linear constraints

### **obj**

A linear expression

### **seti**

S set which contains identifiers interpreted as indeterminates

### **setn**

A set which contains identifiers interpreted as indeterminates

## Options

### **All**

All variables are constrained to be integer

### **NonNegative**

All variables are constrained to be nonnegative

### **DualPrices**

This option is only available in the linear case. It causes the output of the dual-prices in addition to the solution-triplet.

## Return Values

List or a sequence of a list and a set containing the solution of the linear or mixed-integer program.

## MuPAD Functions

`linopt::maximize` | `linopt::plot_data` | `linopt::corners`

# linopt::plot\_data

---

**Purpose** Plot the feasible region of a linear program

**Syntax**

```
linopt::plot_data([constr, obj, <NonNegative>,
<seti>], vars)
linopt::plot_data([constr, obj, <NonNegative>,
<All>], vars)
linopt::plot_data([constr, obj, <setn>, <seti>], vars)
linopt::plot_data([constr, obj, <setn>, <All>], vars)
```

**Description** `linopt::plot_data([constr, obj], vars)` returns a graphical description of the feasible region of the linear program `[constr, obj]`, and the line vertical to the objective function vector through the corner with the maximal objective function value found.

`[constr, obj]` is a linear program with exactly two variables. The problem has the same structure like in `linopt::maximize`. The second parameter `vars` specifies which variable belongs to the horizontal and vertical axis.

## Examples **Example 1**

We plot the feasible region of the given linear program. Here the valid corners of the linear program are easy to see:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8,
 -2*x + y <= -2, y <= 6}, x + y, NonNegative]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```

In this example there is no difference if the Option NonNegative is given for the linear program or not:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8,
 -2*x + y <= -2, y <= 6}, x + y]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```

# linopt::plot\_data

```
delete k, g:
```

## Example 2

Now we give an example where one can see a difference if the variables are constrained to be nonnegative:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```

# linopt::plot\_data

delete k, g:

## Parameters

### **constr**

A set or list of linear constraints

### **obj**

A linear expression

### **seti**

A set which contains identifiers interpreted as indeterminates

### **setn**

A set which contains identifiers interpreted as indeterminates

### **vars**

A list containing the two variables of the linear program described by **constr** and **obj** and the existing options

## Options

### All

All variables are constrained to be integer

### NonNegative

All variables are constrained to be nonnegative

## Return Values

Expression describing a graphical object which can be used by plot.

## MuPAD Functions

`linopt::maximize` | `linopt::minimize` | `linopt::corners`

# linopt::Transparent

---

**Purpose** Return the ordinary simplex tableau of a linear program

**Syntax**

```
linopt::Transparent([constr, obj, <NonNegative>, <seti>])
linopt::Transparent([constr, obj, <NonNegative>, <All>])
linopt::Transparent([constr, obj, <setn>, <seti>])
linopt::Transparent([constr, obj, <setn>, <All>])
```

**Description** `linopt::Transparent([constr, obj])` returns the ordinary simplex tableau of the given linear program given by the constraints `constr` and the linear objective function `obj`.

`[constr, obj]` is a Linear Optimization Problem of the same structure like in `linopt::maximize`. As the result the ordinary simplex tableau of the given problem is returned; this means that equations will be replaced by two unequations and unbounded variables will be replaced by two new variables.

Internally the tableau returned consists of more information than viewable on the screen. Therefore `linopt::Transparent::convert` is provided to perform the transduction into the structure of the screen-tableau. (This can be necessary if the returned tableau shall serve as an input-parameter for another function — e.g. a user defined procedure for the selection of pivot elements.) If an ordinary simplex with two phases is wished, the next step should be the call of `linopt::Transparent::phaseI_tableau`.

All functions of the `linopt` library using the tableau returned by `linopt::Transparent` try to minimize the problem! Therefore it can be necessary to multiply the objective function with `-1` first.

In the simplex tableau returned a special notation is used. "linopt" stands for the tableau them self, "obj" describes the linear objective function, "restr" stands for the vector of restrictions, `slk[1]`, `slk[2]`, ... are the slack variables and the names of the other variables stand for themselves. Variables which are given as row labels indicate that they are part of the base.

## Examples

### Example 1

First a small example, returning the ordinary simplex tableau of the given linear program. One can see that the slack variables are forming the basis:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & y & x \\ \text{"obj"} & & 0 & 0 & 0 & 2 & 1 \\ \text{slk}_1 & & 1 & 1 & 0 & -1 & -1 \\ \text{slk}_2 & & 3 & 0 & 1 & 1 & 1 \end{pmatrix}$$

It follows a little bit larger example:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
 7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x & z \\ \text{"obj"} & & 0 & 0 & 0 & 0 & 1 & -1 & 2 \\ \text{slk}_1 & & 23 & 1 & 0 & 0 & 4 & 3 & -3 \\ \text{slk}_2 & & 10 & 0 & 1 & 0 & -4 & 5 & -3 \\ \text{slk}_3 & & 30 & 0 & 0 & 1 & 4 & 7 & 11 \end{pmatrix}$$

The result of `linopt::Transparent` is of domain type `linopt::Transparent`. So it can be used as input for other `linopt::Transparent::*` function, e.g. for `linopt::Transparent::suggest`:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
t := linopt::Transparent(k):
domtype(t), linopt::Transparent::suggest(t)
```

# linopt::Transparent

---

`linopt::Transparent, OPTIMAL`

`delete k, t:`

## Parameters

**constr**

A set or list of linear constraints

**obj**

A linear expression

**seti**

A set which contains identifiers interpreted as indeterminates

**setn**

A set which contains identifiers interpreted as indeterminates

## Options

**All**

All variables are constrained to be integer

**NonNegative**

All variables are constrained to be nonnegative

## Return Values

Simplex tableau of domain type `linopt::Transparent`.

### MuPAD Functions

```
linopt::Transparent::autostep |
linopt::Transparent::convert |
linopt::Transparent::dual_prices |
linopt::Transparent::phaseI_tableau |
linopt::Transparent::phaseII_tableau |
linopt::Transparent::result | linopt::Transparent::simplex
| linopt::Transparent::suggest |
linopt::Transparent::userstep
```

# linopt::Transparent::autostep

---

**Purpose** Perform the next simplex step

**Syntax** `linopt::Transparent::autostep(tableau)`

**Description** `linopt::Transparent::autostep(tableau)` performs the next step of the simplex algorithm. This is the same step that `linopt::Transparent::suggest` would suggest for the given simplex tableau `tableau`.

Normally `linopt::Transparent::autostep` returns the next simplex tableau. If the calculation of the simplex algorithm is finished `linopt::Transparent::autostep` returns a set containing a solution of the given linear program described by `tableau`.

## Examples

### Example 1

The ordinary simplex tableau of a given linear program is created:

```
k := [{x + y >= 2}, x, NonNegative]:
t := linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

The next two steps of the simplex algorithm are executed for the given simplex tableau:

```
linopt::Transparent::autostep(t);
linopt::Transparent::autostep(%)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & -2 & 1 & -1 & 0 \\ x & 2 & -1 & 1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

delete k, t:

## Example 2

The ordinary simplex tableau of a given linear program is created:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
t := linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 2 & 1 \\ \text{slk}_1 & 1 & 1 & 0 & -1 & -1 \\ \text{slk}_2 & 3 & 0 & 1 & 1 & 1 \end{pmatrix}$$

If the end of the simplex algorithm is reached,  
linopt::Transparent::autostep returns a solution of the given  
linear program:

```
linopt::Transparent::suggest(t),
linopt::Transparent::autostep(t)
```

OPTIMAL, {x = 0, y = 0}

delete k, t:

## Parameters

### tableau

A simplex tableau of domain type linopt::Transparent

# linopt::Transparent::autostep

---

## Return Values

Simplex tableau of domain type `linopt::Transparent` or a set which contains the solution of the linear program.

## References

## MuPAD Functions

```
linopt::Transparent | linopt::Transparent::convert
| linopt::Transparent::dual_prices |
linopt::Transparent::phaseI_tableau |
linopt::Transparent::result | linopt::Transparent::simplex
| linopt::Transparent::suggest |
linopt::Transparent::userstep
```

**Purpose** Delete all slack variables of the first phase from the basis

**Syntax** `linopt::Transparent::clean_basis(tableau)`

**Description** `linopt::Transparent::clean_basis(tableau)` removes the additional slack variables of the phase one of the simplex algorithm from the optimal basic (described by `tableau`) calculated by `linopt::Transparent::phaseI_tableau` and `linopt::Transparent::simplex`.

At the end of the phase one of the 2-phase simplex algorithm, explicitly started by using `linopt::Transparent::phaseI_tableau`, it is necessary to eliminate all artificial variables from the optimal basis before phase two can be started by using `linopt::Transparent::phaseII_tableau`. `linopt::Transparent::clean_basis` performs some pivot steps until all phase one slack variables do not occur in the basis any longer.

## Examples **Example 1**

In this example we first compute an optimal basis for the first phase of the simplex algorithm:

```
t := linopt::Transparent([{x <= 1,y <= 1,x + y >= 2},
 0,NonNegative]):
t := linopt::Transparent::phaseI_tableau(t):
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_4 & \text{slk}_5 & \text{slk}_6 & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & & 0 & 2 & 2 & 0 & 1 & 1 & 1 & 0 & 0 \\ x & & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ y & & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_6 & & 0 & -1 & -1 & 1 & -1 & -1 & -1 & 0 & 0 \end{pmatrix}$$

# linopt::Transparent::clean\_basis

---

As we can see the artificial slack variable `slk[6]` is an element of the optimal basis. An error message is returned if we apply `linopt::Transparent::phaseII_tableau` or `linopt::Transparent::simplex` to this simplex tableau:

```
linopt::Transparent::phaseII_tableau(t);
```

```
Error: Clean the basis from phase I slack variables first. [linopt:
```

So we have to use `linopt::Transparent::clean_basis` before continuing with the appropriate function:

```
t := linopt::Transparent::clean_basis(t);
linopt::Transparent::phaseII_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_4 & \text{slk}_5 & \text{slk}_6 & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ x & & 1 & 0 & -1 & 1 & 0 & -1 & -1 & 0 \\ y & & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ \text{slk}_1 & & 0 & 1 & 1 & -1 & 1 & 1 & 1 & 0 \end{pmatrix}$$
$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & & 0 & 0 & 0 & 0 & 0 \\ x & & 1 & 0 & -1 & -1 & 0 \\ y & & 1 & 0 & 1 & 0 & 1 \\ \text{slk}_1 & & 0 & 1 & 1 & 1 & 0 \end{pmatrix}$$

```
delete t;
```

## Parameters `tableau`

A simplex tableau of domain type `linopt::Transparent`

## Return Values

Simplex tableau of domain type `linopt::Transparent`.

`linopt::Transparent::userstep`

# linopt::Transparent::convert

---

**Purpose** Transform the given tableau into a structure printable on screen

**Syntax** `linopt::Transparent::convert(tableau)`

**Description** `linopt::Transparent::convert` converts `tableau` into a two dimensional array which corresponds with the screen-tableau. One can now access the element in the  $i$ -th row and  $j$ -th column of the simplex tableau by accessing the corresponding element of the array.

Internally the given `tableau` of domain type `linopt::Transparent` contains a lot of more information than the simplex tableau which is printed by some functions of the `linopt` library, e.g. `linopt::Transparent::simplex`, and which is visible on the screen. Furthermore it is not possible to access the element in the  $i$ -th row and  $j$ -th column of `tableau` to get the corresponding element from the simplex tableau which is visible on the screen.

While the internal structure of `tableau` is not known the structure of the two dimensional array is well defined. So it can be easily used in own procedures. See "Example 2" on page 15-33.

## Examples

### Example 1

We convert a simplex tableau of domain type `linopt::Transparent` into a two dimensional array:

```
k := [{x + y >= 2}, x, NonNegative]:
t := linopt::Transparent(k):
a := linopt::Transparent::convert(t):
t, domtype(t);
a, domtype(a)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}, \text{linopt::Transparent}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}, \text{DOM\_ARRAY}$$

delete a, k, t:

## Example 2

We will write another simplex routine `mysimplex` for solving a linear program. For this we define the function `eigenpivot` for finding the pivot element of a given simplex tableau. `eigenpivot` assumes that the simplex tableau is given as a two dimensional array.

Here is the procedure `eigenpivot`, which is not coded in every detail, e.g., the error checking isn't implemented completely:

```
eigenpivot := proc(T: DOM_ARRAY)
 local i,j,m,n,k,l,mini;
 begin
 m := op(T,[0,2,2]):
 n := op(T,[0,3,2]):
 k := 0:
 l := 0:
 mini := unbesetzt:

 for j from 3 to n do
 if T[2,j] < 0 then
 l := j:
 break
 end_if:
 end_for:
 if l=0 then return(OPTIMAL) end_if:
 for i from 3 to m do
 if T[i,l] > 0 and (mini=unbesetzt or T[i,2]/T[i,l] < mini)
 k := i:
 mini := T[k,2]/T[k,l]
 end_if
 end_for
 end
end
```

## linopt::Transparent::convert

---

```
 end_for:
 if k=0 then return(UNBOUNDED) end_if:
 return(T[k,1],T[1,1]):
end_proc:
```

This is the new simplex algorithm `mysimplex` which uses `eigenpivot` and some function from the `linopt` library:

```
mysimplex := proc(P)
 local T;
 begin
 T := linopt::Transparent(P):
 T := linopt::Transparent::phaseI_tableau(T):
 piv := eigenpivot(linopt::Transparent::convert(T)):
 while piv <> OPTIMAL and piv <> UNBOUNDED do
 T := linopt::Transparent::userstep(T,piv):
 piv := eigenpivot(linopt::Transparent::convert(T))
 end_while:

 if piv = UNBOUNDED then
 error(" Phase I unbounded !?")
 end_if:
 if T[2,2] <> 0
 then return(EMPTY)
 end_if:
 T := linopt::Transparent::clean_basis(T):

 T := linopt::Transparent::phaseII_tableau(T):
 piv := eigenpivot(linopt::Transparent::convert(T)):
 while piv <> OPTIMAL and piv <> UNBOUNDED do
 T := linopt::Transparent::userstep(T,piv):
 piv := eigenpivot(linopt::Transparent::convert(T))
 end_while:

 if piv = OPTIMAL
 then return(linopt::Transparent::result(T))
 else return(UNBOUNDED)
 end_if:
 end:
end:
```

```
 end_if
end_proc:
```

We now apply `mysimplex` to a linear program:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8,
 -2*x + y <= -2, y <= 6}, -x - y]:
k := append(k, NonNegative):
mysimplex(k);
```

```
{x = 7, y = 6}
```

```
delete k, eigenpivot, mysimplex:
```

## Parameters

### **tableau**

A simplex tableau of domain type

## Return Values

Two dimensional array, representing the given simplex tableau tableau.

### MuPAD Functions

```
linopt::Transparent | linopt::Transparent::autostep
| linopt::Transparent::phaseI_tableau
| linopt::Transparent::phaseII_tableau
| linopt::Transparent::suggest |
linopt::Transparent::userstep
```

**Purpose** Get the dual solution belonging to the given tableau

**Syntax** `linopt::Transparent::dual_prices(tableau)`

**Description** `linopt::Transparent::dual_prices(tableau)` returns the dual solution of the linear optimization problem given by `tableau`.

This procedure returns the dual solution belonging to the given tableau in form of a set of lists containing two elements, the first one is a restriction and the second one is the value belonging to the slack variable connected to the restriction in the dual solution.

## Examples **Example 1**

Here it is demonstrated that the dual solution of the final tableau is similar to the second element of the result of `linopt::minimize` using the option `DualPrices`:

First we compute the final tableau of the simplex algorithm:

```
k := [{x <= 2, y <= 2, x + 2*y >= 4}, - x + y, NonNegative]:
t := linopt::Transparent(k):
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 1 & \frac{3}{2} & 0 & \frac{1}{2} & 0 & 0 \\ x & 2 & 1 & 0 & 0 & 0 & 1 \\ \text{slk}_2 & 1 & \frac{1}{2} & 1 & \frac{1}{2} & 0 & 0 \\ y & 1 & -\frac{1}{2} & 0 & -\frac{1}{2} & 1 & 0 \end{pmatrix}$$

Now we compute the solutions:

```
linopt::Transparent::dual_prices(t);
linopt::minimize(k, DualPrices)[2]
```

# linopt::Transparent::dual\_prices

---

$$\left\{ \left[ 4 \leq x + 2y, \frac{1}{2} \right], [0 \leq x, 0], \left[ x \leq 2, \frac{3}{2} \right], [0 \leq y, 0], [y \leq 2, 0] \right\}$$

$$\left\{ \left[ 4 \leq x + 2y, \frac{1}{2} \right], [0 \leq x, 0], \left[ x \leq 2, \frac{3}{2} \right], [0 \leq y, 0], [y \leq 2, 0] \right\}$$

```
delete k, t:
```

## Example 2

We compute the dual solution of another linear program:

```
k := [{x <= 2, y <= 2, x + 2*y >= 4}, -x + y, NonNegative]:
t := linopt::Transparent(k);
linopt::Transparent::dual_prices(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & & 0 & 0 & 0 & 1 & -1 \\ \text{slk}_1 & & 2 & 1 & 0 & 0 & 1 \\ \text{slk}_2 & & 2 & 0 & 1 & 0 & 1 \\ \text{slk}_3 & & -4 & 0 & 0 & 1 & -2 \end{pmatrix}$$

$$\left\{ \left[ 4 \leq x + 2y, 0 \right], [0 \leq x, -1], [x \leq 2, 0], [0 \leq y, 1], [y \leq 2, 0] \right\}$$

```
delete k, t:
```

## Parameters

**tableau**

A simplex tableau of domain type `linopt::Transparent`

## Return Values

Set of lists, each containing 2 elements.

## MuPAD Functions

`linopt::Transparent` | `linopt::Transparent::result`

# linopt::Transparent::phaseI\_tableau

---

**Purpose** Start an ordinary phase one of a 2-phase simplex algorithm

**Syntax** `linopt::Transparent::phaseI_tableau(tableau)`

**Description** `linopt::Transparent::phaseI_tableau` explicitly starts an (ordinary) phase one of the simplex algorithm, i.e. rows associated with infeasible basic variables are multiplied with -1 and another identity matrix with new slack variables is added to the given tableau. As soon as an optimal tableau with relative costs 0 is found the calculation can be continued with `linopt::Transparent::clean_basis` and the second phase of the simplex algorithm (`linopt::Transparent::phaseII_tableau`).

## Examples **Example 1**

The first simplex tableau is created and the first phase of the simplex algorithm is started:

```
t := linopt::Transparent([{x + y >= 2}, x, NonNegative]);
t := linopt::Transparent::phaseI_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & & 0 & 0 & 0 & 1 \\ \text{slk}_1 & & -2 & 1 & -1 & -1 \end{pmatrix}$$
$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & & -2 & 0 & 1 & -1 & -1 \\ \text{slk}_2 & & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

We can see that a new slack variable,  $slk_2$ , was added to the tableau. And if we now execute `linopt::Transparent::simplex` we can see that we have just finished the first phase of the simplex algorithm:

```
linopt::Transparent::suggest(t);
```

```
t := linopt::Transparent::simplex(t):
linopt::Transparent::suggest(t)
```

```
slk2, y
```

```
"linopt::Transparent::phaseII_tableau"
```

We continue the simplex algorithm by executing `linopt::Transparent::clean_basis`, `linopt::Transparent::phaseII_tableau` and `linopt::Transparent::simplex`. Observe in this special case `linopt::Transparent::clean_basis` is not necessary:

```
t := linopt::Transparent::clean_basis(t):
t := linopt::Transparent::phaseII_tableau(t):
t := linopt::Transparent::simplex(t);
linopt::Transparent::suggest(t)
```

```
("linopt" "restr" slk1 y x
 "obj" 0 0 0 1
 y 2 -1 1 1)
```

```
OPTIMAL
```

```
delete t:
```

## Parameters

**tableau**

A simplex tableau of domain type `linopt::Transparent`

## Return Values

Simplex tableau of domain type `linopt::Transparent`.

# linopt::Transparent::phasel\_tableau

---

## MuPAD Functions

```
linopt::Transparent | linopt::Transparent::autostep
| linopt::Transparent::convert |
linopt::Transparent::clean_basis |
linopt::Transparent::dual_prices |
linopt::Transparent::phaseII_tableau |
linopt::Transparent::result | linopt::Transparent::simplex
| linopt::Transparent::suggest |
linopt::Transparent::userstep
```

**Purpose** Start phase two of a 2-phase simplex algorithm

**Syntax** `linopt::Transparent::phaseII_tableau(tableau)`

**Description** `linopt::Transparent::phaseII_tableau(tableau)` starts the second phase of the simplex algorithm on the given simplex tableau `tableau`.

After the explicitly started first phase of the simplex algorithm (see `linopt::Transparent::phaseI_tableau`) terminated with an optimal tableau with associated costs 0 and no phase one slack variables in the basis (see `linopt::Transparent::clean_basis`) this procedure can be used to start phase II. The procedure eliminates all artificial variables of phase I and their associated columns and reenters the old objective function modified for the new basis.

## Examples **Example 1**

The first simplex tableau is created and the first phase of the simplex algorithm is finished:

```
t := linopt::Transparent([{x + y >= 2}, x, NonNegative]):
t := linopt::Transparent::simplex(
 linopt::Transparent::phaseI_tableau(t))
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & & 0 & 1 & 0 & 0 & 0 \\ y & & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

One sees that the artificial slack variable `slk[2]` of the first phase is removed by `linopt::Transparent::phaseII_tableau`. In this example it is not necessary to use `linopt::Transparent::clean_basis` for cleaning the basis:

```
linopt::Transparent::phaseII_tableau(t)
```

# linopt::Transparent::phasell\_tableau

---

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

```
delete t:
```

## Example 2

Again the first simplex tableau is created and the first phase of the simplex algorithm is finished:

```
t := linopt::Transparent([{x <= 1, y <= 1, x + y >= 2},
 0, NonNegative]):
t := linopt::Transparent::phaseI_tableau(t):
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_4 & \text{slk}_5 & \text{slk}_6 & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 2 & 2 & 0 & 1 & 1 & 1 & 0 & 0 \\ x & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ y & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_6 & 0 & -1 & -1 & 1 & -1 & -1 & -1 & 0 & 0 \end{pmatrix}$$

In this example the artificial slack variable `slk[6]` is an element of the optimal basis. So we have to use `linopt::Transparent::clean_basis` before continuing with `linopt::Transparent::phaseII_tableau`, otherwise we will get an error message:

```
linopt::Transparent::phaseII_tableau(t)
```

```
Error: Clean the basis from phase I slack variables first. [linopt:
```

```
t := linopt::Transparent::clean_basis(t):
linopt::Transparent::phaseII_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 0 & 0 & 0 \\ x & 1 & 0 & -1 & -1 & 0 & 1 \\ y & 1 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_1 & 0 & 1 & 1 & 1 & 0 & 0 \end{pmatrix}$$

`delete t:`

## Parameters

**tableau**

A simplex tableau of domain type `linopt::Transparent`

## Return Values

Simplex tableau of domain type `linopt::Transparent`.

linopt::Transparent::clean\_basis |  
linopt::Transparent::dual\_prices |  
linopt::Transparent::phaseI\_tableau |  
linopt::Transparent::result | linopt::Transparent::simplex  
| linopt::Transparent::suggest |  
linopt::Transparent::userstep

<b>Purpose</b>	Get the basic feasible solution belonging to the given simplex tableau
<b>Syntax</b>	<code>linopt::Transparent::result(tableau)</code>
<b>Description</b>	<code>linopt::Transparent::result(tableau)</code> returns the basic feasible solution belonging to the given simplex tableau <code>tableau</code> . Only the user defined variables are taken into account - the dual prices can be achieved by use of <code>linopt::Transparent::dual_prices</code> .

## Examples

### Example 1

We first compute an edge for an initial simplex tableau:

```
k := [{x <= 1, y <= 1, x + y >= 2}, 0, NonNegative]:
t := linopt::Transparent(k):
linopt::Transparent::result(t)
```

```
{x = 0, y = 0}
```

Now we compute the edge for the final tableau, which is identical to the optimal solution of the linear program given by `k`. We get the final simplex tableau by using `linopt::Transparent::simplex`:

```
t := linopt::Transparent(k):
t := linopt::Transparent::simplex(t):
linopt::Transparent::result(t)
```

```
{x = 1, y = 1}
```

```
linopt::minimize(k)
```

```
[OPTIMAL, {x = 1, y = 1}, 0]
```

# linopt::Transparent::result

---

delete k, t:

## Parameters

**tableau**

A simplex tableau of domain type `linopt::Transparent`

## Return Values

Set containing the values of the user defined variables for the feasible solution.

## See Also

## MuPAD Functions

`linopt::Transparent` | `linopt::Transparent::dual_prices`

## Purpose

Finish the current phase of the 2-phase simplex algorithm

## Syntax

```
linopt::Transparent::simplex(tableau)
```

## Description

`linopt::Transparent::simplex` runs the current phase of the 2-phase simplex algorithm until the end, i.e. if phase I was explicitly started (see `linopt::Transparent::phaseI_tableau`) the first phase will lead the optimal tableau. Sometimes it can be necessary to eliminate some slack variables of phase one by using `linopt::Transparent::clean_basis`.

If there was no phase I started by the user, `(linopt::Transparent)::simplex` returns the last optimal tableau or the empty set if there was no feasible solution found.

## Examples

### Example 1

We apply `linopt::Transparent::simplex` to an ordinary simplex tableau of a linear program and we get the optimal tableau:

```
k := [{x + y >= 2}, x, NonNegative]:
t := linopt::Transparent(k);
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

Let us proof the obtained result:

```
linopt::Transparent::suggest(t)
```

# linopt::Transparent::simplex

---

OPTIMAL

```
delete k, t:
```

## Example 2

If the first phase of the simplex algorithm was started explicitly, `linopt::Transparent::simplex` returns only the optimal tableau of the first phase:

```
k := [{x + y >= 2}, y, NonNegative]:
t := linopt::Transparent(k):
t := linopt::Transparent::phaseI_tableau(t);
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & & -2 & 0 & 1 & -1 & -1 \\ \text{slk}_2 & & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$
$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & & 0 & 1 & 0 & 0 & 0 \\ y & & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

The next step of the simplex algorithm is computed:

```
linopt::Transparent::suggest(t)
```

```
"linopt::Transparent::phaseII_tableau"
```

With `linopt::Transparent::autostep` we execute the first step of the second phase of the simplex algorithm. One can see that the simplex algorithm is not finished yet:

```
t := linopt::Transparent::autostep(t):
linopt::Transparent::suggest(t);
```

*y, x*

If we then apply `linopt::Transparent::simplex` again we get the optimal solution. Here we don't had to use `linopt::Transparent::clean_basis`, before using `linopt::Transparent::autostep`, because there are no artificial variables in the basis computed by the first `linopt::Transparent::simplex` call above:

```
t := linopt::Transparent::simplex(t);
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 1 & 0 \\ x & 2 & -1 & 1 & 1 \end{pmatrix}$$

OPTIMAL

```
delete k, t:
```

## Parameters

**tableau**

A simplex tableau of domain type `linopt::Transparent`

## Return Values

Simplex tableau of domain type `linopt::Transparent` or the empty set if there was no feasible solution found.

### MuPAD Functions

```
linopt::Transparent | linopt::Transparent::autostep
| linopt::Transparent::convert |
linopt::Transparent::dual_prices |
linopt::Transparent::phaseI_tableau |
linopt::Transparent::result | linopt::Transparent::suggest
| linopt::Transparent::userstep
```

**Purpose** Suggest the next step in the simplex algorithm

**Syntax** `linopt::Transparent::suggest(tableau)`

**Description** `linopt::Transparent::suggest(tableau)` suggests the next step in the simplex algorithm for the given simplex tableau `tableau`.

Normally this suggestion will be a pivot element, i.e. a sequence of a basic and a non-basic variable. If a phase I of the 2-phase simplex algorithm was started explicitly (see `linopt::Transparent::phaseI_tableau`) and the current tableau belongs to a feasible solution the suggestion will be the string `"linopt::Transparent::phaseII_tableau"`. At the end of the calculation the 'suggestion' is the identifier `OPTIMAL`.

The result of `linopt::Transparent::suggest` can be influenced if the global identifier `OPTIMAL` has a value. For this reason the identifier `OPTIMAL` is protected.

## Examples **Example 1**

We have a look at a linear program where the ordinary simplex tableau of the given problem is not the last tableau during the computation of the simplex algorithm. Looking at the ordinary simplex tableau we see that the element of the `slk[2]`-labeled row and the `x`-labeled column is a pivot element:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
 7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative];
t := linopt::Transparent(k);
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x & z \\ \text{"obj"} & 0 & 0 & 0 & 0 & 1 & -1 & 2 \\ \text{slk}_1 & 23 & 1 & 0 & 0 & 4 & 3 & -3 \\ \text{slk}_2 & 10 & 0 & 1 & 0 & -4 & 5 & -3 \\ \text{slk}_3 & 30 & 0 & 0 & 1 & 4 & 7 & 11 \end{pmatrix}$$

# linopt::Transparent::suggest

---

slk<sub>2</sub>, x

```
delete k, t:
```

## Example 2

Here the ordinary simplex tableau still contains the solution of the linear program if the linear objective function is to minimize (see `linopt::Transparent` for more information):

```
k := [{x+y>=-1, x+y<=3}, x+2*y, NonNegative]:
t := linopt::Transparent(k);
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 2 & 1 \\ \text{slk}_1 & 1 & 1 & 0 & -1 & -1 \\ \text{slk}_2 & 3 & 0 & 1 & 1 & 1 \end{pmatrix}$$

OPTIMAL

```
delete k, t:
```

## Example 3

Here we explicitly start the first phase of the simplex algorithm. If we want a solution of the original linear program we have to apply the second phase of the simplex algorithm:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
 7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
t := linopt::Transparent(k):
t := linopt::Transparent::phaseI_tableau(t):
t := linopt::Transparent::simplex(t):
linopt::Transparent::suggest(t)
```

"linopt::Transparent::phaseII\_tableau"

delete k, t:

## Parameters

**tableau**

A simplex tableau of domain type `linopt::Transparent`

## Return Values

Sequence of 2 identifiers, the identifier `OPTIMAL` or the string `"linopt::Transparent::phaseII_tableau"`.

| `linopt::Transparent::convert` |  
`linopt::Transparent::dual_prices` |

# linopt::Transparent::suggest

---

```
linopt::Transparent::phaseI_tableau |
linopt::Transparent::result | linopt::Transparent::simplex
| linopt::Transparent::userstep
```

<b>Purpose</b>	Perform a user defined simplex step
<b>Syntax</b>	<code>linopt::Transparent::userstep(tableau, basvar, nonbasvar)</code>
<b>Description</b>	<code>linopt::Transparent::userstep(tableau, basvar, nonbasvar)</code> performs a user defined simplex step in the tableau with the pivot element defined by <code>basvar</code> and <code>nonbasvar</code> .
<b>Examples</b>	<b>Example 1</b>

We execute the simplex step given by the pivot element (`slk[1], x`):

```
k := [{x + y >= 2}, x, NonNegative]:
t:= linopt::Transparent(k);
linopt::Transparent::userstep(t, slk[1], x)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & & 0 & 0 & 0 & 1 \\ \text{slk}_1 & & -2 & 1 & -1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & & -2 & 1 & -1 & 0 \\ x & & 2 & -1 & 1 & 1 \end{pmatrix}$$

## Example 2

If we specify a wrong pivot element, we will get an error message:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
 7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
t:= linopt::Transparent(k);
linopt::Transparent::userstep(t, x, y)
```

# linopt::Transparent::userstep

---

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x & z \\ \text{"obj"} & 0 & 0 & 0 & 0 & 1 & -1 & 2 \\ \text{slk}_1 & 23 & 1 & 0 & 0 & 4 & 3 & -3 \\ \text{slk}_2 & 10 & 0 & 1 & 0 & -4 & 5 & -3 \\ \text{slk}_3 & 30 & 0 & 0 & 1 & 4 & 7 & 11 \end{pmatrix}$$

Error: The pivot element is not specified or specified incorrectly.

delete k, t:

## Parameters

### **tableau**

A simplex tableau of domain type `linopt::Transparent`

### **basvar**

A basic variable represented by an identifier that has to leave the basis

### **nonbasvar**

A non-basic variable represented by an identifier that has to enter the basis

## Return Values

Simplex tableau of domain type `linopt::Transparent`.

# listlib::insert

---

**Purpose** Insert an element into a list

**Syntax** `listlib::insert(list, element, <function>)`

**Description** `listlib::insert(list, element)` inserts `element` into `list`.

With the function `listlib::insert` any element can be inserted into any list.

With the third optional argument a function can be given that compare the elements of the list with the element to insert and therewith determines the position, the element is inserted. The given function is called with two elements and have to return `TRUE`, if the two elements are in the right order, otherwise `FALSE` (see next paragraph).

The given function is called step by step with an element of the list as first argument and the given element as second argument, until it returns `FALSE`. Then the given element is inserted into the list in *front* of the last proved element (see “Example 2” on page 16-3).

---

**Note** The list must be ordered with regard to the order function, otherwise the element could be inserted at the wrong place.

---

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

## Examples

### Example 1

Insert 3 into the given ordered list:

```
listlib::insert([1, 2, 4, 5, 6], 3)
```

```
[1, 2, 3, 4, 5, 6]
```

Insert 3 into the given descending ordered list. The insert function represents and preserves the order of the list:

```
listlib::insert([6, 5, 4, 2, 1], 3, _not@_less)
```

```
[6, 5, 4, 3, 2, 1]
```

Because identifiers cannot be ordered by `_less`, another function must be given, e.g., the function that represents the systems internal order:

```
listlib::insert([a, b, d, e, f], c, sysorder)
```

```
[a, b, c, d, e, f]
```

## Example 2

Because no function is given as third argument, the function `_less` is used. `_less` is called: `_less(1, 3)`, `_less(2, 3)`, `_less(4, 3)` and then 3 is inserted in front of 4:

```
listlib::insert([1, 2, 4], 3)
```

```
[1, 2, 3, 4]
```

If the list is not ordered right, then the insert position could be wrong:

```
listlib::insert([4, 1, 2], 3)
```

```
[3, 4, 1, 2]
```

## Example 3

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`,

# listlib::insert

---

which returns a smaller number, when the expression has a type with higher priority:

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X)):
priority(x^2), priority(x + 2)
```

1, 3

The function `sortfunc` returns `TRUE`, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x*2)
```

TRUE, FALSE

Now the expression `x*2` is inserted at the “right” place in the list:

```
listlib::insert([x^y, x^2, x*y, -y, x + y], x*2, sortfunc)
```

$[x^y, x^2, 2x, xy, -y, x + y]$

## Parameters

### list

MuPAD list

### element

MuPAD expression to insert

### function

Function that determines the insert position

**Return Values**

Given list enlarged with the inserted element

**See Also****MuPAD Functions**

`_concat` | `append` | `listlib::insertAt`

# listlib::insertAt

---

**Purpose** Insert an element into a list at a given position

**Syntax** `listlib::insertAt(list, element, <pos>)`

**Description** `listlib::insertAt(list, element, pos)` inserts `element` into `list` at position `pos`.

With the function `listlib::insertAt` any element can be inserted into any list at a specified place.

The third argument (the “insert index”) determines the place to insert the element into the given list.

If the insert index is less than 1 the element is inserted in front of the list. If the insertion index is greater than `nops(list)` the element is appended to the list. To append an element to a list the kernel function `append` is faster.

If no third argument is given, the given element is inserted in front of the list.

If the argument `element` is a list too, the elements of this list will be inserted (or appended) instead of the whole list by preserving the order.

## Examples

### Example 1

Insertion 2 at the third place of the given list:

```
listlib::insertAt([1, 1, 1], 2, 3)
```

```
[1, 1, 2, 1]
```

Insertion of an element in front of a list. The third argument is optional in this case:

```
listlib::insertAt([1, 1, 3, 1], 2, 0), listlib::insertAt([1, 1, 3,
```

```
[2, 1, 1, 3, 1], [2, 1, 1, 3, 1]
```

Appending of an element. This could be done faster with `append`:

```
listlib::insertAt([1, 2, 3], 4, 1000), append([1, 2, 3], 4)
```

```
[1, 2, 3, 4], [1, 2, 3, 4]
```

## Parameters

### **list**

A list

### **element**

Any MuPAD object

### **pos**

Any integer

## Return Values

Given list enlarged with the inserted element

## See Also

## MuPAD Functions

`listlib::insert` | `append` | `_concat`

# listlib::merge

---

**Purpose** Merging two ordered lists

**Syntax** `listlib::merge(list1, list2, <function>)`

**Description** `listlib::merge(list1, list2)` merges both lists into one list.

With the third optional argument a function can be given that compare the elements of the lists and therewith determines the order of the elements. The given function is called with two elements and have to return TRUE, if the two elements are in the right order, otherwise FALSE (see next paragraph).

The given function is called step by step with an element of the first list as first argument and an element of the second list as second argument, until it returns FALSE. Then the element of the second list is inserted into the first list in *front* of the last proved element (see “Example 2” on page 16-9).

---

**Note** The lists must be ordered with regard to the order function, otherwise the elements could be inserted at the wrong place.

---

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

## Examples

### Example 1

Merging two ascending ordered lists:

```
listlib::merge([1, 3, 5, 7], [2, 4, 6, 8])
```

```
[1, 2, 3, 4, 5, 6, 7, 8]
```

Merging two descending ordered lists:

```
listlib::merge([7, 5, 3, 1], [8, 6, 4, 2], _not@_less)
```

```
[8, 7, 6, 5, 4, 3, 2, 1]
```

## Example 2

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number, when the expression has a type with higher priority:

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X))
priority(x^2), priority(x + 2)
```

```
1, 3
```

The function `sortfunc` returns `TRUE`, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x^2)
```

```
TRUE, FALSE
```

Now the both lists are merged with regard to the given priority:

```
listlib::merge([x^y, x^2, -y], [x^2, x*y, x + y], sortfunc)
```

```
[xy, x2, 2 x, - y, x y, x + y]
```

```
delete priority, sortfunc:
```

# listlib::merge

---

## Parameters

**list1, list2**

A MuPAD list

## function

A function that determines the merging order

## Return Values

Ordered list that contains the elements of both lists

## See Also

## MuPAD Functions

`listlib::singleMerge` | `listlib::insert` | `_concat` | `zip`

**Purpose** Removes duplicate entries

**Syntax** `listlib::removeDuplicates(list, <KeepOrder>)`

**Description** `listlib::removeDuplicates(list)` removes all duplicates of each entry of the list `list`. The new list is build up from right to left with the order of the *last* occurrence of each entry in `list`. Cf. “Example 1” on page 16-11.

A faster possibibliy to remove duplicate entries is to convert the list into a set and back into a list. You will loose the order of the list entries in this case. Cf. “Example 3” on page 16-11.

## Examples **Example 1**

Per default `listlib::removeDuplicates` removes duplicate entries in reverse order:

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:
listlib::removeDuplicates(list)
```

```
[5, 3, 1, 7]
```

## **Example 2**

With option `KeepOrder` entries are selected in the order of their occurrence:

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:
listlib::removeDuplicates(list, KeepOrder)
```

```
[1, 3, 5, 7]
```

## **Example 3**

If you don't need the order of list entries any more, you may convert the list into a set and back into a list, this is much faster:

# listlib::removeDuplicates

---

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:
[op({op(list)})]
```

```
[1, 3, 5, 7]
```

## Parameters

**list**

A MuPAD list

## Options

**KeepOrder**

`listlib::removeDuplicates(list, KeepOrder)` returns a list of the entries of `list` in the order of their *first* occurrence. The list is build up from left to right. See “Example 2” on page 16-11.

## Return Values

List that contains each entry only once

## See Also

## MuPAD Domains

DOM\_LIST

## MuPAD Functions

`listlib::removeDupSorted`

**Purpose** Remove duplicates of any element from ordered lists

**Syntax** `listlib::removeDupSorted(list)`

**Description** `listlib::removeDupSorted(list)` removes all duplicates of any element of the ordered list `list`.

`listlib::removeDupSorted` does the same as `listlib::removeDuplicates`, but it assumes that the list is sorted and therefore it is faster. A notable gain will only occur, if there are only few duplicates in a long list.

## Examples **Example 1**

`listlib::removeDupSorted` removes all duplicates from the given list:

```
listlib::removeDupSorted([1, 1, 1, 3, 5, 5, 5, 5, 5, 5, 5, 7, 7,
[1, 3, 5, 7]
```

If the list is not ordered, `listlib::removeDupSorted` fails:

```
listlib::removeDupSorted([1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7])
[1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7]
```

**Parameters** **list**  
An ordered MuPAD list

**Return Values** List that contains every element only once

# listlib::removeDupSorted

---

## See Also

### MuPAD Functions

`listlib::removeDuplicates`

**Purpose** Remove elements from a list

**Syntax** `listlib::setDifference(list1, list2)`

**Description** `listlib::setDifference(list1, list2)` removes all elements from `list1`, that are given by `list2`.

---

**Note** The order of the list is not preserved.

---

## Examples

### Example 1

`listlib::setDifference` removes 2, 4, 6 and 8 from the given list:

```
listlib::setDifference([1, 2, 3, 4, 5, 6, 7, 8], [2, 4, 6, 8])
```

```
[1, 3, 5, 7]
```

**Parameters** `list1, list2`

A MuPAD list

**Return Values** First list without all elements of the second list

**See Also**

**MuPAD Functions** `minus`

# listlib::singleMerge

---

**Purpose** Merging of two ordered lists without duplicates

**Syntax** `listlib::singleMerge(list1, list2, <function>)`

**Description** `listlib::singleMerge(list1, list2)` merges the both lists into one list. It is assumed that the lists are “disjunct”, no element appears in both lists. Otherwise such elements are inserted only once in the result list.

With the third optional argument a function can be given that compare the elements of the lists and therewith determines the order of the elements. The given function is called with two elements and have to return TRUE, if the two elements are in the right order, otherwise FALSE (see next paragraph).

The given function is called step by step with an element of the first list as first argument and an element of the second list as second argument, until it returns FALSE. Then the element of the second list is inserted into the first list in *front* of the last proved element (see “Example 3” on page 16-17).

---

**Note** The lists must be ordered with regard to the order function, otherwise the elements could be inserted at the wrong place.

---

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

## Examples

### Example 1

Merging two ascending ordered lists:

```
listlib::singleMerge([1, 3, 5, 7], [2, 4, 6, 8])
```

```
[1, 2, 3, 4, 5, 6, 7, 8]
```

Merging two descending ordered lists:

```
listlib::singleMerge([7, 5, 3, 1], [8, 6, 4, 2], _not@_less)
```

```
[8, 7, 6, 5, 4, 3, 2, 1]
```

## Example 2

Merging two ascending ordered lists with duplicates:

```
listlib::singleMerge([1, 2, 5, 7], [2, 5, 6, 8])
```

```
[1, 2, 5, 6, 7, 8]
```

But the following lists does not contain mutual equal elements:

```
listlib::singleMerge([1, 1, 3, 3], [2, 2, 4, 4])
```

```
[1, 1, 2, 2, 3, 3, 4, 4]
```

## Example 3

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number when the expression has a type with higher priority:

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X))
priority(x^2), priority(x + 2)
```

```
1, 3
```

# listlib::singleMerge

---

The function `sortfunc` returns `TRUE`, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x^2)
```

```
TRUE, FALSE
```

Now the both lists are merged with regard to the given priority:

```
listlib::singleMerge([x^y, x^2, -y], [x^2, x*y, x + y], sortfunc)
```

```
[xy, x2, 2 x, -y, x y, x + y]
```

```
delete priority, sortfunc:
```

## Parameters

**list1, list2**

A MuPAD list

**function**

A function that determines the merging order

## Return Values

Ordered list that contains the elements of both lists

## See Also

## MuPAD Functions

`listlib::merge` | `listlib::insert` | `_concat` | `zip`

## Purpose

Search sublists

## Syntax

```
listlib::sublist(list1, list2, <index>, <Consecutive>)
```

## Description

`listlib::sublist(list1, list2)` determines, whether the list `list1` contains another list `list2`.

With `listlib::sublist` the position of the first appearance of a list in another list can be determined.

The position that was found is returned as integer. If the given list does not contain the given `sublist`, the number 0 is returned.

If an index is given, the search starts at this position. There with multiple occurrence of a `sublist` can be determined.

With the option `Consecutive`, the list must contain the `sublist` in one piece without elements in between.

## Examples

### Example 1

The `sublist` is a part of the list, but not in one piece:

```
listlib::sublist([1, 2, 3, 4, 5, 6, 7, 8], [2, 3, 5, 6])
```

2

```
listlib::sublist([1, 2, 3, 4, 5, 6, 7, 8], [2, 3, 5, 6], Consecutive)
```

0

The list contains the `sublist`, coherent and incoherent:

```
listlib::sublist([1, 2, 3, 4, 5, 1, 3, 5], [1, 3, 5])
```

# listlib::sublist

---

1

```
listlib::sublist([1, 2, 3, 4, 5, 1, 3, 5], [1, 3, 5], Consecutive)
```

6

## Example 2

Find the last occurrence of the sublist inside of the list:

```
POS:= 0:
while listlib::sublist([1, 2, 3, 1, 3, 1, 2, 3], [1, 2, 3], POS + 1)
 POS:= listlib::sublist([1, 2, 3, 1, 3, 1, 2, 3], [1, 2, 3], POS + 1)
end_while:
POS
```

6

```
delete POS:
```

## Parameters

**list1, list2**

MuPAD list

**index**

Integer that determines the first search position

## Options

**Consecutive**

Determines that the sublist `list2` is containing coherent in `list1`

## Return Values

Position of the first element of the containing sublist or zero

**See Also**

**MuPAD  
Functions**      contains | op

# listlib::sublist

---

# misc – Miscellanea

---

misc::breakmap  
misc::genassop  
misc::maprec  
misc::pslq

# misc::breakmap

---

**Purpose** Stops the mapping currently done by maprec

**Syntax** misc::breakmap()

**Description** misc::breakmap() stops the recursive application of a function to all subexpressions of an expression that misc::maprec is just working on. misc::breakmap is useful as a command inside the procedure mapped by misc::maprec in case we know that we are finished with our work and the remaining recursive mapping is not necessary.

## Examples

### Example 1

We want to know whether a given expression contains a particular type `t`. As soon as we have found the first occurrence of `t`, we can terminate our search.

```
myfound := FALSE:
misc::maprec(hold(((23+5.0)/3+4*I)*PI),
 {DOM_COMPLEX}=proc()
 begin
 myfound := misc::breakmap();
 args()
 end_proc):
myfound
```

TRUE

What did we do? We told misc::maprec just to go down the expression tree and look for subexpressions of type `DOM_COMPLEX`; and, whenever such subexpression should be found, to apply a certain procedure to it. That procedure stops the recursive mapping, remembers that we have found the type we had searched for, and returns exactly its argument such that the result returned by misc::maprec equals the input. In the example below, we test whether our given expression contains the type `DOM_POLY`.

```
myfound := FALSE:
misc::maprec(hold(((23+5.0)/3+4*I)*PI),
 {DOM_POLY}=proc()
 begin
 myfound := misc::breakmap();
 args()
 end_proc):
myfound
```

FALSE

Note that you do not need to use this method when searching for subexpressions of a given type; calling `hastype` is certainly more convenient.

## Return Values

`misc::breakmap` always returns TRUE.

## See Also

## MuPAD Functions

`misc::maprec`

# misc::genassop

---

**Purpose** Generates an n-ary associative operator from a binary one

**Syntax** `misc::genassop(binaryop, zeroelement)`

**Description** `misc::genassop(binaryop, zeroelement)` generates an n-ary associative operator from the binary operator `binaryop`, where `zeroelement` is a neutral element for `binaryop`.

`binaryop` must be a function taking two arguments (no matter of what kind) and returning a valid argument to itself. It must satisfy the associative law `binaryop(binaryop(a, b), c) = binaryop(a, binaryop(b, c))`.

`zeroelement` is an object such that `binaryop(a, zeroelement) = a` holds for every `a`.

`misc::genassop` returns a procedure which returns `zeroelement` if it is called without arguments and the argument if it is called with one argument.

---

**Note** `misc::genassop` doesn't check whether `binaryop` is really associative and whether `zeroelement` is really a neutral element for `binaryop`.

---

## Examples

### Example 1

We know that `_plus` is an n-ary operator anyway, but let us assume that `_plus` was only a binary operator. We can create an own n-ary addition as follows:

```
myplus := misc::genassop(_plus, 0)

proc genericAssop() ... end
```

Now we make `myplus` add some values.

```
myplus(3, 4, 8), myplus(-5), myplus()
```

```
15, -5, 0
```

As mentioned in the “Details” section, `myplus` returns the argument if is called with exactly one argument, and it returns the zeroelement `0` if it is called without arguments.

## Parameters

### **binaryop**

A function

### **zeroelement**

An object

## Return Values

`misc::genassop` returns a procedure `f`. That procedure accepts an arbitrary number of arguments of the same kind `binaryop` does; it returns `zeroelement` if it is called without argument, and its only argument if it is called with one argument; its value on  $n$  arguments is inductively defined by  $f(x_1, \dots, x_n) = f(\text{binaryop}(x_1, x_2), x_3, \dots, x_n)$ .

## MuPAD Functions

operator

# misc::maprec

---

<b>Purpose</b>	Map a function to subexpressions of an expression
<b>Syntax</b>	<code>misc::maprec(ex, selector = funci, , &lt;PreMap   PostMap&gt;, &lt;NoOperators&gt;, &lt;Unsimplified&gt;)</code>
<b>Description</b>	<p><code>misc::maprec(ex, selector=funci)</code> maps the function <code>funci</code> to all subexpressions of the expression <code>ex</code> that satisfy a given criterion (defined by <code>selector</code>) and replaces each selected subexpression <code>s</code> by <code>funci(s)</code>.</p> <p>Several different functions may be mapped to subexpressions satisfying different selection criteria.</p> <p><code>misc::maprec(ex, selector<sub>1</sub> = funci<sub>1</sub>, , selector<sub>n</sub> = funci<sub>n</sub>)</code> does two steps: it tests whether <code>ex</code> meets a selection criterion defined by some selector <code>selector_k</code> (and, if yes, replaces <code>ex</code> by <code>funci_k(ex)</code>); and it applies itself recursively to all operands of <code>ex</code>. The order of these steps is determined by the options <code>PreMap</code> and <code>PostMap</code>.</p> <p>Selectors are applied from left to right; if the expression meets some selection criterion, no further selectors are tried.</p> <p><code>selector</code> can have two forms. It can be a set <math>\{t_1, \dots, t_n\}</math>. Here a subexpression <code>s</code> of <code>ex</code> is selected if <code>type(s)</code> is one of the types <math>t_1, \dots, t_n</math>. If it is not a set, a subexpression <code>s</code> of <code>ex</code> is selected if <code>p(s)</code> returns <code>TRUE</code>. As every MuPAD object may be applied as a function to <code>s</code>, <code>p</code> may be of any type in the latter case.</p> <p>In order not to select a subexpression, the selector need not return <code>FALSE</code>; it suffices that it does not return <code>TRUE</code>.</p> <p>If neither the option <code>PreMap</code> nor the option <code>PostMap</code> is given, then <code>PreMap</code> is used.</p> <p>Use a <code>misc::breakmap</code> command inside <code>funci</code> in order to stop the recursive mapping. See the help page of <code>misc::breakmap</code> for an example.</p>

---

**Note** Only subexpressions of domain type `DOM_ARRAY`, `DOM_EXPR`, `DOM_LIST`, `DOM_SET`, and `DOM_TABLE` are mapped recursively, as well as domain elements of a domain `T` for which a slot `T::enableMaprec` exists and equals `TRUE`; a slot `T::map` working properly must then exist, too. To subexpressions of other types, `selector` is applied, but `misc::maprec` is not mapped to their operands. (This is to avoid unwanted substitutions.) If you want to recurse on them, either add an `enableMaprec`-slot, or use a `selector` that selects such subexpressions, and make `funci` initiate another recursive mapping.

---

`misc::maprec` is overloadable. If the domain of a subexpression has a method "maprec", then this method is called with the subexpression and the other arguments of the call.

---

**Note** The subexpression is replaced by the result, but `misc::maprec` is not mapped to its operands; such recursive mapping must be done by the domain method if desired.

---

---

**Note** The operators of expressions (`op(expression, 0)`) are also mapped recursively like all the other operands. Use `NoOperators` to switch this off.

---

## Examples

### Example 1

In the following example every integer of the given expression `a+3+4` is substituted by the value 10. Since `10(n)` returns 10 for every integer `n`, it suffices to write 10 instead of `n -> 10` here.

```
misc::maprec(hold(a+3+4), {DOM_INT} = 10)
```

```
a + 20
```

In the example above, we used `hold` to suppress the evaluation of the expression because otherwise `a+3+4` is evaluated to `a+7` and we get the result:

```
misc::maprec(a+3+4, {DOM_INT} = 10)
```

```
a + 10
```

The simplification of the resulting `10 + 10` to `20` can be avoided by using the option `Unimplified`:

```
misc::maprec(hold(a+3+4), {DOM_INT} = 10, Unimplified)
```

```
a + 10 + 10
```

### Example 2

Now we give an example where the `selector` is a function. We want to eliminate all the prime numbers from an expression.

```
misc::maprec(hold(_plus)(i $ i=1..20), isprime= null(), PostMap)
```

```
133
```

Here `isprime` returns `TRUE` for every prime number between 1 and 20. Every prime number between 1 and 20 is replaced by `null()` (since `null()(p)` gives `null()`) which means the above call computes the sum of all non-prime numbers between 1 and 20.

### Example 3

Normally, `misc::maprec` recurses also into the operators of subexpressions. This may be unwanted in many cases:

```
misc::maprec(a+b, {DOM_IDENT}= (x -> x.1))
```

```
plus1(a1, b1)
```

We just wanted to replace the summands, but not the operator. Using the option `NoOperators` helps:

```
misc::maprec(a+b, {DOM_IDENT}= (x -> x.1), NoOperators)
```

```
a1 + b1
```

## Parameters

### **ex**

Any MuPAD object

### **selector**

Any MuPAD object

### **funci**

Any MuPAD object

## Options

### **PreMap**

For each subexpressions `s` of `ex`, the selector is applied to it *after* visiting all of its subexpressions; `s` may have changed at that time due to substitutions in the subexpressions.

### **PostMap**

For each subexpressions `s` of `ex`, the selector is applied to it *before* visiting its subexpressions. If `s` is selected by `selector`, it

## misc::maprec

---

is replaced by `funci(s)`, and `misc::maprec` is *not* recursively applied to the operands of `funci(s)`; otherwise, `misc::maprec` is recursively applied to the operands of `s`.

### NoOperators

The selector is not applied to the operator of `ex`.

### Unsimplified

The resulting expressions are not further simplified.

### Return Values

`misc::maprec` may return any MuPAD object.

### Overloaded By

`ex`

### See Also

### MuPAD Functions

<b>Purpose</b>	Heuristic detection of relations between real numbers
<b>Syntax</b>	<code>misc::pslq(numberlist, precision)</code>
<b>Description</b>	<p><code>misc::pslq(numberlist, precision)</code> returns a list of integers <math>[k_1, \dots, k_n]</math> such that — denoting the elements of <code>numberlist</code> by <math>a_1, \dots, a_n</math> — the absolute value of <math>\sum_{i=0}^n a_i k_i</math> is less than <math>\frac{1}{\text{precision}}</math> times the Euclidean norm of <code>numberlist</code>, or FAIL if such integers could not be detected.</p> <p>This method can be used to get an idea about linear dependencies, before proving them.</p>
<b>Environment Interactions</b>	<code>misc::pslq</code> is <i>not</i> affected by the current value of DIGITS. Numerical computations are carried out with more significant digits such that the output meets the specification given above.
<b>Examples</b>	<p><b>Example 1</b></p> <p>Does <math>\pi</math> satisfy a polynomial equation of degree at most 2?</p> <pre>misc::pslq([1, PI, PI^2], 20)</pre> <p>FAIL</p> <p><b>Example 2</b></p> <p>Having forgotten the relation between sine and cosine, we can try the heuristic way.</p> <pre>misc::pslq([1, sin(0.32), sin(0.32)^2, cos(0.32), cos(0.32)^2],</pre> <pre>(1 0 -1 0 -1)</pre>

# misc::pslq

---

## Parameters

### **numberlist**

List of real numbers or objects that can be converted to real numbers by the function `float`.

### **precision**

Positive integer

## Return Values

List of integers, or FAIL

## Algorithms

This function has been written by Raymond Manzoni.

The algorithm has been taken from Bailey and Plouffe, *Recognizing numerical constants*. See also Helaman R.P. Ferguson and David Bailey, *A Polynomial Time, Numerically Stable Integer Relation Algorithm*, RNR Technical Report RNR-92-032.

**Purpose** Butcher parameters of Runge-Kutta schemes

**Syntax** `numeric::butcher(EULER1 | RKF43 | xRKF43 | RK4 | RKF34 | xRKF34 | RKF54a | xRKF54a | RKF54b | xRKF54b | DOPRI54 | xDOPRI54 | CK54 | xCK54 | RKF45a | xRKF45a | RKF45b | xRKF45b | DOPRI45 | xDOPRI45 | CK45 | xCK45 | DOPRI65 | xDOPRI65 | DOPRI56 | xDOPRI56 | BUTCHER6 | RKF87 | xRKF87 | RKF78 | xRKF78 | DOPRI87 | xDOPRI87 | DOPRI78 | xDOPRI78 | GAUSS(s) | GAUSS = s, <digits>)`

**Description** `numeric::butcher(method)` returns the Butcher parameters of the Runge-Kutta scheme named `method`.

An  $s$ -stage Runge-Kutta method for the numerical integration of a dynamical system  $\frac{dy}{dt} = f(t, y)$  with step size  $h$  is a map

$$(t, y) \rightarrow (t + h, y + h b_1 k_1 + \dots + h b_s k_s)$$

The “intermediate stages”  $k_1, \dots, k_s$  are defined as the solutions of the algebraic equations

$$k_i = f(t + c_i h, y + h a_{i1} k_1 + \dots + h a_{is} k_s), 1 \leq i \leq s$$

If the  $s \times s$  “Butcher matrix”  $a_{ij}$  is strictly lower triangular, the method is called “explicit”. In this case, the intermediate stages are computed recursively as:

$$\begin{aligned} k_1 &= f(t, y) \\ k_2 &= f(t + c_2 h, y + h a_{21} k_1) \\ &\vdots \\ k_s &= f(t + c_s h, y + h a_{s1} k_1 + \dots + h a_{s,s-1} k_{s-1}) \end{aligned}$$

# numeric::butcher

---

Various numerical schemes arise from different choices of the Butcher parameters: the  $s \times s$ -matrix  $a_{ij}$ , the weights  $b = [b_1, \dots, b_s]$  and the abscissae  $c = [c_1, c_2, \dots, c_s]$ .

Embedded pairs of Runge-Kutta methods consist of two methods that share the matrix  $a_{ij}$  and the abscissae  $c_i$ , but use different weights  $b_i$ .

The returned list `[s, c, a, b1, b2, order1, order2]` contains the Butcher data of the method: `s` is the number of stages, `c` is the list of abscissae, `a` is the Butcher matrix, `b1` and `b2` are lists of weights. The integers `order1` and `order2` are the orders of the scheme when using the weights `b1` or `b2`, respectively, in conjunction with the matrix `a` and the abscissae `c`.

The methods EULER1 (order 1), RK4 (order 4) and BUTCHER6 (order 6) are single methods with `b1 = b2` and `order1 = order2`. All other methods are embedded pairs of Runge-Kutta-Fehlberg (RKFxx), Dormand-Prince (DOPRIxx) or Cash-Karp (CKxx) type. The names indicate the orders of the subprocesses, e.g., CK45 is the Cash-Karp pair of orders 4 and 5. CK54 is the same pair with reversed ordering of the subprocesses. The second subprocess is used to produce a time step of the Runge-Kutta method, the first subprocess is used for estimating the error of the time step.

The methods GAUSS(s) or, equivalently, GAUSS = s are the implicit Gauss methods with `s` stages of order `2s`.

The data of all explicit methods are returned as exact rational numbers. The data of the Gauss methods are returned as floating-point numbers.

The Butcher data are called by the routines `numeric::odesolve`, `numeric::odesolve2`, and `numeric::odesolveGeometric`.

## Environment Interactions

When computing the data for GAUSS(s), the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

The Butcher data of the classical 4 stage, 4th order Runge-Kutta scheme are:

```
numeric::butcher(RK4)
```

$$\left[ 4, \left( 0 \quad \frac{1}{2} \quad \frac{1}{2} \quad 1 \right), \begin{pmatrix} 0 & 0 & 0 & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \left( \frac{1}{6} \quad \frac{1}{3} \quad \frac{1}{3} \quad \frac{1}{6} \right), \left( \frac{1}{6} \quad \frac{1}{3} \quad \frac{1}{3} \quad \frac{1}{6} \right), 4, 4 \right]$$

Note that the weights  $b_1$  and  $b_2$  coincide: this classical method does not provide an embedded pair.

The Butcher data of the (implicit) 3 stage Gauss method:

```
DIGITS := 5:
numeric::butcher(GAUSS(3));
delete DIGITS:
```

$$\left[ 3, \left( 0.1127 \quad 0.5 \quad 0.8873 \right), \begin{pmatrix} 0.13889 & -0.035977 & 0.0097894 \\ 0.30026 & 0.22222 & -0.022485 \\ 0.26799 & 0.48042 & 0.13889 \end{pmatrix}, \left( 0.27778 \quad 0.44444 \quad 0.27778 \right), \left( 0.27778 \quad 0.44444 \quad 0.27778 \right), 6, 6 \right]$$

### Example 2

The Butcher data of the embedded Runge-Kutta-Fehlberg pair RKF34 of orders 3 and 4 are:

# numeric::butcher

---

```
[s, c, a, b1, b2, order1, order2] := numeric::butcher(RKF34):
```

The number of stages  $s$  of the 4th order subprocess is 5, the abscissae  $c$  and the matrix  $a$  are given by:

```
s, c, a
```

$$5, \left(0 \quad \frac{1}{4} \quad \frac{4}{9} \quad \frac{6}{7} \quad 1\right), \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ \frac{1}{4} & 0 & 0 & 0 & 0 \\ \frac{4}{81} & \frac{32}{81} & 0 & 0 & 0 \\ \frac{57}{98} & -\frac{432}{343} & \frac{1053}{686} & 0 & 0 \\ \frac{1}{6} & 0 & \frac{27}{52} & \frac{49}{156} & 0 \end{pmatrix}$$

Using these parameters with the weights

```
b1, b2
```

$$\left(\frac{1}{6} \quad 0 \quad \frac{27}{52} \quad \frac{49}{156} \quad 0\right), \left(\frac{43}{288} \quad 0 \quad \frac{243}{416} \quad \frac{343}{1872} \quad \frac{1}{12}\right)$$

yields a numerical scheme of order 3 or 4, respectively:

```
order1, order2
```

```
3, 4
```

```
delete s, c, a, b1, b2, order1, order2:
```

### Example 3

We plot the stability regions of the two sub-methods of DOPRI78. The stability function of a Runge-Kutta scheme with Butcher parameters  $(c, a, b)$  is given by

$$p(z) = 1 + z \left( \left\langle b, \frac{e}{(1 - z a)} \right\rangle \right),$$

where  $e$  is the column vector  $(1, 1, \dots, 1)^T$ . For an explicit  $s$ -stage scheme (the matrix  $a$  is strictly lower triangular), this stability function reduces to the polynomial

$$p(z) = 1 + \left( \sum_{i=1}^s z^i \left( \left\langle b, a^{i-1} e \right\rangle \right) \right)$$

We compute the coefficients of the stability polynomials associated with the Butcher matrix  $a$  and the weights  $b_1$  and  $b_2$  of the sub-methods of DOPRI78:

```
[s, c, a, b1, b2, order1, order2] := numeric::butcher(DOPRI78):
e := matrix([1 $ s]):
a := float(matrix(a)):
b1 := linalg::transpose(float(matrix(b1))):
b2 := linalg::transpose(float(matrix(b2))):
for i from 1 to s do
 c1[i] := (b1*a^(i-1)*e)[1, 1];
 c2[i] := (b2*a^(i-1)*e)[1, 1];
end_for:
```

We define the stability polynomials:

```
z := x + I*y:
p1 := 1 + _plus(c1[i]*z^i $ i = 1..s):
```

# numeric::butcher

```
p2 := 1 + _plus(c2[i]*z^i $ i = 1..s):
```

The boundary of the stability region  $\{z \in \mathbb{C} \mid |p(z)| < 1\}$  is the curve defined by  $|p(z)| = 1$ . We plot these implicit curves associated with the stability polynomials  $p_1(z)$  and  $p_2(z)$  defined above:

```
plot(plot::Implicit2d(abs(p1) = 1, x = -6..1, y = 0..6,
 Color = RGB::Red, Legend = "Order 7"),
 plot::Implicit2d(abs(p2) = 1, x = -6..1, y = 0..6,
 Color = RGB::Blue, Legend = "Order 8"),
 Scaling = Constrained):
```

```
delete s, c, a, b1, b2, order1, order2, e, c1, c2, z, p1, p2:
```

## Parameters **s**

The number of stages of the Gauss method: a positive integer

## digits

The number of significant digits with which the Butcher data of the methods GAUSS(s) are computed. The default value for digits is the current value of the environment variable DIGITS. This argument is only relevant for the Gauss methods.

## Return Values

A list [s, c, a, b<sub>1</sub>, b<sub>2</sub>, order<sub>1</sub>, order<sub>2</sub>] is returned.

## Algorithms

The Butcher parameters provided in this original paper consist of rational *approximations* of solutions of the order equations of Runge-Kutta systems. The parameters provided by numeric::butcher are *exact* rational solutions of the order equations. The approximations given by Prince and Dormand coincide with the MuPAD exact values through 16 decimal digits.

numeric::odesolve | numeric::odesolve2 |  
numeric::odesolveGeometric

# numeric::complexRound

---

**Purpose** Round a complex number towards the real or imaginary axis

**Syntax** `numeric::complexRound(z, <eps>)`

**Description** `numeric::complexRound(z)` discards small real or imaginary parts of complex floating-point numbers  $z$ .

If the real part of  $z$  satisfies  $\Re(z) < \text{eps} |z|$ , then it is replaced by zero and  $\Im(z)i$  is returned.

If the imaginary part of  $z$  satisfies  $\Im(z) < \text{eps} |z|$ , then it is replaced by zero and  $\Re(z)$  is returned.

With the default of `eps=10^-DIGITS`, this rounding changes a complex floating-point number by less than the relative standard precision.

Only precisions `eps >= 10^-DIGITS` are accepted.

Numerical expressions such as `eps =  $\pi \sqrt{2} 10^{-10}$`  etc. are accepted as `eps`.

This function removes small real or imaginary parts of complex floating-points numbers generated by numerical roundoff. It is used to simplify the floating-point output of `numeric::fsolve`, `numeric::polyroots`, `numeric::polysysroots` and `numeric::sum`.

**Environment Interactions** The function is sensitive to the environment variable `DIGITS`.

**Examples** **Example 1**

Exact numbers are not changed:

```
numeric::complexRound(2 + I/10^20)
```

$$2 + \frac{i}{100000000000000000000}$$

Also the following number has an exact imaginary part and is not rounded:

```
numeric::complexRound(2.0 + sqrt(2)*I/10^20)
```

$$2.0 + \frac{\sqrt{2} i}{100000000000000000000}$$

Rounding occurs for complex floats, if this does not change its value significantly:

```
numeric::complexRound(1.0 + 2.0*I/10^10),
numeric::complexRound(1.0 + 2.0*I/10^11)
```

$$1.0 + 0.0000000002 i, 1.0$$

Note that rounding is based on relative precision, i.e., only the ratio of real and imaginary parts is relevant:

```
numeric::complexRound((1.0 + 2.0*I)/10^100)
```

$$1.0 10^{-100} + 2.0 10^{-100} i$$

```
numeric::complexRound((1.0 + 1.0/10^11*I)/10^100)
```

$$1.0 10^{-100}$$

The relative precision for rounding may be reduced by the optional parameter `eps`:

```
numeric::complexRound(2.0/10^10 + I),
```

# numeric::complexRound

---

```
numeric::complexRound(2.0/10^10 + I, PI/10^5)
```

```
0.0000000002 + 1.0 i, 1.0 i
```

## Parameters

**z**

An arbitrary MuPAD object

**eps**

A real number no less than  $\frac{1}{10^{\text{DIGITS}}}$

## Return Values

If  $z$  is a complex floating-point number, then a real or complex floating-point number is returned. For all other types,  $z$  is returned unchanged.

## See Also

## MuPAD Functions

[ceil](#) | [floor](#) | [frac](#) | [round](#) | [trunc](#)

## Purpose

Interpolation by cubic splines

## Syntax

```
numeric::cubicSpline([x0, y0], [x1, y1], ,
<BoundaryCondition>, <Symbolic>, <NoWarning>)
numeric::cubicSpline([x0, x1,], [y0, y1,],
<BoundaryCondition>, <Symbolic>, <NoWarning>)
numeric::cubicSpline([[x0, x1,], [y0, y1,]],
<BoundaryCondition>, <Symbolic>, <NoWarning>)
```

## Description

`numeric::cubicSpline([x0, y0], [x1, y1], )` returns the cubic spline function interpolating a sequence of coordinate pairs  $[x_i, y_i]$ .

The call `S := numeric::cubicSpline([x0, y0], , [xn, yn])` yields the cubic spline function  $S$  interpolating the data  $[x_0, y_0], \dots, [x_n, y_n]$ , i.e.,  $S(x_i) = y_i$  for  $i = 0, \dots, n$ . The spline function is a piecewise polynomial of

degree  $\leq 3$  on the intervals  $(-\infty, X_1], [X_1, X_2], \dots, [X_{n-1}, \infty)$ .  $S$  and its first two derivatives  $S', S''$  are continuous at the points  $x_1, \dots, x_{n-1}$ . Note that  $S$  extends the polynomial representation on  $[X_0, X_1],$

$[X_{n-1}, X_n]$  to  $(-\infty, X_0]$  and  $[X_{n-1}, \infty)$ , respectively.

By default, NotAKnot boundary conditions are assumed, i.e., the third derivative  $S'''$  is continuous at the points  $x_1$  and  $x_{n-1}$ . With this boundary condition,  $S$  is a cubic polynomial on the intervals  $(-\infty, X_2]$  and  $[X_{n-2}, \infty)$ .

By default, all input data are converted to floating-point numbers. This conversion may be suppressed by the option `Symbolic`.

Without the option `Symbolic`, the abscissae  $x_i$  must be numerical real values in ascending order. If these data are not ordered, then `numeric::cubicSpline` reorders the abscissae internally, issuing a warning. The warning may be switched off by the option `NoWarning`.

The function  $S$  returned by `numeric::cubicSpline` may be called with one, two or three arguments:

# numeric::cubicSpline

---

- The call `S(z)` returns an explicit expression or a number, if `z` is a real number. Otherwise, the symbolic call `S(z)` is returned.
- The call `S(z, [k])` with a nonnegative integer `k` returns the  $k$ -th derivative of  $S$ . Cf. “Example 4” on page 18-18. For  $k > 3$ , zero is returned for any  $z$ .
- The call `S(z, i)` is meant for symbolic arguments  $z$ . The argument  $i$  must be an integer. Internally,  $z$  is assumed to satisfy  $x_i \leq z < x_{i+1}$ , and `S(z, i)` returns the polynomial expression in  $z$  representing the spline function on this interval.
- The call `S(z, i, [k])` with an integer  $i$  and a nonnegative integer  $k$  returns the polynomial representation of the  $k$ -th derivative of the spline function on the interval  $x_i \leq z < x_{i+1}$ .

If `S` is generated with symbolic abscissae  $x_i$  (necessarily using the option `Symbolic`), then the call `S(z)` with numerical  $z$  leads to an error. The call `S(z, i)` must be used for symbolic abscissae!

---

**Note** Note that the interpolation of 2 points  $(x_0, y_0), (x_1, y_1)$  must be specified by `numeric::cubicSpline( [x0, y0] , [x1, y1] )`, not by `numeric::cubicSpline( [x0, x1] , [y0, y1] )!`

---

## Examples

### Example 1

We demonstrate some calls with numerical input data:

```
data := [i, sin(i*PI/20)] $ i= 0..40:
S1 := numeric::cubicSpline(data):
S2 := numeric::cubicSpline(data, Natural):
S3 := numeric::cubicSpline(data, Periodic):
S4 := numeric::cubicSpline(data, Complete = [3, PI]):
```

At the abscissae, the corresponding input data are reproduced:

```
float(data[6][2]), S1(5), S2(5), S3(5), S4(5)
```

0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812

0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812

Interpolation between the abscissae depends on the boundary condition:

S1(4.5), S2(4.5), S3(4.5), S4(4.5)

0.6494470263, 0.6494470123, 0.6494470123, 0.6517696766

These are the cubic polynomials in  $z$  defining the spline on the interval  $x_0 = 0 \leq z < x_1 = 1$ :

expand(S1(z, 0)); expand(S2(z, 0));  
expand(S3(z, 0)); expand(S4(z, 0))

- 0.000632116114  $z^3$  - 0.00002961951081  $z^2$  + 0.1570962007  $z$

0.1570790998  $z$  - 0.0006446347923  $z^3$

- 0.0006446347923  $z^3$  + 1.270549421  $10^{-21}$   $z^2$  + 0.1570790998  $z$

2.080517906  $z^3$  - 4.924083441  $z^2$  + 3.0  $z$

- 0.000632116114  $z^3$  - 0.00002961951081  $z^2$  + 0.1570962007  $z$

# numeric::cubicSpline

---

$$0.1570790998 z - 0.0006446347923 z^3$$
$$- 0.0006446347923 z^3 + 1.270549421 10^{-21} z^2 + 0.1570790998 z$$
$$2.080517906 z^3 - 4.924083441 z^2 + 3.0 z$$

delete data, S1, S2, S3, S4:

## Example 2

We demonstrate some calls with symbolic data:

```
S := numeric::cubicSpline([i, y.i] $ i = 0..3):
```

```
S(1/2)
```

$$0.3125 y_0 + 0.9375 y_1 - 0.3125 y_2 + 0.0625 y_3$$

This is the cubic polynomial in  $z$  defining the spline on the interval  $x_0 = 0 \leq z < x_1 = 1$ :

```
S(z, 0)
```

$$y_0 - z (1.833333333 y_0 - 3.0 y_1 + 1.5 y_2 - 0.3333333333 y_3$$
$$+ z (2.5 y_1 - 1.0 y_0 - 2.0 y_2 + 0.5 y_3 + z (0.1666666667 y_0 - 0.5 y_1 + 0.5 y_2 - 0.1666666667 y_3$$

With the option `Symbolic`, exact arithmetic is used:

```
S := numeric::cubicSpline([i, y.i] $ i = 0..3, Symbolic):
```

```
S(1/2)
```

$$\frac{5 y_0}{16} + \frac{15 y_1}{16} - \frac{5 y_2}{16} + \frac{y_3}{16}$$

Also symbolic boundary data are accepted:

```
S := numeric::cubicSpline([i, exp(i)] $ i = 0..10, Complete = [a
S(0.1)
```

$$0.08341154273 a + 0.00000005947817812 b + 1.020064753$$

```
S := numeric::cubicSpline([0, y0], [1, y1], [2, y2], Symbolic, C
collect(S(z, 0), z)
```

$$\left(\frac{3 a}{4} + \frac{5 y_0}{4} - 2 y_1 + \frac{3 y_2}{4} - \frac{5}{4}\right) z^3 + \left(3 y_1 - \frac{9 y_0}{4} - \frac{7 a}{4} - \frac{3 y_2}{4} + \frac{5}{4}\right) z^2 + a z + y_0$$

$$\left(\frac{3 a}{4} + \frac{5 y_0}{4} - 2 y_1 + \frac{3 y_2}{4} - \frac{5}{4}\right) z^3 + \left(3 y_1 - \frac{9 y_0}{4} - \frac{7 a}{4} - \frac{3 y_2}{4} + \frac{5}{4}\right) z^2 + a z + y_0$$

```
delete S:
```

### Example 3

We demonstrate the use of symbolic abscissae. Here the option Symbolic is mandatory.

```
S := numeric::cubicSpline([x.i, y.i] $ i = 0..2, Symbolic):
```

The spline function S can only be called with 2 arguments. This is the cubic polynomial in z defining the spline on the interval  $x_0 \leq z < x_1$ :

# numeric::cubicSpline

---

S(z, 0)

$$y_0 + (x_0 - z) \left( (x_0 - z) \left( \frac{y_0 - y_1}{(x_0 - x_1)(x_0 - x_2)} - \frac{y_1 - y_2}{(x_0 - x_2)(x_1 - x_2)} \right) + \frac{(y_0 - y_1)(x_1 - 2x_0 + x_2)}{(x_0 - x_1)(x_0 - x_2)} + \frac{(x_0 - y_1)}{(x_0 - x_1)} \right)$$

$$y_0 + (x_0 - z) \left( (x_0 - z) \left( \frac{y_0 - y_1}{(x_0 - x_1)(x_0 - x_2)} - \frac{y_1 - y_2}{(x_0 - x_2)(x_1 - x_2)} \right) + \frac{(y_0 - y_1)(x_1 - 2x_0 + x_2)}{(x_0 - x_1)(x_0 - x_2)} + \frac{(x_0 - y_1)}{(x_0 - x_1)} \right)$$

delete S:

## Example 4

We plot a spline function together with its first three derivatives. The spline approximates the function  $\sin(x)$ :

```
n := 10:
x := array(0..n, [i/n*2*PI $ i = 0..n]):
S := numeric::cubicSpline([x[i], sin(x[i])] $ i = 0..n, Natural):
delete x:
plot(
 plot::Function2d(S(x), x = 0..2*PI, Color = RGB::Black),
 plot::Function2d(S(x, [1]), x = 0..2*PI, Color = RGB::Red),
 plot::Function2d(S(x, [2]), x = 0..2*PI, Color = RGB::Green,
 Mesh = 1000),
 plot::Function2d(S(x, [3]), x = 0..2*PI, Color = RGB::Blue,
 Mesh = 1000)
)
```

delete n, S:

## Example 5

We demonstrate how to generate a phase plot of the differential equation  $x''(t) + x(t)^3 = \sin(t)$ , with initial conditions  $x(0) = x'(0) = 0$ . First, we use `numeric::odesolve` to compute a numerical mesh of solution points  $[x_i, y_i] = [x(t_i), x'(t_i)]$  with  $n + 1$  equidistant time nodes  $t_0, \dots, t_n$  in the interval  $[0, 20]$ :

```
DIGITS := 4: n := 100:
for i from 0 to n do t[i] := 20/n*i: end_for:
f := (t, x) -> [x[2], sin(t) - x[1]^3]:
x[0] := 0: y[0] := 0:
for i from 1 to n do
 [x[i], y[i]] :=
 numeric::odesolve(t[i-1]..t[i], f, [x[i-1], y[i-1]]):
end_for:
```

# numeric::cubicSpline

---

The mesh of the  $(\mathbf{x}(t), \mathbf{x}'(t))$  phase plot consists of the following points:

```
Plotpoints := [[x[i], y[i]] $ i = 0..n]:
```

We wish to connect these points by a spline curve. We define a spline interpoland  $Sx(t)$  approximating the solution  $x(t)$  by interpolating the data  $[t_0, x_0], \dots, [t_n, x_n]$ . A spline interpoland  $Sy(t)$  approximating  $\mathbf{x}'(t)$  is obtained by interpolating the data  $[t_0, y_0], \dots, [t_n, y_n]$ :

```
Sx := numeric::cubicSpline([t[i], x[i]] $ i = 0..n):
Sy := numeric::cubicSpline([t[i], y[i]] $ i = 0..n):
```

Finally, we plot the mesh points together with the interpolating spline curve:

```
plot(
 plot::PointList2d(Plotpoints, PointColor = RGB::Black),
 plot::Curve2d([Sx(z), Sy(z)], z = 0..20, Mesh = 5*(n - 1) + 1,
 LineColor = RGB::Red)
)
```

The functions `plot::Ode2d` and `plot::Ode3d` serve for displaying numerical solutions of ODEs. In fact, they are implemented as indicated by the previous commands. The following call produces the same plot:

```
plot(plot::Ode2d(
 [t[i] $ i = 0..n], f, [x[0], y[0]],
 [(t, x) -> [x[1], x[2]], Style = Points, Color = RGB::Black],
 [(t, x) -> [x[1], x[2]], Style = Splines, Color = RGB::Red])):
```

# numeric::cubicSpline

delete DIGITS, n, i, t, f, x, y, Plotpoints, Sx, Sy:

## Parameters

$x_0, x_1, \dots$

Numerical real values in ascending order

$y_0, y_1, \dots$

Arbitrary expressions

## BoundaryCondition

The type of the boundary condition: either NotAKnot, Natural, Periodic, or Complete = [a, b] with arbitrary arithmetical expressions a, b.

## Options

### Symbolic

With this option, no conversion of the input data to floating point numbers occurs.

Symbolic abscissae  $x_i$  are accepted.

The ordering  $x_0 < x_1 < \dots < x_n$  is assumed by `numeric::cubicSpline`. This ordering is not checked, even if the abscissae are numerical!

## **NoWarning**

The  $x$ -values of the interpolation points must be in ascending order. If the input data violate this condition, the routine issues a warning and reorders the data automatically. With this option, the warning is switched off.

## **NotAKnot**

With the default boundary condition `NotAKnot`, the third derivative  $S'''$  of the spline function is continuous at the points  $x_1$  and  $x_{n-1}$ . With this boundary condition,  $S$  is a polynomial on the intervals  $(-\infty, x_2]$  and  $[x_{n-2}, \infty)$ .

## **Natural**

The boundary condition `Natural` produces a spline function  $S$  satisfying  $S''(x_0) = S''(x_n) = 0$ .

## **Periodic**

The boundary condition `Periodic` produces a spline function  $S$  satisfying  $S(x_0) = S(x_n)$ ,  $S'(x_0) = S'(x_n)$ ,  $S''(x_0) = S''(x_n)$ . With this option, the input data  $y_0, y_n$  must coincide, otherwise an error is raised.

## **Complete**

Option, specified as `Complete = [a, b]`

The boundary condition `Complete = [a, b]` produces a spline function  $S$  satisfying  $S'(x_0) = a$ ,  $S'(x_n) = b$ . Symbolic data  $a, b$  are accepted.

# numeric::cubicSpline

---

## **Return Values**

Spline interpoland: a MuPAD procedure.

## **See Also**

## **MuPAD Functions**

`interpolate` | `numeric::cubicSpline2d`

## Purpose

Interpolation by 2-dimensional bi-cubic splines

## Syntax

`numeric::cubicSpline2d([x0, x1, ..., xn], [y0, y1, ..., ym], z, <[xBC, yBC]>, <Symbolic>)`

## Description

`numeric::cubicSpline2d([ x0, x1, ...], [ y0, y1, ...], z)` returns the bi-cubic spline function interpolating data  $z_{i,j}$  over a rectangular mesh  $(x_i, y_j)$ .

The call `S := numeric::cubicSpline2d([x0, ..., xn], [y0, ..., ym], z, Option)` yields the cubic spline function  $S$  interpolating the data  $(x_i, y_j, z_{i,j})$ , i.e.  $S(x_i, y_j) = z_{i,j}$  for  $i = 0, \dots, n, j = 0, \dots, m$ . The spline function is a piecewise bi-cubic polynomial: on the 'patch'

$$P_{i,j} = \left\{ (X, Y) \mid X_i \leq X < X_{i+1}, Y_j \leq Y < Y_{j+1} \right\}$$

it has the representation

$$S(X, Y) = \sum_{u=0}^3 \left( \sum_{v=0}^3 a_{i,j}^{(u,v)} (X - X_i)^u (Y - Y_j)^v \right)$$

with suitable coefficients  $a_{i,j}^{(u,v)}$  depending on the patch. The spline  $S$  and its partial derivatives  $S_x, S_y, S_{xx}, S_{xy}, S_{yy}, S_{xxy}, S_{xyy}, S_{xxyy}$  are continuous functions over the entire  $x, y$  plane. In the  $x$ -direction,  $S$  extends the polynomial representation on the boundary patches

$[X_0, X_1]$  and  $[X_{n-1}, X_n]$  to  $(-\infty, X_1]$  and  $[X_{n-1}, \infty)$ , respectively. The same holds with respect to the  $y$ -direction.

By default, NotAKnot boundary conditions are assumed, i.e., the partial derivatives  $S_{xxx}, S_{yyy}, \dots, S_{xxxxyy}$ , are continuous at the points with  $x$ -coordinates  $x_1$  and  $x_{n-1}$  or  $y$ -coordinates  $y_1$  and  $y_{m-1}$ .

By default, all input data are converted to floating-point numbers. This conversion may be suppressed by the option `Symbolic`.

## numeric::cubicSpline2d

---

Without the option `Symbolic`, the abscissae  $x_i, y_j$  must be numerical real values in ascending order. If these data are not ordered, then `numeric::cubicSpline2d` reorders the abscissae internally, issuing a warning.

The function `S` returned by `numeric::cubicSpline2d` may be called with two, three, four, or five arguments, respectively:

- The call `S(x, y)` returns an arithmetical expression if  $x$  and  $y$  are numerical expressions. A float is returned if either  $x$  or  $y$  is a float and all parameters involved can be converted to floats.

If either  $x$  or  $y$  contains symbolic objects, the symbolic call `S(x, y)` is returned.

- The call `S(x, y, [u, v])` with nonnegative integers  $u, v$  returns the

partial derivative  $\frac{\partial^v}{\partial y^v} \frac{\partial^u}{\partial x^u} S$  of the spline. If either  $x$  or  $y$  contain symbolic objects, the symbolic call `S(x, y, [u, v])` is returned. The result is 0 if either  $u > 3$  or  $v > 3$ . The calls `S(x, y, [0, 0])` and `S(x, y)` are equivalent.

- The call `S(x, y, i, j)` with nonnegative integers  $i, j$  returns the polynomial representation of the spline on the patch  $p_{i,j}$ . Here,  $x$  and  $y$  may be arbitrary numerical or symbolic arithmetical expressions. Internally,  $(x, y)$  are assumed to lie in the patch  $p_{i,j}$ .
- The call `S(x, y, i, j, [u, v])` with nonnegative integers  $i, j, u, v$  returns the polynomial representation of the partial derivatives of the spline function. In this call,  $x$  and  $y$  may be arbitrary numerical or symbolic arithmetical expressions which are assumed to lie in the patch  $p_{i,j}$ . The result is 0 if either  $u > 3$  or  $v > 3$ . The calls `S(x, y, i, j, [0, 0])` and `S(x, y, i, j)` are equivalent.

If `S` is generated with symbolic abscissae  $x_i, y_j$  (necessarily using the option `Symbolic`), the call `S(x, y, [u, v])` is returned symbolically. The call `S(x, y, i, j, [u, v])` must be used for symbolic abscissae!

## Examples

### Example 1

We demonstrate some calls with numerical input data. The function  $f(x, y) = \sin(2\pi(x + y))$  with  $0 \leq x \leq 1$ ,  $0 \leq y \leq 1$  is to be interpolated by  $n + 1 = 11$  equidistant points in the  $x$ -direction and  $m + 1 = 13$  equidistant points in the  $y$ -direction:

```
f := (x, y) -> sin((x + y)*2*PI):
n := 10: x := [i/n $ i = 0..n]:
m := 12: y := [j/m $ j = 0..m]:
z := array(0..n, 0..m, [[f(i/n, j/m) $ j = 0..m] $ i = 0..n]):
S1 := numeric::cubicSpline2d(x, y, z, [NotAKnot, NotAKnot]):
S2 := numeric::cubicSpline2d(x, y, z, [Natural, Natural]):
S3 := numeric::cubicSpline2d(x, y, z, [NotAKnot, Periodic]):
```

We consider Complete boundary conditions in the  $y$ -direction. They consist of the values  $f_y(x_i, y_0) = f_y(x_i, 0) = 2\pi\cos(2\pi x_i)$  and  $f_y(x_i, y_m) = f_y(x_i, 1) = 2\pi\cos(2\pi x_i)$ :

```
ybc:= [[2*PI*cos(2*PI*i/n) $ i = 0..n],
 [2*PI*cos(2*PI*i/n) $ i = 0..n]]:
S4 := numeric::cubicSpline2d(x, y, z, [Periodic, Complete = ybc])
```

At the mesh points  $(x_i, y_j)$ , the input data  $z_{i,j}$  are reproduced:

```
x := 4/n: y := 8/m:
float(f(x, y)), S1(x, y), S2(x, y), S3(x, y), S4(x, y)
```

0.4067366431, 0.4067366431, 0.4067366431, 0.4067366431, 0.4067366431

Interpolation between the mesh points depends on the boundary condition:

```
x := 0.92: y:= 0.55: S1(x, y), S2(x, y), S3(x, y), S4(x, y)
```

# numeric::cubicSpline2d

---

```
0.1879484554, 0.1897776244, 0.1879457306, 0.1873726747
```

The approximation of the function value  $f(0.92, 0.55)$  is good for the NotAKnot, Periodic, and Complete boundary conditions. The Natural boundary conditions are less appropriate because the second partial derivatives of the function  $f$  do not vanish at the boundaries. Consequently, the approximation error of S2 is larger than the other approximation errors:

```
z := float(f(x, y)):
S1(x, y) - z, S2(x, y) - z, S3(x, y) - z, S4(x, y) - z
```

```
0.0005671407743, 0.002396309797, 0.0005644160155, -0.00000863986878
```

This is the bi-cubic polynomial in  $X, Y$  defining the spline S1 on the patch  $x_0 = 0 \leq X < x_1 = \frac{1}{n}$ ,  $y_3 = \frac{3}{m} \leq Y \leq y_4 = \frac{4}{m}$ :

```
expand(S1(X, Y, 0, 3))
```

```
-804.8629918 X3 Y3 + 6.210308852 X3 Y2 + 323.2124519 X3 Y - 39.06086335 X3 - 373.4077
+ 770.1743348 X2 Y2 - 297.137889 X2 Y + 7.665899226 X2 + 260.7571691 X Y3 - 199.770
+ 10.51686235 X Y + 6.008422078 X + 10.65805697 Y3 - 28.15535765 Y2 + 12.07773495
- 0.426256024
```

```
delete f, n, m, ybc, x, y, z, S1, S2, S3, S4:
```

## Example 2

We demonstrate some calls with symbolic data. With the option Symbolic, exact arithmetic is used:

```
S := numeric::cubicSpline2d(
 [i $ i = 0..3],
 [j $ j = 0..4],
 array(0..3, 0..4, [[z.i.j $ j = 0..4] $ i = 0..3]),
 Symbolic
):
```

```
S(1/2, 3/2)
```

$$\frac{5 z_{01}}{32} - \frac{15 z_{00}}{1024} + \frac{105 z_{02}}{512} - \frac{5 z_{03}}{128} + \frac{5 z_{04}}{1024} - \frac{45 z_{10}}{1024} + \frac{15 z_{11}}{32} + \frac{315 z_{12}}{512} - \frac{15 z_{13}}{128} + \frac{15 z_{14}}{1024} - \frac{105 z_{22}}{512} + \frac{5 z_{23}}{128} - \frac{5 z_{24}}{1024} - \frac{3 z_{30}}{1024} + \frac{z_{31}}{32} + \frac{21 z_{32}}{512} - \frac{z_{33}}{128} + \frac{z_{34}}{1024}$$

This is the bi-cubic polynomial in  $X, Y$  defining the spline with  $x_0 = 0 \leq X \leq x_1 = 1, y_1 = 1 \leq Y \leq y_2 = 2$ :

```
expand(S(X, Y, 0, 1))
```

$$z_{00} + X^2 z_{00} - \frac{X^3 z_{00}}{6} - \frac{5 X^2 z_{10}}{2} + \dots - \frac{X Y z_{34}}{36}$$

```
delete S:
```

### Example 3

We consider a spline interpolation of the function  $f(x, y) = \frac{1}{e^{x^2 + y^2}}$  with  $-1 \leq x \leq 1, -1 \leq y \leq 1$ :

```
n := 10: xmesh := [-1 + 2*i/n $ i = 0..n]:
m := 12: ymesh := [-1 + 2*j/n $ j = 0..m]:
f := (x, y) -> exp(-x^2 - y^2):
z := array(0..n, 0..m,
```

# numeric::cubicSpline2d

```
[[f(-1 + 2*i/n, -1 + 2*j/m) $ j=0..m] $ i = 0..n]):
S := numeric::cubicSpline2d(xmesh, ymesh, z):
```

We plot the spline function  $S(x, y)$ :

```
plotfunc3d(S(x, y), x = -1 .. 1, y = -1 .. 1):
```

We plot the partial derivative  $S_{xxxxyy}(x, y)$ . It is constant on each patch with jumps at the boundaries of the patches. The renderer uses  $[5n + 1, 5m + 1]$  mesh points: in each direction, 4 extra points between adjacent mesh points of the spline are used for the graphical representation:

```
plotfunc3d(S(x, y, [3, 3])/10, x = -1 .. 1, y = -1 .. 1,
Mesh = [5*n + 1, 5*m + 1])
```

```
delete n, xmesh, m, ymesh, f, z, S;
```

### Example 4

We demonstrate the spline interpretation of a surface. We consider a sphere parametrized by spherical coordinates  $u, v$  with  $0 \leq u \leq 2\pi$ ,  $0 \leq v \leq \pi$ :

$$x = \cos(u) \sin(v), \quad y = \sin(u) \sin(v), \quad z = \cos(v)$$

We interpolate the functions  $x, y, z$  over a rectangular mesh in the  $u$ - $v$ -plane. Since  $x, y$  and (trivially)  $z$  are  $2\pi$ -periodic in  $u$ , we choose **Periodic** boundary conditions for  $u$ . For  $v$ , we choose **Complete** boundary conditions with boundary values of the first partial  $v$ -derivative fitting the parametrization:

```
x := (u, v) -> cos(u)*sin(v): x_v := diff(x(u, v), v):
```

## numeric::cubicSpline2d

---

```
y:= (u, v) -> sin(u)*sin(v): y_v := diff(y(u, v), v):
z:= (u, v) -> cos(v): z_v := diff(z(u, v), v):
n := 4: umesh := [i*2*PI/n $ i = 0..n]:
m := 4: vmesh := [j*PI/m $ j = 0..m]:

vBC := Complete = [
 [subs(x_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
 [subs(x_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
X := numeric::cubicSpline2d(umesh, vmesh,
 array(0..n, 0..m, [[x(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
 [Periodic, vBC]):

vBC := Complete = [
 [subs(y_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
 [subs(y_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
Y := numeric::cubicSpline2d(umesh, vmesh,
 array(0..n, 0..m, [[y(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
 [Periodic, vBC]):

vBC := Complete = [
 [subs(z_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
 [subs(z_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
Z := numeric::cubicSpline2d(umesh, vmesh,
 array(0..n, 0..m, [[z(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
 [Periodic, vBC]):
```

With only  $(n + 1)(m + 1) = 5 \cdot 5$  mesh points, the spline surface yields a respectable approximation of a sphere. The interpolation nodes are added to the plot as blue points:

```
plot(
 plot::Surface([X(u, v), Y(u, v), Z(u, v)],
 u = 0..2*PI, v = 0..PI,
 Mesh = [5*n + 1, 5*m + 1],
 Color = RGB::Red),
 plot::Point3d(x(umesh[i], vmesh[j]),
 y(umesh[i], vmesh[j]),
```

```

z(umesh[i], vmesh[j]),
PointSize = 2*unit::mm,
Color = RGB::Blue
) $ i = 1..n+1 $ j = 1..m+1
):

```

```

delete x, x_v, y, y_v, z, z_v, n, m,
umesh, vmesh, vBC, X, Y, Z:

```

## Parameters

**$x_0, x_1, \dots, x_n$**

The  $x$ -coordinates of the nodes: distinct numerical real values in ascending order

**$y_0, y_1, \dots, y_m$**

The  $y$ -coordinates of the nodes: distinct numerical real values in ascending order

# numeric::cubicSpline2d

---

**z**

The function values: an array of the form `array(0..n, 0..m, [...])` with numerical or symbolic arithmetical expressions.

**xBC, yBC**

The type of the boundary condition: the boundary condition in the  $x$ - or  $y$ -direction may be one of the flags `NotAKnot`, `Natural`, `Periodic` or `Complete` = [...].

Complete boundary conditions consist of prescribed values for the derivatives  $S_x$  or  $S_y$ , respectively, along the mesh boundaries in the  $x$ - or  $y$ -direction, respectively. In the  $x$ -direction, these value may be passed in the form `Complete = [[a0, ..., am], [b0, ..., bm]]` with arbitrary numerical or symbolic arithmetical expressions  $a_0, \dots, b_m$ .

In the  $y$ -direction, these value may be passed in the form `Complete = [[a0, ..., an], [b0, ..., bn]]` with arbitrary numerical or symbolic arithmetical expressions  $a_0, \dots, b_n$ .

## Options

### Symbolic

With this option, no conversion of the input data to floating point numbers occurs.

Symbolic abscissae  $x_i, y_j$  are accepted.

The ordering  $x_0 < x_1 < \dots < x_n, y_0 < y_1 < \dots < y_m$  is assumed. This ordering is not checked even if the node coordinates are numerical!

### NotAKnot

With the default boundary condition `xBC = yBC = NotAKnot`, all partial derivatives of the spline function are continuous at the nodes with  $x$ -coordinates  $x_1$  and  $x_{n-1}$  or  $y$ -coordinates  $y_1$  and  $y_{m-1}$ , respectively. With this boundary condition,  $S$  is a polynomial on the union of the patches  $p_{0,j}, p_{1,j}$  and  $p_{n-2,j}, p_{n-1,j}$  or  $p_{i,0}, p_{i,1}$  and  $p_{i,m-2}, p_{i,m-1}$ , respectively.

This boundary condition is recommended if no information on the behaviour of the data near the mesh boundaries is available.

## Natural

The boundary condition `Natural` produces a spline function  $S$  with vanishing second partial derivatives at the boundary of the mesh.

This boundary condition is recommended if it is known that the data correspond to a surface with vanishing curvature near the mesh boundaries.

## Periodic

The boundary condition `Periodic` produces a spline function  $S$  satisfying

$$S(x_0, y) = S(x_n, y), S'(x_0, y) = S'(x_n, y), S''(x_0, y) = S''(x_n, y)$$

Or

$$S(x, y_0) = S(x, y_m), S'(x, y_0) = S'(x, y_m), S''(x, y_0) = S''(x, y_m)$$

Respectively. With this option, the input data  $z_{0,j}, z_{n,j}$ , respectively  $z_{i,0}, z_{i,m}$ , must coincide. Otherwise, an error is raised.

This boundary condition is recommended if the interpolation is to represent a periodic function.

## Complete

Option, specified as `Complete = [...]`

The `xBC` boundary condition `Complete = [[a0, ..., am], [b0, ..., bm]]` produces a spline function  $S$  satisfying  $S_x(x_0, y_j) = a_j, S_x(x_n, y_j) = b_j, j = 0, \dots, m$ .

# numeric::cubicSpline2d

---

The yBC boundary condition `Complete = [[a0, ..., an], [b0, ..., bn]]` produces a spline function  $S$  satisfying  $S_y(x_i, y_0) = a_i$ ,  $S_y(x_i, y_m) = b_i$ ,  $i = 0, \dots, n$ .

Symbolic data  $a_k, b_k$  are accepted.

This boundary condition is recommended if the data  $z_{i,j}$  correspond to a function with known values of the first partial derivatives at the mesh boundaries.

## Return Values

Spline function: a MuPAD procedure.

## See Also

## MuPAD Functions

`interpolate` | `numeric::cubicSpline`

## Purpose

Determinant of a matrix

## Syntax

`numeric::det(A, <mode>, <MinorExpansion>, <NoWarning>)`

## Description

`numeric::det(A)` returns the determinant of the matrix  $A$ .

Without the option `Symbolic`, all entries of  $A$  must be numerical.

Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floats. If symbolic entries are found in the matrix, `numeric::det` automatically switches to `Symbolic` issuing a warning.

The option `Symbolic` should be used if the matrix contains symbolic objects that cannot be converted to floating point numbers.

---

**Note** Matrices  $A$  of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that `linalg::det` must be used, when the determinant is to be computed over the component domain. See “Example 2” on page 18-39. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

---

## Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

Numerical matrices can be processed with or without the option `Symbolic`:

```
A := array(1..3, 1..3, [[1, 1, I], [1, exp(1), I], [1, 2, 2]]):
numeric::det(A), numeric::det(A, Symbolic)
```

```
3.436563657 - 1.718281828 i, e(2-i)-2+i
```

## numeric::det

---

The option `Symbolic` must be used when the matrix has non-numerical entries:

```
A := array(1..2, 1..2, [[1/(x + 1), 1], [1/(x + 2), PI]]):
numeric::det(A, Symbolic)
```

$$\frac{2\pi - X + \pi X - 1}{(X + 1)(X + 2)}$$

If the option `MinorExpansion` is used, symbolic entries are accepted, even if the option `Symbolic` is not specified:

```
detN := numeric::det(A, MinorExpansion);
detS := numeric::det(A, Symbolic, MinorExpansion)
```

$$\frac{0.0000000008 (2676990817.0 x + 6603981634.0)}{(x + 1.0)(x + 2.0)}$$

$$\frac{2\pi - X + \pi X - 1}{(X + 1)(X + 2)}$$

Simplify these results using `Simplify`:

```
Simplify(detN), Simplify(detS)
```

$$\frac{3.141592654}{x + 1.0} - \frac{1.0}{x + 2.0}, \frac{\pi}{x + 1} - \frac{1}{x + 2}$$

```
delete A:
```

### Example 2

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [1, 6]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 1 \bmod 7 & 6 \bmod 7 \end{pmatrix}$$

Note that `numeric::det` computes the determinant of the following matrix:

```
expr(A), numeric::det(A)
```

$$\begin{pmatrix} 6 & 6 \\ 1 & 6 \end{pmatrix}, 30.0$$

The routine `linalg::det` must be used, if the determinant is to be computed over the component domain `Dom::IntegerMod(7)`:

```
linalg::det(A)
```

$$2 \bmod 7$$

```
delete A:
```

### Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of the determinant is subject to severe cancellation effects. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical roundoff:

```
A := linalg::hilbert(15):
```

# numeric::det

---

```
float(numeric::det(A, Symbolic)),
numeric::det(A, HardwareFloats),
numeric::det(A, SoftwareFloats)
```

```
1.058542743 10-124, -3.822215463 10-121, 3.277553006 10-123
```

```
delete A:
```

## Parameters

**A**

A square matrix of domain type `DOM_ARRAY`, or `DOM_HFARRAY`, or of category `Cat::Matrix`

**mode**

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

## Options

**Hard, HardwareFloats, Soft, SoftwareFloats**

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point

numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-39.

---

## Symbolic

This option prevents conversion of the input data to floats. With this option, symbolic entries are accepted. It overrides the option `HardwareFloats`.

---

**Note** This option should not be used for floating-point matrices! The `Symbolic` algorithm does not implement safeguards against numerical instabilities in floating-point operations.

---

## MinorExpansion

With this option, recursive minor expansion along the columns is used. This option may be useful for small matrices with symbolic entries.

This option implies `SoftwareFloats`.

With this option, symbolic entries are accepted even if the option `Symbolic` is not used.

## NoWarning

Suppresses warnings

## Return Values

By default, the determinant is returned as a floating-point number. With the option `Symbolic`, an expression is returned.

## Algorithms

Without the option `Symbolic`,  $QR$ -factorization of  $A$  via Householder transformations is used.

With `Symbolic`,  $LU$ -factorization of  $A$  is used.

Functions**

`linalg::det`

**Related  
Examples**

- “Compute Determinant Numerically”

# numeric::eigenvalues

---

**Purpose** Numerical eigenvalues of a matrix

**Syntax** `numeric::eigenvalues(A, options)`

**Description** `numeric::eigenvalues(A)` returns numerical eigenvalues of the matrix  $A$ .

All entries of  $A$  must be numerical. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

---

**Note** Matrices  $A$  of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that `linalg::eigenvalues` must be used, when the eigenvalues are to be computed over the component domain. Cf. “Example 2” on page 18-46.

---

The eigenvalues are sorted by `numeric::sort`.

---

**Note** Eigenvalues are approximated with an *absolute* precision of  $\frac{r}{\text{DIGITS}}$ , where  $r$  is the spectral radius of  $A$  (i.e.,  $r$  is the maximum of the absolute values of the eigenvalues). Consequently, large eigenvalues should be computed correctly to DIGITS decimal places. The numerical approximations of the small eigenvalues are less accurate.

---

**Environment Interactions** The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

**Examples** **Example 1**

We compute the eigenvalues of the 3 3 Hilbert matrix:

```
numeric::eigenvalues(linalg::hilbert(3))
```

```
[1.408318927, 0.1223270659, 0.002687340356]
```

The following matrix is ill-conditioned. It has very large as well as very small eigenvalues:

```
A := array(1..3, 1..3,
 [[I , PI , exp(1)],
 [2 , 10^100 , 1],
 [10^(-100), 10^(-100), 10^(-100)]
]):
```

Precision goal and working precision are set by DIGITS. With the standard setting of *DIGITS* = 10, the following result is computed with HardwareFloats:

```
numeric::eigenvalues(A)
```

```
[1.0 10100, 5.0 10-101, 1.0 i]
```

```
[1.0 10100, 5.0 10-101, 1.0 i]
```

Note that small eigenvalues may be influenced by roundoff. We increase the working precision by increasing DIGITS. The smallest of the eigenvalues is computed more accurately:

```
DIGITS := 200:
eigenvals := numeric::eigenvalues(A):
DIGITS := 5:
eigenvals;
```

# numeric::eigenvalues

---

$$\left[ 1.0 \cdot 10^{100} + 6.2832 \cdot 10^{-200} i, 1.0 \cdot 10^{-100} + 2.7183 \cdot 10^{-100} i, -6.2832 \cdot 10^{-100} + 1.0 i \right]$$

```
delete A, eigenvals, DIGITS:
```

## Example 2

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))(
 [[6, -1, 4], [0, 3, 3], [0, 0, 3]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 & 4 \bmod 7 \\ 0 \bmod 7 & 3 \bmod 7 & 3 \bmod 7 \\ 0 \bmod 7 & 0 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

Note that `numeric::eigenvalues` computes the eigenvalues of the following matrix:

```
expr(A), numeric::eigenvalues(A)
```

$$\begin{pmatrix} 6 & 6 & 4 \\ 0 & 3 & 3 \\ 0 & 0 & 3 \end{pmatrix}, [6.0, 3.0, 3.0]$$

If the eigenvalues are to be computed over the component domain `Dom::IntegerMod(7)`, `linalg::eigenvalues` should be used:

```
linalg::eigenvalues(A, Multiple)
```

$$[[3 \bmod 7, 2], [6 \bmod 7, 1]]$$

```
delete A:
```

## Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of small eigenvalues is subject to severe roundoff effects. In the following results, both with `HardwareFloats` as well as with `SoftwareFloats`, the small eigenvalues are marred by numerical roundoff:

```
A := linalg::hilbert(15):
numeric::eigenvalues(A, HardwareFloats),
numeric::eigenvalues(A, SoftwareFloats)
```

```
[1.845927746, ..., 8.619013323 10-17, 2.268836709 10-17], [1.845927746, ..., 2.0959300
6.646989777 10-21]
```

```
delete A:
```

## Parameters

**A**

A numerical matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`.

## Options

**Hard, HardwareFloats, Soft, SoftwareFloats**

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by

## numeric::eigenvalues

---

default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-47.

---

## **NoWarning**

## **Related Examples**

- “Compute Eigenvalues and Eigenvectors Numerically”

# numeric::eigenvectors

---

**Purpose** Numerical eigenvalues and eigenvectors of a matrix

**Syntax** `numeric::eigenvectors(A, options)`

**Description** `numeric::eigenvectors(A)` returns numerical eigenvalues and eigenvectors of the matrix  $A$ .

All entries of the matrix must be numerical. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

The eigenvalues are sorted by `numeric::sort`.

The matrix  $X$  provides the eigenvectors: the  $i$ -th column of  $X$  is a numerical eigenvector corresponding to the eigenvalue  $d_i$ . Each column is either zero or normalized to the Euclidean length 1.0.

For matrices with multiple eigenvalues and an insufficient number of eigenvectors, some of the eigenvectors may coincide or may be zero, i.e.,  $X$  is not necessarily invertible.

The list of residues  $res = [res_1, res_2, \dots]$  provides some control over the quality of the numerical spectral data. The residues are given by

$$res_i = \|A x_i - d_i x_i\|_2$$

where  $x_i$  is the normalized eigenvector (the  $i$ -th column of  $X$ ) associated with the numerical eigenvalue  $d_i$ . For Hermitian matrices,  $res_i$  provides an upper bound for the absolute error of  $d_i$ .

With the option `NoResidues`, the computation of the residues is suppressed, the returned value is `NIL`.

If no return type is specified via the option `ReturnType = t`, the domain type of the eigenvector matrix  $X$  depends on the type of the input matrix  $A$ :

- The eigenvectors of an array are returned as an array.

- The eigenvectors of an hfarray are returned as an hfarray.
- The eigenvectors of a dense matrix of type `Dom::DenseMatrix()` are returned as a dense matrix of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices of category `Cat::Matrix`, the eigenvectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

---

**Note** Matrices `A` of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that `linalg::eigenvectors` must be used, when the eigenvalues/vectors are to be computed over the component domain. Cf. “Example 3” on page 18-54.

---

---

**Note** Eigenvalues are approximated with an *absolute* precision of  $\frac{r}{\text{DIGITS}}$ , where  $r$  is the spectral radius of `A` (i.e.,  $r$  is the maximal singular value of `A`). Consequently, large eigenvalues should be computed correctly to `DIGITS` decimal places. The numerical approximations of the small eigenvalues are less accurate.

---

---

**Note** For a numerical algorithm, it is not possible to distinguish between badly separated distinct eigenvalues and multiple eigenvalues. For this reason, `numeric::eigenvectors` and `linalg::eigenvectors` use different return formats: the latter can provide information on the multiplicity of eigenvalues due to its internal exact arithmetic.

---

Use `numeric::eigenvalues` if only eigenvalues are to be computed.

# numeric::eigenvectors

---

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

We compute the spectral data of the 2 2 Hilbert matrix:

```
A := linalg::hilbert(2)
```

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

```
[d, X, res] := numeric::eigenvectors(A):
```

The eigenvalues:

```
d
```

```
[1.267591879, 0.06574145409]
```

The eigenvectors:

```
X
```

$$\begin{pmatrix} 0.8816745988 & -0.4718579255 \\ 0.4718579255 & 0.8816745988 \end{pmatrix}$$

Hilbert matrices are Hermitian, i.e., computing the spectral data is a numerically stable process. This is confirmed by the small residues:

```
res
```

```
[2.355138688 10-16, 1.388645872 10-16]
```

The routine `linalg::hilbert` provides the input as a matrix of type `Dom::Matrix()`. Consequently, the eigenvectors also consist of such a matrix. For further processing, we convert the list of eigenvalues to a diagonal matrix:

```
d := matrix(2, 2, d, Diagonal):
```

We reconstruct the matrix from its spectral data:

```
X*d*X^(-1)
```

```
(1.0 0.5
 0.5 0.3333333333)
```

We extract an eigenvector from the matrix `X` and doublecheck its numerical quality:

```
eigenvector1 := X::dom::col(X, 1);
norm(A*eigenvector1 - d[1, 1]*eigenvector1)
```

```
(0.8816745988
 0.4718579255)
```

```
1.769417945 10-16
```

```
delete A, d, X, res, eigenvector1:
```

## Example 2

We demonstrate a numerically ill-conditioned case. The following matrix has only one eigenvector and cannot be diagonalized.

## numeric::eigenvectors

---

Numerically, the zero vector is returned as the second column of the eigenvector matrix:

```
A := array(1..2, 1..2, [[5, -1], [4, 1]]):
DIGITS := 6:
numeric::eigenvectors(A)
```

```
[3.0, 3.0], (0.447214 0
 0.894427 0), [1.66533 10-16, 0.0]]
```

```
delete A, DIGITS:
```

### Example 3

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [0, 3]])
```

```
(6 mod 7 6 mod 7
 0 mod 7 3 mod 7)
```

Note that `numeric::eigenvectors` computes the spectral data of the following matrix:

```
expr(A)
```

```
(6 6
 0 3)
```

```
numeric::eigenvectors(A, NoResidues)
```

```
[6.0, 3.0], (1.0 0.894427191
 0 -0.4472135955), NIL]
```

The routine `linalg::eigenvectors` should be used if the spectral data are to be computed over the component domain `Dom::IntegerMod(7)`:

```
linalg::eigenvectors(A)
```

$$\left[ \left[ 3 \bmod 7, 1, \begin{bmatrix} 5 \bmod 7 \\ 1 \bmod 7 \end{bmatrix} \right], \left[ 6 \bmod 7, 1, \begin{bmatrix} 1 \bmod 7 \\ 0 \bmod 7 \end{bmatrix} \right] \right]$$

```
delete A:
```

## Example 4

We demonstrate the use of hardware floats. The following matrix is degenerate: it has rank 1. For the double eigenvalue 0, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..3, 1..3, [[1, 2, 3], [2, 4, 6], [3*10^12, 6*10^12,
[d1, X1, res1] := numeric::eigenvectors(A, HardwareFloats):
d1, X1
```

$$\left[ 9.0 \cdot 10^{12}, 0.0, -4.543838814 \cdot 10^{-16} \right], \begin{pmatrix} 3.333333333 \cdot 10^{-13} & 0.9486832981 & 0.96210 \\ 6.666666667 \cdot 10^{-13} & -2.108185107 \cdot 10^{-13} & -0.10127 \\ 1.0 & -0.316227766 & -0.25318 \end{pmatrix}$$

```
[d2, X2, res2] := numeric::eigenvectors(A, SoftwareFloats):
d2, X2
```

$$\left[ 9.0 \cdot 10^{12}, 5.421010862 \cdot 10^{-20}, 0.0 \right], \begin{pmatrix} 0 & 0.9592641938 & 0.9486832981 \\ 0 & -0.06851887098 & 0 \\ 1.0 & -0.2740754839 & -0.316227766 \end{pmatrix}$$

# numeric::eigenvectors

---

```
delete A, d1, X1, res1, d2, X2, res2:
```

## Parameters **A**

A numerical matrix of domain type `DOM_ARRAY`, or `DOM_HFARRAY`, or of category `Cat::Matrix`.

## Options **Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no **HardwareFloats** or **SoftwareFloats** are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix **A** is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`, or if one of the

options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 4” on page 18-55.

---

## **NoResidues**

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues `res`. The return values for these data are `NIL`.

# numeric::eigenvectors

---

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

## ReturnType

Option, specified as `ReturnType = t`

Return the eigenvectors as a matrix of domain type `t`. The following return types `t` are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## NoWarning

Suppresses warnings

## Return Values

List `[d, X, res]`. The list `d = [d1, d2, ...]` contains the numerical eigenvalue. The  $i$ -th column of the matrix `X` is the eigenvector associated with the eigenvalue `di`. The list of residues `res = [res1, res2, ...]` provides error estimates for the numerical eigenvalues.

## Algorithms

The routine implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

## Related Examples

- “Compute Eigenvalues and Eigenvectors Numerically”

## Purpose

Exponential of a matrix

## Syntax

```
numeric::expMatrix(A, <mode>, <method>, options)
numeric::expMatrix(A, x, <mode>, <method>, options)
numeric::expMatrix(A, X, <mode>, <method>, options)
```

## Description

`numeric::expMatrix(A)` returns the exponential  $e^A$  of a square matrix  $A$ .

`numeric::expMatrix(A, x)` with a vector  $x$  returns the vector  $e^A x$ .

`numeric::expMatrix(A, X)` with a matrix  $X$  returns the matrix  $e^A X$ .

If no return type is specified via the option `ReturnType = d`, the domain type of the result depends on the type of the input matrix  $A$ :

- For an array  $A$ , the result is returned as an array.
- For an hfarray  $A$ , the result is returned as an hfarray.
- For a dense matrix  $A$  of type `Dom::DenseMatrix(Ring)`, the result is again a matrix of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices  $A$  of category `Cat::Matrix`, the result is returned as a matrix of type `Dom::Matrix()` over the ring of expressions. This includes input matrices  $A$  of type `Dom::Matrix(Ring)`, `Dom::SquareMatrix(Ring)`, `Dom::MatrixGroup(Ring)` etc.

The components of  $A$  must not contain symbolic objects which cannot be converted to numerical values via `float`. Numerical symbolic expressions such as  $\pi$ ,  $\sqrt{2}$ ,  $e^{-1}$  etc. are accepted. They are converted to floats.

The specification of a method such as `TaylorExpansion` etc. implies `SoftwareFloats`, i.e., the result is computed via the software arithmetic of the MuPAD kernel.

# numeric::expMatrix

---

The methods Diagonalization and Interpolation do not work for all matrices (see below).

With SoftwareFloats, special algorithms are implemented for traceless 2 2 matrices and skew symmetric 3 3 matrices. Specification of a particular method does not have any effect for such matrices.

If  $e^A x$  or  $e^A X$  is required, one should not compute  $e^A$  first and then multiply the resulting matrix with the vector/matrix  $x/X$ . In general, the call `numeric::expMatrix(A, x)` or `numeric::expMatrix(A, X)`, respectively, is faster.

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

We consider a lower triangular matrix given by an array:

```
A := array(1..2, 1..2, [[1, 0] , [1, PI]]):
expA := numeric::expMatrix(A)
```

```
(2.718281828 0
 9.536085572 23.14069263)
```

We consider a vector given by a list  $x1$  and by an equivalent 1-dimensional array  $x2$ , respectively:

```
x1 := [1, 1]:
x2 := array(1..2, [1, 1]):
```

Futher, an equivalent input vector  $X$  of type `Dom::Matrix()` is used:

```
X := matrix(x1):
```

The following three calls all yield a vector represented by an 2 1 array corresponding to the type of the input matrix  $A$ :

```
numeric::expMatrix(A, x1),
numeric::expMatrix(A, x2, Krylov),
numeric::expMatrix(A, X, Diagonalization)
```

```
(2.718281828) (2.718281828) (2.718281828)
 (32.6767782) (32.6767782) (32.6767782)
```

For further processing, the array `expA` is converted to an element of the matrix domain `Dom::Matrix()`:

```
expA := matrix(expA):
```

Now, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further computations:

```
expA*X
```

```
(2.718281828)
 (32.6767782)
```

```
delete A, expA, x1, x2, X:
```

## Example 2

We demonstrate the different precision goals of the methods. Note that software arithmetic is used when a method is specified:

```
A := array(1..3, 1..3, [[1000, 1, 0],
 [0, 1, 1],
 [1/10^100, 0, -1000]]):
```

The default method `TaylorExpansion` computes *each component* of  $e^A$  correctly:

```
numeric::expMatrix(A, SoftwareFloats)
```

## numeric::expMatrix

---

$$\begin{pmatrix} 1.970071114 \cdot 10^{434} & 1.972043157 \cdot 10^{431} & 9.860215786 \cdot 10^{427} \\ 9.860215786 \cdot 10^{327} & 9.870085871 \cdot 10^{324} & 4.935042936 \cdot 10^{321} \\ 9.85035557 \cdot 10^{330} & 9.860215786 \cdot 10^{327} & 4.930107893 \cdot 10^{324} \end{pmatrix}$$

The method `Diagonalization` produces a result, which is accurate in the sense that  $\|\text{error}\|_{\infty} \leq \|e^A\|_{\infty} \frac{1}{10^{\text{DIGITS}}}$  holds. Indeed, the largest components of  $e^A$  are correct. However, `Diagonalization` does not even get the right order of magnitude of the smaller components:

```
numeric::expMatrix(A, Diagonalization)
```

$$\begin{pmatrix} 1.970071114 \cdot 10^{434} & 1.972043157 \cdot 10^{431} & 0 \\ 0 & 2.718281828 & 0 \\ 0 & 0 & 5.075958898 \cdot 10^{-435} \end{pmatrix}$$

Note that  $e^A$  is very sensitive to small changes in  $A$ . After elimination of the small lower triangular element, both methods yield the same result with correct digits for all entries:

```
B := array(1..3, 1..3, [[1000, 1, 0],
 [0, 1, 1],
 [0, 0, -1000]]):
numeric::expMatrix(B, SoftwareFloats)
```

$$\begin{pmatrix} 1.970071114 \cdot 10^{434} & 1.972043157 \cdot 10^{431} & 9.860215786 \cdot 10^{427} \\ 0 & 2.718281828 & 0.002715566262 \\ 0 & 0 & 5.075958897 \cdot 10^{-435} \end{pmatrix}$$

```
numeric::expMatrix(B, Diagonalization)
```

$$\begin{pmatrix} 1.970071114 \cdot 10^{434} & 1.972043157 \cdot 10^{431} & 9.860215786 \cdot 10^{427} \\ 0 & 2.718281828 & 0.002715566262 \\ 0 & 0 & 5.075958898 \cdot 10^{-435} \end{pmatrix}$$

```
delete A, B;
```

### Example 3

Hilbert matrices  $H_{ij} = \frac{1}{i+j-1}$  have real positive eigenvalues. For large dimension, most of these eigenvalues are small and may be regarded as a single cluster. Consequently, the option Krylov is useful:

```
numeric::expMatrix(linalg::hilbert(100), [1 $ 100], Krylov)
```

```
[25.47080919, 18.59337041, ..., 2.863083064, 2.848538965]
```

## Parameters

**A**

A square  $n \times n$  matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix

**x**

# numeric::expMatrix

---

A vector represented by a list  $[x_1, \dots, x_n]$  or a 1-dimensional array `array(1..n, [x_1, \dots, x_n] )`, or a 1-dimensional hfarray `hfarray(1..n, [x_1, \dots, x_n] )`

## **x**

An  $n \times m$  matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix(Ring)` or `Dom::DenseMatrix(Ring)` with a suitable coefficient ring `Ring`

## **mode**

One of the flags `Hard`, `HardwareFloats`, `Soft`, or `SoftwareFloats`

## **method**

One of the flags `Diagonalization`, `Interpolation`, `Krylov`, or `TaylorExpansion`

## **Options**

### **Hard, HardwareFloats, Soft, SoftwareFloats**

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

## **Diagonalization, Interpolation, Krylov, TaylorExpansion**

## numeric::expMatrix

---

The specification of a method implies `SoftwareFloats`, i.e., the result is always computed via the software arithmetic of the MuPAD kernel.

The method `TaylorExpansion` is the default algorithm. It produces fast results for matrices with small norms.

The default method `TaylorExpansion` computes *each individual component* of  $e^A$ ,  $e^A x$ ,  $e^A X$  to a relative precision of about  $10^{(-DIGITS)}$ , unless numerical roundoff prevents reaching this precision goal. Roughly speaking: all digits of all components of the result are reliable up to roundoff effects.

---

**Note** The methods `Diagonalization`, `Interpolation`, and `Krylov` compute the result to a relative precision w.r.t. the norm:

$\|error\|_{\infty} \leq \frac{\|result\|_{\infty}}{10^{DIGITS}}$ . Consequently, if the result has components of different orders of magnitude, then the smaller components have larger relative errors than the large components. Not all digits of the small components are reliable! Cf. “Example 2” on page 18-61.

---

---

**Note** The method `Diagonalization` only works for diagonalizable matrices. For matrices without a basis of eigenvectors, `numeric::expMatrix` may either produce an error or the returned result is dominated by roundoff effects. For symmetric/Hermitian or skew/skew-Hermitian matrices, this method produces reliable results.

---

---

**Note** The method Interpolation may become numerically unstable for certain matrices. The algorithm tries to detect such instabilities and stops with an error message.

---

The method Krylov is only available for computing  $e^A x$  with a vector  $x$ . Also vectors represented by  $n \times 1$  matrices are accepted.

This method is fast when  $x$  is spanned by few eigenvectors of  $A$ . Further, if  $A$  has only few clusters of similar eigenvalues, then this method can be much faster than the other methods. Cf. “Example 3” on page 18-63.

### NoWarning

Suppresses warnings

### ReturnType

Option, specified as `ReturnType = d`

Return the result matrix or vector as a matrix of domain type  $d$ . The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## Return Values

All results are float matrices/vectors. For an  $n \times n$  matrix  $A$ :

- `numeric::expMatrix(A, method)` returns  $e^A$  as an  $n \times n$  matrix,
- `numeric::expMatrix(A, x, method)` returns  $e^A x$  as an  $n \times 1$  matrix,
- `numeric::expMatrix(A, X, method)` returns  $e^A X$  as an  $n \times m$  matrix.

The domain type of the result depends on the domain type of the input matrix  $A$  unless a return type is requested explicitly via `ReturnType = d`.

# numeric::expMatrix

---

## Algorithms

The method `TaylorExpansion` sums the usual Taylor series

$$e^A = 1 + A + \frac{A^2}{2} + \dots$$

in a suitable numerically stable way.

The method `Diagonalization` computes

$$e^A = T \operatorname{diag}(e^{\lambda_1}, e^{\lambda_2}, \dots) T^{-1}$$
 by a diagonalization  $A = T \operatorname{diag}(\lambda_1, \lambda_2, \dots) T^{-1}$ .

The method `Interpolation` computes a polynomial  $P$  interpolating the function `exp` at the eigenvalues of  $A$ . Evaluation of the matrix polynomial yields  $e^A = P(A)$ .

The method `Krylov` reduces  $A$  to a Hessenberg matrix  $H$  and computes an approximation of  $e^A x$  from  $e^H$ . Depending on  $A$  and  $x$ , the dimension of  $H$  may be smaller than the dimension of  $A$ .

`numeric::expMatrix` uses polynomial arithmetic to multiply matrices and vectors. Thus, sparse matrices are handled efficiently based on the MuPAD internal sparse representation of polynomials.

## MuPAD Functions

`exp`

## Purpose

Cholesky factorization of a matrix

## Syntax

`numeric::factorCholesky(A, options)`

## Description

`numeric::factorCholesky(A)` returns the factor  $L$  of the Cholesky factorization  $A = LL^H$  of a positive definite Hermitian matrix  $A$ .

`numeric::factorCholesky(A, Symmetric)` returns the factor  $L$  of a Cholesky type factorization  $A = LL^T$  of a symmetric matrix  $A$ .

The Cholesky factorization of a square Hermitian matrix is  $A = LL^H$ , where  $L$  is a regular complex lower triangular matrix and  $L^H$  is the Hermitian transpose of  $L$  (i.e., the complex conjugate of the transpose of  $L$ ). Such a factorization only exists if  $A$  is positive definite.

By default, a numerical factorization is computed. If the option `Symbolic` is not used, all components of the matrix are converted to floating-point numbers. In this case, the matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as  $\pi$ ,  $\sqrt{2}$ ,  $e^{-1}$  etc. are accepted.

If no return type is specified via the option `ReturnType = d`, the domain type of the Cholesky factor  $L$  depends on the type of the input matrix  $A$ :

- The factor of an array is returned as an array.
- The factor of an hffarray is returned as an hffarray.
- The factor of a dense matrix of type `Dom::DenseMatrix()` is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the factor  $L$  is returned as a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices  $A$  of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

# numeric::factorCholesky

---

The Cholesky factor returned by `numeric::factorCholesky` is normalized such that its diagonal elements are real and positive.

## Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We consider the matrix

```
A := array(1..2, 1..2, [[1, I], [-I, PI]]):
```

We compute a numerical factorization

```
numeric::factorCholesky(A)
```

$$\begin{pmatrix} 1.0 & 0 \\ -1.0 i & 1.46341814 \end{pmatrix}$$

and a symbolic factorization:

```
L := numeric::factorCholesky(A, Symbolic)
```

$$\begin{pmatrix} 1 & 0 \\ -i & \sqrt{\pi - 1} \end{pmatrix}$$

For further processing, the Cholesky factor (of domain type `DOM_ARRAY`) is converted to an element of the matrix domain `Dom::Matrix()`:

```
L := matrix(L):
```

Now, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further computations:

```
L*linalg::transpose(conjugate(L))
```

$$\begin{pmatrix} 1 & i \\ -i & \pi \end{pmatrix}$$

```
delete A, L:
```

## Example 2

The following matrix is not positive definite:

```
A := matrix([[-2, sqrt(2)], [sqrt(2), 1]]):
numeric::factorCholesky(A)
```

```
Error: The matrix is not positive definite within working precision
```

However, a symmetric factorization with a complex Cholesky factor does exist:

```
numeric::factorCholesky(A, Symmetric)
```

$$\begin{pmatrix} 1.414213562 i & 0 \\ -1.0 i & 1.414213562 \end{pmatrix}$$

```
delete A:
```

## Example 3

The option NoCheck should be used when the matrix contains symbolic objects:

```
assume(x > 0): assume(z > 0):
A := array(1..2, 1..2, [[x, conjugate(y)], [y, z]]):
numeric::factorCholesky(A, Symbolic, NoCheck)
```

# numeric::factorCholesky

---

$$\begin{pmatrix} \sqrt{x} & 0 \\ \frac{y}{\sqrt{x}} & \sqrt{z - \frac{|y|^2}{x}} \end{pmatrix}$$

Note that with `NoCheck`, it is assumed that the matrix is Hermitian and positive definite! All upper triangular entries are ignored. The following result implicitly assumes  $u = \text{conjugate}(y)$ :

```
A := array(1..2, 1..2, [[x, u], [y, z]]):
numeric::factorCholesky(A, Symbolic, NoCheck)
```

$$\begin{pmatrix} \sqrt{x} & 0 \\ \frac{y}{\sqrt{x}} & \sqrt{z - \frac{|y|^2}{x}} \end{pmatrix}$$

```
delete A:
```

## Example 4

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned and difficult to factor with low values of `DIGITS`. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical roundoff. Consequently, the factorization with and without hardware floats, respectively, differ significantly:

```
A := linalg::hilbert(13):
L1 := numeric::factorCholesky(A, HardwareFloats):
L2 := numeric::factorCholesky(A, SoftwareFloats):
L1[13, 13] <> L2[13, 13]
```

0.0000001052365221 ≠ 0.00000007585706698

All Hilbert matrices are positive definite. However, in the following call, numerical roundoff makes the hardware floating-point tool think that the matrix is not definite:

```
numeric::factorCholesky(linalg::hilbert(14), HardwareFloats):
```

```
Error: The matrix is not positive definite within working precision
```

A factorization is computed successfully with SoftwareFloats:

```
L := numeric::factorCholesky(linalg::hilbert(14), SoftwareFloats)
norm(linalg::hilbert(14) - L*linalg::transpose(L))
```

```
8.67361738 10-19
```

```
delete A, L1, L2, L:
```

## Parameters

**A**

A square matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix

## Options

**Hard, HardwareFloats, Soft, SoftwareFloats**

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are done using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by

## numeric::factorCholesky

---

default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 4” on page 18-72.

---

## Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix  $A$  may contain symbolic objects. Note that the option `NoCheck` must be used for the Hermitian factorization when non-numerical symbolic objects are present.

## Symmetric

Makes `numeric::factorCholesky` compute a symmetric factorization  $A = LL^T$  rather than a Hermitian factorization  $A = LL^H$ .

The symmetric Cholesky factorization of a square symmetric matrix is  $A = LL^T$ , where  $L$  is a regular complex lower triangular matrix and  $L^T$  is the transpose of  $L$ . The matrix  $A$  does not have to be positive definite. Consequently, with the option `Symmetric` no internal check is performed whether  $A$  is positive definite. Note that the symmetric factorization with regular  $L$  does not exist for all matrices.

For real symmetric positive definite matrices  $A$  the Cholesky factor  $L$  is real and the Hermitian factorization  $A = LL^H$  coincides with the symmetric factorization  $A = LL^T$ .

# numeric::factorCholesky

---

## NoCheck

Prevents `numeric::factorCholesky` from checking that the matrix is Hermitian and positive definite

Without the option `Symmetric`, `numeric::factorCholesky` checks that the matrix  $A$  is Hermitian and positive definite. The option `NoCheck` may be used to suppress these checks. It must be used when the matrix contains symbolic objects. Elements in the upper triangular part of the matrix will never be touched by the algorithm!

---

**Note** With this option, `numeric::factorCholesky` returns a result for matrices that are not Hermitian or not positive definite (i.e., no Cholesky factorization exists)! When using this option, it is the user's responsibility to make sure that the input matrix is appropriate.

---

This option has no effect when the option `Symmetric` is used.

## NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorCholesky` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

## ReturnType

Option, specified as `ReturnType = d`

Return the Cholesky factor as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## Return Values

Depending on the type of the input matrix  $A$ , the lower triangular Cholesky factor  $L$  is returned as a matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`. Its components are real or complex floats, unless the option `Symbolic` is used. Without the option `NoCheck`, an error is raised if the matrix is not Hermitian or not positive definite.

- “Compute Factorizations Numerically”

# numeric::factorLU

---

**Purpose** LU factorization of a matrix

**Syntax** `numeric::factorLU(A, options)`

**Description** `numeric::factorLU(A)` returns a  $LU$  factorization of the matrix  $A$ .

The  $LU$  factorization of a real or complex  $m \times n$  matrix  $A$  is  $PA = LU$ . The  $m \times m$  matrix  $L$  is lower triangular, normalized to 1 along the diagonal. The  $m \times n$  matrix  $U$  is upper triangular, i.e.,  $U_{ij} = 0$  for  $j < i$ . The list  $p = [p_1, \dots, p_m]$  returned by `numeric::factorLU` is a permutation of the numbers  $1, \dots, m$  corresponding to row exchanges of  $A$ . It represents the following  $m \times m$  permutation matrix  $P$  (we assume that the matrix indices range from 1 to  $m$ ):

$$P_{ij} = \delta_{p_i, j} = \begin{cases} 1 & \text{if } j = p_i \\ 0 & \text{if } j \neq p_i \end{cases}$$

Left multiplication of matrices and vectors with  $P$  is realized easily using the permutation list  $p$ :  $Y_{i, j} := X_{p_i, j}$  defines the row permutation  $Y = PX$  of a matrix  $X$ ,  $y_i := x_{p_i}$  defines the row permutation  $y = Px$  of a vector  $x$ .

By default, a numerical factorization with partial pivoting is computed. If the option `Symbolic` is not used, all components of the matrix are converted to floating-point numbers. In this case, the matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as  $\pi$ ,  $\sqrt{2}$ ,  $e^{-1}$  etc. are accepted.

The factorization depends on the pivoting strategy. The results obtained with/without the option `Symbolic` may differ. See “Example 2” on page 18-80. For numerical factorizations, the results obtained with `HardwareFloats` and `SoftwareFloats`, respectively, may differ. See “Example 3” on page 18-81.

If no return type is specified via the option `ReturnType = d`, the domain type of the factors  $L$  and  $U$  depends on the type of the input matrix  $A$ :

- The factors of an array are returned as arrays.
- The factors of an hfarray are returned as hfarrays.
- The factors of a dense matrix of type `Dom::DenseMatrix()` are again dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the factors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

## Environment Interactions

Without the optional argument `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We factor a matrix specified by an array:

```
A := array(1..3, 1..3, [[1, 2, 3], [2, 4, 6], [4, 8, 9]]):
[L, U, p] := numeric::factorLU(A)
```

$$\left[ \begin{pmatrix} 1.0 & 0 & 0 \\ 0.5 & 1.0 & 0 \\ 0.25 & 0 & 1.0 \end{pmatrix}, \begin{pmatrix} 4.0 & 8.0 & 9.0 \\ 0 & 0 & 1.5 \\ 0 & 0 & 0.75 \end{pmatrix}, [3, 2, 1] \right]$$

The factors (of domain type `DOM_ARRAY`) are converted to elements of the matrix domain `Dom::Matrix()`. After the conversion, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further processing:

```
L := matrix(L): U := matrix(U):
L*U
```

# numeric::factorLU

---

$$\begin{pmatrix} 4.0 & 8.0 & 9.0 \\ 2.0 & 4.0 & 6.0 \\ 1.0 & 2.0 & 3.0 \end{pmatrix}$$

The product  $LU$  coincides with  $A$  after exchanging the rows according to the permutation stored in the list  $p$ :

```
PA := array(1..3, 1..3, [[A[p[i], j] $ j=1..3] $ i=1..3])
```

$$\begin{pmatrix} 4 & 8 & 9 \\ 2 & 4 & 6 \\ 1 & 2 & 3 \end{pmatrix}$$

```
delete A, L, U, p, PA:
```

## Example 2

We consider a non-square matrix of dimension 3 2:

```
A := matrix([[3*I, 10], [I, 1], [I, 1]]):
[L1, U1, p1] := numeric::factorLU(A)
```

$$\left[ \begin{pmatrix} 1.0 & 0 & 0 \\ 3.0 & 1.0 & 0 \\ 1.0 & 0 & 1.0 \end{pmatrix}, \begin{pmatrix} 1.0 & i & 1.0 \\ 0 & 7.0 \\ 0 & 0 \end{pmatrix}, [2, 1, 3] \right]$$

Note that the symbolic factorization is different, because a different pivoting strategy is used:

```
[L2, U2, p2] := numeric::factorLU(A, Symbolic)
```

$$\left[ \begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{3} & 1 & 0 \\ \frac{1}{3} & 1 & 1 \end{pmatrix}, \begin{pmatrix} 3 & i & 10 \\ 0 & -\frac{7}{3} \\ 0 & 0 \end{pmatrix}, [1, 2, 3] \right]$$

Here, the matrix factors are of type `Dom::Matrix()`, because the input matrix  $A$  was of this type. We can use the overloaded arithmetic directly. We convert the permutation lists `p1`, `p2` to matrices and verify the relation  $PA = LU$  for the factorization:

```
P1 := matrix(3, 3):
P2 := matrix(3, 3):
for i from 1 to 3 do
 P1[i, p1[i]] := 1;
 P2[i, p2[i]] := 1;
end_for:
P1*A - L1*U1, P2*A - L2*U2
```

$$\begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}$$

```
delete A, L1, U1, p1, L2, U2, p2:
```

### Example 3

We demonstrate the use of hardware floats. The internal rounding of `HardwareFloats` and `SoftwareFloats` differs. Consequently, the following results do not coincide:

```
n := 14:
A := linalg::hilbert(n):
[L1, U1, p1] := numeric::factorLU(A, HardwareFloats):
[L2, U2, p2] := numeric::factorLU(A, SoftwareFloats):
p1, p2
```

# numeric::factorLU

---

```
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 13], [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14]
```

However, both factorizations satisfy  $PA = LU$  numerically:

```
P1A := matrix([[A[p1[i], j] $ j = 1..n] $ i = 1..n]):
P2A := matrix([[A[p2[i], j] $ j = 1..n] $ i = 1..n]):
norm(P1A - L1*U1), norm(P2A - L2*U2)
```

```
8.131516294 10-17, 5.421010862 10-19
```

```
delete n, A, L1, U1, p1, L2, U2, p2, P1A, P2A:
```

## Parameters **A**

An  $m \ n$  matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

## Options **Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point

numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

# numeric::factorLU

---

---

**Note** For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-81.

---

## Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix  $A$  may contain symbolic objects.

With this option, no row exchanges are performed in the internal Gaussian elimination unless necessary.

## NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorLU` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

## ReturnType

Option, specified as `ReturnType = d`

Return the factors as matrices of domain type  $d$ . The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## Return Values

List  $[L, U, p]$  is returned. The domain type of the  $m \times m$  matrix  $L$  and the  $m \times n$  matrix  $U$  depends on the type of the input matrix  $A$ ;  $p$  is a list with  $m$  elements consisting of a permutation of the integers  $1, \dots, m$ . It represents row exchanges in pivoting steps. The components of  $L$  and  $U$  are real or complex floats, unless the option `Symbolic` is used.

# numeric::factorQR

---

**Purpose** QR factorization of a matrix

**Syntax** `numeric::factorQR(A, options)`

**Description** `numeric::factorQR(A)` returns a  $QR$  factorization  $A = QR$  of the matrix  $A$ .

The  $QR$  factorization of a real/complex  $m \times n$  matrix is  $A = QR$ , where the  $m \times m$  matrix  $Q$  is orthogonal/unitary and the  $m \times n$  matrix  $R$  is upper triangular (i.e.,  $R_{ij} = 0$  for  $j < i$ ).

By default, a numerical factorization is computed. The matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as  $\pi$ ,  $\sqrt{2}$ ,  $e^{-1}$  etc. are accepted. They will be converted to floats, unless the option `Symbolic` is used.

The  $R$  factor is normalized such that its diagonal elements  $R_{ii}$  with  $i = 1, \dots, \min(m, n)$  are real and nonnegative.

If no return type is specified via the option `ReturnType = d`, the domain type of the factors  $Q$  and  $R$  depends on the type of the input matrix  $A$ :

- The factors of an array are returned as arrays.
- The factors of an hfarray are returned as hfarrays.
- The factors of a dense matrix of type `Dom::DenseMatrix()` are dense matrices of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices of category `Cat::Matrix`, the factors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices  $A$  of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)`, etc.

**Environment Interactions** Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We consider a quadratic matrix:

```
A := array(1..2, 1..2, [[1, 0] , [1, PI]]):
```

First, we compute a numerical factorization:

```
[Q1, R1] := numeric::factorQR(A)
```

$$\left[ \begin{pmatrix} 0.7071067812 & -0.7071067812 \\ 0.7071067812 & 0.7071067812 \end{pmatrix}, \begin{pmatrix} 1.414213562 & 2.221441469 \\ 0 & 2.221441469 \end{pmatrix} \right]$$

Next, the symbolic factorization is computed:

```
[Q2, R2] := numeric::factorQR(A, Symbolic)
```

$$\left[ \begin{pmatrix} \frac{\sqrt{2}}{2} & -\frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} \end{pmatrix}, \begin{pmatrix} \sqrt{2} & \frac{\pi\sqrt{2}}{2} \\ 0 & \frac{\pi\sqrt{2}}{2} \end{pmatrix} \right]$$

For further processing, the factors (of domain type DOM\_ARRAY) are converted to elements of the matrix domain Dom::Matrix():

```
Q1 := matrix(Q1): R1 := matrix(R1):
Q2 := matrix(Q2): R2 := matrix(R2):
```

Now, the overloaded arithmetical operators +, \*, ^ etc. can be used for further computations:

```
Q1*R1, Q2*R2
```

## numeric::factorQR

---

$$\begin{pmatrix} 1.0 & -4.926614672 \cdot 10^{-16} \\ 1.0 & 3.141592654 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 1 & \pi \end{pmatrix}$$

We finally verify the orthogonality of the factors Q1 and Q2:

```
Q1 * linalg::transpose(Q1), Q2 * linalg::transpose(Q2)
```

$$\begin{pmatrix} 1.0 & -1.569924746 \cdot 10^{-16} \\ -1.569924746 \cdot 10^{-16} & 1.0 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

```
delete A, Q1, R1, Q2, R2:
```

### Example 2

We consider a non-square matrix of rank 1:

```
A := array(1..3, 1..2, [[0, 0], [I, 1], [I, 1]]):
numeric::factorQR(A, Symbolic)
```

$$\left[ \begin{pmatrix} 0 & 1 & 0 \\ \frac{\sqrt{2}i}{2} & 0 & \frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}i}{2} & 0 & -\frac{\sqrt{2}}{2} \end{pmatrix}, \begin{pmatrix} \sqrt{2} & -\sqrt{2}i \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \right]$$

In this case, the  $QR$  factorization is not unique. Note that the numerical factorization yields different factors:

```
numeric::factorQR(A)
```

$$\left[ \begin{pmatrix} 0 & 0.7071067812 i & 0.7071067812 i \\ 0.7071067812 i & 0.5 & -0.5 \\ 0.7071067812 i & -0.5 & 0.5 \end{pmatrix}, \begin{pmatrix} 1.414213562 & -1.414213562 i \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \right]$$

delete A:

### Example 3

We demonstrate the difference between hardware floats and software floats. For rank deficient matrices, the  $QR$  factorization is not unique. Depending on the options, different results are returned for the following matrix of rank 1:

```
A := matrix([[1, 1], [10^4, 10^4], [10^8, 10^8]]):
[Q1, R1] := float(numeric::factorQR(A, Symbolic))
```

$$\left[ \begin{pmatrix} 0.00000000999999995 & 1.0 & 0 \\ 0.0000999999995 & -9.9999999 \cdot 10^{-13} & 0.999999995 \\ 0.999999995 & -0.00000000999999999 & -0.0000999999995 \end{pmatrix}, \begin{pmatrix} 100000000. \\ 0 \\ 0 \end{pmatrix} \right]$$

```
[Q2, R2] := numeric::factorQR(A, SoftwareFloats)
```

$$\left[ \begin{pmatrix} 0.00000000999999995 & -0.0000999999995 & -0.999999995 \\ 0.0000999999995 & 0.99999999 & -0.0000999999998 \\ 0.999999995 & -0.0000999999998 & 0.00000001999999975 \end{pmatrix}, \begin{pmatrix} 100000000. \\ 0 \\ 0 \end{pmatrix} \right]$$

```
[Q3, R3] := numeric::factorQR(A, HardwareFloats)
```

# numeric::factorQR

$$\left[ \begin{pmatrix} 0.000000009999999939 & 0.9999999998 & -0.00002207031223 \\ 0.00009999999995 & -0.00002207031311 & -0.99999999948 \\ 0.9999999995 & -0.000000007792968604 & 0.00009999999997 \end{pmatrix}, \right. \\ \left. \begin{pmatrix} 100000000.5 & 100000000.5 \\ 0 & 0.0000000149011613 \\ 0 & 0 \end{pmatrix} \right]$$

However, all factorizations satisfy  $A = QR$  numerically:

```
norm(A - Q1*R1), norm(A - Q2*R2), norm(A - Q3*R3)
```

```
3.469446952 10-18, 7.327374818 10-11, 0.00000001583248377
```

```
delete A, Q1, R1, Q2, R2, Q3, R3:
```

## Parameters **A**

An  $m \ n$  matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix

## Options **Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by

default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM\_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM\_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM\_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither HardwareFloats nor SoftwareFloats is specified, the user is not informed whether hardware floats or software floats are used.

If HardwareFloats are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-89.

---

## Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix  $A$  may contain symbolic objects.

## NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorQR` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

## ReturnType

Option, specified as `ReturnType = d`

Return the Cholesky factor as a matrix of domain type  $d$ . The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## Return Values

List [Q, R] with matrices Q and R is returned. The domain type of the orthogonal/unitary  $m \times m$  matrix Q and the upper triangular  $m \times n$  matrix R depends on the type of the input matrix A. The components of Q and R are real or complex floats, unless the option `Symbolic` is used.

## Algorithms

Householder transformations are used to compute the numerical factorization. With the option `Symbolic`, Gram-Schmidt orthonormalization of the columns of A is used.

For an invertible square matrix A, the QR factorization is unique up to scaling factors of modulus 1. The normalization of R to real positive diagonal elements determines the factorization uniquely. Consequently, the results obtained with/without the option `Symbolic` coincide for invertible square matrices.

For singular or non-square matrices, the factorization is not unique and the results obtained with/without the option `Symbolic` may differ. Cf. “Example 2” on page 18-88.

- “Compute Factorizations Numerically”

# numeric::fft

---

## Purpose

Fast Fourier Transform

## Syntax

```
numeric::fft(L, <mode>, <ReturnType = t>, <Clean>)
numeric::fft(M, <mode>, <ReturnType = t>, <Clean>)
numeric::fft(A, <mode>, <ReturnType = t>, <Clean>)
```

## Description

`numeric::fft(data)` returns the discrete Fourier transform of the data.

The 1-dimensional discrete Fourier transform  $F = \text{fft}(L)$  of  $N$  data elements  $L_j$  stored in the list  $L = [L_1, \dots, L_N]$  is the list  $F = [F_1, \dots, F_N]$  given by

$$F_k = \sum_{j=1}^N L_j e^{-\frac{i 2 \pi (j-1)(k-1)}{N}}, \quad k = 1, \dots, N$$

`fft` transforms the data by a Fast Fourier Transform (FFT) algorithm.

The  $d$ -dimensional discrete Fourier transform  $F = \text{fft}(A)$  of  $N = n_1 \cdots n_d$  data elements  $(A_{j_1, \dots, j_d})$  stored in the array  $A$  is the array  $F = (F_{k_1, \dots, k_d})$  given by

$$F_{k_1, \dots, k_d} = \sum_{j_1=1}^{n_1} \cdots \sum_{j_d=1}^{n_d} A_{j_1, \dots, j_d} e^{-i 2 \pi \left( \frac{(j_1-1)(k_1-1)}{n_1} + \dots + \frac{(j_d-1)(k_d-1)}{n_d} \right)}$$

with  $k_1 = 1, \dots, n_1, \dots, k_d = 1, \dots, n_d$ .

Data provided by lists or 1-dimensional arrays or `hfarrays` are transformed according to the 1-dimensional transform. Data provided by matrices are transformed according to the 2-dimensional transform. Data provided by multidimensional arrays or `hfarrays` are transformed

according to the multi-dimensional transform matching the format of the input array.

If the data size factorizes ( $N = pq$ , say), the discrete Fourier transform can be computed by  $p$  different Fourier transforms of subsets of the data, each subset having the data size  $q$ . The corresponding 'divide and conquer' algorithm is known as FFT ('Fast Fourier Transform'). The `fft` routine employs the FFT algorithm. It is most efficient, when the data size  $N$  is an integer power of 2 ('radix 2 FFT'). In this case, the algorithm needs  $O(N \log_2(N))$  elementary operations.

---

**Note** More generally, FFT is efficient, if the data size is the product of many small factors!

---

Following Bluestein, the Fourier transform is written as a convolution if the data size  $N$  is a prime. The data are zero-padded to a data length that is an integer power of 2. The convolution is then computed via radix 2 FFTs. Thus, the algorithm needs  $O(N \log_2(N))$  elementary operations even if  $N$  is a prime.

## Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We give a demonstration of 1-dimensional transformations using lists. By default, numerical expressions are converted to floats:

```
L := [1, 2^(1/2), 3*I, PI]:
F := numeric::fft(L)
```

```
[5.555806216 + 3.0 i, 1.0 - 1.272620909 i, - 3.555806216 + 3.0 i, 1.0 - 4.727379091 i]
```

## numeric::fft

---

```
numeric::invfft(F)
```

```
[1.0, 1.414213562 + 2.512840965 10-17 i, 3.0 i, 3.141592654 - 2.512840965 10-17 i]
```

```
numeric::invfft(F, Clean)
```

```
[1.0, 1.414213562, 3.0 i, 3.141592654]
```

Exact arithmetic is used with the option Symbolic:

```
F := numeric::fft(L, Symbolic)
```

```
[$\pi + \sqrt{2} + 1 + 3i$, $\pi i - \sqrt{2}i + 1 - 3i$, $1 - \sqrt{2} - \pi + 3i$, $1 + \sqrt{2}i - \pi i - 3i$]
```

```
numeric::invfft(F, Symbolic)
```

```
[1, $\sqrt{2}$, 3 i, π]
```

Symbolic expressions are accepted. Internally, however, the default method `HardwareFloats` (with `DIGITS < 16`) fails because of the symbolic parameter `x`. The following results are computed with the software arithmetic provided by the MuPAD kernel:

```
L := [x, 2, 3, x]:
numeric::fft(L)
```

```
[2 x + 5.0, x (1.0 + 1.0 i) - 3.0 - 2.0 i, 1.0, x (1.0 - 1.0 i) - 3.0 + 2.0 i]
```

```
numeric::fft(L, Symbolic)
```

```
[2 x +5, x (1 +i) -3 -2 i, 1, x (1 -i) -3 +2 i]
```

```
delete L, F:
```

### Example 2

We give a demonstration of multi-dimensional transformations. First, a 2-dimensional transformation is computed by using an array with 2 indices:

```
A := array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]]):
numeric::fft(A, Symbolic)
```

$$\begin{pmatrix} a + b + c + d + 10 & a - b i - c + d i - 2 + 2 i & a - b + c - d - 2 & a + b i - c - d i - 2 - 2 i \\ 10 - b - c - d - a & c + b i - a - d i - 2 + 2 i & b - a - c + d - 2 & c - b i - a + d i - 2 - 2 i \end{pmatrix}$$

```
numeric::invfft(%, Symbolic)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ a & b & c & d \end{pmatrix}$$

The next example is 3-dimensional as indicated by the format of the array:

```
A := array(1..2, 1..4, 1..2,
 [[sin(j1*PI/2)*cos(j2*3*PI/4)*sin(j3*PI/2)
 $ j3 = 1..2] $ j2 = 1..4] $ j1 = 1..2]):
numeric::fft(A)
```

```
array(1..2, 1..4, 1..2,
 (1, 1, 1) = -1.0,
 (1, 1, 2) = -1.0,
 (1, 2, 1) = - 1.414213562 - 1.0 I,
```

# numeric::fft

---

```
(1, 2, 2) = - 1.414213562 - 1.0 I,
(1, 3, 1) = 1.0,
(1, 3, 2) = 1.0,
(1, 4, 1) = - 1.414213562 + 1.0 I,
(1, 4, 2) = - 1.414213562 + 1.0 I,
(2, 1, 1) = -1.0,
(2, 1, 2) = -1.0,
(2, 2, 1) = - 1.414213562 - 1.0 I,
(2, 2, 2) = - 1.414213562 - 1.0 I,
(2, 3, 1) = 1.0,
(2, 3, 2) = 1.0,
(2, 4, 1) = - 1.414213562 + 1.0 I,
(2, 4, 2) = - 1.414213562 + 1.0 I
)
```

delete A:

### Example 3

Data of arbitrary length can be transformed:

```
L := [1, 2 + I, PI/3]:
numeric::fft(L)
```

```
[4.047197551 + 1.0 i, 0.3424266282 - 1.325151125 i, - 1.389624179 + 0.3251511255 i]
```

delete L:

## Parameters

**L**

A list or a 1-dimensional array(1 .. N, [Symbol::hellip])  
or a 1-dimensional harray(1 .. N, [Symbol::hellip]) of  
arithmetical expressions.

**M**

A matrix of category Cat::Matrix of arithmetical expressions.

**A**

A  $d$ -dimensional array( 1..n\_1,Symbol::hellip,1..n\_d, [Symbol::hellip] ) or a  $d$ -dimensional hfarray( 1..n\_1,Symbol::hellip,1..n\_d, [Symbol::hellip] ) of arithmetical expressions.

**mode**

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

**Options****Hard, HardwareFloats, Soft, SoftwareFloats**

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

With `Soft` and `SoftwareFloats`, symbolic objects are accepted even if they cannot be converted to floating-point numbers. The result consists of arithmetical expressions involving both floating-point numbers as well as symbolic objects. See. “Example 1” on page 18-95.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

### **Symbolic**

Without this option, the floating-point converter `float` is applied to all input data. Use this option if no such conversion is desired. Exact arithmetic is used to compute the Fourier transformation.

This option prevents conversion of the input data to floats.

### ReturnType

Option, specified as `ReturnType = t`

Return the result in a container of domain type `t`. The following return types `t` are available: `DOM_LIST`, or `DOM_ARRAY`, or `DOM_HFARRAY`, or `matrix`, or `densematrix`.

This option determines the domain type `t` of the result.

If no return type is specified by this option, the result is of the same type and format as the input data.

If the return type `DOM_LIST` is specified, the result is always a plain list of floating-point numbers. If the input data are given by a matrix or a multi-dimensional array, the returned list represents the operands of the multi-dimensional Fourier data. E.g., if an  $n_1 n_2$  matrix is entered, the return value is a list with  $n_1 n_2$  values representing the entries of a  $n_1 n_2$  matrix. The first  $n_2$  entries of the list represent the first row of the result, the next  $n_2$  entries represent the second row, etc.

With `ReturnType = matrix` or `ReturnType = densematrix`, only the results of 1 and 2 dimensional Fourier transformations can be represented.

### Clean

Reduce roundoff garbage in the result. All entries of the result with absolute values smaller than  $10^{-(\text{DIGITS})}$  times the maximal absolute value of all operands of the result are set to 0.0. Further, the routine `numeric::complexRound` is applied to all entries of the result.

# numeric::fft

---

---

**Note** The postprocessing of the result is done on the software float level. When using hardware floats, this option may increase the runtime significantly!

---

This option is ignored when used in conjunction with the option `Symbolic`.

## Return Values

List/array/hfarray/matrix of the same length and format as the first input parameter `L/A/M`. The type of the return value can be changed with the option `ReturnType`.

## See Also

## MuPAD Functions

`numeric::invfft`

## Concepts

- “Discrete Fourier Transforms”

**Purpose** Inverse Fast Fourier Transform

**Syntax**  
 numeric::invfft(L, <mode>, <ReturnType = t>, <Clean>)  
 numeric::invfft(M, <mode>, <ReturnType = t>, <Clean>)  
 numeric::invfft(A, <mode>, <ReturnType = t>, <Clean>)

**Description** numeric::invfft(data) returns the inverse discrete Fourier transform.

The inverse discrete Fourier transform  $L = \text{invfft}(F)$  of  $N$  data elements  $F_k$  stored in the list  $F = [F_1, \dots, F_N]$  is the list  $L = [L_1, \dots, L_N]$  given by

$$L_j = \frac{1}{N} \sum_{k=1}^N F_k e^{\frac{i 2 \pi (j-1)(k-1)}{N}}, \quad j = 1, \dots, N$$

invfft transforms the data by a Fast Fourier Transform (FFT) algorithm.

The  $d$ -dimensional inverse discrete Fourier transform  $A = \text{invfft}(F)$  is given by

$$A_{j_1, \dots, j_d} = \frac{1}{N} \sum_{k_1=1}^{n_1} \dots \sum_{k_d=1}^{n_d} F_{k_1, \dots, k_d} e^{i 2 \pi \left( \frac{(j_1-1)(k_1-1)}{n_1} + \dots + \frac{(j_d-1)(k_d-1)}{n_d} \right)}$$

with  $j_1 = 1, \dots, n_1, \dots, j_d = 1, \dots, n_d$ .

Data provided by lists or 1-dimensional arrays or hfarrays are transformed according to the 1-dimensional transform. Data provided by matrices are transformed according to the 2-dimensional transform. Data provided by multidimensional arrays or hfarrays are transformed according to the multidimensional transform matching the format of the input array.

# numeric::invfft

---

If the data size factorizes ( $N = pq$ , say), the inverse discrete Fourier transform can be computed by  $p$  different inverse Fourier transforms of subsets of the data, each subset having the data size  $q$ . The corresponding 'divide and conquer' algorithm is known as FFT ('Fast Fourier Transform'). The `invfft` routine employs the FFT algorithm. It is most efficient, when the data size  $N$  is an integer power of 2 (radix 2 FFT). In this case, the algorithm needs  $O(N \log_2(N))$  elementary operations.

---

**Note** More generally, FFT is efficient, if the data size is the product of many small factors!

---

Following Bluestein, the inverse Fourier transform is written as a convolution if the data size  $N$  is a prime. The data are zero-padded to a data length that is an integer power of 2. The convolution is then computed via radix 2 FFTs. Thus, the algorithm needs  $O(N \log_2(N))$  elementary operations even if  $N$  is a prime.

## Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We give a demonstration of 1-dimensional transformations using lists. By default, numerical expressions are converted to floats:

```
L := [1, 2^(1/2), 3*I, PI]:
F := numeric::fft(L)
```

```
[5.555806216 + 3.0 i, 1.0 - 1.272620909 i, -3.555806216 + 3.0 i, 1.0 - 4.727379091 i]
```

```
numeric::invfft(F)
```

```
[1.0, 1.414213562 + 2.512840965 10-17 i, 3.0 i, 3.141592654 - 2.512840965 10-17 i]
```

```
numeric::invfft(F, Clean)
```

```
[1.0, 1.414213562, 3.0 i, 3.141592654]
```

Exact arithmetic is used with the option Symbolic:

```
F := numeric::fft(L, Symbolic)
```

```
[$\pi + \sqrt{2} + 1 + 3i$, $\pi i - \sqrt{2}i + 1 - 3i$, $1 - \sqrt{2} - \pi + 3i$, $1 + \sqrt{2}i - \pi i - 3i$]
```

```
numeric::invfft(F, Symbolic)
```

```
[1, $\sqrt{2}$, 3 i, π]
```

Symbolic expressions are accepted. Internally, however, the default method `HardwareFloats` (with `DIGITS < 16`) fails because of the symbolic parameter `x`. The following results are computed with the software arithmetic provided by the MuPAD kernel:

```
L := [x, 2, 3, x]:
numeric::fft(L)
```

```
[2 x + 5.0, x (1.0 + 1.0 i) - 3.0 - 2.0 i, 1.0, x (1.0 - 1.0 i) - 3.0 + 2.0 i]
```

```
numeric::fft(L, Symbolic)
```

```
[2 x + 5, x (1 + i) - 3 - 2 i, 1, x (1 - i) - 3 + 2 i]
```

## numeric::invfft

---

```
delete L, F:
```

### Example 2

We give a demonstration of multi-dimensional transformations. First, a 2-dimensional transformation is computed by using an array with 2 indices:

```
A := array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]]):
numeric::fft(A, Symbolic)
```

$$\begin{pmatrix} a+b+c+d+10 & a-b-i-c+d-i-2+2i & a-b+c-d-2 & a+b-i-c-d-i-2-2i \\ 10-b-c-d-a & c+b-i-a-d-i-2+2i & b-a-c+d-2 & c-b-i-a+d-i-2-2i \end{pmatrix}$$

```
numeric::invfft(%, Symbolic)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ a & b & c & d \end{pmatrix}$$

The next example is 3-dimensional as indicated by the format of the array:

```
A := array(1..2, 1..4, 1..2,
 [[[sin(j1*PI/2)*cos(j2*3*PI/4)*sin(j3*PI/2)
 $ j3 = 1..2] $ j2 = 1..4] $ j1 = 1..2]):
numeric::fft(A)
```

```
array(1..2, 1..4, 1..2,
 (1, 1, 1) = -1.0,
 (1, 1, 2) = -1.0,
 (1, 2, 1) = - 1.414213562 - 1.0 I,
 (1, 2, 2) = - 1.414213562 - 1.0 I,
 (1, 3, 1) = 1.0,
 (1, 3, 2) = 1.0,
```

```
(1, 4, 1) = - 1.414213562 + 1.0 I,
(1, 4, 2) = - 1.414213562 + 1.0 I,
(2, 1, 1) = -1.0,
(2, 1, 2) = -1.0,
(2, 2, 1) = - 1.414213562 - 1.0 I,
(2, 2, 2) = - 1.414213562 - 1.0 I,
(2, 3, 1) = 1.0,
(2, 3, 2) = 1.0,
(2, 4, 1) = - 1.414213562 + 1.0 I,
(2, 4, 2) = - 1.414213562 + 1.0 I
)
```

delete A:

### Example 3

Data of arbitrary length can be transformed:

```
L := [1, 2 + I, PI/3]:
numeric::fft(L)
```

```
[4.047197551 + 1.0 i, 0.3424266282 - 1.325151125 i, - 1.389624179 + 0.3251511255 i]
```

delete L:

## Parameters

**L**

A list or a 1-dimensional array(1 .. N, [Symbol::hellip]) or a 1-dimensional harray(1 .. N, [Symbol::hellip]) of arithmetical expressions.

**M**

A matrix of category `Cat::Matrix` of arithmetical expressions.

**A**

A  $d$ -dimensional array( 1..n\_1,Symbol::hellip,1..n\_d, [Symbol::hellip] ) or a  $d$ -dimensional hfarray( 1..n\_1,Symbol::hellip,1..n\_d, [Symbol::hellip] ) of arithmetical expressions.

## mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

## Options

### **Hard, HardwareFloats, Soft, SoftwareFloats**

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

With `Soft` and `SoftwareFloats`, symbolic objects are accepted even if they cannot be converted to floating-point numbers. The result consists of arithmetical expressions involving both floating-point numbers as well as symbolic objects. See. “Example 1” on page 18-104.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

### **Symbolic**

Without this option, the floating-point converter `float` is applied to all input data. Use this option if no such conversion is desired. Exact arithmetic is used to compute the Fourier transformation.

This option prevents conversion of the input data to floats.

## ReturnType

Option, specified as `ReturnType = t`

Return the result in a container of domain type `t`. The following return types `t` are available: `DOM_LIST`, or `DOM_ARRAY`, or `DOM_HFARRAY`, or `matrix`, or `densematrix`.

This option determines the domain type `t` of the result.

If no return type is specified by this option, the result is of the same type and format as the input data.

If the return type `DOM_LIST` is specified, the result is always a plain list of floating-point numbers. If the input data are given by a matrix or a multi-dimensional array, the returned list represents the operands of the multi-dimensional Fourier data. E.g., if an  $n_1 \times n_2$  matrix is entered, the return value is a list with  $n_1 n_2$  values representing the entries of a  $n_1 \times n_2$  matrix. The first  $n_2$  entries of the list represent the first row of the result, the next  $n_2$  entries represent the second row, etc.

With `ReturnType = matrix` or `ReturnType = densematrix`, only the results of 1 and 2 dimensional Fourier transformations can be represented.

## Clean

Reduce roundoff garbage in the result. All entries of the result with absolute values smaller than  $10^{-(\text{DIGITS})}$  times the maximal absolute value of all operands of the result are set to 0.0. Further, the routine `numeric::complexRound` is applied to all entries of the result.

---

**Note** The postprocessing of the result is done on the software float level. When using hardware floats, this option may increase the runtime significantly!

---

This option is ignored when used in conjunction with the option `Symbolic`.

## Return Values

List/array/hfarray/matrix of the same length and format as the first input parameter L/A/M. The type of the return value can be changed with the option `ReturnType`.

## See Also

## MuPAD Functions

`numeric::fft`

## Concepts

- “Discrete Fourier Transforms”

# numeric::fMatrix

---

<b>Purpose</b>	Functional calculus for numerical square matrices
<b>Syntax</b>	<code>numeric::fMatrix(f, A, p<sub>1</sub>, p<sub>2</sub>, , options)</code>
<b>Description</b>	<p><code>numeric::fMatrix(f, A)</code> computes the matrix <math>f(A)</math> with a function <math>f</math> and a square matrix <math>A</math>.</p> <p>If no return type is specified via the option <code>ReturnType = d</code>, the domain type of the result depends on the type of the input matrix <math>A</math>:</p> <ul style="list-style-type: none"><li>• For an array <math>A</math>, the result is returned as an array.</li><li>• For an hffarray <math>A</math>, the result is returned as an array.</li><li>• For a dense matrix <math>A</math> of type <code>Dom::DenseMatrix()</code> the result is a dense matrix of type <code>Dom::DenseMatrix()</code> over the ring of MuPAD expressions.</li><li>• For all other matrices <math>A</math> of category <code>Cat::Matrix</code>, the result is returned as a matrix of type <code>Dom::Matrix()</code> over the ring of MuPAD expressions. This includes input matrices <math>A</math> of type <code>Dom::Matrix(...)</code>, <code>Dom::SquareMatrix(...)</code>, <code>Dom::MatrixGroup(...)</code> etc.</li></ul> <p>The components of <math>A</math> must not contain symbolic objects which cannot be converted to numerical values via <code>float</code>. Numerical symbolic expressions such as <math>\pi</math>, <math>\sqrt{2}</math>, <math>e^{-1}</math> etc. are accepted. They are converted to floats.</p>

---

**Note** The matrix  $A$  must be diagonalizable; `numeric::fMatrix` aborts with an error message if it detects numerically that  $A$  is not diagonalizable. For most non-diagonalizable matrices, however, the numerical algorithm fails to detect this fact and the returned matrix is dominated by round-off effects. It is the user's responsibility to make sure that the diagonalization is feasible and well conditioned.

---

Symmetric/Hermitian and skew/skew Hermitian matrices can always be diagonalized in a numerically stable way; `numeric::fMatrix` produces reliable numerical results for such matrices.

The procedure `f` must accept complex floating-point numbers as first argument. It may return arbitrary MuPAD expressions, provided these can be multiplied with floating-point numbers.

The parameters  $p_1, p_2, \dots$  may be numerical or symbolic objects. They must be accepted by `f` as 2nd argument, 3rd argument etc.

In contrast to the components of  $A$ , numerical symbolic objects such as  $\pi, \sqrt{2}$  etc. passed as parameters  $p_1, p_2, \dots$  are not converted to floats.

Inversion or exponentiation of a matrix may be realized with the functions  $a \rightarrow \frac{1}{a}$  and `exp`, respectively. However, it is recommended to use the specialized algorithms `numeric::inverse` and `numeric::expMatrix` instead. Also matrix evaluation of low degree polynomials should be done with standard matrix arithmetic rather than with `numeric::fMatrix`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We compute the matrix power  $A^{100}$ :

```
A := array(1..2, 1..2, [[2, PI], [exp(-10), 0]]):
numeric::fMatrix(x -> x^100, A)
```

$$\begin{pmatrix} 1.272133133 \cdot 10^{30} & 1.998190806 \cdot 10^{30} \\ 2.887634784 \cdot 10^{25} & 4.535724387 \cdot 10^{25} \end{pmatrix}$$

# numeric::fMatrix

---

Alternatively, you may use the function `_power` which takes the exponent as a second parameter:

```
numeric::fMatrix(_power, A, 100)
```

$$\begin{pmatrix} 1.272133133 \cdot 10^{30} & 1.998190806 \cdot 10^{30} \\ 2.887634784 \cdot 10^{25} & 4.535724387 \cdot 10^{25} \end{pmatrix}$$

```
delete A:
```

## Example 2

We compute the square root of a matrix:

```
A := matrix([[0, 1], [-1, 1]]):
B := numeric::fMatrix(sqrt, A)
```

$$\begin{pmatrix} 0.5773502692 & 0.5773502692 + 1.110223025 \cdot 10^{-16} i \\ -0.5773502692 + 2.775557562 \cdot 10^{-17} i & 1.154700538 - 8.326672685 \cdot 10^{-17} i \end{pmatrix}$$

The small imaginary parts are caused by numerical round-off. We eliminate them by extracting the real parts of the components:

```
B := map(B, Re)
```

$$\begin{pmatrix} 0.5773502692 & 0.5773502692 \\ -0.5773502692 & 1.154700538 \end{pmatrix}$$

We verify that  $B^2$  is  $A$ . Since  $A$  was passed as a matrix of type `Dom::Matrix()`, the matrix  $B$  is also of this type. We may compute the square by the overloaded standard arithmetic using the operator `^`:

B^2

$$\begin{pmatrix} -1.283895372 \cdot 10^{-16} & 1.0 \\ -1.0 & 1.0 \end{pmatrix}$$

delete A, B:

### Example 3

We compute  $e^{t \pi A}$  with a symbolic parameter  $t$ :

```
A := array(1..2, 1..2, [[0, 1], [-1, 0]]):
numeric::fMatrix(exp@_mult, A, t*PI)
```

$$\begin{pmatrix} 0.5 e^{1.0 \pi t i} + 0.5 e^{-1.0 \pi t i} & -0.5 e^{1.0 \pi t i} i + 0.5 e^{-1.0 \pi t i} i \\ 0.5 e^{1.0 \pi t i} i - 0.5 e^{-1.0 \pi t i} i & 0.5 e^{1.0 \pi t i} + 0.5 e^{-1.0 \pi t i} \end{pmatrix}$$

delete A:

### Example 4

We demonstrate the difference between HardwareFloats and SoftwareFloats. The diagonalization of the following matrix is ill-conditioned. The result is dominated by round-off effects:

```
A := array(1..3, 1..3, [[10, 1, 1],
 [0, 1, 1],
 [1, 0, 10^(-14)]]):
numeric::fMatrix(ln, A, SoftwareFloats)
```

## numeric::fMatrix

---

$$\begin{pmatrix} 2.284572396 & 0.2635466905 & 0.2635466905 \\ -4.117444729 & 4.03009691 & 41.43799398 \\ 4.380991419 & -4.117444729 & -41.5253418 \end{pmatrix}$$

```
numeric::fMatrix(ln, A, HardwareFloats)
```

$$\begin{pmatrix} 2.284572396 & 0.2635466905 & 0.2635466905 \\ -3.532353481 & 3.445005663 & 35.5870815 \\ 3.795900172 & -3.532353481 & -35.67442932 \end{pmatrix}$$

In the following case, the round-off effects of `HardwareFloats` makes the algorithm think that the matrix cannot be diagonalized. Consequently, `FAIL` is returned. With `SoftwareFloats`, however, a result is computed:

```
A := array(1..3, 1..3, [[1 , 1 , 1],
 [0 , 1 , 1],
 [10^(-30), 0 , 10^(-30)]]):
numeric::fMatrix(ln, A, SoftwareFloats)
```

`FAIL`

```
numeric::fMatrix(ln, A, HardwareFloats)
```

$$\begin{pmatrix} -5.469808086 \cdot 10^{-17} & 1.000000477 & 0.9999345993 \\ 9.98400946 \cdot 10^{-31} & -5.632422161 \cdot 10^{-17} & 69.07755279 \\ 0 & 0 & -69.07755279 \end{pmatrix}$$

```
delete A:
```

**Parameters**

**f**

A procedure representing a scalar function  $f: \mathbb{C} \rightarrow \mathbb{C}$  or  $f: \mathbb{C} \times P \times \dots \times P \rightarrow \mathbb{C}$ , where  $P$  is a set of parameters

**A**

A square matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix

**P<sub>1</sub>, P<sub>2</sub>, ...**

Arbitrary MuPAD objects accepted by  $f$  as additional input parameters

**Options**

**Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of DIGITS is larger than 15 and the input matrix **A** is not of domain type DOM\_HFARRAY.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no **HardwareFloats** or **SoftwareFloats** are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix **A** is a hardware float array of

# numeric::fMatrix

---

domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

---

**Note** For ill-conditioned matrices, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 4” on page 18-115.

---

## **NoWarning**

Suppresses warnings

## **ReturnType**

Option, specified as `ReturnType = d`

Return the result as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## Return Values

Depending on the type of the input matrix  $A$ , the matrix  $f(A)$  is returned as a matrix of type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()` or `Dom::DenseMatrix()`. If the algorithm thinks that  $A$  is not diagonalizable, then `FAIL` is returned.

## Algorithms

A numerical diagonalization  $A = X \text{diag}(\lambda_1, \lambda_2, \dots) X^{-1}$  is computed. The columns of  $X$  are the (right) eigenvectors of  $A$ , the diagonal entries  $\lambda_1, \lambda_2, \dots$  are the corresponding eigenvalues. The function  $f$  is mapped to the eigenvalues, the matrix result is computed by

$$f(A, p_1, p_2, \dots) = X \text{diag}(f(\lambda_1, p_1, p_2, \dots), f(\lambda_2, p_1, p_2, \dots), \dots) X^{-1}$$

The eigenvector matrix  $X$  may be obtained via `numeric::eigenvectors(A)[2]`.

The condition number  $\|X\|_{\infty} \left\| \frac{1}{X} \right\|_{\infty}$  of the eigenvector matrix is a measure indicating how well conditioned the diagonalization of the matrix  $A$  is. If this number is larger than  $10^{\text{DIGITS}}$ , then not a single digit of the diagonalization data is trustworthy.

The call `numeric::fMatrix(exp, A)` corresponds to `numeric::expMatrix(A, Diagonalization)`.

`numeric::expMatrix` | `numeric::inverse`

# numeric::fsolve

---

**Purpose** Search for a numerical root of a system of equations

**Syntax**

```
numeric::fsolve(eq, x, options)
numeric::fsolve(eq, x = a, options)
numeric::fsolve(eq, x = a .. b, options)
numeric::fsolve(eqs, [x1, x2,], options)
numeric::fsolve(eqs, {x1, x2, }, options)
numeric::fsolve(eqs, [x1 = a1, x2 = a2,], options)
numeric::fsolve(eqs, {x1 = a1, x2 = a2, }, options)
numeric::fsolve(eqs, [x1 = a1 .. b1, x2 = a2 ..
b2,], options)
numeric::fsolve(eqs, {x1 = a1 .. b1, x2 = a2 ..
b2, }, options)
```

**Description** `numeric::fsolve(eqs, ...)` returns a numerical approximation of a solution of the system of equations `eqs`.

This is the MuPAD numerical solver for non-linear systems of equations.

---

**Note** By default, this routine returns only *one* numerical solution!

---

The equations must not contain symbolic objects other than the unknowns that cannot be converted to numerical values via `float`. Symbolic objects such as  $\pi$  or  $\sqrt{2}$  etc. are accepted. The same holds true for starting values and search ranges. Search ranges may contain  $\pm\infty$ . Cf. “Example 2” on page 18-125.

`numeric::fsolve` implements a purely numerical Newton type root search with a working precision set by the environment variable `DIGITS`. Well separated simple roots should be exact within this precision. However, multiple roots or badly separated roots may be computed with a restricted precision. Cf. “Example 3” on page 18-125.

---

**Note** For systems of equations, the expressions defining the equations must have a symbolic derivative!

---

Overdetermined systems (i.e., more equations than indeterminates) are not accepted. However, there may be more indeterminates than equations. Cf. “Example 4” on page 18-125.

Specifying indeterminates  $[x_1, x_2, \dots]$  without starting values or search ranges is equivalent to the search ranges  $[x_1 = -\text{infinity} .. \text{infinity}, x_2 = -\text{infinity} .. \text{infinity}, \dots]$ . Note, however, that the user should assist `numeric::fsolve` by providing specific search ranges whenever possible! If a complex starting point or a search range involving a complex number is specified for at least one of the unknowns, the search is extended to the entire complex plane for all variables for which no explicit search interval is given.

For real equations and real starting points or search ranges, the internal Newton iteration will usually produce real values, i.e., `numeric::fsolve` searches for real roots only (unless square roots, logarithms etc. happen to produce complex values from real input). Use complex starting points or search ranges to search for complex roots of real equations. Cf. “Example 5” on page 18-126.

Starting values and search ranges can be mixed. Cf. “Example 6” on page 18-127.

Search ranges should only be provided if a solution is known to exist inside the search range. Otherwise, the search may take some time before `numeric::fsolve` gives up.

Specification of a search range primarily means that starting points from this range are used for the internal Newton search. For sufficiently small search ranges enclosing a solution the search will usually pick out this solution. However, it may also happen that the Newton iteration drifts towards other solutions.

With the default search strategy `RestrictedSearch`, only solutions from the search range are accepted, even if solutions outside the search

## numeric::fsolve

---

range are found internally. More specifically, if a search range such as  $x = a \dots b$  is specified for the variable  $x$ , then solutions satisfying  $\min(a, b) \leq \operatorname{Re}(x) \leq \max(a, b)$  and  $\min(a, b) \leq \operatorname{Im}(x) \leq \max(a, b)$  are searched for. Thus, the values  $a, b$  specify the bottom left and top right corner of a rectangular search area in the complex plane when the `RestrictedSearch` strategy is used.

With the search strategy `UnrestrictedSearch`, any solution inside or outside the search range is accepted and returned. Cf. “Example 7” on page 18-127.

If starting values for all indeterminates are provided, then a *single* Newton iteration with these initial data is launched. It either leads to a solution or `numeric::fsolve` gives up and returns `FAIL`. The same holds true if search ranges  $x = a \dots a$  or  $[x_1 = a_1 \dots a_1, x_2 = a_2 \dots a_2, \dots]$  of zero length are specified.

---

**Note** The risk of failure is high when providing bad starting values! Starting values are appropriate only if a sufficiently good approximation of the solution is known! On the other hand, providing good starting values is the fastest way to a solution. Cf. “Example 8” on page 18-128.

---

If at least one of the indeterminates has a non-trivial search range, then `numeric::fsolve` uses *several* Newton iterations with different starting values from the search range. Cf. “Example 9” on page 18-128. Search ranges in conjunction with the option `UnrestrictedSearch` provide a higher chance of detecting roots than (bad) starting values!

---

**Note** User defined assumptions such as `assume(x > 0)` are not taken into account in the numerical search! Provide search ranges instead! Cf. “Example 2” on page 18-125.

---

---

**Note** Convergence may be slow for multiple roots! Furthermore, `numeric::fsolve` may fail to detect such roots!

---

Use `linsolve` or `numeric::linsolve` for systems of *linear* equations.

Use `numeric::realroots`, if *all real roots* of a single non-polynomial real equation in a finite range are desired.

Use `polylib::realroots`, if *all real roots* of a real univariate polynomial are desired.

Use `numeric::polyroots`, if *all real and complex roots* of a univariate polynomial are desired.

Use `numeric::solve`, if *all roots* of a multivariate polynomial system are desired.

The routine `numeric::solve` provides a common interface to all these numerical solvers.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We compute roots of the sine function:

```
numeric::fsolve(sin(x) = 0, x)
```

```
[x = 0.0]
```

With the option `Random`, several calls may result in different roots:

```
numeric::fsolve(sin(x), x, Random)
```

# numeric::fsolve

---

```
[x = -226.1946711]
```

```
numeric::fsolve(sin(x), x, Random)
```

```
[x = 97.38937226]
```

Particular solutions can be chosen by an appropriate starting point close to the wanted solution, or by a search interval:

```
numeric::fsolve(sin(x), x = 3),
numeric::fsolve(sin(x), x = -4 .. -3)
```

```
[x = 3.141592653], [x = -3.141592654]
```

The solutions found by `numeric::fsolve` can be used in `subs` and `assign` to substitute or assign the indeterminates:

```
eqs := [x^2 = sin(y), y^2 = cos(x)]:
solution := numeric::fsolve(eqs, [x, y])
```

```
[x = -0.8517004887, y = 0.8116062151]
```

```
eval(subs(eqs, solution))
```

```
[0.7253937224 = 0.7253937224, 0.6587046485 = 0.6587046485]
```

```
assign(solution): x, y
```

```
-0.8517004887, 0.8116062151
```

```
delete eqs, solution, x, y:
```

## Example 2

We demonstrate the use of search ranges. The following system has solutions with positive and negative  $x$ . The solution with  $x \geq 0$  is obtained with the search interval  $x = 0 \dots \infty$ :

```
numeric::fsolve([x^2 = exp(x*y), x^2 = y^2], [x = 0 .. infinity,
[x = 0.753089165, y = -0.753089165]
```

We search for a solution with  $x \leq 0$ :

```
numeric::fsolve([x^2 = exp(x*y), x^2 = y^2], [x = -infinity .. 0
[x = -0.753089165, y = 0.753089165]
```

## Example 3

Multiple roots can only be computed with a restricted precision:

```
numeric::fsolve(expand((x - 1/3)^5), x = 0.3)
[x = 0.3333672906]
```

## Example 4

The following system of equations is degenerate and has a 1-parameter family of solutions. Each call to `numeric::fsolve` picks out one random solution:

```
numeric::fsolve([x^2 - y^2, x^2 - y^2], [x, y], Random) $ i = 1
```

# numeric::fsolve

---

```
[x = 34.70258251, y = 34.70258251], [x = -29.16650501, y = 29.16650501],
[x = 5.933941324, y = -5.933941324]
```

The equation may also be specified as an underdetermined system:

```
numeric::fsolve([x^2 - y^2], [x, y])
```

```
[x = 0.0, y = 0.0]
```

## Example 5

The following equation has no real solution. Consequently, the numerical search with real starting values fails:

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x)
```

```
FAIL
```

With a complex starting value, a solution is found:

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x = I)
```

```
[x = 0.2972513613 + 1.128383965 i]
```

Also complex search ranges may be specified. In the following, the internal starting point is a random value on the line from  $2 + I$  to  $3 + 2*I$ . Solutions are accepted if they lie in the complex rectangle with the bottom left corner  $2 + I$  and the top right corner  $3 + 2*I$ :

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x = 2 + I .. 3 + 2*I)
```

```
[x = 2.844341292 + 1.128383965 i]
```

## Example 6

Starting values and search intervals can be mixed:

```
numeric::fsolve([x^2 + y^2 = 1, y^2 + z^2 = 1, x^2 + z^2 = 1],
 [x = 1, y = 0 .. 10, z])
```

```
[x = 0.7071067812, y = 0.7071067812, z = 0.7071067812]
```

## Example 7

With `UnrestrictedSearch`, search intervals are only used for choosing starting values for the internal Newton search. The numerical iteration may drift towards a solution outside the search range:

```
eqs := [x*sin(10*x) = y^3, y^2 = exp(-2*x/3)]:
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0], UnrestrictedSearch)
```

```
[x = 1.232766201, y = -0.6630386021]
```

With the default strategy `RestrictedSearch`, only solutions inside the search range are accepted:

```
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0])
```

```
[x = 0.9816416007, y = -0.7209295436]
```

In the last search, also the previous solution outside the search range was found. With the option `MultiSolutions`, `numeric::fsolve` returns a sequence of all solutions that were found in the internal search:

```
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0], MultiSolutions)
```

# numeric::fsolve

---

```
[x = 0.9816416007, y = -0.7209295436], [x = 1.232766201, y = -0.6630386021]
```

```
delete eqs:
```

## Example 8

Usually, most of the time is spent internally searching for some (crude) approximations of the root. If high precision roots are required, it is recommended to compute first approximations with moderate values of DIGITS and use them as starting values for a refined search:

```
eq := exp(-x) = x:
DIGITS := 10:
firstApprox := numeric::fsolve(eq, x)
```

```
[x = 0.5671432904]
```

This output is suitable as input defining a starting value for  $x$ :

```
DIGITS := 1000: numeric::fsolve(eq, firstApprox)
```

```
[x = 0.5671432904097838729999686622103555497538...]
```

```
delete eq, firstApprox, DIGITS:
```

## Example 9

Specifying starting values for the indeterminates launches a *single* Newton iteration. This may fail, if the starting values are not sufficiently close to the solution:

```
eq := [x*y = x + y - 4, x/y = x - y + 4]:
numeric::fsolve(eq, [x = 1, y = 1])
```

FAIL

If a search range is specified for at least one of the unknowns, then *several* Newton iterations with random starting values in the search range are used, until a solution is found or until `numeric::fsolve` gives up:

```
numeric::fsolve(eq, [x = 1, y = 0 .. 10])
```

```
[x = 4.02644145 10-14, y = 4.0]
```

```
delete eq:
```

## Parameters

**eq**

An arithmetical expression or an equation in one indeterminate  $x$ . An expression `eq` is interpreted as the equation `eq = 0`.

**eqs**

A list, set, array, or matrix (`Cat::Matrix`) of expressions or equations in several indeterminates  $x_1, x_2, \dots$ . Expressions are interpreted as homogeneous equations.

**x, x<sub>1</sub>, x<sub>2</sub>, ...**

Identifiers or indexed identifiers to be solved for.

**a, a<sub>1</sub>, a<sub>2</sub>, ...**

Real or complex numerical starting values for the internal search. Typically, crude approximations of solution.

**a .. b, a<sub>1</sub> .. b<sub>1</sub>, a<sub>2</sub> .. b<sub>2</sub>, ...**

Ranges of numerical values defining search intervals for the numerical root.

## Options

### RestrictedSearch

Makes `numeric::fsolve` return only numerical roots in the user-defined search range  $x = a \dots b$  and  $[x_1 = a_1 \dots b_1, x_2 = a_2 \dots b_2, \text{Symbol}::\text{hellip}],$  respectively. This is the default search strategy, if a search range is specified for at least one of the unknowns.

Once a root with components  $(r_1, r_2, \dots)$  is found, it is checked whether  $\min(\Re(a_i), \Re(b_i)) \leq \Re(r_i) \leq \max(\Re(a_i), \Re(b_i))$  and  $\min(\Im(a_i), \Im(b_i)) \leq \Im(r_i) \leq \max(\Im(a_i), \Im(b_i))$  is satisfied. If the root is not inside the search range, the search is continued. Note that solutions outside the search range may be found internally. These may be accessed with the option `MultiSolutions`. See “Example 7” on page 18-127.

### UnrestrictedSearch

Allows `numeric::fsolve` to find and return solutions outside the specified search range. With this option, the search range is only used to choose random starting points for the internal numerical search.

This option switches off the search strategy `RestrictedSearch`. With `UnrestrictedSearch`, `numeric::fsolve` stops its internal search whenever a root is found, even if the root is not inside the specified search range. Starting points for the internal Newton search are taken from the search range.

### MultiSolutions

Makes `numeric::fsolve` return all solutions found in the internal search

This option only has an effect when used with the default search strategy `RestrictedSearch`. A sequence of all roots found in the internal search is returned. Cf. “Example 7” on page 18-127.

### Random

With this option, several calls to `numeric::fsolve` with the same input parameters may produce different roots.

With this option, random starting values are chosen for the internal search. Consequently, calling `numeric::fsolve` several times with the same parameters may lead to different solutions. This may be useful when several roots of one and the same equation or set of equations are desired.

## Return Values

Single numerical root is returned as a list of equations `[x = value]` or `[x1 = value1, x2 = value2, ...]`, respectively. FAIL is returned if no solution is found. With the option `MultiSolutions`, sequences of solutions may be returned.

## Algorithms

Internally the set of equations  $f(x) = 0$  is solved by a modified Newton iteration  $X \rightarrow X - t f'(X)^{-1} f(X)$  with some adaptively chosen step size  $t$ . For degenerate or ill-conditioned Jacobians  $f'$  a minimization strategy for  $\langle f, f \rangle$  is implemented. For scalar real equations, `numeric::realroot` is used, if a real finite search range is specified.

## Concepts

- “Solve Equations Numerically”

# numeric::gaussAGM

---

**Purpose** Gauss' arithmetic geometric mean

**Syntax** `numeric::gaussAGM(a, b)`

**Description** `numeric::gaussAGM(a, b)` computes the arithmetic geometric mean of the numbers  $a$  and  $b$ .

The iteration

$$a_{n+1} = \frac{a_n + b_n}{2}, b_{n+1} = (a_n + b_n) \sqrt{\frac{a_n b_n}{(a_n + b_n)^2}}$$

with the starting values  $a_0 = a$ ,  $b_0 = b$  converges quadratically to

some value  $\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} b_n$ . This limit is called Gauss' arithmetic geometric mean of the starting values  $a$ ,  $b$ .

If both arguments  $a$  and  $b$  can be converted to real or complex floating-point numbers, then a floating point value is computed and returned. Otherwise, the symbolic call `numeric::gaussAGM(a, b)` is returned.

If  $a = 0$  or  $b = 0$  or  $a + b = 0$ , then 0.0 is returned, even if  $a$  or  $b$  are symbolic objects.

The following relation to elliptic integrals holds for all complex values  $a$  and  $b$ :

$$\text{numeric::gaussAGM}(a, b) = \frac{\pi}{4} \frac{a + b}{K\left(\sqrt{\left(\frac{a-b}{a+b}\right)^2}\right)}$$

## Environment Interactions

The function is sensitive to the environment variable DIGITS.

## Examples

### Example 1

A floating-point number is returned if the arguments can be converted to floating-point numbers:

```
numeric::gaussAGM(0, 5)
```

```
0.0
```

```
numeric::gaussAGM(sqrt(2), PI)
```

```
2.192033978
```

```
numeric::gaussAGM(-10, PI)
```

```
- 2.377943461 - 2.966350545 i
```

```
numeric::gaussAGM(1 + I, 1 + 2*I)
```

```
1.020054126 + 1.471349363 i
```

A symbolic call is returned if one of the arguments cannot be converted to a float:

```
numeric::gaussAGM(1, b)
```

```
numeric::gaussAGM(1, b)
```

For the special cases  $a = 0$ ,  $b = 0$  and  $a + b = 0$ , the result 0.0 is returned even for symbolic arguments:

# numeric::gaussAGM

---

```
numeric::gaussAGM(a, 0)
```

```
0.0
```

```
numeric::gaussAGM(a, -a)
```

```
0.0
```

## Parameters

**a, b**

arithmetical expressions

## Return Values

Floating point number or a symbolic call `numeric::gaussAGM(a, b)`.

## See Also

## MuPAD Functions

`ellipticK`

**Purpose**

Weights and abscissae of Gauss-Legendre quadrature

**Syntax**

numeric::gldata(n, digits)

**Description**

numeric::gldata(n, digits) returns the weights and the abscissae of the Gauss-Legendre quadrature rule with  $n$  nodes with a precision of `digits` decimal digits.

The Gauss-Legendre quadrature rule  $\sum_{i=1}^n b_i f(c_i)$  produces the exact integral  $\int_0^1 f(x) dx$  for all polynomial integrands  $f(x)$  through degree  $2n - 1$ . The weights  $b_i$  and abscissae  $c_i$  are related to the roots of the  $n$ -th Legendre polynomial.

The weights and abscissae are computed by a straightforward numerical algorithm with a working precision set by the argument `digits`. The resulting floating-point numbers are correct to `digits` leading decimal places.

Typically, the argument `digits` is chosen as the current value of the environment variable `DIGITS`.

The data for  $n = 20, 40, 80, 160$  with `digits`  $\leq 200$  are stored internally. They are returned immediately without any computational costs.

Due to the internal remember mechanism, only the first call to `numeric::gldata` leads to computational costs. For any further call with the same arguments, the data are returned immediately.

For odd  $n$ , the abscissa  $c_{\frac{n+1}{2}} = \frac{1}{2}$  and the corresponding weight  $b_{\frac{n+1}{2}}$  are rational numbers.

**Environment Interactions**

numeric::gldata is *not* sensitive to changes of the environment variable `DIGITS`, because the numerical working precision is specified by the second argument `digits`.

The function uses option `remember`.

# numeric::gldata

---

## Examples

### Example 1

The following call computes the Gauss-Legendre data with a precision given by the current value of the environment variable DIGITS (the default value is DIGITS = 10):

```
[b, c] := numeric::gldata(4, DIGITS)
```

```
[[0.1739274226, 0.3260725774, 0.3260725774, 0.1739274226],
 [0.0694318442, 0.3300094782, 0.6699905218, 0.9305681558]]
```

The Gauss-Legendre data with 4 nodes provide exact numerical quadrature results for polynomials through degree 7:

```
f := x -> x^7:
int(f(x), x= 0..1) = _plus(b[i]*f(c[i]) $ i=1..4)
```

```
 $\frac{1}{8} = 0.125$
```

```
delete b, c, f:
```

### Example 2

For odd  $n$ , exact rational data for  $c_{\frac{n+1}{2}}$  and  $b_{\frac{n+1}{2}}$  are returned. The other data are computed as floating-point approximations:

```
DIGITS := 4: numeric::gldata(5, DIGITS)
```

```
[[0.1185, 0.2393, $\frac{64}{225}$, 0.2393, 0.1185], [0.04691, 0.2308, $\frac{1}{2}$, 0.7692, 0.9531]]
```

```
delete DIGITS:
```

**Parameters****n**

The number of nodes: a positive integer

**digits**

The number of decimal digits: a positive integer

**Return Values**

List [b, c] is returned. The lists  $b = [b_1, \dots, b_n]$  and  $c = [c_1, \dots, c_n]$  are numerical approximations of the weights and abscissae with digits significant digits.

**Algorithms**

The numerical integrator `numeric::quadrature` calls `numeric::gldata` to provide the data for Gaussian quadrature.

**See Also****MuPAD Functions**

`numeric::gtdata` | `numeric::ncdata` | `numeric::int` | `numeric::quadrature`

# numeric::gtdata

---

**Purpose** Weights and abscissae of Gauss-Tschebyscheff quadrature

**Syntax** `numeric::gtdata(n)`

**Description** `numeric::gtdata(n)` returns the weights and the abscissae of the Gauss-Tschebyscheff quadrature rule with  $n$  nodes.

The Gauss-Tschebyscheff quadrature rule  $\sum_{i=1}^n b_i f(c_i)$  produces the

exact integral  $\int_0^1 f(x) dx$  for all integrands of the form  $f(x) = \frac{p(x)}{\sqrt{x(1-x)}}$  with polynomials  $p(x)$  through degree  $2n - 1$ .

The exact weights  $b = [b_1, \dots, b_n]$  and abscissae  $c = [c_1, \dots, c_n]$  are given by

$$b_i = \frac{\pi}{2n} \sin\left(\frac{(2i-1)\pi}{2n}\right), \quad c_i = \frac{1 + \cos\left(\frac{(2i-1)\pi}{2n}\right)}{2}$$

**Environment Interactions** `numeric::gtdata` is not sensitive to the environment variable DIGITS.

The function uses option `remember`.

**Examples** **Example 1**

The following call produces exact data for the quadrature rule with two nodes:

```
numeric::gtdata(2)
```

$$\left[ \left[ \frac{\pi\sqrt{2}}{8}, \frac{\pi\sqrt{2}}{8} \right], \left[ \frac{\sqrt{2}}{4} + \frac{1}{2}, \frac{1}{2} - \frac{\sqrt{2}}{4} \right] \right]$$

**Parameters** **n**

The number of nodes: a positive integer

**Return Values**

List  $[b, c]$  is returned. The lists  $b = [b_1, \dots, b_n]$  and  $c = [c_1, \dots, c_n]$  are the exact weights and abscissae of the Gauss-Tschebyscheff quadrature rule, respectively.

**Algorithms**

The numerical integrator `numeric::quadrature` calls `numeric::gtdata` to provide the data for Gauss-Tschebyscheff quadrature.

`numeric::gldata` | `numeric::ncdata` | `numeric::int` | `numeric::quadrature`

# numeric::indets

---

<b>Purpose</b>	Search for indeterminates
<b>Syntax</b>	<code>numeric::indets(object)</code>
<b>Description</b>	<p><code>numeric::indets(object)</code> returns a set of the indeterminates contained in the object.</p> <p>This is an auxiliary routine used by <code>numeric::polyroots</code>, <code>numeric::quadrature</code>, <code>numeric::realroots</code>, <code>numeric::solve</code> etc. to find indeterminates.</p> <p>It recursively searches the operands of <code>object</code> for indeterminates. In particular, the search is applied to the elements of lists, sets, arrays, tables, etc.</p> <p>Following objects are regarded as indeterminates: identifiers, indexed identifiers and the indeterminates of <code>DOM_POLY</code> objects. Also coefficients of such polynomials are searched for indeterminates.</p> <p>The following objects are <i>not</i> regarded as indeterminates: the numerical constants <code>PI</code>, <code>EULER</code>, and <code>CATALAN</code> (cf. <code>Type::ConstantIdentis</code>) and zero operands of expressions and subexpressions (i.e., the function names in unevaluated function calls such as <code>f(2)</code>, <code>sin(PI/13)</code> etc.). Also integration variables in unevaluated calls of <code>int</code>, <code>numeric::int</code> and <code>numeric::quadrature</code> and summation indices in unevaluated calls of <code>sum</code> and <code>numeric::sum</code> are not considered.</p>

## Examples

### Example 1

Identifiers and indexed identifiers are regarded as indeterminates:

```
numeric::indets([{a + b*PI}, sin(c + sqrt(2) + EULER),
 table(1 = d - cos(e), 2 = f + 0.1*I),
 array(1..2, [g, h]), F(i[2], i[2]),
 D([1], G)(j[1]), k[3 + L[4]])])
```

```
{a, b, c, d, e, f, g, h, i2, j1, kL4.3}
```

Both indeterminates as well as symbolic coefficients are considered in polynomials of domain type DOM\_POLY:

```
numeric::indets(poly(a[1]*x^2 + a[2]*x + a, [x, y]))
```

```
{a, x, y, a1, a2}
```

## Example 2

The zero operands of unevaluated function calls such as  $f(\ )$  or  $\sin(\ )$  are not regarded as indeterminates:

```
numeric::indets(f(a + sin(b) + PI + EULER))
```

```
{a, b}
```

Integration variables and summation indices are not regarded as indeterminates:

```
numeric::indets({int(f(x), x = a..b),
 sum(f(i), i = c..infinity)})
```

```
{a, b, c}
```

## Parameters

### object

An arbitrary MuPAD object

## Return Values

Set of indeterminates is returned, if the argument is an object of some basic data type of the kernel. The empty set is returned, if the object is from some library domain.

# numeric::indets

---

## See Also

## MuPAD Functions

`indets` | `freeIndets`

**Purpose**

Numerical integration (the Float attribute of Int )

**Syntax**

```
numeric::int(f(x), x = a .. b, options)
float(holdint(f(x), x = a .. b, options))
float(freezeint(f(x), x = a .. b, options))
```

**Description**

numeric::int(f(x), x = a..b) computes a numerical approximation of  $\int_a^b f(x) dx$ .

The calls numeric::int(...), float ( freeze(int)(...)), and float ( hold(int)(...)) are equivalent.

The calls numeric::int(...) and numeric::quadrature(...) are almost equivalent: numeric::int calls numeric::quadrature. A numerical result produced by numeric::quadrature is returned as is. Otherwise, hold(numeric::int)(...) is returned.

See the help page of numeric::quadrature for details.

**Environment Interactions**

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

**Examples**

**Example 1**

We demonstrate some equivalent calls for numerical integration:

```
numeric::int(exp(x^2), x = -1..1),
float(hold(int)(exp(x^2), x = -1..1)),
float(freeze(int)(exp(x^2), x = -1..1)),
numeric::quadrature(exp(x^2), x = -1..1)
```

2.925303492, 2.925303492, 2.925303492, 2.925303492

```
numeric::int(max(1/10, cos(PI*x)), x = -2..0.0123),
float(hold(int)(max(1/10, cos(PI*x)), x = -2..0.0123)),
float(freeze(int)(max(1/10, cos(PI*x)), x = -2..0.0123)),
```

## numeric::int

---

```
numeric::quadrature(max(1/10, cos(PI*x)), x = -2..0.0123)
```

```
0.752102471, 0.752102471, 0.752102471, 0.752102471
```

```
numeric::int(exp(-x^2), x = -2..infinity),
float(hold(int)(exp(-x^2), x = -2..infinity)),
float(freeze(int)(exp(-x^2), x = -2..infinity)),
numeric::quadrature(exp(-x^2), x = -2..infinity)
```

```
1.768308316, 1.768308316, 1.768308316, 1.768308316
```

```
numeric::int(sin(x)/x, x = -1..10, GaussLegendre = 5),
float(hold(int)(sin(x)/x, x = -1..10, GaussLegendre = 5)),
float(freeze(int)(sin(x)/x, x = -1..10, GaussLegendre = 5)),
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 5)
```

```
2.604430665, 2.604430665, 2.604430665, 2.604430665
```

The calls `numeric::int(...)`, `float(hold(int)(...))`, and `numeric::quadrature(...)` are equivalent in multiple numerical integrations, too:

```
numeric::int(numeric::int(x*y, x = 0..y), y = 0..1),
numeric::int(numeric::quadrature(x*y, x = 0..y), y = 0..1),
float(freeze(int)(numeric::int(x*y, x = 0..y), y = 0..1)),
float(hold(int)(numeric::quadrature(x*y, x = 0..y), y = 0..1)),
numeric::quadrature(numeric::int(x*y, x = 0..y), y = 0..1),
numeric::quadrature(numeric::quadrature(x*y, x = 0..y), y = 0..1)
```

```
0.125, 0.125, 0.125, 0.125, 0.125, 0.125
```

**Example 2**

The following integral do not exist. Consequently, numerical integration runs into problems:

```
numeric::quadrature(1/x, x = 0..infinity)
```

Warning: Precision goal is not achieved after 10000 function cal

172.711431

Note that numeric::int handles errors produced by numeric::quadrature and returns a symbolic call to numeric::int:

```
numeric::int(1/x, x = 0..infinity)
```

$\text{numeric::int}\left(\frac{1}{x}, x = 0..∞\right)$

**Parameters**

**f(x)**

An arithmetical expression in  $x$

**x**

An identifier or an indexed identifier

**a, b**

arithmetical expressions

**Options**

All options of numeric::quadrature can be used.

**Return Values**

Floating point number or a symbolic call  $\text{numeric::int}(f(x), x = a..b)$  if the integral cannot be evaluated numerically.

# numeric::int

---

## See Also

## MuPAD Functions

[int](#) | [numeric::quadrature](#)

## Concepts

- [“Integration”](#)

**Purpose** Inverse of a matrix

**Syntax** `numeric::inverse(A, options)`

**Description** `numeric::inverse(A)` returns the inverse of the matrix `A`.

If no return type is specified via the option `ReturnType = t`, the domain type of the inverse depends on the type of the input matrix `A`:

- The inverse of an array is returned as an array.
- The inverse of an hfarray is returned as an hfarray.
- The inverse of a dense matrix of type `Dom::DenseMatrix()` is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the inverse is returned as a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The option `Symbolic` should be used if the matrix contains symbolic objects that cannot be converted to floating point numbers.

Without the option `Symbolic`, all entries of `A` must be numerical. Floating point arithmetic is used, the working precision is set by the environment variable `DIGITS`. Exact numerical expressions such as  $\pi + \sqrt{2}$ , `sin(3)` etc. are accepted and converted to floats. If symbolic entries are found in the matrix, `numeric::inverse` automatically switches to `Symbolic`, issuing a warning. This warning may be suppressed via the option `NoWarning`.

---

**Note** Invertibility of the matrix can only be safely detected with exact arithmetic, i.e., using the option `Symbolic`. See “Example 2” on page 18-149.

---

# numeric::inverse

---

---

**Note** Matrices  $A$  of a matrix domain such as `Dom::Matrix(..)` or `Dom::SquareMatrix(..)` are internally converted to arrays over expressions via `expr(A)`. Note that `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Note that  $1/A$  must be used, when the inverse is to be computed over the component domain. See “Example 3” on page 18-152.

---

We recommend to use `numeric::linsolve` or `numeric::matlinsolve` if a sparse system of linear equations is to be solved. In particular, these routines are more efficient than `numeric::inverse` for large sparse systems.

`numeric::linsolve` uses sparse input and output via symbolic equations and features internal sparse arithmetic.

Alternatively, sparse matrices of domain type `Dom::Matrix()` may be used with `numeric::matlinsolve`.

## Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

Numerical matrices can be processed with or without the option `Symbolic`. In the following, the inverses are returned as arrays because the input matrix is an array:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]]):
```

```
numeric::inverse(A), numeric::inverse(A, Symbolic)
```

$$\begin{pmatrix} -1.099071012 & 0.6996903372 \\ 1.049535506 & -0.3498451686 \end{pmatrix}, \begin{pmatrix} \frac{\pi}{\pi-6} & -\frac{2}{\pi-6} \\ -\frac{3}{\pi-6} & \frac{1}{\pi-6} \end{pmatrix}$$

Matrices of category `Cat::Matrix` are accepted. The inverse is returned as a corresponding matrix:

```
A := Dom::Matrix([[2, PI], [0, 1]]):
numeric::inverse(A); domtype(%)
```

$$\begin{pmatrix} 0.5 & -1.570796327 \\ 0 & 1.0 \end{pmatrix}$$

```
Dom::Matrix()
```

```
delete A:
```

## Example 2

The following matrix is not invertible:

```
A := linalg::hilbert(6):
A[6,6] := 5773/63504:
A
```

## numeric::inverse

---

$$\begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} \\ \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} \\ \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} & \frac{1}{10} \\ \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} & \frac{1}{10} & \frac{5773}{63504} \end{pmatrix}$$

With exact arithmetic, `numeric::inverse` detects this fact:

```
numeric::det(A, Symbolic), numeric::inverse(A, Symbolic)
```

```
0, FAIL
```

Due to internal round-off, the matrix is regarded as invertible if float arithmetic is used:

```
numeric::det(A, HardwareFloats), numeric::inverse(A, HardwareFloats)
```

```
-3.239912837 10-28, [[-1.339975706 1011, 4.019927119 1012, -2.813948983 1013, 7.503863956 1013, -8.441846951 1013, 3.37673878 1013],
[4.019927119 1012, -1.205978136 1014, 8.441846951 1014, -2.251159187 1015, 2.532554085 1015, -1.013021634 1015], [-2.813948983 1013, 8.441846951 1014, -5.909292865 1015, 7.091151439 1015, -1.77278786 1016, 7.091151439 1015],
[7.503863956 1013, -2.251159187 1015, 1.575811431 1016, -4.202163815 1016, 4.727400000 1016, -1.890973717 1016], [-8.441846951 1013, 2.532554085 1015, -1.77278786 1016, 2.127345432 1016, -5.318363579 1016, 2.127345432 1016],
[3.37673878 1013, -1.013021634 1015, 7.091151439 1015, -1.890973717 1016, 2.127345432 1016, -8.509381726 1015]]
```

With SoftwareFloats, the internal rounding is slightly different and the kernel of the matrix is detected:

```
numeric::det(A, SoftwareFloats), numeric::inverse(A, SoftwareFloats)
```

```
-3.731550906 10-30, FAIL
```

```
delete A:
```

# numeric::inverse

---

## Example 3

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [1, 6]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 1 \bmod 7 & 6 \bmod 7 \end{pmatrix}$$

Note that `numeric::inverse` computes the inverse of the following matrix:

```
expr(A), numeric::inverse(A)
```

$$\begin{pmatrix} 6 & 6 \\ 1 & 6 \end{pmatrix}, \begin{pmatrix} 0.2 & -0.2 \\ -0.033333333333 & 0.2 \end{pmatrix}$$

The overloaded arithmetic should be used if the inverse is to be computed over the component domain `Dom::IntegerMod(7)`:

```
1/A
```

$$\begin{pmatrix} 3 \bmod 7 & 4 \bmod 7 \\ 3 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

```
delete A:
```

## Example 4

The option `Symbolic` should not be used for float matrices because no internal pivoting is used to stabilize the numerical algorithm:

```
A := matrix([[1.0/10^20, 1.0], [1.0, 1.0]]):
```

```
bad = numeric::inverse(A, Symbolic),
good = numeric::inverse(A)
```

$$\text{bad} = \begin{pmatrix} 0 & 1.0 \\ 1.0 & -1.0 \cdot 10^{-20} \end{pmatrix}, \text{good} = \begin{pmatrix} -1.0 & 1.0 \\ 1.0 & -1.0 \cdot 10^{-20} \end{pmatrix}$$

```
delete A:
```

### Example 5

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned and difficult to invert with low values of DIGITS. The following results, both with HardwareFloats as well as with SoftwareFloats, are marred by numerical round-off. Consequently, the inverses with and without hardware floats, respectively, differ significantly:

```
A := linalg::hilbert(10):
DIGITS := 10:
B1 := numeric::inverse(A, HardwareFloats):
B2 := numeric::inverse(A, SoftwareFloats):
B1[8, 8] <> B2[8, 8]
```

$$3.267405722 \cdot 10^{12} \neq 3.26785917 \cdot 10^{12}$$

```
norm(B1 - B2)
```

```
1681640193.0
```

```
delete A, B1, B2:
```

# numeric::inverse

---

## Parameters     **A**

A square matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

## Options     **Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no **HardwareFloats** or **SoftwareFloats** are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix **A** is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`, or if one of the options **Soft**, **SoftwareFloats** or **Symbolic** is specified, MuPAD

computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill-conditioned matrices, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 2” on page 18-149 and “Example 5” on page 18-153.

---

## Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option prevents conversion of the input data to floats. With this option, symbolic entries are accepted.

# numeric::inverse

---

---

**Note** This option should not be used for floating-point matrices! No internal pivoting is used, unless necessary. Consequently, numerical instabilities may occur in floating-point operations. See “Example 4” on page 18-152.

---

## NoWarning

Without the option `Symbolic`, `numeric::inverse` automatically switches to the `Symbolic` mode with a warning if symbolic coefficients are found. With the option `NoWarning`, this warning is suppressed. Note, however, that `numeric::inverse` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

## ReturnType

Option, specified as `ReturnType = t`

Return the inverse as a matrix of domain type `t`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## Return Values

Depending on the type of the input matrix `A`, the inverse is returned as a matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`. `FAIL` is returned if the inverse cannot be computed.

## Algorithms

Gaussian elimination with partial pivoting is used. Partial pivoting is switched off by the option `Symbolic`.

## See Also

## MuPAD Functions

`linsolve` | `linalg::matlinsolve` | `numeric::linsolve` | `numeric::matlinsolve` | `solve`

## Purpose

Least squares solution of linear equations

## Syntax

`numeric::leastSquares(A, B, <mode>, <method>, options)`

## Description

`numeric::leastSquares(A, B)` computes a matrix  $X$  that solves the linear matrix equation  $AX = B$  in the least squares sense: the columns  $X_j$  of  $X$  minimize  $\|A X_j - B_j\|_2$  where the  $B_j$  are the columns of  $B$ .

For a given vector  $B$ , a vector  $X$  minimizes  $\|A X - B\|_2$  if and only if  $X$  is a solution of the “normal equations”  $A^H A X = A^H B$ , where  $A^H$  is the Hermitian transpose of the  $m \times n$  matrix  $A$ . The solution is unique if  $\text{rank}(A) = n$ .

`numeric::leastSquares` allows to solve several least squares problems simultaneously by combining several ‘right hand sides’  $B_j$  columnwise to a matrix  $B$ .

If no return type is specified via the option `ReturnType = d`, the domain type of the return data depends on the type of the input matrix  $A$ :

- The special solution  $X$  as well as the kernel of an array  $A$  are returned as arrays.
- The special solution and the kernel of an hfarray of domain type `DOM_HFARRAY` are returned as hfarrays.
- For a dense matrix  $A$  of type `Dom::DenseMatrix()`, both the special solution  $X$  as well as the kernel are returned as matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, both the special solution  $X$  as well as the kernel are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices  $A$  of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Without `Symbolic`, the input data are converted to floating-point numbers. The matrix  $A$  must not contain non-convertible parameters, unless `Symbolic` is used. If such objects are found,

## numeric::leastSquares

---

`numeric::leastSquares` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`.

Symbolic parameters in  $B$  are accepted without warning. However, `HardwareFloats` cannot be used if there are any symbolic parameters in  $A$  or  $B$ .

If  $A^H A$  has a non-trivial kernel, the least squares solution  $X$  is not unique. The return value  $X$  is a *special* solution of the equation  $A^H A X = A^H B$ . With the SVD method,  $X$  is the special solution with columns of minimal Euclidean length.

---

**Note** The result computed with `HardwareFloats` may differ from the solution computed with `SoftwareFloats` or `Symbolic`! In particular, this is the case for systems with a non-trivial kernel. Further, the results computed with QRD and SVD may differ.

---

The kernel is computed only in the symbolic mode (option `Symbolic`). All floating-point methods return the value `NIL` for the kernel.

With `Symbolic`, the  $n \times d$  matrix `KernelBasis` is the most general solution of  $A^H A X = 0$ . Its columns span the  $d$ -dimensional kernel of  $A^H A$ .

If the kernel is 0-dimensional, the return value of `KernelBasis` is the integer 0. If `KernelBasis` is returned as an array, the dimension  $d$  of the kernel is `d = op(KernelBasis, [0, 3, 2])`. If `KernelBasis` is returned as a matrix of type `Dom::Matrix()` or `Dom::DenseMatrix()`, the dimension  $d$  of the kernel is `d = KernelBasis::dom::matdim(KernelBasis)[2]`.

---

**Note** Without the option `Symbolic`, the implemented algorithms take care of numerical stabilization.

With `Symbolic`, exact data are assumed. The least squares solutions is computed via `numeric::matlinsolve( AH A, AH B , Symbolic)`. The symbolic strategy tries do maximize speed and does not take care of numerical stabilization! Do not use `Symbolic` for systems involving floating-point entries! In particluar, due to round-off, it may happen that no solution of  $A^H A X = A^H B$  is found. In such a case, `[FAIL, NIL, NIL]` is returned. Cf. “Example 4” on page 18-163.

---

All entries of `A` and `B` must be arithmetical expressions.

---

**Note** Apart from matrices of type `Dom::Matrix(...)`, `Cat::Matrix` objects `A` from matrix domains such as `Dom::DenseMatrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

The same holds true for matrices `B` passed as `Cat::Matrix` objects.

---

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We consider a matrix `A` of rank 1:

```
A := array(1..3, 1..2, [[1, 2], [1, 2], [1, 2]]):
B := [3, 4, 5]:
```

The normal equations have a 1-parameter set of of solutions:

# numeric::leastSquares

---

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, Symbolic)
```

$$\left[ \begin{pmatrix} 4 \\ 0 \end{pmatrix}, \begin{pmatrix} -2 \\ 1 \end{pmatrix}, [\sqrt{2}] \right]$$

The numerical method QRD produces a special solution:

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, QRD)
```

$$\left[ \begin{pmatrix} 4.0 \\ 0 \end{pmatrix}, \text{NIL}, [1.414213562] \right]$$

The numerical method SVD produces a solution  $X$  of minimal norm:

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, SVD)
```

$$\left[ \begin{pmatrix} 0.8 \\ 1.6 \end{pmatrix}, \text{NIL}, [1.414213562] \right]$$

```
delete A, B, X, KernelBasis, Res:
```

## Example 2

We consider an ill-conditioned least squares problem. By construction, the following overdetermined system has an exact solution  $X = [1, 2, \dots, n]$ :

```
m := 10: n := 8:
A := array(1..m, 1..n, [[1/(i + j + 100) $ j=1..n] $ i=1..m]):
B := array(1..m, [_plus(A[i,j]*j $ j=1..n) $ i=1..m]):
numeric::leastSquares(A, B, Symbolic)
```

$$\left[ \begin{pmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \\ 6 \\ 7 \\ 8 \end{pmatrix}, 0, [0] \right]$$

The coefficient matrix  $A$  is rather ill-conditioned:

```
singvals := numeric::singularvalues(A):
conditionOfA := max(op(singvals))/min(op(singvals))
```

6.31539107 10<sup>16</sup>

Consequently, round-off has a drastic effect in a numerical approximation. The methods yield results of different quality:

```
numeric::leastSquares(A, B, QRD)
```

$$\left[ \begin{pmatrix} 205.7634088 \\ -506.7540812 \\ 336.9881724 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \text{NIL}, [0.000000007174860922] \right]$$

```
numeric::leastSquares(A, B, SVD)
```

# numeric::leastSquares

---

$$\begin{bmatrix} 44440.34961 \\ -36432.38255 \\ -44826.69677 \\ -14839.48585 \\ 23895.8882 \\ 45730.9635 \\ 28571.67227 \\ -46506.25357 \end{bmatrix}, \text{NIL}, [0.0000007416898216]$$

delete m, n, A, B, singvals, conditionOfA:

### Example 3

This example involves a symbolic parameter  $c$  in the matrix  $A$ . The option Symbolic must be used:

```
A:= matrix([[c, 2], [1/3, 2/3], [1/7, 2/7]]):
B:= [1, 2, 3]:
numeric::leastSquares(A, B, Symbolic)
```

$$\begin{bmatrix} -\frac{425}{58(c-1)} \\ \frac{483c-58}{116(c-1)} \end{bmatrix}, 0,$$

$$\left[ \sqrt{\left| \frac{425c}{58(c-1)} - \frac{483c-58}{58(c-1)} + 1 \right|^2 + \left| \frac{425}{174(c-1)} - \frac{483c-58}{174(c-1)} + 2 \right|^2 + \left| \frac{425}{406(c-1)} - \frac{483c-58}{406(c-1)} + 3 \right|^2} \right]$$

normal(%)

$$\left[ \left( \begin{array}{c} -\frac{425}{58(c-1)} \\ \frac{483c-58}{116(c-1)} \end{array} \right), 0, \left[ \frac{15\sqrt{58}}{58} \right] \right]$$

delete A, B:

## Example 4

Floating point entries may cause problems in conjunction with the option `Symbolic`, because the computation is not stabilized numerically in the symbolic node. The following matrix  $A$  has rank 2:

```
A := matrix([[1, 30], [10.0^(-15), 31*10.0^(-15)]]):
```

However, due to round-off, the 'normal matrix'  $A^H A$  has rank 1. No solution is found with `Symbolic`:

```
A::dom::transpose(A) * A
```

$$\begin{pmatrix} 1.0 & 30.0 \\ 30.0 & 900.0 \end{pmatrix}$$

```
numeric::leastSquares(A, [31, 32*10^5], Symbolic)
```

```
[FAIL, NIL, NIL]
```

No such problem arises in the numerical schemes. Note, however, that the numerical methods yield different results in this extremely ill-conditioned problem:

```
numeric::leastSquares(A, [31, 32*10^5], QRD)
```

# numeric::leastSquares

---

$$\left[ \begin{pmatrix} -9.6 \cdot 10^{22} \\ 3.2 \cdot 10^{21} \end{pmatrix}, \text{NIL}, [31.0] \right]$$

```
numeric::leastSquares(A, [31, 32*10^5], SVD)
```

$$\left[ \begin{pmatrix} 0.03440621532 \\ 1.03218646 \end{pmatrix}, \text{NIL}, [3200000.0] \right]$$

```
delete A:
```

## Parameters

### A

An  $m \times n$  matrix of domain type DOM\_ARRAY or of category Cat::Matrix

### B

An  $m \times p$  matrix of domain type DOM\_ARRAY or of category Cat::Matrix. Column vectors B may also be represented by a 1-dimensional array(1..m, [B<sub>1</sub>, B<sub>2</sub>, ...]) or by a list [B<sub>1</sub>, B<sub>2</sub>, ...].

### mode

One of the flags Hard, HardwareFloats, Soft, SoftwareFloats, or Symbolic

### method

One of the flags QRD, SVD

## Options

### Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled

C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

## numeric::leastSquares

---

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

### Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used, if the matrix  $A$  contains symbolic parameters that cannot be converted to floating-point numbers.

The normal equations  $A^HAX = A^HB$  are passed to `numeric::matlinsolve` with the option `Symbolic`.

If the least squares problem does not have a unique solution, a special solution  $X$  is returned together with the kernel of  $A^HA$ . Cf. “Example 1” on page 18-159.

---

**Note** This option should not be used for systems with floating-point coefficients! Numerical instabilities may occur in floating-point operations. Further, if the rank of  $A$  is not maximal, then `numeric::leastSquares` may fail to find a solution due to numerical round-off. In such a case, `[FAIL, NIL, NIL]` is returned. Cf. “Example 4” on page 18-163.

---

### QRD

Use a QR decomposition. All entries of  $A$  must be convertible to floating-point values.

This is the default method.

The matrix  $A$  must not contain symbolic parameters that cannot be converted to floating point numbers. If such objects are found, then `numeric::leastSquares` automatically switches to its Symbolic mode, issuing a warning. The computation proceeds with exact arithmetic, using the input data without floating-point conversions.

The warning may be suppressed by the option `NoWarning`.

Symbolic parameters in  $B$  are accepted without warning. They are processed by the floating-point algorithm.

Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floats.

If the least squares problem does not have a unique solution, only a special solution is returned. The kernel is not computed: it is returned as NIL.

The method `QRD` provides a numerically stable way of solving the normal equations  $A^H A X = A^H B$  by a QR decomposition. In extremely ill-conditioned situations, it may be worthwhile to consider the slower, yet more stable method `SVD`.

The conditioning is given by the ratio of the largest singular value of  $A$  divided by the smallest singular value of  $A$ . If this value is large, the problem is ill-conditioned.

Cf. “Example 2” on page 18-160.

## **SVD**

Use a singular value decomposition. All entries of  $A$  must be convertible to floating-point values.

The matrix  $A$  must not contain symbolic parameters that cannot be converted to floating point numbers. If such objects are found, then `numeric::leastSquares` automatically switches to its

# numeric::leastSquares

---

symbolic mode, issuing a warning. The computation proceeds with exact arithmetic, using the input data without floating point conversions.

The warning may be suppressed by the option `NoWarning`.

Symbolic parameters in  $B$  are accepted without warning. They are processed by the floating-point algorithm.

Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floats.

If the least squares problem does not have a unique solution, the columns  $X_j$  of the solution  $X$  have a minimal Euclidean length

$$\|X_j\|_2$$

The kernel is not computed: it is returned as `NIL`.

A singular value decomposition  $A = UDV^H$  is used to solve the normal equations in the form  $D^2V^HX = DU^HB$ . For small or zero singular values  $d_i$  in  $D = \text{diag}(d_1, d_2, \dots)$ , the corresponding components of  $V^Hx$  are set to zero.

Usually, the numerical method SVD is slower than the default method QRD. However, in ill-conditioned situations, it is numerically more stable.

The conditioning is given by the ratio of the largest singular value of  $A$  divided by the smallest singular value of  $A$ . If this value is large, the problem is ill-conditioned.

## **NoWarning**

Suppresses warnings

If symbolic coefficients are found in  $A$ , `numeric::leastSquares` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed.

## **ReturnType**

Option, specified as `ReturnType = d`

Return the (special) solution and the kernel as matrices of domain type  $d$ . The following return types  $d$  are available: `DOM_ARRAY`, or `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## Return Values

A list `[X, KernelBasis, Residues]` is returned.

The (special) least squares solution  $X$  is an  $n \times p$  matrix.

With `Symbolic`, `KernelBasis` is an  $n \times d$  matrix ( $d$  is the dimension of the kernel of  $A^H A$ ). Its columns span the kernel of  $A^H A$ . If the kernel is trivial, `KernelBasis` is the integer 0.

Without `Symbolic`, the kernel is not computed. The value `NIL` is returned for the `KernelBasis`.

The list of arithmetical expressions `Residues` consists of the minimized least squares deviations  $\|A X_j - B_j\|_2$  corresponding to the columns of  $X$  and  $B$ .

`numeric::singularvectors`

# numeric::linsolve

---

**Purpose** Solve a system of linear equations

**Syntax** `numeric::linsolve(eqs, <vars>, options)`

**Description** `numeric::linsolve(eqs, vars)` solves a system of linear equations `eqs` for the unknowns `vars`.

`numeric::linsolve` is a fast numerical linear solver. It is also a recommended solver for linear systems with exact or symbolic coefficients (using `Symbolic`).

Expressions are interpreted as homogeneous equations. E.g., the input `[x = y - 1, x - y]` is interpreted as the system of equations `[x = y - 1, x - y = 0]`.

---

**Note** Without the option `Symbolic`, the input data are converted to floating-point numbers. The coefficient matrix  $A$  of the system  $Ax = b$  represented by `eqs` must not contain non-convertible parameters, unless the option `Symbolic` is used! If such objects are found, then `numeric::linsolve` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`. Symbolic parameters in the “right hand side”  $b$  are accepted without warning.

---

The numerical working precision is set by the environment variable `DIGITS`.

The solutions are returned as a list of solved equations of the form

$$[x_1 = \text{value}_1, x_2 = \text{value}_2, \dots]$$

where  $x_1, x_2, \dots$  are the unknowns. These simplified equations should be regarded as constraints on the unknowns. E.g., if an unknown  $x_1$ , say, does not turn up in the form `[x1 = ..., ...]` in the solution, then there is no constraint on this unknown; it is an arbitrary parameter.

Generally, all unknowns that do not turn up on the left hand side of the solved equations are arbitrary parameters spanning the solution space. Cf. “Example 9” on page 18-180.

In particular, if the empty list is returned as the solution, there are no constraints whatsoever on the unknowns, i.e., the system is trivial.

The ordering of the solved equations corresponds to the ordering of the unknowns vars. It is recommended that the user specifies vars by a *list* of unknowns. This guarantees that the solved equations are returned in the expected order. If vars are specified by a set, or if no vars are specified at all, then an internal ordering is used.

If no unknowns are specified by vars, numeric::linsolve solves for all symbolic objects in eqs. The unknowns are determined internally by `indets(eqs, PolyExpr)`.

numeric::linsolve returns the general solution of the system eqs. It is valid for arbitrary complex values of the symbolic parameters which may be present in eqs. If no such solution exists, FAIL is returned. Solutions that are valid only for special values of the symbolic parameters may be obtained with the option ShowAssumptions. See “Example 2” on page 18-173, “Example 3” on page 18-174, “Example 4” on page 18-175, and “Example 11” on page 18-182.

The solved equations representing the solution are suitable as input for assign and subs. See “Example 8” on page 18-180.

numeric::linsolve is suitable for solving large sparse systems. See “Example 6” on page 18-177.

If eqs represents a system with a banded coefficient matrix, then this is detected and used by numeric::linsolve. Note that in this case, it is important to specify both the equations as well as the unknowns by lists to guarantee the desired form of the coefficient matrix. When using sets, the data may be reordered internally leading to a loss of band structure and, consequently, of efficiency. See “Example 6” on page 18-177.

# numeric::linsolve

---

---

**Note** `numeric::linsolve` is tuned for speed. For this reason, it does not check systematically that the equations `eqs` are indeed linear in the unknowns! For non-linear equations, strange things may happen; `numeric::linsolve` might even return wrong results! See “Example 5” on page 18-175.

---

---

**Note** `numeric::linsolve` does not react to any properties of the unknowns or of symbolic parameters that are set via `assume`.

---

---

**Note** Gaussian elimination with partial pivoting is used. Without the option `Symbolic`, floating-point arithmetic is used and the pivoting strategy takes care of numerical stabilization. With `Symbolic`, exact data are assumed and the pivoting strategy tries to maximize speed, not taking care of numerical stabilization! See “Example 7” on page 18-179.

---

## Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

Equations and variables may be entered as sets or lists:

```
numeric::linsolve({x = y - 1, x + y = z}, {x, y});
numeric::linsolve([x = y - 1, x + y = z], {x, y});
numeric::linsolve({x = y - 1, x + y = z}, [x, y]);
numeric::linsolve([x = y - 1, x + y = z], [x, y])
```

```
[x = 0.5 z - 0.5, y = 0.5 z + 0.5]
```

```
[x = 0.5 z - 0.5, y = 0.5 z + 0.5]
```

```
[x = 0.5 z - 0.5, y = 0.5 z + 0.5]
```

```
[x = 0.5 z - 0.5, y = 0.5 z + 0.5]
```

With the option `Symbolic`, exact arithmetic is used. The following system has a 1-parameter set of solution; the unknown  $x_3$  is arbitrary:

```
numeric::linsolve([x[1] + x[2] = 2, x[1] - x[2] = 2*x[3]],
 [x[1], x[2], x[3]], Symbolic)
```

```
[X1 = X3 + 1, X2 = 1 - X3]
```

The unknowns may be expressions:

```
numeric::linsolve([f(0) - sin(x + 1) = 2, f(0) = 1 - sin(x + 1)],
 [f(0), sin(x + 1)])
```

```
[f(0) = 1.5, sin(x + 1) = -0.5]
```

The following system does not have a solution:

```
numeric::linsolve([x + y = 1, x + y = 2], [x, y])
```

```
FAIL
```

## Example 2

We demonstrate some examples with symbolic coefficients. Note that the option `Symbolic` has to be used:

# numeric::linsolve

---

```
eqs := [x + a*y = b, x + A*y = b]:
numeric::linsolve(eqs, [x, y], Symbolic)
```

```
[x = b, y = 0]
```

Note that for  $a = A$ , this is not the general solution. Using the option `ShowAssumptions`, it turns out that the above result is the general solution subject to the assumption  $a \neq A$ :

```
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

```
[[x = b, y = 0], [], [A - a ≠ 0]]
```

```
delete eqs:
```

### Example 3

We give a further demonstration of the option `ShowAssumptions`. The following system does not have a solution for all values of the parameter  $a$ :

```
numeric::linsolve([x + y = 1, x + y = a], [x, y], Symbolic)
```

```
FAIL
```

With `ShowAssumptions`, `numeric::linsolve` investigates under which conditions (on the parameter  $a$ ) there is a solution:

```
numeric::linsolve([x + y = 1, x + y = a], [x, y], Symbolic,
 ShowAssumptions)
```

```
[[x = 1 - y], [a - 1 = 0], []]
```

We conclude that there is a 1-parameter set of solutions for  $a = 1$ . The constraint in `a` is a linear equation, since the parameter `a` enters the equations linearly. If `a` is regarded as an unknown rather than as a parameter, the constraint becomes part of the solution:

```
numeric::linsolve([x + y = 1, x + y = a], [x, y, a], Symbolic,
 ShowAssumptions)
```

```
[[x = 1 - y, a = 1], [], []]
```

## Example 4

With exact arithmetic, `PI` is regarded as a symbolic parameter. The following system has a solution subject to the constraint  $PI = 1$ :

```
numeric::linsolve([x = x - y + 1, y = PI], [x, y],
 Symbolic, ShowAssumptions)
```

```
[[y = pi], [1 - pi = 0], []]
```

With floating-point arithmetic, `PI` is converted to  $3.1415\dots$ . The system has no solution:

```
numeric::linsolve([x = x - y + 1, y = PI], [x, y],
 ShowAssumptions)
```

```
[FAIL, [], []]
```

## Example 5

Since `numeric::linsolve` does not do a systematic internal check for non-linearities, the user should make sure that the equations to be solved are indeed linear in the unknowns. Otherwise, strange things may happen. Garbage is produced for the following non-linear systems:

## numeric::linsolve

---

```
a := sin(x):
numeric::linsolve([y = 1 - a, x = y], [x, y], Symbolic)
```

$$[x = 1 - \sin(x17^3), y = 1 - \sin(x17^3)]$$

```
numeric::linsolve([a*x + y = 1, x = y], [x, y], Symbolic)
```

$$\left[ x = \frac{1}{\sin(x18^3) + 1}, y = \frac{1}{\sin(x18^3) + 1} \right]$$

Polynomial non-linearities are usually detected. Regarding  $x$ ,  $y$ ,  $c$  as unknowns, the following quadratic system yields an error:

```
numeric::linsolve([x*c + y = 1, x = y], Symbolic)
```

```
Error: This system does not seem to be linear. [numeric::linsolve]
```

```
Error:
This system does not seem to be linear. [numeric::linsolve]
```

This system is linear in  $x$ ,  $y$  if  $c$  is regarded as a parameter:

```
numeric::linsolve([x*c + y = 1, x = y], [x, y], Symbolic)
```

$$\left[ x = \frac{1}{c + 1}, y = \frac{1}{c + 1} \right]$$

```
delete a:
```

## Example 6

We solve a large sparse system. The coefficient matrix has only 3 diagonal bands. Note that both the equations as well as the variables are passed as lists. This guarantees that the band structure is not lost internally:

```
n := 500: x[0] := 0: x[n + 1] := 0:
eqs := [x[i-1] - 2*x[i] + x[i+1] = 1 $ i = 1..n]:
vars := [x[i] $ i = 1..n]:
numeric::linsolve(eqs, vars)
```

$[x_1 = -250.0, x_2 = -499.0, x_3 = -747.0, x_4 = -994.0, \dots, x_{498} = -747.0, x_{499} = -499.0, x_{500} = -250.0]$

The band structure is lost if the equations or the unknowns are specified by sets. The following call takes more time than the previous call:

```
numeric::linsolve({op(eqs)}, {x[i] $ i = 1..n})
```

$[x_1 = -250.0, x_2 = -499.0, x_3 = -747.0, x_4 = -994.0, \dots, x_{498} = -747.0, x_{499} = -499.0, x_{500} = -250.0]$

# numeric::linsolve

[ $x_1 = -250.0, x_2 = -499.0, x_3 = -747.0, x_4 = -994.0, x_5 = -1240.0, x_6 = -1485.0, x_7 = -17$

 $x_{224} = -31024.0, x_{225} = -31050.0, x_{226} = -31075.0, x_{227} = -31099.0, x_{228} = -31122.0, x_{229}$   
 $x_{230} = -31165.0, x_{231} = -31185.0, x_{232} = -31204.0, x_{233} = -31222.0, x_{234} = -31239.0, x_{235}$   
 $x_{236} = -31270.0, x_{237} = -31284.0, x_{238} = -31297.0, x_{239} = -31309.0, x_{240} = -31320.0, x_{241}$   
 $x_{242} = -31339.0, x_{243} = -31347.0, x_{244} = -31354.0, x_{245} = -31360.0, x_{246} = -31365.0, x_{247}$   
 $x_{248} = -31372.0, x_{249} = -31374.0, x_{250} = -31375.0, x_{251} = -31375.0, x_{252} = -31374.0, x_{253}$   
 $x_{254} = -31369.0, x_{255} = -31365.0, x_{256} = -31360.0, x_{257} = -31354.0, x_{258} = -31347.0, x_{259}$

```
delete n, x, eqs, vars:
```

## Example 7

The option `Symbolic` should not be used for equations with floating-point coefficients, because the symbolic pivoting strategy favors efficiency instead of numerical stability.

```
eqs := [x + 10^20*y = 10^20, x + y = 0]:
```

The float approximation of the exact solution is:

```
map(numeric::linsolve(eqs, [x, y], Symbolic), map, float)
```

```
[x = -1.0, y = 1.0]
```

We now convert the exact coefficients to floating-point numbers:

```
feqs := map(eqs, map, float)
```

```
[x + 1.0 1020 y = 1.0 1020, x + y = 0.0]
```

The default pivoting strategy stabilizes floating-point operations. Consequently, one gets a correct result:

```
numeric::linsolve(feqs, [x, y])
```

```
[x = -1.0, y = 1.0]
```

With `Symbolic`, the pivoting strategy optimizes speed, assuming exact arithmetic. Numerical instabilities may occur if floating-point coefficients are involved. The following incorrect result is caused by internal round-off effects (“cancellation”):

# numeric::linsolve

---

```
numeric::linsolve(feqs, [x, y], Symbolic)
```

```
[x = 0.0, y = 1.0]
```

```
delete eqs, feqs:
```

## Example 8

We demonstrate that the simplified equations representing the solution can be used for further processing with `subs`:

```
eqs := [x + y = 1, x + y = a]:
[Solution, Constraints, Pivots] :=
 numeric::linsolve(eqs, [x, y], ShowAssumptions)
```

```
[[x = 1.0 - 1.0 y], [1.0 a - 1.0 = 0], []]
```

```
subs(eqs, Solution)
```

```
[1.0 = 1, 1.0 = a]
```

The solution can be assigned to the unknowns via `assign`:

```
assign(Solution):
x, y, eqs
```

```
1.0 - 1.0 y, y, [1.0 = 1, 1.0 = a]
```

```
delete eqs, Solution, Constraints, Pivots, x:
```

## Example 9

If the solution of the linear system is not unique, then some of the unknowns are used as “free parameters” spanning the solution space.

In the following example, the unknowns  $z$ ,  $w$  are such parameters. They do not turn up on the left hand side of the solved equations:

```
eqs := [x + y = z, x + 2*y = 0, 2*x - z = -3*y, y + z = 0]:
vars := [x, y, z, w]:
Solution := numeric::linsolve(eqs, vars, Symbolic)
```

```
[x = 2 z, y = -z]
```

You may define a function such as the following `NewSolutionList` to rename your free parameters to “myName1”, “myName2” etc. and fill up your list of solved equations accordingly:

```
NewSolutionList :=
proc(Solution : DOM_LIST, vars : DOM_LIST, myName : DOM_STRING)
local i, solvedVars, newEquation;
begin
 solvedVars := map(Solution, op, 1);
 for i from 1 to nops(vars) do
 if not has(solvedVars, vars[i]) then
 newEquation := vars[i] = genident(myName);
 Solution := listlib::insertAt(
 subs(Solution, newEquation), newEquation, i)
 end_if
 end_for:
 Solution
end_proc:
```

```
NewSolutionList(Solution, vars, "FreeParameter")
```

```
[x = 2 FreeParameter1, y = - FreeParameter1, z = FreeParameter1, w = FreeParameter1]
```

```
delete eqs, vars, Solution, NewSolutionList:
```

## Example 10

We demonstrate the difference between hardware and software arithmetic. The following problem is very ill-conditioned. The results, both with HardwareFloats as well as with SoftwareFloats, are marred by numerical round-off:

```
n:= 10:
eqs:= [(_plus(x[j]/(i + j -1) $ j = 1..n) = 1) $ i = 1..n]:
vars:= [x[i] $ i = 1..n]:
numeric::linsolve(eqs, vars, SoftwareFloats);
numeric::linsolve(eqs, vars, HardwareFloats)
```

```
[x1 = -9.999986342, x2 = 989.9988244, x3 = -23759.97502, x4 = 240239.7733, x5 = -1261260.035,
x6 = 3783777.035, x7 = -6726715.139, x8 = 7001275.306, x9 = -3938217.537, x10 = 923780]
```

```
[x1 = -9.997364824, x2 = 989.7718609, x3 = -23755.13378, x4 = 240195.7143, x5 = -1261260.035,
x6 = 3783198.501, x7 = -6725765.49, x8 = 7000357.238, x9 = -3937735.418, x10 = 923780]
```

This is the exact solution:

```
numeric::linsolve(eqs, vars, Symbolic);
```

```
[x1 = -10, x2 = 990, x3 = -23760, x4 = 240240, x5 = -1261260, x6 = 3783780, x7 = -6726720,
x8 = 7001280, x9 = -3938220, x10 = 923780]
```

```
delete eqs, vars:
```

## Example 11

We demonstrate how a complete solution of the following linear system in  $x, y$  with symbolic parameters  $a, b, c, d$  may be found:

```
eqs := [x + y = d, a*x + b*y = 1, x + c*y = 1]:
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$\left[ \left[ x = -\frac{b d - 1}{a - b}, y = \frac{a d - 1}{a - b} \right], [a - b + c + b d - a c d - 1 = 0], [b - a \neq 0] \right]$$

This is the general solution, assuming  $a \neq b$ . We now set  $b = a$  to investigate further solution branches:

```
eqs := subs(eqs, b = a):
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$\left[ \left[ x = \frac{c d - 1}{c - 1}, y = -\frac{d - 1}{c - 1} \right], [1 - a d = 0], [c - 1 \neq 0] \right]$$

This is the general solution for  $a = b$ , assuming  $c \neq 1$ . We finally set  $c = 1$  to obtain the last solution branch:

```
eqs := subs(eqs, c = 1):
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$[[x = d - y], [1 - a d = 0, 1 - d = 0], []]$$

From the constraints on the symbolic parameters  $a$  and  $d$ , we conclude that there is a special 1-parameter solution  $x = 1 - y$  for  $a = b = c = d = 1$ .

```
delete eqs:
```

## Parameters

### eqs

A list, set, array, or matrix (Cat::Matrix) of linear equations or arithmetical expressions

### vars

A list or set of unknowns to solve for. Unknowns may be identifiers or indexed identifiers or arithmetical expressions.

## Options

### **Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of **DIGITS** is larger than 15 and the input matrix **A** is not of domain type **DOM\_HFARRAY**.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no **HardwareFloats** or **SoftwareFloats** are requested explicitly, the following strategy is used: If the current value of **DIGITS** is smaller than 16 or if the matrix **A** is a hardware float array of domain type **DOM\_HFARRAY**, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of **DIGITS** is larger than 15 and the input matrix **A** is not of domain type **DOM\_HFARRAY**, or if one of the options **Soft**, **SoftwareFloats** or **Symbolic** is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill-conditioned systems, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 10” on page 18-182.

---

## Symbolic

Prevents conversion of input data to floating-point numbers. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used if the coefficients of the equations contain symbolic parameters that cannot be converted to floating-point numbers.

---

**Note** This option should not be used for equations with floating-point coefficients! Numerical instabilities may occur in floating-point operations. See “Example 7” on page 18-179.

---

## ShowAssumptions

Returns information on internal assumptions on symbolic parameters in `eqs`.

This option is only useful if the equations contain symbolic parameters. Consequently, it should only be used in conjunction with the option `Symbolic`.

---

**Note** The format of the return value is changed to `[Solution, Constraints, Pivots]`.

---

`Solution` is a set of simplified equations representing the general solution subject to `Constraints` and `Pivots`.

`Constraints` is a list of equations for symbolic parameters in `eqs`, which are necessary and sufficient to make the system solvable.

Such constraints arise if Gaussian elimination of the original equations leads to equations of the form  $0 = c$ , where  $c$  is some expression involving symbolic parameters in the “right hand side” of the system. All such equations are collected in `Constraints`. `numeric::linsolve` assumes that these equations are satisfied and returns a solution.

If no such constraints arise, the return value of `Constraints` is the empty list.

`Pivots` is a list of inequalities involving symbolic parameters in the coefficient matrix  $A$  of the linear system  $Ax = b$  represented by `eqs`. Internally, division by pivot elements occurs in the Gaussian elimination. The expressions collected in `Pivots` are

the numerators of the pivot elements that contain symbolic parameters. If only numerical pivot elements were used, the return value of `Pivots` is the empty list.

---

**Note** The option `ShowAssumptions` changes the return strategy for “unsolvable” systems. Without the option `Symbolic`, `FAIL` is returned whenever Gaussian elimination produces an equation  $0 = c$  with non-zero  $c$ . With `ShowAssumptions`, such equations are returned via `Constraints`, provided  $c$  involves symbolic parameters.

---

If  $c$  is a purely numerical value, then `[FAIL, [], []]` is returned.

---

See “Example 2” on page 18-173, “Example 3” on page 18-174, “Example 4” on page 18-175, and “Example 11” on page 18-182.

## NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::linsolve` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; `numeric::linsolve` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

## Return Values

Without the option `ShowAssumptions`, a list of simplified equations is returned. It represents the general solution of the system `eqs`. `FAIL` is returned if the system is not solvable.

With `ShowAssumptions`, a list `[Solution, Constraints, Pivots]` is returned. `Solution` is a list of simplified equations representing the general solution of `eqs`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `eqs`. Internally, these were assumed to hold true when solving the system.

`[FAIL, [], []]` is returned if the system is not solvable.

# numeric::linsolve

### MuPAD Functions

`linalg::matlinsolve` | `linsolve` | `numeric::fsolve`  
| `numeric::inverse` | `numeric::matlinsolve` |  
`numeric::polyroots` | `numeric::polysysroots` |  
`numeric::realroots` | `polylib::realroots` | `solve`

**Purpose** Solve a linear matrix equation

**Syntax** `numeric::matlinsolve(A, B, options)`

**Description** `numeric::matlinsolve(A, B)` returns the matrix solution  $X$  of the matrix equation  $AX = B$  together with the kernel of the matrix  $A$ .

`numeric::matlinsolve` is a fast numerical linear solver for both sparse and dense systems. It is also a recommended solver for linear systems with exact or symbolic coefficients (use option `Symbolic`).

If no return type is specified via the option `ReturnType = d`, the domain type of the return data depends on the type of the input matrix  $A$ :

- The special solution  $X$  as well as the kernel of an array  $A$  are returned as arrays.
- The special solution  $X$  as well as the kernel of an hfarray  $A$  are returned as hfarrays.
- For a dense matrix  $A$  of type `Dom::DenseMatrix()`, both the special solution  $X$  as well as the kernel of  $A$  are returned as matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, both the special solution  $X$  as well as the kernel of  $A$  are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices  $A$  of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Without `Symbolic`, exact numerical input data such as `PI + sqrt(2)`, `sin(3)` etc. are converted to floating-point numbers. Floating point arithmetic is used. Its precision is given the environment variable `DIGITS`. If symbolic data are found that cannot be converted to floating-point numbers, `numeric::matlinsolve` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`.

## numeric::matlinsolve

---

With `Symbolic`, symbolic parameters in the coefficient matrix  $A$  as well as in the right hand side  $B$  are accepted and processed without a warning.

With `SoftwareFloats`, the right hand side  $B$  may contain symbolic parameters that cannot be converted to floating-point numbers. All entries of the coefficient matrix  $A$ , however, must be convertible to floating-point numbers.

With `HardwareFloats`, neither  $A$  nor  $B$  must contain symbolic parameters that cannot be converted to floating-point numbers.

$X$  is a *special* solution of the equation  $AX = B$ . If  $A$  has a non-trivial kernel, the solution  $X$  is not unique.

---

**Note** The result computed with `HardwareFloats` may differ from the solution computed with `SoftwareFloats` or `Symbolic`! In particular, this is the case for systems with a non-trivial kernel.

---

Cf. “Example 9” on page 18-199.

The  $n \times d$  matrix `KernelBasis` is the most general solution of  $AX = 0$ . Its columns span the  $d$ -dimensional kernel of  $A$ .

Thus, the kernel of  $A$  may be computed via `numeric::matlinsolve(A, [0, ..., 0])[2]`.

If the kernel is 0-dimensional, the return value of `KernelBasis` is the integer 0. If `KernelBasis` is returned as an array, the dimension  $d$  of the kernel is `d = op(KernelBasis, [0, 3, 2])`. If `KernelBasis` is returned as a matrix of type `Dom::Matrix()` or `Dom::DenseMatrix()`, the dimension  $d$  of the kernel is `d = KernelBasis::dom::matdim(KernelBasis)[2]`.

---

**Note** Due to round-off errors, some or all basis vectors in the kernel of  $A$  may be missed in the numerical modes.

---

The special solution  $X$  in conjunction with `KernelBasis` provides the general solution of  $AX = B$ . Solutions generated without the option `ShowAssumptions` are valid for arbitrary complex values of the symbolic parameters which may be present in  $A$  and  $B$ . If no such solution exists, then `[FAIL,NIL]` is returned. Solutions that are valid only for special values of the symbolic parameters may be obtained with `ShowAssumptions`. See “Example 3” on page 18-194, “Example 4” on page 18-195, and “Example 7” on page 18-197.

`numeric::matlinsolve` internally uses a sparse representation of the matrices. It is suitable for solving large sparse systems. See “Example 5” on page 18-195.

---

**Note** `numeric::matlinsolve` does not react to any assumptions on symbolic parameters in  $A, B$  that are set via `assume`.

---

---

**Note** Gaussian elimination with partial pivoting is used. Without the option `Symbolic`, the pivoting strategy takes care of numerical stabilization. With `Symbolic`, exact data are assumed. The symbolic pivoting strategy tries to maximize speed and does not take care of numerical stabilization! Do not use `Symbolic` for linear systems involving floating-point entries! See “Example 6” on page 18-196.

---

# numeric::matlinsolve

---

---

**Note** Apart from matrices of type `Dom::Matrix(...)`, `Cat::Matrix` objects `A` from matrix domains such as `Dom::DenseMatrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Note that `linalg::matlinsolve` must be used, when the solution is to be computed over the component domain. See . “Example 8” on page 18-199.

---

## Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We use equivalent input formats ( $B_1$ ,  $B_2$ ) to represent a vector with components  $[a, \pi]$ . First, this vector is defined as a 2-dimensional array:

```
A := array(1..2, 1..3, [[1, 2, 3],[1, 1, 2]]):
B1 := array(1..2, 1..1, [[a], [PI]]):
numeric::matlinsolve(A, B1)
```

$$\left[ \begin{pmatrix} 6.283185307 - 1.0 a \\ 1.0 a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix} \right]$$

Next, we use a 1-dimensional array and compute an exact solution:

```
B2 := array(1..2, [a, PI]):
numeric::matlinsolve(A, B2, Symbolic)
```

$$\left[ \begin{pmatrix} 2\pi - a \\ a - \pi \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix} \right]$$

Now, a list is used to specify the vector. No internal assumptions were used by `numeric::matlinsolve` to obtain the solution:

```
B3 := [a, PI]:
numeric::matlinsolve(A, B3, ShowAssumptions)
```

$$\left[ \begin{pmatrix} 6.283185307 - 1.0 a \\ 1.0 a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix}, [], [] \right]$$

Finally, we use `Dom::Matrix` objects to specify the system. Note that the results are returned as corresponding matrix objects:

```
A := matrix([[1, 2, 3],[1, 1, 2]]):
B4 := matrix([a, PI]):
numeric::matlinsolve(A, B4)
```

$$\left[ \begin{pmatrix} 6.283185307 - 1.0 a \\ 1.0 a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix} \right]$$

```
delete A, B1, B2, B3, B4:
```

## Example 2

We invert a matrix by solving  $AX = 1$ :

```
A := hfarray(1..3, 1..3, [[1, 1, 0], [0, 1, 1], [0, 0, 1]]):
```

# numeric::matlinsolve

---

```
B := matrix::identity(3, 3):
InverseOfA := numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} 1.0 & -1.0 & 1.0 \\ 0.0 & 1.0 & -1.0 \\ 0.0 & 0.0 & 1.0 \end{pmatrix}$$

```
delete A, B, InverseOfA:
```

### Example 3

We solve an equation with a symbolic parameter  $x$ :

```
A := matrix([[2, 2, 3], [1, 1, 2], [3, 3, 5]]):
B := matrix([sin(x)^2, cos(x)^2, 0]):
[X, Kernel, Constraints, Pivots] :=
 numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[ \begin{pmatrix} 5 \sin(x)^2 \\ 0 \\ -3 \sin(x)^2 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}, [\cos(x)^2 + \sin(x)^2 = 0], [] \right]$$

This solution holds subject to the constraint  $\sin(x)^2 + \cos(x)^2 = 0$  on the parameter  $x$ . `numeric::matlinsolve` does not investigate the `Constraints` and does not realize that they cannot be satisfied. We check the consistency of the “result” by inserting the solution into the original system. Since the input matrix  $A$  was of type `Dom::Matrix()`, the results  $X$  and `Kernel` were returned as corresponding matrices. The overloaded operators `*` and `-` for matrix multiplication and subtraction can be used:

```
A*X - B, A*Kernel
```

$$\begin{pmatrix} 0 \\ -\cos(x)^2 - \sin(x)^2 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

delete A, B, X, Kernel, Constraints, Pivots:

## Example 4

We give a further demonstration of the option ShowAssumptions. The following system does not have a solution for all values of the parameter a:

```
A := array(1..2, 1..2, [[1, 1], [1, 1]]):
B := array(1..2, 1..1, [[1], [a]]):
numeric::matlinsolve(A, B, Symbolic)
```

[FAIL, NIL]

With ShowAssumptions, numeric::matlinsolve investigates under which conditions (on the parameter a) there is a solution:

```
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$\left[ \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix}, [a - 1 = 0], [] \right]$

We conclude that there is a 1-dimensional solution space for  $a = 1$ .

delete A, B:

## Example 5

We solve a sparse system with 3 diagonal bands:

# numeric::matlinsolve

---

```
n := 100:
A := matrix(n, n, [1, -2, 1], Banded):
B := array(1..n, [1 $ n]):
numeric::matlinsolve(A, B)
```

$$\begin{bmatrix} -50.0 \\ -99.0 \\ -147.0 \\ \dots \\ -147.0 \\ -99.0 \\ -50.0 \end{bmatrix}, 0$$

```
delete n, A, B:
```

## Example 6

The option `Symbolic` should not be used for equations with floating-point coefficients, because the symbolic pivoting strategy favors efficiency instead of numerical stability.

```
A := array(1..2, 1..2, [[1, 10^20], [1, 1]]):
B := array(1..2, 1..1, [[10^20], [0]]):
```

The float approximation of the exact solution is:

```
map(numeric::matlinsolve(A, B, Symbolic)[1], float)
```

$$\begin{pmatrix} -1.0 \\ 1.0 \end{pmatrix}$$

We now convert the exact input data to floating-point approximations:

```
A := map(A, float): B := map(B, float):
```

The default pivoting strategy of the floating-point algorithm stabilizes floating-point operations. Consequently, one gets a correct result:

```
numeric::matlinsolve(A, B)[1]
```

$$\begin{pmatrix} -1.0 \\ 1.0 \end{pmatrix}$$

With the option `Symbolic`, however, the pivoting strategy optimizes speed, assuming exact arithmetic. Numerical instabilities may occur if floating-point coefficients are involved. The following result is caused by internal round-off effects (“cancellation”):

```
numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} 0 \\ 1.0 \end{pmatrix}$$

We need to increase `DIGITS` to obtain a better result:

```
DIGITS := 20:
numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} -1.0000000149011611938 \\ 1.0 \end{pmatrix}$$

```
delete A, B, DIGITS:
```

## Example 7

We demonstrate how a complete solution of the following linear system with symbolic parameters may be found:

```
A := array(1..3, 1..2, [[1, 1], [a, b], [1, c]]):
B := array(1..3, 1..1, [[1], [1], [1]]):
```

# numeric::matlinsolve

---

```
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[ \left( \begin{array}{c} -\frac{b-1}{a-b} \\ \frac{a-1}{a-b} \end{array} \right), 0, [-(a-1)(c-1) = 0], [b-a \neq 0] \right]$$

This is the general solution assuming  $a \neq b$ . We now set  $b = a$  to investigate further solution branches:

```
A := subs(A, b = a):
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[ \left( \begin{array}{c} 1 \\ 0 \end{array} \right), 0, [1-a = 0], [c-1 \neq 0] \right]$$

This is the general solution for  $a = b$ , assuming  $c \neq 1$ . We finally set  $c = 1$  to obtain the last solution branch:

```
A := subs(A, c = 1):
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[ \left( \begin{array}{c} 1 \\ 0 \end{array} \right), \left( \begin{array}{c} -1 \\ 1 \end{array} \right), [1-a = 0], [] \right]$$

From the constraint on  $a$ , we conclude that there is a 1-dimensional solution space for the special values  $a = b = c = 1$  of the symbolic parameters.

```
delete A, B:
```

## Example 8

Matrices from a domain such as `Dom::Matrix(...)` are converted to arrays with numbers or expressions. Hence, `numeric::matlinsolve` finds no solution for the following system:

```
M := Dom::Matrix(Dom::IntegerMod(7)):
A := M([[1, 4], [6, 3], [3, 2]]):
B := M([[9], [5], [0]]):
numeric::matlinsolve(A, B)
```

[FAIL, NIL]

Use `linalg::matlinsolve` to solve the system over the coefficient field of the matrices. A solution does exist over the field `Dom::IntegerMod(7)`:

```
linalg::matlinsolve(A, B)
```

$$\begin{pmatrix} 1 \text{ mod } 7 \\ 2 \text{ mod } 7 \end{pmatrix}$$

```
delete M, A, B:
```

## Example 9

We demonstrate the difference between `Symbolic`, `HardwareFloats`, and `SoftwareFloats`. The following matrix  $A$  has a 1-dimensional kernel. Due to round-off, a further spurious kernel vector appears with `SoftwareFloats`. No kernel vector is detected with `HardwareFloats`:

```
A := matrix([[2*10^14 + 2, 2*10^(-9), 2*10^(-4)],
 [3*10^15 + 3, 3*10^(-8), 3*10^(-3)],
 [4*10^16 + 4, 4*10^(-7), 4*10^(-2)]
]):
```

# numeric::matlinsolve

---

```
b := matrix([2*10^(-9), 3*10^(-8), 4*10^(-7)]):
float(numeric::matlinsolve(A, b, Symbolic));
numeric::matlinsolve(A, b, SoftwareFloats);
numeric::matlinsolve(A, b, HardwareFloats)
```

$$\left[ \begin{pmatrix} 0 \\ 1.0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ -100000.0 \\ 1.0 \end{pmatrix} \right]$$

$$\left[ \begin{pmatrix} 1.0 \cdot 10^{-23} \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \cdot 10^{-23} & -1.0 \cdot 10^{-18} \\ 1.0 & 0 \\ 0 & 1.0 \end{pmatrix} \right]$$

$$\left[ \begin{pmatrix} 0 \\ 1.0 \\ 0 \end{pmatrix}, 0 \right]$$

```
delete A, b:
```

## Parameters

**A**

An  $m \ n$  matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix

**B**

An  $m \ p$  matrix of domain type DOM\_ARRAY, DOM\_HFARRAY, or of category Cat::Matrix. Column vectors B may also be represented by a 1-dimensional array(1..m, [B<sub>1</sub>, B<sub>2</sub>, ... ]), a 1-dimensional hfarray(1..m, [B<sub>1</sub>, B<sub>2</sub>, ... ]), or by a list [B<sub>1</sub>, B<sub>2</sub>, ...].

## Options

### Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately  $10^{308}$  and not smaller than approximately  $10^{-308}$ .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.

- The data contains symbolic objects.
- The data contains numbers larger than  $10^{308}$  or smaller than  $10^{-308}$  that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

---

**Note** For ill-conditioned matrices, the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 9” on page 18-199.

---

## Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used if the matrix  $A$  contains symbolic parameters that cannot be converted to floating-point numbers.

---

**Note** This option should not be used for matrices with floating-point entries! Numerical instabilities may occur in floating-point operations. Cf. “Example 6” on page 18-196.

---

## ShowAssumptions

Returns information on internal assumptions on symbolic parameters in  $A$  and  $B$ . With this option, either exact arithmetic or `SoftwareFloats` are used.

This option is only useful if the matrices contain symbolic parameters. Consequently, it should only be used in conjunction with the option `Symbolic`.

---

**Note** This option changes the format of the return value to  $[X, \text{KernelBasis}, \text{Constraints}, \text{Pivots}]$ .

---

$X$  and `KernelBasis` represent the general solution subject to `Constraints` and `Pivots`.

`Constraints` is a list of equations for symbolic parameters in  $B$  which are necessary and sufficient for  $AX = B$  to be solvable.

Such constraints arise if Gaussian elimination leads to equations of the form  $0 = c$ , where  $c$  is some expression involving symbolic parameters contained in  $B$ . All such equations are collected in `Constraints`; `numeric::matlinsolve` assumes that these equations are satisfied and returns a special solution  $X$ .

If no such constraints arise, the return value of `Constraints` is the empty list.

`Pivots` is a list of inequalities involving symbolic parameters in  $A$ . Internally, division by pivot elements occurs in the Gaussian elimination. The expressions collected in `Pivots` are the numerators of those pivot elements that involve symbolic parameters contained in  $A$ . If only numerical pivot elements are used, then the return value of `Pivots` is the empty list.

---

**Note** `Constraints` usually is a list of *non-linear* equations for the symbolic parameters. It is not investigated by `numeric::matlinsolve`, i.e., solutions may be returned, even if the `Constraints` cannot be satisfied. See “Example 3” on page 18-194.

---

---

**Note** This option changes the return strategy for “unsolvable” systems. Without the option `ShowAssumptions`, the result `[FAIL,NIL]` is returned, whenever Gaussian elimination produces an equation  $0 = c$  with non-zero  $c$ . With `ShowAssumptions`, such equations are returned via `Constraints`, provided  $c$  involves symbolic parameters. If  $c$  is a purely numerical value, then `[FAIL, NIL, [], []]` is returned.

---

See “Example 3” on page 18-194, “Example 4” on page 18-195, and “Example 7” on page 18-197.

## NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::matlinsolve` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; `numeric::matlinsolve` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

## ReturnType

Option, specified as `ReturnType = d`

Return the (special) solution and the kernel as matrices of domain type  $d$ . The following return types  $d$  are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

## Sparse

Use a sparse internal representation for matrices.

This option only has an effect when used in conjunction with `HardwareFloats`. With the `Sparse` option, the linear solver uses a sparse representation of the matrices to save memory and increase efficiency. However, if the coefficient matrix is not sparse, this option will cost some additional memory and runtime.

## Return Values

Without the option `ShowAssumptions`, a list `[X, KernelBasis]` is returned. The (special) solution `X` is an  $n \times p$  matrix. `KernelBasis` is an  $n \times d$  matrix ( $d$  is the dimension of the kernel of  $A$ ). Its columns span the kernel of  $A$ . If the kernel is trivial, `KernelBasis` is the integer 0.

`[FAIL, NIL]` is returned if the system is not solvable.

With `ShowAssumptions`, a list `[X, KernelBasis, Constraints, Pivots]` is returned. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in  $A$  and  $B$ . Internally these were assumed to hold true when solving the system. `[FAIL, NIL, [], []]` is returned if the system is not solvable.

## MuPAD Functions

`linalg::matlinsolve` | `linsolve` | `numeric::inverse` | `numeric::linsolve` | `solve`

# numeric::ncdata

---

**Purpose** Weights and abscissae of Newton-Cotes quadrature

**Syntax** `numeric::ncdata(n)`

**Description** `numeric::ncdata(n)` returns the weights and the abscissae of the Newton-Cotes quadrature rule with  $n$  equidistant nodes.

The Newton-Cotes quadrature rule  $\sum_{i=1}^n b_i f(c_i)$  produces the exact integral  $\int_0^1 f(x) dx$  for all polynomials  $f$  through degree  $n - 1$ . If  $n$  is odd, then the quadrature rule is exact through degree  $n$ .

The equidistant abscissae  $c = [c_1, \dots, c_n]$  are given by  $c_i = \frac{i-1}{n-1}$ .

**Environment Interactions** `numeric::ncdata` is not sensitive to the environment variable DIGITS. The function uses option `remember`.

## Examples **Example 1**

The following call produces exact data for the quadrature rule with four nodes:

```
numeric::ncdata(4)
```

```
[[[1/8, 3/8, 3/8, 1/8], [0, 1/3, 2/3, 1]]]
```

**Parameters** `n`

The number of nodes: a positive integer

**Return Values** List `[b, c]` is returned. The lists `b = [b1, ..., bn]` and `c = [c1, ..., cn]` are the rational weights and abscissae of the Newton-Cotes quadrature rule, respectively.

## Algorithms

The numerical integrator `numeric::quadrature` calls `numeric::ncdata` to provide the data for Newton-Cotes quadrature.

## MuPAD Functions

`numeric::gldata` | `numeric::gtdata` | `numeric::int` |  
`numeric::quadrature`

# numeric::odesolve

---

## Purpose

Numerical solution of an ordinary differential equation

## Syntax

```
numeric::odesolve(f, t0 .. t, Y0, <method>, <RelativeError =
rtol>, <AbsoluteError = atol>, <Stepsize = h>, <MaxStepsize =
hmax>, <Alldata = n>, <Symbolic>)
numeric::odesolve(t0 .. t, f, Y0, <method>, <RelativeError =
rtol>, <AbsoluteError = atol>, <Stepsize = h>, <MaxStepsize =
hmax>, <Alldata = n>, <Symbolic>)
```

## Description

`numeric::odesolve(f, t0..t, Y0)` returns a numerical approximation of the solution  $Y(t)$  of the first order differential equation (dynamical system)  $\frac{dY}{dt} = f(t, Y)$ ,  $Y(t_0) = Y_0$  with  $t, t_0 \in \mathbb{R}$  and  $Y(t), Y_0 \in \mathbb{C}^n$ .

`numeric::odesolve` is a general purpose solver able to deal with initial value problems of various kinds of ordinary differential equations.

Equations  $y^{(p)} = f(t, y, y', \dots, y^{(p-1)})$  of order  $p$  can be solved by `numeric::odesolve` after reformulation to dynamical system form. This can always be achieved by writing the equation as a first order system

$$\frac{d}{dt} \begin{pmatrix} Y_1 \\ \dots \\ Y_{p-1} \\ Y_p \end{pmatrix} = \begin{pmatrix} Y_2 \\ \dots \\ Y_p \\ f(t, Y_1, \dots, Y_p) \end{pmatrix}$$

for the vector  $Y = [Y_1, \dots, Y_p] = [y, y', \dots, y^{(p-1)}]$ . See “Example 4” on page 18-214.

The following single-step Runge-Kutta-type methods are implemented:

- EULER1 (order 1)
- RKF43 (order 3)
- xRKF43 (order 3)

- RKF34 (order 4)
- xRKF34 (order 4)
- RK4 (order 4)
- RKF54a (order 4)
- RKF54b (order 4)
- DOPRI54 (order 4)
- xDOPRI54 (order 4)
- CK54 (order 4)
- xRKF54a (order 4)
- xRKF54b (order 4)
- xCK54 (order 4)
- RKF45a (order 5)
- RKF45b (order 5)
- DOPRI45 (order 5)
- CK45 (order 5)
- xRKF45a (order 5)
- xRKF45b (order 5)
- xDOPRI45 (order 5)
- xCK45 (order 5)
- DOPRI65 (order 5)
- xDOPRI65 (order 5)
- DOPRI56 (order 6)
- xDOPRI56 (order 6)
- BUTCHER6 (order 6)
- RKF87 (order 7)

## numeric::odesolve

---

- xRKF87 (order 7)
- DOPRI87 (order 7)
- xDOPRI87 (order 7)
- RKF78 (order 8)
- xRKF78 (order 8)
- DOPRI78 (order 8)
- xDOPRI78 (order 8)
- GAUSS(s) (order 2s)
- GAUSS = s

For the Gauss methods, GAUSS(s) is equivalent to GAUSS = s. The positive integer s indicates the number of stages. The order of the s stage Gauss method is 2s.

The utility function `numeric::ode2vectorfield` may be used to produce the input parameters  $f$ ,  $t_0$ ,  $Y_0$  from a set of differential expressions representing the ODE. See “Example 1” on page 18-212.

The input data  $t_0$ ,  $t$  and  $Y_0$  must not contain symbolic objects which cannot be converted to floating point values via `float`. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted.

The vector field  $f$  defining the dynamical system  $Y' = f(t, Y)$  must be represented by a procedure with two input parameters: the scalar time  $t$  and the vector  $Y$ . `numeric::odesolve` internally calls this function with real floating-point values  $t$  and a list  $Y$  of floating-point values. It has to return the vector  $f(t, Y)$  either as a list or as a 1-dimensional array. The output of  $f$  may contain numerical expressions such as  $\pi$ ,  $e^2$  etc. However, all values must be convertible to real or complex floating point numbers by `float`.

Autonomous systems, where  $f(t, Y)$  does not depend on  $t$ , must also be represented by a procedure with 2 arguments  $t$  and  $Y$ .

Scalar functions  $Y$  also must be represented by a list or an array with one element. For instance, the input data for the scalar initial value problem  $y' = t \sin(y)$ ,  $y(0) = 1$  may be of the form

```
f := proc(t,Y) /* Y is a 1-dimensional vector */
local y; /* represented by a list with */
begin /* one element: Y = [y]. */
 y := Y[1];
 [t*sin(y)] /* the output is a list with 1
 element */
end_proc:
Y0 := [1]: /* the initial value */
```

The numerical precision is controlled by the global variable DIGITS: an adaptive control of the step size keeps local relative discretization errors below  $rtol=10^{-DIGITS}$ , unless a different tolerance is specified via the option `RelativeError = rtol`. For small values of the solution vector  $Y$ , the absolute discretization error can be bounded by the threshold `atol` specified via the option `AbsoluteError = atol`.

If `AbsoluteError` is not specified, only relative discretization errors are controlled and kept below `rtol`.

The error control may be switched off by specifying a fixed `Stepsize = h`.

---

**Note** Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

---

With `Y := t -> numeric::odesolve(f, t_0..t, Y_0)`, the numerical solution can be represented by a MuPAD function: the call `Y(t)` will start the numerical integration from  $t_0$  to  $t$ . A more

# numeric::odesolve

---

sophisticated form of this function may be generated via  $Y := \text{numeric::odesolve2}(f, t_0, Y_0)$ .

This equips  $Y$  with a remember mechanism that uses previously computed values to speed up the computation. See “Example 2” on page 18-213.

For systems of the special form  $Y' = f(t, Y)$   $Y$  with a matrix valued function  $f(t, Y)$ , there is a special solver `numeric::odesolveGeometric` which preserves geometric features of the system more faithfully than `numeric::odesolve`.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We compute the numerical solution  $y(10)$  of the initial value problem  $y' = t \sin(y)$ ,  $y(0) = 2$ :

```
f := proc(t, Y) begin [t*sin(Y[1])] end_proc:
numeric::odesolve(f, 0..10, [2])
```

```
[3.141592654]
```

Alternatively, the utility function `numeric::ode2vectorfield` can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] :=
[numeric::ode2vectorfield({y'(t) = t*sin(y(t)), y(0) = 2}, [y(t)]
```

```
[proc f(t, Y) ... end, 0, [2]]
```

```
numeric::odesolve(f, t0..10, Y0)
```

```
[3.141592654]
```

```
delete f, t0, Y0:
```

## Example 2

We consider  $y' = y$ ,  $y(0) = 1$ . The numerical solution may be represented by the function

```
Y := t -> numeric::odesolve((t,Y) -> Y, 0..t, [1]):
```

Calling  $Y(t)$  starts the numerical integration:

```
Y(-5), Y(0), Y(1), Y(PI)
```

```
[0.006737946999], [1.0], [2.718281828], [23.14069263]
```

```
delete Y:
```

## Example 3

We compute the numerical solution  $Y(\pi) = [x(\pi), y(\pi)]$  of the system

$$x' = x + y, y' = x - y, x(0) = 1, y(0) = \sqrt{-1}$$

```
f := (t, Y) -> [Y[1] + Y[2], Y[1] - Y[2]]: Y0 := [1, I]:
numeric::odesolve(f, 0..PI, Y0)
```

```
[72.57057163 + 30.05484302 i, 30.05484302 + 12.46088558 i]
```

# numeric::odesolve

---

The solution of a linear dynamical system  $Y' = A Y$  with a constant matrix  $A$  is  $Y(t) = e^{tA} Y_0$ . The solution of the system above can also be computed by:

```
t := PI: tA := array(1..2, 1..2, [[t, t], [t, -t]]):
numeric::expMatrix(tA, Y0)
```

```
(72.57057163 + 30.05484303 i)
(30.05484303 + 12.46088558 i)
```

```
delete f, Y0, t, tA:
```

## Example 4

We compute the numerical solution  $y(1)$  of the differential equation  $y'' = y^2$  with initial conditions  $y(0) = 0$ ,  $y'(0) = 1$ . The second order equation is converted to a first order system for the vector  $Y = [y, y'] = [y, z]$ :

$$y' = z, z' = y^2, y(0) = 0, z(0) = 1$$

```
f := proc(t, Y) begin [Y[2], Y[1]^2] end_proc:
Y0 := [0, 1]:
numeric::odesolve(f, 0..1, Y0)
```

```
[1.087473533, 1.362851121]
```

```
delete f, Y0:
```

## Example 5

We demonstrate how numerical data can be obtained on a user defined time mesh  $t[i]$ . The initial value problem is  $y' = \sin(t) - y$ ,  $y(0) = 1$ ,

the sample points are  $t_0 = 0.0$ ,  $t_1 = 0.1$ , ...,  $t_{100} = 10.0$ . First, we define the differential equation and the initial condition:

```
f := (t, Y) -> [sin(t) - Y[1]]:
Y[0] := [1]:
```

We define the time mesh:

```
for i from 0 to 100 do t[i] := i/10 end_for:
```

The equation is integrated iteratively from  $t[i-1]$  to  $t[i]$  with a working precision of 4 significant decimal places:

```
DIGITS := 4:
for i from 1 to 100 do
 Y[i] := numeric::odesolve(f, t[i-1]..t[i], Y[i-1])
end_for:
```

The following mesh data are produced:

```
[t[i], Y[i]] $ i = 0..100
```

```
[0, [1]], [1/10, [0.9097]], [1/5, [0.8374]], [3/10, [0.7813]], [2/5, [0.7397]], ..., [99/10, [0.2159]],
```

## numeric::odesolve

---

[0, [1]], [ $\frac{1}{10}$ , [0.9097]], [ $\frac{1}{5}$ , [0.8374]], [ $\frac{3}{10}$ , [0.7813]], [ $\frac{2}{5}$ , [0.7397]], [ $\frac{1}{2}$ , [0.7107]], [ $\frac{3}{5}$ , [0.6907]], [ $\frac{7}{10}$ , [0.6846]], [ $\frac{4}{5}$ , [0.6843]], [ $\frac{9}{10}$ , [0.6907]], [1, [0.7024]], [ $\frac{11}{10}$ , [0.7181]], [ $\frac{6}{5}$ , [0.7366]], [ $\frac{7}{5}$ , [0.7776]], [ $\frac{3}{2}$ , [0.7981]], [ $\frac{8}{5}$ , [0.8172]], [ $\frac{17}{10}$ , [0.8343]], [ $\frac{9}{5}$ , [0.8485]], [ $\frac{19}{10}$ , [0.8591]], [ $\frac{21}{10}$ , [0.8677]], [ $\frac{11}{5}$ , [0.8647]], [ $\frac{23}{10}$ , [0.8564]], [ $\frac{12}{5}$ , [0.8425]], [ $\frac{5}{2}$ , [0.8229]], [ $\frac{13}{5}$ , [0.7976]], [ $\frac{27}{10}$ , [0.7665]], [ $\frac{14}{5}$ , [0.7298]], [ $\frac{29}{10}$ , [0.6876]], [3, [0.6402]], [ $\frac{31}{10}$ , [0.5879]], [ $\frac{16}{5}$ , [0.5311]], [ $\frac{33}{10}$ , [0.4702]], [ $\frac{17}{5}$ , [0.4057]], [ $\frac{7}{2}$ , [0.3381]], [ $\frac{18}{5}$ , [0.2681]], [ $\frac{37}{10}$ , [0.1962]], [ $\frac{19}{5}$ , [0.1233]], [ $\frac{39}{10}$ , [0.04945]], [4, [-0.02411]], [ $\frac{41}{10}$ , [-0.09687]], [ $\frac{21}{5}$ , [-0.1682]], [ $\frac{43}{10}$ , [-0.2373]], [ $\frac{22}{5}$ , [-0.3067]], [ $\frac{9}{2}$ , [-0.3667]], [ $\frac{23}{5}$ , [-0.4257]], [ $\frac{47}{10}$ , [-0.4801]], [ $\frac{24}{5}$ , [-0.5295]], [ $\frac{49}{10}$ , [-0.5733]], [5, [-0.6161]], [ $\frac{51}{10}$ , [-0.6428]], [ $\frac{26}{5}$ , [-0.6677]], [ $\frac{53}{10}$ , [-0.6858]], [ $\frac{27}{5}$ , [-0.697]], [ $\frac{11}{2}$ , [-0.701]], [ $\frac{28}{5}$ , [-0.7107]], [ $\frac{57}{10}$ , [-0.6877]], [ $\frac{29}{5}$ , [-0.6705]], [ $\frac{59}{10}$ , [-0.6466]], [6, [-0.6161]], [ $\frac{61}{10}$ , [-0.5794]], [ $\frac{31}{5}$ , [-0.5311]], [ $\frac{63}{10}$ , [-0.4888]], [ $\frac{32}{5}$ , [-0.4358]], [ $\frac{13}{2}$ , [-0.3785]], [ $\frac{33}{5}$ , [-0.3173]], [ $\frac{67}{10}$ , [-0.2529]], [ $\frac{34}{5}$ , [-0.2048]], [ $\frac{69}{10}$ , [-0.1171]], [7, [-0.04709]], [ $\frac{71}{10}$ , [0.02345]], [ $\frac{36}{5}$ , [0.09378]], [ $\frac{73}{10}$ , [0.1632]], [ $\frac{37}{5}$ , [0.2167]], [ $\frac{15}{2}$ , [0.2965]], [ $\frac{38}{5}$ , [0.3591]], [ $\frac{77}{10}$ , [0.4181]], [ $\frac{39}{5}$ , [0.4729]], [ $\frac{79}{10}$ , [0.523]], [8, [0.5679]], [ $\frac{81}{10}$ , [0.6072]], [ $\frac{41}{5}$ , [0.6404]], [ $\frac{83}{10}$ , [0.6671]], [ $\frac{42}{5}$ , [0.6873]], [ $\frac{17}{2}$ , [0.7006]], [ $\frac{43}{5}$ , [0.7006]], [ $\frac{87}{10}$ , [0.7061]], [ $\frac{44}{5}$ , [0.6982]], [ $\frac{89}{10}$ , [0.6834]], [9, [0.6618]], [ $\frac{91}{10}$ , [0.6336]], [ $\frac{46}{5}$ , [0.599]], [ $\frac{93}{10}$ , [0.5585]], [ $\frac{47}{5}$ , [0.5124]], [ $\frac{19}{2}$ , [0.4611]], [ $\frac{48}{5}$ , [0.4053]], [ $\frac{97}{10}$ , [0.3454]], [ $\frac{49}{5}$ , [0.2811]], [ $\frac{99}{10}$ , [0.2159]], [10, [0.1476]]

These data can be displayed by a list plot:

```
plotpoints := [[t[i], op(Y[i])] $ i = 0..100]:
plot(plot::PointList2d(plotpoints, PointColor = RGB::Black)):
```

The same plot can be obtained directly via `plot::Ode2d`:

```
plot(plot::Ode2d(
 [t[i] $ i = 0..100], f, Y[0],
 [(t, Y) -> [t, Y[1]], Style = Points, Color = RGB::Black]))
```

```
delete f, t, DIGITS, Y, plotpoints:
```

## Example 6

We compute the numerical solution  $y(1)$  of  $y' = y$ ,  $y(0) = 1$  by the classical 4-th order Runge-Kutta method RK4. By internal local extrapolation, its effective order is 5:

```
f := (t, Y) -> Y:
DIGITS := 13:
numeric::odesolve(f, 0..1, [1], RK4)
```

```
[2.718281828459]
```

Next, we use local extrapolation xRK78 of the 8-th order submethod of the Runge-Kutta-Fehlberg pair RK78. This scheme has effective order 9:

```
numeric::odesolve(f, 0..1, [1], xRK78)
```

```
[2.718281828459]
```

Both methods yield the same result because of the internal adaptive error control. However, due to its higher order, the method xRK78 is faster.

```
delete f, DIGITS:
```

## Example 7

We consider the stiff ODE  $y' = 10^4(\cos(t) - y)$ ,  $y(0) = 1$ . The default method DOPRI78 is explicit and not very efficient in solving very stiff problems:

```
f := (t, Y) -> [10^4*(cos(t) - Y[1])]:
t0 := time():
numeric::odesolve(f, 0..1, [1]), (time() - t0)*msec
```

```
[0.5403864476], 16065.004 msec
```

We use the implicit A-stable method GAUSS(6). For this stiff problem, it is more efficient than the default method DOPRI78:

```
t0 := time():
numeric::odesolve(f, 0..1, [1], GAUSS(6)), (time() - t0)*msec
```

```
[0.5403864476], 796.05 msec
```

```
delete t0:
```

## Example 8

We consider the initial value problem  $y' = -10^{20} y (1 - \cos(y))$ ,  $y(0) = 1$ . We note that the numerical evaluation of the right hand side of the equation suffers from cancellation effects, when  $|y|$  is small.

```
f := (t, Y) -> [-10^20*Y[1]*(1 - cos(Y[1]))]:
Y0 := [1]:
```

We first attempt to compute  $y(1)$  with a working precision of 6 digits using the default setting `RelativeError = 10^-DIGITS=10^-6`:

```
DIGITS := 6: numeric::odesolve(f, 0..1, Y0)
```

```
[0.000000000329271]
```

Due to numerical round-off in the internal steps, no digit of this result is correct. Next, we use a working precision of 20 significant decimal places to eliminate roundoff effects:

```
DIGITS := 20:
numeric::odesolve(f, 0..1, Y0, RelativeError = 10^-6)
```

```
[0.00000000010000000007495004558]
```

Since relative local discretization errors are of the magnitude  $10^{-6}$ , not all displayed digits are trustworthy. We finally use a working precision of 20 digits and constrain the local relative discretization errors by the tolerance  $10^{-10}$ :

```
numeric::odesolve(f, 0..1, Y0, RelativeError = 10^-10)
```

```
[0.0000000001000000000003105061]
```

```
delete f, Y0, DIGITS:
```

## Example 9

We compute the numerical solution  $y(1)$  of  $y' = y$ ,  $y(0) = 1$  with various methods and various constant step sizes. We compare the result with the exact solution  $y(1) = e = 2.718281828\dots$

```
f := (t, Y) -> Y:
Y0 := [1]:
```

We first use the Euler method of order 1 with two different step sizes:

```
Y := numeric::odesolve(f, 0..1, Y0, EULER1, Stepsize = 0.1):
Y, globalerror = float(exp(1)) - Y[1]
```

```
[2.59374246], globalerror = 0.1245393684
```

Decreasing the step size by a factor of 10 should reduce the global error by a factor of 10. Indeed:

```
Y := numeric::odesolve(f, 0..1, Y0, EULER1, Stepsize = 0.01):
Y, globalerror = float(exp(1)) - Y[1]
```

```
[2.704813829], globalerror = 0.01346799904
```

Next, we use the classical Runge-Kutta method of order 4 with two different step sizes:

```
Y := numeric::odesolve(f, 0..1, Y0, RK4, Stepsize = 0.1):
Y, globalerror = float(exp(1)) - Y[1]
```

```
[2.718279744], globalerror = 0.00000208432388
```

# numeric::odesolve

---

Decreasing the step size by a factor of 10 in a 4-th order scheme should reduce the global error by a factor of  $10^4$ . Indeed:

```
Y := numeric::odesolve(f, 0..1, Y0, RK4, Stepsize = 0.01):
Y, globalerror = float(exp(1)) - Y[1]
```

```
[2.718281828], globalerror = 0.0000000002246438591
```

```
delete f, Y0, Y:
```

## Example 10

We integrate  $y' = y^2$ ,  $y(0) = 1$  over the interval  $t \in [0, 0.99]$  with a working precision of 4 digits. The exact solution is  $y(t) = \frac{1}{1-t}$ . Note the singularity at  $t = 1$ .

```
DIGITS := 4:
f := (t, Y) -> [Y[1]^2]:
Y0 := [1]:
```

The option `Alldata`, equivalent to `Alldata = 1`, yields all mesh data generated during the internal adaptive process:

```
numeric::odesolve(f, 0..0.99, Y0, Alldata)
```

```
[[0.0, [1.0]], [0.4933, [1.974]], [0.74, [3.846]], [0.8633, [7.314]], [0.9249, [13.32]], [0.9558, [20.00]],
[0.9712, [34.71]], [0.9866, [74.68]], [0.99, [99.97]]]
```

With `Alldata = 2`, only each second point is returned:

```
numeric::odesolve(f, 0..0.99, Y0, Alldata = 2)
```

```
[[0.0, [1.0]], [0.74, [3.846]], [0.9249, [13.32]], [0.9712, [34.71]], [0.99, [99.97]]]
```

One can control the time mesh using the option `Stepsize = h`:

```
numeric::odesolve(f, 0..0.99, Y0, Stepsize=0.1, Alldata = 1)
```

```
[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]]
 [0.8, [5.0]], [0.9, [10.0]], [0.99, [94.3]]]
```

However, with the option `Stepsize = h`, no automatic error control is provided by `numeric::odesolve`. Note the poor approximation  $y(t) = 94.3$  for  $t = 0.99$  (the exact value is  $y(0.99) = 100.0$ ). The next computation with smaller step size yields better results:

```
numeric::odesolve(f, 0..0.99, Y0, Stepsize = 0.01, Alldata = 10)
```

```
[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]]
 [0.8, [5.0]], [0.9, [10.0]], [0.99, [100.0]]]
```

“Example 5” on page 18-214 demonstrates how accurate numerical data on a user defined time mesh can be generated using the automatic error control of `numeric::odesolve`.

```
delete DIGITS, f, Y0:
```

## Example 11

The second order equation  $y'' + \sin(y) = 0$  is written as the dynamical system  $y' = z, z' = -\sin(y)$  for the vector  $Y = [y, z]$ . A single symbolic step

$$[y(t_0), z(t_0)] \rightarrow [y(t_0 + h), z(t_0 + h)]$$

of the Euler method is computed:

# numeric::odesolve

---

```
f := proc(t, Y) begin [Y[2], -sin(Y[1])] end_proc:
numeric::odesolve(f, t0..t0+h, [y0, z0], EULER1, Symbolic)
```

```
[y0 + h z0, z0 - h sin(y0)]
```

```
delete f:
```

## Parameters

**f**

A procedure representing the vector field

**t<sub>0</sub>**

A numerical real value for the initial time

**t**

A numerical real value (the “time”)

**Y<sub>0</sub>**

A list or 1-dimensional array of numerical values representing the initial condition

**method**

One of the Runge-Kutta schemes listed below.

## Options

**BUTCHER6, CK45, CK54, DOPRI45, DOPRI54, DOPRI56, DOPRI65, DOPRI78, DOPRI87, EULER1, RK4, RKF34, RKF43, RKF45a, RKF45b, RKF54a, RKF54b, RKF78, RKF87, xCK45, xCK54, xDOPRI45, xDOPRI54, xDOPRI56, xDOPRI65, xDOPRI78, xDOPRI87, xRKF34, xRKF43, xRKF45a, xRKF45b, xRKF54a, xRKF54b, xRKF78, xRKF87**

Name of the Runge-Kutta scheme. See “Example 6” on page 18-218. For details on these schemes, see the Algorithms section.

**GAUSS**

Name of the Runge-Kutta scheme specified as GAUSS (s) or GAUSS = s.

The methods `GAUSS(s)` or, equivalently, `GAUSS = s` are the implicit Gauss methods with `s` stages of order  $2s$ .

These methods are implicit A-stable schemes. The time steps are rather costly to compute. The Gauss methods are useful for integrating stiff ODEs. For non-stiff ODEs, there is usually no need to change the default method `DOPRI78`. This method is an embedded Runge-Kutta pair of orders 7 and 8.

Further, the Gauss methods are symplectic methods. When used with constant step size (`Stepsize = h`), numerical integration of Hamiltonian systems benefits from this property.

See “Example 7” on page 18-219.

## RelativeError, AbsoluteError

Option specified as `RelativeError = rtol` forces internal numerical Runge-Kutta steps to use step sizes with relative local discretization errors below `rtol`. This tolerance must be a positive

numerical real value not smaller than  $\frac{1}{10^{DIGITS}}$ . The default tolerance is `RelativeError = 10^(-DIGITS)`.

Option specified as `AbsoluteError = atol` forces internal numerical Runge-Kutta steps to use step sizes with absolute local discretization errors below `atol`. This tolerance must be a nonnegative numerical real value. The default tolerance is `AbsoluteError = 10^(-10*DIGITS)`.

The internal control mechanism estimates the local discretization error of a Runge-Kutta step and adjusts the step size adaptively to keep this error below the specified tolerances `rtol` or `atol`, respectively. The code uses the criterion

$$\|\text{discretization error}\|_{\infty} = \max(\|Y\|_{\infty} \text{rtol}, \text{atol})$$

For accepting a solution vector `Y`. Roughly speaking, the relative error is controlled when the solution `Y` is sufficiently large. For

# numeric::odesolve

---

very small solution values  $Y$ , absolute discretization errors are kept below the threshold `atol`.

Specify `AbsoluteError = 0` if only control of the relative discretization errors is desired.

The error control may be switched off by specifying a fixed `Stepsize = h`.

The default setting of  $rtol = \frac{1}{10^{DIGITS}}$ ,  $atol = \frac{1}{10^{10 \cdot DIGITS}}$  ensures that the local discretization errors are of the same order of magnitude as numerical roundoff.

Usually there is no need to use these options to change this setting. However, occasionally the numerical evaluation of the Runge-Kutta steps may be ill-conditioned or step sizes are so small that the time parameter cannot be incremented by the step size within working precision. In such a case these options may be used to bound the local discretization errors and use a higher working precision given by `DIGITS`.

Only positive real numerical values  $rtol \geq \frac{1}{10^{DIGITS}}$  are accepted.

---

**Note** The global error of the result returned by `numeric::odesolve` is usually larger than the local errors bounded by `rtol`, `atol`, respectively. Although the result is displayed with `DIGITS` decimal places one should not expect that all of them are correct. The relative precision of the final result is `rtol` at best!

---

See “Example 8” on page 18-220.

## Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size  $h$  which must be a positive numerical value.

By default, `numeric::odesolve` uses an adaptive step size control mechanism in the numerical iteration. The option `Stepsize = h` switches off this adaptive mechanism and uses the Runge-Kutta method specified (or the default method `DOPRI78`) with constant step size  $h$ .

A final step with smaller step size is used to match the end  $t$  of the integration interval  $t_0..t$  if  $\frac{t-t_0}{h}$  is not an integer.

---

**Note** With this option, there is no automatic error control! Depending on the problem and on the order of the method the result may be a poor numerical approximation of the exact solution.

---

There is usually no need to invoke this option. However, occasionally the built-in adaptive error control mechanism may fail when integrating close to a singularity. In such a case this option may be used to customize a control mechanism for the global error by using different step sizes and investigating the convergence of the corresponding results.

Cf. “Example 9” on page 18-221.

## **MaxStepsize**

Option, specified as `MaxStepsize = hmax`

Restricts adaptive step sizes to values not larger than  $h_{\max}$ ;  $h_{\max}$  must be a positive numerical value.

By default, `numeric::odesolve` uses an adaptive step size control mechanism in the numerical iteration. The option `MaxStepsize = hmax` restricts the adaptive step size to values no larger than  $h_{\max}$ .

# numeric::odesolve

---

If a larger stepsize  $h$  is requested explicitly by `Stepsize = h`, the option `MaxStepsize = hmax` reduces  $h$  to  $h_{\max}$ .

## Alldata

Option, specified as `Alldata = n`

Makes `numeric::odesolve` return a list of numerical mesh points generated by the internal Runge-Kutta iteration. The integer  $n$  controls the size of the output list.

With this option, `numeric::odesolve` returns a list of numerical mesh points  $[[t_0, Y_0], [t_1, Y_1], \dots, [t, Y(t)]]$  generated by the internal Runge-Kutta iteration.

The integer  $n$  controls the size of the output list. For  $n = 1$ , all internal mesh points are returned. This case may also be invoked by entering the simplified option `Alldata`, which is equivalent to `Alldata = 1`. For  $n > 1$ , only each  $n$ -th mesh point is stored in the list. The list always contains the initial point  $[t_0, Y_0]$  and the final point  $[t, Y(t)]$ . For  $n \leq 0$ , only the data  $[[t_0, Y_0], [t, Y(t)]]$  are returned.

The output list may be useful to inspect the internal numerical process. Also further graphical processing of the mesh data may be useful.

Cf. "Example 10" on page 18-222.

## Symbolic

Makes `numeric::odesolve` return a vector of symbolic expressions representing a single symbolic step of the Runge-Kutta iteration.

The call `numeric::odesolve(f, t_0..t, Y_0, < method >, Symbolic)` returns a vector (list or array) of expressions representing a single step of the numerical scheme with step size  $t - t_0$ . In this mode symbolic values for  $t_0$ ,  $t$  and the components of  $Y_0$  are accepted.

This option may be useful if the specified numerical method applied to a given differential equation is to be investigated symbolically.

Cf. “Example 11” on page 18-223.

## Return Values

The solution vector  $Y(t)$  is returned as a list or as a 1-dimensional array of floating-point values. The type of the result vector coincides with the type of the input vector  $Y_0$ .

With the option `Alldata`, a list of mesh data is returned.

## Algorithms

All methods presently implemented are adaptive versions of Runge-Kutta type single step schemes.

The methods `RKF43`, `RKF34`, `RKF54a`, `RKF54b`, `RKF45a`, `RKF45b`, `RKF87`, `RKF78`, `DOPRI54`, `DOPRI45`, `DOPRI65`, `DOPRI56`, `DOPRI87`, `DOPRI78`, `CK54`, `CK45` are embedded pairs of Runge-Kutta-Fehlberg, Dormand-Prince and Cash-Karp type, respectively. Estimates of the local discretization error are obtained in the usual way by comparing the results of the two submethods of the pair. The names indicate the orders of the subprocesses. For instance, `RKF34` and `RKF43` denote the same embedded Runge-Kutta-Fehlberg pair with orders 3 and 4. In `RKF34` the result of the fourth order submethod is accepted, whereas `RKF43` advances using the result of the third order submethod. In both cases the discretization error of the lower order subprocess is estimated and controlled.

For the single methods `EULER1` (the first order Euler scheme), `RK4` (the classical fourth order Runge-Kutta scheme) and `BUTCHER6` (a Runge-Kutta scheme of order 6), the relative local error is controlled by comparing steps with different step sizes. The effective order of these methods is increased by one through local extrapolation.

Local extrapolation is also available for the submethods of the embedded pairs. For instance, the method `xRKF78` uses extrapolation of the 8-th order subprocess of `RKF78`, yielding a method of effective order 9. The 7-th order subprocess is ignored. The cheap error estimate based on the embedded pair is not used implying some loss of efficiency when comparing `RKF78` (order 8) and `xRKF78` (effective order 9).

The call `numeric::butcher(method)` returns the Butcher data of the methods used in `numeric::odesolve`. Here `method` is one of EULER1, RKF43, RK4, RKF34, RKF54a, RKF54b, DOPRI54, CK54, RKF45a, RKF45b, DOPRI45, CK45, DOPRI65, DOPRI56, BUTCHER6, RKF87, DOPRI87, RKF78, DOPRI78.

---

**Note** Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

---

---

**Note** The run time of the numerical integration with a method of order  $p$  grows like  $O\left(10^{\frac{\text{DIGITS}}{p+1}}\right)$ , when DIGITS is increased. Computations with high precision goals are very expensive! High order methods such as the default method DOPRI78 should be used.

---

Presently, only single step methods of Runge-Kutta type are implemented. Stiff problems cannot be handled efficiently with explicit methods such as the default method DOPRI78. For stiff problems, one may use one of the implicit A-stable methods GAUSS(s). See “Example 7” on page 18-219.

For problems of the special type  $Y' = f(t, Y) Y$  with a matrix valued function  $f(t, Y)$ , there is a specialized (“geometric”) integration routine `numeric::odesolveGeometric`. Generally, `numeric::odesolve` is faster than the geometric integrator. However, `odesolveGeometric` preserves certain invariants of the system more faithfully.

### Concepts

- “Solve Equations Numerically”

# numeric::odesolve2

---

**Purpose** Numerical solution of an ordinary differential equation

**Syntax** `numeric::odesolve2(f, t0, Y0, <method>, <RememberLast>, <RelativeError = rtol>, <AbsoluteError = atol>, <Stepsize = h>, <MaxStepsize = hmax>)`

**Description** `numeric::odesolve2( f, t0, Y0, )` returns a function representing the numerical solution  $Y(t)$  of the first order differential equation (dynamical system)  $\frac{dY}{dt} = f(t, Y)$ ,  $Y(t_0) = Y_0$  with  $t, t_0 \in \mathbb{R}$  and  $Y(t), Y_0 \in \mathbb{C}^n$ .

The utility function `numeric::ode2vectorfield` may be used to produce the input parameters `f`, `t0`, `Y0` from a set of differential expressions representing the ODE. Cf. “Example 1” on page 18-233.

The function generated by `Y := numeric::odesolve2(f, t0, Y0)` is essentially

`Y := t -> numeric::odesolve(t_0..t, f, Y_0).`

Numerical integration is launched, when `Y` is called with a real numerical argument. The call `Y(t)` returns the solution vector in a format corresponding to the type of the initial condition  $Y_0$  with which `Y` was defined: `Y(t)` either yields a list or a 1-dimensional array.

If `t` is not a real numerical value, then `Y(t)` returns a symbolic function call.

See the help page of `numeric::odesolve` for details on the parameters and the options.

The options `Alldata = n` and `Symbolic` accepted by `numeric::odesolve` have no effect: `numeric::odesolve2` ignores these options.

---

**Note** Without `RememberLast`, the function `Y` remembers all values it has computed. When calling `Y(t)`, it searches its remember table for the time  $T$  closest to  $t$  and integrates from  $T$  to  $t$  using the previously computed  $Y(T)$  as initial value. This reduces the costs of a call considerably, if `Y` has to be evaluated many times (e.g., when plotting). However, the result  $Y(t)$  depends on the history of the MuPAD session! This can lead to unexpected side effects. See “Example 3” on page 18-236. We recommend to call `Y` only with a monotonically increasing (or decreasing) sequence of values  $t$  starting from  $t_0$ . Further, the function must be re-initialized whenever `DIGITS` is increased. See “Example 4” on page 18-238.

---

## Environment Interactions

The function returned by `numeric::odesolve2` is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Without `RememberLast`, the function returned by `numeric::odesolve2` uses option `remember`.

## Examples

### Example 1

The numerical solution of the initial value problem  $y' = t \sin(y)$ ,  $y(0) = 2$  is represented by the following function  $Y = [y]$ :

```
f := (t, Y) -> [t*sin(Y[1])]:
```

Alternatively, the utility function `numeric::ode2vectorfield` can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] :=
 [numeric::ode2vectorfield({y'(t) = t*sin(y(t)), y(0) = 2}, [y(
 [proc f(t, Y) ... end, 0, [2]]
```

## numeric::odesolve2

---

```
Y := numeric::odesolve2(f, t0, Y0)
```

```
proc Y(t) ... end
```

The procedure Y starts the numerical integration when called with a numerical argument:

```
Y(-2), Y(0), Y(0.1), Y(PI + sqrt(2))
```

```
[2.968232567], [2.0], [2.004541745], [3.141552691]
```

Calling Y with a symbolic argument yields a symbolic call:

```
Y(t), Y(t + 5), Y(t^2 - 4)
```

```
Y(t), Y(t + 5), Y(t2 - 4)
```

```
eval(subs(%, t = PI))
```

```
[3.13235701], [3.141592654], [3.141592611]
```

The numerical solution can be plotted. Note that Y(t) returns a list, so we plot the list element Y(t)[1]:

```
plotfunc2d(Y(t)[1], t = -5..5):
```

delete f, t0, Y0, Y:

### Example 2

We consider the differential equation  $y'' = y^2$  with initial conditions  $y(0) = 0, y'(0) = 1$ . The second order equation is converted to a first order system for  $Y = [Y_1, Y_2] = [y, y']$ :

$$Y_1' = Y_2, Y_2' = Y_1^2, Y_1(0) = 0, Y_2(0) = 1$$

```
f := (t, Y) -> [Y[2], Y[1]^2]:
t0 := 0: Y0 := [0, 1]:
Y := numeric::odesolve2(f, t0, Y0):
Y(1), Y(PI)
```

## numeric::odesolve2

---

```
[1.087473533, 1.362851121], [1274.867469, 37166.52262]
```

```
delete f, t0, Y0, Y:
```

### Example 3

We demonstrate a pitfall with the remember mechanism built into the functions returned by `numeric::odesolve2`. Consider the initial value problem  $y' = t \sin(y)$ ,  $y(0) = 2$ :

```
DIGITS := 5:
Y := numeric::odesolve2((t, Y) -> [t*sin(Y[1])], 0, [2]):
```

The following result is computed and stored in the remember table of `Y`:

```
Y(8.0)
```

```
[3.1416]
```

The following value `Y(4.1)` is obtained using the previously computed `Y(8.0)`, integrating backward in time from  $t = 8.0$  to  $t = 4.1$ :

```
Y(4.1)
```

```
[0.0001802]
```

```
Y := subsop(Y, 5 = NIL):
```

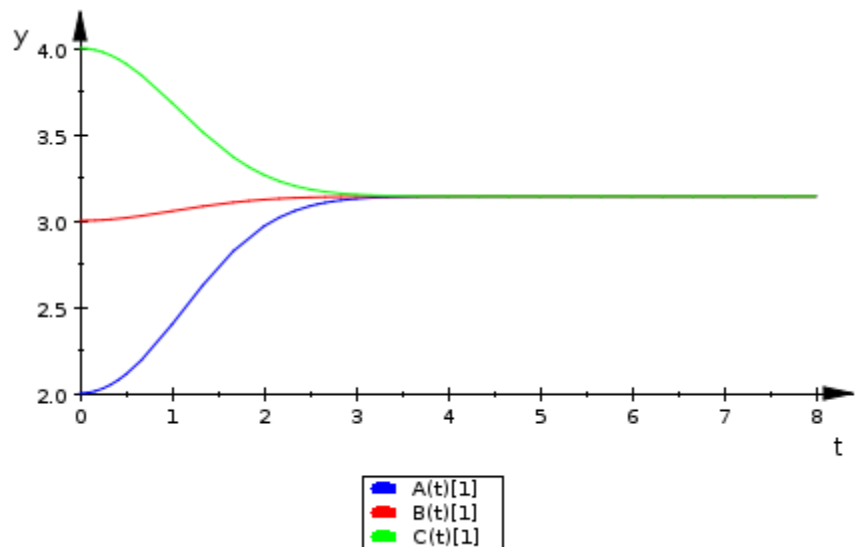

The direct integration from the initial time  $t_0 = 0$  to  $t = 4.1$  yields a more accurate result than the previous computation:

```
Y(4.1)
```

[3.1413]

The reason for this phenomenon becomes obvious, when the solution of the ode is computed for various initial values  $Y(0) = 2, 3, 4$ :

```
A := numeric::odesolve2((t, Y) -> [t*sin(Y[1])], 0, [2]):
B := numeric::odesolve2((t, Y) -> [t*sin(Y[1])], 0, [3]):
C := numeric::odesolve2((t, Y) -> [t*sin(Y[1])], 0, [4]):
plotfunc2d(A(t)[1], B(t)[1], C(t)[1], t = 0..8, Mesh = 25):
```

In fact, all solutions with initial values  $Y(0)$  in the interval  $[0, 2\pi]$  approach the same attracting point  $Y(\infty) = \pi$ . While numerical integration forward in time is a very stable process, it is virtually impossible to recover the correct solution curve integrating backward in time starting at a point close to the attractor.

```
delete DIGITS, Y, A, B, C:
```

# numeric::odesolve2

---

## Example 4

We consider the system

$$x' = x + y, y' = x - y, x(0) = 1, y(0) = \sqrt{-1}$$

```
f := (t, Y) -> [Y[1] + Y[2], Y[1] - Y[2]]:
Y := numeric::odesolve2(f, 0, [1, I]):
DIGITS := 5:
Y(1)
```

```
[3.5465 + 1.3683 i, 1.3683 + 0.80988 i]
```

Increasing DIGITS does not lead to a more accurate result because of the remember mechanism:

```
DIGITS := 15: Y(1)
```

```
[3.54648112716477 + 1.36829878277279 i, 1.36829878277279 + 0.809883561619181 i]
```

This is the previous value computed with 5 digits, printed with 15 digits. Indeed, only 5 digits are correct. For getting a result that is accurate to full precision, one has to erase the remember table via `Y:=subsop(Y,5=NIL)`. Alternatively, one may create a new numerical solution with a fresh (empty) remember table:

```
Y := numeric::odesolve2(f, 0, [1, I]):
Y(1)
```

```
[3.54648242861716 + 1.36829887200859 i, 1.36829887200859 + 0.80988468459998 i]
```

```
delete f, Y, DIGITS:
```

## Example 5

We demonstrate the effect of the option `RememberLast`. We consider the ODE

$$y'(t) = -y + \sin(t), \quad y(0) = 1$$

```
f := (t, Y) -> [-Y[1] + sin(t)]:
Y := numeric::odesolve2(f, 0, [1]):
Z := numeric::odesolve2(f, 0, [1], RememberLast):
```

After many calls of `Y`, its remember table has grown large. In each call, searching the remember table for input parameters close to the present time value becomes expensive. Created with `RememberLast`, the procedure `Z` does not remember all its previously computed values apart from the last one. Consequently, it becomes faster than `Y`:

```
time(for i from 1 to 1000 do Y(i/100) end)*msec,
time(for i from 1 to 1000 do Z(i/100) end)*msec
```

11592.724 msec, 4352.272 msec

Apart from the efficiency, the values returned by `Y` and `Z` coincide:

```
Y(10.5), Z(10.5)
```

[- 0.2020381113], [- 0.2020381113]

```
delete f, Y, Z, i:
```

## Parameters **f**

A procedure representing the vector field of the dynamical system

# numeric::odesolve2

---

**t<sub>0</sub>**

A numerical real value for the initial time

**Y<sub>0</sub>**

A list or 1-dimensional array of numerical values representing the initial value

**method**

One of the Runge-Kutta schemes listed below.

## Options

**BUTCHER6, CK45, CK54, DOPRI45, DOPRI54, DOPRI56, DOPRI65, DOPRI78, DOPRI87, EULER1, GAUSS, RK4, RKF34, RKF43, RKF45a, RKF45b, RKF54a, RKF54b, RKF78, RKF87, xCK45, xCK54, xDOPRI45, xDOPRI54, xDOPRI56, xDOPRI65, xDOPRI78, xDOPRI87, xRKF34, xRKF43, xRKF45a, xRKF45b, xRKF54a, xRKF54b, xRKF78, xRKF87**

Option, specified as GAUSS = s

Name of the Runge-Kutta scheme. For details, see the documentation of `numeric::odesolve`.

**RememberLast**

Modifies the internal remember mechanism: the procedure returned by `numeric::odesolve2` does not remember the results of all previous calls, but only the result of the last call.

Without this option, the procedure returned by `numeric::odesolve2` employs option `remember` to remember the results of all preceding calls. If the function is called very often (hundreds or thousands of times), the `remember` table grows large and searching this table for entries close to the current time value may become costly. With `RememberLast`, the procedure returned by `numeric::odesolve2` does not use option `remember` to remember *all* previous results but implements a very simple and inexpensive mechanism to remember only the result of the very last call.

This option is highly recommended when the numerical procedure returned by `numeric::odesolve2` is to be called often (hundreds of thousands of times) with monotonically increasing or decreasing time values. Cf. “Example 5” on page 18-239.

## RelativeError

Option, specified as `RelativeError = rtol`

Forces internal numerical Runge-Kutta steps to use step sizes with relative local discretization errors below `rtol`. This tolerance

must be a positive numerical real value not smaller than  $\frac{1}{10^{\text{DIGITS}}}$ . The default tolerance is `RelativeError = 10^(-DIGITS)`. See the help page of `numeric::odesolve` for further details.

## AbsoluteError

Option, specified as `AbsoluteError = atol`

Forces internal numerical Runge-Kutta steps to use step sizes with absolute local discretization errors below `atol`. This tolerance must be a non-negative numerical real value. The default tolerance is `AbsoluteError = 10^(-10*DIGITS)`. See the help page of `numeric::odesolve` for further details.

## Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h`. `h` must be a positive real value. See the help page of `numeric::odesolve` for further details.

## MaxStepsize

Option, specified as `MaxStepsize = hmax`

Restricts adaptive step sizes to values not larger than  $h_{\max}$ ;  $h_{\max}$  must be a positive numerical value. See the help page of `numeric::odesolve` for further details.

# numeric::odesolve2

## Concepts

- “Solve Equations Numerically”

## Purpose

Numerical solution of an ordinary differential equation on a homogeneous manifold

## Syntax

```
numeric::odesolveGeometric(f, t_0 .. t, Y_0, <LieGroupAction =
LAMBDA>, <method>, <RelativeError = tol>, <Stepsize
= h>, <Alldata = n>)
numeric::odesolveGeometric(t_0 .. t, f, Y_0, <LieGroupAction =
LAMBDA>, <method>, <RelativeError = tol>, <Stepsize
= h>, <Alldata = n>)
```

## Description

`numeric::odesolveGeometric(f, t_0..t, Y_0 )` approximates

the solution of  $\frac{dY(t)}{dt} = f(t, Y(t)) Y(t)$ , where  $f(t, Y(t))$  returns  $n \times n$  matrices and  $Y \in \mathbb{C}^{n \times m}$ .

`numeric::odesolveGeometric` is a “geometrical integrator” for ordinary differential equations on homogeneous manifolds embedded in the space of  $n \times m$  matrices.

The call `numeric::odesolveGeometric(f, t_0..t, Y_0 )` returns a numerical approximation of the solution  $Y(t)$  of the first order differential equation (dynamical system)

$$\frac{dY(t)}{dt} = f(t, Y(t)) Y(t), Y(t_0) = Y_0$$

with  $t, t_0 \in \mathbb{R}$ . Here,  $Y(t)$  is a curve of  $n \times m$  matrices ( or vectors in  $\mathbb{R}^n$  or  $\mathbb{C}^n$ ). The function  $f$  must produce  $n \times n$  matrices as return values.

The following geometrical feature is preserved by the numerical solution: If the matrices produced by  $f$  lie in some Lie subalgebra  $g$  of the  $n \times n$  matrices, then, within the numerical working precision, the approximation produced by `numeric::odesolveGeometric` stays on the homogeneous manifold  $\{m Y_0 \mid m \in G\}$ , where  $G$  is the matrix Lie group of  $g$ .

# numeric::odesolveGeometric

As an introductory example, consider the ODE  $\frac{dY}{dt} = f(t, Y) Y$ , where  $Y$  is a vector in  $\mathbb{R}^n$  and  $f$  produces skew symmetric matrices. The solution lies on the orbit of the orthogonal group  $SO(n)$  generated by the skew symmetric matrices through the initial point  $Y_0 \in \mathbb{R}^n$ . Here,  $SO(n)$  acts on  $\mathbb{R}^n$  by standard matrix multiplication. The homogeneous manifold given by the orbit of  $SO(n)$  through  $Y_0$  is the sphere

$$\{G Y_0 \mid G \in SO(n)\} = \{Y \in \mathbb{R}^n \mid \langle Y, Y \rangle = \langle Y_0, Y_0 \rangle\}$$

Using standard numerical schemes, the numerical solution drifts away from this manifold in the course of the integration. The geometrical “Lie group” integrator `numeric::odesolveGeometric`, however, produces a numerical solution that stays on this manifold, preserving the invariants of the group action. In this case, the invariant  $\langle Y, Y \rangle$  is preserved numerically. See “Example 1” on page 18-247.

With  $Y(t) = G(t)Y_0$ , the matrix ODE

$$\frac{dG(t)}{dt} = f(t, G(t) Y_0) G(t), \quad G(t_0) = 1_{n,n}$$

is solved on the space  $\mathbb{C}^{n \times n}$  of the complex  $n \times n$  matrices ( $1_{n,n}$  is the identity matrix). Following Munthe-Kaas [1], the ansatz  $G(t) = e^{u(t)}$  reduces a time step for the ode above to the solution of the matrix ODE

$$\frac{du}{dt} = \text{dexpinv}(u, f) = f - \frac{[u, f]}{2} + \frac{[u, [u, f]]}{12} + \dots, \quad u(t_0) = 0$$

where  $f = f(t, e^{u(t)} Y_0)$  and  $[u, f] = uf - fu$  is the commutator on the Lie algebra of  $n \times n$  matrices. In each step, the

ODE for  $u$  is solved numerically in a classical way by the Runge-Kutta scheme specified by the parameter `method`. Finally, `numeric::odesolveGeometric` performs the time step  $t_0 \rightarrow t_0 + h$  by computing  $Y(t_0 + h) = G(t_0 + h) Y_0 = e^{u(h)} Y_0$ .

If the matrices produced by  $f(t, Y)$  lie in a Lie subalgebra  $g$  of the  $n$   $n$  matrices, then the numerical solution  $u$  also lies in  $g$ . The matrix  $G = e^u$  is an element of the corresponding Lie group, and  $Y = GY_0$  lies on the orbit of the Lie group through the initial value  $Y_0$ . Thus, the geometrical invariants of the homogeneous manifold are preserved in the course of the numerical integration.

The input data  $t_0$  and  $t$  must not contain symbolic objects which cannot be converted to floating point values via `float`. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted.

The initial condition  $Y_0$  defines the space in which the homogeneous manifold containing the solution is embedded.

If  $Y_0$  is a list with  $n$  entries or a 1-dimensional array `array(1..n)`, then the solution  $Y(t)$  consists of vectors from a submanifold of  $\mathbb{R}^n$  or  $\mathbb{C}^n$ , respectively.

If  $Y_0$  is specified as a 2-dimensional array `array(1..n, 1..m)` or as a matrix of the corresponding dimension generated by the function `matrix`, then the solution  $Y(t)$  consists of matrices from a submanifold of the space  $\mathbb{C}^{n \times m}$  of  $n \times m$  matrices.

Internally, 2-dimensional  $n \times m$  arrays are used to represent the points on the manifold where  $m = 1$  for vectors in  $\mathbb{R}^n$  or  $\mathbb{C}^n$ . It is recommended to specify  $Y_0$  in the form `array(1..n, 1..m)` in order to avoid the overhead of internal conversions.

The “vector field”  $f$  defining the dynamical system  $\frac{dY}{dt} = f(t, Y) Y$  must be represented by a procedure with two input parameters: the scalar time  $t$  and the matrix or vector  $Y$ . Internally,  $f$  is called with real

# numeric::odesolveGeometric

---

floating-point values  $t$  and matrices/vectors  $Y$  of the same domain type as the initial condition  $Y_0$ .

The procedure `f` has to return an  $n \times n$  matrix either as an array(1..n, 1..n) or as a corresponding matrix object of category `Cat::Matrix` (generated by the function `matrix`).

It is recommended that the procedure returns an array of the type array(1..n, 1..n). This avoids the overhead of internal conversions.

The return value of `f` may contain numerical expressions such as  $\pi$ ,  $\sqrt{2}$  etc. However, all values must be convertible to real or complex floating point numbers by `float`.

Autonomous systems, where  $f(t, Y)$  does not depend on  $t$ , must be represented by a procedure with two arguments `t` and `Y`, too.

The optional arguments `method`, `RelativeError = tol`, and

`Stepsize = h` determine how the ODE  $\frac{du}{dt} = \text{dexpinv}(u, f)$  is solved. They correspond to the methods of the classical ODE solver `numeric::odesolve`.

The numerical precision is controlled by the global variable `DIGITS`: an adaptive control of the step size keeps local relative discretization errors

below  $\text{tol} = \frac{1}{10^{\text{DIGITS}}}$ , unless a different tolerance is specified via the option `RelativeError = tol`. The error control may be switched off by specifying a fixed `Stepsize = h`.

---

**Note** Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

---

With `Y := t -> numeric::odesolveGeometric(f, t_0..t, Y_0)`, the numerical solution can be represented by a MuPAD function: the call `Y(t)` will start the numerical integration from  $t_0$  to  $t$ .

Classical integration preserves the geometrical invariants up to the relative precision of the solution whereas the geometrical integrator

preserves the invariants independent of *tol* up to the working precision set by DIGITS: departure from the homogeneous manifold is a pure roundoff effect.

`numeric::odesolveGeometric` is useful when a tolerance *tol* much

larger than  $\frac{1}{\text{DIGITS}}$  is specified by `RelativeError = tol`. For small tolerances, you may consider to use the classical solver `numeric::odesolve` instead.

Since classical integration is significantly faster, larger values of DIGITS and smaller tolerances for the discretization error may be used in `numeric::odesolve`. Depending on the concrete problem, this may lead to better results than produced by `numeric::odesolveGeometric`.

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

We consider the initial value problem

$$\frac{dY}{dt} = \begin{pmatrix} (J_2 - J_3) Y_2 Y_3 \\ (J_3 - J_1) Y_3 Y_1 \\ (J_1 - J_2) Y_1 Y_2 \end{pmatrix}, \quad Y(0) = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

for  $Y = [Y_1, Y_2, Y_3] \in \mathbb{R}^3$  with fixed parameters  $J_1 = \frac{1}{2}$ ,  $J_2 = 1$ ,  $J_3 = 2$ . Writing this ODE as

$$\frac{dY}{dt} = \begin{pmatrix} 0 & -J_3 Y_3 & J_2 Y_2 \\ J_3 Y_3 & 0 & -J_1 Y_1 \\ -J_2 Y_2 & J_1 Y_1 & 0 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = f_1(t, Y) Y$$

# numeric::odesolveGeometric

it is clear that the solution is restricted to the orbit of the orthogonal group  $SO(3)$  through the initial point ( $f_1$  produces skew symmetric matrices). The invariant of this action is

$H_1(Y) = \langle Y, Y \rangle = Y_1^2 + Y_2^2 + Y_3^2$ , i.e., the solution is restricted to a sphere. Writing the ODE as

$$\begin{aligned} \frac{dY}{dt} &= \begin{pmatrix} 0 & J_2 Y_3 & -J_3 Y_2 \\ -J_1 Y_3 & 0 & J_3 Y_1 \\ J_1 Y_2 & -J_2 Y_1 & 0 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = f_2(t, Y) Y \\ &= \begin{pmatrix} 0 & Y_3 & -Y_2 \\ -Y_3 & 0 & Y_1 \\ Y_2 & -Y_1 & 0 \end{pmatrix} \begin{pmatrix} J_1 & 0 & 0 \\ 0 & J_2 & 0 \\ 0 & 0 & J_3 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} \end{aligned}$$

it is clear that the solution is also restricted to the orbit of the “J-orthogonal” group  $SO(J, 3)$  through the initial point. This group consists of matrices  $G$  satisfying  $G^T J G = J$ , where  $J = \text{diag}(J_1, J_2, J_3)$ . The invariant of this group action is

$H_2(Y) = \langle Y, J Y \rangle = J_1 Y_1^2 + J_2 Y_2^2 + J_3 Y_3^2$ , i.e., the solution is restricted to an ellipsoid.

We consider the first representation and compute a numerical solution that is restricted to a sphere:

```
f1 := proc(t, Y) begin
 array(1..3, 1..3, [[0, -J3*Y[3], J2*Y[2]],
 [J3*Y[3], 0, -J1*Y[1]],
 [-J2*Y[2], J1*Y[1], 0]])
end_proc:
J1 := 1/2: J2 := 1: J3 := 2:
tol := 10^(-2):
Gsolve:= (f, t0_t, Y0) ->
 numeric::odesolveGeometric(f, t0_t, Y0, RelativeError = tol):
```

```

Y(0) := [1.0, 1.0, 1.0];
Y(1) := Gsolve(f1, 0..1, Y(0));
Y(2) := Gsolve(f1, 1..2, Y(1));
Y(3) := Gsolve(f1, 2..3, Y(2));
Y(4) := Gsolve(f1, 3..4, Y(3));
Y(5) := Gsolve(f1, 4..5, Y(4))

```

[1.0, 1.0, 1.0]

[- 0.1234874253, 1.573899124, 0.7124551935]

[- 1.188837997, 0.6164504304, 1.098477621]

[- 0.7811791671, - 1.258922776, 0.8971468953]

[0.3530511101, - 1.520952843, 0.7497048516]

[1.281782142, - 0.1892246302, 1.149447075]

The invariant  $H_1$  is preserved numerically up to the working precision set by DIGITS:

```

H1 := Y -> Y[1]^2 + Y[2]^2 + Y[3]^2:
H1(Y(i)) - H1(Y(0)) $ i = 1..5

```

3.045480534 10<sup>-14</sup>, - 2.691596945 10<sup>-14</sup>, 4.011374566 10<sup>-14</sup>, 3.491859579 10<sup>-13</sup>, 2.8517

## numeric::odesolveGeometric

---

The invariant  $H_2$  is only preserved within the relative precision of the solution set by the option `RelativeError = tol`:

```
H2 := Y -> J1*Y[1]^2 + J2*Y[2]^2 + J3*Y[3]^2:
H2(Y(i)) - H2(Y(0)) $ i = 1..5
```

```
-0.00003216929769, -0.00001480619998, -0.0002478937317, -0.0002651787298, -0.00
```

Now, we solve the ODE using the second representation:

```
f2 := proc(t, Y) begin
 array(1..3, 1..3, [[0 , J2*Y[3], -J3*Y[2]],
 [-J1*Y[3], 0 , J3*Y[1]],
 [J1*Y[2], -J2*Y[1], 0]])
end_proc:

Y(0) := [1.0, 1.0, 1.0];
Y(1) := Gsolve(f2, 0..1, Y(0));
Y(2) := Gsolve(f2, 1..2, Y(1));
Y(3) := Gsolve(f2, 2..3, Y(2));
Y(4) := Gsolve(f2, 3..4, Y(3));
Y(5) := Gsolve(f2, 4..5, Y(4))
```

```
[1.0, 1.0, 1.0]
```

```
[-0.1234661822, 1.573904531, 0.7124614294]
```

```
[-1.188842584, 0.6165012417, 1.098465492]
```

```
[-0.7810696492, -1.258800682, 0.8973254548]
```

[0.3534089311, - 1.520647212, 0.7500610376]

[1.28178089, - 0.1880404787, 1.149599855]

Now, the invariant  $H_2$  is preserved to working precision, whilst  $H_1$  is only preserved to the tolerance specified by `RelativeError = tol`:

$H_2(Y(i)) - H_2(Y(0)) \text{ } \$ \text{ } i = 1..5$

2.70894418 10<sup>-14</sup>, 5.287437155 10<sup>-15</sup>, 2.071884331 10<sup>-13</sup>, 1.704608676 10<sup>-13</sup>, 2.2680468

$H_1(Y(i)) - H_1(Y(0)) \text{ } \$ \text{ } i = 1..5$

0.0000206606336, 0.00004690748333, - 0.0001580733145, - 0.0001426238818, - 0.000

`delete J1, J2, J3, Gsolve, f1, f2, Y, H1, H2:`

## Example 2

We consider the “Toda lattice equations”

$$\frac{da_i}{dt} = a_i (b_i - b_{i+1}), \quad i \in \{1, \dots, n-1\}$$

$$\frac{db_i}{dt} = 2 (a_{i-1}^2 - a_i^2), \quad i \in \{1, \dots, n\}$$

with  $a_0 = a_n = 0$ . Introducing the tridiagonal  $n \times n$  matrices

# numeric::odesolveGeometric

---

$$Y = \begin{pmatrix} b_1 & a_1 & & \\ a_1 & \dots & \dots & \\ & \dots & \dots & a_{n-1} \\ & & a_{n-1} & b_n \end{pmatrix}, f(Y) = \begin{pmatrix} 0 & -a_1 & & \\ a_1 & \dots & \dots & \\ & \dots & \dots & -a_{n-1} \\ & & a_{n-1} & 0 \end{pmatrix},$$

these equations can be encoded by the matrix ODE

$\frac{dY}{dt} = f(Y) Y - Y f(Y)$ . The solution  $Y(t)$  is known to be “isospectral”, i.e., the eigenvalues of  $Y(t)$  do not depend on the time parameter  $t$ . As mentioned in the description of the option `LieGroupAction`, the solution of this type of matrix ODE is given by the group action  $Y(t) = G(t)Y(0)G(t)^{-1} = G(t)Y(0)G(t)^T$ , where  $G(t)$  are orthogonal matrices (note that  $f(Y)$  is skew symmetric). The eigenvalues of the matrices  $Y(t)$  are invariants of the group action.

The exact dynamics also preserves the tridiagonal form of the matrices. The numerical dynamics, however, fills in further elements. The following vector field  $f$  ignores all elements outside the central bands:

```
f := proc(t, Y)
local i, r;
begin
 r := array(1..n, 1..n, [[0 $ n] $ n]);
 for i from 1 to n - 1 do
 r[i + 1, i] := Y[i, i + 1];
 r[i, i + 1] := -Y[i, i + 1];
 end_for;
 return(r)
end_proc;
```

In the following, the initial value  $Y(0)$  is specified by a matrix generated by the function `matrix`. Consequently, both arguments  $G$  and  $Y$  are passed to the Lie group action `LAMBDA` as corresponding matrices. They can be multiplied by the multiplication operator `*`:

```
LAMBDA:= proc(G, Y)
begin
 G*Y*(G::dom::transpose(G))
end_proc:
```

We define the initial value:

```
n := 3:
Y(0) := matrix(n, n, [1, 1, 1], Banded)
```

$$\begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}$$

Now, the dynamics is integrated from  $t = 0$  to  $t = 1$ :

```
tol := 10^(-4):
Y(1) := numeric::odesolveGeometric(f, 0..1, Y(0),
 LieGroupAction = LAMBDA, RelativeError = tol)
```

$$\begin{pmatrix} -0.256354686 & 0.4591148565 & -1.716329601 \cdot 10^{-14} \\ 0.4591148565 & 1.0 & 0.4591148565 \\ -1.716329601 \cdot 10^{-14} & 0.4591148565 & 2.256354686 \end{pmatrix}$$

The invariants of the dynamics are the eigenvalues of the matrices  $Y(t)$ . They are preserved numerically:

```
numeric::eigenvalues(Y(0)) = numeric::eigenvalues(Y(1))
```

```
[2.414213562, 1.0, -0.4142135624] = [2.414213562, 1.0, -0.4142135624]
```

## numeric::odesolveGeometric

---

For comparison, we also solve the Toda lattice equations by classical numerics using `numeric::odesolve`. The system is encoded by a vector

$$Y = [b_1, \dots, b_n, a_1, \dots, a_{n-1}] \text{ in } \mathbb{R}^{2n-1}:$$

```
f := proc(t, Y)
local a, b, i;
begin
 b := [Y[i] $ i = 1..n];
 a := [Y[n + i] $ i = 1..n-1];
 [-2*a[1]^2, // = d/dt b[1]
 2*(a[i-1]^2 - a[i]^2) $ i = 2..n-1, // = d/dt b[i]
 2*a[n-1]^2, // = d/dt b[n]
 a[i]*(b[i] - b[i+1]) $ i = 1..n-1 // = d/dt a[i]
]
end_proc:

solution := numeric::odesolve(f, 0..1, [1 $ 2*n - 1],
 RelativeError = tol);

[-0.2563650696, 1.0, 2.25636507, 0.459099923, 0.459099923]
```

The invariants are only preserved up to the precision of the solution determined by the tolerance set via `RelativeError = tol`:

```
Y(1) := array(1..n, 1..n, [[0 $ n] $ n]):
for i from 1 to n do
 Y(1)[i, i] := solution[i];
end_for:
for i from 1 to n-1 do
 Y(1)[i, i + 1] := solution[n + i];
 Y(1)[i + 1, i] := solution[n + i];
end_for:

Y(1)
```

$$\begin{pmatrix} -0.2563650696 & 0.459099923 & 0 \\ 0.459099923 & 1.0 & 0.459099923 \\ 0 & 0.459099923 & 2.25636507 \end{pmatrix}$$

```
numeric::eigenvalues(Y(1))
```

```
[2.414213091, 1.0, -0.4142130909]
```

Comparing these data with the previously computed eigenvalues of the initial condition  $Y(0)$ , one sees that the invariants are not preserved numerically to the working precision determined by DIGITS.

```
delete f, LAMBDA, n, Y, tol, solution, i:
```

## Parameters

**f**

A procedure accepting two parameters ( $t$ ,  $Y$ )

**t<sub>0</sub>**

A numerical real value for the initial time

**t**

A numerical real value (the “time”)

**Y<sub>0</sub>**

The initial condition: a list, a 1-dimensional array(1..n), a 2-dimensional array(1..n, 1..m), or an  $n \times m$  matrix of category `Cat::Matrix` with numerical entries

## Options

**LieGroupAction**

Option, specified as `LieGroupAction = LAMBDA`

The procedure `LAMBDA = proc(G, Y) ... end_proc` defines the action of the group element  $G$  (an  $n \times n$  matrix) on the point  $Y$  on the homogeneous manifold (an  $n \times m$  matrix or an  $n$  dimensional

# numeric::odesolveGeometric

---

vector). This procedure must return a corresponding point (a matrix or a vector).

The default action is the usual matrix multiplication  
 $(G, Y) \rightarrow G Y$ .

With this option, the default group action LAMBDA:  $(G, Y) \rightarrow G Y$  of the  $n \times n$  matrices  $G$  acting on the  $n \times m$  matrices or  $n$  dimensional vectors  $Y$  by left multiplication may be replaced by other group actions.

As a group action, the procedure LAMBDA must satisfy  $LAMBDA(1_n, Y) = Y$  and

$$LAMBDA(G_2, LAMBDA(G_1, Y)) = LAMBDA(G_2 G_1, Y)$$

numeric::odesolveGeometric computes the solution of the matrix ODE

$$\frac{dG(t)}{dt} = f(t, LAMBDA(G(t), Y_0)) G(t), G(t_0) = 1_{n,n}$$

On the space  $\mathbb{C}^{n \times n}$  of the  $n \times n$  matrices and returns  $Y(t) = LAMBDA(G(t), Y_0)$ .

For the standard group action  $LAMBDA(G, Y) = GY$ , this is the solution of the ODE  $\frac{dY}{dt} = f(t, Y) Y$ .

For homogeneous manifolds embedded in the  $n \times n$  matrices, the group action  $LAMBDA(G, Y) = GYG^{-1}$  may be considered. For this action, the curve  $Y(t) = LAMBDA(G(t), Y_0)$  returned by numeric::odesolveGeometric is the solution of the ODE

$$\frac{dY}{dt} = f(t, Y) Y - Y f(t, Y). \text{ Cf. "Example 2" on page 18-251.}$$

LAMBDA(G, Y) is called with  $n \times m$  matrices or  $n$  dimensional vectors  $Y$  of the same domain type as the initial condition  $Y_0$ . If  $Y_0$

is a matrix generated by the function `matrix`, then also the  $n \times n$  matrix  $G$  is passed to `LAMBDA` as such a matrix object. In all other cases,  $G$  is passed as a 2-dimensional array (1..n, 1..n).

The procedure `LAMBDA` should return a 2-dimensional array (1..n, 1..m) or a corresponding matrix of category `Cat::Matrix`.

If the initial condition  $Y_0$  is specified by a list or a 1-dimensional array (1..n), `LAMBDA` may also return a corresponding list or array.

Internally, the return value of `LAMBDA` is converted to a 2-dimensional array (1..n, 1..m) where  $m = 1$  if a list or a 1-dimensional array is returned.

It is recommended that `LAMBDA` returns a 2-dimensional array (1..n, 1..m) in order to avoid the overhead of internal conversions.

## RelativeError

Option, specified as `RelativeError = tol`

Forces internal numerical Runge-Kutta steps to use step sizes with local discretization errors below `tol`. This tolerance must

be a numerical real value  $\geq \frac{1}{10^{\text{DIGITS}}}$ . The default tolerance is  $\frac{1}{10^{\text{DIGITS}}}$ .

The internal control mechanism estimates the local relative discretization error of a Runge-Kutta step and adjusts the step size adaptively to keep this error below `tol`.

The default setting of `tol = \frac{1}{10^{\text{DIGITS}}}` ensures that the local discretization errors are of the same order of magnitude as numerical roundoff.

Usually there is no need to use this option to change this setting. However, occasionally the numerical evaluation of the Runge-Kutta steps may be ill-conditioned or step sizes are so small that the time parameter cannot be incremented by the step

# numeric::odesolveGeometric

---

size within working precision. In such a case, this option may be used to bound the local discretization error by *tol* and use a higher working precision given by DIGITS.

Only real numerical values  $\text{tol} \geq \frac{1}{10^{\text{DIGITS}}}$  are accepted.

---

**Note** Usually, the global error of the numeric approximation returned by `numeric::odesolveGeometric` is larger than the local errors bounded by *tol*. Although the result is displayed with DIGITS decimal places, one should not expect that all of them are correct. The relative precision of the final result is *tol* at best!

---

## Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size *h*. *h* must be a numerical real value.

By default, `numeric::odesolveGeometric` uses an adaptive step size control mechanism in the numerical iteration. The option `Stepsize = h` switches off this adaptive mechanism and uses the Runge-Kutta method specified by `method` (or the default method DOPRI78) with constant step size *h*.

A final step with smaller step size is used to match the end *t* of the integration interval  $t_0..t$ , if  $\frac{t-t_0}{h}$  is not an integer.

---

**Note** With this option, there is no automatic error control! Depending on the problem and on the order of the method, the result may be a poor numerical approximation of the exact solution.

---

There is usually no need to invoke this option. However, occasionally the builtin adaptive error control mechanism may fail when integrating close to a singularity. In such a case, this option may be used to customize a control mechanism for the global error by using different step sizes and investigating the convergence of the corresponding results.

## Alldata

Option, specified as `Alldata = n`

With this option, `numeric::odesolveGeometric` returns a list of numerical mesh points  $[[t_0, Y_0], [t_1, Y_1], \dots, [t, Y(t)]]$  generated by the internal Runge-Kutta iteration.

The integer  $n$  controls the size of the output list. For  $n = 1$ , all internal mesh points are returned. This case may also be invoked by entering the simplified option `Alldata`, which is equivalent to `Alldata = 1`. For  $n > 1$ , only each  $n$ -th mesh point is stored in the list. The list always contains the initial point  $[t_0, Y_0]$  and the final point  $[t, Y(t)]$ . For  $n \leq 0$ , only the data  $[[t_0, Y_0], [t, Y(t)]]$  are returned.

The output list may be useful to inspect the internal numerical process. Also further graphical processing of the mesh data may be useful.

## Return Values

The solution  $Y(t)$  is returned as a list or as an array of floating-point values. The type of the result matrix/vector coincides with the type of the input matrix/vector  $Y_0$ .

With the option `Alldata`, a list of mesh data is returned.

**Purpose** Convert an ode system to vectorfield notation

**Syntax** `numeric::ode2vectorfield(IVP, fields)`

**Description** `numeric::ode2vectorfield` converts a system of ordinary differential equations of arbitrary order to a vector field representation suitable for the numerical ODE solver `numeric::odesolve2`.

`numeric::ode2vectorfield` and `numeric::odeToVectorField` are equivalent.

`numeric::ode2vectorfield` is a utility function to generate input parameters for the numerical ODE solver `numeric::odesolve2`. This solver requires a procedure representing the vectorfield  $f(t, Y)$  of a first order system of differential equations (dynamic system)  $\frac{dY}{dt} = f(t, Y)$  and initial data  $Y_0 = Y(t_0)$ . Given an initial value problem IVP consisting of (possibly higher order) differential expressions together with initial conditions, `numeric::ode2vectorfield` converts the higher order equations to an equivalent system of first order ODEs and returns the input parameters for `numeric::odesolve2`.

Higher-order differential equations can always be represented as an equivalent dynamic system  $\frac{dY}{dt} = f(t, Y)$  with some vector  $Y$ . E.g., the  $n$ -th order equation

$$y^{(n)} = g(t, y, y', \dots, y^{(n-1)})$$

may be written as the first order system

$$\frac{dY}{dt} = [y', \dots, y^{(n-1)}, g(t, y, \dots, y^{(n-1)})]$$

for the vector  $Y = [y, y', \dots, y^{(n-1)}]$ .

## numeric::ode2vectorfield

---

The input list `fields` corresponds to the vector  $Y$ . It must be a *complete* specification of all functions and their derivatives through but *not including the highest derivatives* of the unknown functions. E.g., for the second order differential equation  $y''(t) = y(t)$ , the appropriate list of unknown fields is  $[y(t), y'(t)]$ . The differential equations  $y''(t) = z(t)$ ,  $z'(t) = y(t)$  are of second order in  $y$  and of first order in  $z$ . Hence, the appropriate list of unknown fields is  $[y(t), y'(t), z(t)]$ .

The ordering of the fields in `list` determines the ordering of the components of the list that the numerical solver produces as the solution vector. Cf. "Example 2" on page 18-264.

The differential equations must be linear in the highest derivatives of the unknown functions involved. E.g., the ODE  $y'(t)^2 = y(t)$  is not admitted. However, equations such as  $y_2(t) y_1'(t) = y_1(t)$ ,  $y_1(t) y_2'(t) = y_2(t)$  are accepted and

converted to  $y_1'(t) = \frac{y_1(t)}{y_2(t)}$ ,  $y_2'(t) = \frac{y_2(t)}{y_1(t)}$ .

A *complete* specification of initial conditions must be contained in IVP: for each component in `list`, an initial value must be provided. The initial conditions may be specified by linear equations which will be solved for the initial values of the unknown fields automatically. E.g., for `fields = [y(t), y'(t), z(t)]`, initial conditions may be specified explicitly by  $y(t_0) = 1$ ,  $y'(t_0) = 2$ ,  $z(t_0) = 3$ , say, or via linear equations such as  $y(t_0) + z(t_0) = y'(t_0)$ ,  $y(t_0) = z(t_0)$ ,  $z(t_0) = 2 y(t_0)$ . Cf. "Example 3" on page 18-265.

The differential equations, the initial 'time'  $t_0$ , and the initial conditions may involve symbolic parameters. However, such parameters must evaluate to numerical objects, when the sequence returned by `numeric::ode2vectorfield` is passed to the numerical solver.

The vectorfield procedure `f` and the initial values  $Y_0$  returned by `numeric::ode2vectorfield` can also be used by the functions `numeric::odesolve`, `plot::Ode2d`, `plot::Ode3d`. Cf. "Example 3" on page 18-265.

## Examples

### Example 1

We consider the initial value problem

$$y'(t) = t \sin(y(t)), \quad y(0) = 1$$

The solver `numeric::odesolve2` requires the procedure  $f:(t, Y) \rightarrow t \sin(Y_1)$  for the 1-dimensional vector  $Y = [y(t)]$  specified by `fields`. The utility `numeric::ode2vectorfield` accepts a more convenient representation via arithmetical expressions:

```
IVP := {y'(t) = t*sin(y(t)), y(t0) = y0}:
fields := [y(t)]:
IVP := numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, t0, [y0]
```

This sequence may be passed to the numerical solver which returns a procedure representing the numerical solution:

```
t0 := 0: y0 := 1:
Y := numeric::odesolve2(IVP)
```

```
proc Y(t) ... end
```

Calling the numerical solution `Y` invokes the numerical integration from the initial 'time'  $t_0 = 0$  to the 'time' specified in the call to `Y`:

```
Y(0), Y(1), Y(2), Y(3)
```

```
[1.0], [1.466404006], [2.655911348], [3.100928494]
```

# numeric::ode2vectorfield

---

```
delete IVP, fields, Y:
```

## Example 2

We consider the second order initial value problem

$$y''(t) = t \sin(y(t)), \quad y(0) = 1, \quad y'(0) = 0$$

The corresponding vectorfield representation involves the vector  $Y = [y(t), y'(t)]$  specified by `fields`:

```
IVP := {y''(t) = t*sin(y(t)), y(0) = 1, y'(0) = 0}:
fields := [y(t), y'(t)]:
numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, 0, [1, 0]
```

This sequence is accepted by `numeric::odesolve2`. The numerical solution `Y` returns lists representing the components of the vector specified by `fields`:

```
Y := numeric::odesolve2(%):
Y(5)
```

```
[1.916536393, -0.8765542819]
```

With a reordering of the unknown fields, the numerical solver returns the solution vector with rearranged components:

```
fields := [y'(t), y(t)]:
Y := numeric::odesolve2(numeric::ode2vectorfield(IVP, fields)):
Y(5)
```

```
[- 0.8765542819, 1.916536393]
```

```
delete IVP, fields, Y:
```

### Example 3

The following IVP involves the unknown fields  $u(t)$ ,  $v(t)$ ,  $w(t)$ . Since it is of second order in  $u$ , of first order in  $v$  and of third order in  $w$ , the list of unknowns  $[y(t), y'(t), v(t), w(t), w'(t), w''(t)]$  is appropriate:

```
IVP := {u''(t) - u(t)*v'(t) = exp(-t)*v'(t), v'(t) = w''(t),
 u'(t)*w'''(t) = t + u'(t),
 u(PI) = 3, u'(PI) = 1,
 v(PI) = 0,
 w(PI) = w'(PI), w'(PI) = 2 - w(PI), w''(PI) = 3*w(PI)}:
fields := [u(t), u'(t), v(t), w(t), w'(t), w''(t)]:
ivp := numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, pi, [3, 1, 0, 1, 1, 3]
```

```
Y := numeric::odesolve2(ivp):
Y(5)
```

```
[195.9501263, 604.3872242, 13.15053015, 13.29454726, 14.15053015, 10.04763196]
```

We plot the components  $v$ ,  $w$ , and  $w''$  of the solution vector:

```
plotfunc2d(Y(t)[3], Y(t)[4], Y(t)[6], t = PI .. 5,
 Colors = [RGB::Red, RGB::Green, RGB::Blue]):
```

# numeric::ode2vectorfield

Alternatively, we use the vectorfield procedure `ivp[1]` and the initial conditions `ivp[3]` as input parameters for `plot::Ode2d`:

```
plot(plot::Ode2d([PI + i*(5 - PI)/30 $ i = 0..30],
 ivp[1], ivp[3],
 [(t, Y) -> [t, Y[3]], Color = RGB::Red],
 [(t, Y) -> [t, Y[4]], Color = RGB::Green],
 [(t, Y) -> [t, Y[6]], Color = RGB::Blue])):
```

delete IVP, fields, ivp, Y:

## Parameters

### IVP

The initial value problem: a list or a set of equations involving univariate function calls  $y_1(t)$ ,  $y_2(t)$  etc. and derivatives  $y_1'(t)$ ,  $y_1''(t)$ , ...,  $y_2'(t)$ ,  $y_2''(t)$  etc. The differential equations must be quasi-linear: the highest derivative of each of the dependent functions  $y_1(t)$ ,  $y_2(t)$  etc. must enter the equations linearly. IVP must also contain corresponding initial conditions specified by linear equations in the expressions  $y_1(t_0)$ ,  $y_1'(t_0)$ , ...,  $y_2(t_0)$ ,  $y_2'(t_0)$  etc. Alternatively, arithmetical expressions may be specified which are interpreted as equations with vanishing right hand side.

### fields

# numeric::ode2vectorfield

---

The vector of the dynamical system equivalent to IVP: a list of symbolic function calls such as  $[y_1(t), y_1'(t), \text{dots}, y_2(t), y_2'(t), \text{dots}]$  representing the unknown fields to be solved for.

## Return Values

Sequence  $f, t_0, Y_0$ . These data represent the dynamical system

$\frac{dY}{dt} = f(t, Y)$  with the initial condition  $Y(t_0) = Y_0$  equivalent to IVP.

The vectorfield  $f:(t, Y) \rightarrow f(t, Y)$  is a procedure,  $t_0$  is a numerical expression representing the initial 'time', and  $Y_0$  is a list of numerical expressions representing the components of the initial vector  $Y_0$ .

## Concepts

- "Solve Equations Numerically"

**Purpose** Convert an ode system to vectorfield notation

**Syntax** `numeric::odeToVectorField(IVP, fields)`

**Description** `numeric::odeToVectorField` converts a system of ordinary differential equations of arbitrary order to a vector field representation suitable for the numerical ODE solver `numeric::odesolve2`.

`numeric::odeToVectorField` and `numeric::ode2vectorfield` are equivalent.

`numeric::odeToVectorField` is a utility function to generate input parameters for the numerical ODE solver `numeric::odesolve2`. This solver requires a procedure representing the vectorfield  $f(t, Y)$  of a first order system of differential equations (dynamic system)  $\frac{dY}{dt} = f(t, Y)$  and initial data  $Y_0 = Y(t_0)$ . Given an initial value problem IVP consisting of (possibly higher order) differential expressions together with initial conditions, `numeric::odeToVectorField` converts the higher order equations to an equivalent system of first order ODEs and returns the input parameters for `numeric::odesolve2`.

Higher-order differential equations can always be represented as an equivalent dynamic system  $\frac{dY}{dt} = f(t, Y)$  with some vector  $Y$ . E.g., the  $n$ -th order equation

$$y^{(n)} = g(t, y, y', \dots, y^{(n-1)})$$

may be written as the first order system

$$\frac{dY}{dt} = [y', \dots, y^{(n-1)}, g(t, y, \dots, y^{(n-1)})]$$

for the vector  $Y = [y, y', \dots, y^{(n-1)}]$ .

## numeric::odeToVectorField

---

The input list `fields` corresponds to the vector  $Y$ . It must be a *complete* specification of all functions and their derivatives through but *not including the highest derivatives* of the unknown functions. E.g., for the second order differential equation  $y''(t) = y(t)$ , the appropriate list of unknown fields is  $[y(t), y'(t)]$ . The differential equations  $y''(t) = z(t)$ ,  $z'(t) = y(t)$  are of second order in  $y$  and of first order in  $z$ . Hence, the appropriate list of unknown fields is  $[y(t), y'(t), z(t)]$ .

The ordering of the fields in `list` determines the ordering of the components of the list that the numerical solver produces as the solution vector. Cf. "Example 2" on page 18-272.

The differential equations must be linear in the highest derivatives of the unknown functions involved. E.g., the ODE  $y'(t)^2 = y(t)$  is not admitted. However, equations such as  $y_2(t) y_1'(t) = y_1(t)$ ,  $y_1(t) y_2'(t) = y_2(t)$  are accepted and

converted to  $y_1'(t) = \frac{y_1(t)}{y_2(t)}$ ,  $y_2'(t) = \frac{y_2(t)}{y_1(t)}$ .

A *complete* specification of initial conditions must be contained in IVP: for each component in `list`, an initial value must be provided. The initial conditions may be specified by linear equations which will be solved for the initial values of the unknown fields automatically. E.g., for `fields = [y(t), y'(t), z(t)]`, initial conditions may be specified explicitly by  $y(t_0) = 1$ ,  $y'(t_0) = 2$ ,  $z(t_0) = 3$ , say, or via linear equations such as  $y(t_0) + z(t_0) = y'(t_0)$ ,  $y(t_0) = z(t_0)$ ,  $z(t_0) = 2 y(t_0)$ . Cf. "Example 3" on page 18-273.

The differential equations, the initial 'time'  $t_0$ , and the initial conditions may involve symbolic parameters. However, such parameters must evaluate to numerical objects, when the sequence returned by `numeric::odeToVectorField` is passed to the numerical solver.

The vectorfield procedure `f` and the initial values  $Y_0$  returned by `numeric::odeToVectorField` can also be used by the functions `numeric::odesolve`, `plot::Ode2d`, `plot::Ode3d`. Cf. "Example 3" on page 18-273.

## Examples

### Example 1

We consider the initial value problem

$$y'(t) = t \sin(y(t)), \quad y(0) = 1$$

The solver `numeric::odesolve2` requires the procedure  $f:(t, Y) \rightarrow t \sin(Y_1)$  for the 1-dimensional vector  $Y = [y(t)]$  specified by `fields`. The utility `numeric::ode2vectorfield` accepts a more convenient representation via arithmetical expressions:

```
IVP := {y'(t) = t*sin(y(t)), y(t0) = y0}:
fields := [y(t)]:
IVP := numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, t0, [y0]
```

This sequence may be passed to the numerical solver which returns a procedure representing the numerical solution:

```
t0 := 0: y0 := 1:
Y := numeric::odesolve2(IVP)
```

```
proc Y(t) ... end
```

Calling the numerical solution `Y` invokes the numerical integration from the initial 'time'  $t_0 = 0$  to the 'time' specified in the call to `Y`:

```
Y(0), Y(1), Y(2), Y(3)
```

```
[1.0], [1.466404006], [2.655911348], [3.100928494]
```

# numeric::odeToVectorField

---

```
delete IVP, fields, Y:
```

## Example 2

We consider the second order initial value problem

$$y''(t) = t \sin(y(t)), \quad y(0) = 1, \quad y'(0) = 0$$

The corresponding vectorfield representation involves the vector  $Y = [y(t), y'(t)]$  specified by `fields`:

```
IVP := {y''(t) = t*sin(y(t)), y(0) = 1, y'(0) = 0}:
fields := [y(t), y'(t)]:
numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, 0, [1, 0]
```

This sequence is accepted by `numeric::odesolve2`. The numerical solution `Y` returns lists representing the components of the vector specified by `fields`:

```
Y := numeric::odesolve2(%):
Y(5)
```

```
[1.916536393, -0.8765542819]
```

With a reordering of the unknown fields, the numerical solver returns the solution vector with rearranged components:

```
fields := [y'(t), y(t)]:
Y := numeric::odesolve2(numeric::ode2vectorfield(IVP, fields)):
Y(5)
```

```
[- 0.8765542819, 1.916536393]
```

```
delete IVP, fields, Y:
```

### Example 3

The following IVP involves the unknown fields  $u(t)$ ,  $v(t)$ ,  $w(t)$ . Since it is of second order in  $u$ , of first order in  $v$  and of third order in  $w$ , the list of unknowns  $[y(t), y'(t), v(t), w(t), w'(t), w''(t)]$  is appropriate:

```
IVP := {u''(t) - u(t)*v'(t) = exp(-t)*v'(t), v'(t) = w''(t),
 u'(t)*w'''(t) = t + u'(t),
 u(PI) = 3, u'(PI) = 1,
 v(PI) = 0,
 w(PI) = w'(PI), w'(PI) = 2 - w(PI), w''(PI) = 3*w(PI)}:
fields := [u(t), u'(t), v(t), w(t), w'(t), w''(t)]:
ivp := numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, pi, [3, 1, 0, 1, 1, 3]
```

```
Y := numeric::odesolve2(ivp):
Y(5)
```

```
[195.9501263, 604.3872242, 13.15053015, 13.29454726, 14.15053015, 10.04763196]
```

We plot the components  $v$ ,  $w$ , and  $w''$  of the solution vector:

```
plotfunc2d(Y(t)[3], Y(t)[4], Y(t)[6], t = PI .. 5,
 Colors = [RGB::Red, RGB::Green, RGB::Blue]):
```

# numeric::odeToVectorField

Alternatively, we use the vectorfield procedure `ivp[1]` and the initial conditions `ivp[3]` as input parameters for `plot::Ode2d`:

```
plot(plot::Ode2d([PI + i*(5 - PI)/30 $ i = 0..30],
 ivp[1], ivp[3],
 [(t, Y) -> [t, Y[3]], Color = RGB::Red],
 [(t, Y) -> [t, Y[4]], Color = RGB::Green],
 [(t, Y) -> [t, Y[6]], Color = RGB::Blue])):
```

delete IVP, fields, ivp, Y:

## Parameters

1.822838993
```

```
delete p:
```

## Parameters

**p**

A univariate polynomial expression or a univariate polynomial of domain type `DOM_POLY`.

## Return Values

Nonnegative real floating-point number or infinity.

## See Also

## MuPAD Functions

RootOf | numeric::fsolve | numeric::polyroots  
| numeric::polysysroots | numeric::realroot |  
numeric::realroots | polylib::realroots | solve

## Purpose

Numerical roots of a univariate polynomial

## Syntax

```
numeric::polyroots(eqs, <FixedPrecision>, <SquareFree>,
<Factor>, <NoWarning>)
```

## Description

`numeric::polyroots(eqs)` returns numerical approximations of all real and complex roots of the univariate polynomials `eqs`.

The coefficients may be real or complex numbers. Also symbolic coefficients are accepted if they can be converted to floats.

The trivial polynomial  $eqs = 0$  results in an error message. The empty list is returned for constant polynomials  $eqs \neq 0$ .

Multiple roots are listed according to their multiplicities, i.e., the length of the root list coincides with the degree of `eqs`.

The root list is sorted by `numeric::sort`.

Up to roundoff effects, the numerical roots should be accurate to DIGITS significant digits, unless the option `FixedPrecision` is used.

All floating-point entries in `eqs` are internally approximated by rational numbers: `numeric::polyroots(eqs)` computes the roots of `numeric::rationalize(eqs, Minimize)`.

For polynomial expressions in factored form, the numerical search is applied to each factor separately.

It is recommended to use `numeric::realroots` or `polylib::realroots` if `eqs` is a real polynomial and only real roots are of interest.

## Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

## Examples

### Example 1

Both polynomial expressions as well as DOM\_POLY objects may be used to specify the polynomial:

```
numeric::polyroots(x^3 - 3*x - sqrt(2))
```

## numeric::polyroots

---

```
[1.931851653, -0.5176380902, -1.414213562]
```

```
numeric::polyroots(PI*z^4 + I*z + 0.1)
```

```
[0.5936837297 - 0.3729248918 i, 0.6455316068 i, 0.1003181767 i, -0.5936837297 - 0.3729248918 i]
```

```
numeric::polyroots(poly(x^5 - x^2, [x]))
```

```
[1.0, 0.0, 0.0, -0.5 + 0.8660254038 i, -0.5 - 0.8660254038 i]
```

### Example 2

The following polynomial has exact coefficients:

```
p := poly((x - 1)*(x - PI)^3, [x]):
numeric::polyroots(p)
```

```
[3.141592654, 3.141592654, 3.141592654, 1.0]
```

Note that roundoff errors in the coefficients of eqs have a dramatic effect on multiple roots:

```
p := poly((x - 1.0)*(x - float(PI))^3, [x]):
numeric::polyroots(p)
```

```
[3.144422386, 3.140177788 - 0.00244957836 i, 3.140177788 + 0.00244957836 i, 0.999999999]
```

These are the roots of the following rationalized polynomial:

```
numeric::rationalize(p, Minimize)
```

$$\text{poly}\left(x^4 - \frac{461286 x^3}{44249} + \frac{176627 x^2}{4525} - \frac{2515405 x}{41498} + \frac{1837649}{59267}, [x]\right)$$

delete p:

### Example 3

The multiple root  $\frac{1}{3}$  of the following polynomial can only be computed with restricted precision by fixed precision arithmetic:

```
p := poly((x^2 - 6*x + 8)*(x - I/3)^5, [x]):
numeric::polyroots(p, FixedPrecision)
```

```
[4.0, 2.0, 0.006617926628 + 0.330782186 i, 0.004459639998 + 0.3388505458 i,
- 0.0003838250804 + 0.3262671926 i, - 0.003866386513 + 0.3392634968 i,
- 0.006827355033 + 0.3315032456 i]
```

Without the option FixedPrecision, the working precision is increased internally to compute better approximations:

```
numeric::polyroots(p)
```

```
[4.0, 2.0, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i]
```

delete p:

### Example 4

The following polynomial has badly separated roots. numeric::polyroots does not manage to separate them properly:

```
p := poly(_mult((x - 1 - i/10^9) $ i=0..5), [x]):
numeric::polyroots(p)
```

# numeric::polyroots

---

```
[1.000000003, 1.000000003, 1.000000003, 1.000000003, 1.000000003, 0.9999999987]
```

One can preprocess the polynomial by a symbolic factorization:

```
numeric::polyroots(p, Factor)
```

```
[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]
```

Alternatively, one can increase the working precision to separate the roots:

```
DIGITS := 20:
numeric::polyroots(p)
```

```
[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]
```

```
delete p, DIGITS:
```

## Parameters

**eqs**

A univariate polynomial expression or a univariate polynomial of domain type `DOM_POLY`. The function also accepts a list, set, array, or matrix (`Cat::Matrix`) of polynomial expressions.

## Options

**FixedPrecision**

This option provides the fastest way to obtain approximations of the roots by a numerical search with a fixed internal precision of  $2DIGITS$  decimal places.

Note that badly isolated roots or multiple roots will usually not be approximated to `DIGITS` decimals when using this option. The problem of finding such roots is numerically ill-conditioned, i.e., such roots cannot be found to full precision with fixed precision

arithmetic. Typically, a  $q$ -fold root will be approximated only to about  $\frac{2 \text{ DIGITS}}{q}$  decimal places. Cf. “Example 3” on page 18-281. Without this option, `numeric::polyroots` internally increases the working precision until all roots are found to `DIGITS` decimal places.

## SquareFree

With this option, a symbolic square free factorization is computed via `polylib::sqrfree(eqs)`. The numerical root finding algorithm is then applied to each square free factor.

This option is recommended, when  $p$  is known to have multiple roots. Such roots force `numeric::polyroots` to increase the working precision internally increasing the costs of the numerical search. A square free factorization reduces the multiplicity of each root to one, speeding up the final numerical search.

For polynomials with real rational coefficients, a square free factorization is always used, i.e., this option does not have any effect for such polynomials. For all other types of coefficients, a square free factorization may be costly and must be requested by this option.

Multiple roots of `eqs` can be successfully dealt with by this option. However, for badly separated distinct roots the square free factorization will not improve the performance of the numerical search.

## Factor

With this option, a symbolic factorizations of `eqs` via `factor` are computed. The numerical root finding algorithm is then applied to each factor.

This option is useful, when `eqs` can be successfully factorized (e.g., when each expression from `eqs` has multiple roots). The numerical search on the factors is much more efficient than the search on the original polynomial. On the other hand, symbolic factorization of `eqs` may be costly.

# numeric::polyroots

---

## **NoWarning**

Suppresses warnings

## **Return Values**

List of numerical roots.

## **Algorithms**

The numerical root finding algorithm implemented by `numeric::polyroots` is Laguerre's method: W.H. Press, B.P. Flannery, S.A. Teukolsky and W.T. Vetterling: *Numerical Recipes in C*, Cambridge University Press, 1988.

`RootOf` | `numeric::fsolve` | `numeric::polysysroots` |  
`numeric::realroot` | `numeric::realroots` | `polylib::realroots`  
| `solve`

## Purpose

Numerical roots of a system of polynomial equations

## Syntax

```
numeric::polysysroots(eqs, <NoWarning>)
numeric::polysysroots(eqs, vars, <NoWarning>)
```

## Description

`numeric::polysysroots(eqs, ...)` returns numerical approximations of all real and complex roots of the polynomial system of equations `eqs`.

The coefficients of the polynomials may contain symbolic parameters.

If no unknowns are specified by `vars`, then `numeric::indets(eqs)` is used in place of `vars`.

In most cases, the solution is returned as a set of lists of solved equations of the form

$$[x_1 = \text{value}_1, x_2 = \text{value}_2, \dots]$$

where  $x_1, x_2, \dots$  are the unknowns. These simplified equations should be regarded as constraints on the unknowns. E.g., if an unknown  $x_1$ , say, does not turn up in the form  $x_1 = \dots$  in the solution, then there is no constraint on this unknown and it is an arbitrary parameter. This holds true in general for all unknowns that do not turn up on the left hand side of the solved equations. Cf. "Example 2" on page 18-287.

If no explicit solutions can be computed, expressions of the form

$$\begin{pmatrix} x_1 \\ x_2 \\ \dots \end{pmatrix} \in S \text{ may be returned, where } S \text{ is the solution set.}$$

The ordering of the unknowns in `vars` determines the ordering of the solved equations. If a `setvars` is used, then an internal ordering is used.

# numeric::polysysroots

---

---

**Note** If the solution set of eqs is not finite, then `numeric::polysysroots` may return solutions with some of the unknowns remaining as free parameters. In this case the representation of the solution depends on the ordering of the unknowns! Cf. “Example 3” on page 18-287. Further, if higher degree polynomials are involved, then `numeric::polysysroots` may fail to compute roots. Cf. “Example 5” on page 18-289. The same may happen, when eqs contains symbolic parameters.

---

You may try `numeric::fsolve` to compute a single numerical root, if `numeric::polysysroots` cannot compute all roots of the system. Note, however, that `numeric::fsolve` does not accept symbolic parameters in the equations.

We recommend to use `numeric::polyroots` to compute all roots of a single univariate polynomial with numerical coefficients.

`numeric::polysysroots` is a hybrid routine: it calls the symbolic solver `solve(eqs, vars, BackSubstitution = FALSE)` and processes its symbolic result numerically. Cf. “Example 4” on page 18-288.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

Equations, expressions as well as `DOM_POLY` objects may be used to specify the polynomials:

```
numeric::polysysroots(x^2 = PI^2, x)
```

```
{[x = 3.141592654], [x = -3.141592654]}
```

```
numeric::polysysroots({x^2 + y^2 - 1, x^2 - y^2 = 1/2}, [x, y])
```

```
{[x = 0.8660254038, y = 0.5], [x = 0.8660254038, y = -0.5], [x = -0.8660254038, y = 0.5], [x = -0.8660254038, y = -0.5]}
```

```
numeric::polysysroots({poly(x^2 + y + 1), y^2 + x = 1}, [x, y])
```

```
{[x = -0.4533978515, y = -1.20556943], [x = 0.2266988258 + 1.467711509 i, y = 1.102784715 - 0.6654569512 i], [x = 0, y = -1.0], [x = 0.2266988258 - 1.467711509 i, y = 1.102784715 + 0.6654569512 i]}
```

Symbolic parameters are accepted:

```
numeric::polysysroots(x^2 + y + exp(z), [x, y])
```

```
{[x = sqrt(-1.0 y - 1.0 e^z)], [x = -1.0 sqrt(-1.0 y - 1.0 e^z)]}
```

## Example 2

The returned solutions may contain some of the unknowns remaining as free parameters:

```
numeric::polysysroots({x^2 + y^2 = z}, [x, y, z])
```

```
{[x = sqrt(z - 1.0 y^2)], [x = -1.0 sqrt(z - 1.0 y^2)]}
```

## Example 3

The ordering of the unknowns determines the representation of the solution, if the solution set is not finite. First, the following equation is solved for x leaving y as a free parameter:

```
numeric::polysysroots({x^3 = y^2}, [x, y])
```

# numeric::polysysroots

---

$$\left\{ \left[ x = (y^2)^{1/3} \right], \left[ x = (y^2)^{1/3} (-0.5 + 0.8660254038 i) \right], \left[ x = (y^2)^{1/3} (-0.5 - 0.8660254038 i) \right] \right\}$$

Reordering the unknowns leads to a representation with x as a free parameter:

```
numeric::polysysroots({x^3 = y^2}, [y, x])
```

$$\left\{ \left[ y = \sqrt{x^3} \right], \left[ y = -1.0 \sqrt{x^3} \right] \right\}$$

## Example 4

The symbolic solver produces a RootOf solution of the following system:

```
eqs := {y^2 - y = x, x^3 = y^3 + x}:
solve(eqs, BackSubstitution = FALSE)
```

$$\left( \frac{x}{y} \right) \in \left\{ \left( \frac{0}{0} \right) \right\} \cup \left\{ \left( \frac{y^2 - y}{z_1} \right) \mid z_1 \in \text{RootOf}(z^5 - 3z^4 + 3z^3 - 2z^2 - z + 1, z) \right\}$$

Internally, numeric::polysysroots calls solve and processes this result numerically:

```
numeric::polysysroots(eqs, [x, y])
```

$$\left\{ \left[ x = 2.237302267, y = 2.077118343 \right], \left[ x = -1.445049623 - 0.1279930535 i, y = 0.441542078 + 1.094745154 i \right], \left[ x = 0.8911259621, y = -0.5682349751 \right], \left[ x = -0.2383289841, y = 0.6080324763 \right], \left[ x = -1.445049623 + 0.1279930535 i, y = 0.441542078 - 1.094745154 i \right], \left[ x = 0, y = 0 \right] \right\}$$

```
delete eqs:
```

## Example 5

The following equation is solved for the first of the specified unknowns:

```
eqs := y^5 - PI*y = x:
solve(eqs, [x, y])
```

$$\{[x = z^5 - \pi z, y = z]\}$$

numeric::polysysroots processes this output numerically:

```
numeric::polysysroots(eqs, [x, y])
```

$$\{[x = y^5 - 3.141592654 y]\}$$

The equation is solved for y when the unknowns are reordered. However, no simple representation of the solution exists, so a RootOf object is returned:

```
solve(eqs, [y, x])
```

$$\left(\frac{y}{x}\right) \in \bigcup_{z_2 \in \mathbb{C}} \left\{ \left(\frac{z_1}{z_2}\right) \mid z_1 \in \text{RootOf}(z^5 - \pi z - z_2, z) \right\}$$

The roots represented by the RootOf expression cannot be computed numerically, because the symbolic parameter x is involved:

```
numeric::polysysroots(eqs, [y, x])
```

$$\left(\frac{y}{x}\right) \in \bigcup_{z_2 \in \mathbb{C}} \left\{ \left(\frac{z_1}{z_2}\right) \mid z_1 \in \text{RootOf}(z^5 - \pi z - z_2, z) \right\}$$

# numeric::polysysroots

---

delete eqs:

## Parameters

**eqs**

A polynomial equation or a list, set, array, or matrix (Cat::Matrix) of such equations. Also expressions and polynomials of domain type DOM\_POLY are accepted wherever an equation is expected. They are interpreted as homogeneous equations.

**vars**

An unknown or a list or set of unknowns. Unknowns may be identifiers or indexed identifiers.

## Options

**NoWarning**

By default, the roots are double-checked, automatically. Warnings are issued if a solution seems to be marred by some numerical instability. With this option, this check is suppressed and no warnings will be issued.

## Return Values

a set of lists of equations or an expression of the form  $\left( \begin{matrix} x_1 \\ x_2 \end{matrix} \right) \in S$ , where  $x_1, x_2, \dots$  are the unknowns and  $S$  is the solution set:

The set  $\{\}$  containing an empty list is returned, if no solutions can be computed.

## Purpose

Numerical approximation of products

## Syntax

```
numeric::product(f, i = a .. b)
numeric::product(f, i in RootOf(p, <x>))
numeric::product(f, i = RootOf(p, <x>))
numeric::product(f, i in {x1, x2, ...})
numeric::product(f, i = {x1, x2, ...})
```

## Description

`numeric::product(f, i = a..b)` computes a numerical

approximation of  $\prod_{i=a}^b f(i)$ .

`numeric::product(f, i = RootOf(p,x))` computes a numerical approximation of the product of  $f$  over the roots of the polynomial  $p$ .

`numeric::product(f, i in { x1, x2, ... })` computes a numerical

approximation of  $\prod_{i \in \{x_1, x_2, \dots\}} f(i)$ .

The call `numeric::product(...)` is equivalent to calling the `float` attribute of `product` via `float ( hold( product )(...))`, `float ( freeze( product )(...))` or `product::float(...)`.

If there are other symbolic parameters in  $f$ , apart from the variable  $i$ , a symbolic call to `numeric::product` is returned. Numerical expressions such as  $e^\pi$ ,  $\sqrt{2}$  etc. are accepted and converted to floating-point numbers.

---

**Note** For finite products, `numeric::product` just returns `_mult ( float(f) $ i=a..b)`. Cf. “Example 3” on page 18-293.

---

The call `numeric::product(f, i = { x1, x2, ... })` computes numerical approximations of `x[1]`, `x[2]` etc., substitutes these values into  $f(i)$  and multiplies the results.

The calls `numeric::product(f, i in { x1, x2, ... })` and `numeric::product(f, i = { x1, x2, ... })` are equivalent.

# numeric::product

---

The call `numeric::product (f, i in RootOf(p, x))` computes numerical approximations of all roots of  $p$ , substitutes these values into  $f(i)$  and multiplies the results. Cf. “Example 2” on page 18-293.

The calls `numeric::product(f, i in RootOf(p, x))` and `numeric::product(f, i = RootOf(p, x))` are equivalent.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision and influences the maximum number of steps used in the computation.

## Examples

### Example 1

We demonstrate some equivalent calls for numerical products:

```
numeric::product(1+1/k^2, k = 1..infinity),
float(hold(product)(1+1/k^2, k = 1..infinity)),
float(freeze(product)(1+1/k^2, k = 1..infinity)),
product::float(1+1/k^2, k = 1..infinity);
```

3.67607791, 3.67607791, 3.67607791, 3.67607791

`product` fails to find a closed form for the following product:

```
product(1 - 1/4^k, k = 1..infinity);
```

$$\prod_{k=1}^{\infty} \frac{2^{2k} - 1}{2^{2k}}$$

`float` implicitly uses `numeric::product` to compute a numerical approximation:

```
float(%);
```

0.6885375371

The exact value of the following infinite product is  $e^{(1-\sqrt{2})\zeta(\frac{1}{2})}$ :

```
numeric::product(exp((-1)^(k+1)*k^(-1/2)), k = 1..infinity)
= float(exp((1-sqrt(2))*zeta(1/2)))
```

1.831066609 = 1.831066609

## Example 2

We calculate an approximation of the product over the roots of a polynomial:

```
numeric::product(sin(r), r = RootOf(x^2 - PI^2/4, x))
```

- 1.0

If the polynomial expression contains additional indeterminates, a symbolic call to `numeric::product` is returned:

```
numeric::product(r+PI, r = RootOf(x^8 + c*x - PI^2/4, x))
```

```
numeric::product(r + 3.141592654, r = RootOf(x^8 + c x - 2.4674011, x))
```

## Example 3

`numeric::product` can also be used to compute finite products:

```
numeric::product(1-1/k^2, k = 2..10^n) $ n in { 2, 3, 4 }
```

0.505, 0.5005, 0.50005

# numeric::product

---

However, since `numeric::product` uses `_mult` internally anyway, it is more efficient to call `_mult` directly:

```
_mult(float(1-1/k^2) $ k = 2..10^n) $ n in { 2, 3, 4 }
```

```
0.505, 0.5005, 0.50005
```

## Example 4

The following product is returned symbolically because it contains the additional indeterminate `k`:

```
numeric::product(1-1/n^k, n = 2..infinity)
```

```
numeric::product(1.0 - $\frac{1.0}{n^{1.0 k}}$, n = 2..∞)
```

## Parameters

**f**

An arithmetical expression depending on `i`

**i**

The product index: an identifier or indexed identifier

**a, b**

integers or  $\pm\infty$  satisfying  $a \leq b$

**p**

A univariate polynomial expression in `x`

**x**

Indeterminate

**x<sub>1</sub>, x<sub>2</sub>, ...**

numerical expressions

## Return Values

floating-point number or a symbolic expression of type `numeric::product`.

## Algorithms

Infinite products are calculated by summing the series  $\sum_{i=a}^{\infty} \ln(f)$  via `numeric::sum`.

`numeric::product` uses `numeric::polyroots` to calculate numerical approximations to the roots of a polynomials.

## See Also

## MuPAD Functions

`_mult` | `product` | `numeric::sum` | `numeric::polyroots`

# numeric::quadrature

---

**Purpose** Numerical integration ( Quadrature )

**Syntax** `numeric::quadrature(f(x), x = a .. b, <GaussLegendre = n | GaussTschebyscheff = n | NewtonCotes = n>, <Adaptive = v>, <MaxCalls = m>)`

**Description** `numeric::quadrature(f(x), x = a..b)` computes a numerical approximation of  $\int_a^b f(x) dx$ .

`numeric::quadrature` returns itself symbolically if the integrand  $f(x)$  contains symbolic objects apart from the integration variable  $x$  that cannot be converted to numerical values via `float`. Symbolic objects such as  $\pi$  or  $\sqrt{2}$  etc. are accepted.

The integrand  $f(x)$  should be integrable in the Riemann sense. In particular,  $f(x)$  should be bounded on the integration interval  $x = a..b$ . Certain types of mild singularities are handled, but numerical convergence is not guaranteed and will be slow in most cases. Also discontinuities and singularities of (higher) derivatives of  $f(x)$  slow down numerical convergence. For integrands with irregular points, it is recommended to split the integration into several parts, using subintervals on which the integrand is smooth. Cf. “Example 4” on page 18-301.

Integrands given by user-defined procedures can be handled. See “Example 4” on page 18-301 and “Example 5” on page 18-302.

`numeric::quadrature` returns itself symbolically if the boundaries  $a, b$  contain symbolic objects that cannot be converted to numerical values via `float`. Symbolic objects such as  $\pi$  or  $\sqrt{2}$  etc. as well as `infinity` and `-infinity` are accepted.

---

**Note** For infinite ranges, the user should make sure that the integral

exists! If  $f(x)$  does not decay as fast as  $\mathcal{O}\left(\frac{1}{|x|^2}\right)$  at infinity, then convergence may be slow.

---

Boundaries  $a > b$  are accepted, using  $\int_a^b f(x) dx = - \int_b^a f(x) dx$ .

For complex values of  $a, b$ , the integration is to be understood as a contour integral along a straight line from  $a$  to  $b$ . Complex boundaries must not involve infinity.

Multi-dimensional integration such as

```
numeric::quadrature (numeric::quadrature(f(x,y), y =
A(x)..B(x)), x = a..b)
```

is possible. See “Example 3” on page 18-300 and “Example 5” on page 18-302.

Internally, an adaptive mechanism based on a fixed quadrature rule specified by `method = n` is used. It tries to keep the relative quadrature

error of the result below  $\frac{1}{10^{\text{DIGITS}}}$ . The last digit(s) of the result may be incorrect due to roundoff effects.

The routine `numeric::quadrature` is purely numerical: no symbolic check for singularities etc. is carried out.

## Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

## Examples

### Example 1

We demonstrate the standard calls for adaptive numerical integration:

```
numeric::quadrature(exp(x^2), x = -1..1)
```

```
2.925303492
```

```
numeric::quadrature(max(1/10, cos(PI*x)), x = -2..0.0123)
```

```
0.752102471
```

# numeric::quadrature

---

```
numeric::quadrature(exp(-x^2), x = -2..infinity)
```

```
1.768308316
```

The precision goal is set by DIGITS:

```
DIGITS := 50:
```

```
numeric::quadrature(besselJ(0, x), x = 0..PI)
```

```
1.3475263146739901712314731279612149642205400522774
```

Note that due to the internal adaptive mechanism, the choice of different methods should not have any significant effect on the quadrature result:

```
DIGITS := 10:
```

```
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 5),
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 160),
numeric::quadrature(sin(x)/x, x = -1..10, NewtonCotes = 8)
```

```
2.604430665, 2.604430665, 2.604430665
```

## Example 2

The user should make sure that the integrand is well defined and sufficiently regular. The following fails, because Newton-Cotes quadrature tries to evaluate the integrand at the boundaries:

```
numeric::quadrature(sin(x)/x, x = 0..1, NewtonCotes = 8)
```

```
Error: Division by zero. [_power]
Evaluating: Quadsum
```

One may cure this problem by assigning a value to  $f(0)$ . The integrand is passed to the integrator as `hold(f)` to prevent premature evaluation of  $f(x)$  to  $\sin(x)/x$ . Internally, `numeric::quadrature` replaces  $x$  by numerical values and then evaluates the integrand. Note that one has to define `f(0.0) := 1` rather than `f(0) := 1`:

```
f := x -> sin(x)/x:
f(0.0) := 1:
numeric::quadrature(hold(f)(x), x = 0..1, NewtonCotes = 8)
```

0.9460830704

The default method (Gauss-Legendre quadrature) does not evaluate the integrand at the end points:

```
numeric::quadrature(sin(x)/x, x = 0..1)
```

0.9460830704

Nevertheless, problems may still arise for improper integrals:

```
numeric::quadrature(ln((1 + x^4)^2 - 1), x = 0 .. 1)
```

Warning: Precision goal is not achieved after 10000 function cal

- 3.213735532

In this example, the integrand is evaluated close to 0. The expression  $(1 + x^4)^2 - 1$  suffers from severe numerical cancellation and is dominated by round-off. A numerically stable representation is  $(1 + x^4)^2 - 1 = x^4(x^4 + 2)$ :

# numeric::quadrature

---

```
numeric::quadrature(ln(x^4*(x^4 + 2)), x = 0..1)

-3.218234378
```
