```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Store and examine the full random-effects design matrix.

```
D = full(designMatrix(lme, 'random'));
```

The first three columns of matrix `D` contain the indicator variables `fitlme` creates for the three levels (Loamy, Silty, Sandy, respectively) of the first grouping variable, `Soil`. The next 15 columns contain the indicator variables created for the second grouping variable, `Tomato` nested under `Soil`. These are basically the elementwise products of the dummy variables representing the levels of `Soil` (Loamy, Silty, and Sandy, respectively) and the levels of `Tomato` (Cherry, Grape, Heirloom, Plum, Vine, respectively).

# LinearMixedModel.designMatrix

---

## Subset of the Random-Effects Design Matrix

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. # dfittool

---

**Purpose** Open Distribution Fitting app

**Syntax**

```
dfittool
dfittool(y)
dfittool(y,cens)
dfittool(y,cens,freq)
dfittool(y,cens,freq,dsname)
```

**Description** `dfittool` opens the Distribution Fitting app or brings focus to the app if it is already open. Use the Distribution Fitting app to import data from the workspace, fit distributions to the data, and display the fitted distribution over plots of the empirical distributions.

`dfittool(y)` displays the Distribution Fitting app and creates a data set with data specified by the vector `y`.

`dfittool(y,cens)` uses the vector `cens` to specify whether the observation `y(j)` is censored, (`cens(j)==1`) and/or observed, exactly (`cens(j)==0`). If `cens` is omitted or empty, no `y` values are censored.

`dfittool(y,cens,freq)` uses the vector `freq` to specify the frequency of each element of `y`. If `freq` is omitted or empty, all `y` values have a frequency of 1.

`dfittool(y,cens,freq,dsname)` creates a data set with the name `dsname` using the data vector `y`, censoring indicator `cens`, and frequency vector `freq`.

**See Also** `mle` | `randtool` | `disttool`

**Purpose**

Number of dimensions

**Description**

Number of dimensions in the point set. The `Dimensions` property of a point set contains a positive integer that indicates the number of dimensions for which the points have values. For example, a point set with `Dimensions=5` produces points that each have five values.

Set this property by specifying the number of dimensions when constructing a new point set. After construction, you cannot change the value. The default number of dimensions is 2.

## dataset.DimNames property

---

**Purpose** Two-element cell array of strings giving names of dimensions of data set

**Description** A two-element cell array of strings giving the names of the two dimensions of the data set. The default is {'Observations' 'Variables'}.

**Purpose** Display categorical array

**Syntax** `disp(A)`

**Description** `disp(A)` prints the categorical array `A` without printing the array name. In all other ways it's the same as leaving the semicolon off an expression, except that empty arrays don't display.

**See Also** `categorical` | `display`

# classregtree.disp

---

<b>Purpose</b>	Display classregtree object
<b>Syntax</b>	<code>display(t)</code>
<b>Description</b>	<code>display(t)</code> prints the classregtree object <code>t</code> .
<b>See Also</b>	<code>classregtree</code>   <code>view</code>

<b>Purpose</b>	Display cvpartition object
<b>Syntax</b>	<code>disp(c)</code>
<b>Description</b>	<code>disp(c)</code> prints the cvpartition object <code>c</code> .
<b>See Also</b>	<code>cvpartition</code>

# dataset disp

---

**Purpose** Display dataset array

**Syntax** `disp(ds)`

**Description** `disp(ds)` prints the dataset array `ds`, including variable names and observation names (if present), without printing the dataset name. In all other ways it's the same as leaving the semicolon off an expression.

For numeric or categorical variables that are 2-D and have three or fewer columns, `disp` prints the actual data using either short `g`, long `g`, or bank format, depending on the current command line setting. Otherwise, `disp` prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, `disp` prints quoted strings. Otherwise, `disp` prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, `disp` prints the contents of each cell (or its size and type if too large). Otherwise, `disp` prints the size of each dataset element.

For time series variables, `disp` prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, `disp` prints the actual data. Otherwise, `disp` prints the size and type of each dataset element.

For other types of variables, `disp` prints the size and type of each dataset element.

**See Also** `dataset` | `display` | `format`

**Purpose** Display generalized linear regression model

**Syntax** `disp mdl`

**Description** `disp mdl` displays the `mdl` linear model.

**Input Arguments** **mdl**  
Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

## Examples **Display a Generalized Linear Regression Model**

Create and display a generalized linear regression model.

Create a generalized linear regression model of Poisson data.

```
X = 2 + randn(100,1);  
mu = exp(1 + X/2);  
y = poissrnd(mu);  
mdl = fitglm(X,y,...  
    'y ~ x1','distr','poisson');
```

Display the model.

```
disp(mdl)
```

```
Generalized Linear regression model:
```

```
log(y) ~ 1 + x1  
Distribution = Poisson
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	0.9581	0.090294	10.611	2.6519e-26

# LinearMixedModel.disp

---

**Purpose** Display linear mixed-effects model

**Syntax** `display(lme)`

**Description** `display(lme)` displays the fitted linear mixed-effects model `lme`.

**Input Arguments** **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

**Examples** **Randomized Block Design**

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Display the model.

```
disp(lme)
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	15
Fixed effects coefficients	3
Random effects coefficients	5
Covariance parameters	2

Formula:

```
QCDev ~ 1 + Shift + (1 | Operator)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
59.012	62.552	-24.506	49.012

Fixed effects coefficients (95% CIs):

# LinearMixedModel.disp

---

'Res Std'                    0.76439                    0.49315                    1.1848

This display includes the model performance statistics, Akaike information criterion (AIC), Bayesian information criterion (BIC), loglikelihood, and deviance.

The fixed-effects coefficients table includes the names and estimates of the coefficients in the first two columns. The third column SE shows the standard errors of the coefficients. The column tStat includes the *t*-statistic values that correspond to each coefficient. DF is the residual degrees of freedom, and the pValue is the *p*-value that corresponds to the corresponding *t*-statistic value. The columns Lower and Upper display the lower and upper limits of a 95% confidence interval for each fixed-effects coefficient.

The first table for the random effects shows the types and the estimates of the random effects covariance parameters, with the lower and upper limits of a 95% confidence interval for each parameter. The display also shows the name of the grouping variable, operator, and the total number of levels, 5.

The second table for the random effects shows the estimate of the observation error, with the lower and upper limits of a 95% confidence interval.

## Definitions

### Akaike and Bayesian Information Criteria

Akaike information criterion (AIC) is  $AIC = -2*\log L_M + 2*(nc + p + 1)$ , where  $\log L_M$  is the maximized log likelihood (or maximized restricted log likelihood) of the model, and  $nc + p + 1$  is the number of parameters estimated in the model.  $p$  is the number of fixed-effects coefficients, and  $nc$  is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is  $BIC = -2*\log L_M + \ln(n_{eff})*(nc + p + 1)$ , where  $\log L_M$  is the maximized log likelihood (or maximized restricted log likelihood) of the model,  $n_{eff}$  is the effective number of observations, and  $(nc + p + 1)$  is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then  $n_{eff} = n$ , where  $n$  is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then  $n_{eff} = n - p$ .

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated,  $p$ . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

## Deviance

`LinearMixedModel` computes the deviance of model  $M$  as minus two times the loglikelihood of that model. Let  $L_M$  denote the maximum value of the likelihood function for model  $M$ . Then, the deviance of model  $M$  is

$$-2 * \log L_M.$$

A lower value of deviance indicates a better fit. Suppose  $M_1$  and  $M_2$  are two different models, where  $M_1$  is nested in  $M_2$ . Then, the fit of the models can be assessed by comparing the deviances  $Dev_1$  and  $Dev_2$  of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log LM_2 - \log LM_1).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom  $v$  equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in  $M_1$  and  $M_2$ . You can get the  $p$ -value for this test using `1 - chi2cdf(Dev, V)`, where  $Dev = Dev_2 - Dev_1$ .

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

# LinearMixedModel.disp

---

$H_0: D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}$ ,  $D$  is a  $q$ -by- $q$  symmetric positive semidefinite matrix.  
 $H_1: D$  is a  $(q+1)$ -by- $(q+1)$  symmetric positive semidefinite matrix.

That is,  $H_1$  states that the last row and column of  $D$  are different from zero. Here, the bigger model  $M_2$  has  $q + 1$  parameters and the smaller model  $M_1$  has  $q$  parameters. And  $Dev$  has a 50:50 mixture of  $\chi^2_q$  and  $\chi^2_{(q+1)}$  distributions (Stram and Lee, 1994).

# NonLinearModel.disp

---

**Purpose** Display nonlinear regression model

**Syntax** `disp(md1)`

**Description** `disp(md1)` displays the `md1` nonlinear model at the command line.

**Input Arguments** **md1**  
Nonlinear regression model, constructed by `fitnlm`.

## Examples **Display a Nonlinear Regression Model**

Create and display a nonlinear regression model.

Load the reaction data, and specify both a model function and starting values for the iterations.

```
load reaction
modelfun = 'rate~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
beta0 = [1 .05 .02 .1 2];
```

Create a model of the data.

```
mdl = fitnlm(reactants,rate,modelfun,beta0);
```

Display the model.

```
disp(mdl)
```

```
Nonlinear regression model:
    rate ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. constant model: 1.81e+03, p-value = 7.36e-12

<b>Purpose</b>	Display cvpartition object
<b>Syntax</b>	<code>display(c)</code>
<b>Description</b>	<code>display(c)</code> prints the cvpartition object <code>c</code> . <code>cvpartition</code> calls <code>display</code> when a you do not use a semicolon to terminate a statement.
<b>See Also</b>	<code>cvpartition</code>

# dataset.display

---

**Purpose** Display dataset array

**Syntax** `display(ds)`

**Description** `display(ds)` prints the dataset array `ds`, including variable names and observation names (if present). `dataset` calls `display` when a you do not use a semicolon to terminate a statement

For numeric or categorical variables that are 2-D and have three or fewer columns, `display` prints the actual data. Otherwise, `display` prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, `display` prints quoted strings. Otherwise, `display` prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, `display` prints the contents of each cell (or its size and type if too large). Otherwise, `display` prints the size of each dataset element.

For time series variables, `display` prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, `display` prints the actual data. Otherwise, `display` prints the size and type of each dataset element.

For other types of variables, `display` prints the size and type of each dataset element.

**See Also** `dataset` | `display` | `format`

<b>Purpose</b>	Display Gaussian mixture distribution object
<b>Syntax</b>	<code>display(obj)</code>
<b>Description</b>	<code>display(obj)</code> prints a text representation of the <code>gmdistribution</code> object <code>obj</code> . <code>gmdistribution</code> calls <code>display</code> when a you do not use a semicolon to terminate a statement.

**Description**        `display(nb)` prints a text representation of the NaiveBayes object `nb`. NaiveBayes calls `display` when a you do not use a semicolon to terminate a statement.

**See Also**            NaiveBayes | display

<b>Purpose</b>	Display piecwisedistribution object
<b>Syntax</b>	<code>display(A)</code>
<b>Description</b>	<code>display(A)</code> prints a text representation of the piecwisedistribution object <code>A</code> , without printing the object name. <code>piecwisedistribution</code> calls <code>display</code> when a you do not use a semicolon to terminate a statement.
<b>See Also</b>	<code>piecwisedistribution</code>

# ProbDist.DistName property

---

**Purpose** Read-only string containing probability distribution name of ProbDist object

**Description** DistName is a read-only property of the ProbDist class. DistName is a string containing the type of distribution used to create the object.

**Values** Possible values are:

- 'kernel'
- 'beta'
- 'binomial'
- 'birnbaumsaunders'
- 'exponential'
- 'extreme value'
- 'gamma'
- 'generalized extreme value'
- 'generalized pareto'
- 'inversegaussian'
- 'logistic'
- 'loglogistic'
- 'lognormal'
- 'nakagami'
- 'negative binomial'
- 'normal'
- 'poisson'
- 'rayleigh'
- 'rician'

## ProbDist.DistName property

---

- 'tlocationscale'
- 'weibull'

Use this information to view and compare the type of distribution used to create distribution objects.

# NaiveBayes.Dist property

---

**Purpose** Distribution names

**Description** The `Dist` property is a string or a 1-by-NDims cell array of strings indicating the types of distributions for all the features. If all the features use the same type of distribution, `Dist` is a single string. Otherwise `Dist(j)` indicates the distribution type used for the `j`th feature.

The valid strings for this property are the following:

'normal'	Normal distribution.
'kernel'	Kernel smoothing density estimate.
'mvmn'	Multivariate multinomial distribution.
'mn'	Multinomial bag-of-tokens model.

## gmdistribution.DistName property

---

**Purpose** Type of distribution

**Description** The string 'gaussian mixture distribution'.

# disttool

---

<b>Purpose</b>	Interactive density and distribution plots
<b>Syntax</b>	<code>disttool</code>
<b>Description</b>	<code>disttool</code> is a graphical interface for exploring the effects of changing parameters on the plot of a cdf or pdf.
<b>See Also</b>	<code>randtool</code>   <code>dfittool</code>

**Purpose** Convert categorical array to double array

**Syntax** `B = double(A)`

**Description** `B = double(A)` converts the categorical array `A` to a double array. Each element of `B` contains the internal categorical level code for the corresponding element of `A`.

**See Also** `single`

# dataset.double

---

**Purpose** Convert dataset variables to double array

**Syntax** `b = double(A)`  
`b = double(a,vars)`

**Description** `b = double(A)` returns the contents of the dataset A, converted to one double array. The classes of the variables in the dataset must support the conversion.

`b = double(a,vars)` returns the contents of the dataset variables specified by vars. vars is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

**See Also** `dataset` | `single` | `replacedata`

## Purpose

Drop levels

## Syntax

```
B = droplevels(A)
B = droplevels(A,oldlevels)
```

## Description

`B = droplevels(A)` removes unused levels from the categorical array `A`. `B` is a categorical array with the same size and values as `A`, but with a list of potential levels that includes only those present in some element of `A`.

`B = droplevels(A,oldlevels)` removes specified levels from the categorical array `A`. `oldlevels` is a cell array of strings or a 2-D character matrix specifying the levels to be removed.

`droplevels` removes levels, but does not remove elements. Elements of `B` that correspond to elements of `A` having levels in `oldlevels` all have an undefined level.

## Examples

### Example 1

Drop unused age levels from the data in `hospital.mat`:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','%d'),{'s'});
AgeGroup = ordinal(hospital.Age,labels,[],edges);
AgeGroup = droplevels(AgeGroup);
getlabels(AgeGroup)
ans =
    '20s'    '30s'    '40s'    '50s'
```

### Example 2

- 1 Load patient data from the CSV file `hospital.dat` and store the information in a dataset array with observation names given by the first column in the data (patient identification):

```
patients = dataset('file','hospital.dat',...
                  'delimiter',';',...)
```

## categorical.droplevels

---

```
'ReadObsNames', true);
```

- 2 Make the {0,1}-valued variable `smoke` nominal, and change the labels to 'No' and 'Yes':

```
patients.smoke = nominal(patients.smoke, {'No', 'Yes'});
```

- 3 Add new levels to `smoke` as placeholders for more detailed histories of smokers:

```
patients.smoke = addlevels(patients.smoke, ...  
                           {'0-5 Years', '5-10 Years', 'LongTerm'});
```

- 4 Assuming the nonsmokers have never smoked, relabel the 'No' level:

```
patients.smoke = setlabels(patients.smoke, 'Never', 'No');
```

- 5 Drop the undifferentiated 'Yes' level from `smoke`:

```
patients.smoke = droplevels(patients.smoke, 'Yes');
```

Warning: OLDLEVELS contains categorical levels that were present in A, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.

- 6 Set each smoker to one of the new levels, by observation name:

```
patients.smoke('YPL-320') = '5-10 Years';
```

### See Also

`addlevels` | `getlabels` | `islevel` | `mergelevels` | `reorderlevels`

<b>Purpose</b>	Create dummy variables
<b>Syntax</b>	<code>D = dummyvar(group)</code>
<b>Description</b>	<p><code>D = dummyvar(group)</code> returns a matrix <code>D</code> containing zeros and ones, whose columns are dummy variables for the grouping variable <code>group</code>. Columns of <code>group</code> represent categorical predictor variables, with values indicating categorical levels. Rows of <code>group</code> represent observations across variables.</p> <p><code>group</code> can be a numeric vector or categorical column vector representing levels within a single variable, a cell array containing one or more grouping variables, or a numeric matrix or cell array of categorical column vectors representing levels within multiple variables. If <code>group</code> is a numeric vector or matrix, values in any column must be positive integers in the range from 1 to the number of levels for the corresponding variable. In this case, <code>dummyvars</code> treats each column as a separate numeric grouping variable. With multiple grouping variables, the sets of dummy variable columns are in the same order as the grouping variables in <code>group</code>.</p> <p>The order of the dummy variable columns in <code>D</code> matches the order of the groups defined by <code>group</code>. When <code>group</code> is a categorical vector, the groups and their order match the output of the <code>getlabels(group)</code> method. When <code>group</code> is a numeric vector, <code>dummyvar</code> assumes that the groups and their order are <code>1:max(group)</code>. In this respect, <code>dummyvars</code> treats a numeric grouping variable differently than <code>grp2idx</code>.</p> <p>If <code>group</code> is <math>n</math>-by-<math>p</math>, <code>D</code> is <math>n</math>-by-<math>S</math>, where <math>S</math> is the sum of the number of levels in each of the columns of <code>group</code>. The number of levels <math>s</math> in any column of <code>group</code> is the maximum positive integer in the column or the number of categorical levels. Levels are considered distinct if they appear in different columns of <code>group</code>, even if they have the same value. Columns of <code>D</code> are, from left to right, dummy variables created from the first column of <code>group</code>, followed by dummy variables created from the second column of <code>group</code>, etc.</p> <p><code>dummyvar</code> treats NaN values or undefined categorical levels in <code>group</code> as missing data and returns NaN values in <code>D</code>.</p>

# dummyvar

---

Dummy variables are used in regression analysis and ANOVA to indicate values of categorical predictors.

---

**Note** If a column of 1s is introduced in the matrix  $D$ , the resulting matrix  $X = [\text{ones}(\text{size}(D,1),1) \ D]$  will be rank deficient. The matrix  $D$  itself will be rank deficient if `group` has multiple columns. This is because dummy variables produced from any column of `group` always sum to a column of 1s. Regression and ANOVA calculations often address this issue by eliminating one dummy variable (implicitly setting the coefficients for dropped columns to zero) from each group of dummy variables produced by a column of `group`.

---

## Examples

Suppose you are studying the effects of two machines and three operators on a process. Use `group` to organize predictor data on machine-operator combinations:

```
machine = [1 1 1 1 2 2 2 2]';
operator = [1 2 3 1 2 3 1 2]';
group = [machine operator]
group =
     1     1
     1     2
     1     3
     1     1
     2     2
     2     3
     2     1
     2     2
```

Use `dummyvar` to create dummy variables for a regression or ANOVA calculation:

```
D = dummyvar(group)
D =
     1     0     1     0     0
```

1	0	0	1	0
1	0	0	0	1
1	0	1	0	0
0	1	0	1	0
0	1	0	0	1
0	1	1	0	0
0	1	0	1	0

The first two columns of D represent observations of machine 1 and machine 2, respectively; the remaining columns represent observations of the three operators.

# dwtest

---

## Purpose

Durbin-Watson test

## Syntax

```
p = dwtest(r,x)
p = dwtest(r,x,Name,Value)
[p,dw] = dwtest( ___ )
```

## Description

`p = dwtest(r,x)` returns the  $p$ -value for the Durbin-Watson test of the null hypothesis that the residuals from a linear regression are uncorrelated. The alternative hypothesis is that there is autocorrelation among the residuals.

`p = dwtest(r,x,Name,Value)` returns the  $p$ -value for the Durbin-Watson test with additional options specified by one or more name-value pair arguments. For example, you can conduct a one-sided test or calculate the  $p$ -value using a normal approximation.

`[p,dw] = dwtest( ___ )` also returns the Durbin-Watson test statistic, `dw`, using any of the input arguments from the previous syntaxes.

## Input Arguments

### **x** - Design matrix

matrix

Design matrix for a linear regression, specified as a matrix. Include a column of 1 values in the design matrix so the model contains a constant term.

### **Data Types**

single | double

### **r** - Regression residuals

vector

Regression residuals, specified as a vector. Obtain `r` by performing a linear regression using a function such as `regress`, or by using the backslash operator.

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Tail', 'right', 'Method', 'approximate'` specifies a right-tailed hypothesis test and calculates the  $p$ -value using a normal approximation.

## 'Method' - Computation method for $p$ -value

`'exact'` | `'approximate'`

Computation method for the  $p$ -value, specified as the comma-separated pair consisting of `'Method'` and one of the following.

`'exact'` Calculate an exact  $p$ -value using the Pan algorithm. This is the default if the sample size is less than 400.

`'approximate'` Calculate the  $p$ -value using a normal approximation. This is the default if the sample size is 400 or larger.

**Example:** `'Method', 'exact'`

## 'Tail' - Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

'both'	Test the alternate hypothesis that autocorrelation among the residuals is not zero.
'right'	Test the alternative hypothesis that autocorrelation among the residuals is greater than zero.
'left'	Test the alternative hypothesis that autocorrelation among the residuals is less than zero.

Example: 'Tail', 'right'

## Output Arguments

### **p - p-value**

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

### **dw - Test statistic**

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

## Examples

### **Test Residuals for Correlation**

Load the sample census data.

```
load census;
```

Create a design matrix using the census date (cdate) as the predictor. Add a column of 1 values to include a constant term.

```
n = length(cdate);  
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among the residuals,  $r$ .

```
[p,dw] = dwtest(r,x)
```

```
p =  
    0
```

```
dw =  
    0.1308
```

The returned value  $p = 0$  indicates rejection of the null hypothesis at the 5% significance level.

### One-Sided Hypothesis Test

Load the sample census data.

```
load census;
```

Create a design matrix using the census date (`cdate`) as the predictor. Add a column of 1 values to include a constant term.

```
n = length(cdate);  
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among regression residuals, against the alternative hypothesis that the autocorrelation is greater than zero.

```
[p,dw] = dwtest(r,x,'Tail','right')
```

```
p =  
    0
```

dw =  
0.1308

The returned value  $p = 0$  indicates rejection of the null hypothesis at the 5% significance level, in favor of the alternative hypothesis that the autocorrelation among residuals is greater than zero.

## Definitions **Durbin-Watson Test**

The Durbin-Watson test is used to test if linear regression residuals are uncorrelated, against the alternative that autocorrelation exists.

The test statistic is

$$d = \frac{\sum_{t=2}^T (e_t - e_{t-1})^2}{\sum_{t=1}^T e_t^2},$$

where  $T$  is the number of observations, and  $e_t$  is the residual at time  $t$ .

The  $p$ -value can be calculated exactly using the Pan algorithm. Alternatively, the  $p$ -value can be estimated using a normal approximation. Significantly small  $p$ -values indicate correlation among residuals.

**See Also** regress

**Purpose**

Durbin-Watson test of linear model

**Syntax**

```
P = dwtest mdl
[P,DW] = dwtest mdl
[P,DW] = dwtest mdl,method
[P,DW] = dwtest mdl,method,tail
```

**Description**

`P = dwtest(mdl)` returns the  $p$ -value of the Durbin-Watson test on the `mdl` linear model.

`[P,DW] = dwtest(mdl)` returns the Durbin-Watson statistic.

`[P,DW] = dwtest(mdl,method)` specifies the method `dwtest` uses to compute the  $p$ -value.

`[P,DW] = dwtest(mdl,method,tail)` specifies the alternative hypothesis.

**Input Arguments****mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

**method**

Algorithm for computing the  $p$ -value:

- 'exact' — Calculates an exact  $p$ -value using Pan's algorithm.
- 'approximate' — Calculates the  $p$ -value using a normal approximation.

**Default:** 'exact' when the sample size is less than 400, 'approximate' otherwise

**tail**

`dwtest` tests whether `mdl` has no serial correlation against one of these alternative hypotheses:

# LinearModel.dwtest

---

Tail	Alternative Hypothesis
'both'	Serial correlation is not 0.
'right'	Serial correlation is greater than 0 (right-tailed test).
'left'	Serial correlation is less than 0 (left-tailed test).

**Default:** 'both'

## Output Arguments

**P**

*p*-value of the test, a scalar. `dwtest` tests if the residuals are uncorrelated, against the alternative that there is autocorrelation among them. Small values of **P** indicate that the residuals are correlated.

**DW**

Value of the Durbin-Watson statistic, a scalar.

## Definitions

### Durbin-Watson Statistic

Let  $r$  be the vector of residuals (in `mdl.residuals.response`). The Durbin-Watson statistic is

$$DW = \frac{\sum_{i=1}^{n-1} (r_{i+1} - r_i)^2}{\sum_{i=1}^n r_i^2}.$$

## Examples

### Test Residuals for Autocorrelation

Examine whether the residuals from a fitted model of census data over time have autocorrelated residuals.

Load the census data and create a linear model.

```
load census
mdl = fitlm(cdate,pop);
```

Find the  $p$ -value of the Durbin-Watson autocorrelation test.

```
P = dwtest(mdl)
```

```
P =
```

```
0
```

There is significant autocorrelation in the residuals.

## Algorithms

Approximate calculation of the  $p$ -value uses a normal approximation [1]. Exact calculation uses Pan's algorithm [2].

## How To

- “Linear Regression” on page 9-12

**Purpose** Empirical cumulative distribution function

**Syntax**  
`[f,x] = ecdf(y)`  
`[f,x] = ecdf(y,Name,Value)`  
`[f,x,flo,fup] = ecdf( ___ )`

`ecdf( ___ )`  
`ecdf(ax, ___ )`

**Description** `[f,x] = ecdf(y)` returns the empirical cumulative distribution function (cdf), `f`, evaluated at the points in `x`, using the data in the vector `y`.

In survival and reliability analysis, this empirical cdf is called the Kaplan-Meier estimate. And the data might correspond to survival or failure times.

`[f,x] = ecdf(y,Name,Value)` returns the empirical function values, `f`, evaluated at the points in `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the type of function to evaluate or which data is censored.

`[f,x,flo,fup] = ecdf( ___ )` also returns the 95% lower and upper confidence bounds for the evaluated function values. You can use any of the input arguments in the previous syntaxes.

`ecdf` computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

`ecdf( ___ )` plots the evaluated function.

`ecdf(ax, ___ )` plots the evaluated function using axes with the handle, `ax`, instead of the current axes returned by `gca`.

## Input Arguments

### **y - Input data**

column vector

Input data, specified as a column vector. For example, in survival or reliability analysis, data might be survival or failure times for each item or individual.

### **Data Types**

single | double

### **ax - Axes handle**

handle

Axes handle for the figure ecdf plots to, specified as a handle.

For instance, if `h` is a handle for a figure, then `ecdf` can plot to that figure as follows.

**Example:** `ecdf(h,x)`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'censoring',c,'function','cumulative hazard','alpha',0.025,'bounds','on'` specifies that `ecdf` returns the cumulative hazard function and plots the 97.5% confidence bounds, accounting for the censored data specified by vector `c`.

### **'censoring' - Indicator of censored data**

array of 0s (default) | vector of 0s and 1s

Indicator of censored data, specified as the comma-separated pair including `'censoring'` and a Boolean array of the same size as `x`. Enter 1 for observations that are right-censored and 0 for observations that are fully observed. Default is all observations are fully observed.

For instance, if vector `cdata` stores the censored data information, you can enter the censoring information as follows.

**Example:** `'censoring',cdata`

### **Data Types**

logical

### **'frequency' - Frequency of observations**

array of 1s (default) | vector of nonnegative scalars

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and a vector containing nonnegative integer counts. This vector is the same size as the vector `x`. The  $j$ th element of this vector gives the number of times the  $j$ th element of `x` was observed. Default is one observation per element of `x`.

For instance, if `failurefreq` is a vector of frequencies, then you can enter it as follows.

**Example:** `'frequency',failurefreq`

### **Data Types**

single | double

### **'alpha' - Confidence level**

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of the evaluated function, specified as the comma-separated pair consisting of `'alpha'` and a scalar value between in the range (0,1). Default is 0.05 for 95% confidence. For a given value `alpha`, the confidence level is  $100(1 - \alpha)\%$ .

For instance, for a 99% confidence interval, you can specify the `alpha` value as follows.

**Example:** `'alpha',0.01`

### **Data Types**

single | double

### **'function' - Type of function returned**

'cdf' (default) | 'survivor' | 'cumulative hazard'

Type of function that `ecdf` evaluates and returns, specified as the comma-separated pair consisting of 'function' and one of the following.

'cdf'	Default. Cumulative distribution function.
'survivor'	Survivor function.
'cumulative hazard'	Cumulative hazard function.

**Example:** 'function', 'cumulative hazard'

### Data Types

char

### 'bounds' - Indicator for including bounds

'off' (default) | 'on'

Indicator for including bounds, specified as the comma-separated pair consisting of 'bounds' and one of the following.

'off'	Default. Specify to omit bounds.
'on'	Specify to include bounds.

---

**Note** This name-value argument is used only for plotting.

---

**Example:** 'bounds', 'on'

### Data Types

char

## Output Arguments

### **f** - Function values

column vector

Function values evaluated at the points in **x**, returned as a column vector.

### **x** - Distinct observed points

column vector

Distinct observed points in data vector **y**, returned as a column vector.

### **flo** - Lower confidence bound

column vector

Lower confidence bound for the evaluated function, returned as a column vector. `ecdf` computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

### **fup** - Upper confidence bound

column vector

Upper confidence bound for the evaluated function, returned as a column vector. `ecdf` computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

## Examples

### **Compute Empirical Cumulative Distribution Function**

Compute the Kaplan-Meier estimate of the cumulative distribution function (cdf) for simulated survival data.

Generate survival data from a Weibull distribution with parameters 3 and 1.

```
rng('default') % for reproducibility
failuretime = random('wbl',3,1,15,1);
```

Compute the Kaplan-Meier estimate of the cdf for survival data.

```
[f,x] = ecdf(failuretime);
```

```
[f,x]
```

```
ans =
```

0	0.0895
0.0667	0.0895
0.1333	0.1072
0.2000	0.1303
0.2667	0.1313
0.3333	0.2718
0.4000	0.2968
0.4667	0.6147
0.5333	0.6684
0.6000	1.3749
0.6667	1.8106
0.7333	2.1685
0.8000	3.8350
0.8667	5.5428
0.9333	6.1910
1.0000	6.9825

Plot the estimated cdf.

```
figure()  
plot(x,f)
```

## Empirical Hazard Function of Right-Censored Data

Compute and plot the hazard function of simulated right-censored survival data.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng('default') % for reproducibility  
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

---

Assuming that the end of the study is at time 0.9, generate a logical array that indicates simulated failure times that are larger than 0.9 as censored data, and store this information in a vector.

```
T = 0.9;  
cens = (failuretime>T);
```

Plot the empirical hazard function for the data.

```
ecdf(failuretime,'function','cumulative hazard',...  
'censoring',cens,'bounds','on');
```

## Compare Empirical Cumulative Distribution Function (CDF) with Known CDF

Generate right-censored survival data and compare the empirical cumulative distribution function (cdf) with the known cdf.

Generate failure times from an exponential distribution with mean failure time of 15.

```
rng('default')  
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.

```
d = exprnd(30,75,1);
```

Generate the observed failure times. They are the minimum of the generated failure times and the drop-out times.

```
t = min(y,d);
```

Create a logical array that indicates generated failure times that are larger than the drop-out times. The data for which this is true are censored.

```
censored = (y>d);
```

Compute the empirical cdf and confidence bounds.

```
[f,x,flo,fup] = ecdf(t,'censoring',censored);
```

Plot the cdf and confidence bounds.

```
figure()  
ecdf(t,'censoring',censored,'bounds','on');  
hold on
```

Superimpose a plot of the known population cdf.

```
xx = 0:.1:max(t);  
yy = 1-exp(-xx/15);  
plot(xx,yy,'g-','LineWidth',2)  
axis([0 50 0 1])  
legend('Empirical','LCB','UCB','Population',...  
       'Location','SE')  
hold off
```

## Empirical Survivor Function with 99% Confidence Bounds

Generate survival data and plot the empirical survivor function with 99% confidence bounds.

Generate lifetime data from a Weibull distribution with parameters 100 and 2.

```
rng('default') % for reproducibility  
R = wblrnd(100,2,100,1);
```

Plot the survivor function for the data with 99% confidence bounds.

```
ecdf(R, 'function', 'survivor', 'alpha', 0.01, 'bounds', 'on')  
hold on
```

Fit the Weibull survivor function.

```
x = 1:1:250;  
wblsurv = 1-cdf('weibull',x,100,2);  
plot(x,wblsurv,'g-', 'LineWidth',2)  
legend('Empirical','LCB','UCB','Population',...  
      'Location','NE')
```

The survivor function based on the actual distribution is within the confidence bounds.

## Definitions

### Greenwood's Formula

Approximation for the variance of Kaplan-Meier estimator.

The variance estimate is given by

$$V(S(t)) = S^2(t) \sum_{t_i < T} \frac{d_i}{r_i(r_i - d_i)},$$

where  $r_i$  is the number at risk at time  $t_i$ , and  $d_i$  is the number of failures at time  $t_i$ .

`cdfplot` | `ecdfhist`

# ecdfhist

---

**Purpose** Histogram based on empirical cumulative distribution function

**Syntax** `[n,c] = ecdfhist(f,x)`  
`[n,c] = ecdfhist(f,x,m)`

`n = ecdfhist(f,x,centers)`

`ecdfhist( ___ )`

**Description** `[n,c] = ecdfhist(f,x)` returns the heights, `n`, of histogram bars for 10 equally spaced bins and the position of the bin centers, `c`.

`ecdfhist` computes the bar heights from the increases in the empirical cumulative distribution function, `f`, at evaluation points, `x`. It normalizes the bar heights so that the area of the histogram is equal to 1. In contrast, `hist` produces bars with heights representing bin counts.

`[n,c] = ecdfhist(f,x,m)` returns the histogram bars using `m` bins.

`n = ecdfhist(f,x,centers)` returns the heights of the histogram bars with bin centers specified by `centers`.

`ecdfhist( ___ )` plots the histogram bars.

## Input Arguments

### **f** - Empirical cdf values

vector

Empirical cdf values at given evaluation points, `x`, specified as a vector.

For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

**Example:** `[f,x] = ecdf(failure); ecdfhist(f,x);`

### **Data Types**

single | double

**x - Evaluation points**

vector

Evaluation points at which empirical cdf values, `f`, are calculated, specified as a vector.

For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

**Example:** `[f,x] = ecdf(failure); ecdfhist(f,x);`

**Data Types**

single | double

**m - Number of bins**

scalar

Number of bins, specified as a scalar.

For instance, you can draw a histogram with 8 bins as follows.

**Example:** `ecdfhist(f,x,8)`

**Data Types**

single | double

**centers - Center points of bins**

vector

Center points of bins, specified as a vector.

**Example:** `centers = 2:2:10; ecdfhist(f,x,centers);`

**Data Types**

single | double

**Output Arguments****n - Heights of histogram bars**

row vector

Heights of histogram bars `ecdfhist` calculates based on the empirical cdf values, returned as a row vector.

**c - Position of bin centers**

row vector

Position of bin centers, returned as a row vector.

## Examples

### Return Histogram Bar Heights and Bin Centers

Compute the histogram bar heights based on the empirical cumulative distribution function.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```
T = 0.9;
cens = (failuretime>T);
```

Compute the empirical cumulative distribution function for the data.

```
[f,x] = ecdf(failuretime,'censoring',cens);
```

Now, find the bar heights of the histogram using the cumulative distribution function estimate.

```
n = ecdfhist(f,x);
[n' c']
```

```
ans =
```

```
2.3529    0.0715
1.7647    0.1565
1.4117    0.2415
1.5294    0.3265
1.0588    0.4115
0.4706    0.4965
```

```

0.4706    0.5815
0.9412    0.6665
0.2353    0.7515
0.2353    0.8365

```

### Return Bar Heights and Bin Centers for a Given Number of Bins

Compute the bar heights for six bins using the empirical cumulative distribution function and also return the bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

```

rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);

```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```

T = 0.9;
cens = (failuretime>T);

```

First, compute the empirical cumulative distribution function for the data.

```

[f,x] = ecdf(failuretime,'censoring',cens);

```

Now, estimate the histogram with six bins using the cumulative distribution function estimate.

```

[n,c] = ecdfhist(f,x,6);
[n' c']

```

```

ans =

```

```

1.9764    0.0998
1.7647    0.2415
1.1294    0.3831

```

```
0.4235    0.5248
0.7764    0.6665
0.2118    0.8081
```

## Draw Histogram for Given Bin Centers

Draw the histogram of the empirical cumulative distribution histogram for specified bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```
T = 0.9;
cens = (failuretime>T);
```

Define bin centers.

```
centers = 0.1:0.1:1;
```

Compute the empirical cumulative distribution function for the data and draw the histogram for specified bin centers.

```
[f,x] = ecdf(failuretime,'censoring',cens);
ecdfhist(f,x,centers)
axis([0 1 0 2.5])
```

### Compare Histogram with Known Probability Distribution Function

Generate right-censored survival data and compare the histogram from cumulative distribution function with the known probability distribution function.

Generate failure times from an exponential distribution with mean failure time of 15.

```
rng('default')  
y = exprnd(15,75,1);
```

## ecdfhist

---

Generate drop-out times from an exponential distribution with mean failure time of 30.

```
d = exprnd(30,75,1);
```

Record the minimum of these times as the observed failure times.

```
t = min(y,d);
```

Generate censoring by finding the generated failure times that are greater than the drop-out times.

```
censored = (y>d);
```

Calculate the empirical cdf and plot a histogram using the empirical cumulative distribution function.

```
[f,x] = ecdf(t,'censoring',censored);  
ecdfhist(f,x)  
set(get(gca,'Children'),'FaceColor',[.8 .8 1])  
hold on
```

Superimpose a plot of the known population pdf.

```
xx = 0:.1:max(t);  
yy = exp(-xx/15)/15;  
plot(xx,yy,'r-','LineWidth',2)  
hold off
```

# ClassificationKNN.edge

---

<b>Purpose</b>	Edge of $k$ -nearest neighbor classifier
<b>Syntax</b>	<code>E = edge(md1,X,Y)</code> <code>E = edge(md1,X,Y,Name,Value)</code>
<b>Description</b>	<code>E = edge(md1,X,Y)</code> returns the classification edge for <code>md1</code> with data <code>X</code> and classification <code>Y</code> . <code>E = edge(md1,X,Y,Name,Value)</code> computes the edge with additional options specified by one or more <code>Name,Value</code> pair arguments.
<b>Input Arguments</b>	<b>md1</b> <i>k</i> -nearest neighbor classifier, created by <code>ClassificationKNN.fit</code> . <b>X</b> Matrix of predictor values. Each column of <code>X</code> represents one variable, and each row represents one observation. <b>Y</b> A numeric vector, vector of categorical variables (nominal or ordinal), logical vector, character array, or cell array of strings, with the same number of rows as <code>X</code> . Each row of <code>Y</code> represents the classification of the corresponding row of <code>X</code> . <b>Name-Value Pair Arguments</b> Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code> . <b>'weights'</b> Observation weights, a numeric vector of length <code>size(X,1)</code> . If you supply <code>weights</code> , <code>edge</code> computes weighted classification edge. <b>Default:</b> <code>ones(size(X,1))</code>

## Output Arguments

**E**

Classification edge, a scalar that is the mean classification margin (see “Margin” on page 21-757).

## Definitions

### Edge

The *edge* is the mean value of the classification *margin*.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

Margin is a column vector with the same number of rows as *X*.

### Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-2608.

## Examples

### Edge Calculation

Construct a *k*-nearest neighbor classifier for the Fisher iris data, where *k* = 5.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for five-nearest neighbors.

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5);
```

# ClassificationKNN.edge

---

Examine the edge of the classifier for minimum, mean, and maximum observations classified 'setosa', 'versicolor', and 'virginica' respectively.

```
NewX = [min(X);mean(X);max(X)];  
Y = {'setosa';'versicolor';'virginica'};  
E = edge mdl,NewX,Y
```

```
E =
```

```
1
```

The classifier has no doubt that the Y entries are correct classifications (all five nearest neighbors of each NewX point classify as the corresponding Y entry).

## Concepts

- “Classification Using Nearest Neighbors” on page 16-9

## Purpose

Classification edge

## Syntax

`E = edge(obj,X,Y)`  
`E = edge(obj,X,Y,Name,Value)`

## Description

`E = edge(obj,X,Y)` returns the classification edge for `obj` with data `X` and classification `Y`.

`E = edge(obj,X,Y,Name,Value)` computes the edge with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **obj**

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `ClassificationDiscriminant.fit`.

### **X**

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

### **Y**

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'weights'**

Observation weights, a numeric vector of length `size(X,1)`. If you supply weights, `edge` computes the weighted classification edge.

# CompactClassificationDiscriminant.edge

---

**Default:** ones(size(X,1))

## Output Arguments

**E**

Edge, a scalar representing the weighted average value of the margin.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are the class probabilities in `Obj.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.

### Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

## Examples

Compute the classification edge and margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = ClassificationDiscriminant.fit(X,species);
E = edge(obj,X,species)
```

```
E =
    0.4980
```

```
M = margin(obj,X,species);  
M(end-10:end)
```

```
ans =  
    0.6551  
    0.4838  
    0.6551  
   -0.5127  
    0.5659  
    0.4611  
    0.4949  
    0.1024  
    0.2787  
   -0.1439  
   -0.4444
```

The classifier trained on all the data is better:

```
obj = ClassificationDiscriminant.fit(meas,species);  
E = edge(obj,meas,species)
```

```
E =  
    0.9454
```

```
M = margin(obj,meas,species);  
M(end-10:end)
```

```
ans =  
    0.9983  
    1.0000  
    0.9991  
    0.9978  
    1.0000  
    1.0000  
    0.9999  
    0.9882
```

# CompactClassificationDiscriminant.edge

ClassificationDiscriminant | loss | margin | predict

## How To

- “Discriminant Analysis” on page 15-3

## Purpose

Classification edge

## Syntax

```
E = edge(ens,X,Y)
E = edge(ens,X,Y,Name,Value)
```

## Description

`E = edge(ens,X,Y)` returns the classification edge for `ens` with data `X` and classification `Y`.

`E = edge(ens,X,Y,Name,Value)` computes the edge with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A classification ensemble constructed with `fitensemble`, or a compact classification ensemble constructed with `compact`.

### **X**

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `ens`.

### **Y**

Class labels, with the same data type as exists in `ens`. The number of elements of `Y` must equal the number of rows of `X`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `ens.NTrained`. `edge` uses only these learners for calculating loss.

**Default:** 1:NTrained

# CompactClassificationEnsemble.edge

---

## 'mode'

String representing the meaning of the output E:

- 'ensemble' — E is a scalar value, the edge for the entire ensemble.
- 'individual' — E is a vector with one element per trained learner.
- 'cumulative' — E is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## 'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in `ens`.

When `UseObsForLearner(i,j)` is true, learner j is used in predicting the class of row i of X.

**Default:** `true(N,T)`

## 'weights'

Observation weights, a numeric vector of length `size(X,1)`. If you supply weights, `edge` computes weighted classification edge.

**Default:** `ones(size(X,1))`

## Output Arguments

### E

The classification edge, a vector or scalar depending on the setting of the mode name-value pair. Classification edge is weighted average classification margin.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix  $X$ .

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`. If you supply weights in the `weights` name-value pair, those weights are used instead of class probabilities.

## Examples

Make a boosted ensemble classifier for the `ionosphere` data, and find the classification edge for the last few rows:

```
load ionosphere
ens = fitensemble(X,Y,'AdaboostM1',100,'Tree');
E = edge(ens,X(end-10:end,:),Y(end-10:end))
```

```
E =
    8.3310
```

## See Also

`margin` | `edge`

# CompactClassificationTree.edge

---

<b>Purpose</b>	Classification edge
<b>Syntax</b>	<code>E = edge(tree,X,Y)</code> <code>E = edge(tree,X,Y,Name,Value)</code>
<b>Description</b>	<code>E = edge(tree,X,Y)</code> returns the classification edge for <code>tree</code> with data <code>X</code> and classification <code>Y</code> . <code>E = edge(tree,X,Y,Name,Value)</code> computes the edge with additional options specified by one or more <code>Name,Value</code> pair arguments.
<b>Input Arguments</b>	<b>tree</b> A classification tree created by <code>ClassificationTree.fit</code> , or a compact classification tree created by <code>compact</code> . <b>X</b> A matrix where each row represents an observation, and each column represents a predictor. The number of columns in <code>X</code> must equal the number of predictors in <code>tree</code> . <b>Y</b> Class labels, with the same data type as exists in <code>tree</code> . The number of elements of <code>Y</code> must equal the number of rows of <code>X</code> . <b>Name-Value Pair Arguments</b> Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code> . <b>'weights'</b> Observation weights, a numeric vector of length <code>size(X,1)</code> . If you supply <code>weights</code> , <code>edge</code> computes weighted classification edge. <b>Default:</b> <code>ones(size(X,1))</code>

## Output Arguments

**E**

The edge, a scalar representing the weighted average value of the margin.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as the matrix  $X$ .

### Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

**1**

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

# CompactClassificationTree.edge

**2**

Prune the tree:

```
tree1 = prune(tree, 'level', 1);
view(tree1, 'mode', 'graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

### 3

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
```

# CompactClassificationTree.edge

---

```
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range (.95, 1) instead of the expected 5 observations.

## Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

## Examples

Compute the classification margin and edge for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
tree = ClassificationTree.fit(X,species);
E = edge(tree,X,species)

E =
    0.6299

M = margin(tree,X,species);
M(end-10:end)

ans =
    0.1111
    0.1111
    0.1111
   -0.2857
```

```
0.6364
0.6364
0.1111
0.7500
1.0000
0.6364
0.2000
```

The classification tree trained on all the data is better:

```
tree = ClassificationTree.fit(meas,species);
E = edge(tree,meas,species)
```

```
E =
    0.9384
```

```
M = margin(tree,meas,species);
M(end-10:end)
```

```
ans =
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
```

# grandset.end

---

**Purpose** Last index in indexing expression for point set

**Syntax** `end(p,k,n)`

**Description** `end(p,k,n)` is called for indexing expressions involving the point set `p` when `end` is part of the `k`-th index out of `n` indices. For example, the expression `p(end-1,:)` calls `p`'s `end` method with `end(p,1,2)`.

**See Also** `grandset`

## Purpose

Extreme value cumulative distribution function

## Syntax

```
p = evcdf(x,mu,sigma)
[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = evcdf( __ , 'upper' )
```

## Description

`p = evcdf(x,mu,sigma)` returns the cumulative distribution function (cdf) for the type 1 extreme value distribution, with location parameter `mu` and scale parameter `sigma`, at each of the values in `x`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is a 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1 - `alpha`)% confidence bounds. `plo` and `pup` are arrays of the same size as `p`, containing the lower and upper confidence bounds.

`[p,plo,pup] = evcdf( __ , 'upper' )` returns the complement of the type 1 extreme value distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The function `evcdf` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\frac{X - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `P`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating  $X$ . See “Extreme Value Distribution” on page B-35 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

## How To

- “Extreme Value Distribution” on page B-35

**Purpose**

Extreme value parameter estimates

**Syntax**

```
parmhat = evfit(data)
[parmhat,parmci] = evfit(data)
[parmhat,parmci] = evfit(data,alpha)
[...] = evfit(data,alpha,censoring)
[...] = evfit(data,alpha,censoring,freq)
[...] = evfit(data,alpha,censoring,freq,options)
```

**Description**

`parmhat = evfit(data)` returns maximum likelihood estimates of the parameters of the type 1 extreme value distribution given the data in the vector `data`. `parmhat(1)` is the location parameter,  $\mu$ , and `parmhat(2)` is the scale parameter,  $\sigma$ .

`[parmhat,parmci] = evfit(data)` returns 95% confidence intervals for the parameter estimates on the  $\mu$  and  $\sigma$  parameters in the 2-by-2 matrix `parmci`. The first column of the matrix of the extreme value fit contains the lower and upper confidence bounds for the parameter  $\mu$ , and the second column contains the confidence bounds for the parameter  $\sigma$ .

`[parmhat,parmci] = evfit(data,alpha)` returns  $100(1 - \text{alpha})\%$  confidence intervals for the parameter estimates, where `alpha` is a value in the range  $[0 \ 1]$  specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = evfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = evfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = evfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood

estimates. You can create options using the function `statset`. Enter `statset('evfit')` to see the names and default values of the parameters that `evfit` accepts in the options structure. See the reference page for `statset` for more information about these options.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating  $x$ . See “Extreme Value Distribution” on page B-35 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

## How To

- “Extreme Value Distribution” on page B-35

**Purpose**

Extreme value inverse cumulative distribution function

**Syntax**

`X = evinv(P,mu,sigma)`  
`[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)`

**Description**

`X = evinv(P,mu,sigma)` returns the inverse cumulative distribution function (cdf) for a type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`, evaluated at the values in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)` produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` is a scalar that specifies  $100(1 - \alpha)\%$  confidence bounds for the estimated parameters, and has a default value of 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `evinv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where  $q$  is the  $P$ th quantile from an extreme value distribution with parameters  $\mu = 0$  and  $\sigma = 1$ . The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `X`. See “Extreme Value Distribution” on page B-35 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

`icdf` | `evcdf` | `evpdf` | `evstat` | `evfit` | `evlike` | `evrnd`

**Purpose** Test handle equality

**Syntax**  
`h1 == h2`  
`tf = eq(h1, h2)`

**Description** `h1 == h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise equality result. If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = eq(h1, h2)` stores the result in a logical array of the same dimensions.

# CompactTreeBagger.error

---

**Purpose** Error (misclassification probability or MSE)

**Syntax**  
`err = error(B,X,Y)`  
`err = error(B,X,Y, 'param1',val1, 'param2',val2, ...)`

**Description** `err = error(B,X,Y)` computes the misclassification probability (for classification trees) or mean squared error (MSE, for regression trees) for each tree, for predictors `X` given true response `Y`. For classification, `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. For regression, `Y` must be a numeric vector. `err` is a vector with one error measure for each of the `NTrees` trees in the ensemble `B`.

`err = error(B,X,Y, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

`'mode'` String indicating how the method computes errors. If set to `'cumulative'` (default), error computes cumulative errors and `err` is a vector of length `NTrees`, where the first element gives error from `trees(1)`, second element gives error from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `err` is a vector of length `NTrees`, where each element is an error from each tree in the ensemble. If set to `'ensemble'`, `err` is a scalar showing the cumulative error for the entire ensemble.

`'trees'` Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes, where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

- 'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
- 'useifort' Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`CompactTreeBagger.error`

# classregtree.eval

---

**Purpose** Predicted responses

**Syntax**

```
yfit = eval(t,X)
yfit = eval(t,X,s)
[yfit,nodes] = eval(...)
[yfit,nodes,cnums] = eval(...)
[...] = t(X)
[...] = t(X,s)
```

**Description** `yfit = eval(t,X)` takes a classification or regression tree `t` and a matrix `X` of predictors, and produces a vector `yfit` of predicted response values. For a regression tree, `yfit(i)` is the fitted response value for a point having the predictor values `X(i,:)`. For a classification tree, `yfit(i)` is the class into which the tree assigns the point with data `X(i,:)`.

`yfit = eval(t,X,s)` takes an additional vector `s` of pruning levels, with 0 representing the full, unpruned tree. `t` must include a pruning sequence as created by `classregtree` or by `prune`. If `s` has  $k$  elements and `X` has  $n$  rows, the output `yfit` is an  $n$ -by- $k$  matrix, with the  $j$ th column containing the fitted values produced by the `s(j)` subtree. `s` must be sorted in ascending order.

To compute fitted values for a tree that is not part of the optimal pruning sequence, first use `prune` to prune the tree.

`[yfit,nodes] = eval(...)` also returns a vector `nodes` the same size as `yfit` containing the node number assigned to each row of `X`. Use `view` to display the node numbers for any node you select.

`[yfit,nodes,cnums] = eval(...)` is valid only for classification trees. It returns a vector `cnum` containing the predicted class numbers.

NaN values in `X` are treated as missing. If `eval` encounters a missing value when it attempts to evaluate the split rule at a branch node, it cannot determine whether to proceed to the left or right child node. Instead, it sets the corresponding fitted value equal to the fitted value assigned to the branch node.

`[...] = t(X)` or `[...] = t(X,s)` also invoke `eval`.

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```

# classregtree.eval

Click to display:  Magnification:  Pruning level:

Find assigned class names:

```
sfit = eval(t,meas);
```

Compute that proportion is correctly classified:

```
pct = mean(strcmp(sfit,species))  
pct =  
    0.9800
```

# evalclusters

---

## Purpose

Evaluate clustering solutions

## Syntax

```
eva = evalclusters(x,clust,criterion)
eva = evalclusters(x,clust,criterion,Name,Value)
```

## Description

`eva = evalclusters(x,clust,criterion)` creates a clustering evaluation object containing data used to evaluate the optimal number of data clusters.

`eva = evalclusters(x,clust,criterion,Name,Value)` creates a clustering evaluation object using additional options specified by one or more name-value pair arguments.

## Input Arguments

### **x - Input data**

matrix

Input data, specified as an  $N$ -by- $P$  matrix.  $N$  is the number of observations, and  $P$  is the number of variables.

### **Data Types**

single | double

### **clust - Clustering algorithm**

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with <code>'EmptyAction'</code> set to <code>'singleton'</code> and <code>'Replicates'</code> set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with <code>'Linkage'</code> set to <code>'ward'</code> .
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with <code>'SharedCov'</code> set to <code>true</code> and <code>'Replicates'</code> set to 5.

If `Criterion` is `'CalinskHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can specify a clustering algorithm using the `function_handle` (`@`) operator. The function must be of the form

```
C = clustfun(DATA,K)
```

where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric  $n$ -by- $K$  matrix of score for  $n$  observations and  $K$  classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `Criterion` is `'CalinskHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a  $n$ -by- $K$  matrix containing the proposed clustering solutions.  $n$  is the number of observations in the sample data, and  $K$  is the number of proposed clustering solutions. Column  $j$  contains the cluster indices for each of the  $N$  points in the  $j$ th clustering solution.

### **criterion - Clustering evaluation criterion**

```
'CalinskiHarabasz' | 'DaviesBouldin' | 'gap' | 'silhouette'
```

Clustering evaluation criterion, specified as one of the following.

'CalinskiHarabasz'	Create a <code>CalinskiHarabaszEvaluation</code> clustering evaluation object containing Calinski-Harabasz index values.
'DaviesBouldin'	Create a <code>DaviesBouldinEvaluation</code> cluster evaluation object containing Davies-Bouldin index values.
'gap'	Create a <code>GapEvaluation</code> cluster evaluation object containing gap criterion values.
'silhouette'	Create a <code>SilhouetteEvaluation</code> cluster evaluation object containing silhouette values.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'KList', [1:5], 'Distance', 'cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

## For All Criteria

### 'KList' - List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name string

or a function handle. When `criterion` is 'gap', `clust` must be a string or a function handle, and you must specify `KList`.

**Example:** 'KList',[1:6]

## For Silhouette and Gap

### 'Distance' - Distance metric

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

'sqEuclidean'	Squared Euclidean distance
'Euclidean'	Euclidean distance
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)
'Hamming'	Percentage of coordinates that differ
'Jaccard'	Percentage of nonzero coordinates that differ

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (@) operator. The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by- $n$  vector corresponding to a single row of the input matrix `X`, and `XJ` is an  $m_2$ -by- $n$  matrix corresponding to multiple rows of

X. `distfun` must return an  $m_2$ -by-1 vector of distances `d2`, whose  $k$ th element is the distance between `XI` and `XJ(k, :)`.

If `Criterion` is `'silhouette'`, you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.
- If `Clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

**Example:** `'Distance', 'Euclidean'`

## For Silhouette Only

### **'ClusterPriors' - Prior probabilities for each cluster**

`'empirical'` (default) | `'equal'`

Prior probabilities for each cluster, specified as the comma-separated pair consisting of `'ClusterPriors'` and one of the following.

'empirical'	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.
'equal'	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.

**Example:** 'ClusterPriors', 'empirical'

### For Gap Only

#### 'B' - Number of reference data sets

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of 'B' and a positive integer value.

**Example:** 'B', 150

#### 'ReferenceDistribution' - Reference data generation method

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA'	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix $x$ .
'uniform'	Generate reference data uniformly over the range of each feature in the data matrix $x$ .

**Example:** 'ReferenceDistribution', 'uniform'

## 'SearchMethod' - Method for selecting optimal number of clusters

'firstmaxse' | 'globalmaxse'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

'firstmaxse'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where  $K$  is the number of clusters,  $\text{Gap}(K)$  is the gap value for the clustering solution with  $K$  clusters, and  $\text{SE}(K + 1)$  is the standard error of the clustering solution with  $K + 1$  clusters. This is the default if the sorted `KList` contains consecutive integer values.

'globalmaxse'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where  $K$  is the number of clusters,  $\text{Gap}(K)$  is the gap value for the clustering solution with  $K$  clusters,  $\text{GAPMAX}$  is the largest gap value, and  $\text{SE}(\text{GAPMAX})$  is the standard error corresponding to the largest gap value. This is the default if `KList` contains only one value, or contains any nonconsecutive integer values.

**Example:** 'SearchMethod', 'globalmaxse'

**Output Arguments****eva - Clustering evaluation data**

clustering evaluation object

Clustering evaluation data, returned as a clustering evaluation object.

**Examples****Evaluate the Clustering Solution Using Calinski-Harabasz Criterion**

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using kmeans.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])
```

```
eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150
InspectecedK: [1 2 3 4 5 6]
CriterionValues: [1x6 double]
OptimalK: 3
```

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

**Evaluate a Matrix of Clustering Solutions**

Use an input matrix of proposed clustering solutions to evaluate the optimal number of clusters.

## evalclusters

---

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use `kmeans` to create an input matrix of proposed clustering solutions for the sepal length measurements, using 1, 2, 3, 4, 5, and 6 clusters.

```
clust = zeros(size(meas,1),6);  
for i=1:6  
    clust(:,i) = kmeans(meas,i,'emptyaction','singleton',...  
        'replicate',5);  
end
```

Each row of `clust` corresponds to one sepal length measurement. Each of the six columns corresponds to a clustering solution containing 1 to 6 clusters.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
eva = evalclusters(meas,clust,'CalinskiHarabasz')
```

```
eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150  
InspectedK: [1 2 3 4 5 6]  
CriterionValues: [NaN 513.9245 561.6278 530.7658 459.5058 473.6577]  
OptimalK: 3
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

## Specify Clustering Algorithm with a Function Handle

Use a function handle to specify the clustering algorithm, then evaluate the optimal number of clusters.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use a function handle to specify the clustering algorithm.

```
myfunc = @(X,K)(kmeans(X, K, 'emptyaction','singleton',...  
    'replicate',5));
```

Evaluate the optimal number of clusters for the sepal length data using the Calinski-Harabasz criterion.

```
eva = evalclusters(meas,myfunc,'CalinskiHarabasz',...  
    'klist',[1:6])
```

```
eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150
```

```
InspectedK: [1 2 3 4 5 6]
```

```
CriterionValues: [NaN 513.9245 561.6278 530.7658 459.5058 473.6577]
```

```
OptimalK: 3
```

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

# evpdf

---

**Purpose** Extreme value probability density function

**Syntax**  $Y = \text{evpdf}(X, \mu, \sigma)$

**Description**  $Y = \text{evpdf}(X, \mu, \sigma)$  returns the pdf of the type 1 extreme value distribution with location parameter  $\mu$  and scale parameter  $\sigma$ , evaluated at the values in  $X$ .  $X$ ,  $\mu$ , and  $\sigma$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for  $\mu$  and  $\sigma$  are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating  $X$ . See “Extreme Value Distribution” on page B-35 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

# evstat

---

**Purpose** Extreme value mean and variance

**Syntax** `[M,V] = evstat(mu,sigma)`

**Description** `[M,V] = evstat(mu,sigma)` returns the mean of and variance for the type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other input. The default values for `mu` and `sigma` are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima. See “Extreme Value Distribution” on page B-35 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

<b>Superclasses</b>	ToolboxFittableParametricDistribution
<b>Purpose</b>	Exponential probability distribution object
<b>Description</b>	<p>prob.ExponentialDistribution is an object consisting of parameters, a model description, and sample data for an exponential probability distribution.</p> <p>Create a probability distribution object with specified parameter values using <code>makedist</code>. Alternatively, fit a distribution to data using <code>fitdist</code> or the Distribution Fitting app.</p>
<b>Construction</b>	<p><code>pd = makedist('Exponential')</code> creates an exponential probability distribution object using the default parameter values.</p> <p><code>pd = makedist('Exponential','mu',mu)</code> creates an exponential probability distribution object using the specified parameter value.</p>
	<b>Input Arguments</b>
	<b>mu - Mean</b> 1 (default)   positive scalar value Mean of the exponential distribution, specified as a positive scalar value.
	<b>Data Types</b> single   double
<b>Properties</b>	<b>mu</b> Mean of the exponential distribution, stored as a positive scalar value.
	<b>Data Types</b> single   double
	<b>DistributionName</b> Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

# prob.ExponentialDistribution

---

## Data Types

char

## InputData

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

single | double

## IsTruncated

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the

estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

**Data Types**

single | double

**ParameterDescription**

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

**Data Types**

char

**ParameterIsFixed**

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

**Data Types**

logical

**ParameterNames**

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

**Data Types**

char

**ParameterValues**

Values of distribution parameters, stored as a vector. This property is read-only.

**Data Types**

single | double

**Truncation**

# prob.ExponentialDistribution

---

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Definitions

### Exponential Distribution

The exponential distribution is used to model events that occur randomly over time, and its main application area is studies of lifetimes. It is a special case of the gamma distribution with the shape parameter  $\alpha = 1$ .

The exponential distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$\mu > 0$

The probability density function (pdf) is

$$f(x | \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}} ; x \geq 0.$$

## Examples

### Create an Exponential Distribution Object Using Default Parameters

Create an exponential distribution object using the default parameter values.

```
pd = makedist('Exponential')
```

```
pd =
```

# prob.ExponentialDistribution

---

## Concepts

- “Exponential Distribution” on page B-32
- Class Attributes
- Property Attributes

**Purpose** Exponential cumulative distribution function

**Syntax**

```
p = expcdf(x,mu)
[p,plo,pup] = expcdf(x,mu,pcov,alpha)
[p,plo,pup] = expcdf( __ , 'upper' )
```

**Description** `p = expcdf(x,mu)` computes the exponential cdf at each of the values in `x` using the corresponding mean parameter `mu`. `x` and `mu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive.

`[p,plo,pup] = expcdf(x,mu,pcov,alpha)` produces confidence bounds for `Pp` when the input mean parameter `mu` is an estimate. `pcov` is the variance of the estimated `mu`. `alpha` specifies `100(1 - alpha)%` confidence bounds. The default value of `alpha` is `0.05`. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of `mu`. If you estimate `mu` from a set of data, you can get a more accurate set of bounds by applying `expfit` to the data to get a confidence interval for `mu`, and then evaluating `expinv` at the lower and upper endpoints of that interval.

`[p,plo,pup] = expcdf( __ , 'upper' )` returns the complement of the exponential cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the `'upper'` argument with any of the prior syntaxes.

The exponential cdf is

$$p = F(x | u) = \int_0^x \frac{1}{\mu} e^{-\frac{t}{\mu}} dt = 1 - e^{-\frac{x}{\mu}}$$

The result, `p`, is the probability that a single observation from an exponential distribution will fall in the interval `[0 x]`.

## Examples

### Compute the Exponential CDF

The following code shows that the median of the exponential distribution is  $\mu \log(2)$ .

```
mu = 10:10:60;  
p = expcdf(log(2)*mu,mu)
```

```
p =  
0.5000 0.5000 0.5000 0.5000 0.5000 0.5000
```

What is the probability that an exponential random variable is less than or equal to the mean,  $\mu$ ?

```
mu = 1:6;  
x = mu;  
p = expcdf(x,mu)
```

```
p =  
0.6321 0.6321 0.6321 0.6321 0.6321 0.6321
```

## How To

- “Exponential Distribution” on page B-32

**Purpose**

Exponential parameter estimates

**Syntax**

```
muhat = expfit(data)
[muhat,muci] = expfit(data)
[muhat,muci] = expfit(data,alpha)
[...] = expfit(data,alpha,censoring)
[...] = expfit(data,alpha,censoring,freq)
```

**Description**

`muhat = expfit(data)` estimates the mean of an exponentially distributed sample data. Each entry of `muhat` corresponds to the data in a column of data.

`[muhat,muci] = expfit(data)` returns 95% confidence intervals for the mean parameter estimates in matrix `muci`. The first row of `muci` contains the lower bounds of the confidence intervals, and the second row contains the upper bounds.

`[muhat,muci] = expfit(data,alpha)` returns  $100(1 - \alpha)\%$  confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = expfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = expfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

**Examples**

The following estimates the mean  $\mu$  of exponentially distributed data, and returns a 95% confidence interval for the estimate:

```
mu = 3;
data = exprnd(mu,100,1); % Simulated data
```

# expfit

---

```
[muhat,muci] = expfit(data)
muhat =
    2.7511
muci =
    2.2826
    3.3813
```

**Superclasses** NeighborSearcher

**Purpose** Nearest neighbors search using exhaustive search

**Description** An ExhaustiveSearcher object performs *k*NN (*k*-nearest neighbor) search using exhaustive search. Search objects store information about the data used, and the distance metric and parameters. The search performance for this object, compared with the KDTreeSearcher object, tends to be better for larger dimensions (10 or more) and worse for smaller dimensions. For more information on search objects, see “What Are Search Objects?” on page 16-17.

**Construction** `NS = ExhaustiveSearcher(X, 'Name', Value)` constructs an ExhaustiveSearcher object based on X, where rows of X correspond to observations and columns correspond to variables, using one or more optional name/value pairs. You can then use this object to find neighbors in X nearest to the query points.

`NS = createns(X, 'NSMethod', 'exhaustive', 'Name', Value)` creates an ExhaustiveSearcher object based on X using createns, where rows of X correspond to observations and columns correspond to variables, using one or more optional name/value pairs. You can use this object to find neighbors in X nearest to the query points.

### Name-Value Pair Arguments

Both the ExhaustiveSearcher and the createns functions accept one or more of the following optional name/value pairs as input:

#### ‘Distance’

A string or function handle specifying the default distance metric used when you call the knnsearch method.

- 'euclidean' — Euclidean distance (default).
- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between rows in X and the query matrix is scaled by dividing by the corresponding element of the standard

# ExhaustiveSearcher

---

deviation computed from  $X$ ,  $S = \text{nanstd}(X)$ . To specify another value for  $S$ , use the `Scale` argument.

- `'cityblock'` — City block distance.
- `'chebychev'` — Chebychev distance (maximum coordinate difference).
- `'minkowski'` — Minkowski distance.
- `'mahalanobis'` — Mahalanobis distance, computed using a positive definite covariance matrix  $C$ . The default value of  $C$  is  $\text{nancov}(X)$ . To change the value of  $C$ , use the `Cov` parameter.
- `'cosine'` — One minus the cosine of the included angle between observations (treated as vectors).
- `'correlation'` — One minus the sample linear correlation between observations (treated as sequences of values).
- `'spearman'` — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- `'hamming'` — Hamming distance, percentage of coordinates that differ.
- `'jaccard'` — One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
- `custom distance function` — A distance function specified using `@` (for example, `@distfun`). A distance function must be of the form `function D2 = distfun(ZI, ZJ)`, taking as arguments a 1-by- $n$  vector  $ZI$  containing a single row from  $X$  or from the query points  $Y$ , an  $m2$ -by- $n$  matrix  $ZJ$  containing multiple rows of  $X$  or  $Y$ , and returning an  $m2$ -by-1 vector of distances  $D2$ , whose  $j$ th element is the distance between the observations  $ZI$  and  $ZJ(j,:)$ .

For more information on these distance metrics, see “Distance Metrics” on page 16-9.

## 'P'

A positive scalar indicating the exponent of Minkowski distance. This parameter is only valid when Distance is 'minkowski'. Default is 2.

## 'Cov'

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when Distance is 'mahalanobis'. Default is `nancov(X)`.

## 'Scale'

A vector **S** with the length equal to the number of columns in **X**. Each coordinate of **X** and each query point is scaled by the corresponding element of **S** when computing the standardized Euclidean distance. This parameter is only valid when Distance is 'seuclidean'. Default is `nanstd(X)`.

## Properties

### **X**

A matrix used to create the object

### **Distance**

A string specifying a built-in distance metric or a function handle that you provide when you create the object. This property is the default distance metric used when you call the `knnsearch` method to find nearest neighbors for future query points.

### **DistParameter**

Specifies the additional parameter for the chosen distance metric. The value is:

- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance.
- If 'Distance' is 'mahalanobis': A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance.

# ExhaustiveSearcher

---

- If 'Distance' is 'seuclidean': A vector representing the scale value of the data when computing the 'seuclidean' distance.
- Otherwise: Empty.

## Methods

knnsearch	Find $k$ -nearest neighbors using ExhaustiveSearcher object
rangesearch	Find all neighbors within specified distance using object

## Examples

Create an ExhaustiveSearcher object using the constructor:

```
load fisheriris
x = meas(:,3:4);
NS = ExhaustiveSearcher(x,'distance','minkowski')

NS =

    ExhaustiveSearcher

    Properties:
        X: [150x2 double]
        Distance: 'minkowski'
        DistParameter: 2
```

---

Create an ExhaustiveSearcher object using createns:

```
load fisheriris
x = meas(:,3:4);
NS = createns(x,'NsMethod','exhaustive',...
             'distance','minkowski')
```

NS =

ExhaustiveSearcher

Properties:

X: [150x2 double]  
Distance: 'minkowski'  
DistParameter: 2

For more in-depth examples using the `knnsearch` method, see the method reference page or see “Classifying Query Data Using `knnsearch`” on page 16-18.

## How To

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-12
- “Distance Metrics” on page 16-9

# expinv

---

**Purpose** Exponential inverse cumulative distribution function

**Syntax**  
`X = expinv(P,mu)`  
`[X,XLO,XUP] = expinv(X,mu,pcov,alpha)`

**Description** `X = expinv(P,mu)` computes the inverse of the exponential cdf with parameters specified by mean parameter `mu` for the corresponding probabilities in `P`. `P` and `mu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive and the values in `P` must lie on the interval `[0 1]`.

`[X,XLO,XUP] = expinv(X,mu,pcov,alpha)` produces confidence bounds for `X` when the input mean parameter `mu` is an estimate. `pcov` is the variance of the estimated `mu`. `alpha` specifies `100(1 - alpha)%` confidence bounds. The default value of `alpha` is `0.05`. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of `mu`. If you estimate `mu` from a set of data, you can get a more accurate set of bounds by applying `expfit` to the data to get a confidence interval for `mu`, and then evaluating `expinv` at the lower and upper end points of that interval.

The inverse of the exponential cdf is

$$x = F^{-1}(p | \mu) = -\mu \ln(1 - p)$$

The result, `x`, is the value such that an observation from an exponential distribution with parameter `μ` will fall in the range `[0 x]` with probability `p`.

**Examples** Let the lifetime of light bulbs be exponentially distributed with `μ = 700` hours. What is the median lifetime of a bulb?

```
expinv(0.50,700)
ans =
```

485.2030

Suppose you buy a box of “700 hour” light bulbs. If 700 hours is the mean life of the bulbs, half of them will burn out in less than 500 hours.

**How To**

- “Exponential Distribution” on page B-32

# explike

---

**Purpose** Exponential negative log-likelihood

**Syntax**  
`nlogL = explike(param,data)`  
`[nlogL,avar] = explike(param,data)`  
`[...] = explike(param,data,censoring)`  
`[...] = explike(param,data,censoring,freq)`

**Description** `nlogL = explike(param,data)` returns the negative of the log-likelihood for the exponential distribution. `param` is the mean parameter, `mu`. `nlogL` is a scalar.

`[nlogL,avar] = explike(param,data)` returns the inverse of Fisher's information, `avar`, a scalar. If the input parameter value in `param` is the maximum likelihood estimate, `avar` is its asymptotic variance. `avar` is based on the observed Fisher's information, not the expected information.

`[...] = explike(param,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = explike(param,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

**See Also** `expcdf` | `exppdf` | `expstat` | `expfit` | `expinv` | `exprnd`

**How To** • “Exponential Distribution” on page B-32

**Purpose** Write dataset array to file

**Syntax**

```
export(DS, 'file', filename)
export(DS)
export(DS, 'file', filename, 'Delimiter', delim)
export(DS, 'XLSfile', filename)
export(DS, 'XPTfile', filename)
export(DS, ..., 'WriteVarNames', false)
export(DS, ..., 'WriteObsNames', false)
```

**Description** `export(DS, 'file', filename)` writes the dataset array `DS` to a tab-delimited text file, including variable names and observation names, if present. If the observation names exist, the name in the first column of the first line of the file is the first dimension name for the dataset (by default, 'Observations'). `export` overwrites any existing file named `filename`.

`export(DS)` writes to a text file whose default name is the name of the dataset array `DS` appended by `'.txt'`. If `export` cannot construct the file name from the dataset array input, it writes to the file `'dataset.txt'`. `export` overwrites any existing file.

`export(DS, 'file', filename, 'Delimiter', delim)` writes the dataset array `DS` to a text file using the delimiter `delim`. `delim` must be one of the following:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

`export(DS, 'XLSfile', filename)` writes the dataset array `DS` to a Microsoft® Excel spreadsheet file, including variable names and observation names (if present). You can specify the `'Sheet'` and

'Range' parameter name/value pairs, with parameter values as accepted by the `xlsread` function.

`export(DS, 'XPTFile', filename)` writes the dataset array `DS` to a SAS XPORT format file. When writing to an XPORT format file, variables must be scalar valued. `export` saves observation names to a variable called `obsnames`, unless the `WriteObsNames` parameter described below is `false`. The XPORT format restricts the length of variable names to eight characters; longer variable names are truncated.

`export(DS, ..., 'WriteVarNames', false)` does not write the variable names to the text file. `export(DS, ..., 'WriteVarNames', true)` is the default, writing the names as column headings in the first line of the file.

`export(DS, ..., 'WriteObsNames', false)` does not write the observation names to the text file. `export(DS, ..., 'WriteObsNames', true)` is the default, writing the names as the first column of the file.

In some cases, `export` creates a text file that does not represent `A` exactly, as described below. If you use `dataset` to read the file back into MATLAB, the new dataset array may not have exactly the same contents as the original dataset array. Save `A` as a MAT-file if you need to import it again as a dataset array.

`export` writes out numeric variables using long `g` format, and categorical or character variables as unquoted strings.

For non-character variables with more than one column, `export` writes out multiple delimiter-separated fields on each line, and constructs suitable column headings for the first line of the file.

`export` writes out variables that have more than two dimensions as a single empty field in each line of the file.

For cell-valued variables, `export` writes out the contents of each cell only when the cell contains a single row, and writes out a single empty field otherwise.

In some cases, `export` creates a file that cannot be read back into MATLAB using `dataset`. Writing a dataset array that contains a cell-valued variable whose cell contents are not scalars results in a mismatch in the file between the number of fields on each line and the number of column headings on the first line. Writing a dataset array that contains a cell-valued variable whose cell contents are not all the same length results in a different number of fields on each line in the file. Therefore, if you might need to import a dataset array again, save it as a `.mat` file.

## Examples

Move data between external text files and dataset arrays in the MATLAB workspace:

```
A = dataset('file','sat2.dat','delimiter',' ','')
A =
    Test          Gender          Score
    'Verbal'      'Male'          470
    'Verbal'      'Female'        530
    'Quantitative' 'Male'          520
    'Quantitative' 'Female'        480

export(A(A.Score > 500,:), 'file', 'HighScores.txt')

B = dataset('file', 'HighScores.txt', 'delimiter', '\t')
B =
    Test          Gender          Score
    'Verbal'      'Female'        530
    'Quantitative' 'Male'          520
```

## See Also

`dataset`

# exp pdf

---

**Purpose** Exponential probability density function

**Syntax** `Y = exp pdf(X, mu)`

**Description** `Y = exp pdf(X, mu)` returns the pdf of the exponential distribution with mean parameter `mu`, evaluated at the values in `X`. `X` and `mu` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive.

The exponential pdf is

$$y = f(x | \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}$$

The exponential pdf is the gamma pdf with its first parameter equal to 1.

The exponential distribution is appropriate for modeling waiting times when the probability of waiting an additional period of time is independent of how long you have already waited. For example, the probability that a light bulb will burn out in its next minute of use is relatively independent of how many minutes it has already burned.

## Examples

```
y = exp pdf(5, 1:5)
y =
    0.0067    0.0410    0.0630    0.0716    0.0736
```

```
y = exp pdf(1:5, 1:5)
y =
    0.3679    0.1839    0.1226    0.0920    0.0736
```

**How To** • “Exponential Distribution” on page B-32

**Purpose** Exponential random numbers

**Syntax**  
`R = exprnd(mu)`  
`R = exprnd(mu,m,n,...)`  
`R = exprnd(mu,[m,n,...])`

**Description** `R = exprnd(mu)` generates random numbers from the exponential distribution with mean parameter `mu`. `mu` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `mu`.

`R = exprnd(mu,m,n,...)` or `R = exprnd(mu,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the exponential distribution with mean parameter `mu`. `mu` can be a scalar or an array of the same size as `R`.

**Examples**

```
n1 = exprnd(5:10)
n1 =
    7.5943    18.3400    2.7113    3.0936    0.6078    9.5841

n2 = exprnd(5:10,[1 6])
n2 =
    3.2752    1.1110    23.5530    23.4303    5.7190    3.9876

n3 = exprnd(5,2,3)
n3 =
    24.3339    13.5271    1.8788
     4.7932     4.3675    2.6468
```

# expstat

---

**Purpose** Exponential mean and variance

**Syntax** `[m,v] = expstat(mu)`

**Description** `[m,v] = expstat(mu)` returns the mean of and variance for the exponential distribution with parameters `mu`. `mu` can be a vectors, matrix, or multidimensional array. The mean of the exponential distribution is  $\mu$ , and the variance is  $\mu^2$ .

**Examples**

```
[m,v] = expstat([1 10 100 1000])  
m =  
    1    10    100    1000  
v =  
    1    100   10000  1000000
```

<b>Superclasses</b>	ToolboxFittableParametricDistribution
<b>Purpose</b>	Extreme value probability distribution object
<b>Description</b>	<p>prob.ExtremeValueDistribution is an object consisting of parameters, a model description, and sample data for an extreme value probability distribution.</p> <p>Create a probability distribution object with specified parameter values using <code>makedist</code>. Alternatively, fit a distribution to data using <code>fitdist</code> or the Distribution Fitting app.</p>
<b>Construction</b>	<p><code>pd = makedist('ExtremeValue')</code> creates an extreme value probability distribution object using the default parameter values.</p> <p><code>pd = makedist('ExtremeValue','mu',mu,'sigma',sigma)</code> creates an extreme value probability distribution object using the specified parameter values.</p>
	<b>Input Arguments</b>
	<b>mu - Location parameter</b> 0 (default)   scalar value
	Location parameter of the extreme value distribution, specified as a scalar value.
	<b>Data Types</b> single   double
	<b>sigma - Scale parameter</b> 1 (default)   nonnegative scalar value
	Scale parameter of the extreme value distribution, specified as a nonnegative scalar value.
	<b>Data Types</b> single   double

# prob.ExtremeValueDistribution

---

## Properties

### **mu**

Location parameter of the extreme value distribution, stored as a scalar value.

### **Data Types**

single | double

### **sigma**

Scale parameter of the extreme value distribution, stored as a nonnegative scalar value.

### **Data Types**

single | double

### **DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

### **Data Types**

char

### **InputData**

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

### **Data Types**

single | double

### **IsTruncated**

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated.

If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

# prob.ExtremeValueDistribution

---

## Data Types

logical

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object

pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Extreme Value Distribution

The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, for example, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

The extreme value distribution uses the following parameters.

# prob.ExtremeValueDistribution

---

Parameter	Description	Support
mu	Location parameter	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \sigma^{-1} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right) ; \quad -\infty < x < \infty.$$

This form of the probability density function is suitable for modeling the minimum value. To model the maximum value, use the negative of the original values.

## Examples

### Create an Extreme Value Distribution Object Using Default Parameters

Create an extreme value distribution object using the default parameter values.

```
pd = makedist('ExtremeValue')
```

```
pd =
```

```
ExtremeValueDistribution
```

```
Extreme Value distribution
```

```
mu = 0
```

```
sigma = 1
```

### Create an Extreme Value Distribution Object Using Specified Parameters

Create an extreme value distribution object by specifying the parameter values.

```
pd = makedist('ExtremeValue', 'mu', -1, 'sigma', 2)
```

```
pd =  
  
ExtremeValueDistribution  
  
Extreme Value distribution  
    mu = -1  
    sigma = 2
```

Compute the standard deviation for the distribution.

```
s = std(pd)
```

```
s =  
  
    2.5651
```

## Concepts

- “Extreme Value Distribution” on page B-35
- Class Attributes
- Property Attributes

# factoran

---

**Purpose** Factor analysis

**Syntax**

```
lambda = factoran(X,m)
[lambda,psi] = factoran(X,m)
[lambda,psi,T] = factoran(X,m)
[lambda,psi,T,stats] = factoran(X,m)
[lambda,psi,T,stats,F] = factoran(X,m)
[...] = factoran(...,param1,val1,param2,val2,...)
```

**Definitions** factoran computes the maximum likelihood estimate (MLE) of the factor loadings matrix  $\Lambda$  in the factor analysis model

$$x = \mu + \Lambda f + e$$

where  $x$  is a vector of observed variables,  $\mu$  is a constant vector of means,  $\Lambda$  is a constant  $d$ -by- $m$  matrix of factor loadings,  $f$  is a vector of independent, standardized common factors, and  $e$  is a vector of independent specific factors.  $x$ ,  $\mu$ , and  $e$  are of length  $d$ .  $f$  is of length  $m$ .

Alternatively, the factor analysis model can be specified as

$$\text{cov}(x) = \Lambda\Lambda^T + \Psi$$

where  $\Psi = \text{cov}(e)$  is a  $d$ -by- $d$  diagonal matrix of specific variances.

**Description** `lambda = factoran(X,m)` returns the maximum likelihood estimate, `lambda`, of the factor loadings matrix, in a common factor analysis model with  $m$  common factors.  $X$  is an  $n$ -by- $d$  matrix where each row is an observation of  $d$  variables. The  $(i, j)$ th element of the  $d$ -by- $m$  matrix `lambda` is the coefficient, or loading, of the  $j$ th factor for the  $i$ th variable. By default, `factoran` calls the function `rotatefactors` to rotate the estimated factor loadings using the 'varimax' option.

`[lambda,psi] = factoran(X,m)` also returns maximum likelihood estimates of the specific variances as a column vector `psi` of length  $d$ .

`[lambda,psi,T] = factoran(X,m)` also returns the  $m$ -by- $m$  factor loadings rotation matrix `T`.

[lambda,psi,T,stats] = factoran(X,m) also returns a structure stats containing information relating to the null hypothesis,  $H_0$ , that the number of common factors is m. stats includes the following fields:

Field	Description
loglike	Maximized log-likelihood value
dfe	Error degrees of freedom = $((d-m)^2 - (d+m))/2$
chisq	Approximate chi-squared statistic for the null hypothesis
p	Right-tail significance level for the null hypothesis

factoran does not compute the chisq and p fields unless dfe is positive and all the specific variance estimates in psi are positive (see “Heywood Case” on page 21-843 below). If X is a covariance matrix, then you must also specify the 'nobs' parameter if you want factoran to compute the chisq and p fields.

[lambda,psi,T,stats,F] = factoran(X,m) also returns, in F, predictions of the common factors, known as factor scores. F is an n-by-m matrix where each row is a prediction of m common factors. If X is a covariance matrix, factoran cannot compute F. factoran rotates F using the same criterion as for lambda.

[...] = factoran(...,param1,va11,param2,va12,...) enables you to specify optional parameter name/value pairs to control the model fit and the outputs. The following are the valid parameter/value pairs.

Parameter	Value	
'xtype'	Type of input in the matrix X. 'xtype' can be one of:	
	'data'	Raw data (default)
	'covariance'	Positive definite covariance or correlation matrix

# factoran

Parameter	Value	
'scores'	Method for predicting factor scores. 'scores' is ignored if X is not raw data.	
	'wls' 'Bartlett'	Synonyms for a weighted least-squares estimate that treats F as fixed (default)
	'regression' 'Thomson'	Synonyms for a minimum mean squared error prediction that is equivalent to a ridge regression
'start'	Starting point for the specific variances $\psi$ in the maximum likelihood optimization. Can be specified as:	
	'random'	Chooses $d$ uniformly distributed values on the interval [0,1].
	'Rsquared'	Chooses the starting vector as a scale factor times $\text{diag}(\text{inv}(\text{corrcoef}(X)))$ (default). For examples, see Jöreskog [2].
	Positive integer	Performs the given number of maximum likelihood fits, each initialized as with 'random'. factoran returns the fit with the highest likelihood.
	Matrix	Performs one maximum likelihood fit for each column of the specified matrix. The $i$ th optimization is initialized with the values from the $i$ th column. The matrix must have $d$ rows.

Parameter	Value	
'rotate'	Method used to rotate factor loadings and scores. 'rotate' can have the same values as the 'Method' parameter of rotatefactors. See the reference page for rotatefactors for a full description of the available methods.	
	'none'	Performs no rotation.
	'equamax'	Special case of the orthomax rotation. Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'orthomax'	Orthogonal rotation that maximizes a criterion based on the variance of the loadings.  Use the 'coeff', 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'parsimax'	Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'pattern'	Performs either an oblique rotation (the default) or an orthogonal rotation to best match a specified pattern matrix. Use the 'type' parameter to choose the type of rotation. Use the 'target' parameter to specify the pattern matrix.

# factoran

---

Parameter	Value
	<p>'procrustes'</p> <p>Performs either an oblique (the default) or an orthogonal rotation to best match a specified target matrix in the least squares sense.</p> <p>Use the 'type' parameter to choose the type of rotation. Use 'target' to specify the target matrix.</p>
	<p>'promax'</p> <p>Performs an oblique procrustes rotation to a target matrix determined by factoran as a function of an orthomax solution.</p> <p>Use the 'power' parameter to specify the exponent for creating the target matrix. Because 'promax' uses 'orthomax' internally, you can also specify the parameters that apply to 'orthomax'.</p>
	<p>'quartimax'</p> <p>Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.</p>
	<p>'varimax'</p> <p>Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.</p>

Parameter	Value
	<p>Function</p> <p>Function handle to rotation function of the form</p> $[B, T] = \text{myrotation}(A, \dots)$ <p>where A is a d-by-m matrix of unrotated factor loadings, B is a d-by-m matrix of rotated loadings, and T is the corresponding m-by-m rotation matrix.</p> <p>Use the <code>factoran</code> parameter <code>'userargs'</code> to pass additional arguments to this rotation function. See “Example 4” on page 21-848.</p>
<code>'coeff'</code>	Coefficient, often denoted as $\gamma$ , defining the specific <code>'orthomax'</code> criterion. Must be from 0 to 1. The value 0 corresponds to <code>quartimax</code> , and 1 corresponds to <code>varimax</code> . Default is 1.
<code>'normalize'</code>	Flag indicating whether the loading matrix should be row-normalized (1) or left unnormalized (0) for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is 1.
<code>'reltol'</code>	Relative convergence tolerance for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is <code>sqrt(eps)</code> .
<code>'maxit'</code>	Iteration limit for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is 250.
<code>'target'</code>	Target factor loading matrix for <code>'procrustes'</code> rotation. Required for <code>'procrustes'</code> rotation. No default value.
<code>'type'</code>	Type of <code>'procrustes'</code> rotation. Can be <code>'oblique'</code> (default) or <code>'orthogonal'</code> .

Parameter	Value
'power'	Exponent for creating the target matrix in the 'promax' rotation. Must be $\geq 1$ . Default is 4.
'userargs'	Denotes the beginning of additional input values for a user-defined rotation function. <code>factoran</code> appends all subsequent values, in order and without processing, to the rotation function argument list, following the unrotated factor loadings matrix A. See “Example 4” on page 21-848.
'nobs'	If X is a covariance or correlation matrix, indicates the number of observations that were used in its estimation. This allows calculation of significance for the null hypothesis even when the original data are not available. There is no default. 'nobs' is ignored if X is raw data.
'delta'	Lower bound for the specific variances $\psi_i$ during the maximum likelihood optimization. Default is 0.005.
'optimopts'	Structure that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. Create this structure with the function <code>statset</code> . Enter <code>statset('factoran')</code> to see the names and default values of the parameters that <code>factoran</code> accepts in the <code>options</code> structure. See the reference page for <code>statset</code> for more information about these options.

## Tips

### Observed Data Variables

The variables in the observed data matrix X must be linearly independent, i.e.,  $\text{cov}(X)$  must have full rank, for maximum likelihood estimation to succeed. `factoran` reduces both raw data and a covariance matrix to a correlation matrix before performing the fit.

factoran standardizes the observed data  $X$  to zero mean and unit variance before estimating the loadings  $\lambda$ . This does not affect the model fit, because MLEs in this model are invariant to scale. However,  $\lambda$  and  $\psi$  are returned in terms of the standardized variables, i.e.,  $\lambda\lambda' + \text{diag}(\psi)$  is an estimate of the correlation matrix of the original data  $X$  (although not after an oblique rotation). See “Example 1” on page 21-843 and “Example 3” on page 21-845.

### Heywood Case

If elements of  $\psi$  are equal to the value of the 'delta' parameter (i.e., they are essentially zero), the fit is known as a Heywood case, and interpretation of the resulting estimates is problematic. In particular, there can be multiple local maxima of the likelihood, each with different estimates of the loadings and the specific variances. Heywood cases can indicate overfitting (i.e.,  $m$  is too large), but can also be the result of underfitting.

### Rotation of Factor Loadings and Scores

Unless you explicitly specify no rotation using the 'rotate' parameter, factoran rotates the estimated factor loadings,  $\lambda$ , and the factor scores,  $F$ . The output matrix  $T$  is used to rotate the loadings, i.e.,  $\lambda = \lambda_0 T$ , where  $\lambda_0$  is the initial (unrotated) MLE of the loadings.  $T$  is an orthogonal matrix for orthogonal rotations, and the identity matrix for no rotation. The inverse of  $T$  is known as the primary axis rotation matrix, while  $T$  itself is related to the reference axis rotation matrix. For orthogonal rotations, the two are identical.

factoran computes factor scores that have been rotated by  $\text{inv}(T')$ , i.e.,  $F = F_0 * \text{inv}(T')$ , where  $F_0$  contains the unrotated predictions. The estimated covariance of  $F$  is  $\text{inv}(T' * T)$ , which, for orthogonal or no rotation, is the identity matrix. Rotation of factor loadings and scores is an attempt to create a more easily interpretable structure in the loadings matrix after maximum likelihood estimation.

## Examples

### Example 1

Load the carbig data, and fit the default model with two factors.

# factoran

---

```
load carbig

X = [Acceleration Displacement Horsepower MPG Weight];
X = X(all(~isnan(X),2),:);
[Lambda,Psi,T,stats,F] = factoran(X,2,...
                                'scores','regression');
inv(T'*T) % Estimated correlation matrix of F, == eye(2)
Lambda*Lambda'+diag(Psi) % Estimated correlation matrix
Lambda*inv(T)           % Unrotate the loadings
F*T'                    % Unrotate the factor scores

biplot(Lambda,...         % Create biplot of two factors
       'LineWidth',2,...
       'MarkerSize',20)
```

### Example 2

Although the estimates are the same, the use of a covariance matrix rather than raw data doesn't let you request scores or significance level:

```
[Lambda,Psi,T] = factoran(cov(X),2,'xtype','cov')
[Lambda,Psi,T] = factoran(corrcoef(X),2,'xtype','cov')
```

### Example 3

Use promax rotation:

```
[Lambda,Psi,T,stats,F] = factoran(X,2,'rotate','promax',...
    'powerpm',4);
```

```
inv(T'*T) % Est'd corr of F,  
          % no longer eye(2)  
Lambda*inv(T'*T)*Lambda'+diag(Psi) % Est'd corr of X
```

Plot the unrotated variables with oblique axes superimposed.

```
invT = inv(T)  
Lambda0 = Lambda*invT  
  
line([-invT(1,1) invT(1,1) NaN -invT(2,1) invT(2,1)], ...  
      [-invT(1,2) invT(1,2) NaN -invT(2,2) invT(2,2)], ...  
      'Color','r','linewidth',2)  
hold on  
biplot(Lambda0,...  
       'LineWidth',2,...  
       'MarkerSize',20)  
xlabel('Loadings for unrotated Factor 1')  
ylabel('Loadings for unrotated Factor 2')
```

Plot the rotated variables against the oblique axes:

```
biplot(Lambda, 'LineWidth', 2, 'MarkerSize', 20)
```

## Example 4

Syntax for passing additional arguments to a user-defined rotation function:

```
[Lambda,Psi,T] = ...  
    factoran(X,2,'rotate',@myrotation,'userargs',1,'two');
```

# TreeBagger.FBoot property

---

**Purpose** Fraction of in-bag observations

**Description** The FBoot property is the fraction of observations to be randomly selected with replacement for each bootstrap replica. The size of each replica is given by  $n \cdot \text{FBoot}$ , where  $n$  is the number of observations in the training set. The default value is 1.

**Purpose**

$F$  cumulative distribution function

**Syntax**

```
p = fcdf(x,v1,v2)
p = fcdf(x,v1,vv2,'upper')
```

**Description**

`p = fcdf(x,v1,v2)` computes the  $F$  cdf at each of the values in  $x$  using the corresponding numerator degrees of freedom  $v_1$  and denominator degrees of freedom  $v_2$ .  $x$ ,  $v_1$ , and  $v_2$  can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.  $v_1$  and  $v_2$  parameters must contain real positive values.

`p = fcdf(x,v1,vv2,'upper')` returns the complement of the  $F$  cdf at each value in  $x$ , using an algorithm that more accurately computes the extreme upper tail probabilities.

The  $F$  cdf is

$$p = F(x | v_1, v_2) = \int_0^x \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right]}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{t^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)t\right]^{\frac{v_1+v_2}{2}}} dt$$

The result,  $p$ , is the probability that a single observation from an  $F$  distribution with parameters  $v_1$  and  $v_2$  will fall in the interval  $[0, x]$ .

**Examples****Compute  $F$  Distribution CDF**

The following illustrates a useful mathematical identity for the  $F$  distribution.

```
nu1 = 1:5;
nu2 = 6:10;
x = 2:6;
```

```
F1 = fcdf(x,nu1,nu2)
```

# fcdf

# GeneralizedLinearModel.feval

---

For binomial models, `feval` uses 1 as the `BinomialSize` parameter, so `ypred` is predicted probabilities.

For models with an offset, `feval` uses 0 as the offset value.

## Examples

### Predict Responses Using `feval`

Generate a generalized linear model, and plot its responses to a range of input data.

Generate artificial data for the model, Poisson random numbers with two underlying predictors  $X(1)$  and  $X(2)$ .

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Generate a range of values for  $X(1)$  and  $X(2)$ , and plot the model predictions at those values.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Z = feval(mdl,Xtest1,Xtest2);
surf(Xtest1,Xtest2,Z)
```

## Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument.

`random` predicts with added noise.

# LinearModel.feval

---

**Purpose** Evaluate linear regression model prediction

**Syntax** `ypred = feval mdl, Xnew1, Xnew2, ..., Xnewn`

**Description** `ypred = feval(mdl, Xnew1, Xnew2, ..., Xnewn)` returns the predicted response of `mdl` to the input `[Xnew1, Xnew2, ..., Xnewn]`.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **Xnew1, Xnew2, ..., Xnewn**

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a dataset array or an array of doubles, where each column of the array represents one predictor.

## Output Arguments

### **ypred**

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

For models with an offset, `feval` uses 0 as the offset value.

## Examples

### **Plot Different Categorical Levels**

Fit a mileage model to the `smallcar` data, including the `Year` categorical predictor. Superimpose fitted curves on a scatter plot of the data.

Load the data and fit a model.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create a scatter plot of the mileage versus weight.

```
gscatter(ds.Weight,ds.MPG,ds.Year);
```

Use feval to plot curves of the model predictions for the various years and weights.

```
w = linspace(min(ds.Weight),max(ds.Weight))';
line(w,feval(mdl,w,'70'),'Color','r')
```

# LinearModel.feval

```
line(w, feval mdl, w, '76', 'Color', 'g')  
line(w, feval mdl, w, '82', 'Color', 'b')
```

## Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

`random` predicts with added noise.

## How To

- “Linear Regression Workflow” on page 9-44
- “Linear Regression” on page 9-12

# NonLinearModel.feval

---

**Purpose** Evaluate nonlinear regression model prediction

**Syntax** `ypred = feval mdl, Xnew1, Xnew2, ..., Xnewn`

**Description** `ypred = feval(mdl, Xnew1, Xnew2, ..., Xnewn)` returns the predicted response of `mdl` to the input `[Xnew1, Xnew2, ..., Xnewn]`.

## Input Arguments

### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

### **Xnew1, Xnew2, ..., Xnewn**

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a dataset array or an array of doubles, where each column of the array represents one predictor.

## Output Arguments

### **ypred**

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

## Examples

### **Predict a Nonlinear Model from a Dataset Array**

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average automobile.

Load the data and create a nonlinear model.

```
load carbig
```

```
ds = dataset(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(ds,modelfun,beta0);
```

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using `nanmean`.

```
Xnew = nanmean([Horsepower Weight]);
MPGnew = feval(mdl,Xnew)
```

```
MPGnew =

    21.8073
```

## Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

`random` predicts with added noise.

# ff2n

---

**Purpose** Two-level full factorial design

**Syntax** `dFF2 = ff2n(n)`

**Description** `dFF2 = ff2n(n)` gives factor settings `dFF2` for a two-level full factorial design with `n` factors. `dFF2` is  $m$ -by- $n$ , where  $m$  is the number of treatments in the full-factorial design. Each row of `dFF2` corresponds to a single treatment. Each column contains the settings for a single factor, with values of 0 and 1 for the two levels.

**Examples**

```
dFF2 = ff2n(3)
dFF2 =
  0  0  0
  0  0  1
  0  1  0
  0  1  1
  1  0  0
  1  0  1
  1  1  0
  1  1  1
```

**See Also** `fullfact`

**Purpose**

Proximity matrix for training data

**Syntax**

```
B = fillProximities(B)
B = fillProximities(B, 'param1', val1, 'param2', val2, ...)
```

**Description**

`B = fillProximities(B)` computes a proximity matrix for the training data and stores it in the `Properties` field of `B`.

`B = fillProximities(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

`'trees'`        Either `'all'` or a vector of indices of the trees in the ensemble to be used in computing the proximity matrix. Default is `'all'`.

`'nprint'`        Number of training cycles (grown trees) after which `TreeBagger` displays a diagnostic message showing training progress. Default is no diagnostic messages.

**See Also**

`CompactTreeBagger.outlierMeasure` |  
`CompactTreeBagger.proximity`

# grandstream.findobj

---

**Purpose** Find objects matching specified conditions

**Syntax** `hm = findobj(h, 'conditions')`

**Description** The `findobj` method of the `handle` class follows the same syntax as the MATLAB `findobj` command, except that the first argument must be an array of handles to objects.

`hm = findobj(h, 'conditions')` searches the handle object array `h` and returns an array of handle objects matching the specified conditions. Only the public members of the objects of `h` are considered when evaluating the conditions.

**See Also** `findobj` | `grandstream`

**Purpose** Find property of MATLAB handle object

**Syntax** `p = findprop(h,'propname')`

**Description** `p = findprop(h,'propname')` finds and returns the `meta.property` object associated with property name `propname` of scalar handle object `h`. `propname` must be a string. It can be the name of a property defined by the class of `h` or a dynamic property added to scalar object `h`.

If no property named `propname` exists for object `h`, an empty `meta.property` array is returned.

**See Also** `dynamicprops` | `findobj` | `meta.property` | `grandstream`

**Purpose**  $F$  inverse cumulative distribution function

**Syntax**  $X = \text{finv}(P, V1, V2)$

**Description**  $X = \text{finv}(P, V1, V2)$  computes the inverse of the  $F$  cdf with numerator degrees of freedom  $V1$  and denominator degrees of freedom  $V2$  for the corresponding probabilities in  $P$ .  $P$ ,  $V1$ , and  $V2$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

$V1$  and  $V2$  parameters must contain real positive values, and the values in  $P$  must lie on the interval  $[0\ 1]$ .

The  $F$  inverse function is defined in terms of the  $F$  cdf as

$$x = F^{-1}(p | v_1, v_2) = \{x : F(x | v_1, v_2) = p\}$$

where

$$p = F(x | v_1, v_2) = \int_0^x \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right]}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{t^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)t\right]^{\frac{v_1+v_2}{2}}} dt$$

## Examples

Find a value that should exceed 95% of the samples from an  $F$  distribution with 5 degrees of freedom in the numerator and 10 degrees of freedom in the denominator.

```
x = finv(0.95,5,10)
x =
    3.3258
```

You would observe values greater than 3.3258 only 5% of the time by chance.

**How To**      • “F Distribution” on page B-41

# ClassificationDiscriminant.fit

---

**Purpose** Fit discriminant analysis classifier

**Syntax**  
`obj = ClassificationDiscriminant.fit(X,Y)`  
`obj = ClassificationDiscriminant.fit(X,Y,Name,Value)`

**Description**  
`obj = ClassificationDiscriminant.fit(X,Y)` returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) `X` and output (response) `Y`.  
`obj = ClassificationDiscriminant.fit(X,Y,Name,Value)` fits a classifier with additional options specified by one or more `Name, Value` pair arguments. If you use one of the following five options, `obj` is of class `ClassificationPartitionedModel`: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Otherwise, `obj` is of class `ClassificationDiscriminant`.

## Input Arguments

### X

Matrix of numeric predictor values. Each column of `X` represents one variable, and each row represents one observation.

`ClassificationDiscriminant.fit` considers NaN values in `X` as missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `X` in the fit.

### Y

Numeric vector, vector of categorical variables (nominal or ordinal), logical vector, character array, or cell array of strings. Each row of `Y` represents the classification of the corresponding row of `X`.

`ClassificationDiscriminant.fit` considers NaN values in `Y` to be missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `Y` in the fit.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding

value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## 'ClassNames'

Array of class names. Use the data type that exists in Y.

Use ClassNames to order the classes or to select a subset of classes for training.

**Default:** Class names that exist in Y

## 'Cost'

Square matrix, where  $Cost(i, j)$  is the cost of classifying a point into class  $j$  if its true class is  $i$ . Alternatively, Cost can be a structure S having two fields: S.ClassNames containing the group names as a variable of the same type as Y, and S.ClassificationCosts containing the cost matrix.

**Default:**  $Cost(i, j)=1$  if  $i \neq j$ , and  $Cost(i, j)=0$  if  $i=j$

## 'crossval'

If 'on', creates a cross-validated classifier with 10 folds. You can use 'kfold', 'holdout', 'leaveout', or 'cvpartition' parameters to override this cross-validation setting. You can only use one of these options at a time for creating a cross-validated classifier: 'cvpartition', 'holdout', 'kfold', or 'leaveout'.

Alternatively, cross validate obj later using the crossval method.

**Default:** 'off'

## 'cvpartition'

Partition created with cvpartition to use in a cross-validated classifier. You can only use one of these options at a time for

# ClassificationDiscriminant.fit

---

creating a cross-validated classifier: 'cvpartition', 'holdout', 'kfold', or 'leaveout'.

## 'delta'

Threshold on linear coefficients, a nonnegative scalar. If a coefficient of `obj` has magnitude smaller than `delta`, `obj` sets this coefficient to 0, and so you can eliminate the corresponding predictor from the model. Set `delta` to a higher value to eliminate more predictors.

`delta` must be 0 for quadratic discriminant models.

**Default:** 0

## 'discrimType'

String specifying the discriminant type. Case-insensitive. One of:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

**Default:** 'linear'

## 'fillCoeffs'

String, either 'on' or 'off', specifying whether to populate the `Coeffs` property in the classifier object. Setting to 'on' can be computationally intensive, especially when cross validating.

**Default:** 'on', except 'off' when cross validating

## 'gamma'

Parameter for regularizing the correlation matrix of predictors.

- Linear discriminant — Scalar from 0 to 1.
  - If you pass a value strictly between 0 and 1, `ClassificationDiscriminant.fit` sets the discriminant type to `'Linear'`.
  - If you pass 0 for gamma and `'Linear'` for `DiscrimType`, and if the correlation matrix is singular, `ClassificationDiscriminant.fit` sets gamma to the minimal value required for inverting the covariance matrix.
  - If you set gamma to 1, `ClassificationDiscriminant.fit` sets the discriminant type to `'diagLinear'`.
- Quadratic discriminant — Either 0 or 1.
  - If you pass 0 for gamma and `'Quadratic'` for `DiscrimType`, and if one of the classes has a singular covariance matrix, `ClassificationDiscriminant.fit` errors.
  - If you set gamma to 1, `ClassificationDiscriminant.fit` sets the discriminant type to `'diagQuadratic'`.

## **'holdout'**

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these options at a time for creating a cross-validated classifier: `'cvpartition'`, `'holdout'`, `'kfold'`, or `'leaveout'`.

## **'kfold'**

Number of folds to use in a cross-validated classifier, a positive integer. You can only use one of these options at a time for creating a cross-validated classifier: `'cvpartition'`, `'holdout'`, `'kfold'`, or `'leaveout'`.

# ClassificationDiscriminant.fit

---

**Default:** 10

## **'leaveout'**

Use leave-one-out cross validation by setting to 'on'. You can only use one of these options at a time for creating a cross-validated classifier: 'cvpartition', 'holdout', 'kfold', or 'leaveout'.

## **'PredictorNames'**

Cell array of names for the predictor variables, in the order in which they appear in X.

**Default:** {'x1', 'x2', ...}

## **'prior'**

Prior probabilities for each class. Specify as one of:

- A string:
  - 'empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, they are used to compute the class probabilities.
  - 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as Y
  - S.ClassProbs containing a vector of corresponding probabilities

**Default:** 'empirical'

## **'ResponseName'**

Name of the response variable Y, a string.

**Default:** 'Y'

## 'SaveMemory'

When 'on', `ClassificationDiscriminant.fit` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. When 'off', `ClassificationDiscriminant.fit` computes and stores the full covariance matrix in `obj`.

Set `SaveMemory` to 'on' when `X` has thousands of predictors.

**Default:** 'off'

## 'ScoreTransform'

Function handle for transforming scores, or string representing a built-in transformation function.

String	Formula
'symmetric'	$2x - 1$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set score for the class with the largest score to 1, and scores for all other classes to 0.
'symmetricismax'	Set score for the class with the largest score to 1, and scores for all other classes to -1.
'none'	$x$
'logit'	$1/(1 + e^{-x})$
'doublelogit'	$1/(1 + e^{-2x})$

# ClassificationDiscriminant.fit

---

String	Formula
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$

You can include your own function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

**Default:** 'none'

## 'weights'

Vector of observation weights. The length of weights is the number of rows in X. ClassificationDiscriminant.fit normalizes the weights to sum to 1.

**Default:** ones(size(X,1),1)

## Output Arguments

### obj

Discriminant analysis classifier. You can use obj to predict the response of new data using the predict method.

## Definitions

### Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (gmdistribution).
  - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
  - For quadratic discriminant analysis, both means and covariances of each class vary.

predict classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.
- $\hat{P}(k | x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y | k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

For details, see “How the predict Method Classifies” on page 15-6.

## Examples

Construct a discriminant analysis classifier for the Fisher iris data:

```
load fisheriris
obj = ClassificationDiscriminant.fit(meas, species)

obj =
ClassificationDiscriminant:
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NObservations: 150
  DiscrimType: 'linear'
  Mu: [3x4 double]
  Coeffs: [3x3 struct]
```

## Alternatives

The classify function also performs discriminant analysis. classify is usually more awkward to use:

# ClassificationDiscriminant.fit

---

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross validation.
- `classify` requires you to fit the classifier when changing prior probabilities.

## See Also

`ClassificationDiscriminant` | `ClassificationTree.fit`

## How To

- “Discriminant Analysis” on page 15-3

**Purpose** Fit  $k$ -nearest neighbor classifier

**Syntax** `mdl = ClassificationKNN.fit(X,Y)`  
`mdl = ClassificationKNN.fit(X,Y,Name,Value)`

**Description** `mdl = ClassificationKNN.fit(X,Y)` returns a classification model based on the input variables (also known as predictors, features, or attributes)  $X$  and output (response)  $Y$ .

`mdl = ClassificationKNN.fit(X,Y,Name,Value)` fits a model with additional options specified by one or more `Name,Value` pair arguments.

If you use one of these options, `mdl` is of class `ClassificationPartitionedModel`: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Otherwise, `mdl` is of class `ClassificationKNN`.

## Input Arguments

### **X**

Matrix of predictor values. Each column of  $X$  represents one variable, and each row represents one observation.

### **Y**

A numeric vector, vector of categorical variables (nominal or ordinal), logical vector, character array, or cell array of strings, with the same number of rows as  $X$ . Each row of  $Y$  represents the classification of the corresponding row of  $X$ .

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'BreakTies'**

# ClassificationKNN.fit

---

String specifying the method `predict` uses to break ties if multiple classes have the same smallest cost. By default, ties occur when multiple classes have the same number of nearest points among the  $K$  nearest neighbors.

- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.
- 'smallest' — Use the smallest index among tied groups.

**Default:** 'smallest'

## 'BucketSize'

Maximum number of data points in the leaf node of the *kd*-tree. This argument is meaningful only when `NSMethod` is 'kdtree'.

**Default:** 50

## 'CategoricalPredictors'

Specification of which predictors are categorical:

- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

When you set `CategoricalPredictors` to 'all', the default `Distance` is 'hamming'.

**Default:** []

## 'ClassNames'

Array of class names. Use the data type that exists in  $Y$ .

Use `ClassNames` to order the classes or to select a subset of classes for training.

**Default:** Class names in `Y`

## **'Cost'**

Square matrix, where  $\text{Cost}(i, j)$  is the cost of classifying a point into class  $j$  if its true class is  $i$ . Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

**Default:**  $\text{Cost}(i, j) = 1$  if  $i \neq j$ , and  $\text{Cost}(i, j) = 0$  if  $i = j$

## **'Cov'**

Positive definite matrix, the covariance matrix when computing the Mahalanobis distance. This argument is only valid when `'Distance'` is `'mahalanobis'`.

**Default:** `nancov(X)`

## **'crossval'**

If `'on'`, create a cross-validated model with 10 folds. Use the `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'` parameters to override this cross-validation setting. You can only use one parameter at a time to create a cross-validated model.

Alternatively, cross validate `model` later using the `crossval` method.

**Default:** `'off'`

## **'cvpartition'**

Partition created with `cvpartition` to use in a cross-validated model. You can only use one of these four options at a time for creating a cross-validated model: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

## **'Distance'**

# ClassificationKNN.fit

---

String or function handle specifying the distance metric. The allowable strings depend on the `NSMethod` parameter, which you set in `ClassificationKNN.fit`, and which exists as a field in `ModelParams`.

<b>NSMethod</b>	<b>Distance Metric Names</b>
exhaustive	Any distance metric of <code>ExhaustiveSearcher</code>
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

For definitions, see “Distance Metrics” on page 16-9.

The distance metrics of `ExhaustiveSearcher`:

<b>Value</b>	<b>Description</b>
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.

Value	Description
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix $C$ . The default value of $C$ is the sample covariance matrix of $X$ , as computed by <code>nancov(X)</code> . To specify a different value for $C$ , use the 'Cov' name-value pair.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between $X$ and a query point is scaled, meaning divided by a scale value $S$ . The default value of $S$ is the standard deviation computed from $X$ , $S = \text{nanstd}(X)$ . To specify another value for $S$ , use the Scale name-value pair.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form  <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> <li>• ZI is a 1-by-N vector containing one row of X or Y.</li> <li>• ZJ is an M2-by-N matrix containing multiple rows of X or Y.</li> </ul>

# ClassificationKNN.fit

Value	Description
	<ul style="list-style-type: none"><li>• D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J, :).</li></ul>

**Default:** 'euclidean', except the default is 'hamming' when CategoricalPredictors is 'all'

## 'DistanceWeight'

String or function handle specifying the distance weighting function.

DistanceWeight	Meaning
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance <sup>2</sup>
@fcn	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

**Default:** 'equal'

## 'Exponent'

Positive scalar specifying the exponent of Minkowski distance. This argument is only valid when 'Distance' is 'minkowski'.

**Default:** 2

## 'holdout'

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated model: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## **'IncludeTies'**

Logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the *K*th smallest distance. If `IncludeTies` is `true`, `predict` includes all these neighbors. Otherwise, `predict` uses exactly *K* neighbors.

**Default:** `false`

## **'kfold'**

Number of folds to use in a cross-validated model, a positive integer. You can only use one of these four options at a time for creating a cross-validated model: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**Default:** 10

## **'leaveout'**

Use leave-one-out cross validation by setting to 'on'. You can only use one of these four options at a time for creating a cross-validated model: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## **'NSMethod'**

String specifying the nearest neighbor search method:

- 'kdtree' — Create and use a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
  - 'euclidean'

# ClassificationKNN.fit

---

- 'cityblock'
- 'minkowski'
- 'chebyshev'
- 'exhaustive' — Use the exhaustive search algorithm. The distance values from all points in X to each point in Y are computed to find nearest neighbors.

**Default:** 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'

## 'NumNeighbors'

Positive integer specifying the number of nearest neighbors in X to find for classifying each point when predicting.

**Default:** 1

## 'PredictorNames'

Cell array of names for the predictor variables, in the order in which they appear in X.

**Default:** {'x1', 'x2', ...}

## 'prior'

Prior probabilities for each class. Specify as one of:

- A string:
  - 'empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, they are used to compute the class probabilities.
  - 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class)

- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as Y
  - S.ClassProbs containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

**Default:** 'empirical'

### **'ResponseName'**

Name of the response variable Y, a string.

**Default:** 'Response'

### **'Scale'**

Vector containing nonnegative values, with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

**Default:** `nanstd(X)`

### **'weights'**

Vector of observation weights. The length of `weights` is the number of rows in X. `ClassificationKNN.fit` normalizes the weights in each class to add up to the value of the prior probability of the class.

**Default:** `ones(size(X,1),1)`

# ClassificationKNN.fit

---

## Output Arguments

**mdl**

*k*-nearest neighbor classifier model.

## Definitions

### Prediction

ClassificationKNN predicts the classification of a point  $X_{new}$  using a procedure equivalent to this:

- 1 Find the NumNeighbors points in the training set  $X$  that are nearest to  $X_{new}$ .
- 2 Find the NumNeighbors response values  $Y$  to those nearest points.
- 3 Assign the classification label  $Y_{new}$  that has largest posterior probability among the values in  $Y$ .

For details, see “Posterior Probability” on page 21-2608 in the predict documentation.

## Examples

### Construct a KNN Classifier

Construct a *k*-nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5)
```

```
mdl =
```

```
ClassificationKNN:
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
```

```
ResponseName: 'Y'  
ClassNames: {'setosa' 'versicolor' 'virginica'}  
ScoreTransform: 'none'  
NObservations: 150  
Distance: 'euclidean'  
NumNeighbors: 5
```

## Use a Different Metric

To use the Minkowski metric, you must use an exhaustive searcher.

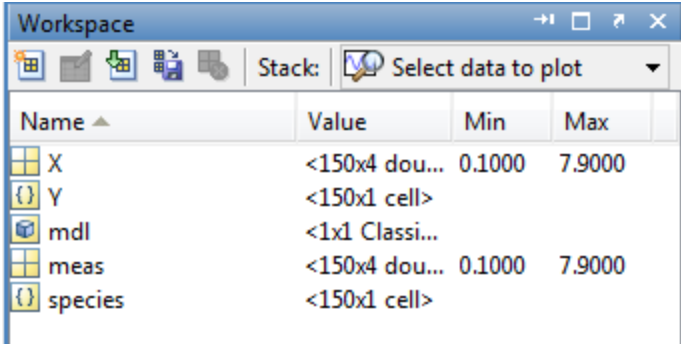

Load the data.

```
load fisheriris  
X = meas;  
Y = species;
```

Construct a classifier for 3-nearest neighbors with the Minkowski metric.

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',3,...  
    'NSMethod','exhaustive','Distance','minkowski');
```

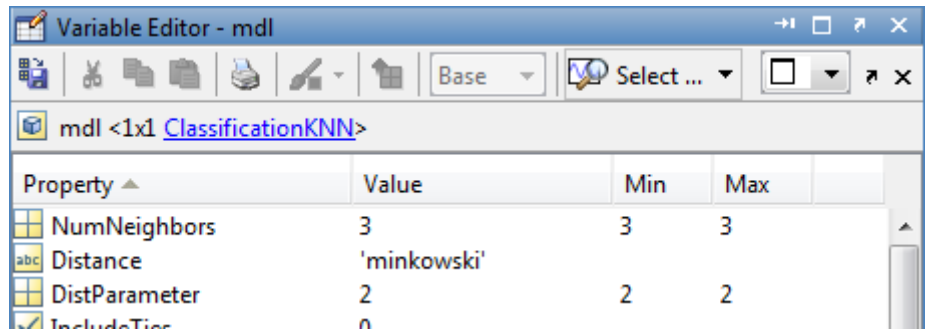

To examine mdl properties, double-click mdl in the Workspace window to open the Variable Editor.

The screenshot shows the MATLAB Workspace window with a table of variables. The table has columns for Name, Value, Min, and Max. The variables listed are X, Y, mdl, meas, and species.

Name	Value	Min	Max
X	<150x4 dou...	0.1000	7.9000
Y	<150x1 cell>		
mdl	<1x1 Classi...		
meas	<150x4 dou...	0.1000	7.9000
species	<150x1 cell>

## Purpose

Fit classification tree

## Syntax

```
tree = ClassificationTree.fit(X,Y)
tree = ClassificationTree.fit(X,Y,Name,Value)
```

## Description

`tree = ClassificationTree.fit(X,Y)` returns a classification tree based on the input variables (also known as predictors, features, or attributes) `X` and output (response) `Y`. `tree` is a binary tree, where each branching node is split based on the values of a column of `X`.

`tree = ClassificationTree.fit(X,Y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ,NameN,ValueN`.

Note that using the `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'` options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

## Input Arguments

### X

A matrix of floating-point predictor values. Each column of `X` represents one variable, and each row represents one observation.

`ClassificationTree.fit` considers NaN values in `X` as missing values. `ClassificationTree.fit` does not use observations with all missing values for `X` in the fit. `ClassificationTree.fit` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

### Y

A numeric vector, vector of categorical variables (nominal or ordinal), logical vector, character array, or cell array of strings. Each row of `Y` represents the classification of the corresponding

# ClassificationTree.fit

---

row of  $X$ . For numeric  $Y$ , consider using `RegressionTree.fit` instead of `ClassificationTree.fit`.

`ClassificationTree.fit` considers NaN values in  $Y$  to be missing values. `ClassificationTree.fit` does not use observations with missing values for  $Y$  in the fit.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'AlgorithmForCategorical'

Algorithm to find the best split on a categorical predictor with  $L$  levels for data with  $K \geq 3$  classes. The available algorithms are:

'Exact'	Consider all $2^{L-1} - 1$ combinations
'PullLeft'	Pull left by purity
'PCA'	Principle component-based partition[1]
'OVAbyClass'	One versus all by class

Descriptions of the algorithms are in “Splitting Categorical Predictors” on page 16-56.

**Default:** `ClassificationTree.fit` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For  $K = 2$  classes, `ClassificationTree.fit` always performs the exact search.

## 'CategoricalPredictors'

List of categorical predictors. Pass `CategoricalPredictors` as one of:

- A numeric vector with indices from 1 to  $p$ , where  $p$  is the number of columns of  $X$ .
- A logical vector of length  $p$ , where a true entry means that the corresponding column of  $X$  is a categorical variable.
- 'all', meaning all predictors are categorical.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.

**Default:** []

## 'ClassNames'

Array of class names. Use the data type that exists in  $Y$ .

Use `ClassNames` to order the classes or to select a subset of classes for training.

**Default:** The class names that exist in  $Y$

## 'Cost'

Square matrix, where  $Cost(i, j)$  is the cost of classifying a point into class  $j$  if its true class is  $i$ . Alternatively, `Cost` can be a structure  $S$  having two fields: `S.ClassNames` containing the group names as a variable of the same type as  $Y$ , and `S.ClassificationCosts` containing the cost matrix.

**Default:**  $Cost(i, j) = 1$  if  $i \neq j$ , and  $Cost(i, j) = 0$  if  $i = j$

# ClassificationTree.fit

---

## **'crossval'**

Flag to grow a cross-validated decision tree. Possible values are 'on' or 'off'.

If 'on', `ClassificationTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'kfold', 'holdout', 'leaveout', or 'cvpartition' name-value pair arguments. Note that you can only use one of these four options ('kfold', 'holdout', 'leaveout', or 'cvpartition') at a time when creating a cross-validated tree.

Alternatively, cross validate `tree` later using the `crossval` method.

**Default:** 'off'

## **'cvpartition'**

Partition created with `cvpartition` to use in a cross-validated tree.

Note that if you use 'cvpartition', you cannot use any of the 'kfold', 'holdout', or 'leaveout' name-value pair arguments.

## **'holdout'**

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1.

Note that if you use 'holdout', you cannot use any of the 'cvpartition', 'kfold', or 'leaveout' name-value pair arguments.

## **'kfold'**

Number of folds to use in a cross-validated tree, a positive integer.

Note that if you use 'kfold', you cannot use any of the 'cvpartition', 'holdout', or 'leaveout' name-value pair arguments.

**Default:** 10

## **'leaveout'**

Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'leaveout', you cannot use any of the 'cvpartition', 'holdout', or 'kfold' name-value pair arguments.

## **'MaxCat'**

ClassificationTree.fit splits a categorical predictor using the exact search algorithm if the predictor has at most MaxCat levels in the split node. Otherwise, ClassificationTree.fit finds the best categorical split using one of the inexact algorithms.

Specify MaxCat as a numeric nonnegative scalar value. Passing a small value can lead to loss of accuracy and passing a large value can lead to long computation time and memory overload.

**Default:** 10

## **'MergeLeaves'**

When 'on', ClassificationTree.fit merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', ClassificationTree.fit does not merge leaves.

**Default:** 'on'

## **'MinLeaf'**

Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf,

# ClassificationTree.fit

---

ClassificationTree.fit uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** 1

## 'MinParent'

Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, ClassificationTree.fit uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** 10

## 'NVarToSample'

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

**Default:** 'all'

## 'PredictorNames'

A cell array of names for the predictor variables, in the order in which they appear in X.

**Default:** {'x1', 'x2', ...}

## 'prior'

Prior probabilities for each class. Specify as one of:

- A string:
  - 'empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, they are used to compute the class probabilities.
  - 'uniform' sets all class probabilities equal.

- A vector (one scalar value for each class)
- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as Y
  - S.ClassProbs containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

**Default:** 'empirical'

## **'Prune'**

When 'on', `ClassificationTree.fit` grows the classification tree, and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree.fit` grows the classification tree without pruning.

**Default:** 'on'

## **'PruneCriterion'**

String with the pruning criterion, either 'error' or 'impurity'.

**Default:** 'error'

## **'ResponseName'**

Name of the response variable Y, a string.

**Default:** 'Response'

## **'ScoreTransform'**

# ClassificationTree.fit

Function handle for transforming scores, or string representing a built-in transformation function.

String	Formula
'symmetric'	$2x - 1$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set score for the class with the largest score to 1, and scores for all other classes to 0.
'symmetricismax'	Set score for the class with the largest score to 1, and scores for all other classes to -1.
'none'	$x$
'logit'	$1/(1 + e^{-x})$
'doublelogit'	$1/(1 + e^{-2x})$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$

You can include your own function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

**Default:** 'none'

## 'SplitCriterion'

Criterion for choosing a split. One of 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

**Default:** 'gdi'

## 'Surrogate'

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `ClassificationTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Default:** 'off'

## 'weights'

Vector of observation weights. The length of `weights` is the number of rows in `X`. `ClassificationTree.fit` normalizes the weights in each class to add up to the value of the prior probability of the class.

**Default:** `ones(size(X,1),1)`

## Output Arguments

### `tree`

A classification tree object.

Note that using the 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned

tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, tree is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

## Definitions

### Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*. Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes  $i$  at the node, and  $p(i)$  is the observed fraction of classes with class  $i$  that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('`deviance`') — With  $p(i)$  defined as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('`twoing`') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let  $L(i)$  denote the fraction of members of class  $i$  in the left child node after a split, and  $R(i)$  denote the fraction of members of class  $i$  in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where  $P(L)$  and  $P(R)$  are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If  $j$  is the class with largest number of training samples at a node, the node error is

$$1 - p(j).$$

## Examples

Construct a classification tree for the data in `ionosphere.mat`:

```
load ionosphere
tc = ClassificationTree.fit(X,Y)

tc =

ClassificationTree
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    CategoricalPredictors: []
    NObservations: 351
```

Properties, Methods

# ClassificationTree.fit

---

# GeneralizedLinearModel.fit

---

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

## Data Types

single | double | logical

## X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X.

## Data Types

single | double | logical

## y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in y is the response for the corresponding row of X.

## Data Types

single | double

## modelspec - Model specification

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form 'Y ~ terms'

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p+1)$  matrix, namely terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-915.

**Example:** `'quadratic'`

# GeneralizedLinearModel.fit

---

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## 'BinomialSize' - Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter  $n$  for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

## Data Types

single | double

## 'CategoricalVars' - Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the dataset array `ds`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in dataset array `ds`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.

- If data is in matrix X, then the default value of this name-value pair argument is an empty matrix []. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** 'CategoricalVars',[2,3]

**Example:** 'CategoricalVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

### 'DispersionFlag' - Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

**Example:** 'DispersionFlag',true

### 'Distribution' - Distribution of the response variable

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

# GeneralizedLinearModel.fit

---

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

**Example:** 'Distribution','gamma'

## **'Exclude' - Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## **Data Types**

single | double | logical

## **'Intercept' - Indicator for constant term**

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

## **'Link' - Link function**

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'complloglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> <li>• S.Link — The link function</li> <li>• S.Inverse — The inverse link function</li> <li>• S.Derivative — The derivative of the link function</li> </ul>	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship  $f(\mu) = X*b$  between the mean response  $\mu$  and the linear combination of predictors  $X*b$ .

# GeneralizedLinearModel.fit

---

For more information on the canonical link functions, see [Definitions](#).

**Example:** 'Link', 'probit'

## 'Offset' - Offset variable

[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

## Data Types

single | double | char

## 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the dataset array `ds`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in the `ds` dataset array, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in ds except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column in dataset array ds (default) | string for variable name  
| logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the dataset array ds, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a dataset array ds.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

**Example:** 'ResponseVar','yield'

**Example:** 'ResponseVar',[4]

**Example:** 'ResponseVar',logical([0 0 0 1 0 0])

## Data Types

single | double | logical | char

### 'VarNames' - Names of variables in fit

{ 'x1', 'x2', ..., 'xn', 'y' } (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings including the names for the columns of X first, and the name for the response variable y last.

# GeneralizedLinearModel.fit

---

'VarNames' is not applicable to variables in a dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

## Example:

```
'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}
```

## Data Types

cell

## 'Weights' - Observation weights

ones(n,1) (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

## Data Types

single | double

## Output Arguments

### mdl - Generalized linear model

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable. The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a dataset array, then 0 must represent the response variable depending on the position of the response variable in the dataset array. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    1    0    0    0
    0    0    1    0
    0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

# GeneralizedLinearModel.fit

---

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    0    1    0    0
    0    0    1    0
    0    0    0    1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```
    0    0    0
    1    0    0
    0    1    0
    1    1    0
    0    2    0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

$$y \sim 1 + x1*x2 + x2^2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.000196
x1	0.54418	0.57125	0.95261	0.343
x2	-0.012781	0.0060312	-2.1192	0.0368
x1:x2	-0.00010892	0.00017925	-0.6076	0.5
x2^2	9.7518e-07	7.5389e-07	1.2935	0.199

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
```

```
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

```
mdl =
```

Linear regression model:

$$y \sim 1 + x2$$

# GeneralizedLinearModel.fit

---

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form

`'Y ~ terms'`,

where

- `Y` is the response name.
- `terms` contains
  - Variable names
  - `+` means include the next variable
  - `-` means do not include the next variable
  - `:` defines an interaction, a product of terms
  - `*` defines an interaction **and all lower-order terms**
  - `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower order terms as well
  - `()` groups terms

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include - 1 in the formula.

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.

'Y ~ A + B + C - 1' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A\*B term.

'Y ~ A\*B + C' is the same as the previous example because  $A*B = A + B + A:B$ .

'Y ~ A\*B\*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A\*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k, where k is a positive integer	A, A <sup>2</sup> , ..., A <sup>k</sup>
A + B	A, B
A*B	A, B, A*B
A:B	A*B only

# GeneralizedLinearModel.fit

Wilkinson Notation	Factors in Standard Notation
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

## Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

## Examples

### Fit a Generalized Linear Model

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
```

```
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

Generalized Linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight  
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

The large  $p$ -value indicates the model might not differ statistically from a constant.

## Alternatives

You can also construct a generalized linear model using `fitglm`.

# GeneralizedLinearModel.fit

---

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

**Purpose** Gaussian mixture parameter estimates

**Syntax**

```
obj = gmdistribution.fit(X,k)
obj = gmdistribution.fit(...,param1,val1,param2,val2,...)
```

**Description** `obj = gmdistribution.fit(X,k)` uses an Expectation Maximization (EM) algorithm to construct an object `obj` of the `gmdistribution` class containing maximum likelihood estimates of the parameters in a Gaussian mixture model with `k` components for data in the  $n$ -by- $d$  matrix `X`, where  $n$  is the number of observations and  $d$  is the dimension of the data.

`gmdistribution` treats NaN values as missing data. Rows of `X` with NaN values are excluded from the fit.

`obj = gmdistribution.fit(...,param1,val1,param2,val2,...)` provides control over the iterative EM algorithm. Parameters and values are listed below.

Parameter	Value
'Start'	<p>Method used to choose initial component parameters. One of the following:</p> <ul style="list-style-type: none"> <li>'randSample' — To select <code>k</code> observations from <code>X</code> at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element <code>j</code> on the diagonal is the variance of <code>X(:,j)</code>. This is the default.</li> <li><code>S</code> — A structure array with fields <code>mu</code>, <code>Sigma</code>, and <code>PComponents</code>. See <code>gmdistribution</code> for descriptions of values.</li> <li><code>s</code> — A vector of length <math>n</math> containing an initial guess of the component index for each point.</li> </ul>
'Replicates'	A positive integer giving the number of times to repeat the EM algorithm, each time with a new set of

# gmdistribution.fit

---

Parameter	Value
	parameters. The solution with the largest likelihood is returned. A value larger than 1 requires the 'randSample' start method. The default is 1.
'CovType'	'diagonal' if the covariance matrices are restricted to be diagonal; 'full' otherwise. The default is 'full'.
'SharedCov'	Logical true if all the covariance matrices are restricted to be the same (pooled estimate); logical false otherwise.
'Regularize'	A nonnegative regularization number added to the diagonal of covariance matrices to make them positive-definite. The default is 0.
'Options'	Options structure for the iterative EM algorithm, as created by <code>statset</code> . <code>gmdistribution.fit</code> uses the parameters 'Display' with a default value of 'off', 'MaxIter' with a default value of 100, and 'TolFun' with a default value of $1e-6$ .

In some cases, `gmdistribution` may converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues may result in an ill-conditioned covariance matrix:

- The number of dimension of your data is relatively high and there are not enough observations.
- Some of the features (variables) of your data are highly correlated.
- Some or all the features are discrete.
- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Pre-process your data to remove correlated features.
- Set 'SharedCov' to true to use an equal covariance matrix for every component.
- Set 'CovType' to 'diagonal'.
- Use 'Regularize' to add a very small positive number to the diagonal of every covariance matrix.
- Try another set of initial values.

In other cases `gmdistribution` may pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Trying another set of initial values may avoid this issue without altering your data or model.

## Examples

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function:

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

# gmdistribution.fit

---

Next, fit a two-component Gaussian mixture model:

```
options = statset('Display','final');  
obj = gmdistribution.fit(X,2,'Options',options);  
10 iterations, log-likelihood = -7046.78  
  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Among the properties of the fit are the parameter estimates:

```
ComponentMeans = obj.mu
```

```
ComponentMeans =
```

```
    0.9391    2.0322
   -2.9823   -4.9737
```

```
ComponentCovariances = obj.Sigma
```

```
ComponentCovariances(:, :, 1) =
```

```
    1.7786   -0.0528
   -0.0528    0.5312
```

# gmdistribution.fit

---

```
ComponentCovariances(:,:,2) =  
    1.0491   -0.0150  
   -0.0150    0.9816  
  
MixtureProportions = obj.PComponents  
MixtureProportions =  
    0.5000    0.5000
```

The Akaike information is minimized by the two-component model:

```
AIC = zeros(1,4);  
obj = cell(1,4);  
for k = 1:4  
    obj{k} = gmdistribution.fit(X,k);  
    AIC(k) = obj{k}.AIC;  
end  
  
[minAIC,numComponents] = min(AIC);  
numComponents  
numComponents =  
    2  
  
model = obj{2}  
model =  
Gaussian mixture distribution  
with 2 components in 2 dimensions  
Component 1:  
Mixing proportion: 0.500000  
Mean:    0.9391    2.0322  
Component 2:  
Mixing proportion: 0.500000  
Mean:   -2.9823   -4.9737
```

Both the Akaike and Bayes information are negative log-likelihoods for the data with penalty terms for the number of estimated parameters. They are often used to determine an appropriate number of components for a model when the number of components is unspecified.

`gmdistribution` | `cluster`

# LinearModel.fit

---

**Purpose** Create linear regression model

**Syntax**

```
mdl = LinearModel.fit(ds)
mdl = LinearModel.fit(X,y)
mdl = LinearModel.fit(...,modelspec)
mdl = LinearModel.fit(...,Name,Value)
mdl = LinearModel.fit(...,modelspec,Name,Value)
```

**Description**

`mdl = LinearModel.fit(ds)` creates a linear model of a dataset array `ds`.

`mdl = LinearModel.fit(X,y)` creates a linear model of the responses `y` to a data matrix `X`.

`mdl = LinearModel.fit(...,modelspec)` creates a linear model of the specified type.

`mdl = LinearModel.fit(...,Name,Value)` or `mdl = LinearModel.fit(...,modelspec,Name,Value)` creates a linear model with additional options specified by one or more `Name,Value` pair arguments.

- Tips**
- Use the function `fitlm` instead of `LinearModel.fit`.
  - Use robust fitting (`RobustOpts` name-value pair) to reduce the effect of outliers automatically.
  - Do not use robust fitting when you want to subsequently adjust a model using `step`.
  - For other methods or properties of the `LinearModel` object, see `LinearModel`.

**Input Arguments**

**ds - Input data**  
dataset array

Input data, specified as a dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and

response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### Data Types

single | double | logical

### X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

### Data Types

single | double | logical

### y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### Data Types

single | double

### modelspec - Model specification

string naming the model |  $t$ -by- $(p + 1)$  terms matrix | string of the form 'Y ~ terms'

# LinearModel.fit

---

Model specification, specified as one of the following. The choice is the starting model for `stepwiselm`.

- A string naming the model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p + 1)$  matrix, namely terms matrix, specifying terms to include in the model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus 1 is for the response variable.
- A string representing a formula in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-939.

**Example:** 'quadratic'

**Example:** 'y ~ X1 + X2^2 + X1:X2'

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'CategoricalVars' - Categorical variables**

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of 'CategoricalVars' and either a cell array of strings of the names of the categorical variables in the dataset array `ds`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in dataset array `ds`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** 'CategoricalVars',[2,3]

**Example:** 'CategoricalVars',logical([0 1 1 0 0 0])

### **Data Types**

single | double | logical

## 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

## 'Intercept' - Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

## 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the dataset array ds, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in the ds dataset array, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in ds except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

### Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column in dataset array ds (default) | string for variable name  
| logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the dataset array ds, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a dataset array ds.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

**Example:** 'ResponseVar','yield'

**Example:** 'ResponseVar',[4]

**Example:** 'ResponseVar',logical([0 0 0 1 0 0])

### Data Types

single | double | logical | char

### 'RobustOpts' - Indicator of robust fitting type

'off' (default) | 'on' | string | structure with string or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of the following.

# LinearModel.fit

---

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.
- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.
- String — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the string `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) \cdot \sin(r) \cdot / r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) \cdot (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 \cdot / (1 + r.^2)$	2.385
'fair'	$w = 1 \cdot / (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 \cdot / \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) \cdot / r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 \cdot * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985

The value  $r$  in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h}),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are  $p$  columns in  $X$ , the smallest  $p$  absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

**Example:** `'RobustOpts', 'andrews'`

### 'VarNames' - Names of variables in fit

{ 'x1', 'x2', ..., 'xn', 'y' } (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the

# LinearModel.fit

---

names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

## Example:

```
'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}
```

## Data Types

cell

## 'Weights' - Observation weights

ones(n,1) (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

## Data Types

single | double

## Output Arguments

### mdl - Linear model

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, mdl, see the LinearModel class page.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable. The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a dataset array, then 0 must represent the response variable depending on the position of the response variable in the dataset array. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

T =

```
0    0    0    0
1    0    0    0
0    0    1    0
```

# LinearModel.fit

---

```
0 0 0 1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...  
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
0 0 0 0  
0 1 0 0  
0 0 1 0  
0 0 0 1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall  
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```
0 0 0
1 0 0
0 1 0
1 1 0
0 2 0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.000196
x1	0.54418	0.57125	0.95261	0.343
x2	-0.012781	0.0060312	-2.1192	0.0368
x1:x2	-0.00010892	0.00017925	-0.6076	0.5
x2^2	9.7518e-07	7.5389e-07	1.2935	0.199

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

# LinearModel.fit

---

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

$$y \sim 1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form

`'Y ~ terms'`,

where

- `Y` is the response name.
- `terms` contains
  - Variable names
  - `+` means include the next variable
  - `-` means do not include the next variable
  - `:` defines an interaction, a product of terms
  - `*` defines an interaction **and all lower-order terms**

- $\wedge$  raises the predictor to a power, exactly as in  $*$  repeated, so  $\wedge$  includes lower order terms as well
- $()$  groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include  $-1$  in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where $k$ is a positive integer	$A, A^2, \dots, A^k$

# LinearModel.fit

---

Wilkinson Notation	Factors in Standard Notation
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Examples

### Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a default linear model to the data.

```
mdl = LinearModel.fit(X,y)
```

```
mdl =
```

```
Linear regression model:
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913

x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 2.45  
R-squared: 0.982, Adjusted R-Squared 0.974  
F-statistic vs. constant model: 111, p-value = 4.76e-07

## Linear Regression with Categorical Predictor and Nonlinear Model

Fit a model of a dataset array that contains a categorical predictor.  
Use a nonlinear response formula.

Load the carsmall data.

```
load carsmall
```

Construct a dataset containing continuous predictor variable `Weight`,  
nominal predictor variable `Year`, and response variable `MPG`.

```
ds = dataset(MPG,Weight);  
ds.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight2`.  
(You don't have to include `Weight` explicitly in your formula because it  
is a lower-order term of `Weight2`. For details, see "Formula" on page  
21-938.)

```
mdl = fitlm(ds,'MPG ~ Year + Weight^2')
```

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ 1 + Weight + Year + Weight^2
```

```
Estimated Coefficients:
```

# LinearModel.fit

---

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 2.78

R-squared: 0.885, Adjusted R-Squared 0.88

F-statistic vs. constant model: 172, p-value = 5.52e-41

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year (for more information on dummy variables see “Dummy Indicator Variables” on page 2-55). The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164Weight + 2.0887(Year\_76) + 8.1864(Year\_82) + 1.557e-06Weight^2$$

## Simultaneously Specify the Variables and Use Formula

Simultaneously identify response and predictor variables and specify the model using formula in linear regression.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data.

```
mdl = LinearModel.fit(hospital, 'Weight~1+Age*Sex*Smoker-Age:Sex:Smoker', 'MPG')
```

```
mdl =
```

Linear regression model:

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.09699
Smoker_1	3.0425	10.446	0.29127	0.7714
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.05037
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.8031
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.7821

Number of observations: 100, Error degrees of freedom: 93

Root Mean Squared Error: 8.75

R-squared: 0.898, Adjusted R-Squared 0.892

F-statistic vs. constant model: 137, p-value = 6.91e-44

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with gender at the 5% significance level.

## Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

Linear regression model (robust fit):

# LinearModel.fit

---

$$y \sim 1 + x1 + x2 + x3 + x4$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.65

R-squared: 0.979, Adjusted R-Squared 0.969

F-statistic vs. constant model: 94.6, p-value = 9.03e-07

## Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

## Alternatives

You can also construct a linear model using `fitlm`.

You can construct a model in a range of possible models using `stepwiselm`. However, you cannot use robust regression and stepwise regression together.

## How To

- “Linear Regression” on page 9-12

## Purpose

Fit linear mixed-effects model using dataset arrays

## Syntax

```
lme = LinearMixedModel.fit(ds, formula)
lme = LinearMixedModel.fit(ds, formula, Name, Value)
```

## Description

`lme = LinearMixedModel.fit(ds, formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the dataset array `ds`.

`lme = LinearMixedModel.fit(ds, formula, Name, Value)` returns a linear mixed-effects model with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

## Tips

- Use the function `fitlme` instead of `LinearMixedModel.fit`.
- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

## Input Arguments

**ds - Input data**  
dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-51). You must specify the model for the variables using `formula`.

### Data Types

single | double | char | cell

### formula - Formula for model specification

string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. For full description, see “Formula” on page 21-966.

**Example:** 'y ~ treatment +(1|block)'

## Data Types

char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'CovariancePattern' - Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are  $R$  random-effects terms, then the value of 'CovariancePattern' must be a cell array of length  $R$ , where each element  $r$  of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the  $r$ th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where  $\sigma_b^2$  is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where  $\sigma_{b1}^2$  is the common variance of the random-effects terms and  $\sigma_{b1,b2}$  is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if  $\text{PAT}(a,b) = \text{false}$ , then the (a,b) element of

the corresponding covariance matrix is constrained to be 0.

**Example:** `'CovariancePattern','Diagonal'`

**Example:** `'CovariancePattern',{'Full','Diagonal'}`

## 'FitMethod' - Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

<code>'ML'</code>	Default. Maximum likelihood estimation
<code>'REML'</code>	Restricted maximum likelihood estimation

**Example:** `'FitMethod','REML'`

## 'Weights' - Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length  $n$ , where  $n$  is the number of observations.

## Data Types

`single` | `double`

## 'Exclude' - Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

**Example:** `'Exclude',[13,67]`

# LinearMixedModel.fit

---

## Data Types

single | double | logical

## 'DummyVarCoding' - Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

**Example:** 'DummyVarCoding','effects'

## 'Optimizer' - Optimization algorithm

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If

you don't specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.

**Example:** `'Optimizer','fminunc'`

## **'OptimizerOptions' - Options for optimization algorithm**

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinevton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinevton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

## **'TolFun' - Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

# LinearMixedModel.fit

---

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

## **'TolX' - Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

## **'MaxIter' - Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

## **'Display' - Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

## **'StartMethod' - Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'                      Default. An internally defined default value.

'random'                        A random initial value.

**Example:** 'StartMethod', 'random'

## **'Verbose' - Indicator to display optimization process on screen**

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

**Example:** 'Verbose', true

## 'CheckHessian' - Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

**Example:** 'CheckHessian', true

## Output Arguments

### lme - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Examples

### Random-Intercept Model

Load the sample data.

```
load flu
```

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns

# LinearMixedModel.fit

---

corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with the nationwide a random intercept that varies by `Date`. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 WtdILI_i + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable `Date`.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable `Date` and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b \sim N(0, \sigma_b^2)$  and the error term has the distribution,  $\varepsilon \sim N(0, \sigma^2)$ .

```
lme = LinearMixedModel.fit(flu2,'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
FluRate ~ 1 + WtdILI + (1 | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
-----	-----	---------------	----------

286.24      302.83      -139.12                      278.24

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	0.16385	0.057525	2.8484	466	0.0046
'WtdILI'	0.7236	0.032219	22.459	466	3.0e-46

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.17146

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits for the standard deviation of the random-effects term,  $\sigma^2_b$ , do not include 0 (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned} \hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 WtdILI_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749, \end{aligned}$$

where  $\hat{b}$  is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level);
```

```
y_hat =  
    1.4674
```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);  
F(28)  
  
ans =  
    1.4674
```

## Randomized-Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `LinearMixedModel.fit` creates a matrix called a 'fixed effects design

matrix' to describe the effect of Shift. This matrix has two columns, *Shift\_Evening* and *Shift\_Morning*, where

$$Shift\_Evening = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad Shift\_Morning = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

Morning Shift:  $QCDev_{im} = \beta_0 + \beta_2 Shift - Morning_i + b_{0m} + \varepsilon_{im}$ ,  $m = 1, 2, \dots, 5$ ,

Evening Shift:  $QCDev_{im} = \beta_0 + \beta_1 Shift - Evening_i + b_{0m} + \varepsilon_{im}$ ,

Night Shift:  $QCDev_{im} = \beta_0 - \beta_1 Shift - Evening_i - \beta_2 Shift - Morning_i + b_{0m} + \varepsilon_{im}$ .

where  $b \sim N(0, \sigma_b^2)$  and  $\varepsilon \sim N(0, \sigma^2)$ .

```
lme = LinearMixedModel.fit(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```
lme =

'(Intercept)'	'(Intercept)'	'std'	2.0457	0.

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.85462	0.52357	1.395

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B =
```

```
0.5775  
1.1757  
-2.1715  
2.3655  
-1.9472
```

The estimated absolute deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}\hat{y}_{Evening,Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift\_Evening + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
```

```
F(shift.Shift=='Evening' & shift.Operator=='3')  
  
ans =  
  
    0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working in the morning shift is

$$\begin{aligned}\hat{y}_{Morning,Operator3} &= \hat{\beta}_0 + \hat{\beta}_2 Shift\_Morning + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value in the following way.

```
F(shift.Shift=='Morning' & shift.Operator=='3')  
  
ans =  
  
    0.5613
```

The operator tends to make a smaller magnitude of error in the morning shift.

## Split-Plot Experiment

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and

# LinearMixedModel.fit

loamy. Each block is divided into five plots, where five types of tomato plants, (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. Then, the tomato plants in the plots are divided into subplots, where each subplot is treated by one of the four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S * T)_{jk} + \varepsilon_{imjk},$$

where  $i = 1, 2, \dots, 60$ , the index  $m$  corresponds to the fertilizer types,  $j$  corresponds to the tomato types, and  $k = 1, 2, 3$  corresponds to the blocks (soil).  $S_k$  represents the  $k$ th soil type, and  $(S * T)_{jk}$  represents the  $j$ th tomato type nested in the  $k$ th soil type.  $I[F]_{im}$  is the dummy variable representing level  $m$  of the fertilizer. Similarly,  $I[T]_{ij}$  is the dummy variable representing the level  $j$  of the tomato type.

The random effects and observation error have the following prior distributions:  $b_{0k} \sim N(0, \sigma^2_S)$ ,  $b_{0jk} \sim N(0, \sigma^2_{S * T})$ , and  $\varepsilon_{imjk} \sim N(0, \sigma^2)$ .

```
lme = LinearMixedModel.fit(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (
```

```
lme =
```

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term will be tested.

## Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

# LinearMixedModel.fit

---

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six two-week time periods. This is simulated data.

Store the data in a dataset array. Define `Subject` and `Program` as categorical variables.

```
ds = dataset(InitialWeight,Program,Subject,Week,y);
ds.Subject = nominal(ds.Subject);
ds.Program = nominal(ds.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`LinearMixedModel.fit` uses Program A as a reference and creates the necessary dummy variables  $I[.]$ . Since the model already has an intercept, `LinearMixedModel.fit` only creates dummy variables for program types B, C, D. This is also known as the 'reference' method of coding dummy variables. This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .  $\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{1m}$  and  $b_{0m}$  are random effects.  $IW$  stands for initial weight and  $I[.]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have the

following prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
lme = LinearMixedModel.fit(ds, 'y ~ InitialWeight + Program*Week + (Week | Subject)')
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	120

'Program_D:Week'	0.033114	0.095394	0.34713	111

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

# LinearMixedModel.fit

---

Name1	Name2	Type	Estimate	
'(Intercept)'	'(Intercept)'	'std'	0.18407	L
'Week'	'(Intercept)'	'corr'	0.66841	C
'Week'	'Week'	'std'	0.15033	C

Group: Error			
Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The  $p$ -values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in Program B is significantly different relative to the weight loss of subjects who are in Program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

## Definitions

### Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms. Suppose a dataset array `ds` contains the following:

- A response variable,  $y$
- Predictor variables,  $X_j$ , which can be continuous or grouping variables
- Grouping variables,  $g_1, g_2, \dots, g_R$ ,

where the grouping variables in  $X_j$  and  $g_r$  can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix  $X$ , `random1` is a specification of the random-effects design matrix  $Z_1$  corresponding to grouping variable  $g_1$ ,

and similarly  $\text{random}_R$  is a specification of the random-effects design matrix  $Z_R$  corresponding to grouping variable  $g_R$ . You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$X^k$ , where $k$ is a positive integer	$X, X^2, \dots, X^k$
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$ )
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using  $-1$ . Here are some examples for linear mixed-effects model specification.

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, $X1$ and $X2$ . This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	Fixed effects for $X1$ and $X2$ . The implicit intercept term is suppressed by including $-1$ .

# LinearMixedModel.fit

Formula	Description
'y ~ 1 + (1   g1)'	Intercept plus random effect for each level of the grouping variable g1.
'y ~ X1 + (1   g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1   g1)'	Random intercept and slope, with possible correlation between them.
'y ~ X1 + (1   g1) + (-1 + X1   g1)'	Independent random intercept and slope.
'y ~ 1 + (1   g1) + (1   g2) + (1   g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

## Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where  $D$  is a  $q$ -by- $q$  symmetric and positive semidefinite matrix, parameterized by a variance component vector  $\theta$ ,  $q$  is the number of variables in the random-effects term, and  $\sigma^2$  is the observation error variance. Since the covariance matrix of the random effects,  $D$ , is symmetric, it has  $q(q+1)/2$  free parameters. Suppose  $L$  is the lower triangular Cholesky factor of  $D(\theta)$  such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the  $q^*(q+1)/2$ -by-1 unconstrained parameter vector  $\theta$  is formed from elements in the lower triangular part of  $L$ . For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

## Log-Cholesky Parameterization

When the diagonal elements of  $L$  in Cholesky parameterization are constrained to be positive, then the solution for  $L$  is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of  $L$  are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing  $L_{ii} \geq 0$ ,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

## Alternatives

You can also construct a linear mixed-effects model using `fitlme`. If your data is in matrix format, then use `fitlmematrix`.

# LinearMixedModel.fit

---

## See Also

[LinearMixedModel](#) | [fitlmematrix](#) | [fitlmecompare](#) | [anova](#) |

## Purpose

Create Naive Bayes classifier object by fitting training data

## Syntax

```
nb = NaiveBayes.fit(training, class)
nb = NaiveBayes.fit(..., 'param1',val1, 'param2',val2, ...)
```

## Description

`nb = NaiveBayes.fit(training, class)` builds a `NaiveBayes` classifier object `nb`. `training` is an N-by-D numeric matrix of training data. Rows of `training` correspond to observations; columns correspond to features. `class` is a classing variable for `training` taking K distinct levels. Each element of `class` defines which class the corresponding row of `training` belongs to. `training` and `class` must have the same number of rows.

`nb = NaiveBayes.fit(..., 'param1',val1, 'param2',val2, ...)` specifies one or more of the following name/value pairs:

- `'Distribution'` – a string or a 1-by-D cell vector of strings, specifying which distributions `fit` uses to model the data. If the value is a string, `fit` models all the features using one type of distribution. `fit` can also model different features using different types of distributions. If the value is a cell vector, its `j`th element specifies the distribution `fit` uses for the `j`th feature. The available types of distributions are:

`'normal'`            Normal (Gaussian) distribution.  
(default)

`'kernel'`            Kernel smoothing density estimate.

# NaiveBayes.fit

---

- |        |   |
|--------|---|
| 'mvmn' | Multivariate multinomial distribution for discrete data. <code>fit</code> assumes each individual feature follows a multinomial model within a class. The parameters for a feature include the probabilities of all possible values that the corresponding feature can take.  |
| 'mn'   | Multinomial distribution for classifying the count-based data such as the bag-of-tokens model. In the bag-of-tokens model, the value of the $j$ th feature is the number of occurrences of the $j$ th token in this observation, so it must be a non-negative integer. When 'mn' is used, <code>fit</code> considers each observation as multiple trials of a multinomial distribution, and considers each occurrence of a token as one trial. The number of categories (bins) in this multinomial model is the number of distinct tokens, i.e., the number of columns of training. |
- 'Prior' – The prior probabilities for the classes, specified as one of the following:

'empirical' (default)	<code>fit</code> estimates the prior probabilities from the relative frequencies of the classes in training.
'uniform'	The prior probabilities are equal for all classes.

vector	A numeric vector of length $K$ specifying the prior probabilities in the class order of <code>class</code> .
structure	A structure <code>S</code> containing class levels and their prior probabilities. <code>S</code> must have two fields: <ul style="list-style-type: none"><li>• <code>S.prob</code>: A numeric vector of prior probabilities.</li><li>▪ <code>S.class</code>: A vector of the same type as <code>class</code>, containing unique class levels indicating the class for the corresponding element of <code>prob</code>. <code>S.class</code> must contain all the <math>K</math> levels in <code>class</code>. It can also contain classes that do not appear in <code>class</code>. This can be useful if <code>training</code> is a subset of a larger training set. <code>fit</code> ignores any classes that appear in <code>S.class</code> but not in <code>class</code>.</li></ul>

If the prior probabilities don't sum to one, `fit` will normalize them.

- `'KSWidth'` – The bandwidth of the kernel smoothing window. The default is to select a default bandwidth automatically for each combination of feature and class, using a value that is optimal for a Gaussian distribution. You can specify the value as one of the following:

scalar	Width for all features in all classes.
row vector	1-by- $D$ vector where the $j$ th element is the bandwidth for the $j$ th feature in all classes.
column vector	$K$ -by-1 vector where the $i$ th element specifies the bandwidth for all features in the $i$ th class. $K$ represents the number of class levels.

# NaiveBayes.fit

---

**matrix** K-by-D matrix  $M$  where  $M(i, j)$  specifies the bandwidth for the  $j$ th feature in the  $i$ th class.

**structure** A structure  $S$  containing class levels and their bandwidths.  $S$  must have two fields:

- **S.width** – A numeric array of bandwidths specified as a row vector, or a matrix with  $D$  columns.
- **S.class** – A vector of the same type as **class**, containing unique class levels indicating the class for the corresponding row of **width**.
- **'KSSupport'** – The regions where the density can be applied. It can be a string, a two-element vector as shown below, or a 1-by- $D$  cell array of these values:

<b>'unbounded'</b> (default)	The density can extend over the whole real line.
<b>'positive'</b>	The density is restricted to positive values.
<b>[L,U]</b>	A two-element vector specifying the finite lower bound $L$ and upper bound $U$ for the support of the density.
- **'KSType'** – The type of kernel smoother to use. It can be a string or a 1-by- $D$  cell array of strings. Each string can be **'normal'** (default), **'box'**, **'triangle'**, or **'epanechnikov'**.

## How To

- “Naive Bayes Classification” on page 15-38
- “Grouping Variables” on page 2-51

## Purpose

Fit nonlinear regression model

## Syntax

```
mdl = NonLinearModel.fit(ds,modelfun,beta0)
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)
```

## Description

`mdl = NonLinearModel.fit(ds,modelfun,beta0)` fits the model specified by `modelfun` to variables in the dataset array `ds`, and returns the nonlinear model `mdl`. `NonLinearModel.fit` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = NonLinearModel.fit(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name, Value` pair arguments.

## Tips

- Use the function `fitnlm` instead of `NonLinearModel.fit`.

## Input Arguments

### **ds** - Input data

dataset array

Input data, specified as a dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### Data Types

single | double | logical

### **X** - Predictor variables

# NonLinearModel.fit

---

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## **y** - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## **modelfun** - Functional form of the model

function handle | string of the form 'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - $b$  is a coefficient vector with the same number of elements as `beta0`.
  - $x$  is a matrix with the same number of columns as  $X$  or the number of predictor variable columns of  $ds$ .

`modelfun(b,x)` returns a column vector that contains the same number of rows as  $x$ . Each row of the vector is the result of evaluating `modelfun` on the corresponding row of  $x$ . In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call.

- String of the form  $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ , where  $f$  represents a scalar function of the scalar coefficient variables  $b_1, \dots, b_j$  and the scalar data variables  $x_1, \dots, x_k$ .

## beta0 - Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. NonLinearModel starts its search for optimal coefficients from beta0.

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'CoefficientNames' - Names of the model coefficients

{'b1', 'b2', ..., 'bk'} (default) | cell array of strings

Names of the model coefficients, specified as a cell array of strings.

## Data Types

char

## 'ErrorModel' - Form of the error variance model

'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable  $e$  in combination with independent components: the function value  $f$ , and one or two parameters  $a$  and  $b$

# NonLinearModel.fit

---

'constant' (default)	$y = f + ae$
'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f )e$

The only allowed error model when using `Weights` is 'constant'.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

---

**Example:** 'ErrorModel', 'proportional'

## 'ErrorParameters' - Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	$a$	1
'proportional'	$b$	1
'combined'	$a, b$	[1,1]

You can only use the 'constant' error model when using `Weights`.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

---

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for  $a$  and the starting value 2 for  $b$  as follows.

**Example:** 'ErrorParameters',[1,2]

## Data Types

char

## 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

## 'Options' - Options for controlling the iterative fitting procedure

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('nlinfit')`.

# NonLinearModel.fit

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"><li>• 'off' — Displays no information.</li><li>• 'final' — Displays the final output.</li><li>• 'iter' — Displays iterative output to the Command Window.</li></ul>	'off'
FunValCheck	String indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 21-1143	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 21-1143 for the default, which depends on RobustWgtFun.

Option	Meaning	Default
ToIFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
ToIX	Termination tolerance for the parameters. Positive scalar.	1e-8

## Data Types

struct

### 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the dataset array ds, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in the ds dataset array, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in ds except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column in dataset array ds (default) | string for variable name  
| logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a

# NonLinearModel.fit

---

string of the variable name in the dataset array `ds`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a dataset array `ds`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

## Data Types

`single` | `double` | `logical` | `char`

## 'VarNames' - Names of variables in fit

`{'x1','x2',...,'xn','y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

## Example:

`'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

## Data Types

`cell`

## 'Weights' - Observation weights

`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have  $n$  elements, where  $n$  is the number of rows in `ds` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by  $MSE * (1/W(i))$ , where `MSE` is the mean squared error.

### Data Types

`single` | `double` | `function_handle`

## Output Arguments

### `mdl` - Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

# NonLinearModel.fit

## Examples

### Nonlinear Model from a Dataset Array

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```
load carbig
ds = dataset(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(ds,modelfun,beta0)
```

```
mdl =
```

Nonlinear regression model:

```
MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387

Root Mean Squared Error: 3.96

R-Squared: 0.745, Adjusted R-Squared 0.743

F-statistic vs. constant model: 283, p-value = 1.79e-113

## Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
```

```
mdl =
```

Nonlinear regression model:

```
y ~ b1 + b2*x1^b3 + b4*x2^b5
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
--	----------	----	-------	--------

# NonLinearModel.fit

b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387  
Root Mean Squared Error: 3.96  
R-Squared: 0.745, Adjusted R-Squared 0.743  
F-statistic vs. constant model: 283, p-value = 1.79e-113

## Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = NonLinearModel.fit(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step
0	1.82248e+06		
1	678600	788810	1691.07
2	616716	6.12739e+06	45.4738

```
%%%      Many iterations deleted      %%%  
  
      122      6068.48      1.56393      0.629325  
      123      6068.48      1.13809      0.432543  
      124      6068.48      0.295962      0.297511  
  
Iterations terminated: relative change in SSE less than OPTIONS.TolFun
```

## Specify Nonlinear Regression Using Model String Syntax

Specify a nonlinear regression model for estimation using a function handle or model string syntax.

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0)
```

```
mdl =
```

```
Nonlinear regression model:  
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309

# NonLinearModel.fit

---

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a string expression to specify the Hougén-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';  
mdl2 = NonLinearModel.fit(X,y,myfun,beta0)
```

```
mdl2 =
```

Nonlinear regression model:

$$y \sim (b_1 \cdot x_2 - x_3 / b_5) / (1 + b_2 \cdot x_1 + b_3 \cdot x_2 + b_4 \cdot x_3)$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

## Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
```

```
b = [1;3;2];
```

```
x = exprnd(2,100,1);
```

```
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
```

```
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a string expression to specify the model.

```
b0 = [2;2;2];
```

```
modelstr = 'y ~ b1 + b2*exp(-b3*x)';
```

```
mdl = NonLinearModel.fit(x,y,modelstr,b0,'Options',opts)
```

```
mdl =
```

```
Nonlinear regression model (robust fit):
```

```
y ~ b1 + b2*exp( - b3*x)
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26
b3	2.9732	0.38496	7.7232	1.0346e-11

```
Number of observations: 100, Error degrees of freedom: 97
```

```
Root Mean Squared Error: 0.501
```

# NonLinearModel.fit

---

R-Squared: 0.807, Adjusted R-Squared 0.803  
F-statistic vs. constant model: 203, p-value = 2.34e-35

## Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
```

Nonlinear regression model:

$y \sim \text{hougen}(b,X)$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	0.83085	0.58224	1.427	0.19142
b2	0.04095	0.029663	1.3805	0.20477
b3	0.025063	0.019673	1.274	0.23842
b4	0.080053	0.057812	1.3847	0.20353
b5	1.8261	1.281	1.4256	0.19183

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.037  
R-Squared: 0.998, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11

## Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
```

```
Nonlinear regression model:  
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86702	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075158	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 1.27  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

# NonLinearModel.fit

---

**Algorithms** NonLinearModel.fit uses the same fitting algorithm as nlinfit.

**Alternatives** You can also construct a nonlinear model using fitnlm.

## Purpose

Binary decision tree for regression

## Syntax

```
tree = RegressionTree.fit(X,Y)
tree = RegressionTree.fit(X,Y,Name,Value)
```

## Description

`tree = RegressionTree.fit(X,Y)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) `X` and output (response) `Y`. `tree` is a binary tree where each branching node is split based on the values of a column of `X`.

`tree = RegressionTree.fit(X,Y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ,NameN,ValueN`.

Note that using the `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'` options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

## Input Arguments

### X

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

`RegressionTree.fit` considers NaN values in `X` as missing values. `RegressionTree.fit` does not use observations with all missing values for `X` the fit. `RegressionTree.fit` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

### Y

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

# RegressionTree.fit

---

`RegressionTree.fit` considers NaN values in `Y` to be missing values. `RegressionTree.fit` does not use observations with missing values for `Y` in the fit.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'CategoricalPredictors'**

List of categorical predictors. Pass `CategoricalPredictors` as one of:

- A numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- `'all'`, meaning all predictors are categorical.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.

**Default:** []

## **'crossval'**

Flag to grow a cross-validated decision tree. Possible values are `'on'` or `'off'`.

If 'on', `RegressionTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'kfold', 'holdout', 'leaveout', or 'cvpartition' name-value pair arguments. Note that you can only use one of these four options ('kfold', 'holdout', 'leaveout', or 'cvpartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

**Default:** 'off'

## **'cvpartition'**

Partition created with `cvpartition` to use in cross-validated tree.

Note that if you use 'cvpartition', you cannot use any of the 'kfold', 'holdout', or 'leaveout' name-value pair arguments.

## **'holdout'**

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1.

Note that if you use 'holdout', you cannot use any of the 'cvpartition', 'kfold', or 'leaveout' name-value pair arguments.

## **'kfold'**

Number of folds to use in a cross-validated tree, a positive integer.

Note that if you use 'kfold', you cannot use any of the 'cvpartition', 'holdout', or 'leaveout' name-value pair arguments.

**Default:** 10

## **'leaveout'**

# RegressionTree.fit

---

Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'leaveout', you cannot use any of the 'cvpartition', 'holdout', or 'kfold' name-value pair arguments.

## **'MergeLeaves'**

When 'on', RegressionTree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', RegressionTree does not merge leaves.

**Default:** 'on'

## **'MinLeaf'**

Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** 1

## **'MinParent'**

Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** 10

## **'NVarToSample'**

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

**Default:** 'all'

## **'PredictorNames'**

A cell array of names for the predictor variables, in the order in which they appear in X.

**Default:** { 'x1', 'x2', ... }

## **'Prune'**

When 'on', RegressionTree computes the full tree and the optimal sequence of pruned subtrees. When 'off' RegressionTree computes the full tree without pruning.

**Default:** 'on'

## **'PruneCriterion'**

String with the pruning criterion, always 'error'.

**Default:** 'error'

## **'QEToler'**

Defines tolerance on quadratic error per node for regression trees. Splitting nodes stops when quadratic error per node drops below  $QEToler * QED$ , where QED is the quadratic error for the entire data computed before the decision tree is grown.

**Default:** 1e-6

## **'ResponseName'**

Name of the response variable Y, a string.

**Default:** 'Y'

## **'ResponseTransform'**

Function handle for transforming the raw response values. The function handle should accept a matrix of response values and

# RegressionTree.fit

---

return a matrix of the same size. The default string 'none' means  $@(x)x$ , or no transformation.

Add or change a ResponseTransform function by dot addressing:

```
tree.ResponseTransform = @function
```

**Default:** 'none'

## 'SplitCriterion'

Criterion for choosing a split, always the string 'MSE', meaning mean squared error.

**Default:** 'MSE'

## 'Surrogate'

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `RegressionTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `RegressionTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `RegressionTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Default:** 'off'

## 'Weights'

Vector of observation weights. The length of weights is the number of rows in X.

**Default:** `ones(size(X,1),1)`

## Output Arguments

**tree**

A regression tree object.

Note that using the 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition' options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

## Examples

Load the data in `carsmall.mat`, and make a regression tree to predict the mileage of cars based on their weights and numbers of cylinders:

```
load carsmall
tree = RegressionTree.fit([Weight, Cylinders],MPG,...
    'MinParent',20,...
    'PredictorNames',{'W','C'})
```

```
tree =
```

```
RegressionTree
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
    ResponseTransform: 'none'
    CategoricalPredictors: []
    NObservations: 94
```

Properties, Methods

# RegressionTree.fit

---

Predict the mileage of a car that weighs 2200 lbs and has four cylinders:

```
predict(tree, [2200, 4])
```

```
ans =  
    29.6111
```

## See Also

`predict`

## How To

- “Splitting Categorical Predictors” on page 16-56

**Purpose** Create generalized linear regression model

**Syntax**

```
mdl = fitglm(ds)
mdl = fitglm(X,y)
mdl = fitglm( ___,modelspec)
mdl = fitglm( ___,Name,Value)
```

**Description** `mdl = fitglm(ds)` returns a generalized linear model fit to variables in the dataset array `ds`. By default, `fitglm` takes the last variable as the response variable.

`mdl = fitglm(X,y)` returns a generalized linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitglm( ___,modelspec)` returns a generalized linear model of the type you specify in `modelspec`.

`mdl = fitglm( ___,Name,Value)` returns a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, the distribution of the response variable, and the link function to use.

## Input Arguments

### **ds - Input data**

dataset array

Input data, specified as a dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

## Data Types

single | double | logical

## X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## modelspec - Model specification

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form 'Y ~ terms'

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p+1)$  matrix, namely “Terms Matrix” on page 21-1013, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a “Formula” on page 21-1016 in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-1017.

**Example:** `'quadratic'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Example:

```
'Distribution','normal','link','probit','Exclude',[23,59]
```

specifies that the distribution of the response is normal, and instructs `fitglm` to use the probit link function and exclude the 23rd and 59th observations from the fit.

## 'BinomialSize' - Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

## Data Types

single | double

## 'CategoricalVars' - Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the dataset array `ds`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in dataset array `ds`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars',[2,3]`

**Example:** `'CategoricalVars',logical([0 1 1 0 0 0])`

### Data Types

single | double | logical

### 'DispersionFlag' - Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

**Example:** `'DispersionFlag',true`

### 'Distribution' - Distribution of the response variable

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

**Example:** 'Distribution','gamma'

### **'Exclude' - Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

### **Data Types**

single | double | logical

### **'Intercept' - Indicator for constant term**

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

Example: 'Intercept', false

### 'Link' - Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comloglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> <li>• S.Link — The link function</li> <li>• S.Inverse — The inverse link function</li> <li>• S.Derivative — The derivative of the link function</li> </ul>	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship  $f(\mu) = X^*b$  between the mean response  $\mu$  and the linear combination of predictors  $X^*b$ .

For more information on the canonical link functions, see [Definitions](#).

**Example:** 'Link', 'probit'

## 'Offset' - Offset variable

[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

## Data Types

single | double | char

## 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the dataset array `ds`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in the `ds` dataset array, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `ds` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** `'PredictorVars',[2,3]`

**Example:** `'PredictorVars',logical([0 1 1 0 0 0])`

### Data Types

`single | double | logical | cell`

### 'ResponseVar' - Response variable

last column in dataset array `ds` (default) | string for variable name  
| logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the dataset array `ds`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a dataset array `ds`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

### Data Types

`single | double | logical | char`

### 'VarNames' - Names of variables in fit

`{'x1','x2',...,'xn','y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

'VarNames' is not applicable to variables in a dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

**Example:**

```
'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}
```

**Data Types**

cell

**'Weights' - Observation weights**

ones(n,1) (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

**Data Types**

single | double

## Output Arguments

**mdl - Generalized linear model**

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

## Examples

**Fit a Logistic Regression Model**

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital  
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions between the variables age, weight, and sex. Smoker is the response variable.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Fit a logistic binomial model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

Generalized Linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

All of the p-values (under pValue) are large. This means none of the coefficients are significant. The large  $p$ -value for the test of the model, 0.535, indicates that this model might not differ statistically from a constant model.

## GLM for Poisson Response

Create sample data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,7);
mu = exp(X(:,[1 3 6]))* [.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = fitglm(X,y,'linear','Distribution','poisson')
```

```
mdl =
```

```
Generalized Linear regression model:
```

```
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 + x6 + x7
Distribution = Poisson
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	0.88723	0.070969	12.502	7.3149e-36
x1	0.44413	0.052337	8.4858	2.1416e-17
x2	0.0083388	0.056527	0.14752	0.88272
x3	0.21518	0.063416	3.3932	0.00069087
x4	-0.058386	0.065503	-0.89135	0.37274
x5	-0.060824	0.073441	-0.8282	0.40756
x6	0.34267	0.056778	6.0352	1.5878e-09
x7	0.04316	0.06146	0.70225	0.48252

```
100 observations, 92 error degrees of freedom
```

```
Dispersion: 1
```

```
Chi^2-statistic vs. constant model: 119, p-value = 1.55e-22
```

The  $p$ -values of  $2.14e-17$ ,  $0.00069$ , and  $1.58e-09$  indicate that the coefficients of the variables  $x_1$ ,  $x_3$ , and  $x_6$  are statistically significant.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable. The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a dataset array, then 0 must represent the response variable depending on the position of the response variable in the dataset array. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
0 0 0 0
1 0 0 0
0 0 1 0
0 0 0 1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

T =

```
0 0 0 0
0 1 0 0
0 0 1 0
0 0 0 1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

T =

```

    0    0    0
    1    0    0
    0    1    0
    1    1    0
    0    2    0

```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

mdl =

Linear regression model:

$$y \sim 1 + x1*x2 + x2^2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.000196
x1	0.54418	0.57125	0.95261	0.343
x2	-0.012781	0.0060312	-2.1192	0.0368
x1:x2	-0.00010892	0.00017925	-0.6076	0.5
x2^2	9.7518e-07	7.5389e-07	1.2935	0.199

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];  
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:  
y ~ 1 + x2

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of fitlm in the previous step.

## Formula

A formula for model specification is a string of the form

```
'Y ~ terms',
```

where

- Y is the response name.
- *terms* contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable

- `:` defines an interaction, a product of terms
- `*` defines an interaction **and all lower-order terms**
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower order terms as well
- `()` groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include `-1` in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

### Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k, where k is a positive integer	A, A <sup>2</sup> , ..., A <sup>k</sup>
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

## Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

**Tips**

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For methods such as `plotResiduals` or `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

**Alternative Functionality**

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

# fitlm

---

**Purpose** Create linear regression model

**Syntax**

```
mdl = fitlm(ds)
mdl = fitlm(ds,modelspec)

mdl = fitlm(X,y)
mdl = fitlm(X,y,modelspec)

mdl = fitlm( __ ,Name,Value)
```

**Description** `mdl = fitlm(ds)` returns a linear model fit to variables in the dataset array `ds`. By default, `fitlm` takes the last variable as the response variable.

`mdl = fitlm(ds,modelspec)` returns a linear model of the type you specify in `modelspec` fit to variables in the dataset array `ds`.

`mdl = fitlm(X,y)` returns a linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitlm(X,y,modelspec)` returns a linear model of the type you specify in `modelspec` for the responses `y`, fit to the data matrix `X`.

`mdl = fitlm( __ ,Name,Value)` returns a linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, perform robust regression, or use observation weights.

## **Input Arguments**

**ds - Input data**  
dataset array

Input data, specified as a dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response

variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### Data Types

single | double | logical

### X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

### Data Types

single | double | logical

### y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### Data Types

single | double

### modelspec - Model specification

string naming the model |  $t$ -by- $(p + 1)$  terms matrix | string of the form 'Y ~ terms'

Model specification, specified as one of the following. The choice is the starting model for `stepwiselm`.

- A string naming the model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p + 1)$  matrix, namely terms matrix, specifying terms to include in the model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus 1 is for the response variable.
- A string representing a formula in the form

'Y ~ terms',

where the terms are in Wilkinson Notation.

**Example:** 'quadratic'

**Example:** `'y ~ X1 + X2^2 + X1:X2'`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **Example:**

`'Intercept',false,'PredictorVars',[1,3],'ResponseVar',5,'RobustOpts'`, specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning constant, first and third variables are the predictor variables, and fifth variable is the response variable.

### **'CategoricalVars' - Categorical variables**

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the dataset array `ds`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in dataset array `ds`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars',[2,3]`

**Example:** `'CategoricalVars',logical([0 1 1 0 0 0])`

### **Data Types**

single | double | logical

## **'Exclude' - Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## **Data Types**

single | double | logical

## **'Intercept' - Indicator for constant term**

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

## **'PredictorVars' - Predictor variables**

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the dataset array ds, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in the ds dataset array, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in ds except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

### Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column in dataset array `ds` (default) | string for variable name  
| logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the dataset array `ds`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a dataset array `ds`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** 'ResponseVar','yield'

**Example:** 'ResponseVar',[4]

**Example:** 'ResponseVar',logical([0 0 0 1 0 0])

### Data Types

single | double | logical | char

### 'RobustOpts' - Indicator of robust fitting type

'off' (default) | 'on' | string | structure with string or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of the following.

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.

- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.
- String — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the string `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985

The value  $r$  in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h}),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD}/0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are  $p$  columns in  $X$ , the smallest  $p$  absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

**Example:** `'RobustOpts', 'andrews'`

### 'VarNames' - Names of variables in fit

`{ 'x1', 'x2', ..., 'xn', 'y' }` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of  $X$  first, and the name for the response variable  $y$  last.

`'VarNames'` is not applicable to variables in a dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

**Example:**

```
'VarNames',{ 'Horsepower','Acceleration','Model_Year','MPG' }
```

**Data Types**

cell

**'Weights' - Observation weights**

ones(n,1) (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

**Data Types**

single | double

## Output Arguments

**mdl - Linear model**

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, mdl, see the LinearModel class page.

## Examples

**Linear Regression with Categorical Predictor and Quadratic Term**

Fit a quadratic linear regression model to variables in a dataset array. The data includes continuous and categorical predictor variables.

Load the sample data.

```
load carsmall
```

Construct a dataset array containing continuous predictor variable `Weight` and response variable `MPG`. Add the nominal predictor variable `Year`.

```
ds = dataset(MPG,Weight);
ds.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight2`. You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight2`. For details, see “Formula” on page 21-1035.

```
mdl = fitlm(ds,'MPG ~ Year + Weight^2')
```

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ 1 + Weight + Year + Weight^2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 2.78
```

```
R-squared: 0.885, Adjusted R-Squared 0.88
```

```
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`fitlm` creates two dummy (indicator) variables for the nominal variables, `Year`. The dummy variable `Year_76` takes the value 1 if the model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. 1970 is the reference year (for details on dummy variables, see “Dummy Indicator Variables” on page 2-55). The fitted model is

$$\hat{MPG} = 54.206 - 0.0164Weight + 2.0887(Year\_76) + 8.1864(Year\_82) + 1.557e - 06Weight^2$$

## Simultaneously Specify the Variables and Use Formula

Simultaneously identify response and predictor variables and specify the model using a formula in linear regression.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Indicate which variable is the response variable and identify the continuous and categorical predictors using name-value pair arguments.

```
mdl = fitlm(hospital, 'Weight~1+Age*Sex*Smoker-Age:Sex:Smoker', 'ResponseVariable');
```

```
mdl =
```

Linear regression model:

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.78211

Number of observations: 100, Error degrees of freedom: 93

Root Mean Squared Error: 8.75

R-squared: 0.898, Adjusted R-Squared 0.892

F-statistic vs. constant model: 137, p-value = 6.91e-44

The  $t$ -statistics in `tStat` and corresponding  $p$ -values in `pValue` indicate that patient weights do not seem to differ significantly according to age, or the status of smoking, or the interaction of these factors with gender at the 5% significance level.

### Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % Predictor variables
y = heat; % Response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
```

```
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.65

R-squared: 0.979, Adjusted R-Squared 0.969

F-statistic vs. constant model: 94.6, p-value = 9.03e-07

## Definitions

## Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable. The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a dataset array, then 0 must represent the response variable depending on the position of the response variable in the dataset array. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
0 0 0 0
1 0 0 0
0 0 1 0
```

```
0 0 0 1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

T =

```
0 0 0 0
0 1 0 0
0 0 1 0
0 0 0 1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

T =

```
0 0 0
1 0 0
0 1 0
1 1 0
0 2 0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0], 'upper', T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

$$y \sim 1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of fitlm in the previous step.

### Formula

A formula for model specification is a string of the form

`'Y ~ terms'`,

where

- Y is the response name.
- *terms* contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - \* defines an interaction **and all lower-order terms**

- $\wedge$  raises the predictor to a power, exactly as in  $*$  repeated, so  $\wedge$  includes lower order terms as well
- $()$  groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include  $-1$  in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where $k$ is a positive integer	$A, A^2, \dots, A^k$

Wilkinson Notation	Factors in Standard Notation
$A + B$	A, B
$A*B$	A, B, $A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	A, B, C, $A*B$
$A + B + C + A:B$	A, B, C, $A*B$
$A*B*C - A:B:C$	A, B, C, $A*B$ , $A*C$ , $B*C$
$A*(B + C)$	A, B, C, $A*B$ , $A*C$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

# fitlme

---

**Purpose** Fit linear mixed-effects model

**Syntax**  
`lme = fitlme(ds,formula)`  
`lme = fitlme(ds,formula,Name,Value)`

**Description** `lme = fitlme(ds,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the dataset array `ds`.

`lme = fitlme(ds,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

## Input Arguments

### **ds - Input data**

dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-51). You must specify the model for the variables using `formula`.

### **Data Types**

single | double | char | cell

### **formula - Formula for model specification**

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see “Formula” on page 21-1059.

**Example:** `'y ~ treatment + (1|block)'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### Example:

```
'CovariancePattern', 'Diagonal', 'Optimizer', 'fminunc', 'OptimizerOptions'
```

specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and `fitlme` uses the `fminunc` optimization algorithm with the custom optimization parameters defined in variable `opt`.

### 'CovariancePattern' - Pattern of covariance matrix

```
'FullCholesky' (default) | string | square symmetric logical matrix |  
cell array of strings or logical matrices
```

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are  $R$  random-effects terms, then the value of `'CovariancePattern'` must be a cell array of length  $R$ , where each element  $r$  of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the  $r$ th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

'CompSymm'

where  $\sigma^2_{b_1}$  is the common variance of the random-effects terms.

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma^2_{b_1} & \sigma_{b_1,b_2} & \sigma_{b_1,b_2} \\ \sigma_{b_1,b_2} & \sigma^2_{b_1} & \sigma_{b_1,b_2} \\ \sigma_{b_1,b_2} & \sigma_{b_1,b_2} & \sigma^2_{b_1} \end{pmatrix}$$

where  $\sigma^2_{b_1}$  is the common variance of the random-effects terms and  $\sigma_{b_1,b_2}$  is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if  $\text{PAT}(a,b) = \text{false}$ , then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

**Example:** 'CovariancePattern', 'Diagonal'

**Example:** 'CovariancePattern', {'Full', 'Diagonal'}

### 'FitMethod' - Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'	Default. Maximum likelihood estimation
'REML'	Restricted maximum likelihood estimation

**Example:** 'FitMethod','REML'

### **'Weights' - Observation weights**

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$ , where  $n$  is the number of observations.

#### **Data Types**

single | double

### **'Exclude' - Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

**Example:** 'Exclude',[13,67]

#### **Data Types**

single | double | logical

### **'DummyVarCoding' - Coding to use for dummy variables**

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

**Example:** 'DummyVarCoding','effects'

### 'Optimizer' - Optimization algorithm

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code>

with 'Algorithm' set to  
'quasi-newton'.

**Example:** 'Optimizer','fminunc'

## **'OptimizerOptions' - Options for optimization algorithm**

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinewton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinewton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

## **'TolFun' - Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

## **'TolX' - Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**'MaxIter' - Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**'Display' - Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**'StartMethod' - Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'	Default. An internally defined default value.
-----------	---

'random'	A random initial value.
----------	-------------------------

**Example:** 'StartMethod', 'random'

**'Verbose' - Indicator to display optimization process on screen**

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

**Example:** 'Verbose', true

**'CheckHessian' - Indicator to check positive definiteness of Hessian**

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

**Example:** 'CheckHessian',true

## Output Arguments

### lme - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Examples

### Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, `WtdILI`, and a random intercept that varies by `Date`. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_i + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable `Date`.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable `Date` and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b \sim N(0, \sigma_b^2)$  and the error term has the distribution,  $\varepsilon \sim N(0, \sigma^2)$ .

```
lme = fitlme(flu2, 'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
FluRate ~ 1 + WtdILI + (1 | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	0.16385	0.057525	2.8484	466	0.0045
'WtdILI'	0.7236	0.032219	22.459	466	3.05e-45

```
Random effects covariance parameters (95% CIs):
```

```

Group: Date (52 Levels)
      Name1              Name2              Type      Estimate      Lower      Upper
      '(Intercept)'      '(Intercept)'      'std'      0.17146      0.13227    0.22226
Group: Error
      Name              Estimate      Lower      Upper
      'Res Std'        0.30201      0.28217    0.32324

```

The confidence limits for the standard deviation of the random-effects term,  $\sigma_b^2$ , do not include 0 (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}
 \hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 WtdILI_{28} + \hat{b}_{10/30/2005} \\
 &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\
 &= 1.46749,
 \end{aligned}$$

where  $\hat{b}$  is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```

beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics
STATS.Level = nominal(STATS.Level);

ans =
    1.4674
```

## Randomized Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and fitlme creates a matrix called a “fixed effects design matrix” to describe the effect of shift. This matrix has two columns, *Shift\_Evening* and *Shift\_Morning*, where

$$Shift\_Evening = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad Shift\_Morning = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} .$$

The model corresponds to

Morning Shift:  $QCDev_{im} = \beta_0 + \beta_2 Shift - Morning_i + b_{0m} + \varepsilon_{im}$ ,  $m = 1, 2, \dots, 5$ ,  
 Evening Shift:  $QCDev_{im} = \beta_0 + \beta_1 Shift - Evening_i + b_{0m} + \varepsilon_{im}$ ,  
 Night Shift:  $QCDev_{im} = \beta_0 - \beta_1 Shift - Evening_i - \beta_2 Shift - Morning_i + b_{0m} + \varepsilon_{im}$ ,

where  $b \sim N(0, \sigma^2_b)$  and  $\varepsilon \sim N(0, \sigma^2)$ .

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')

-1.9472

```

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}
 \hat{y}_{Evening, Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift\_Evening + \hat{b}_{03} \\
 &= 3.6525 - 0.53293 - 2.1715 \\
 &= 0.94807.
 \end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

$$\begin{aligned}\hat{y}_{Morning,Operator3} &= \hat{\beta}_0 + \hat{\beta}_2 Shift\_Morning + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value as follows.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
```

```
ans =
```

```
0.5613
```

The operator tends to make a smaller magnitude of error during the morning shift.

## Split-Plot Experiment

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
```

```
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S^* T)_{jk} + \varepsilon_{imjk},$$

where  $i = 1, 2, \dots, 60$ , index  $m$  corresponds to the fertilizer types,  $j$  corresponds to the tomato types, and  $k = 1, 2, 3$  corresponds to the blocks (soil).  $S_k$  represents the  $k$ th soil type, and  $(S^* T)_{jk}$  represents the  $j$ th tomato type nested in the  $k$ th soil type.  $I[F]_{im}$  is the dummy variable representing level  $m$  of the fertilizer. Similarly,  $I[T]_{ij}$  is the dummy variable representing level  $j$  of the tomato type.

The random effects and observation error have these prior distributions:  $b_{0k} \sim N(0, \sigma_S^2)$ ,  $b_{0jk} \sim N(0, \sigma_{S^*T}^2)$ , and  $\varepsilon_{imjk} \sim N(0, \sigma^2)$ .

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
lme =
```

The  $p$ -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the anova method after refitting the model using 'effects' contrasts.

The confidence interval for the standard deviations of the random-effects terms ( $\sigma^2_{\epsilon}$ ), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term (`1 | Soil`).

```
lme = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)')
```

```
lme =
```

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

## Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a dataset array. Define `Subject` and `Program` as categorical variables.

```
ds = dataset(InitialWeight,Program,Subject,Week,y);
ds.Subject = nominal(ds.Subject);
ds.Program = nominal(ds.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables  $I[\cdot]$ . Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables. This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .  $\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{1m}$  and  $b_{0m}$  are random effects.  $IW$  stands for initial weight and  $I[\cdot]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program B. The random effects and observation error have these prior distributions:  $b_{0m} \sim N(0, \sigma^2_0)$ ,  $b_{1m} \sim N(0, \sigma^2_1)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
lme = fitlme(ds, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:

'Program_D:Week'	0.033114	0.095394	0.34713	111

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.18407
'Week'	'(Intercept)'	'corr'	0.66841
'Week'	'Week'	'std'	0.15033

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The  $p$ -values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different

relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

## Definitions

### Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms. Suppose a dataset array `ds` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1`, `g2`, ..., `gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix  $X$ , `random1` is a specification of the random-effects design matrix  $Z_1$  corresponding to grouping variable `g1`, and similarly `randomR` is a specification of the random-effects design matrix  $Z_R$  corresponding to grouping variable `gR`. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$X^k$ , where $k$ is a positive integer	$X$ , $X^2$ , ..., $X^k$

Wilkinson Notation	Factors in Standard Notation
$X1 + X2$	X1, X2
$X1 * X2$	X1, X2, $X1.*X2$ (elementwise multiplication of X1 and X2)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include X2
$X1 * X2 + X3$	X1, X2, X3, $X1 * X2$
$X1 + X2 + X3 + X1 : X2$	X1, X2, X3, $X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	X1, X2, X3, $X1 * X2$ , $X1 * X3$ , $X2 * X3$
$X1 * (X2 + X3)$	X1, X2, X3, $X1 * X2$ , $X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	Fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1   g1)'	Intercept plus random effect for each level of the grouping variable g1.
'y ~ X1 + (1   g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1   g1)'	Random intercept and slope, with possible correlation between them.

Formula	Description
'y ~ X1 + (1   g1) + (-1 + X1   g1)'	Independent random intercept and slope.
'y ~ 1 + (1   g1) + (1   g2) + (1   g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

### Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where  $D$  is a  $q$ -by- $q$  symmetric and positive semidefinite matrix, parameterized by a variance component vector  $\theta$ ,  $q$  is the number of variables in the random-effects term, and  $\sigma^2$  is the observation error variance. Since the covariance matrix of the random effects,  $D$ , is symmetric, it has  $q(q+1)/2$  free parameters. Suppose  $L$  is the lower triangular Cholesky factor of  $D(\theta)$  such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the  $q^*(q+1)/2$ -by-1 unconstrained parameter vector  $\theta$  is formed from elements in the lower triangular part of  $L$ . For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

## Log-Cholesky Parameterization

When the diagonal elements of  $L$  in Cholesky parameterization are constrained to be positive, then the solution for  $L$  is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of  $L$  are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing  $L_{ii} \geq 0$ ,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

## Alternatives

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

## See Also

`LinearMixedModel` | `fitlmematrix`

# fitlmematrix

---

**Purpose** Fit linear mixed-effects model

**Syntax**

```
lme = fitlmematrix(X,y,Z,[])  
lme = fitlmematrix(X,y,Z,G)  
lme = fitlmematrix(__,Name,Value)
```

**Description** `lme = fitlmematrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where  $n$  is the number of observations. Using `fitlmematrix(X,Y,Z,[])` without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using the 'CovariancePattern' name-value pair argument.

`lme = fitlmematrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = fitlmematrix(__,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

## Input Arguments

### **X - Fixed-effects design matrix**

*n*-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where  $n$  is the number of observations, and  $p$  is the number of fixed-effects

predictor variables. Each row of  $X$  corresponds to one observation, and each column of  $X$  corresponds to one variable.

**Data Types**

single | double

**y - Response values**

$n$ -by-1 vector

Response values, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations.

**Data Types**

single | double

**Z - Random-effects design**

$n$ -by- $q$  matrix | cell array of  $R$   $n$ -by- $q(r)$  matrices,  $r = 1, 2, \dots, R$

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then  $Z$  must be an  $n$ -by- $q$  matrix, where  $n$  is the number of observations and  $q$  is the number of variables in the random-effects term.
- If there are  $R$  random-effects terms, then  $Z$  must be a cell array of length  $R$ . Each cell of  $Z$  contains an  $n$ -by- $q(r)$  design matrix  $Z\{r\}$ ,  $r = 1, 2, \dots, R$ , corresponding to each random-effects term. Here,  $q(r)$  is the number of random effects term in the  $r$ th random effects design matrix,  $Z\{r\}$ .

**Data Types**

single | double | cell

**G - Grouping variable or variables**

$n$ -by-1 vector | cell array of  $R$   $n$ -by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then  $G$  must be an  $n$ -by-1 vector corresponding to a single grouping variable with  $M$  levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then G must be a cell array of length  $R$ . Each cell of G contains a grouping variable  $G\{r\}$ ,  $r = 1, 2, \dots, R$ , with  $M(r)$  levels.

$G\{r\}$  can be a categorical vector, numeric vector, character array, or cell array of strings.

## Data Types

single | double | char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

### Example:

`'CovariancePattern', 'Diagonal', 'DummyVarCoding', 'full', 'Optimizer', 'fminunc` specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the `fminunc` optimization algorithm.

## 'FixedEffectPredictors' - Names of columns in fixed-effects design matrix

`{'x1', 'x2', ..., 'xP'}` (default) | cell array of length  $p$

Names of columns in the fixed-effects design matrix  $X$ , specified as the comma-separated pair consisting of `'FixedEffectPredictors'` and a cell array of length  $p$ .

For example, if you have a constant term and two predictors, say `TimeSpent` and `Gender`, where `Female` is the reference level for `Gender`, as the fixed effects, then you can specify the names of your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

**Example:**

```
'FixedEffectPredictors',{ 'Intercept', 'TimeSpent', 'Gender_Male' },
```

**Data Types**

cell

**'RandomEffectPredictors' - Names of columns in random-effects design matrix or cell array**

cell array of length  $q$  | cell array of length  $R$  with elements of length  $q(r)$ ,  $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array  $Z$ , specified as the comma-separated pair consisting of 'RandomEffectPredictors' and either of the following:

- A cell array of length  $q$  when  $Z$  is an  $n$ -by- $q$  design matrix. In this case, the default is {'z1', 'z2', ..., 'zQ'}.
- A cell array of length  $R$ , when  $Z$  is a cell array of length  $R$  with each element  $Z\{r\}$  of length  $q(r)$ ,  $r = 1, 2, \dots, R$ . In this case, the default is {'z11', 'z12', ..., 'z1Q(1)' }, ..., {'zr1', 'zr2', ..., 'zrQ(r)' }.

For example, suppose you have correlated random effects for intercept and a variable named Acceleration. Then, you can specify the random-effects predictor names as follows.

**Example:**

```
'RandomEffectPredictors',{ 'Intercept', 'Acceleration' }
```

If you have two random effects terms, one for the intercept and the variable Acceleration grouped by variable g1, and the second for the intercept, grouped by the variable g2, then you specify the random-effects predictor names as follows.

**Example:**

```
'RandomEffectPredictors',{ {'Intercept', 'Acceleration'}, {'Intercept'} }
```

**Data Types**

cell

**'ResponseVarName' - Name of response variable**

'y' (default) | string

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a string.

For example, if your response variable name is `score`, then you can specify it as follows.

**Example:** 'ResponseVarName', 'score'

## Data Types

char

## 'RandomEffectGroups' - Names of random effects grouping variables

'g' or {'g1', 'g2', ..., 'gR'} (default) | string | cell array of strings

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- String — If there is only one random-effects term, that is, if  $G$  is a vector, then the value of 'RandomEffectGroups' is a string containing the name for the grouping variable  $G$ . The default is 'g'.
- Cell array of strings — If there are multiple random-effects terms, that is, if  $G$  is a cell array of length  $R$ , then the value of 'RandomEffectGroups' is a cell array of length  $R$ , where each cell contains the name for the grouping variable  $G\{r\}$ . The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, `z1` and `z2`, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

**Example:** 'RandomEffectGroups', {'sex', 'subject'}

## Data Types

char | cell

## 'CovariancePattern' - Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are  $R$  random-effects terms, then the value of 'CovariancePattern' must be a cell array of length  $R$ , where each element  $r$  of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the  $r$ th random-effects term. The options for each element follow.

- 'FullCholesky' Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.
- 'Full' Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.
- 'Diagonal' Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where  $\sigma_b^2$  is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where  $\sigma_{b1}^2$  is the common variance of the random-effects terms and  $\sigma_{b1,b2}$  is the common covariance

between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if  $PAT(a,b) = \text{false}$ , then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

**Example:** 'CovariancePattern', 'Diagonal'

**Example:** 'CovariancePattern', {'Full', 'Diagonal'}

## 'FitMethod' - Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

**Example:** 'FitMethod', 'REML'

## 'Weights' - Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$ , where  $n$  is the number of observations.

### Data Types

single | double

## **'Exclude' - Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

**Example:** 'Exclude',[13,67]

## **Data Types**

single | double | logical

## **'DummyVarCoding' - Coding to use for dummy variables**

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

**Example:** 'DummyVarCoding','effects'

## **'Optimizer' - Optimization algorithm**

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinewton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

**Example:** 'Optimizer','fminunc'

### 'OptimizerOptions' - Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasinewton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinewton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

**'TolFun' - Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

**'TolX' - Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**'MaxIter' - Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**'Display' - Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**'StartMethod' - Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'	Default. An internally defined default value.
'random'	A random initial value.

**Example:** 'StartMethod', 'random'

### 'Verbose' - Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

**Example:** 'Verbose', true

### 'CheckHessian' - Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

**Example:** 'CheckHessian', true

## Output Arguments

### lme - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Examples      No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;  
X = [ones(size(Weight)), Weight];  
Z = ones(size(y));  
lme = fitlmematrix(X,y,Z,Model_Year)
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	94

## Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned} y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ & + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ & + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im}, \end{aligned}$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .  $\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{0m}$  and  $b_{1m}$  are random effects.  $IW$  stands for initial weight and  $I[\cdot]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have these prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;
```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC',...
'RandomEffectPredictors',{'Intercept','Week'}},'RandomEffectGroups',G);

lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	120
Fixed effects coefficients	9
Random effects coefficients	40
Covariance parameters	4

Formula:

# fitlmematrix

Linear Mixed Formula with 10 predictors.

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
-22.981	13.257	24.49	-48.981

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pVal
'Intercept'	0.66105	0.25892	2.5531	111	0.0115
'InitWeight'	0.0031879	0.0013814	2.3078	111	0.0228
'PrgB'	0.36079	0.13139	2.746	111	0.0072
'PrgC'	-0.033263	0.13117	-0.25358	111	0.8000
'PrgD'	0.11317	0.13132	0.86175	111	0.3880
'Week'	0.1732	0.067454	2.5677	111	0.0115
'Week_PrgB'	0.038771	0.095394	0.40644	111	0.6870
'Week_PrgC'	0.030543	0.095394	0.32018	111	0.7470
'Week_PrgD'	0.033114	0.095394	0.34713	111	0.7310

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	Lower
'Intercept'	'Intercept'	'std'	0.18407	0.1220
'Week'	'Intercept'	'corr'	0.66841	0.2100
'Week'	'Week'	'std'	0.15033	0.1100

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The  $p$ -values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the compare method.

## Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into a tall array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 WtdILI_i + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable `Date`.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable `Date` and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b_{0m} \sim N(0, \sigma_{FR}^2)$  and the error term has the distribution,  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

# fitlmematrix

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept','NationalRate'},  
'RandomEffectPredictors',{'Intercept'},'RandomEffectGroups',{'Date'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue
'Intercept'	0.16385	0.057525	2.8484	466	0.0046
'NationalRate'	0.7236	0.032219	22.459	466	3.0502e-45

```
Random effects covariance parameters (95% CIs):
```

```
Group: Date (52 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.17146	0.13227	0.22226

```
Group: Error
```

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term  $\sigma_{b_{0m}}^2$ , do not include zero (0.13227, 0.22226), which indicates that

the random-effects term is significant. You can also test the significance of the random-effects using compare method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 WtdILLI_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where  $\hat{b}$  is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level);

y_hat =

    1.4674
```

You can simply display the fitted value using the fitted(lme) method.

```
F = fitted(lme);
F(28)

ans =

    1.4674
```

## Randomized Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix,  $X1$  and  $X2$ , where

$$Shift\_Evening = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad Shift\_Morning = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 Shift\_Morning_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 Shift\_Evening_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 Shift\_Evening_i - \beta_2 Shift\_Morning_i + b_{0m} + \varepsilon_{im},$$

where  $i$  represents the observations, and  $m$  represents the operators,  $i = 1, 2, \dots, 15$ , and  $m = 1, 2, \dots, 5$ . The random effects and the observation error have these distributions:  $b_{0m} \sim N(0, \sigma_{b_{0m}}^2)$  and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
```

```
Z = ones(15,1);

 -1.9472
```

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{Y}_{Evening, Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift\_Evening + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
  0.9481
```

## Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having these distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ , and  $b_{1m} \sim N(0, \sigma_1^2)$ .  $m$  represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{'Intercept'}, {'Acceleration'}}, 'RandomEffectGroups', {'Model_Year'}, 'M
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3

# fitmematrix

---

Random effects coefficients            26  
Covariance parameters                 3

Formula:

$y \sim \text{Intercept} + \text{Acceleration} + \text{Horsepower} + (\text{Intercept} \mid \text{Model\_Year})$

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pVal
'Intercept'	49.839	2.0518	24.291	389	5.61
'Acceleration'	-0.58565	0.10846	-5.3995	389	1.16
'Horsepower'	-0.16534	0.0071227	-23.213	389	1.97

Random effects covariance parameters (95% CIs):

Group: Model\_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	8.0669e-07	NaN	NaN

Group: Model\_Year (13 Levels)

Name1	Name2	Type	Estimate
'Acceleration'	'Acceleration'	'std'	0.18783

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.7258	3.4698	4.0007

The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case, the random-effects terms has this prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left( 0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where  $m$  represents the model year.

First, prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;
```

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2193.5	2221.3	-1089.7	2179.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF
'Intercept'	50.133	2.2652	22.132	389
'Acceleration'	-0.58327	0.13394	-4.3545	389
'Horsepower'	-0.16954	0.0072609	-23.35	389

Random effects covariance parameters (95% CIs):

Group: Model\_Year (13 Levels)

Name1	Name2	Type	Estimate
'Intercept'	'Intercept'	'std'	3.3475
'Acceleration'	'Intercept'	'corr'	-0.87971
'Acceleration'	'Acceleration'	'std'	0.33789

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the compare method.

## Specify the Covariance Pattern

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

weight contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define Subject and Program as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} \\ + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .

$\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{1m}$  and  $b_{1m}$  are random effects.  $IW$  stands for initial weight and  $I[.]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have these prior distributions:  $b_{0m} \sim N(0, \sigma^2_0)$ ,  $b_{1m} \sim N(0, \sigma^2_1)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{'Intercept','Week'},...
'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')
```

```
lme =
```

'Intercept'	'Intercept'	'std'	0.16561	0.1289

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10272	0.088014	0.11987

## Alternative Functionality

You can also fit a linear mixed-effects model using `fitlme(ds, formula)`, where `ds` is a dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`.

## Definitions

### Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where  $D$  is a  $q$ -by- $q$  symmetric and positive semidefinite matrix, parameterized by a variance component vector  $\theta$ ,  $q$  is the number of variables in the random-effects term, and  $\sigma^2$  is the observation error variance. Since the covariance matrix of the random effects,  $D$ , is symmetric, it has  $q(q+1)/2$  free parameters. Suppose  $L$  is the lower triangular Cholesky factor of  $D(\theta)$  such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the  $q^*(q+1)/2$ -by-1 unconstrained parameter vector  $\theta$  is formed from elements in the lower triangular part of  $L$ . For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

### Log-Cholesky Parameterization

When the diagonal elements of  $L$  in Cholesky parameterization are constrained to be positive, then the solution for  $L$  is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of  $L$  are used to guarantee unique parameterization.

# fitlmematrix

---

For example, for the 3-by-3 example in Cholesky parameterization, enforcing  $L_{ii} \geq 0$ ,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

## See Also

[fitlmeLinearMixedModel](#) | [compare](#) |

**Purpose**

Fit probability distribution object to data

**Syntax**

```
pd = fitdist(x,distname)
pd = fitdist(x,distname,Name,Value)

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)
[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)
```

**Description**

`pd = fitdist(x,distname)` creates a probability distribution object by fitting the distribution specified by `distname` to the data in column vector `x`.

`pd = fitdist(x,distname,Name,Value)` creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)` creates probability distribution objects by fitting the distribution specified by `distname` to the data in `x` based on the grouping variable `groupvar`. It returns a cell array of fitted probability distribution objects, `pdca`, a cell array of group labels, `gn`, and a cell array of grouping variable levels, `gl`.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)` returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

**Input Arguments****x - Input data**

column vector

Input data, specified as a column vector. `fitdist` ignores NaN values in `x`. Additionally, any NaN values in the censoring vector or frequency vector causes `fitdist` to ignore the corresponding values in `x`.

## Data Types

single | double

## distname - Distribution name

string

Distribution name, specified as one of the following strings. The distribution specified by `distname` determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta'	Beta distribution	prob.BetaDistribution
'Binomial'	Binomial distribution	prob.BinomialDistribution
'BirnbbaumSaunders'	Birnbbaum-Saunders distribution	prob.BirnbbaumSaundersDistribution
'Burr'	Burr distribution	prob.BurrDistribution
'Exponential'	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma'	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueDistribution
'GeneralizedPareto'	Generalized Pareto distribution	prob.GeneralizedParetoDistribution
'InverseGaussian'	Inverse Gaussian distribution	prob.InverseGaussianDistribution
'Kernel'	Kernel distribution	prob.KernelDistribution
'Logistic'	Logistic distribution	prob.LogisticDistribution
'Loglogistic'	Loglogistic distribution	prob.LoglogisticDistribution

Distribution Name	Description	Distribution Class
'Lognormal'	Lognormal distribution	prob.LognormalDistribution
'Multinomial'	Multinomial distribution	prob.MultinomialDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistribution
'Normal'	Normal distribution	prob.NormalDistribution
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution
'Rician'	Rician distribution	prob.RicianDistribution
'tLocationScale'	$t$ Location-Scale distribution	prob.tLocationScaleDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

### groupvar - Grouping variable

categorical array | logical or numeric vector | cell array of strings

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of strings with values 'Male' and 'Female', you can use `Gender` as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender,Smoker}`

divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

**Example:** {Gender,Smoker}

## Data Types

single | double | logical | cell | char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `fitdist(x,'Kernel','Kernel','triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

## 'Censoring' - Logical flag for censored data

0 (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of `'Censoring'` and a vector of logical values that is the same size as input vector `x`. The value is 1 when the corresponding element in `x` is a right-censored observation and 0 when the corresponding elements is an exact observation. The default is a vector of 0s, indicating that all observations are exact.

`fitdist` ignores any NaN values in this censoring vector. Additionally, any NaN values in `x` or the frequency vector causes `fitdist` to ignore the corresponding values in the censoring vector.

## Data Types

logical

## 'Frequency' - Observation frequency

1 (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of `'Frequency'` and a vector of nonnegative integer values

that is the same size as input vector `x`. Each element of the frequency vector specifies the frequencies for the corresponding elements in `x`. The default is a vector of 1s, indicating that each value in `x` only appears once.

`fitdist` ignores any NaN values in this frequency vector are ignored by the fitting calculations. Additionally, any NaN values in `x` or the censoring vector causes `fitdist` to ignore the corresponding values in the frequency vector.

**Data Types**

logical

**'Options' - Control parameters**

structure

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of 'Options' and a structure you create using `statset`.

**Data Types**

struct

**'NTrials' - Number of trials**

positive integer value

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of 'NTrials' and a positive integer value. You must specify `distname` as 'Binomial' to use this option.

**Data Types**

single | double

**'Theta' - Threshold parameter**

0 (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of 'Theta' and a scalar value. You must specify `distname` as 'GeneralizedPareto' to use this option.

## Data Types

single | double

### 'Kernel' - Kernel smoother type

'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following:

- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

You must specify `distname` as 'Kernel' to use this option.

### 'Support' - Kernel density support

'unbounded' (default) | 'positive' | two-element vector

Kernel density support, specified as the comma-separated pair consisting of 'Support' and a string or two-element vector. The string must be one of the following.

'unbounded'	Density can extend over the whole real line.
'positive'	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify `distname` as 'Kernel' to use this option.

## Data Types

single | double

### 'Width' - Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes. You must specify `distname` as 'Kernel' to use this option.

**Data Types**

single | double

**Output Arguments****pd - Probability distribution**

probability distribution object

Probability distribution, returned as a probability distribution object. The distribution specified by `distname` determines the class type of the returned probability distribution object.

**pdca - Probability distribution objects**

cell array

Probability distribution objects of the type specified by `distname`, returned as a cell array.

**gn - Group labels**

cell array of strings

Group labels, returned as a cell array of strings.

**gl - Grouping variable levels**

cell array of strings

Grouping variable levels, returned as a cell array of strings containing one column for each grouping variable.

**Examples****Fit a Normal Distribution to Data**

Load the sample data. Create a vector containing the patients' weight data.

# fitdist

---

```
load hospital;  
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu =      154    [148.728, 159.272]  
sigma = 26.5714  [23.3299, 30.8674]
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;  
pdf = pdf(pd,x_values);  
plot(x_values,pdf,'LineWidth',2)
```

### Fit a Kernel Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital;  
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

# fitdist

---

```
pd = fitdist(x,'Kernel','Kernel','epanechnikov')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = epanechnikov
```

```
Bandwidth = 14.3792
```

```
Support = unbounded
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;  
pdf = pdf(pd,x_values);  
plot(x_values,pdf)
```

### Fit Normal Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital;  
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

# fitdist

---

```
gender = hospital.Sex;  
[pdca,gn,gl] = fitdist(x, 'Normal', 'By', gender)
```

```
pdca =
```

```
Column 1
```

```
[1x1 prob.NormalDistribution]
```

```
Column 2
```

```
[1x1 prob.NormalDistribution]
```

```
gn =
```

```
'Female'
```

```
'Male'
```

```
gl =
```

```
'Female'
```

```
'Male'
```

The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two strings of the group labels. The cell array `gl` contains two strings of the group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender.

```
female = pdca{1} % distribution for females
```

```
female =
```

```
NormalDistribution
```

```
Normal distribution
    mu = 130.472    [128.183, 132.76]
    sigma = 8.30339 [6.96947, 10.2736]

male = pdca{2} % distribution for males

male =

NormalDistribution

Normal distribution
    mu = 180.532    [177.833, 183.231]
    sigma = 9.19322 [7.63933, 11.5466]
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure;
plot(x_values,femalepdf,'LineWidth',2)
hold on;
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
legend(gn,'Location','NorthEast');
hold off;
```

# fitdist

## Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital;  
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```
gender = hospital.Sex;  
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');
```

View each distribution in the cell array pdca to see the kernel distributions for each gender.

```
female = pdca{1} % distribution for females
```

```
female =
```

```
KernelDistribution
```

```
Kernel = triangle  
Bandwidth = 4.25894  
Support = unbounded
```

```
male = pdca{2} % distribution for males
```

```
male =
```

```
KernelDistribution
```

```
Kernel = triangle  
Bandwidth = 5.08961  
Support = unbounded
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure;  
plot(x_values,femalepdf,'LineWidth',2)

```

## Algorithms

The `fitdist` function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.

- For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

## Alternative Functionality

### App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

# fitensemble

---

## Purpose

Fitted ensemble for classification or regression

## Syntax

```
ens = fitensemble(X,Y,method,nlearn,learners)
ens = fitensemble(X,Y,method,nlearn,learners,Name,Value)
```

## Description

`ens = fitensemble(X,Y,method,nlearn,learners)` creates an ensemble model that predicts responses to data. The ensemble consists of models listed in `learners`.

`ens = fitensemble(X,Y,method,nlearn,learners,Name,Value)` creates an ensemble model with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## Tips

- If `X` has categorical predictors with many levels, use 'GentleBoost' or 'LogitBoost' for binary classification. Using other algorithms in this case would likely cause long training times and can exhaust memory.

## Input Arguments

### X

Matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

### Y

For classification, `Y` is a categorical variable, character array, or cell array of strings. Each row of `Y` represents the classification of the corresponding row of `X`.

For regression, `Y` is a numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

### method

Case-insensitive string consisting of one of the following.

- For classification with two classes:

- 'AdaBoostM1'
- 'LogitBoost'
- 'GentleBoost'
- 'RobustBoost' (requires an Optimization Toolbox license)
- 'LPBoost' (requires an Optimization Toolbox license)
- 'TotalBoost' (requires an Optimization Toolbox license)
- 'RUSBoost'
- 'Subspace'
- 'Bag'
- For classification with three or more classes:
  - 'AdaBoostM2'
  - 'LPBoost' (requires an Optimization Toolbox license)
  - 'TotalBoost' (requires an Optimization Toolbox license)
  - 'RUSBoost'
  - 'Subspace'
  - 'Bag'
- For regression:
  - 'LSBoost'
  - 'Bag'

'Bag' applies to all methods. So when you use 'Bag', indicate whether you want a classifier or regressor with the `type` name-value pair set to 'classification' or 'regression'.

### **nlearn**

Number of ensemble learning cycles, a positive integer (or the string 'AllPredictorCombinations', see the next paragraph). At every training cycle, fitensemble loops over all learner templates in

learners and trains one weak learner for every template. The total number of trained learners in `ens` is `nlearn*numel(learners)`.

If you set `method` to `'Subspace'`, you can set `nlearn` to `'AllPredictorCombinations'`. With this setting, `fitensemble` constructs learners for all possible combinations of predictors taken `NPredToSample` at a time. This gives a total of `nchoosek(size(X,2),NPredToSample)` learners in the ensemble. You can use only one learner template for this setting.

`nlearn` for ensembles can vary from a few dozen to a few thousand. Usually, an ensemble with a good predictive power needs from a few hundred to a few thousand weak learners. You do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and, if necessary, train more weak learners using the `resume` method of the ensemble.

## learners

One of the following:

- A string with the name of a weak learner:
  - `'Discriminant'` (applies only to `'Subspace'`)
  - `'KNN'` (applies only to `'Subspace'`)
  - `'tree'` (applies to all methods except `'Subspace'`)
- A single weak learner template you create with `ClassificationTree.template`, `RegressionTree.template`, `ClassificationKNN.template`, or `ClassificationDiscriminant.template`.
- A cell array of weak learner templates. Usually you should supply only one weak learner template.

Ensemble performance depends on the parameters of the weak learners, and you can get poor performance using weak learners with default parameters. Specify the parameters for the weak learners in the template. Specify parameters for the ensemble in the `fitensemble` name-value pairs.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### All Ensembles:

#### 'CategoricalPredictors'

List of categorical predictors. Pass `CategoricalPredictors` as one of:

- A numeric vector with indices from 1 to  $p$ , where  $p$  is the number of columns of  $X$ .
- A logical vector of length  $p$ , where a true entry means that the corresponding column of  $X$  is a categorical variable.
- 'all', meaning all predictors are categorical.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is the name of a predictor variable. The names must match entries in the `PredictorNames` property. Pad the names with extra blanks so each row of the character matrix has the same length.

You can set `CategoricalPredictors` for these learners:

- 'Tree'
- 'KNN', when all predictors are categorical

**Default:** []

#### 'crossval'

If 'on', grows a cross-validated learner with 10 folds. You can use 'kfold', 'holdout', 'leaveout', or 'cvpartition' parameters to

override this cross-validation setting. You can only use one of these four parameters ('kfold', 'holdout', 'leaveout', or 'cvpartition') at a time when creating a cross-validated learner.

**Default:** 'off'

## **'cvpartition'**

Partition created with cvpartition to use in a cross-validated learner. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## **'fresample'**

Fraction of the training set to be selected by resampling for every weak learner. A numeric scalar from 0 to 1. This parameter has no effect unless you grow an ensemble by bagging or set 'resample' to 'on'. The default setting is the one used most often for an ensemble grown by resampling.

**Default:** 1

## **'holdout'**

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated learner: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## **'kfold'**

Number of folds to use in a cross-validated learner, a positive integer. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**Default:** 10

## **'leaveout'**

Use leave-one-out cross validation by setting to 'on'. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**'NPredToSample'**

Number of predictors in each random subspace learner, a positive integer from 1 to `size(X,2)`.

**Default:** 1

**'nprint'**

Printout frequency, a positive integer scalar. Set to 'off' for no printout. Use this parameter to track how many weak learners have been trained so far. This is useful when you train ensembles with many learners on large datasets. If you use one of the cross-validation options, this parameter defines the printout frequency per number of cross-validation folds.

**Default:** 'off'

**'PredictorNames'**

Cell array of names for the predictor variables, in the order in which they appear in X.

**Default:** {'x1', 'x2', ...}

**'replace'**

'on' or 'off'. If 'on', sample with replacement. If 'off', sample without replacement. This parameter has no effect unless you grow an ensemble by bagging or set `resample` to 'on'. If you set `resample` to 'on' and `replace` to 'off', `fitensemble` samples training observations assuming uniform weights, and boosts by reweighting observations.

**Default:** 'on'

## **'resample'**

'on' or 'off'. If 'on', grow an ensemble by resampling, with the resampling fraction given by `fresample`, and sampling with or without replacement given by `replace`.

- Boosting — When 'off', the boosting algorithm reweights observations at every learning iteration. When 'on', the algorithm samples training observations using updated weights as the multinomial sampling probabilities.
- Bagging — You can use only the default value of this parameter ('on').

**Default:** 'off' for boosting, 'on' for bagging

## **'ResponseName'**

Name of the response variable  $Y$ , a string.

**Default:** 'Y'

## **'type'**

String, either 'classification' or 'regression'. Specify type when the method is 'bag'.

## **'weights'**

Vector of observation weights. The length of weights is the number of rows in  $X$ .

**Default:** `ones(size(X,1),1)`

## **Classification Ensembles:**

### **'classnames'**

Array of class names. Specify a data type the same as exists in  $Y$ .

**Default:** Class names that exist in  $Y$

### **'cost'**

Square matrix  $C$ , where  $C(i, j)$  is the cost of classifying a point into class  $j$  if its true class is  $i$ . Alternatively, `cost` can be a structure  $S$  having two fields:  $S.ClassNames$  containing the group names as a categorical variable, character array, or cell array of strings; and  $S.ClassificationCosts$  containing the cost matrix  $C$ .

**Default:**  $C(i, j) = 1$  if  $i \neq j$ , and  $C(i, j) = 0$  if  $i = j$

### **'prior'**

Prior probabilities for each class. Specify as one of:

- A string:
  - `'empirical'` determines class probabilities from class frequencies in  $Y$ . If you pass observation weights, they are used to compute the class probabilities.
  - `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure  $S$  with two fields:
  - $S.ClassNames$  containing the class names as a categorical variable, character array, or cell array of strings
  - $S.ClassProbs$  containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

**Default:** `'empirical'`

**AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, RUSBoost, and LSBoost:**

## **'LearnRate'**

Learning rate for shrinkage, a numeric scalar from 0 to 1. If you set the learning rate to less than 1, the ensemble requires more learning iterations but often achieves a better accuracy. 0.1 is a popular choice for an ensemble grown with shrinkage.

**Default:** 1

## **RUSBoost:**

### **'RatioToSmallest'**

Either a numeric scalar or vector with  $K$  elements when there are  $K$  classes. Every element of this vector is the sampling proportion for this class with respect to the class with fewest observations in  $Y$ . If you pass a scalar, `fitensemble` uses this sampling proportion for all classes. For example, suppose you have class A with 100 observations and class B with 10 observations. If you pass `[2 1]` for `'RatioToSmallest'`, every learner in the ensemble is trained on 20 observations of class A and 10 observations of class B. If you pass 2 or `[2 2]`, every learner is trained on 20 observations of class A and 20 observations of class B. If you pass `'ClassNames'`, `fitensemble` matches elements in the array of class names to elements in this vector.

**Default:** `ones(K,1)`

## **LPBoost and TotalBoost:**

### **'MarginPrecision'**

Margin precision, a numeric scalar between 0 and 1. `MarginPrecision` affects the number of boosting iterations required for conversion. Use a small value to grow an ensemble with many learners, and use a large value to grow an ensemble with few learners.

**Default:** 0.01

**RobustBoost:****'RobustErrorGoal'**

Target classification error for `RobustBoost`, a numeric scalar from 0 to 1. Usually there is an optimal range for this parameter for your training data. If you set the error goal too low or too high, `RobustBoost` can produce a model with poor classification accuracy.

**Default:** 0.1

**'RobustMarginSigma'**

Spread of the distribution of classification margins over the training set for `RobustBoost`, a numeric positive scalar. You should consult literature on `RobustBoost` before setting this parameter

**Default:** 0.1

**'RobustMaxMargin'**

Maximal classification margin for `RobustBoost` in the training set, a nonnegative numeric scalar. `RobustBoost` minimizes the number of observations in the training set with classification margins below `RobustMaxMargin`.

**Default:** 0

**Output Arguments****ens**

Ensemble object for predicting characteristics. The class of `ens` depends on settings. In the following table, cross-validation names are `crossval`, `kfold`, `holdout`, `leaveout`, and `cvpartition`.

# fitensemble

Settings	Class
resample name-value pair is 'off', and you don't set a cross-validation name-value pair.	ClassificationEnsemble
resample name-value pair is 'off', and you don't set a cross-validation name-value pair.	RegressionEnsemble
resample name-value pair is 'on', type is 'classification', and you don't set a cross-validation name-value pair.	ClassificationBaggedEnsemble
resample name-value pair is 'on', type is 'regression', and you don't set a cross-validation name-value pair.	RegressionBaggedEnsemble
method is a classification method, and you set a cross-validation name-value pair.	ClassificationPartitionedEnsemble
method is a regression method, and you set a cross-validation name-value pair.	RegressionPartitionedEnsemble

## Examples

Train a boosting ensemble, and inspect the resubstitution loss:

```
load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
plot(resubLoss(ada,'mode','cumulative'));
xlabel('Number of decision trees');
ylabel('Resubstitution error');
```

Train a regression ensemble to predict car mileage based on the number of cylinders, engine displacement, horsepower, and weight. Predict the mileage for a four-cylinder car with a 200 cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

# fitensemb

---

```
load carsmall
X = [Cylinders,Displacement,Horsepower,Weight];
xnames = {'Cylinders','Displacement','Horsepower','Weight'};
t = RegressionTree.template('Surrogate','on');
rens = fitensemble(X,MPG,'LSBoost',100,t,'PredictorNames',xnames)

rens =
classreg.learning.regr.ReggressionEnsemble:
    PredictorNames: {'Cylinders' 'Displacement' 'Horsepower' 'Weight'}
    CategoricalPredictors: []
    ResponseName: 'Y'
    ResponseTransform: 'none'
    NObservations: 94
    NTrained: 100
    Method: 'LSBoost'
    LearnerNames: {'Tree'}
    ReasonForTermination: [1x77 char]
    FitInfo: [100x1 double]
    FitInfoDescription: [2x83 char]
    Regularization: []

predict(rens,[4 200 150 3000])

ans =
    20.4982
```

---

Train and estimate the generalization error on a holdout sample:

```
load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
    'holdout',0.5);
plot(kfoldLoss(ada,'mode','cumulative'));
xlabel('Number of decision trees');
ylabel('Holdout error');
```

## How To

- “Supervised Learning (Machine Learning) Workflow and Algorithms” on page 16-2

- “Ensemble Methods” on page 16-59

**Purpose**

Fit nonlinear regression model

**Syntax**

```
mdl = fitnlm(ds,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm( ___,modelfun,beta0,Name,Value)
```

**Description**

`mdl = fitnlm(ds,modelfun,beta0)` fits the model specified by `modelfun` to variables in the dataset array `ds`, and returns the nonlinear model `mdl`.

`fitnlm` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = fitnlm(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = fitnlm( ___,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments****ds - Input data**

dataset array

Input data, specified as a dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

You specify the response and predictor names in your model string. If you do not provide a model string, you can set a different column as the response variable by using the `ResponseVar` name-value pair argument. You can select a subset of the columns as predictors by using the `PredictorVars` name-value pair argument.

**Data Types**

single | double | logical

## **X - Predictor variables**

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

### **Data Types**

single | double | logical

## **y - Response variable**

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### **Data Types**

single | double

## **modelfun - Functional form of the model**

function handle | string of the form 'y ~  
 $f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - $b$  is a coefficient vector with the same number of elements as `beta0`.
  - $x$  is a matrix with the same number of columns as  $X$  or the number of predictor variable columns of `ds`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as  $x$ . Each row of the vector is the result of evaluating `modelfun` on the corresponding row of  $x$ . In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call.

- String of the form  $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ , where  $f$  represents a scalar function of the scalar coefficient variables  $b_1, \dots, b_j$  and the scalar data variables  $x_1, \dots, x_k$ .

### **beta0 - Coefficients**

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. NonLinearModel starts its search for optimal coefficients from beta0.

### **Data Types**

single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**Example:** 'ErrorModel', 'combined', 'Exclude', 2, 'Options', opt specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure opt to control the iterative fitting procedure.

### **'CoefficientNames' - Names of the model coefficients**

{ 'b1', 'b2', ..., 'bk' } (default) | cell array of strings

Names of the model coefficients, specified as a cell array of strings.

### **Data Types**

char

### **'ErrorModel' - Form of the error variance model**

'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable  $e$  in combination with independent components: the function value  $f$ , and one or two parameters  $a$  and  $b$

'constant' (default)

$$y = f + ae$$

'proportional'

$$y = f + bfe$$

'combined'

$$y = f + (a + b|f|)e$$

The only allowed error model when using `Weights` is 'constant'.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

---

**Example:** 'ErrorModel', 'proportional'

### 'ErrorParameters' - Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	$a$	1
'proportional'	$b$	1
'combined'	$a, b$	[1,1]

You can only use the 'constant' error model when using `Weights`.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

---

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for  $a$  and the starting value 2 for  $b$  as follows.

**Example:** 'ErrorParameters',[1,2]

### Data Types

single | double

### 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

### Data Types

single | double | logical

### 'Options' - Options for controlling the iterative fitting procedure

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('fitnlm')`.

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> <li>• 'off' — Displays no information.</li> <li>• 'final' — Displays the final output.</li> <li>• 'iter' — Displays iterative output to the Command Window.</li> </ul>	'off'
FunValCheck	String indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 21-1143	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 21-1143 for the default, which depends on RobustWgtFun.

Option	Meaning	Default
ToIFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
ToIX	Termination tolerance for the parameters. Positive scalar.	1e-8

### Data Types

struct

#### 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the dataset array `ds`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in the `ds` dataset array, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `ds` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

### Data Types

single | double | logical | cell

#### 'ResponseVar' - Response variable

last column in dataset array `ds` (default) | string for variable name  
| logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable

name in the dataset array `ds`, or a logical or numeric index vector indicating which column is the response variable.

If you supply a model string, it specifies the response variable. Otherwise, when fitting a dataset array, `'ResponseVar'` indicates which dataset variable `fitnlm` should use as the response.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

### Data Types

`single` | `double` | `logical` | `char`

### 'VarNames' - Names of variables in fit

`{'x1','x2',...,'xn','y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

### Example:

`'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

### Data Types

`cell`

### 'Weights' - Observation weights

`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have  $n$  elements, where  $n$  is the number of rows in `ds` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by  $\text{MSE} * (1/W(i))$ , where `MSE` is the mean squared error.

### Data Types

single | double | function\_handle

## Output Arguments

### `mdl` - Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

## Examples

### Nonlinear Model from a Dataset Array

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
ds = dataset(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(ds,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
```

```
MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177

## Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
```

$$y \sim b_1 + b_2 * x_1^{b_3} + b_4 * x_2^{b_5}$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387  
 Root Mean Squared Error: 3.96  
 R-Squared: 0.745, Adjusted R-Squared 0.743  
 F-statistic vs. constant model: 283, p-value = 1.79e-113

### Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = fitnlm(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step
-----------	-----	---------------------	-----------------

```
-----  
      0      1.82248e+06  
      1      678600      788810      1691.07  
      2      616716      6.12739e+06      45.4738  
  
%%%      Many iterations deleted      %%%  
  
      122      6068.48      1.56393      0.629325  
      123      6068.48      1.13809      0.432543  
      124      6068.48      0.295962      0.297511  
  
Iterations terminated: relative change in SSE less than OPTIONS.TolFun
```

## Specify Nonlinear Regression Using Model String Syntax

Specify a nonlinear regression model for estimation using a function handle or model string syntax.

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = fitnlm(X,y,@hougen,beta0)
```

```
mdl =
```

```
Nonlinear regression model:  
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654

b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
 Root Mean Squared Error: 0.193  
 R-Squared: 0.999, Adjusted R-Squared 0.998  
 F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a string expression to specify the  
 Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = fitnlm(X,y,myfun,beta0)
```

mdl2 =

Nonlinear regression model:

$$y \sim (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
 Root Mean Squared Error: 0.193  
 R-Squared: 0.999, Adjusted R-Squared 0.998  
 F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

## Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a string expression to specify the model.

```
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';
```

```
mdl = fitnlm(x,y,modelstr,b0,'Options',opts)
```

```
mdl =
```

```
Nonlinear regression model (robust fit):
y ~ b1 + b2*exp( - b3*x)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26

```
b3      2.9732      0.38496      7.7232      1.0346e-11
```

```
Number of observations: 100, Error degrees of freedom: 97
Root Mean Squared Error: 0.501
R-Squared: 0.807, Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35
```

### Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	0.83085	0.58224	1.427	0.19142
b2	0.04095	0.029663	1.3805	0.20477

b3	0.025063	0.019673	1.274	0.23842
b4	0.080053	0.057812	1.3847	0.20353
b5	1.8261	1.281	1.4256	0.19183

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.037  
R-Squared: 0.998, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11

## Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = fitnlm(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
```

Nonlinear regression model:  
y ~ hougen(b,X)

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86702	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075158	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
 Root Mean Squared Error: 1.27  
 R-Squared: 0.999, Adjusted R-Squared 0.998  
 F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

## Purpose

Fit linear mixed-effects model using design matrices

## Syntax

```
lme = LinearMixedModel.fitmatrix(X,y,Z,[])  
lme = LinearMixedModel.fitmatrix(X,y,Z,G)  
lme = LinearMixedModel.fitmatrix( __,Name,Value)
```

## Description

`lme = LinearMixedModel.fitmatrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `LinearMixedModel.fitmatrix(X,Y,Z,[])` without a specified covariance pattern most likely will result in a non-identifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using 'CovariancePattern' name-value pair argument.

`lme = LinearMixedModel.fitmatrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = LinearMixedModel.fitmatrix( __,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

## Tips

- Use the function `fitlmematrix` instead of `LinearMixedModel.fitmatrix`.

# LinearMixedModel.fitmatrix

---

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

## Input Arguments

### **X - Fixed-effects design matrix**

*n*-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of X corresponds to one observation, and each column of X corresponds to one variable.

### **Data Types**

single | double

### **y - Response values**

*n*-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

### **Data Types**

single | double

### **Z - Random-effects design**

*n*-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then Z must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then Z must be a cell array of length *R*. Each cell of Z contains an *n*-by-*q*(*r*) design matrix Z{*r*}, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, Z{*r*}.

### **Data Types**

single | double | cell

## **G - Grouping variable or variables**

*n*-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.

**G** can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then **G** must be a cell array of length *R*. Each cell of **G** contains a grouping variable **G**{*r*}, *r* = 1, 2, ..., *R*, with *M*(*r*) levels.

**G**{*r*} can be a categorical vector, numeric vector, character array, or cell array of strings.

## **Data Types**

single | double | char | cell

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**,**Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**,**Value1**,...,**NameN**,**ValueN**.

## **'FixedEffectPredictors' - Names of columns in fixed-effects design matrix**

{'x1','x2',..., 'xP'} (default) | cell array of length *p*

Names of columns in the fixed-effects design matrix **X**, specified as the comma-separated pair consisting of **'FixedEffectPredictors'** and a cell array of length *p*.

For example, if you have a constant term and two predictors, say **TimeSpent** and **Gender**, where **Female** is the reference level for **Gender**, as the fixed effects, then you can specify the names of

# LinearMixedModel.fitmatrix

---

your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

**Example:**

```
'FixedEffectPredictors',{ 'Intercept', 'TimeSpent', 'Gender_Male' },
```

**Data Types**

cell

**'RandomEffectPredictors' - Names of columns in random-effects design matrix or cell array**

cell array of length  $q$  | cell array of length  $R$  with elements of length  $q(r)$ ,  $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array  $Z$ , specified as the comma-separated pair consisting of `'RandomEffectPredictors'` and either of the following:

- A cell array of length  $q$  when  $Z$  is an  $n$ -by- $q$  design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length  $R$ , when  $Z$  is a cell array of length  $R$  with each element  $Z\{r\}$  of length  $q(r)$ ,  $r = 1, 2, \dots, R$ . In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

**Example:**

```
'RandomEffectPredictors',{ 'Intercept', 'Acceleration' }
```

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

**Example:**

```
'RandomEffectPredictors',{ {'Intercept', 'Acceleration'}, {'Intercept'}}
```

## Data Types

cell

### 'ResponseVarName' - Name of response variable

'y' (default) | string

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a string.

For example, if your response variable name is `score`, then you can specify it as follows.

**Example:** 'ResponseVarName', 'score'

## Data Types

char

### 'RandomEffectGroups' - Names of random effects grouping variables

'g' or {'g1', 'g2', ..., 'gR'} (default) | string | cell array of strings

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- String — If there is only one random-effects term, that is, if  $G$  is a vector, then the value of 'RandomEffectGroups' is a string containing the name for the grouping variable  $G$ . The default is 'g'.
- Cell array of strings — If there are multiple random-effects terms, that is, if  $G$  is a cell array of length  $R$ , then the value of 'RandomEffectGroups' is a cell array of length  $R$ , where each cell contains the name for the grouping variable  $G\{r\}$ . The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, `z1` and `z2`, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

**Example:** 'RandomEffectGroups', {'sex', 'subject'}

# LinearMixedModel.fitmatrix

---

## Data Types

char | cell

### 'CovariancePattern' - Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are  $R$  random-effects terms, then the value of 'CovariancePattern' must be a cell array of length  $R$ , where each element  $r$  of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the  $r$ th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where  $\sigma_b^2$  is the common variance of the random-effects terms.

# LinearMixedModel.fitmatrix

---

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where  $\sigma_{b1}^2$  is the common variance of the random-effects terms and  $\sigma_{b1,b2}$  is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if  $PAT(a,b) = \text{false}$ , then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

**Example:** 'CovariancePattern', 'Diagonal'

**Example:** 'CovariancePattern', {'Full', 'Diagonal'}

**'FitMethod' - Method for estimating parameters**

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'	Default. Maximum likelihood estimation
'REML'	Restricted maximum likelihood estimation

**Example:** 'FitMethod', 'REML'

## 'Weights' - Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$ , where  $n$  is the number of observations.

## Data Types

single | double

## 'Exclude' - Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

**Example:** 'Exclude', [13,67]

## Data Types

single | double | logical

## 'DummyVarCoding' - Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

# LinearMixedModel.fitmatrix

---

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

**Example:** 'DummyVarCoding','effects'

## 'Optimizer' - Optimization algorithm

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> .

with 'Algorithm' set to  
'quasi-newton'.

**Example:** 'Optimizer','fminunc'

## 'OptimizerOptions' - Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasnewton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasnewton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

## 'TolFun' - Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

## 'TolX' - Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

### 'MaxIter' - Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

### 'Display' - Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

### 'StartMethod' - Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'	Default. An internally defined default value.
'random'	A random initial value.

**Example:** 'StartMethod', 'random'

### 'Verbose' - Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

**Example:** 'Verbose', true

## 'CheckHessian' - Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

**Example:** 'CheckHessian',true

## Output Arguments

### lme - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Examples

### No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where MPG is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;  
X = [ones(size(Weight)), Weight];  
Z = ones(size(y));  
lme = LinearMixedModel.fitmatrix(X,y,Z,Model_Year)
```

```
lme =
```

## Longitudinal Study with Covariate

Navigate to a folder containing sample data.

`cd(matlabroot)`

# LinearMixedModel.fitmatrix

---

```
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .  $\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{0m}$  and  $b_{1m}$  are random effects.  $IW$  stands for initial weight and  $I[.]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:  $b_{0m} \sim N(0, \sigma^2_0)$ ,  $b_{1m} \sim N(0, \sigma^2_1)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
Subject = nominal(Subject);  
Program = nominal(Program);  
D = dummyvar(Program); % Create dummy variables for Program  
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...  
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];  
Z = [ones(120,1), Week];  
G = Subject;
```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...  
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Wee'  
'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	120
Fixed effects coefficients	9
Random effects coefficients	40
Covariance parameters	4

Formula:

Linear Mixed Formula with 10 predictors.

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
-22.981	13.257	24.49	-48.981

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF
'Intercept'	0.66105	0.25892	2.5531	111
'InitWeight'	0.0031879	0.0013814	2.3078	111
'PrgB'	0.36079	0.13139	2.746	111
'PrgC'	-0.033263	0.13117	-0.25358	111
'PrgD'	0.11317	0.13132	0.86175	111
'Week'	0.1732	0.067454	2.5677	111

# LinearMixedModel.fitmatrix

---

'Week_PrgB'	0.038771	0.095394	0.40644	111	0.
'Week_PrgC'	0.030543	0.095394	0.32018	111	0.
'Week_PrgD'	0.033114	0.095394	0.34713	111	0.

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	Lower
'Intercept'	'Intercept'	'std'	0.18407	0.122
'Week'	'Intercept'	'corr'	0.66841	0.210
'Week'	'Week'	'std'	0.15033	0.110

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The  $p$ -values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects that are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

## Random-Intercept Model

Load the sample data.

```
load flu
```

`flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into a tall array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by Date. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 WtdILL_i + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable Date.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable Date and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b_{0m} \sim N(0, \sigma_{FR}^2)$  and the error term has the distribution,  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
y = flu2.FluRate;  
X = [ones(468,1) flu2.WtdILL];  
Z = [ones(468,1)];  
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept'},  
'RandomEffectPredictors',{'Intercept'},'RandomEffectGroups',{'Date'});
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

Formula:

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

# LinearMixedModel.fitmatrix

---

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'Intercept'	0.16385	0.057525	2.8484	466	0.004
'NationalRate'	0.7236	0.032219	22.459	466	3.0502

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'Intercept'	'Intercept'	'std'	0.17146	0.13227

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term  $\sigma^2_{b_{0m}}$ , do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using compare method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 WtdILLI_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where  $\hat{b}$  is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
```

```
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level);

y_hat =

    1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)

ans =

    1.4674
```

## Randomized-Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data set shows the deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the

# LinearMixedModel.fitmatrix

---

coefficients sum to zero. You need to create two contrast coded variables in the fixed-effects design matrix,  $X1$  and  $X2$ , where

$$\text{Shift\_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad \text{Shift\_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + \varepsilon_{im},$$

where  $i$  represents the observations, and  $m$  represents the operators,  $i = 1, 2, \dots, 15$ , and  $m = 1, 2, \dots, 5$ . The random effects and the observation error have the following distributions:  $b_{0m} \sim N(0, \sigma^2_{b_{0m}})$  and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{'Intercept'},'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')
```

```
lme =
```

```
Linear mixed-effects model fit by REML
```

# LinearMixedModel.fitmatrix

Model information:

Number of observations	15
Fixed effects coefficients	3
Random effects coefficients	5
Covariance parameters	2

Formula:

$y \sim \text{Intercept} + S\_Morning + S\_Evening + (\text{Intercept} \mid \text{Operator})$

Model fit statistics:

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

`B = randomEffects(lme)`

B =

0.5775  
1.1757

# LinearMixedModel.fitmatrix

---

```
-2.1715  
2.3655  
-1.9472
```

The estimated deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening,Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift\_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value in the following way.

```
F = fitted(lme);  
F(shift.Shift=='Evening' & shift.Operator=='3')  
  
ans =  
  
0.9481
```

## Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ , and  $b_{1m} \sim N(0, \sigma_1^2)$ .  $m$  represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

# LinearMixedModel.fitmatrix

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept'},{'Acceleration'},'RandomEffectGroups',{'Model_Year'},'M
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	3

```
Formula:
```

```
y ~ Intercept + Acceleration + Horsepower + (Intercept | Model_Year)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	p
'Intercept'	49.839	2.0518	24.291	389	5
'Acceleration'	-0.58565	0.10846	-5.3995	389	-
'Horsepower'	-0.16534	0.0071227	-23.213	389	-

```
Random effects covariance parameters (95% CIs):
```

# LinearMixedModel.fitmatrix

```
Group: Model_Year (13 Levels)
  Name1      Name2      Type      Estimate      Lower      Upper
  'Intercept' 'Intercept' 'std'      8.0669e-07      NaN
Group: Model_Year (13 Levels)
  Name1      Name2      Type      Estimate
  'Acceleration' 'Acceleration' 'std'      0.18783
Group: Error
  Name      Estimate      Lower      Upper
  'Res Std' 3.7258      3.4698      4.0007
```

The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case the random-effects terms have the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left( 0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where  $m$  represents the model year.

First prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;
```

```
lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2193.5	2221.3	-1089.7	2179.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	p
'Intercept'	50.133	2.2652	22.132	389	7
'Acceleration'	-0.58327	0.13394	-4.3545	389	1
'Horsepower'	-0.16954	0.0072609	-23.35	389	0

Random effects covariance parameters (95% CIs):

Group: Model\_Year (13 Levels)

Name1	Name2	Type	Estimate
'Intercept'	'Intercept'	'std'	3.3479
'Acceleration'	'Intercept'	'corr'	-0.8797
'Acceleration'	'Acceleration'	'std'	0.3378

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. You can compare these two models using the compare method.

## Specify the Covariance Pattern

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week are the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} \\ + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .

$\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{1m}$  and  $b_{1m}$  are random effects.  $IW$  stands for initial weight and  $I[.]$  is a dummy

variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...  
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...  
'RandomEffectPredictors',{{'Intercept','Week'}},...

## Definitions

### Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where  $D$  is a  $q$ -by- $q$  symmetric and positive semidefinite matrix, parameterized by a variance component vector  $\theta$ ,  $q$  is the number of variables in the random-effects term, and  $\sigma^2$  is the observation error variance. Since the covariance matrix of the random effects,  $D$ , is symmetric, it has  $q(q+1)/2$  free parameters. Suppose  $L$  is the lower triangular Cholesky factor of  $D(\theta)$  such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the  $q*(q+1)/2$ -by-1 unconstrained parameter vector  $\theta$  is formed from elements in the lower triangular part of  $L$ . For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

## Log-Cholesky Parameterization

When the diagonal elements of  $L$  in Cholesky parameterization are constrained to be positive, then the solution for  $L$  is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of  $L$  are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing  $L_{ii} \geq 0$ ,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

## Alternatives

You can also fit a linear mixed-effects model using `fitlme(ds, formula)`, where `ds` is a dataset array containing the response  $y$ , the predictor variables  $X$ , and the grouping variables, and `formula` is of the form ' $y \sim \text{fixed} + (\text{random}_1 | g_1) + \dots + (\text{random}_R | g_R)$ '.

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X, y, Z, G)`.

# LinearMixedModel.fitmatrix

---

## See Also

`fitlmeLinearMixedModel` |

**Purpose** Fitted responses from a linear mixed-effects model

**Syntax**  
`yfit = fitted(lme)`  
`yfit = fitted(lme,Name,Value)`

**Description** `yfit = fitted(lme)` returns the fitted conditional response from the linear mixed-effects model `lme`.

`yfit = fitted(lme,Name,Value)` returns the fitted response from the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify if you want to compute the fitted marginal response.

## Input Arguments

### **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Conditional' - Indicator for conditional response**

`True` (default) | `False`

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and either of the following.

# LinearMixedModel.fitted

---

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

**Example:** 'Conditional','False'

## Output Arguments

### **yfit - Fitted response values**

*n*-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

## Examples

### **Compute Fitted Conditional and Marginal Responses**

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by Date.

Region is a categorical variable. You can specify the contrasts for categorical variables using the `DummyVarCoding` name-value pair argument when fitting the model. When you do not specify the contrasts, `fitlme` uses the 'reference' contrast by default. Because the model has an intercept, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example,  $I[MidAtl]$  is the dummy variable representing the region MidAtl. For details, see “Dummy Indicator Variables” on page 2-55.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[MidAtl]_i + \beta_2 I[ENCentral]_i + \beta_3 I[WNCentral]_i + \beta_4 I[SAtl]_i + \beta_5 I[ESCentral]_i + \beta_6 I[WSCentral]_i + \beta_7 I[Mtn]_i + \beta_8 I[Pac]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable Date,  $\beta_j$ ,  $j = 0, 1, \dots, 8$ , are the fixed-effects coefficients, with  $\beta_0$  being the coefficient for region NE.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable Date, and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b_{0m} \sim N(0, \sigma_b^2)$  and the error term has the distribution,  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

Linear mixed-effects model fit by ML

'Region_Pac'	-0.16013	0.052221	-3.0665	459

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.6443

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The  $p$ -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term,  $\sigma^2_b$ , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')

y_hat =

    1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for  $\beta_0$  and `beta(4)` corresponds to the estimate for  $\beta_3$ . You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')

ans =

    1.2884
```

The estimated marginal response for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005}^{(\text{marginal})} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] \\ &= 1.2233 + 0.23687 \\ &= 1.46017.\end{aligned}$$

Compute the fitted marginal response.

```
F = fitted(lme,'Conditional',false);
```

# LinearMixedModel.fitted

---

```
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =
```

```
1.4602
```

## Plot Residuals vs. Fitted Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a dataset array. Define `Subject` and `Program` as categorical variables.

```
ds = dataset(InitialWeight,Program,Subject,Week,y);
ds.Subject = nominal(ds.Subject);
ds.Program = nominal(ds.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(ds,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F,R,'bx')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure();  
gscatter(F,R,Program)
```

# LinearMixedModel.fitted

## Definitions

### Fitted Conditional and Marginal Response

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model, `lme`, has an  $n$ -by- $p$  fixed-effects design matrix  $X$  and an  $n$ -by- $q$  random-effects design matrix  $Z$ . Also, suppose the  $p$ -by-1 estimated fixed-effects vector is  $\hat{\beta}$ , and the  $q$ -by-1

estimated best linear unbiased predictor (BLUP) vector of random effects is  $\hat{b}$ . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

# categorical.flipud

---

**Purpose** Flip categorical matrix in up/down direction

**Syntax** `B = flipud(A)`

**Description** `B = flipud(A)` returns the 2-D categorical matrix `A` with rows preserved and columns flipped in the up/down direction.

**See Also** `flipdim` | `fliplr` | `permute` | `rot90`

## Purpose

Estimates of fixed effects and related statistics

## Syntax

```
beta = fixedEffects(lme)
[beta,betanames] = fixedEffects(lme)
[beta,betanames,stats] = fixedEffects(lme)
[beta,betanames,stats] = fixedEffects(lme,Name,Value)
```

## Description

`beta = fixedEffects(lme)` returns the estimated fixed-effects coefficients, `beta`, of the linear mixed-effects model `lme`.

`[beta,betanames] = fixedEffects(lme)` also returns the names of estimated fixed-effects coefficients in `betanames`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betanames,stats] = fixedEffects(lme)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics in `stats`.

`[beta,betanames,stats] = fixedEffects(lme,Name,Value)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

# LinearMixedModel.fixedEffects

---

specify several name and value pair arguments in any order as  
Name1, Value1, . . . , NameN, ValueN.

## 'Alpha' - Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value  $\alpha$ , the confidence level is  $100*(1-\alpha)\%$ .

For example, for 99% confidence intervals, you can specify the confidence level as follows.

**Example:** 'Alpha', 0.01

## Data Types

single | double

## 'DFMethod' - Method for computing approximate degrees of freedom

'Residual' (default) | 'Satterthwaite' | 'None'

Method for computing approximate degrees of freedom for the  $t$ -statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'Residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$ , where $n$ is the number of observations and $p$ is the number of fixed effects.
'Satterthwaite'	Satterthwaite approximation.
'None'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

**Example:** 'DFMethod', 'Satterthwaite'

## Output Arguments

### **beta** - Fixed-effects coefficients estimates

vector

Fixed-effects coefficients estimates of the fitted linear mixed-effects model `lme`, returned as a vector.

### **betanames** - Names of fixed-effects coefficients

dataset array

Names of fixed-effects coefficients in `beta`, returned as a dataset array.

### **stats** - Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Name	Name of the fixed effect coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is zero
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic

# LinearMixedModel.fixedEffects

---

Lower	Lower limit of a 95% confidence interval for the fixed-effect coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effect coefficient

## Examples

### Display Fixed-Effects Coefficient Estimates and Names

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

The data set `weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a dataset array. Define `Subject` and `Program` as categorical variables.

```
ds = dataset(InitWeight,Program,Subject,Week,y);
ds.Subject = nominal(ds.Subject);
ds.Program = nominal(ds.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(ds,'y ~ InitWeight + Program*Week + (Week|Subject)');
```

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

```
[beta,betanames] = fixedEffects(lme);

    'Program_D'  
    'Week'  
    'Program_B:Week'  
    'Program_C:Week'  
    'Program_D:Week'
```

## Compute Coefficient Estimates and Related Statistics

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a dataset array.

# LinearMixedModel.fixedEffects

---

```
ds = dataset(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(ds, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficients estimates and related statistics.

```
[~,~,stats] = fixedEffects(lme)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.05
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	50.133	2.2652	22.132	389	7.77e-45
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.70e-05
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.10e-47

The small  $p$ -values (under pValue) indicate that all fixed-effects coefficients are significant.

## Compute Confidence Intervals with Specified Options

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The

performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);  
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = fixedEffects(lme, 'alpha', 0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	3.1196	0.88681	3.5178	12	0.0025
'Shift_Morning'	-0.3868	0.48344	-0.80009	12	0.4361
'Shift_Night'	1.9856	0.48344	4.1072	12	0.0007

Compute the 99% confidence intervals for fixed-effects coefficients, using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = fixedEffects(lme, 'DFMethod', 'Satterthwaite', 'alpha', 0.01)
```

```
stats =
```

# LinearMixedModel.fixedEffects

---

Fixed effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01

Name	Estimate	SE	tStat	DF	pV
'(Intercept)'	3.1196	0.88681	3.5178	6.123	0.
'Shift_Morning'	-0.3868	0.48344	-0.80009	10	0.
'Shift_Night'	1.9856	0.48344	4.1072	10	0.

The Satterthwaite approximation usually produces smaller DF values than the residual method. That is why it produces larger  $p$ -values (pValue) and larger confidence intervals (see Lower and Upper).

[LinearMixedModel](#) | [fitlmecoefCI](#) | [coefTest](#) | [randomEffects](#) |

**Purpose**  $F$  probability density function

**Syntax**  $Y = \text{fpdf}(X, V1, V2)$

**Description**  $Y = \text{fpdf}(X, V1, V2)$  computes the  $F$  pdf at each of the values in  $X$  using the corresponding numerator degrees of freedom  $V1$  and denominator degrees of freedom  $V2$ .  $X$ ,  $V1$ , and  $V2$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.  $V1$  and  $V2$  parameters must contain real positive values, and the values in  $X$  must lie on the interval  $[0 \infty)$ .

The probability density function for the  $F$  distribution is

$$y = f(x | v_1, v_2) = \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right]}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{x^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)x\right]^{\frac{v_1+v_2}{2}}}$$

**Examples**  $y = \text{fpdf}(1:6, 2, 2)$

$y =$

**How To** • “F Distribution” on page B-41

# fracfact

---

**Purpose** Fractional factorial design

**Syntax**  
`X = fracfact(gen)`  
`[X,conf] = fracfact(gen)`  
`[X,conf] = fracfact(gen,Name,Value)`

**Description** `X = fracfact(gen)` creates the two-level fractional factorial design defined by the generator string `gen`.

`[X,conf] = fracfact(gen)` returns a cell array of strings containing the confounding pattern for the design.

`[X,conf] = fracfact(gen,Name,Value)` creates a fractional factorial designs with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **gen**

Either a cell array of strings where each cell contains one “word,” or a string consisting of “words” separated by spaces. “Words” consist of case-sensitive letters or groups of letters, where 'a' represents string 1, 'b' represents string 2, ..., 'A' represents string 27, ..., 'Z' represents string 52.

Each word defines how the corresponding factor’s levels are defined as products of generators from a  $2^K$  full-factorial design.  $K$  is the number of letters of the alphabet in `gen`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'FactorNames'**

Cell array specifying the name for each factor.

**Default:** {'X1', 'X2', ...}

### 'MaxInt'

Positive integer setting the maximum level of interaction to include in the confounding output.

**Default:** 2

## Output Arguments

### X

The two-level fractional factorial design. X is a matrix of size N-by-P, where

- $N = 2^K$ , where K is the number of letters of the alphabet in gen.
- P is the number of words in gen.

Because X is a two-level design, the components of X are  $-1$ . For the meaning of X, see “Fractional Factorial Designs” on page 18-5.

### conf

Cell array of strings containing the confounding pattern for the design.

## Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:

```
x = fracfact('a b c abc')
```

```
x =
    -1    -1    -1    -1
    -1    -1     1     1
    -1     1    -1     1
    -1     1     1    -1
     1    -1    -1     1
     1    -1     1    -1
     1     1    -1    -1
     1     1     1     1
```

# fracfact

---

Find generators for a six-factor design that uses four factors and achieves resolution IV using fracfactgen. Use the result to specify the design:

```
generators = fracfactgen('a b c d e f',4, ... % 4 factors  
4) % resolution 4
```

```
generators =  
'a'  
'b'  
'c'  
'd'  
'bcd'  
'acd'
```

```
x = fracfact(generators)
```

```
x =  
-1 -1 -1 -1 -1 -1  
-1 -1 -1 1 1 1  
-1 -1 1 -1 1 1  
-1 -1 1 1 -1 -1  
-1 1 -1 -1 1 -1  
-1 1 -1 1 -1 1  
-1 1 1 1 1 -1  
1 -1 -1 -1 -1 1  
1 -1 -1 1 1 -1  
1 -1 1 -1 1 -1  
1 -1 1 1 -1 1  
1 1 -1 -1 1 1  
1 1 -1 1 -1 -1  
1 1 1 -1 -1 -1  
1 1 1 1 1 1
```

**How To**

• “Fractional Factorial Designs” on page 18-5

# fracfactgen

---

**Purpose** Fractional factorial design generators

**Syntax**

```
generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)
```

**Description** `generators = fracfactgen(terms)` uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by `terms`. `terms` is a string consisting of words formed from the 52 case-sensitive letters a-Z, separated by spaces. Use 'a' - 'z' for the first 26 factors, and, if necessary, 'A' - 'Z' for the remaining factors. For example, `terms = 'a b c ab ac'`. Single-character words indicate main effects to be estimated; multiple-character words indicate interactions. Alternatively, `terms` is an  $m$ -by- $n$  matrix of 0s and 1s where  $m$  is the number of model terms to be estimated and  $n$  is the number of factors. For example, if `terms` contains rows `[0 1 0 0]` and `[1 0 0 1]`, then the factor `b` and the interaction between factors `a` and `d` are included in the model. `generators` is a cell array of strings with one generator per cell. Pass `generators` to `fracfact` to produce the fractional-factorial design and corresponding confounding pattern.

`generators = fracfactgen(terms,k)` returns generators for a two-level fractional-factorial design with  $2^k$ -runs, if possible. If `k` is [], `fracfactgen` finds the smallest design.

`generators = fracfactgen(terms,k,R)` finds a design with resolution `R`, if possible. The default resolution is 3.

A design of *resolution R* is one in which no  $n$ -factor interaction is confounded with any other effect containing less than  $R - n$  factors. Thus a resolution III design does not confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If `fracfactgen` is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model.

If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

`generators = fracfactgen(terms,k,R,basic)` also accepts a vector `basic` specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in `terms`.

## Examples

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require  $2^4 = 16$  runs. The `fracfactgen` function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only  $2^3 = 8$  runs:

```
generators = fracfactgen('a b c d',3,4)
generators =
  'a'
  'b'
  'c'
  'abc'
```

The more economical design and the corresponding confounding pattern are returned by `fracfact`:

```
[dfF,confounding] = fracfact(generators)
dfF =
  -1  -1  -1  -1
  -1  -1   1   1
  -1   1  -1   1
  -1   1   1  -1
   1  -1  -1   1
   1  -1   1  -1
   1   1  -1  -1
   1   1   1   1
confounding =
  'Term'      'Generator'    'Confounding'
  'X1'        'a'            'X1'
  'X2'        'b'            'X2'
```

# fracfactgen

---

'X3'	'c'	'X3'
'X4'	'abc'	'X4'
'X1*X2'	'ab'	'X1*X2 + X3*X4'
'X1*X3'	'ac'	'X1*X3 + X2*X4'
'X1*X4'	'bc'	'X1*X4 + X2*X3'
'X2*X3'	'bc'	'X1*X4 + X2*X3'
'X2*X4'	'ac'	'X1*X3 + X2*X4'
'X3*X4'	'ab'	'X1*X2 + X3*X4'

The confounding pattern shows, for example, that the two-way interaction between X1 and X2 is confounded by the two-way interaction between X3 and X4.

## How To

- “Fractional Factorial Designs” on page 18-5

**Purpose**

Friedman's test

**Syntax**

```
p = friedman(X, reps)
p = friedman(X, reps, displayopt)
[p, table] = friedman(...)
[p, table, stats] = friedman(...)
```

**Description**

`p = friedman(X, reps)` performs the nonparametric Friedman's test to compare column effects in a two-way layout. Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman's test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of `X` represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input `reps` indicates the number of replicates in each "cell," which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (`reps=2`). The subscripts indicate row, column, and replicate, respectively.

$$\begin{bmatrix} x_{111} & x_{121} & x_{131} \\ x_{112} & x_{122} & x_{132} \\ x_{211} & x_{221} & x_{231} \\ x_{212} & x_{222} & x_{232} \end{bmatrix}$$

Friedman's test assumes a model of the form

$$x_{ijk} = \mu + \alpha_i + \beta_j + \varepsilon_{ijk}$$

where  $\mu$  is an overall location parameter,  $\alpha_i$  represents the column effect,  $\beta_j$  represents the row effect, and  $\varepsilon_{ijk}$  represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The  $p$  that `friedman` returns is the  $p$  value for the null hypothesis that  $\alpha_i = 0$ . If the  $p$  value is near zero, this casts doubt on the null hypothesis. A sufficiently small  $p$  value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical  $p$  value to determine whether a result is “statistically significant” is left to the researcher. It is common to declare a result significant if the  $p$  value is less than 0.05 or 0.01.

`friedman` also displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if `reps` is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman’s chi-square statistic.
- The sixth shows the  $p$  value for the chi-square statistic.

`p = friedman(X, reps, displayopt)` enables the ANOVA table display when `displayopt` is 'on' (default) and suppresses the display when `displayopt` is 'off'.

`[p,table] = friedman(...)` returns the ANOVA table (including column and row labels) in cell array `table`. (You can copy a text version of the ANOVA table to the clipboard by selecting Copy Text from the **Edit** menu.

`[p,table,stats] = friedman(...)` returns a `stats` structure that you can use to perform a follow-up multiple comparison test. The `friedman` test evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. Sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying the `stats` structure as input.

### Assumptions

Friedman's test makes the following assumptions about the data in `X`:

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

## Examples

### Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn =
    5.5000    4.5000    3.5000
```

# friedman

---

5.5000	4.5000	4.0000
6.0000	4.0000	3.0000
6.5000	5.0000	4.0000
7.0000	5.5000	5.0000
7.0000	5.0000	4.5000

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

```
p = friedman(popcorn,3)
```

```
p =
```

```
0.0010
```

Friedman's ANOVA Table					
Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	99.75	2	49.875	13.76	0.001
Interaction	0.0833	2	0.0417		
Error	16.1667	12	1.3472		
Total	116	17			

Test for column effects after row effects are removed

The small value of  $p = 0.001$  indicates the popcorn brand affects the yield of popcorn.

## **See Also**

`anova2` | `multcompare` | `kruskalwallis`

**Purpose**  $F$  random numbers

**Syntax**  
`R = frnd(V1,V2)`  
`R = frnd(V1,V2,m,n,...)`  
`R = frnd(V1,V2,[m,n,...])`

**Description** `R = frnd(V1,V2)` generates random numbers from the  $F$  distribution with numerator degrees of freedom  $V1$  and denominator degrees of freedom  $V2$ .  $V1$  and  $V2$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for  $V1$  or  $V2$  is expanded to a constant array with the same dimensions as the other input.

`R = frnd(V1,V2,m,n,...)` or `R = frnd(V1,V2,[m,n,...])` generates an  $m$ -by- $n$ -by-... array containing random numbers from the  $F$  distribution with parameters  $V1$  and  $V2$ .  $V1$  and  $V2$  can each be scalars or arrays of the same size as  $R$ .

**Examples**

```
n1 = frnd(1:6,1:6)
n1 =
    0.0022    0.3121    3.0528    0.3189    0.2715    0.9539

n2 = frnd(2,2,[2 3])
n2 =
    0.3186    0.9727    3.0268
    0.2052  148.5816    0.2191

n3 = frnd([1 2 3;4 5 6],1,2,3)
n3 =
    0.6233    0.2322   31.5458
    2.5848    0.2121    4.4955
```

**See Also** `random` | `fpdf` | `fcdf` | `finv` | `fstat`

**How To**

- “F Distribution” on page B-41

# fstat

---

**Purpose**  $F$  mean and variance

**Syntax** `[M,V] = fstat(V1,V2)`

**Description** `[M,V] = fstat(V1,V2)` returns the mean of and variance for the  $F$  distribution with numerator degrees of freedom  $V1$  and denominator degrees of freedom  $V2$ .  $V1$  and  $V2$  can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of  $M$  and  $V$ . A scalar input for  $V1$  or  $V2$  is expanded to a constant arrays with the same dimensions as the other input.

The mean of the  $F$  distribution for values of  $v_2$  greater than 2 is

$$\frac{v_2}{v_2 - 2}$$

The variance of the  $F$  distribution for values of  $v_2$  greater than 4 is

$$\frac{2v_2^2(v_1 + v_2 - 2)}{v_1(v_2 - 2)^2(v_2 - 4)}$$

The mean of the  $F$  distribution is undefined if  $v_2$  is less than 3. The variance is undefined for  $v_2$  less than 5.

**Examples** `fstat` returns NaN when the mean and variance are undefined.

```
[m,v] = fstat(1:5,1:5)
m =
    NaN    NaN    3.0000    2.0000    1.6667
v =
    NaN    NaN    NaN    NaN    8.8889
```

**See Also** `fpdf` | `fcdf` | `finv` | `frnd`

**How To** • “F Distribution” on page B-41

**Purpose**

Interactive contour plot

**Syntax**

```
fsurfht(fun,xlims,ylim)  
fsurfht(fun,xlims,ylim,p1,p2,p3,p4,p5)
```

**Description**

`fsurfht(fun,xlims,ylim)` is an interactive contour plot of the function specified by the text variable `fun`. The  $x$ -axis limits are specified by `xlims` in the form `[xmin xmax]`, and the  $y$ -axis limits are specified by `ylim` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylim,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current  $x$  value and  $y$  value. You can drag these reference lines and watch the calculated  $z$ -values (at the top of the plot) update simultaneously. Alternatively, you can type the  $x$  value and  $y$  value into editable text fields on the  $x$ -axis and  $y$ -axis.

**Examples**

Plot the Gaussian likelihood function for the `gas.mat` data.

```
load gas
```

Create a function containing the following commands, and name it `gauslike.m`.

```
function z = gauslike(mu,sigma,p1)  
n = length(p1);  
z = ones(size(mu));  
for i = 1:n  
z = z .* (normpdf(p1(i),mu,sigma));  
end
```

The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters  $\mu$  and  $\sigma$  as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

```
fsurfht('gauslike',[112 118],[3 5],price1)
```

The sample mean is the  $x$  value at the maximum, but the sample standard deviation is *not* the  $y$  value at the maximum.

```

mumax = mean(price1)
mumax =
    115.1500
sigmax = std(price1)*sqrt(19/20)
sigmax =
    3.7719

```

# fullfact

---

**Purpose** Full factorial design

**Syntax** `dFF = fullfact(levels)`

**Description** `dFF = fullfact(levels)` gives factor settings `dFF` for a full factorial design with  $n$  factors, where the number of levels for each factor is given by the vector `levels` of length  $n$ . `dFF` is  $m$ -by- $n$ , where  $m$  is the number of treatments in the full-factorial design. Each row of `dFF` corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

**Examples** The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

```
dFF = fullfact([2 4])
dFF =
     1     1
     2     1
     1     2
     2     2
     1     3
     2     3
     1     4
     2     4
```

**See Also** `ff2n`

**Purpose**

Gage repeatability and reproducibility study

**Syntax**

```
gagerr(y, {part, operator})  
gagerr(y, GROUP)  
gagerr(y, part)  
gagerr(..., param1, val1, param2, val2, ...)  
[TABLE, stats] = gagerr(...)
```

**Description**

`gagerr(y, {part, operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, or cell arrays of strings. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 x standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If  $NDC > 5$ , the measurement system is capable.
- If  $NDC < 2$ , the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:

- If  $PRR < 10\%$ , the measurement system is capable.

- If  $PRR > 30\%$ , the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

`gagerr(y, GROUP)` performs a gage R&R study on measurements in `y` with part and operator represented in `GROUP`. `GROUP` is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in `GROUP` should be the same as the number of elements in `y`.

`gagerr(y, part)` performs a gage R&R study on measurements in `y` without operator information. The assumption is that all variability is contributed by `part`.

`gagerr(..., param1, val1, param2, val2, ...)` performs a gage R&R study using one or more of the following parameter name/value pairs:

- `'spec'` — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:

- If  $PTR < 0.1$ , the measurement system is capable.
- If  $PTR > 0.3$ , the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
- `'printtable'` — A string with a value `'on'` or `'off'` that indicates whether the tabular output should be printed in the command window or not. The default value is `'on'`.
- `'printgraph'` — A string with a value `'on'` or `'off'` that indicates whether the bar graph should be plotted or not. The default value is `'on'`.
- `'randomoperator'` — A logical value, `true` or `false`, that indicates whether the effect of operator is random or not. The default value is `true`.

- 'model' — The model to use, specified by one of:
  - 'linear' — Main effects only (default)
  - 'interaction' — Main effects plus two-factor interactions
  - 'nested' — Nest operator in part

The default value is 'linear'.

[TABLE, stats] = gagerr(...) returns a 6-by-5 matrix TABLE and a structure stats. The columns of TABLE, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of TABLE, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. stats is a structure containing summary statistics for the performance of the measurement system. The fields of stats are:

- ndc — Number of distinct categories
- prr — Percentage of gage R&R of total variations
- ptr — Precision-to-tolerance ratio. The value is NaN if the parameter 'spec' is not given.

## Examples

### Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, y, operators do on the parts.

```
rng(1234, 'twister')           % for reproducibility
y = randn(100,1);             % measurements
part = ceil(3*rand(100,1));    % parts
operator = ceil(4*rand(100,1)); % operators
```

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

```
gagerr(y, {part, operator}, 'randomoperator', true)
```

Columns 1 through 4

'Source'	'Variance'	'% Variance'	'sigma'
'Gage R&R'	[ 0.9715]	[ 99.2653]	[0.9857]
' Repeatability'	[ 0.9535]	[ 97.4201]	[0.9765]

# gamcdf

---

**Purpose** Gamma cumulative distribution function

**Syntax**  
`gamcdf(x,a,b)`  
`[p,plo,pup] = gamcdf(x,a,b,pcov,alpha)`  
`[p,plo,pup] = gamcdf( __ , 'upper' )`

**Description** `gamcdf(x,a,b)` returns the gamma cdf at each of the values in `x` using the corresponding shape parameters in `a` and scale parameters in `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must be positive.

`[p,plo,pup] = gamcdf(x,a,b,pcov,alpha)` produces confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1-alpha)% confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = gamcdf( __ , 'upper' )` returns the complement of the gamma cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The gamma cdf is

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

The result, `p`, is the probability that a single observation from a gamma distribution with parameters `a` and `b` will fall in the interval `[0 x]`.

`gammainc` is the gamma distribution with `b` fixed at 1.

**Examples****Compute Gamma Distribution CDF**

The mean of the gamma distribution is the product of the parameters,  $ab$ . In this example, the mean approaches the median as it increases (i.e., the distribution becomes more symmetric).

```
a = 1:6;  
b = 5:10;  
prob = gamcdf(a.*b,a,b)
```

```
prob =  
    0.6321    0.5940    0.5768    0.5665    0.5595    0.5543
```

# gamfit

---

## Purpose

Gamma parameter estimates

## Syntax

```
phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)
```

## Description

`phat = gamfit(data)` returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector `data`.

`[phat,pci] = gamfit(data)` returns MLEs and 95% percent confidence intervals. The first row of `pci` is the lower bound of the confidence intervals; the last row is the upper bound.

`[phat,pci] = gamfit(data,alpha)` returns  $100(1 - \alpha)\%$  confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

`[...] = gamfit(data,alpha,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(data,alpha,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any nonnegative values.

`[...] = gamfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('gamfit')` to see the names and default values of the parameters that `gamfit` accepts in the `options` structure.

## Examples

Fit a gamma distribution to random data generated from a specified gamma distribution:

```
a = 2; b = 4;
data = gamrnd(a,b,100,1);

[p,ci] = gamfit(data)
p =
    2.1990    3.7426
ci =
    1.6840    2.8298
    2.7141    4.6554
```

# prob.GammaDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Gamma probability distribution object

**Description** prob.GammaDistribution is an object consisting of parameters, a model description, and sample data for a gamma probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Gamma')` creates a gamma probability distribution object using the default parameter values.

`pd = makedist('Gamma','a',a,'b',b)` creates a gamma probability distribution object using the specified parameter values.

## Input Arguments

### **a** - Shape parameter

1 (default) | positive scalar value

Shape parameter for the gamma distribution, specified as a positive scalar value.

### Data Types

single | double

### **b** - Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the gamma distribution, specified as a nonnegative scalar value.

### Data Types

single | double

## Properties

**a**

Shape parameter for the gamma distribution, stored as a positive scalar value.

**Data Types**

single | double

**b**

Scale parameter for the gamma distribution, stored as a nonnegative scalar value.

**Data Types**

single | double

**DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

**Data Types**

char

**InputData**

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

**Data Types**

single | double

**IsTruncated**

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

**Data Types**

logical

# prob.GammaDistribution

---

## **NumParameters**

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## **Data Types**

single | double

## **ParameterCovariance**

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## **Data Types**

single | double

## **ParameterDescription**

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## **Data Types**

char

## **ParameterIsFixed**

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

## **Data Types**

logical

## **ParameterNames**

Names of distribution parameters, stored as a cell array of strings.  
This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This  
property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a  
vector containing the lower and upper truncation boundaries.  
This property is read-only.

## Data Types

single | double

## Methods

## Definitions

### Gamma Distribution

The gamma distribution is a two-parameter family of distributions used to model sums of exponentially distributed random variables. The chi-square and the exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution uses the following parameters.

Parameter	Description	Support
a	Shape parameter	$a > 0$
b	Scale parameter	$b \geq 0$

The probability density function (pdf) is

$$f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}} ; \quad x > 0,$$

where  $\Gamma(\cdot)$  is the Gamma function.

## Examples

### Create a Gamma Distribution Object Using Default Parameters

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 1
```

```
  b = 1
```

### Create a Gamma Distribution Object Using Specified Parameters

Create a gamma distribution object by specifying the parameter values.

```
pd = makedist('Gamma', 'a',2,'b',4)
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 2
```

```
  b = 4
```

Compute the mean of the distribution.

## Concepts

- “Gamma Distribution” on page B-43
- Class Attributes
- Property Attributes

**Purpose** Gamma inverse cumulative distribution function

**Syntax** `X = gaminv(P,A,B)`  
`[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)`

**Description** `X = gaminv(P,A,B)` computes the inverse of the gamma cdf with shape parameters in `A` and scale parameters in `B` for the corresponding probabilities in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `P` must lie on the interval `[0 1]`.

The gamma inverse function in terms of the gamma cdf is

$$x = F^{-1}(p | a, b) = \{x : F(x | a, b) = p\}$$

where

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

`[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)` produces confidence bounds for `P` when the input parameters `A` and `B` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1-alpha)% confidence bounds. `PLO` and `PUP` are arrays of the same size as `P` containing the lower and upper confidence bounds.

**Algorithms** There is no known analytical solution to the integral equation above. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

**Examples** This example shows the relationship between the gamma cdf and its inverse function.

# gaminv

---

```
a = 1:5;  
b = 6:10;  
x = gaminv(gamcdf(1:5,a,b),a,b)  
x =  
    1.0000    2.0000    3.0000    4.0000    5.0000
```

## See Also

## How To

- “Gamma Distribution” on page B-43

**Purpose**

Gamma negative log-likelihood

**Syntax**

```
nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)
```

**Description**

`nlogL = gamlike(params,data)` returns the negative of the gamma log-likelihood of the parameters, `params`, given `data`. `params(1)=A`, shape parameters, and `params(2)=B`, scale parameters.

`[nlogL,AVAR] = gamlike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = gamlike(params,data,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any non-negative values.

`gamlike` is a utility function for maximum likelihood estimation of the gamma distribution. Since `gamlike` returns the negative gamma log-likelihood function, minimizing `gamlike` using `fminsearch` is the same as maximizing the likelihood.

**Examples**

Compute the negative log-likelihood of parameter estimates computed by the `gamfit` function:

```
a = 2; b = 3;
r = gamrnd(a,b,100,1);
```

```
[nlogL,AVAR] = gamlike(gamfit(r),r)
nlogL =
    267.5648
AVAR =
```

## How To

- “Gamma Distribution” on page B-43

<b>Purpose</b>	Gamma probability density function
<b>Syntax</b>	<code>Y = gampdf(X,A,B)</code>
<b>Description</b>	<p><code>Y = gampdf(X,A,B)</code> computes the gamma pdf at each of the values in <code>X</code> using the corresponding shape parameters in <code>A</code> and scale parameters in <code>B</code>. <code>X</code>, <code>A</code>, and <code>B</code> can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in <code>A</code> and <code>B</code> must all be positive, and the values in <code>X</code> must lie on the interval <math>[0 \infty)</math>.</p> <p>The gamma pdf is</p>

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

The gamma probability density function is useful in reliability models of lifetimes. The gamma distribution is more flexible than the exponential distribution in that the probability of a product surviving an additional period may depend on its current age. The exponential and  $\chi^2$  functions are special cases of the gamma function.

<b>Examples</b>	The exponential distribution is a special case of the gamma distribution.

# gamstat

---

**Purpose** Gamma mean and variance

**Syntax** `[M,V] = gamstat(A,B)`

**Description** `[M,V] = gamstat(A,B)` returns the mean of and variance for the gamma distribution with shape parameters in *A* and scale parameters in *B*. *A* and *B* can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of *M* and *V*. A scalar input for *A* or *B* is expanded to a constant array with the same dimensions as the other input.

The mean of the gamma distribution with parameters *a* and *b* is  $ab$ . The variance is  $ab^2$ .

**Examples** `[m,v] = gamstat(1:5,1:5)`

```
m =  
    1    4    9   16   25  
v =  
    1    8   27   64  125
```

```
[m,v] = gamstat(1:5,1./(1:5))
```

```
m =  
    1    1    1    1    1  
v =  
  1.0000  0.5000  0.3333  0.2500  0.2000
```

**See Also** `gampdf` | `gamcdf` | `gaminv` | `gamfit` | `gamlike` | `gamrnd`

**How To** • “Gamma Distribution” on page B-43

**Purpose** Greater than or equal relation for handles

**Syntax** `h1 >= h2`

**Description** `h1 >= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ge(h1, h2)` stores the result in a logical array of the same dimensions.

### Generalized Extreme Value Distribution

The generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. It combines three simpler distributions into a single form, allowing a continuous range of possible shapes that include all three of the simpler distributions.

The three distribution types correspond to the limiting distribution of block maxima from different classes of underlying distributions:

- Type 1 — Distributions whose tails decrease exponentially, such as the normal distribution
- Type 2 — Distributions whose tails decrease as a polynomial, such as Student's  $t$  distribution
- Type 3 — Distributions whose tails are finite, such as the beta distribution

The generalized extreme value distribution uses the following parameters.

Parameter	Description	Support
k	Shape parameter	$-\infty \leq k \leq \infty$
sigma	Scale parameter	$\sigma \geq 0$
mu	Location parameter	$-\infty \leq \mu \leq \infty$

# prob.GeneralizedExtremeValueDistribution

---

The probability density function (pdf) for a Type 1 distribution, where shape parameter  $k = 0$ , is

$$f(x | 0, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\exp\left(-\frac{(x-\mu)}{\sigma}\right) - \frac{(x-\mu)}{\sigma}\right) ; \quad -\infty < x < \infty.$$

When  $k \neq 0$ , the pdf is

$$f(x | k, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left[-\left(1 + k \frac{(x-\mu)}{\sigma}\right)^{-\frac{1}{k}}\right] \left(1 + k \frac{(x-\mu)}{\sigma}\right)^{-1-\frac{1}{k}}$$

for

$$1 + k \frac{(x-\mu)}{\sigma} > 0.$$

For the Type 2 case,  $k > 0$  and  $x \geq \mu - \frac{\sigma}{k}$ . For the Type 3 case,  $k < 0$

and  $x < \mu - \frac{\sigma}{k}$ .

## Examples

### Create a Generalized Extreme Value Distribution Object Using Default Parameters

Create a generalized extreme value distribution object using the default parameter values.

```
pd = makedist('GeneralizedExtremeValue')
```

```
pd =
```

```
GeneralizedExtremeValueDistribution
```

```
Generalized Extreme Value distribution  
k = 0
```

# prob.GeneralizedExtremeValueDistribution

---

```
sigma = 1  
mu = 0
```

## Create a Generalized Extreme Value Distribution Object Using Specified Parameters

Create a generalized extreme value distribution object by specifying values for the parameters.

```
pd = makedist('GeneralizedExtremeValue','k',0,'sigma',2,'mu',1)
```

```
pd =
```

```
GeneralizedExtremeValueDistribution
```

```
Generalized Extreme Value distribution
```

```
k = 0  
sigma = 2  
mu = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
2.1544
```

# GeneralizedLinearModel

---

**Purpose** Generalized linear regression model class

**Description** An object comprising training data, model description, diagnostic information, and fitted coefficients for a generalized linear regression. Predict model responses with the `predict` or `feval` methods.

**Construction** `mdl = fitglm(ds)` or `mdl = fitglm(X,y)` creates a generalized linear model of a dataset array `ds`, or of the responses `y` to a data matrix `X`. For details, see `fitglm`.

`mdl = stepwiseglm(ds)` or `mdl = stepwiseglm(X,y)` creates a generalized linear model of a dataset array `ds`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiseglm`.

## Input Arguments

### **ds** - Input data

dataset array

Input data, specified as a dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### **Data Types**

single | double | logical

### **X** - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

### Data Types

single | double | logical

### **y** - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### Data Types

single | double

## Properties

### CoefficientCovariance

Covariance matrix of coefficient estimates.

### CoefficientNames

Cell array of strings containing a label for each coefficient.

### Coefficients

Table of coefficient values in a dataset array. **Coefficients** has one row for each coefficient and these columns:

- Estimate — Estimated coefficient value
- SE — Standard error of the estimate
- tStat —  $t$  statistic for a test that the coefficient is zero
- pValue —  $p$ -value for the  $t$  statistic

# GeneralizedLinearModel

---

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

## Deviance

Deviance of the fit. It is useful for comparing two models when one is a special case of the other. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 21-1266.

## DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

## Diagnostics

Dataset array with diagnostics helpful in finding outliers and influential observations. The structure contains the following fields:

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with $p$ coefficients and $n$ observations, the average value of Leverage is $p/n$ . An observation

Field	Meaning	Utility
		with Leverage larger than $2*p/n$ can be an outlier.
CooksDistance	Cook's measure of scaled change in fitted values	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an $n$ -by- $n$ matrix such that $\text{Fitted} = \text{HatMatrix} * Y$ , where $Y$ is the response vector and $\text{Fitted}$ is the vector of fitted response values.

All of these quantities are computed on the scale of the linear predictor. So, for example, in the equation that defines the hat matrix,

```
Yfit = glm.Fitted.LinearPredictor
Y = glm.Fitted.LinearPredictor + glm.Residuals.LinearPredictor
```

## Dispersion

Scale factor of the variance of the response. Dispersion multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is  $p(1-p)/n$ , where  $p$  is the probability parameter and  $n$  is the sample size parameter. If Dispersion is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If Dispersion is larger than 1, the data are "overdispersed" relative to the binomial distribution.

## DispersionEstimated

Logical value indicating whether fitglm used the Dispersion property to compute standard errors for the coefficients in Coefficients.SE. If DispersionEstimated is false, fitglm used the theoretical value of the variance.

# GeneralizedLinearModel

---

- DispersionEstimated can be false only for 'binomial' or 'poisson' distributions.
- Set DispersionEstimated by setting the DispersionFlag name-value pair in fitglm.

## Distribution

Structure with the following fields relating to the generalized distribution:

Field	Description
Name	Name of the distribution, one of 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gamma'.
DevianceFunction	Function that computes the components of the deviance as a function of the fitted parameter values and the response values.
VarianceFunction	Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When DispersionEstimated is true, Dispersion multiplies the variance function in the computation of the coefficient standard errors.

## Fitted

Table of predicted (fitted) values based on the training data, a dataset array with one row for each observation and the following columns.

Field	Description
Response	Predicted values on the scale of the response.
LinearPredictor	Predicted values on the scale of the linear predictor. These are the same as the link function applied to the Response fitted values.
Probability	Fitted probabilities (this column is included only with the binomial distribution).

To obtain any of the columns as a vector, index into the property using dot notation. For example, in the model `mdl`, the vector `f` of fitted values on the response scale is

```
f = mdl.Fitted.Response
```

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

## Formula

Object containing information about the model.

## Link

Structure with fields relating to the link function. The link is a function  $f$  that links the distribution parameter  $\mu$  to the fitted linear combination  $Xb$  of the predictors:

$$f(\mu) = Xb.$$

The structure has the following fields.

Field	Description
Name	Name of the link function, or '' if you specified the link as a function handle rather than a string.
LinkFunction	The function that defines $f$ , a function handle.
DevianceFunction	Derivative of $f$ , a function handle.
VarianceFunction	Inverse of $f$ , a function handle.

## LogLikelihood

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

## ModelCriterion

# GeneralizedLinearModel

---

AIC and other information criteria for comparing models. A structure with fields:

- AIC — Akaike information criterion
- AICc — Akaike information criterion corrected for sample size
- BIC — Bayesian information criterion
- CAIC — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

## **NumCoefficients**

Number of coefficients in the model, a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

## **NumEstimatedCoefficients**

Number of estimated coefficients in the model, a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

## **NumObservations**

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original dataset or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

## **NumPredictors**

Number of variables `fitlm` used as predictors for fitting.

## **NumVariables**

Number of variables in the data. `NumVariables` is the number of variables in the original dataset when the fit is based on a dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

## ObservationInfo

Dataset with the same number of rows as the input data (ds or X).

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

## ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

## Offset

Vector with the same length as the number of rows in the data, passed from `fitglm` or `stepwiseglm` in the `Offset` name-value pair. The fitting function used `Offset` as a predictor variable, but

# GeneralizedLinearModel

---

with the coefficient set to exactly 1. In other words, the formula for fitting was

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by specifying  $\log(A)$  as an offset, you can force the model to satisfy this theoretical constraint.

## PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

## Residuals

Dataset array containing a table of residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
LinearPredictor	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors.
Pearson	Raw residuals divided by the estimated standard deviation of the response.
Anscombe	Residuals defined on transformed data with the transformation chosen to remove skewness.
Deviance	Residuals based on the contribution of each observation to the deviance.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

## **ResponseName**

String giving naming the response variable.

## **Rsquared**

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}.$$

`Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

# GeneralizedLinearModel

---

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

## SSE

Sum of squared errors (residuals).

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## SSR

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## SST

Total sum of squares, the sum of squared deviations of  $y$  from  $\text{mean}(y)$ .

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## Steps

Structure that is empty unless `stepwiselm` constructed the model.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model

Field	Description
Upper	Formula representing the upper bound model, model cannot contain more terms than Upper
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Dataset representing the steps taken in the fit

The History dataset has one row for each step including the initial fit, and the following variables (columns).

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"><li>• 'Start' — First step</li><li>• 'Add' — A term is added</li><li>• 'Remove' — A term is removed</li></ul>
TermName	<ul style="list-style-type: none"><li>• 'Start' step: The starting model specification</li><li>• 'Add' or 'Remove' steps: The term moved in that step</li></ul>
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code> )
DF	Regression degrees of freedom after this step
delDF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step

# GeneralizedLinearModel

---

Field	Description
FStat	$F$ statistic that led to this step
PValue	$p$ -value of the $F$ statistic

## VariableInfo

Dataset array containing metadata about Variables. There is one row for each term in the model, and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"><li>• Continuous variable — Two-element vector <math>[min, max]</math>, the minimum and maximum values</li><li>• Categorical variable — Cell array of distinct variable values</li></ul>
InModel	Logical vector, where true indicates the variable is in the model
IsCategorical	Logical vector, where true indicates a categorical variable

## VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a dataset, this property provides the names of the variables in that dataset.
- If the fit is based on a predictor matrix and response vector, VariableNames is the values in the VarNames name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

## Variables

Dataset array containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a dataset array, `Variables` is a copy of that dataset. Otherwise, `Variables` is a dataset created from the input data matrix `X` and response vector `y`.

## Methods

<code>addTerms</code>	Add terms to generalized linear model
<code>coefCI</code>	Confidence intervals of coefficient estimates of generalized linear model
<code>coefTest</code>	Linear hypothesis test on generalized linear regression model coefficients
<code>devianceTest</code>	Analysis of deviance
<code>disp</code>	Display generalized linear regression model
<code>feval</code>	Evaluate generalized linear regression model prediction
<code>fit</code>	Create generalized linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of generalized linear regression model
<code>plotResiduals</code>	Plot residuals of generalized linear regression model
<code>plotSlice</code>	Plot of slices through fitted generalized linear regression surface

# GeneralizedLinearModel

---

predict	Predict response of generalized linear regression model
random	Simulate responses for generalized linear regression model
removeTerms	Remove terms from generalized linear model
step	Improve generalized linear regression model by adding or removing terms
stepwise	Create generalized linear regression model by stepwise regression

## Definitions Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

## Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

## Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$  and a diagonal weight matrix  $W$ :

$$H = X(X^T W X)^{-1} X^T W^T.$$

$W$  has diagonal elements  $w_i$ :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- $g$  is the link function mapping  $y_i$  to  $x_i b$ .
- $g'$  is the derivative of the link function  $g$ .
- $V$  is the variance function.
- $\mu_i$  is the  $i$ th mean.

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

## Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

# Generalized Linear Model

---

## Cook's Distance

The Cook's distance  $D_i$  of observation  $i$  is

$$D_i = w_i \frac{e_i^2}{p\hat{\phi}} \frac{h_{ii}}{(1-h_{ii})^2},$$

where

- $\hat{\phi}$  is the dispersion parameter (estimated or theoretical).
- $e_i$  is the linear predictor residual,  $g(y_i) - x_i\hat{\beta}$ , where
  - $g$  is the link function.
  - $y_i$  is the observed response.
  - $x_i$  is the observation.
  - $\hat{\beta}$  is the estimated coefficient vector.
- $p$  is the number of coefficients in the regression model.
- $h_{ii}$  is the  $i$ th diagonal element of the Hat Matrix  $H$ .

## Deviance

Deviance of a model  $M_1$  is twice the difference between the loglikelihood of that model and the saturated model,  $M_S$ . The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are  $n$  observations  $y_i$ ,  $i = 1, 2, \dots, n$ , with potentially different values for  $X_i^T\beta$ , then you can define a saturated model with  $n$  parameters. Let  $L(b, y)$  denote the maximum value of the likelihood function for a model. Then the deviance of model  $M_1$  is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where  $b_1$  are the estimated parameters for model  $M_1$  and  $b_S$  are the estimated parameters for the saturated model. The deviance has a chi-square distribution with  $n - p$  degrees of freedom, where  $n$  is the

number of parameters in the saturated model and  $p$  is the number of parameters in model  $M_1$ .

If  $M_1$  and  $M_2$  are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances  $D_1$  and  $D_2$  of these models. The difference of the deviances is

$$\begin{aligned} D &= D_2 - D_1 = -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom  $v$  equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in  $M_1$  and  $M_2$ . You can get the  $p$ -value for this test using `1 - chi2cdf(D, V)`, where  $D = D_2 - D_1$ .

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds, modelspec, 'Distribution', 'binomial')
```

# GeneralizedLinearModel

---

```
mdl =
```

```
Generalized Linear regression model:
```

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
```

```
Distribution = Binomial
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

```
100 observations, 93 error degrees of freedom
```

```
Dispersion: 1
```

```
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535
```

The large  $p$ -value indicates the model might not differ statistically from a constant.

## Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...  
    'constant','upper','linear','Distribution','poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
```

Generalized Linear regression model:

```
log(y) ~ 1 + x5 + x10 + x15  
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

100 observations, 96 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20

# prob.GeneralizedParetoDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Generalized Pareto probability distribution object

**Description** prob.GeneralizedParetoDistribution is an object consisting of parameters, a model description, and sample data for a generalized Pareto probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('GeneralizedParetoDistribution')` creates a generalized Pareto probability distribution object using default parameter values.

`pd = makedist('GeneralizedParetoDistribution','k',k,'sigma',sigma,'theta',theta)` creates a generalized Pareto probability distribution object using the specified parameter values.

## Input Arguments

### **k - Shape parameter**

1 (default) | scalar value

Shape parameter for the generalized Pareto distribution, specified as a scalar value.

### **Data Types**

single | double

### **sigma - Scale parameter**

1 (default) | nonnegative scalar value

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

### **Data Types**

single | double

## **theta - Location parameter**

1 (default) | scalar value

Location parameter for the generalized Pareto distribution, specified as a scalar value.

## **Data Types**

single | double

## **Properties**

### **k**

Shape parameter for the generalized Pareto distribution, stored as a scalar value.

## **Data Types**

single | double

### **sigma**

Scale parameter for the generalized Pareto distribution, stored as a nonnegative scalar value.

## **Data Types**

single | double

### **theta**

Location parameter for the generalized Pareto distribution, stored as a scalar value.

## **Data Types**

single | double

### **DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## **Data Types**

char

### **InputData**

# prob.GeneralizedParetoDistribution

---

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

## Data Types

single | double

## IsTruncated

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

**Data Types**

single | double

**ParameterDescription**

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

**Data Types**

char

**ParameterIsFixed**

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

**Data Types**

logical

**ParameterNames**

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

**Data Types**

char

**ParameterValues**

Values of distribution parameters, stored as a vector. This property is read-only.

**Data Types**

single | double

**Truncation**

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

### Generalized Pareto Distribution

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease polynomially, such as the Student's  $t$ , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.

Parameter	Description	Support
k	Shape parameter	$-\infty < k < \infty$
sigma	Scale parameter	$\sigma \geq 0$
theta	Location parameter	$-\infty < \theta < \infty$

The probability density function (pdf) of the generalized Pareto distribution with shape parameter  $k \neq 0$  is

# prob.GeneralizedParetoDistribution

---

$$f(x | k, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \left(1 + k \frac{(x - \theta)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for  $x > \theta$ , when  $k > 0$ , or for  $\theta < x < -\frac{\sigma}{k}$ , when  $k < 0$ .

For  $k = 0$ , the pdf is

$$y = f(x | 0, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \exp\left(-\frac{(x - \theta)}{\sigma}\right)$$

for  $x > \theta$ .

If  $k = 0$  and  $\theta = 0$ , the generalized Pareto distribution is equivalent

to the exponential distribution. If  $k > 0$  and  $\theta = \frac{\sigma}{k}$ , the generalized Pareto distribution is equivalent to the Pareto distribution.

## Examples

### Create a Generalized Pareto Distribution Object Using Default Parameters

Create a generalized Pareto distribution object using the default parameter values.

```
pd = makedist('GeneralizedPareto')
```

```
pd =
```

```
GeneralizedParetoDistribution
```

```
Generalized Pareto distribution
```

```
    k = 1  
    sigma = 1  
    theta = 1
```

## Create a Generalized Pareto Distribution Object Using Specified Parameters

Create a generalized Pareto distribution object by specifying parameter values.

```
pd = makedist('GeneralizedPareto','k',0,'sigma',2,'theta',1)
```

```
pd =
```

```
GeneralizedParetoDistribution
```

```
Generalized Pareto distribution
```

```
    k = 0
```

```
    sigma = 2
```

```
    theta = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
    2.1544
```

## Concepts

- “Generalized Pareto Distribution” on page B-53
- Class Attributes
- Property Attributes

# geocdf

---

**Purpose** Geometric cumulative distribution function

**Syntax**  
`y = geocdf(x,P)`  
`y = geocdf(x,P, 'upper')`

**Description** `y = geocdf(x,P)` computes the geometric cdf at each of the values in `x` using the corresponding probabilities in `P`. `x` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `P` must lie on the interval `[0 1]`.

`y = geocdf(x,P, 'upper')` returns the complement of the geometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The geometric cdf is

$$y = F(x | p) = \sum_{i=0}^{\text{floor}(x)} pq^i$$

where  $q = 1 - p$ .

The result, `y`, is the probability of observing up to `x` trials before a success, when the probability of success in any given trial is `p`.

## Examples **Compute Geometric Distribution CDF**

Suppose you toss a fair coin repeatedly. If the coin lands face up (heads), that is a success. What is the probability of observing three or fewer tails before getting a heads?

```
p = geocdf(3,0.5)
```

```
p =  
0.9375
```

**See Also** `cdf` | `geopdf` | `geoinv` | `geostat` | `geornd` | `mle`

**How To**

- “Geometric Distribution” on page B-57

**Purpose** Geometric inverse cumulative distribution function

**Syntax** `X = geoinv(Y,P)`

**Description** `X = geoinv(Y,P)` returns the smallest positive integer  $X$  such that the geometric cdf evaluated at  $X$  is equal to or exceeds  $Y$ . You can think of  $Y$  as the probability of observing  $X$  successes in a row in independent trials where  $P$  is the probability of success in each trial.

$Y$  and  $P$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for  $P$  or  $Y$  is expanded to a constant array with the same dimensions as the other input. The values in  $P$  and  $Y$  must lie on the interval  $[0\ 1]$ .

**Examples** The probability of correctly guessing the result of 10 coin tosses in a row is less than 0.001 (unless the coin is not fair).

```
psychic = geoinv(0.999,0.5)
psychic =
     9
```

The example below shows the inverse method for generating random numbers from the geometric distribution.

```
rndgeo = geoinv(rand(2,5),0.5)
rndgeo =
     0     1     3     1     0
     0     1     0     2     0
```

**See Also** `icdf` | `geocdf` | `geopdf` | `geostat` | `geornd`

**How To** • “Geometric Distribution” on page B-57

**Purpose** Geometric mean

**Syntax** `m = geomean(x)`  
`geomean(X,dim)`

**Description** `m = geomean(x)` calculates the geometric mean of a sample. For vectors, `geomean(x)` is the geometric mean of the elements in `x`. For matrices, `geomean(X)` is a row vector containing the geometric means of each column. For N-dimensional arrays, `geomean` operates along the first nonsingleton dimension of `X`.

`geomean(X,dim)` takes the geometric mean along the dimension `dim` of `X`.

The geometric mean is

$$m = \left[ \prod_{i=1}^n x_i \right]^{\frac{1}{n}}$$

**Examples** The arithmetic mean is greater than or equal to the geometric mean.

```
x = exprnd(1,10,6);
```

```
geometric = geomean(x)
```

```
geometric =  
    0.7466    0.6061    0.6038    0.2569    0.7539    0.3478
```

```
average = mean(x)
```

```
average =  
    1.3509    1.1583    0.9741    0.5319    1.0088    0.8122
```

**See Also** `mean` | `median` | `harmmean` | `trimmean`

**How To** • “Geometric Distribution” on page B-57

**Purpose** Geometric probability density function

**Syntax** `Y = geopdf(X,P)`

**Description** `Y = geopdf(X,P)` computes the geometric pdf at each of the values in `X` using the corresponding probabilities in `P`. `X` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `P` must lie on the interval `[0 1]`.

The geometric pdf is

$$y = f(x | p) = pq^x I_{(0,1,\dots)}(x)$$

where  $q = 1 - p$ .

**Examples** Suppose you toss a fair coin repeatedly. If the coin lands face up (heads), that is a success. What is the probability of observing exactly three tails before getting a heads?

```
p = geopdf(3,0.5)
```

```
p =  
0.0625
```

**See Also** `pdf` | `geocdf` | `geoinv` | `geostat` | `geornd`

**How To** • “Geometric Distribution” on page B-57

**Purpose** Geometric random numbers

**Syntax**

```
R = geornd(P)
R = geornd(P,m,n,...)
R = geornd(P,[m,n,...])
```

**Description** `R = geornd(P)` generates geometric random numbers with probability parameter `P`. `P` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `P`. The geometric distribution is useful when you want to model the number of successive failures preceding a success, where the probability of success in any given trial is the constant `P`. The parameters in `P` must lie in the interval `[0 1]`.

`R = geornd(P,m,n,...)` or `R = geornd(P,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the geometric distribution with probability parameter `P`. `P` can be a scalar or an array of the same size as `R`.

**Examples**

```
r1 = geornd(1 ./ 2.^(1:6))
r1 =
     2    10     2     5     2    60
```

```
r2 = geornd(0.01,[1 5])
r2 =
    65    18   334   291    63
```

```
r3 = geornd(0.5,1,6)
r3 =
     0     7     1     3     1     0
```

**See Also** `random` | `geopdf` | `geocdf` | `geoinv` | `geostat`

**How To**

- “Geometric Distribution” on page B-57

# geostat

---

**Purpose** Geometric mean and variance

**Syntax** `[M,V] = geostat(P)`

**Description** `[M,V] = geostat(P)` returns the mean of and variance for the geometric distribution with corresponding probabilities in P.

The mean of the geometric distribution with parameter  $p$  is  $q/p$ , where  $q = 1-p$ . The variance is  $q/p^2$ .

**Examples**

```
[m,v] = geostat(1./(1:6))
m =
    0    1.0000    2.0000    3.0000    4.0000    5.0000
v =
    0    2.0000    6.0000   12.0000   20.0000   30.0000
```

**See Also** `geopdf` | `geocdf` | `geoinv` | `geornd`

**How To**

- “Geometric Distribution” on page B-57

**Superclasses** ClusterCriterion

**Purpose** Gap criterion clustering evaluation object

**Description** clustering.evaluation.GapEvaluation is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using evalclusters.

**Construction** `eva = evalclusters(x,clust,'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x,clust,'Gap',Name,Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

## Input Arguments

### **x - Input data**

matrix

Input data, specified as an  $N$ -by- $P$  matrix.  $N$  is the number of observations, and  $P$  is the number of variables.

### **Data Types**

single | double

### **clust - Clustering algorithm**

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

# clustering.evaluation.GapEvaluation

---

'kmeans'	Cluster the data in $X$ using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in $X$ using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in $X$ using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If Criterion is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using the function\_handle (@) operator. The function must be of the form

```
C = clustfun(DATA,K)
```

where DATA is the data to be clustered, and K is the number of clusters. The output of clustfun must be one of the following:

- A vector of integers representing the cluster index for each observation in DATA. There must be K unique values in this vector.
- A numeric  $n$ -by- $K$  matrix of score for  $n$  observations and  $K$  classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If Criterion is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify clust as a  $n$ -by- $K$  matrix containing the proposed clustering solutions.  $n$  is the number of observations in the sample data, and  $K$  is the number of proposed clustering solutions. Column  $j$  contains the cluster indices for each of the  $N$  points in the  $j$ th clustering solution.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

## B - Number of reference data sets

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of `'B'` and a positive integer value.

**Example:** `'B',150`

## Distance - Distance metric

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

<code>'sqEuclidean'</code>	Squared Euclidean distance
<code>'Euclidean'</code>	Euclidean distance
<code>'cityblock'</code>	Sum of absolute differences
<code>'cosine'</code>	One minus the cosine of the included angle between points (treated as vectors)
<code>'correlation'</code>	One minus the sample correlation between points (treated as sequences of values)

# clustering.evaluation.GapEvaluation

---

'Hamming'	Percentage of coordinates that differ
'Jaccard'	Percentage of nonzero coordinates that differ

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (`@`) operator. The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by- $n$  vector corresponding to a single row of the input matrix `X`, and `XJ` is an  $m_2$ -by- $n$  matrix corresponding to multiple rows of `X`. `distfun` must return an  $m_2$ -by-1 vector of distances `d2`, whose  $k$ th element is the distance between `XI` and `XJ(k, :)`.

If `Criterion` is 'silhouette', you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is 'linkage', and `Distance` is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses Euclidean distance and Ward linkage.
- If `Clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

**Example:** 'Distance', 'Euclidean'

**KList - List of number of clusters to evaluate**

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when `clust` is a clustering algorithm name string or a function handle. When `criterion` is 'gap', `clust` must be a string or a function handle, and you must specify KList.

**Example:** 'KList',[1:6]

## **ReferenceDistribution - Reference data generation method**

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA'	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix <code>x</code> .
'uniform'	Generate reference data uniformly over the range of each feature in the data matrix <code>x</code> .

**Example:** 'ReferenceDistribution','uniform'

## **SearchMethod - Method for selecting optimal number of clusters**

'firstmaxse' | 'globalmaxse'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

# clustering.evaluation.GapEvaluation

---

'firstmaxse'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where  $K$  is the number of clusters,  $\text{Gap}(K)$  is the gap value for the clustering solution with  $K$  clusters, and  $\text{SE}(K + 1)$  is the standard error of the clustering solution with  $K + 1$  clusters. This is the default if the sorted `KList` contains consecutive integer values.

'globalmaxse'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where  $K$  is the number of clusters,  $\text{Gap}(K)$  is the gap value for the clustering solution with  $K$  clusters,  $\text{GAPMAX}$  is the largest gap value, and  $\text{SE}(\text{GAPMAX})$  is the standard error corresponding to the largest gap value. This is the default if `KList` contains only one value, or contains any nonconsecutive integer values.

**Example:** 'SearchMethod', 'globalmaxse'

## Properties

**B**

Number of data sets generated from the reference distribution, stored as a positive integer value.

## ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name string or function handle. If the clustering solutions are provided in the input, ClusteringFunction is empty.

## **CriterionName**

Name of the criterion used for clustering evaluation, stored as a valid criterion name string.

## **CriterionValues**

Criterion values corresponding to each proposed number of clusters in InspectedK, stored as a vector of numerical values.

## **Distance**

Distance measure used for clustering data, stored as a valid distance measure name string.

## **ExpectedLogW**

Expectation of the natural logarithm of  $W$  based on the generated reference data, stored as a vector of scalar values.  $W$  is the within-cluster dispersion computed using the distance measurement Distance.

## **InspectedK**

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

## **LogW**

Natural logarithm of  $W$  based on the input data, stored as a vector of scalar values.  $W$  is the within-cluster dispersion computed using the distance measurement Distance.

## **Missing**

Logical flag for excluded data, stored as a column vector of logical values. If Missing equals true, then the corresponding value in the data matrix  $x$  is not used in the clustering solution.

# clustering.evaluation.GapEvaluation

---

## **NumObservations**

Number of observations in the data matrix  $X$ , minus the number of missing (NaN) values in  $X$ , stored as a positive integer value.

## **OptimalK**

Optimal number of clusters, stored as a positive integer value.

## **OptimalY**

Optimal clustering solution corresponding to **OptimalK**, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, **OptimalY** is empty.

## **ReferenceDistribution**

Reference data generation method, stored as a valid reference distribution name string.

## **SE**

Standard error of the natural logarithm of  $W$  with respect to the reference data for each number of clusters in **InspectedK**, stored as a vector of scalar values.  $W$  is the within-cluster dispersion computed using the distance measurement **Distance**.

## **SearchMethod**

Method for determining the optimal number of clusters, stored as a valid search method name string.

## **StdLogW**

Standard deviation of the natural logarithm of  $W$  with respect to the reference data for each number of clusters in **InspectedK**.  $W$  is the within-cluster dispersion computed using the distance measurement **Distance**.

## **X**

Data used for clustering, stored as a matrix of numerical values.

## Methods

### Inherited Methods

compact	Compact clustering evaluation object
plot	Plot clustering evaluation object criterion values

## Definitions

### Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

$$\text{Gap}_n(k) = E_n^* \{ \log(W_k) \} - \log(W_k),$$

where  $n$  is the sample size,  $k$  is the number of clusters being evaluated, and  $W_k$  is the pooled within-cluster dispersion measurement

$$W_k = \sum_{r=1}^k \frac{1}{2n_r} D_r,$$

where  $n_r$  is the number of data points in cluster  $r$ , and  $D_r$  is the sum of the pairwise distances for all points in cluster  $r$ .

The expected value  $E_n^* \{ \log(W_k) \}$  is determined by Monte Carlo sampling from a reference distribution, and  $\log(W_k)$  is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the

# clustering.evaluation.GapEvaluation

---

gap criterion is more computationally expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

## Examples

### Evaluate the Clustering Solution Using Gap Criterion

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using kmeans.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
InspectecedK: [1 2 3 4 5 6]
CriterionValues: [1x6 double]
OptimalK: 4
```

The OptimalK value indicates that, based on the gap criterion, the optimal number of clusters is three.

Plot the gap criterion values for each number of clusters tested.

```
figure;
plot(eva);
```

Based on the plot, the maximum value of the gap criterion occurs at five clusters. However, the value at four clusters is within one standard error of the maximum, so the suggested optimal number of clusters is four.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
figure;  
PetalLength = meas(:,3);
```

# clustering.evaluation.GapEvaluation

```
PetalWidth = meas(:,4);  
ClusterGroup = eva.OptimalY;  
figure;  
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgk','xod^');
```

The plot shows cluster 1 in the lower-left corner, completely separated from the other three clusters. Cluster 1 contains flowers with the smallest petal widths and lengths. Cluster 4 is in the upper-right corner, and contains flowers with the largest petal widths and lengths.

Clusters 2 and 3 are near the center of the plot, and contain flowers with measurements between the two extremes.

## Concepts

- Class Attributes
- Property Attributes

# dataset.get

---

**Purpose** Access dataset array properties

**Syntax**

```
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

**Description**

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by the string `PropertyName`.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

**Examples** Create a dataset array from Fisher's iris data and access the information:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
              {meas,'SL','SW','PL','PW'},...
              'ObsNames',NameObs);

get(iris)
Description: ''
Units: {}
DimNames: {'Observations' 'Variables'}
UserData: []
ObsNames: {150x1 cell}
VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}

ON = get(iris,'ObsNames');
ON(1:3)
```

```
ans =  
  'Obs1'  
  'Obs2'  
  'Obs3'
```

**See Also**

set | summary

# categorical.getlabels

---

**Purpose** Access categorical array labels

**Syntax** `labels = getlabels(A)`

**Description** `labels = getlabels(A)` returns the labels of the levels in the categorical array `A` as a cell array of strings `labels`. For ordinal `A`, the labels are returned in the order of the levels.

## **Examples** **Example 1**

Display levels in a nominal and an ordinal array:

```
standings = nominal({'Leafs','Canadiens','Bruins'});
getlabels(standings)
ans =
    'Bruins'    'Canadiens'    'Leafs'
```

```
standings = ordinal(1:3,{'Leafs','Canadiens','Bruins'});
getlabels(standings)
ans =
    'Leafs'    'Canadiens'    'Bruins'
```

## **Example 2**

Display age groups containing data in `hospital.mat`:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','%d'),{'s'});
AgeGroup = ordinal(hospital.Age,labels,[],edges);
AgeGroup = droplevels(AgeGroup);
getlabels(AgeGroup)
ans =
    '20s'    '30s'    '40s'    '50s'
```

**See Also** `getlevels` | `setlabels`

**Purpose** Get categorical array levels

**Syntax** `S = getlevels(A)`

**Description** `S = getlevels(A)` returns the levels for the categorical array `A`. `S` is a vector with the same type as `A`.

**See Also** `getlabels`

# gevcdf

---

<b>Purpose</b>	Generalized extreme value cumulative distribution function
<b>Syntax</b>	<pre>p = gevcdf(x,k,sigma,mu) p = gevcdf(x,k,sigma,mu, 'upper')</pre>
<b>Description</b>	<p><code>p = gevcdf(x,k,sigma,mu)</code> returns the cdf of the generalized extreme value (GEV) distribution with shape parameter <code>k</code>, scale parameter <code>sigma</code>, and location parameter, <code>mu</code>, evaluated at the values in <code>x</code>. The size of <code>p</code> is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.</p> <p><code>p = gevcdf(x,k,sigma,mu, 'upper')</code> returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.</p> <p>Default values for <code>k</code>, <code>sigma</code>, and <code>mu</code> are 0, 1, and 0, respectively.</p> <p>When <math>k &lt; 0</math>, the GEV is the type III extreme value distribution. When <math>k &gt; 0</math>, the GEV distribution is the type II, or Frechet, extreme value distribution. If <math>w</math> has a Weibull distribution as computed by the <code>wblcdf</code> function, then <math>-w</math> has a type III extreme value distribution and <math>1/w</math> has a type II extreme value distribution. In the limit as <math>k</math> approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the <code>evcdf</code> function.</p> <p>The mean of the GEV distribution is not finite when <math>k \geq 1</math>, and the variance is not finite when <math>k \geq 1/2</math>. The GEV distribution has positive density only for values of <math>X</math> such that <math>k*(X-mu)/sigma &gt; -1</math>.</p>
<b>References</b>	<p>[1] Embrechts, P., C. Klüppelberg, and T. Mikosch. <i>Modelling Extremal Events for Insurance and Finance</i>. New York: Springer, 1997.</p> <p>[2] Kotz, S., and S. Nadarajah. <i>Extreme Value Distributions: Theory and Applications</i>. London: Imperial College Press, 2000.</p>
<b>See Also</b>	<code>cdf</code>   <code>gevpdf</code>   <code>gevinv</code>   <code>gevstat</code>   <code>gevfit</code>   <code>gevlike</code>   <code>gevrnd</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Generalized Extreme Value Distribution” on page B-48</li></ul>

**Purpose** Generalized extreme value parameter estimates

**Syntax**

```
parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)
```

**Description**

`parmhat = gevfit(X)` returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in X. `parmhat(1)` is the shape parameter, `k`, `parmhat(2)` is the scale parameter, `sigma`, and `parmhat(3)` is the location parameter, `mu`.

`[parmhat,parmci] = gevfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gevfit(X,alpha)` returns  $100(1-\alpha)\%$  confidence intervals for the parameter estimates.

`[...] = gevfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gevfit')` for parameter names and default values. Pass in `[]` for `alpha` to use the default values.

When  $k < 0$ , the GEV is the type III extreme value distribution. When  $k > 0$ , the GEV distribution is the type II, or Frechet, extreme value distribution. If  $w$  has a Weibull distribution as computed by the `wblfit` function, then  $-w$  has a type III extreme value distribution and  $1/w$  has a type II extreme value distribution. In the limit as  $k$  approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evfit` function.

The mean of the GEV distribution is not finite when  $k \geq 1$ , and the variance is not finite when  $k \geq 1/2$ . The GEV distribution is defined for  $k*(X-\mu)/\sigma > -1$ .

# gevrnd

---

**Purpose** Generalized extreme value random numbers

**Syntax**  
R = gevrnd(k, sigma, mu)  
R = gevrnd(k, sigma, mu, m, n, ...)  
R = gevrnd(k, sigma, mu, [m, n, ...])

**Description** R = gevrnd(k, sigma, mu) returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter k, scale parameter sigma, and location parameter, mu. The size of R is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of R is the size of the other parameters.

R = gevrnd(k, sigma, mu, m, n, ...) or R = gevrnd(k, sigma, mu, [m, n, ...]) generates an m-by-n-by-... array containing random numbers from the GEV distribution with parameters k, sigma, and mu. The k, sigma, mu parameters can each be scalars or arrays of the same size as R.

When  $k < 0$ , the GEV is the type III extreme value distribution. When  $k > 0$ , the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wblrnd function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evrnd function.

The mean of the GEV distribution is not finite when  $k \geq 1$ , and the variance is not finite when  $k \geq 1/2$ . The GEV distribution has positive density only for values of X such that  $k*(X-mu)/sigma > -1$ .

**How To**

- “Generalized Extreme Value Distribution” on page B-48

# gevstat

---

**Purpose** Generalized extreme value mean and variance

**Syntax** `[M,V] = gevstat(k,sigma,mu)`

**Description** `[M,V] = gevstat(k,sigma,mu)` returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The sizes of `M` and `V` are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When  $k < 0$ , the GEV is the type III extreme value distribution. When  $k > 0$ , the GEV distribution is the type II, or Frechet, extreme value distribution. If  $w$  has a Weibull distribution as computed by the `wblstat` function, then  $-w$  has a type III extreme value distribution and  $1/w$  has a type II extreme value distribution. In the limit as  $k$  approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evstat` function.

The mean of the GEV distribution is not finite when  $k \geq 1$ , and the variance is not finite when  $k \geq 1/2$ . The GEV distribution has positive density only for values of  $X$  such that  $k*(X-\mu)/\text{sigma} > -1$ .

**How To** • “Generalized Extreme Value Distribution” on page B-48

**Purpose**

Interactively add line to plot

**Syntax**

```
gline(h)
gline
hline = gline(...)
```

**Description**

`gline(h)` allows you to draw a line segment in the figure with handle `h` by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

`gline` with no input arguments defaults to `h = gcf` and draws in the current figure.

`hline = gline(...)` returns the handle `hline` to the line.

**Examples**

Use `gline` to connect two points in a plot:

```
x = 1:10;

y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```

# gline

---

## See Also

`refline` | `refcurve` | `lsline`

**Purpose**

Generalized linear model regression

**Syntax**

```
b = glmfit(X,y,distr)
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)
```

**Description**

`b = glmfit(X,y,distr)` returns a  $(p + 1)$ -by-1 vector `b` of coefficient estimates for a generalized linear regression of the responses in `y` on the predictors in `X`, using the distribution `distr`. `X` is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. `distr` can be any of the following strings: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, `y` is an  $n$ -by-1 vector of observed responses. For the binomial distribution, `y` can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

---

**Note** By default, `glmfit` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmfit` using the 'constant' parameter, below.

---

`glmfit` treats NaNs in either `X` or `y` as missing values, and ignores them.

`b = glmfit(X,y,distr,param1,val1,param2,val2,...)` additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.

Parameter	Value	Description
'link'	'identity', default for the distribution 'normal'	$\mu = Xb$
	'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
	'logit', default for the distribution 'binomial'	$\log(\mu/(1 - \mu)) = Xb$
	'probit'	$\text{norminv}(\mu) = Xb$
	'comploglog'	$\log(-\log(1 - \mu)) = Xb$
	'reciprocal', default for the distribution 'gamma'	$1/\mu = Xb$
	'loglog'	$\log(-\log(\mu)) = Xb$
	p (a number), default for the distribution 'inverse gaussian' (with $p = -2$ )	$\mu^p = Xb$
'link'	cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI).	Custom-defined link function. You must provide <ul style="list-style-type: none"> <li>• FL(mu)</li> <li>• FD = dFL(mu) / dmu</li> <li>• FI = FL^(-1)</li> </ul>

Parameter	Value	Description
'estdisp'	'on'	Estimates a dispersion parameter for the binomial or Poisson distribution.
	'off' (Default for binomial or Poisson distribution)	Uses the theoretical value of 1.0 for those distributions.
'offset'	Vector	Used as an additional predictor variable, but with a coefficient value fixed at 1.0.
'weights'	Vector of prior weights, such as the inverses of the relative variance of each observation	
'constant'	'on' (default)	Includes a constant term in the model. The coefficient of the constant term is the first element of b.
	'off'	Omit the constant term.

`[b,dev] = glmfit(...)` returns `dev`, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test whether the model with more terms is significantly better than the model with fewer terms.

`[b,dev,stats] = glmfit(...)` returns `dev` and `stats`.

`stats` is a structure with the following fields:

- `beta` — Coefficient estimates `b`
- `dfe` — Degrees of freedom for error
- `s` — Theoretical or estimated dispersion parameter

- `sfit` — Estimated dispersion parameter
- `se` — Vector of standard errors of the coefficient estimates `b`
- `coeffcorr` — Correlation matrix for `b`
- `covb` — Estimated covariance matrix for `B`
- `t` —  $t$  statistics for `b`
- `p` —  $p$ -values for `b`
- `resid` — Vector of residuals
- `residp` — Vector of Pearson residuals
- `residd` — Vector of deviance residuals
- `resida` — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then `stats.s` is set equal to `stats.sfit`. Also, the elements of `stats.se` differ by the factor `stats.s` from their theoretical values.

## Examples

### Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...  
     3300 3500 3700 3900 4100 4300]';  
n = [48 42 31 34 31 21 23 23 21 16 17 21]';  
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each `y` value is the number of successes in corresponding number of trials `inn`, and `x` contains the predictor variable values.

Fit a probit regression model for `y` on `x`.

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,'probit','size',n);  
plot(x, y./n, 'o', x, yfit./n, '-','LineWidth',2)
```

### Use Custom-defined Link Function

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists

of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

```
X = meas(51:end,:);  
y = strcmp('versicolor',species(51:end));
```

Define three function handles, created using @, that define the link, the derivative of the link, and the inverse link for a logit link function, and store them in a cell array.

```
link = @(mu) log(mu ./ (1-mu));  
derlink = @(mu) 1 ./ (mu .* (1-mu));  
invlink = @(resp) 1 ./ (1 + exp(-resp));  
F = {link, derlink, invlink};
```

Fit a logistic regression using `glmfit` with the link function you defined.

```
b = glmfit(X,y,'binomial','link',F)
```

```
b =  
  
    42.6378  
     2.4652  
     6.6809  
    -9.4294  
   -18.2861
```

Now, fit a generalized linear model using the `logit` link function and compare the results.

```
b = glmfit(X,y,'binomial','link','logit')
```

```
b =  
  
    42.6378  
     2.4652  
     6.6809
```

---

-9.4294  
-18.2861

# glmval

---

**Purpose** Generalized linear model values

**Syntax**  
`yhat = glmval(b,X,link)`  
`[yhat,dylo,dyhi] = glmval(b,X,link,stats)`  
`[...] = glmval(...,param1,val1,param2,val2,...)`

**Description** `yhat = glmval(b,X,link)` computes predicted values for the generalized linear model with link function `link` and predictors `X`. Distinct predictor variables should appear in different columns of `X`. `b` is a vector of coefficient estimates as returned by the `glmfit` function. `link` can be any of the strings or the custom-defined link functions used as values for the 'link' name-value pair argument in the `glmfit` function.

---

**Note** By default, `glmval` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmval` using the 'constant' parameter, below.

---

`[yhat,dylo,dyhi] = glmval(b,X,link,stats)` also computes 95% confidence bounds for the predicted values. When the `stats` structure output of the `glmfit` function is specified, `dylo` and `dyhi` are also returned. `dylo` and `dyhi` define a lower confidence bound of `yhat-dylo`, and an upper confidence bound of `yhat+dyhi`. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

`[...] = glmval(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are:

Parameter	Value
'confidence' — the confidence level for the confidence bounds	A scalar between 0 and 1
'size' — the size parameter (N) for a binomial model	A scalar, or a vector with one value for each row of X
'offset' — used as an additional predictor variable, but with a coefficient value fixed at 1.0	A vector
'constant'	<ul style="list-style-type: none"> <li>'on' — Includes a constant term in the model. The coefficient of the constant term is the first element of b.</li> <li>'off' — Omit the constant term</li> </ul>
'simultaneous' — Compute simultaneous confidence intervals (true), or compute non-simultaneous confidence intervals (default false)	true or false

## Examples

### Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in corresponding number of trials inn, and x contains the predictor variable values.

Fit a generalized linear model for y on x using a probit link function.

```
b = glmfit(x,[y n],'binomial','link','probit');
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,'probit','size',n);  
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)
```

## Use Custom-defined Link Function

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...  
     3300 3500 3700 3900 4100 4300]';  
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
```

```
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each  $y$  value is the number of successes in corresponding number of trials in  $n$ , and  $x$  contains the predictor variable values.

Now define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a probit link function, and store them in a cell array.

```
link = @(mu) norminv(mu);  
derlink = @(mu) 1 ./ normpdf(norminv(mu));  
invlink = @(resp) normcdf(resp);  
F = {link, derlink, invlink};
```

Fit a generalized linear model for  $y$  on  $x$  using the link function you defined.

```
b = glmfit(x,[y n],'binomial','link',F);
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the  $x$  values.

```
yfit = glmval(b,x,F,'size',n);  
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)
```

## Purpose

Glyph plot

## Syntax

```
glyphplot(X)
glyphplot(X, 'glyph', 'face')
glyphplot(X, 'glyph', 'face', 'features', f)
glyphplot(X, ..., 'grid', [rows, cols])
glyphplot(X, ..., 'grid', [rows, cols], 'page', p)
glyphplot(X, ..., 'centers', C)
glyphplot(X, ..., 'centers', C, 'radius', r)
glyphplot(X, ..., 'obslabels', labels)
glyphplot(X, ..., 'standardize', method)
glyphplot(X, ..., prop1, val1, ...)
h = glyphplot(X, ...)
```

## Description

`glyphplot(X)` creates a star plot from the multivariate data in the  $n$ -by- $p$  matrix  $X$ . Rows of  $X$  correspond to observations, columns to variables. A star plot represents each observation as a “star” whose  $i$ th spoke is proportional in length to the  $i$ th coordinate of that observation. `glyphplot` standardizes  $X$  by shifting and scaling each column separately onto the interval  $[0, 1]$  before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats NaNs in  $X$  as missing values, and does not plot the corresponding rows of  $X$ . `glyphplot(X, 'glyph', 'star')` is a synonym for `glyphplot(X)`.

`glyphplot(X, 'glyph', 'face')` creates a face plot from  $X$ . A face plot represents each observation as a “face,” whose  $i$ th facial feature is drawn with a characteristic proportional to the  $i$ th coordinate of that observation. The features are described in “Face Features” on page 21-1327 Face Features.

`glyphplot(X, 'glyph', 'face', 'features', f)` creates a face plot where the  $i$ th element of the index vector  $f$  defines which facial feature will represent the  $i$ th column of  $X$ .  $f$  must contain integers from 0 to 17, where 0 indicate that the corresponding column of  $X$  should not be plotted. See “Face Features” on page 21-1327 for more information.

# glyphplot

---

`glyphplot(X, ..., 'grid', [rows, cols])` organizes the glyphs into a rows-by-cols grid.

`glyphplot(X, ..., 'grid', [rows, cols], 'page', p)` organizes the glyph into one or more pages of a rows-by-cols grid, and displays the page `p`. If `p` is a vector, `glyphplot` displays multiple pages in succession. If `p` is 'all', `glyphplot` displays all pages. If `p` is 'scroll', `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X, ..., 'centers', C)` creates a plot with each glyph centered at the locations in the  $n$ -by-2 matrix `C`.

`glyphplot(X, ..., 'centers', C, 'radius', r)` creates a plot with glyphs positioned using `C`, and scale the glyphs so the largest has radius `r`.

`glyphplot(X, ..., 'obslabels', labels)` labels each glyph with the text in the character array or cell array of strings `labels`. By default, the glyphs are labelled 1:N. Use '' for blank labels.

`glyphplot(X, ..., 'standardize', method)` standardizes `X` before making the plot. Choices for `method` are

- 'column' — Maps each column of `X` separately onto the interval  $[0, 1]$ . This is the default.
- 'matrix' — Maps the entire matrix `X` onto the interval  $[0, 1]$ .
- 'PCA' — Transforms `X` to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval  $[0, 1]$ .
- 'off' — No standardization. Negative values in `X` may make a star plot uninterpretable.

`glyphplot(X, ..., prop1, val1, ...)` sets properties to the specified property values for all line graphics objects created by `glyphplot`.

`h = glyphplot(X, ...)` returns a matrix of handles to the graphics objects created by `glyphplot`. For a star plot, `h(:, 1)` and `h(:, 2)` contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, `h(:, 1)` and `h(:, 2)` contain object handles

to the lines making up each face and to the pupils, respectively. `h(:,3)` contains handles to the text objects for the labels, if present.

### Face Features

The following table describes the correspondence between the columns of the vector `f`, the value of the 'Features' input parameter, and the facial features of the glyph plot. If `X` has fewer than 17 columns, unused features are displayed at their default value.

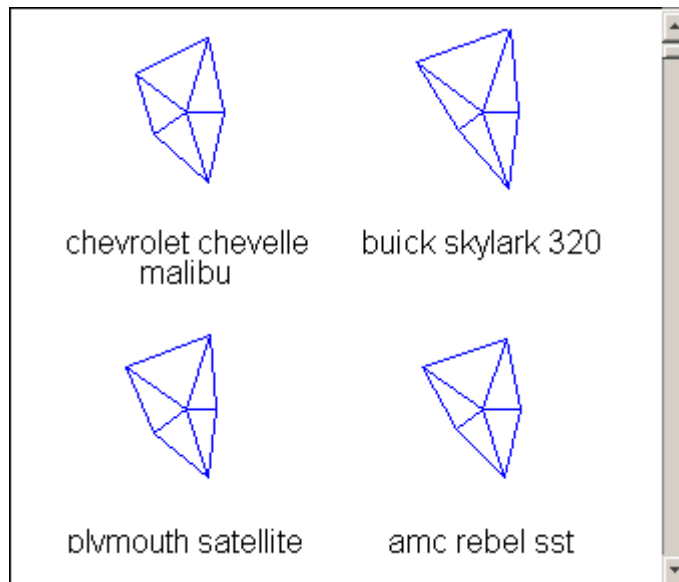

Column	Facial Feature
1	Size of face
2	Forehead/jaw relative arc length
3	Shape of forehead
4	Shape of jaw
5	Width between eyes
6	Vertical position of eyes
7	Height of eyes
8	Width of eyes (this also affects eyebrow width)
9	Angle of eyes (this also affects eyebrow angle)
10	Vertical position of eyebrows
11	Width of eyebrows (relative to eyes)
12	Angle of eyebrows (relative to eyes)
13	Direction of pupils
14	Length of nose
15	Vertical position of mouth
16	Shape of mouth
17	Mouth arc length

# glyphplot

## Examples

```
load carsmall
X = [Acceleration Displacement Horsepower MPG Weight];

glyphplot(X, 'standardize', 'column', ...
          'obslabels', Model, ...
          'grid', [2 2], ...
          'page', 'scroll');
```

```
glyphplot(X, 'glyph', 'face', ...
          'obslabels', Model, ...
          'grid', [2 3], ...
          'page', 9);

# gmdistribution

---

**Purpose** Gaussian mixture models

**Description** An object of the `gmdistribution` class defines a Gaussian mixture distribution, which is a multivariate distribution that consists of a mixture of one or more multivariate Gaussian distribution components. The number of components for a given `gmdistribution` object is fixed. Each multivariate Gaussian component is defined by its mean and covariance, and the mixture is defined by a vector of mixing proportions.

**Construction** To create a Gaussian mixture distribution by specifying the distribution parameters, use the `gmdistribution` constructor. To fit a Gaussian mixture distribution model to data, use `gmdistribution.fit`.

<code>fit</code>	Gaussian mixture parameter estimates
<code>gmdistribution</code>	Construct Gaussian mixture distribution

**Properties** All objects of the class have the properties listed in the following table.

<code>CovType</code>	Type of covariance matrices
<code>DistName</code>	Type of distribution
<code>mu</code>	Input matrix of means $\mu$
<code>NComponents</code>	Number $k$ of mixture components
<code>NDimensions</code>	Dimension $d$ of multivariate Gaussian distributions
<code>PComponents</code>	Input vector of mixing proportions
<code>SharedCov</code>	<code>true</code> if all covariance matrices are restricted to be the same
<code>Sigma</code>	Input array of covariances

Objects constructed with `fit` have the additional properties listed in the following table.

AIC	Akaike Information Criterion
BIC	Bayes Information Criterion
Converged	Determine if algorithm converged
Iters	Number of iterations
NlogL	Negative of log-likelihood
RegV	Value of 'Regularize' parameter

## Methods

<code>cdf</code>	Cumulative distribution function for Gaussian mixture distribution
<code>cluster</code>	Construct clusters from Gaussian mixture distribution
<code>disp</code>	Display Gaussian mixture distribution object
<code>display</code>	Display Gaussian mixture distribution object
<code>fit</code>	Gaussian mixture parameter estimates
<code>mahal</code>	Mahalanobis distance to component means
<code>pdf</code>	Probability density function for Gaussian mixture distribution
<code>posterior</code>	Posterior probabilities of components
<code>random</code>	Random numbers from Gaussian mixture distribution

subsasgn	Subscripted reference for Gaussian mixture distribution object
suboref	Subscripted reference for Gaussian mixture distribution object

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Fit a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function. Fit the resulting data.

Generate the data using 1000 points from each distribution.

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];
```

```
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Fit a two-component Gaussian mixture model.

```
options = statset('Display','final');  
obj = gmdistribution.fit(X,2,'Options',options);
```

```
18 iterations, log-likelihood = -7058.35
```

Plot the fit.

```
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

# gmdistribution

## Related Examples

- “Normal Distribution” on page B-110

## Concepts

**Purpose** Construct Gaussian mixture distribution

**Syntax** `obj = gmdistribution(mu,sigma,p)`

**Description** `obj = gmdistribution(mu,sigma,p)` constructs an object `obj` of the `gmdistribution` class defining a Gaussian mixture distribution.

`mu` is a  $k$ -by- $d$  matrix specifying the  $d$ -dimensional mean of each of the  $k$  components.

`sigma` specifies the covariance of each component. The size of `sigma` is:

- $d$ -by- $d$ -by- $k$  if there are no restrictions on the form of the covariance. In this case, `sigma(:, :, I)` is the covariance of component  $I$ .
- 1-by- $d$ -by- $k$  if the covariance matrices are restricted to be diagonal, but not restricted to be same across components. In this case, `sigma(:, :, I)` contains the diagonal elements of the covariance of component  $I$ .
- $d$ -by- $d$  matrix if the covariance matrices are restricted to be the same across components, but not restricted to be diagonal. In this case, `sigma` is the pooled estimate of covariance.
- 1-by- $d$  if the covariance matrices are restricted to be diagonal and the same across components. In this case, `sigma` contains the diagonal elements of the pooled estimate of covariance.

`p` is an optional 1-by- $k$  vector specifying the mixing proportions of each component. If `p` does not sum to 1, `gmdistribution` normalizes it. The default is equal proportions.

**Examples** Create a `gmdistribution` object defining a two-component mixture of bivariate Gaussian distributions:

```
mu = [1 2; -3 -5];  
sigma = cat(3, [2 0; 0 .5], [1 0; 0 1]);  
p = ones(1,2)/2;  
obj = gmdistribution(mu,sigma,p);
```

# gmdistribution

---

```
ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

**Purpose**

Add case names to plot

**Syntax**

```
gname(cases)
gname
h = gname(cases,line_handle)
```

**Description**

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array or a cell array of strings, in which each row of the character array or each element of the cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a cell array of strings or a character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

`h = gname(cases,line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

**Examples**

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```
load cities
education = ratings(:,6);
arts = ratings(:,7);
```

# gname

```
plot(education, arts, '+' )  
gname(names)
```

Click the point at the top of the graph to display its label, “New York.”

When <code>k &gt; 0</code> and <code>theta = sigma/k</code>, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when <math>k \geq 1</math>, and the variance is not finite when <math>k \geq 1/2</math>. When <math>k \geq 0</math>, the GP has positive density for</p> <p><code>x &gt; theta</code>, or, when</p> $k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$
<b>References</b>	<p>[1] Embrechts, P., C. Klüppelberg, and T. Mikosch. <i>Modelling Extremal Events for Insurance and Finance</i>. New York: Springer, 1997.</p> <p>[2] Kotz, S., and S. Nadarajah. <i>Extreme Value Distributions: Theory and Applications</i>. London: Imperial College Press, 2000.</p>
<b>See Also</b>	<code>cdf</code>   <code>gppdf</code>   <code>gpinv</code>   <code>gpstat</code>   <code>gpfit</code>   <code>gplike</code>   <code>gprnd</code>
<b>How To</b>	<ul style="list-style-type: none"> <li>“Generalized Pareto Distribution” on page B-53</li> </ul>

**Purpose** Generalized Pareto parameter estimates

**Syntax**

```
parmhat = gpfif(X)  
[parmhat,parmci] = gpfif(X)  
[parmhat,parmci] = gpfif(X,alpha)  
[...] = gpfif(X,alpha,options)
```

**Description** `parmhat = gpfif(X)` returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in `X`. `parmhat(1)` is the tail index (shape) parameter, `K` and `parmhat(2)` is the scale parameter, `sigma`. `gpfif` does not fit a threshold (location) parameter.

`[parmhat,parmci] = gpfif(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gpfif(X,alpha)` returns  $100(1-\text{alpha})\%$  confidence intervals for the parameter estimates.

`[...] = gpfif(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gpfif')` for parameter names and default values.

Other functions for the generalized Pareto, such as `gpcdf` allow a threshold parameter, `theta`. However, `gpfif` does not estimate `theta`. It is assumed to be known, and subtracted from `X` before calling `gpfif`.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when  $K \geq 1$ , and the variance is not finite when  $K \geq 1/2$ . When  $K \geq 0$ , the GP has positive density for

`X > theta`, or, when  $K < 0$ , for

$$0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$$

**How To** • “Generalized Pareto Distribution” on page B-53

**Purpose**

Matrix of scatter plots by group

**Syntax**

```
gplotmatrix(x,y,group)
gplotmatrix(x,y,group,clr,sym,siz)
gplotmatrix(x,y,group,clr,sym,siz,doleg)
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,ynam)
[h,ax,bigax] = gplotmatrix(...)
```

**Description**

`gplotmatrix(x,y,group)` creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of `x` against a column of `y`. All plots are grouped by the grouping variable `group`.

`x` and `y` are matrices with the same number of rows. If `x` has  $p$  columns and `y` has  $q$  columns, the figure contains a  $p$ -by- $q$  matrix of scatter plots. If you omit `y` or specify it as the empty matrix, `[]`, `gplotmatrix` creates a square matrix of scatter plots of columns of `x` against each other.

`group` is a grouping variable that can be a categorical variable, vector, string array, or cell array of strings. `group` must have the same number of rows as `x` and `y`. Points with the same value of `group` are placed in the same group, and appear on the graph with the same marker and color. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`); in that case, observations are in the same group if they have common values of all grouping variables.

`gplotmatrix(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a string array of colors recognized by the `plot` function. The default for `clr` is `'bgrcmyk'`. `sym` is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `DefaultLineMarkerSize` property. If you do not specify enough values for all groups, `gplotmatrix` cycles through the specified values as needed.

`gplotmatrix(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (`doleg` is `'on'`, the default) or not (`doleg` is `'off'`).

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)` controls what appears along the diagonal of a plot matrix of *y* versus *x*. Allowable values are 'none', to leave the diagonals blank, 'hist', to plot histograms, or 'variable', to write the variable names. `gplotmatrix` displays histograms along the diagonal only when there is only one variable (i.e., `gplotmatrix(x,[],[],[],[],[],[], 'hist')`).

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,yname)` specifies the names of the columns in the *x* and *y* arrays. These names are used to label the *x*- and *y*-axes. *xname* and *yname* must be character arrays or cell arrays of strings, with one name for each column of *x* and *y*, respectively.

`[h,ax,bigax] = gplotmatrix(...)` returns three arrays of handles. *h* is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in *G*. *ax* is a matrix of handles to the axes of the individual plots. If *dispopt* is 'hist', *ax* contains one extra row of handles to invisible axes in which the histograms are plotted. *bigax* is a handle to big (invisible) axes framing the entire plot matrix. *bigax* is fixed to point to the current axes, so a subsequent `title`, `xlabel`, or `ylabel` command will produce labels that are centered with respect to the entire plot matrix.

## Create Matrix of Scatter Plots With Grouped Data

This example shows how to create a matrix of scatter plots using grouped sample data.

Load the sample data.

```
load discrim;
```

The ratings array contains rating values for 329 U.S. cities in the nine different categories listed in the `categories` array. The group array contains a city size code that is equal to 2 for the 26 largest cities, and 1 otherwise.

Create a matrix of scatter plots to compare the first two categories, climate and housing, with categories 4 (crime) and 7 (arts). Specify group as the grouping variable to visually distinguish the data for large and small cities.

```
figure;  
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group);
```

The figure displays a matrix of scatter plots for the specified comparisons, with each city size group represented by a different color.

For better clarity, you can adjust the appearance of the graphs by specifying colors and plotting symbols, and labeling the axes with the rating categories.

# gplotmatrix

```
figure;  
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...  
    'br','o',[],'on','',categories(1:2,:),...  
    categories([4 7],:));
```

## How To

- “Grouping Variables” on page 2-51

**Purpose**

Generalized Pareto random numbers

**Syntax**

```
R = gprnd(K,sigma,theta)
R = gprnd(K,sigma,theta,m,n,...)
R = gprnd(K,sigma,theta,[m,n,...])
```

**Description**

`R = gprnd(K,sigma,theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter `K`, scale parameter `sigma`, and threshold (location) parameter, `theta`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gprnd(K,sigma,theta,m,n,...)` or `R = gprnd(K,sigma,theta,[m,n,...])` generates an `m`-by-`n`-by-... array. The `K`, `sigma`, `theta` parameters can each be scalars or arrays of the same size as `R`.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when  $K \geq 1$ , and the variance is not finite when  $K \geq 1/2$ . When  $K \geq 0$ , the GP has positive density for

$X > \text{theta}$ , or, when

$$0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}$$

**Purpose** Generalized Pareto mean and variance

**Syntax** `[M,V] = gpstat(K,sigma,theta)`

**Description** `[M,V] = gpstat(K,sigma,theta)` returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter `K`, scale parameter `sigma`, and threshold (location) parameter, `theta`.

The default value for `theta` is 0.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when  $K \geq 1$ , and the variance is not finite when  $K \geq 1/2$ . When  $K \geq 0$ , the GP has positive density for  $X > \theta$ , or when

$$K < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

## Purpose

Train additional trees and add to ensemble

## Syntax

```
B = growTrees(B,ntrees)
B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)
```

## Description

`B = growTrees(B,ntrees)` grows `ntrees` new trees and appends them to those trees already stored in the ensemble `B`.

`B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'nprint'` Specifies that a diagnostic message showing training progress should display after every value training cycles (grown trees). Default is no diagnostic messages.

`'options'` A struct that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- `'UseParallel'` — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.

# TreeBagger.growTrees

---

- **UseSubstreams** — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- **Streams** — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `growTrees` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
  - You have an open `Parallel` pool
  - `UseParallel` is `true`
  - `UseSubstreams` is `false`In that case, use a cell array the same size as the `Parallel` pool.

**Purpose** Create index vector from grouping variable

**Syntax** `[G,GN]=grp2idx(S)`  
`[G,GN,GL] = grp2idx(S)`

**Description** `[G,GN]=grp2idx(S)` creates an index vector `G` from the grouping variable `S`. `S` can be a categorical, numeric, or logical vector; a cell vector of strings; or a character matrix with each row representing a group label. The result `G` is a vector taking integer values from 1 up to the number `K` of distinct groups. `GN` is a cell array of strings representing group labels. `GN(G)` reproduces `S` (aside from any differences in type).

The order of `GN` depends on the grouping variable:

- For numeric and logical grouping variables, the order is the sorted order of `S`.
- For categorical grouping variables, the order is the order of `getlabels(S)`.
- For string grouping variables, the order is the order of first appearance in `S`.

`[G,GN,GL] = grp2idx(S)` returns a column vector `GL` representing the group levels. The set of groups and their order in `GL` and `GN` are the same, except that `GL` has the same type as `S`. If `S` is a character matrix, `GL(G,:)` reproduces `S`, otherwise `GL(G)` reproduces `S`.

`grp2idx` treats NaNs (numeric or logical), empty strings (char or cell array of strings), or `<undefined>` values (categorical) in `S` as missing values and returns NaNs in the corresponding rows of `G`. `GN` and `GL` don't include entries for missing values.

**Examples** Load the data in `hospital.mat` and create a categorical grouping variable:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
AgeGroup = ordinal(hospital.Age, labels, [], edges);
```

```
ages = hospital.Age(1:5)
ages =
    38
    43
    38
    40
    49

group = AgeGroup(1:5)
group =
    30s
    40s
    30s
    40s
    40s

indices = grp2idx(group)
indices =
    4
    5
    4
    5
    5
```

## How To

- “Grouping Variables” on page 2-51

**Purpose**

Summary statistics organized by group

**Syntax**

```
statarray = grpstats(ds,groupvar)
statarray = grpstats(ds,groupvar,whichstats)
statarray = grpstats(ds,groupvar,whichstats,Name,Value)

means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',
    alpha)

grpstats(X,group,alpha)
```

**Description**

`statarray = grpstats(ds,groupvar)` returns a dataset array with the means for the data groups in the dataset array `ds` determined by the values of the grouping variable or variables specified in `groupvar`.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a cell array of strings containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in `ds` (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`.

`statarray = grpstats(ds,groupvar,whichstats)` returns the group values for the summary statistics types specified in `whichstats`.

`statarray = grpstats(ds,groupvar,whichstats,Name,Value)`  
uses additional options specified by one or more `Name,Value` pair arguments.

`means = grpstats(X,group)` returns a column vector or matrix with the means of the groups of the data in the matrix or vector `X` determined by the values of the grouping variable or variables, `group`. The rows of `means` correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in `means` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `group` is a cell array of grouping variables, then there is a row in `means` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If `X` is a matrix, then `means` is a matrix with the same number of columns as `X`. Each column of `means` has the group means for the corresponding column of `X`.

`[stats1,...,statsN] = grpstats(X,group,whichstats)` returns column vectors or arrays with group values for the summary statistic types specified in `whichstats`.

`[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)` specifies the significance level for confidence and prediction intervals.

`grpstats(X,group,alpha)` plots the means of the groups of data in the vector or matrix `X` determined by the values of the grouping variable, `group`. The grouping variable values are on the horizontal plot axis. Each group mean has  $100 \times (1 - \alpha)\%$  confidence intervals.

- If `X` is a matrix, then `grpstats` plots the means and confidence intervals for each column of `X`.
- If `group` is a cell array of grouping variables, then `grpstats` plots the means and confidence intervals for the groups of data in `X` determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

## Input Arguments

### **ds** - Input data

dataset array

Input data, specified as a `dataset` array. The dataset array must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for dataset array variables that have a numeric or logical data type. If any variables in `ds` (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument `DataVars` to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

### **groupvar** - Identifiers for the grouping variables

cell array of strings | vector of positive integers | logical vector | []

Identifiers for the grouping variables in the input dataset array, `ds`, specified as one of the following:

String or cell array of strings	Names of the grouping variables
Positive integer or vector of positive integers	Variable numbers of the grouping variables

Vector of logical values with number of elements equal to the number of variables in <code>ds</code>	Logical indicator with value <code>true</code> for grouping variables and <code>false</code> otherwise
<code>[]</code>	No groups (returns summary statistics for all data)

Any variable that is identified by `groupvar` as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, or cell array of strings.

For example, consider an input dataset array, `ds`, with six variables. The fourth variable is named `Gender`. To be a valid grouping variable, the data type of `Gender` might be a cell array of strings or a nominal array, with the unique values `Male` and `Female`. To specify the variable `Gender` as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(ds, 'Gender')`
- `statarray = grpstats(ds, 4)`
- `statarray = grpstats(ds, logical([0 0 0 1 0 0]))`

## Data Types

`double` | `logical` | `cell` | `char`

## whichstats - Types of summary statistics

`string` | `function handle`

Types of summary statistics to compute, specified as a string or function handle, or a cell array of strings and function handles. Use a cell array to specify multiple types of summary statistics.

Possible string values are:

<code>'mean'</code>	Mean
<code>'sem'</code>	Standard error of the mean
<code>'numel'</code>	Count, or number, of non-NaN elements
<code>'gname'</code>	Group name

'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Range
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

**Example:** `[stat1,stat2] = grpstats(X,group,{'mean','sem'})`

You can specify different significance levels for the 'meanci' and 'predci' options using the name-value pair argument, Alpha.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time `grpstats` calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an *nvals*-by-1 column vector for descriptive statistics of length *nvals* (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-*ncols* row vector, or an *nvals*-by-*ncols* matrix, where *ncols* is the number of columns in the input data matrix.

**Example:** `[stat1,stat2,stat3] = grpstats(X,group,{'mean','std',@skewness})`

### Data Types

char | function\_handle

### alpha - Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify 'meanci' or 'predci' in `whichstats`, you can use `alpha` to specify the significance level for the confidence or prediction

intervals. If you specify `alpha`, then `grpstats` returns  $100 \times (1 - \alpha)\%$  confidence or prediction intervals. If you do not specify `alpha`, then `grpstats` returns 95% intervals (`alpha = 0.05`).

- Use `alpha` with the `grpstats(X,group,alpha)` syntax to plot group means and corresponding  $100 \times (1 - \alpha)\%$  confidence intervals.

### Data Types

double

### X - Input data

vector | matrix

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

### Data Types

double | single

### group - Grouping variable

categorical array | logical or numeric vector | cell array of strings | []

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data `X`. Observations (rows) with the same value of the grouping variable are in the same group. Use [] to compute summary statistics for all data, without using groups.

For example, if `Gender` is a cell array of strings with values 'Male' and 'Female', you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'DataVars',[1,3,4],'Alpha',0.01` specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

### 'Alpha' - Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

When you include `'meanci'` or `'predci'` in `whichstats`, you can use `Alpha` to specify the significance level for confidence or prediction intervals. If you specify the value  $\alpha$ , then `grpstats` returns  $100 \times (1 - \alpha)\%$  confidence or prediction intervals.

If you do not specify a value for `Alpha`, then `grpstats` returns 95% intervals ( $\alpha = 0.05$ ).

**Example:** `'Alpha',0.1`

### Data Types

double

### 'DataVars' - Variable names or columns

cell array of strings | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input dataset array you want to compute summary statistics for, specified as the comma-separated pair consisting of 'DataVars' and a cell array of strings, vector of positive integers, or a logical vector. Use a string to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (true if you want to compute summary statistics, false otherwise).

You must specify DataVars if there are any variables in `ds` (other than the grouping variables specified in `groupvar`) that are not numeric or logical arrays. Summary statistics can only be calculated for dataset array variables that have a numeric or logical data type.

**Example:** 'DataVars',{ 'Height', 'Weight' }

### Data Types

double | cell | char

### 'VarNames' - Variable names for output dataset array

cell array of strings

Variable names for the output dataset array, `statarray`, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input dataset array, `ds`. This prefix corresponds to the summary statistic name.

**Example:** 'VarNames',{ 'MaleMean', 'FemaleMean' }

### Data Types

cell

## Output Arguments

### `statarray` - Group summary statistics

dataset array

Group summary statistics, returned as a dataset array. `statarray` contains summary statistic values for the groups of data in the dataset array `ds` determined by the levels of the grouping variables specified by `groupvar`. There is a row in `statarray` for each observed value

or combination of values in the variables specified by `groupvar`. The dataset array, `statarray`, contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in `ds` (other than those specified by `groupvar`), or for only the variables specified using `DataVars`.

The total number of variables in `statarray` is  $ngroupvars + 1 + ndatavars \times nstats$ , where *ngroupvars* is the number of variables in `groupvar`, *ndatavars* is the number of variables for which summary statistics are computed, and *nstats* is the number of summary statistic types specified in `whichstats`.

`grpstats` assigns default names to the variables in `statarray`, unless you specify variable names using the name-value pair argument `VarNames`.

### **means - Group means**

column vector | array

Group means for the groups of data in the vector or matrix `X` determined by the levels of `group`, returned as an *ngroups*-by-*ncols* array. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in `X`. If `X` is a vector, then `means` is a column vector.

### **stats1,...,statsN - Group summary statistics**

column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix `X` determined by the levels of `group`, returned as *ngroups*-by-*ncols* arrays. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in `X`. You must specify an output argument for each type of summary statistic specified in `whichstats`.

If a summary statistic type in which `stats` returns a value of length *nvals* (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an *ngroups-by-ncols-by-nvals* array.

## Examples

### Dataset Array Summary Statistics Organized by Group

Load the sample data.

```
load('hospital')
```

The dataset array, `hospital`, has 100 observations and 7 variables.

Create a dataset array with only the variables `Sex`, `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:, {'Sex', 'Age', 'Weight', 'Smoker'});
```

`Sex` is a nominal array, with levels `Male` and `Female`. The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, grouped by the levels in `Sex`.

```
statarray = grpstats(ds, 'Sex')
```

```
statarray =
```

	Sex	GroupCount	mean_Age	mean_Weight	mean_Smoker
Female	Female	53	37.717	130.47	0.24528
Male	Male	47	38.915	180.53	0.44681

`statarray` is a dataset array with two rows, corresponding to the levels in `Sex`. `GroupCount` is the number of observations in each group. The means of `Age`, `Weight`, and `Smoker`, grouped by `Sex`, are given in `mean_Age`, `mean_Weight`, and `mean_Smoker`.

Compute the mean for `Age` and `Weight`, grouped by the values in `Smoker`.

```
statarray = grpstats(ds, 'Smoker', 'mean', 'DataVars', {'Age', 'Weight'})
```

```
statarray =
```

	Smoker	GroupCount	mean_Age	mean_Weight
0	false	66	37.97	149.91
1	true	34	38.882	161.94

In this case, not all variables in `ds` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```
statarray = grpstats(ds, {'Sex', 'Smoker'}, {'min', 'max'}, ...
                    'DataVars', 'Weight')
```

```
statarray =
```

	Sex	Smoker	GroupCount	min_Weight	max_Weight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

### Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```
load('hospital')
```

The dataset array, `hospital`, has 100 observations and 7 variables.

Create a dataset array with only the variables `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:, {'Age', 'Weight', 'Smoker'});
```

The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, with no grouping.

```
statarray = grpstats(ds, [], {'mean', 'min', 'max'})
```

```
statarray =
```

	GroupCount	mean_Age	min_Age	max_Age	mean_Weight	
All	100	38.28	25	50	154	
	min_Weight	max_Weight	mean_Smoker	min_Smoker	max_S	
All	111	202	0.34	false	true	

The observation name `All` indicates that all observations in `ds` were used to compute the summary statistics.

## Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

```
load('carsmall')
```

All variables are measured for 100 cars. `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). `Cylinders` has three unique values, 4, 6, and 8, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

```
means = grpstats(Acceleration,Origin)
```

```
means =  
    18.0500  
    16.3778  
    15.5000  
    15.8867  
    16.6000  
    14.4377
```

`means` is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

```
means = grpstats(Acceleration,{Origin,Cylinders})
```

```
means =  
    18.0500  
    16.3375  
    16.7000  
    15.5000  
    15.9143  
    15.5000  
    16.6000  
    17.0818  
    16.5267  
    11.6406
```

There are 18 possible combinations of grouping variable values because `Origin` has 6 unique values and `Cylinders` has 3 unique values. Only 10 of the possible combinations appear in the data, so `means` is a 10-by-1 vector of group means corresponding to the observed combinations of values.

# grpstats

---

Return the group names along with the mean acceleration for each group.

```
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},...
                        {'mean','gname'})
```

```
means =
```

```
17.0818
16.5267
11.6406
18.0500
15.9143
15.5000
16.3375
16.7000
16.6000
15.5000
```

```
grps =
```

```
'USA'      '4'
'USA'      '6'
'USA'      '8'
'France'   '4'
'Japan'    '4'
'Japan'    '6'
'Germany'  '4'
'Germany'  '6'
'Sweden'   '4'
'Italy'    '4'
```

The output `grps` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

## Multiple Summary Statistics for a Matrix Organized by Group

Load the sample data.

```
load('carsmall')
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum, median, and maximum acceleration, grouped by country of origin.

```
[grpMin,grpMed,grpMax,grp] = grpstats(Acceleration,Origin,...  
                                     {'min','median','max','gname'})
```

```
grpMin =
```

```
8.0000  
15.3000  
13.9000  
12.2000  
15.7000  
15.5000
```

```
grpMed =
```

```
14.7000  
17.5000  
15.7000  
15.3000  
16.6000  
15.5000
```

```
grpMax =
```

```
22.2000
21.9000
18.2000
24.6000
17.5000
15.5000
```

```
grp =
    'USA'
    'France'
    'Japan'
    'Germany'
    'Sweden'
    'Italy'
```

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

## Plot Prediction Intervals for a New Observation in Each Group

Load the sample data.

```
load('carsmall')
```

The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```
[means,pred,grp] = grpstats(Weight,Model_Year,...
    {'mean','predci','gname'},'Alpha',0.1);
```

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```
ngrps = length(grp); % Number of groups

figure()
errorbar((1:ngrps)', means, pred(:,2) - means)
set(gca, 'xtick', 1:ngrps, 'xticklabel', grp)
title('90% Prediction Intervals for Weight by Year')
```

### Plot Group Means and Confidence Intervals

Load the sample data.

```
load('carsmall')
```

The variables `Acceleration` and `Weight` are the acceleration and weight values measured for 100 cars. The variable `Cylinders` is the number of cylinders in each car. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by `Cylinders`, with 95% confidence intervals.

```
grpstats(Acceleration,Cylinders,0.05)
```

The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by Cylinders, and 95% confidence intervals. Scale the Weight values by 1000 so the means of Weight and Acceleration are the same order of magnitude.

```
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```

The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both Cylinders and Model\_Year. Specify 95% confidence intervals.

```
grpstats(Acceleration,{Cylinders,Model_Year},0.05)
```

There are nine possible combinations of grouping variable values because there are three unique values in `Cylinders` and three unique values in `Model_Year`. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

## Algorithms

- `grpstats` treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- `grpstats` ignores empty group names.

# gscatter

---

## Purpose

Scatter plot by group

## Syntax

```
gscatter(x,y,group)
gscatter(x,y,group,clr,sym,siz)
gscatter(x,y,group,clr,sym,siz,doleg)
gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)
h = gscatter(...)
```

## Description

`gscatter(x,y,group)` creates a scatter plot of `x` and `y`, grouped by `group`. `x` and `y` are vectors of the same size. `group` is a grouping variable in the form of a categorical variable, vector, string array, or cell array of strings. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group and appear on the graph with the same marker and color.

`gscatter(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a string array of colors recognized by the `plot` function. The default for `clr` is `'bgrcmk'`. `sym` is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `'DefaultLineMarkerSize'` property. If you do not specify enough values for all groups, `gscatter` cycles through the specified values as needed.

`gscatter(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (`doleg` is `'on'`, the default) or not (`doleg` is `'off'`).

`gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)` specifies the name to use for the `x`-axis and `y`-axis labels. If the `x` and `y` inputs are simple variable names and `xnam` and `ynam` are omitted, `gscatter` labels the axes with the variable names.

`h = gscatter(...)` returns an array of handles to the lines on the graph.

**Examples****Scatter Plot of Climate and Housing Ratings**

Load the sample data.

```
load discrim
```

discrim data set has ratings of cities according to nine factors such as climate, housing, education, and health in the matrix ratings .

Look at the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix group. Also choose different colors and plotting symbols for each group.

```
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')  
xlabel('climate');  
ylabel('housing');
```

**See Also** [gplotmatrix](#) | [grpstats](#) | [scatter](#)

**How To** • “Grouping Variables” on page 2-51

**Purpose** Greater than relation for handles

**Syntax** `h1 > h2`

**Description** `h1 > h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = gt(h1, h2)` stores the result in a logical array of the same dimensions.

# haltonset

---

**Superclasses** grandset

**Purpose** Halton quasi-random point sets

**Description** haltonset is a quasi-random point set class that produces points from the Halton sequence.

**Construction** haltonset Construct Halton quasi-random point set

## Methods

### Inherited Methods

Methods in the following table are inherited from grandset.

disp	Display grandset object
end	Last index in indexing expression for point set
length	Length of point set
ndims	Number of dimensions in matrix
net	Generate quasi-random point set
scramble	Scramble quasi-random point set
size	Number of dimensions in matrix
suboref	Subscripted reference for grandset

## Properties

### Inherited Properties

Properties in the following table are inherited from grandset.

Dimensions	Number of dimensions
Leap	Interval between points

ScrambleMethod	Settings that control scrambling
Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set P is based

## Copy Semantics

Handle. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

`sobolset`

## How To

- “Quasi-Random Point Sets” on page 6-16

# haltonset

---

**Purpose** Construct Halton quasi-random point set

**Syntax**  
`p = haltonset(d)`  
`p = haltonset(d,prop1,val1,prop2,val2,...)`

**Description**  
`p = haltonset(d)` constructs a  $d$ -dimensional point set `p` of the `haltonset` class, with default property settings.  
`p = haltonset(d,prop1,val1,prop2,val2,...)` specifies property name/value pairs used to construct `p`.

The object `p` returned by `haltonset` encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of point set indices (maximum value of  $2^{53}$ ). Values of the point set are not generated and stored in memory until you access `p` using `net` or parenthesis indexing.

**Examples**  
Generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

# harmmean

---

**Purpose** Harmonic mean

**Syntax** `m = harmmean(X)`  
`harmmean(X,dim)`

**Description** `m = harmmean(X)` calculates the harmonic mean of a sample. For vectors, `harmmean(x)` is the harmonic mean of the elements in `x`. For matrices, `harmmean(X)` is a row vector containing the harmonic means of each column. For  $N$ -dimensional arrays, `harmmean` operates along the first nonsingleton dimension of `X`.

`harmmean(X,dim)` takes the harmonic mean along dimension `dim` of `X`.

The harmonic mean is

$$m = \frac{n}{\sum_{i=1}^n \frac{1}{x_i}}$$

**Examples** The arithmetic mean is greater than or equal to the harmonic mean.

```
x = exprnd(1,10,6);
```

```
harmonic = harmmean(x)
harmonic =
    0.3382    0.3200    0.3710    0.0540    0.4936    0.0907
```

```
average = mean(x)
average =
    1.3509    1.1583    0.9741    0.5319    1.0088    0.8122
```

**See Also** `mean` | `median` | `geomean` | `trimmean`

**Purpose**

Bivariate histogram

**Syntax**

```

hist3(X)
hist3(X,nbins)
hist3(X,ctr)
hist3(X,'Edges',edges)
N = hist3(X,...)
[N,C] = hist3(X,...)
hist3(...,param1,val1,param2,val2,...)

```

**Description**

`hist3(X)` bins the elements of the  $m$ -by-2 matrix  $X$  into a 10-by-10 grid of equally spaced containers, and plots a histogram. Each column of  $X$  corresponds to one dimension in the bin grid.

`hist3(X,nbins)` plots a histogram using an `nbins(1)`-by-`nbins(2)` grid of bins. `hist3(X,'Nbins',nbins)` is equivalent to `hist3(X,nbins)`.

`hist3(X,ctr)`, where `ctr` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins centered on `ctr{1}` in the first dimension and on `ctr{2}` in the second. `hist3` assigns rows of  $X$  falling outside the range of that grid to the bins along the outer edges of the grid, and ignores rows of  $X$  containing NaNs. `hist3(X,'Ctrs',ctr)` is equivalent to `hist3(X,ctr)`.

`hist3(X,'Edges',edges)`, where `edges` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins with edges at `edges{1}` in the first dimension and at `edges{2}` in the second. The  $(i,j)$ th bin includes the value  $X(k,:)$  if

$$\begin{aligned} \text{edges}\{1\}(i) &\leq X(k,1) < \text{edges}\{1\}(i+1) \\ \text{edges}\{2\}(j) &\leq X(k,2) < \text{edges}\{2\}(j+1) \end{aligned}$$

Rows of  $X$  that fall on the upper edges of the grid, `edges{1}(end)` or `edges{2}(end)`, are counted in the  $(I,j)$ th or  $(i,J)$ th bins, where  $I$  and  $J$  are the lengths of `edges{1}` and `edges{2}`. `hist3` does not count rows of  $X$  falling outside the range of the grid. Use `-Inf` and `Inf` in `edges` to include all non-NaN values.

# hist3

---

`N = hist3(X, ...)` returns a matrix containing the number of elements of `X` that fall in each bin of the grid, and does not plot the histogram.

`[N,C] = hist3(X, ...)` returns the positions of the bin centers in a 1-by-2 cell array of numeric vectors, and does not plot the histogram.

`hist3(ax,X, ...)` plots onto an axes with handle `ax` instead of the current axes. See the axes reference page for more information about handles to plots.

`hist3(...,param1,val1,param2,val2,...)` allows you to specify graphics parameter name/value pairs to fine-tune the plot.

## Examples

### Plot Density Histogram with Intensity Map

Load the sample data.

```
load seamount
```

Correct grid for negative y-values and draw histogram in 2D.

```
hold on  
dat = [-y,x];  
hist3(dat)
```

Extract histogram data.

```
n = hist3(dat); % default is to 10x10 bins
n1 = n';
n1(size(n,1) + 1, size(n,2) + 1) = 0;
```

Generate grid for 2-D projected view of intensities.

```
xb = linspace(min(dat(:,1)),max(dat(:,1)),size(n,1)+1);
yb = linspace(min(dat(:,2)),max(dat(:,2)),size(n,1)+1);
```

# hist3

Make a pseudocolor plot.

```
h = pcolor(xb,yb,n1);
```

Set the z-level and colormap of the displayed grid, and display the default 3-D perspective view.

```
set(h, 'zdata', ones(size(n1)) * -max(max(n)))  
colormap(hot) % heat map
```

```
title('Seamount:Data Point Density Histogram and Intensity Map');  
grid on  
view(3);
```

Seamount:Data Point Density Histogram and Intensity Map

### Histogram with Semi-Transparent Bars

Load the sample data.

```
load carbig
```

# hist3

---

Use the data to make histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];  
hist3(X,[7 7]);  
xlabel('MPG'); ylabel('Weight');
```

Make a histogram with semi-transparent bars.

```
hist3(X,[7 7],'FaceAlpha',.65);  
xlabel('MPG'); ylabel('Weight');
```

```
set(gcf, 'renderer', 'opengl');
```

Specify bin centers, different in each direction; get back counts, but don't make the plot.

```
cnt = hist3(X, {0:10:50 2000:500:5000});
```

## Histogram Bars Colored According to Height

Load the sample data.

```
load carbig
```

Make a histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];  
hist3(X,[7 7]);  
xlabel('MPG'); ylabel('Weight');  
set(gcf,'renderer','opengl');
```

Color the bars based on the frequency of the observations, i.e. according to the height of the bars.

```
set(get(gca,'child'),'FaceColor','interp','CDataMode','auto');
```

# hist3

---

<b>Purpose</b>	Histogram with a distribution fit
<b>Syntax</b>	<pre>histfit(data) histfit(data,nbins) histfit(data,nbins,dist)  h = histfit( __ )</pre>
<b>Description</b>	<p><code>histfit(data)</code> plots a histogram of values in <code>data</code> using the number of bins equal to the square root of the number of elements in <code>data</code> and fits a normal density function.</p> <p><code>histfit(data,nbins)</code> plots a histogram using <code>nbins</code> bins and fits a normal density function.</p> <p><code>histfit(data,nbins,dist)</code> plots a histogram with <code>nbins</code> bins and fits a density function from the distribution specified by <code>dist</code>.</p> <p><code>h = histfit( __ )</code> returns a vector of handles <code>h</code>, where <code>h(1)</code> is the handle to the histogram and <code>h(2)</code> is the handle to the density curve. It can include any of the input arguments in previous syntaxes.</p>
<b>Input Arguments</b>	<p><b>data - Input data</b> vector Input data, specified as a vector.</p> <p><b>Example:</b> <code>data = [1.5 2.5 4.6 1.2 3.4]</code></p> <p><b>Example:</b> <code>data = [1.5 2.5 4.6 1.2 3.4]'</code></p> <p><b>Data Types</b> double   single</p> <p><b>nbins - Number of bins</b> positive integer   []</p>

# histfit

---

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use `[]` for the default number of bins when fitting a distribution.

**Example:** `y = histfit(x,8)`

**Example:** `y = histfit(x,10,'gamma')`

**Example:** `y = histfit(x,[],'weibull')`

## Data Types

`double` | `single`

## dist - Distribution to fit

`'normal'` (default) | string

Distribution to fit to the histogram, specified as a string. The following table shows the supported distributions.

dist	Description
<code>'beta'</code>	Beta
<code>'birnbaumsaunders'</code>	Birnbaum-Saunders
<code>'burr'</code>	Burr Type XII
<code>'exponential'</code>	Exponential
<code>'extreme value'</code> or <code>'ev'</code>	Extreme value
<code>'gamma'</code>	Gamma
<code>'generalized extreme value'</code> or <code>'gev'</code>	Generalized extreme value
<code>'generalized pareto'</code> or <code>'gp'</code>	Generalized Pareto (threshold 0)
<code>'inversegaussian'</code>	Inverse Gaussian
<code>'logistic'</code>	Logistic
<code>'loglogistic'</code>	Loglogistic
<code>'lognormal'</code>	Lognormal

<b>dist</b>	<b>Description</b>
'nakagami'	Nakagami
'negative binomial' or 'nbin'	Negative binomial
'normal'	Normal
'poisson'	Poisson
'rayleigh'	Rayleigh
'rician'	Rician
'tlocationscale'	t location-scale
'weibull' or 'wbl'	Weibull
'kernel'	Nonparametric kernel-smoothing distribution. The density is evaluated at 100 equally spaced points that cover the range of the data in data. It works best with continuously distributed samples.

**Data Types**

char

**Output Arguments****h - Handles for the plot**

plot handle

Handles for the plot, returned as a vector, where  $h(1)$  is the handle to the histogram, and  $h(2)$  is the handle to the density curve.

**Examples****Histogram with a Normal Distribution Fit**

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng('default'); % for reproducibility
r = normrnd(10,1,100,1);
```

# histfit

Construct a histogram with a normal distribution fit.

```
histfit(r)
```

## Histogram for a Given Number of Bins

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng('default'); % for reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```
histfit(r,6)
```

### Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng('default') % for reproducibility
```

# histfit

---

```
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```
histfit(b,10,'beta')
```

## Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng('default') % for reproducibility  
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```
histfit(b,10,'kernel')
```

### Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

# histfit

---

```
rng('default'); % for reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
h = histfit(r,10,'normal')
```

Change the bar colors of the histogram.

```
set(h(1),'FaceColor',[.8 .8 1])
```

Change the color of the density curve.

```
set(h(2),'Color',[.2 .2 .2])
```

**See Also** `hist` | `normfit` | `dfittool`

# hmmdecode

---

**Purpose** Hidden Markov model posterior state probabilities

**Syntax**

```
PSTATES = hmmdecode(seq,TRANS,EMIS)
[PSTATES,logpseq] = hmmdecode(...)
[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)
hmmdecode(...,'Symbols',SYMBOLS)
```

**Description** PSTATES = hmmdecode(seq,TRANS,EMIS) calculates the posterior state probabilities, PSTATES, of the sequence seq, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state  $k$  at step  $i$ , given the observed sequence of symbols, sym. You specify the model by a transition probability matrix, TRANS, and an emissions probability matrix, EMIS. TRANS( $i, j$ ) is the probability of transition from state  $i$  to state  $j$ . EMIS( $k, seq$ ) is the probability that symbol seq is emitted from state  $k$ .

PSTATES is an array with the same length as seq and one row for each state in the model. The ( $i, j$ )th element of PSTATES gives the probability that the model is in state  $i$  at the  $j$ th step, given the sequence seq.

---

**Note** The function hmmdecode begins with the model in state 1 at step 0, prior to the first emission. hmmdecode computes the probabilities in PSTATES based on the fact that the model begins in state 1.

---

[PSTATES,logpseq] = hmmdecode(...) returns logpseq, the logarithm of the probability of sequence seq, given transition matrix TRANS and emission matrix EMIS.

[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...) returns the forward and backward probabilities of the sequence scaled by S.

hmmdecode(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

## Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
pStates = hmmdecode(seq,trans,emis);  
[seq,states] = hmmgenerate(100,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'})  
pStates = hmmdecode(seq,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'});
```

## See Also

[hmmgenerate](#) | [hmmestimate](#) | [hmmviterbi](#) | [hmmtrain](#)

# hmmestimate

---

**Purpose** Hidden Markov model parameter estimates from emissions and states

**Syntax**

```
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOIE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)
```

**Description**

[TRANS,EMIS] = hmmestimate(seq,states) calculates the maximum likelihood estimate of the transition, TRANS, and emission, EMIS, probabilities of a hidden Markov model for sequence, seq, with known states, states.

hmmestimate(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmestimate(...,'Statenames',STATENAMES) specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

hmmestimate(...,'Pseudoemissions',PSEUDOIE) specifies pseudocount emission values in the matrix PSEUDO. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOIE should be a matrix of size  $m$ -by- $n$ , where  $m$  is the number of states in the hidden Markov model and  $n$  is the number of possible emissions. If the  $i \rightarrow k$  emission does not occur in seq, you can set PSEUDOIE(i,k) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.

hmmestimate(...,'Pseudotransitions',PSEUDOTR) specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size  $m$ -by- $m$ , where  $m$  is the number of states in the hidden

Markov model. If the  $i \rightarrow j$  transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

### Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence `states`, or the emission might never occur in the sequence `seq`. In either case, the algorithm returns a probability of 0 for the given transition or emission in `TRANS` or `EMIS`. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of `PSEUDO` or `PSEUDOTR` to 1. For example, if the transition  $i \rightarrow j$  does not occur in `states`, set `PSEUOTR(i, j) = 1`. This forces `TRANS(i, j)` to be positive.

If you have an estimate for the expected number of transitions  $i \rightarrow j$  in a sequence of the same length as `states`, and the actual number of transitions  $i \rightarrow j$  that occur in `seq` is substantially less than what you expect, you can set `PSEUOTR(i, j)` to the expected number. This increases the value of `TRANS(i, j)`. For transitions that do occur in `states` with the frequency you expect, set the corresponding entry of `PSEUDOTR` to 0, which does not increase the corresponding entry of `TRANS`.

If you do not know the sequence of states, use `hmmtrain` to estimate the model parameters.

[1] Durbin, R., S. Eddy, A. Krogh, and G. Mitchison. *Biological Sequence Analysis*. Cambridge, UK: Cambridge University Press, 1998.

## Examples

```
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmmestimate(seq,states);
```

# hmmestimate

---

## **See Also**

`hmmgenerate` | `hmmdecode` | `hmmviterbi` | `hmmtrain`

**Purpose** Hidden Markov model states and emissions

**Syntax** `[seq,states] = hmmgenerate(len,TRANS,EMIS)`  
`hmmgenerate(...,'Symbols',SYMBOLS)`  
`hmmgenerate(...,'Statenames',STATENAMES)`

**Description** `[seq,states] = hmmgenerate(len,TRANS,EMIS)` takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate

- A random sequence `seq` of emission symbols
- A random sequence `states` of states

The length of both `seq` and `states` is `len`.  $\text{TRANS}(i,j)$  is the probability of transition from state  $i$  to state  $j$ .  $\text{EMIS}(k,l)$  is the probability that symbol  $l$  is emitted from state  $k$ .

---

**Note** The function `hmmgenerate` begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state  $i_1$ , with probability  $T_{1i_1}$ , and generates an emission  $a_{k_1}$  with probability  $E_{i_1k_1}$ . `hmmgenerate` returns  $i_1$  as the first entry of `states`, and  $a_{k_1}$  as the first entry of `seq`.

---

`hmmgenerate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

`hmmgenerate(...,'Statenames',STATENAMES)` specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of

# hmmgenerate

---

the output states is be 1 with probability 0.95 and 2 with probability 0.05.

## Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'},...
    'Statenames',{'fair';'loaded'})
```

## See Also

[hmmviterbi](#) | [hmmdecode](#) | [hmmestimate](#) | [hmmtrain](#)

**Purpose**

Hidden Markov model parameter estimates from emissions

**Syntax**

```
[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)
```

**Description**

[ESTTR,ESTEMIT] = `hmmtrain(seq,TRGUESS,EMITGUESS)` estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. `seq` can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. `TRGUESS` and `EMITGUESS` are initial estimates of the transition and emission probability matrices. `TRGUESS(i,j)` is the estimated probability of transition from state `i` to state `j`. `EMITGUESS(i,k)` is the estimated probability that symbol `k` is emitted from state `i`.

`hmmtrain(...,'Algorithm',algorithm)` specifies the training algorithm. *algorithm* can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.

`hmmtrain(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmtrain(...,'Tolerance',tol)` specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is `1e-4`.

`hmmtrain(...,'Maxiterations',maxiter)` specifies the maximum number of iterations for the estimation process. The default maximum is 100.

`hmmtrain(..., 'Verbose', true)` returns the status of the algorithm at each iteration.

`hmmtrain(..., 'Pseudoemissions', PSEUDOE)` specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size  $m$ -by- $n$ , where  $m$  is the number of states in the hidden Markov model and  $n$  is the number of possible emissions. If the  $i \rightarrow k$  emission does not occur in `seq`, you can set `PSEUDOE(i, k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmtrain(..., 'Pseudotransitions', PSEUDOTR)` specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size  $m$ -by- $m$ , where  $m$  is the number of states in the hidden Markov model. If the  $i \rightarrow j$  transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

## Tolerance

The input argument `'tolerance'` controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for `tolerance`:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of 'tolerance' is .0001. Increasing the tolerance decreases the number of steps the hmmtrain algorithm executes before it terminates.

**maxiterations**

The maximum number of iterations, 'maxiterations', controls the maximum number of steps the algorithm executes before it terminates. If the algorithm executes maxiter iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of 'maxiterations' to make the algorithm reach the desired tolerance before terminating.

# hmmviterbi

---

**Purpose** Hidden Markov model most probable state path

**Syntax**  
`STATES = hmmviterbi(seq,TRANS,EMIS)`  
`hmmviterbi(...,'Symbols',SYMBOLS)`  
`hmmviterbi(...,'Statenames',STATENAMES)`

**Description** `STATES = hmmviterbi(seq,TRANS,EMIS)` given a sequence, `seq`, calculates the most likely path through the hidden Markov model specified by transition probability matrix, `TRANS`, and emission probability matrix `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(i,k)` is the probability that symbol `k` is emitted from state `i`.

---

**Note** The function `hmmviterbi` begins with the model in state 1 at step 0, prior to the first emission. `hmmviterbi` computes the most likely path based on the fact that the model begins in state 1.

---

`hmmviterbi(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmviterbi(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

## Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6 1/6 1/6 1/6 1/6 1/6;

# categorical.horzcat

---

**Purpose** Horizontal concatenation for categorical arrays

**Syntax** `C = horzcat(dim,A,B,...)`  
`C = horzcat(A,B)`

**Description** `C = horzcat(dim,A,B,...)` horizontally concatenates the categorical arrays `A,B,...`. For matrices, all inputs must have the same number of rows. For n-D arrays, all inputs must have the same sizes except in the second dimension. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs, as determined by their labels. `C = horzcat(A,B)` is called for the syntax `[A B]`.

**See Also** `cat` | `vertcat`

**Purpose** Horizontal concatenation for dataset arrays

**Syntax** `ds = horzcat(ds1, ds2, ...)`

**Description** `ds = horzcat(ds1, ds2, ...)` horizontally concatenates the dataset arrays `ds1`, `ds2`, ... . You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and `horzcat` includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. `horzcat` concatenates by matching observation names when present, or by position for datasets that do not have observation names.

**See Also** `cat` | `vertcat`

# hougen

---

**Purpose** Hougen-Watson model

**Syntax** `yhat = hougen(beta,x)`

**Description** `yhat = hougen(beta,x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

$$\hat{y} = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

**References** [1] Bates, D. M., and D. G. Watts. *Nonlinear Regression Analysis and Its Applications*. Hoboken, NJ: John Wiley & Sons, Inc., 1988.

**See Also** `rsmdemo`

**Purpose** Hypergeometric cumulative distribution function

**Syntax** `hygecdf(x,M,K,N)`  
`hygecdf(x,M,K,N,'upper')`

**Description** `hygecdf(x,M,K,N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x,M,K,N,'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

$$p = F(x | M, K, N) = \sum_{i=0}^x \frac{\binom{K}{i} \binom{M-K}{N-i}}{\binom{M}{N}}$$

The result,  $p$ , is the probability of drawing up to  $x$  of a possible  $K$  items in  $N$  drawings without replacement from a group of  $M$  objects.

## Examples **Compute Hypergeometric Distribution CDF**

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

`p = hygecdf(2,100,20,10)`

`p =`  
 0.6812

# hygecdf

---

---

<b>Purpose</b>	Hypergeometric inverse cumulative distribution function
<b>Syntax</b>	hygeinv(P,M,K,N)
<b>Description</b>	hygeinv(P,M,K,N) returns the smallest integer $X$ such that the hypergeometric cdf evaluated at $X$ equals or exceeds $P$ . You can think of $P$ as the probability of observing $X$ defective items in $N$ drawings without replacement from a group of $M$ items where $K$ are defective.
<b>Examples</b>	<p>Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?</p> <pre>x = hygeinv(0.99,1000,10,50) x =     3</pre> <p>What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?</p> <pre>x = hygeinv(0.50,1000,10,50) x =     0</pre>
<b>See Also</b>	icdf   hygecdf   hygepdf   hygestat   hygernd

# hygepdf

---

**Purpose** Hypergeometric probability density function

**Syntax** `Y = hygepdf(X,M,K,N)`

**Description** `Y = hygepdf(X,M,K,N)` computes the hypergeometric pdf at each of the values in `X` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `X`, `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in `M`, `K`, and `N` must all be positive integers, with  $N \leq M$ . The values in `X` must be less than or equal to all the parameter values.

The hypergeometric pdf is

$$y = f(x | M, K, N) = \frac{\binom{K}{x} \binom{M-K}{N-x}}{\binom{M}{N}}$$

The result, `y`, is the probability of drawing exactly `x` of a possible `K` items in `n` drawings without replacement from a group of `M` objects.

**Examples** Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

```
p = hygepdf(0:5,100,20,10)
p =
    0.0951    0.2679    0.3182    0.2092    0.0841    0.0215
```

**See Also** `pdf` | `hygecdf` | `hygeinv` | `hygestat` | `hygernd`

**Purpose** Hypergeometric random numbers

**Syntax**  
R = hygernd(M,K,N)  
R = hygernd(M,K,N,m,n,...)  
R = hygernd(M,K,N,[m,n,...])

**Description** R = hygernd(M,K,N) generates random numbers from the hypergeometric distribution with corresponding size of the population, M, number of items with the desired characteristic in the population, K, and number of samples drawn, N. M, K, and N can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of R. A scalar input for M, K, or N is expanded to a constant array with the same dimensions as the other inputs.

R = hygernd(M,K,N,m,n,...) or R = hygernd(M,K,N,[m,n,...]) generates an m-by-n-by-... array. The M, K, N parameters can each be scalars or arrays of the same size as R.

**Examples**  
numbers = hygernd(1000,40,50)  
numbers =  
1

**See Also** random | hygepdf | hygecdf | hygeinv | hygestat

# hygestat

---

**Purpose** Hypergeometric mean and variance

**Syntax** `[MN,V] = hygestat(M,K,N)`

**Description** `[MN,V] = hygestat(M,K,N)` returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, M, number of items with the desired characteristic in the population, K, and number of samples drawn, N. Vector or matrix inputs for M, K, and N must have the same size, which is also the size of MN and V. A scalar input for M, K, or N is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters M, K, and N is  $NK/M$ , and the variance is  $NK(M-K)(M-N) / [M^2(M-1)]$ .

**Examples** The hypergeometric distribution approaches the binomial distribution, where  $p = K/M$ , as M goes to infinity.

```
[m,v] = hygestat(10.^(1:4),10.^(0:3),9)
m =
    0.9000    0.9000    0.9000    0.9000
v =
    0.0900    0.7445    0.8035    0.8094
```

```
[m,v] = binostat(9,0.1)
m =
    0.9000
v =
    0.8100
```

**Purpose**

Inverse cumulative distribution functions

**Syntax**

```
Y = icdf(name,X,A)
Y = icdf(name,X,A,B)
Y = icdf(name,X,A,B,C)
```

**Description**

`Y = icdf(name,X,A)` computes the inverse cumulative distribution function for the one-parameter family of distributions specified by `name`. Parameter values for the distribution are given in `A`. The inverse cumulative distribution function is evaluated at the values in `X` and its values are returned in `Y`.

If `X` and `A` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`. If `A` is a scalar, it is expanded to a constant matrix the same size as `X`.

`Y` is the common size of `X` and `A` after any necessary scalar expansion.

`Y = icdf(name,X,A,B)` computes the inverse cumulative distribution function for two-parameter families of distributions, where parameter values are given in `A` and `B`.

If `X`, `A`, and `B` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A` and `B`. If either `A` or `B` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, and `B` after any necessary scalar expansion.

`Y = icdf(name,X,A,B,C)` computes the inverse cumulative distribution function for three-parameter families of distributions, where parameter values are given in `A`, `B`, and `C`.

If `X`, `A`, `B`, and `C` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`, `B`, and `C`. If any of `A`, `B` or `C` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, `B` and `C` after any necessary scalar expansion.

## Examples

Compute the icdf of the normal distribution with mean 0 and standard deviation 1 at inputs 0.1, 0.3, ..., 0.9:

```
x1 = icdf('Normal',0.1:0.2:0.9,0,1)
x1 =
    -1.2816   -0.5244    0    0.5244    1.2816
```

The order of the parameters is the same as for `norminv`.

Compute the icdfs of Poisson distributions with rate parameters 0, 1, ..., 4 at inputs 0.1, 0.3, ..., 0.9, respectively:

```
x2 = icdf('Poisson',0.1:0.2:0.9,0:4)
x2 =
    NaN    0    2    4    7
```

The order of the parameters is the same as for `poissinv`.

# piecewisedistribution.icdf

---

**Purpose** Inverse cumulative distribution function for piecewise distribution

**Syntax** `X = icdf(obj,P)`

**Description** `X = icdf(obj,P)` returns an array `X` of values of the inverse cumulative distribution function for the piecewise distribution object `obj`, evaluated at the values in the array `P`.

**Examples** Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432

icdf(obj,p)
ans =
   -1.7766
    1.8432
```

**See Also** `paretotails` | `cdf`

<b>Purpose</b>	Return inverse cumulative distribution function (ICDF) for ProbDistUnivKernel object	
<b>Syntax</b>	$Y = \text{icdf}(PD, P)$	
<b>Description</b>	$Y = \text{icdf}(PD, P)$ returns $Y$ , an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object $PD$ , evaluated at values in $P$ .	
<b>Input Arguments</b>	$PD$	An object of the class ProbDistUnivKernel.
	$P$	A numeric array of values from 0 to 1 where you want to evaluate the ICDF.
<b>Output Arguments</b>	$Y$	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object $PD$ .

# inconsistent

---

**Purpose** Inconsistency coefficient

**Syntax**  $Y = \text{inconsistent}(Z)$   
 $Y = \text{inconsistent}(Z, d)$

**Description**  $Y = \text{inconsistent}(Z)$  computes the inconsistency coefficient for each link of the hierarchical cluster tree  $Z$ , where  $Z$  is an  $(m-1)$ -by-3 matrix generated by the linkage function. The inconsistency coefficient characterizes each link in a cluster tree by comparing its height with the average height of other links at the same level of the hierarchy. The higher the value of this coefficient, the less similar the objects connected by the link.

$Y = \text{inconsistent}(Z, d)$  computes the inconsistency coefficient for each link in the hierarchical cluster tree  $Z$  to depth  $d$ , where  $d$  is an integer denoting the number of levels of the cluster tree that are included in the calculation. By default,  $d=2$ .

The output,  $Y$ , is an  $(m-1)$ -by-4 matrix formatted as follows.

Column	Description
1	Mean of the heights of all the links included in the calculation.
2	Standard deviation of the heights of all the links included in the calculation.
3	Number of links included in the calculation.
4	Inconsistency coefficient.

For each link,  $k$ , the inconsistency coefficient is calculated as:

$$Y(k, 4) = (z(k, 3) - Y(k, 1)) / Y(k, 2)$$

For leaf nodes, nodes that have no further nodes under them, the inconsistency coefficient is set to 0.

## Examples

```
X = gallery('uniformdata',[10 2],12);
Y = pdist(X);
Z = linkage(Y,'single');
dendrogram(Z)
```

```
W = inconsistent(Z,3)
```

```
W =
```

<b>Purpose</b>	Read-only structure containing information about input data to ProbDist object
<b>Description</b>	<p>InputData is a read-only property of the ProbDist class. InputData is a structure containing information about input data to a ProbDist object. It includes the following fields:</p> <ul style="list-style-type: none"><li>• data</li><li>• cens</li><li>• freq</li></ul>
<b>Values</b>	<p>Possible values for the three fields in the structure are any data supplied to the <code>fitdist</code> function:</p> <ul style="list-style-type: none"><li>• <code>data</code> — Data passed to the <code>fitdist</code> function when creating the ProbDist object. This field is empty if the ProbDist object was created without fitting to data, that is by using the <code>ProbDistUnivParam.ProbDistUnivParam</code> constructor.</li><li>• <code>cens</code> — The vector supplied with the 'censoring' parameter when creating the ProbDist object using the <code>fitdist</code> function. This field is empty if the ProbDist object was created without fitting to data, that is by using the <code>ProbDistUnivParam.ProbDistUnivParam</code> constructor.</li><li>• <code>freq</code> — The vector supplied with the 'frequency' parameter when creating the ProbDist object using the <code>fitdist</code> function. This field is empty if the ProbDist object was created without fitting to data, that is by using the <code>ProbDistUnivParam.ProbDistUnivParam</code> constructor.</li></ul> <p>Use this information to view and compare the data supplied to create distributions.</p>

# categorical.int8

---

**Purpose** Convert categorical array to signed 8-bit integer array

**Syntax** `B = int8(A)`

**Description** `B = int8(A)` converts the categorical array `A` to a signed 8-bit integer array. Each element of `B` contains the internal categorical level code for the corresponding element of `A`.

Undefined elements of `A` are assigned the value 0 in `B`. If `A` contains more than `intmax('int8')` levels, the internal codes will saturate to `intmax('int8')` when cast to `int8`.

Each element of <code>B</code> contains the internal categorical level code for the corresponding element of <code>A</code>.</p> <p>Undefined elements of <code>A</code> are assigned the value 0 in <code>B</code>.</p>
<b>See Also</b>	<code>double</code>   <code>uint64</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Integers”</li></ul>

# interactionplot

---

**Purpose** Interaction plot for grouped data

**Syntax**  
`interactionplot(Y,GROUP)`  
`interactionplot(Y,GROUP,'varnames',VARNAMES)`  
`[h,AX,bigax] = interactionplot(...)`

**Description** `interactionplot(Y,GROUP)` displays the two-factor interaction plot for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `Y` is a vector, the rows give the means of each entry in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or a single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position  $(i,j)$  is the interaction of the two variables whose names are given at row diagonal  $(i,i)$  and column diagonal  $(j,j)$ , respectively.

`interactionplot(Y,GROUP,'varnames',VARNAMES)` displays the interaction plot with user-specified grouping variable names `VARNAMES`. `VARNAMES` is a character matrix or a cell array of strings, one per grouping variable. Default names are 'X1', 'X2', ... .

`[h,AX,bigax] = interactionplot(...)` returns a handle `h` to the figure window, a matrix `AX` of handles to the subplot axes, and a handle `bigax` to the big (invisible) axes framing the subplots.

## Examples **Display Interaction Plots**

Randomly generate data for a response variable `y` .

```
rng('default'); % for reproducibility  
y = randn(1000,1);
```

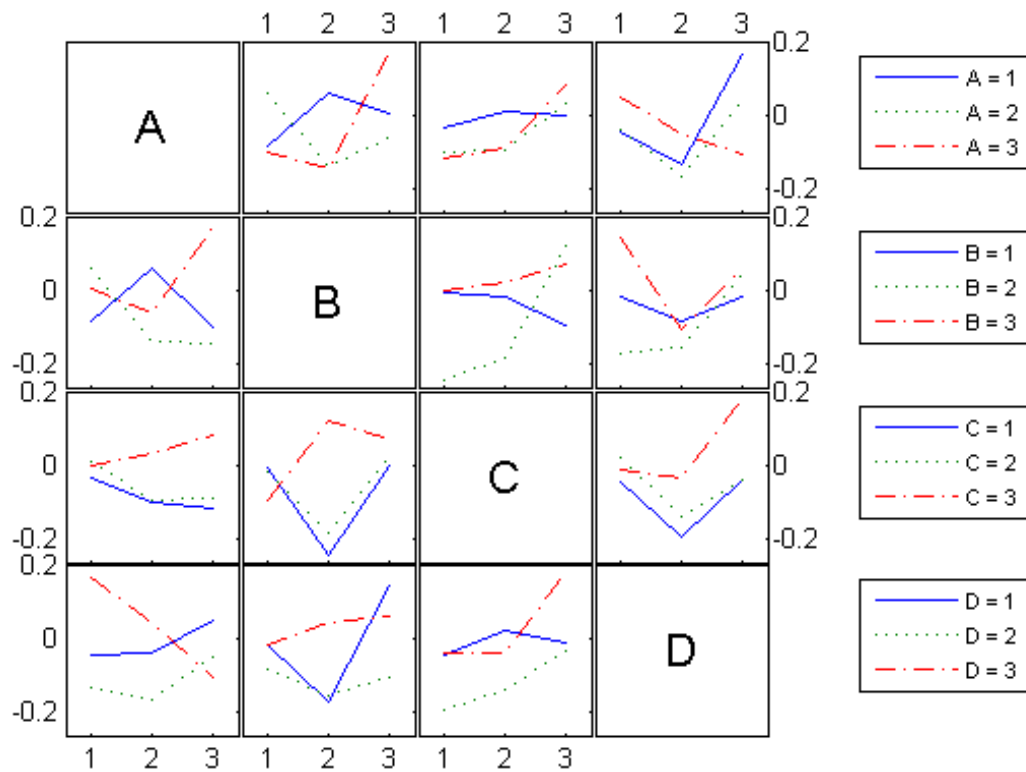

Randomly generate data for four three-level factors.

```
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```
interactionplot(y,group,'varnames',{'A','B','C','D'})
```

# interactionplot

**See Also** [maineffectsplot](#) | [multivarichart](#)

**Purpose** Set intersection for categorical arrays

---

**Note** In a future release, the behavior of `categorical.intersect` will change to be consistent with the MATLAB function `intersect`. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for `intersect`.

---

**Syntax**

```
C = intersect(A,B)
[C,IA,IB] = intersect(A,B)
[...] = intersect(A,B,'rows')
[...] = intersect(...,'R2012a')
[...] = intersect(...,'legacy')
[...] = intersect(A,B,setOrder)
[...] = intersect(A,B,'rows',setOrder)
```

**Description** `C = intersect(A,B)` for categorical vectors A and B, returns a categorical vector C containing the values common to the two vectors with no repetitions. The result C is sorted. The set of categorical levels for C is the sorted union of the sets of levels of the inputs.

`[C,IA,IB] = intersect(A,B)` also returns index vectors IA and IB such that `C = A(IA)` and `C = B(IB)`. If there are repeated common values in A or B, then the index of the last occurrence of each repeated value is returned.

`[...] = intersect(A,B,'rows')` for categorical matrices A and B with the same number of columns, returns the rows common to the two matrices. The rows of the matrix C are sorted. The set of categorical levels for C is the sorted union of the sets of levels of the inputs. The optional outputs IA and IB are index vectors such that `C = A(IA,:)` and `C = B(IB,:)`.

## categorical.intersect

---

`[...] = intersect(..., 'R2012a')` adopts the future behavior of `intersect`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `B`, or `'rows'`.

`[...] = intersect(..., 'legacy')` preserves the current behavior of `intersect`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `B`, or `'rows'`.

`[...] = intersect(A,B,setOrder)` and `[...] = intersect(A,B, 'rows', setOrder)` returns the observations of `C` in a specific order. `setOrder='sorted'` returns the values or rows of `C` in sorted order. `setOrder='stable'` returns the values or rows of `C` in the same order as `A`. If `A` and `B` are row vectors, then `C` is also a row vector. Otherwise, `C` is a column vector. If `A` and `B` are column vectors, then `C` is also a column vector. If there are repeated common values in `A` or `B`, then the index of the first occurrence of each repeated value is returned.

### See Also

`ismember` | `setdiff` | `setxor` | `union` | `unique`

## Purpose

Set intersection for dataset array observations

## Syntax

```
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( ___ )
```

## Description

`C = intersect(A,B)` for dataset arrays `A` and `B` returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are in sorted order.

`C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observations in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, then those values are taken from the first occurrence.

`C = intersect(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = intersect( ___ )` also returns index vectors `iA` and `iB` such that `C = A(iA,:)` and `C = B(iB,:)`. If there are repeated observations in `A` or `B`, then `intersect` returns the index of the first occurrence. You can use any of the previous input arguments.

## Input Arguments

### **A,B**

Input dataset arrays.

### **vars**

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in `A` and `B` that `intersect` considers.

Specify `vars` as `[]` to use its default value of all variables.

# dataset.intersect

---

## setOrder

Flag indicating the sorting order for the observations in C. The possible values of setOrder are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A.

## Output Arguments

### C

Dataset array with the common set of observations in A and B, with repetitions removed. C is in sorted order (by default), or the order specified by setOrder.

### iA

Index vector, indicating the observations in A that are common to B. The vector iA contains the index to the first occurrence of any repeated observations in A.

### iB

Index vector, indicating the observations in B that are common to A. The vector iB contains the index to the first occurrence of any repeated observations in B.

## Examples

### Intersection of Two Dataset Arrays

Navigate to the folder containing sample data, and load sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);
```

Return the intersection and index vectors.

```
[C,iA,iB] = intersect(A,B);
```

```
C =
```

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

There is one observation in common between A and B.

Find the observation in the original dataset arrays.

```
A(iA,:)
```

```
ans =
```

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

```
B(iB,:)
```

```
ans =
```

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

# prob.InverseGaussianDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Inverse Gaussian probability distribution object

**Description** `prob.InverseGaussianDistribution` is an object consisting of parameters, a model description, and sample data for an inverse Gaussian probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('InverseGaussian')` creates an inverse Gaussian probability distribution object using the default parameter values.

`pd = makedist('InverseGaussian','mu',mu,'lambda',lambda)` creates an inverse Gaussian probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Scale parameter**

1 (default) | positive scalar value

Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

### **Data Types**

single | double

### **lambda - Shape parameter**

1 (default) | positive scalar value

Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

### **Data Types**

single | double

## Properties

### **mu**

Scale parameter for the inverse Gaussian distribution, stored as a positive scalar value.

#### **Data Types**

single | double

### **lambda**

Shape parameter for the inverse Gaussian distribution, stored as a positive scalar value.

#### **Data Types**

single | double

### **DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

#### **Data Types**

char

### **InputData**

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

#### **Data Types**

single | double

### **IsTruncated**

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated.

# prob.InverseGaussianDistribution

---

If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object

proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions **Inverse Gaussian Distribution**

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.

Parameter	Description	Support
mu	Scale parameter	$\mu > 0$
lambda	Shape parameter	$\lambda > 0$

The probability density function (pdf) is

$$f(x | \mu, \lambda) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right\} ; \quad x > 0.$$

## Examples

### Create an Inverse Gaussian Distribution Object Using Default Parameters

Create an inverse Gaussian distribution object using the default parameter values.

```
pd = makedist('InverseGaussian')
```

```
pd =
```

```
InverseGaussianDistribution
```

```
Inverse Gaussian distribution
```

```
mu = 1
```

```
lambda = 1
```

### Create an Inverse Gaussian Distribution Object Using Specified Parameters

Create an inverse Gaussian distribution object by specifying parameter values.

## Concepts

- “Inverse Gaussian Distribution” on page B-63
- Class Attributes
- Property Attributes

**Purpose** Inverse prediction

**Syntax**  
`X0 = invpred(X,Y,Y0)`  
`[X0,DXLO,DXUP] = invpred(X,Y,Y0)`  
`[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)`

**Description** `X0 = invpred(X,Y,Y0)` accepts vectors `X` and `Y` of the same length, fits a simple regression, and returns the estimated value `X0` for which the height of the line is equal to `Y0`. The output, `X0`, has the same size as `Y0`, and `Y0` can be an array of any size.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0)` also computes 95% inverse prediction intervals. `DXLO` and `DXUP` define intervals with lower bound `X0 - DXLO` and upper bound `X0+DXUP`. Both `DXLO` and `DXUP` have the same size as `Y0`.

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to `-Inf` or `+Inf`, and some may extend over the entire real line.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)` specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

Name	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 \cdot (1 - \text{alpha})\%$ . Default is <code>alpha=0.05</code> for 95% confidence.
'predopt'	Either <code>'observation'</code> , the default value to compute the intervals for <code>X0</code> at which a new observation could equal <code>Y0</code> , or <code>'curve'</code> to compute intervals for the <code>X0</code> value at which the curve is equal to <code>Y0</code> .

# invpred

---

## Examples

```
x = 4*rand(25,1);  
y = 10 + 5*x + randn(size(x));  
scatter(x,y)  
x0 = invpred(x,y,20)
```

[polyfit](#) | [polyval](#) | [polyconf](#) | [polytool](#)

<b>Purpose</b>	Inverse permute dimensions of categorical array
<b>Syntax</b>	<code>A = ipermute(B,order)</code>
<b>Description</b>	<code>A = ipermute(B,order)</code> is the inverse of <code>permute</code> . <code>ipermute</code> rearranges the dimensions of the categorical array <code>B</code> so that <code>permute(A,order)</code> will produce <code>B</code> . The array produced has the same values of <code>A</code> but the order of the subscripts needed to access any particular element are rearranged as specified by <code>order</code> . The elements of <code>order</code> must be a rearrangement of the numbers from 1 to <code>n</code> .
<b>See Also</b>	<code>permute</code>

# iqr

---

**Purpose** Interquartile range

**Syntax** `y = iqr(X)`  
`iqr(X,dim)`

**Description** `y = iqr(X)` returns the interquartile range of the values in `X`. For vector input, `y` is the difference between the 75th and the 25th percentiles of the sample in `X`. For matrix input, `y` is a row vector containing the interquartile range of each column of `X`. For N-dimensional arrays, `iqr` operates along the first nonsingleton dimension of `X`.

`iqr(X,dim)` calculates the interquartile range along the dimension `dim` of `X`.

**Tips** The IQR is a robust estimate of the spread of the data, since changes in the upper and lower 25% of the data do not affect it. If there are outliers in the data, then the IQR is more representative than the standard deviation as an estimate of the spread of the body of the data. The IQR is less efficient than the standard deviation as an estimate of the spread when the data is all from the normal distribution.

Multiply the IQR by 0.7413 to estimate  $\sigma$  (the second parameter of the normal distribution.)

**Examples** This Monte Carlo simulation shows the relative efficiency of the IQR to the sample standard deviation for normal data.

```
x = normrnd(0,1,100,100);
s = std(x);
s_IQR = 0.7413*iqr(x);
efficiency = (norm(s-1)./norm(s_IQR-1)).^2
efficiency =
    0.3297
```

<b>Purpose</b>	Return interquartile range (IQR) for ProbDistUnivKernel object		
<b>Syntax</b>	$Y = \text{iqr}(PD)$		
<b>Description</b>	$Y = \text{iqr}(PD)$ returns $Y$ , the interquartile range for the ProbDistUnivKernel object $PD$ . The interquartile range is the distance between the 75th and 25th percentiles.		
<b>Input Arguments</b>	<table><tr><td><math>PD</math></td><td>An object of the class ProbDistUnivKernel.</td></tr></table>	$PD$	An object of the class ProbDistUnivKernel.
$PD$	An object of the class ProbDistUnivKernel.		
<b>Output Arguments</b>	<table><tr><td><math>Y</math></td><td>The value of the interquartile range for the ProbDistUnivKernel object <math>PD</math>.</td></tr></table>	$Y$	The value of the interquartile range for the ProbDistUnivKernel object $PD$ .
$Y$	The value of the interquartile range for the ProbDistUnivKernel object $PD$ .		
<b>See Also</b>	<a href="#">iqr</a>   <a href="#">ProbDistUnivKernel.icdf</a>		

# ProbDistUnivParam.iqr

---

<b>Purpose</b>	Return interquartile range (IQR) for ProbDistUnivParam object	
<b>Syntax</b>	$Y = \text{iqr}(PD)$	
<b>Description</b>	$Y = \text{iqr}(PD)$ returns $Y$ , the interquartile range for the ProbDistUnivParam object $PD$ . The interquartile range is the distance between the 75th and 25th percentiles.	
<b>Input Arguments</b>	$PD$	An object of the class ProbDistUnivParam.
<b>Output Arguments</b>	$Y$	The value of the interquartile range for the ProbDistUnivParam object $PD$ .
<b>See Also</b>	<a href="#">iqr</a>   <a href="#">ProbDistUnivParam.icdf</a>	

<b>Purpose</b>	Interquartile range of probability distribution object
<b>Syntax</b>	<code>r = iqr(pd)</code>
<b>Description</b>	<code>r = iqr(pd)</code> returns the interquartile range <code>r</code> of the probability distribution <code>pd</code> .
<b>Input Arguments</b>	<p><b>pd - Probability distribution</b> probability distribution object</p> <p>Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using <code>makedist</code>. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using <code>fitdist</code> or the Distribution Fitting app.</p>
<b>Output Arguments</b>	<p><b>r - Interquartile range</b> scalar value</p> <p>Interquartile range of the probability distribution, returned as a scalar value. The value of <code>r</code> is the difference between the values of the 75th and 25th percentile of the probability distribution.</p>
<b>Examples</b>	<p><b>Interquartile Range of a Fitted Distribution</b></p> <p>Load the sample data. Create a vector containing the first column of students' exam grade data.</p> <pre>load examgrades; x = grades(:,1);</pre> <p>Create a normal distribution object by fitting it to the data.</p> <pre>pd = fitdist(x,'Normal')</pre> <pre>pd =  NormalDistribution</pre>

# prob.TruncatableDistribution.iqr

---

```
Normal distribution
  mu = 75.0083 [73.4321, 76.5846]
  sigma = 8.7202 [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```
r = iqr(pd)
```

```
r =
```

```
11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```
y = icdf(pd, [0.25, 0.75])
```

```
y =
```

```
69.1266 80.8900
```

Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```
y(2) - y(1)
```

```
ans =
```

```
11.7634
```

Use `boxplot` to visualize the interquartile range.

```
boxplot(x)
```

The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

# classregtree.isbranch

---

**Purpose** Test node for branch

**Syntax** `ib = isbranch(t)`  
`ib = isbranch(t,nodes)`

**Description** `ib = isbranch(t)` returns an  $n$ -element logical vector `ib` that is true for each branch node and false for each leaf node.

`ib = isbranch(t,nodes)` takes a vector `nodes` of node numbers and returns a vector of logical values for the specified nodes.

**Examples** Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})

t =

**Purpose** True for empty categorical array

**Syntax** TF = isEmpty(A)

**Description** TF = isEmpty(A) returns true (1) if A is an empty categorical array and false (0) otherwise. An empty array has no elements, that is numel(A)==0.

**See Also** numel | size

# dataset.isempty

---

**Purpose** True for empty dataset array

**Syntax** `tf = isempty(A)`

**Description** `tf = isempty(A)` returns true (1) if A is an empty dataset and false (0) otherwise. An empty array has no elements, that is `prod(size(A))==0`.

**See Also** `size`

**Purpose** True if categorical arrays are equal

**Syntax** TF = isequal(A,B)  
TF = isequal(A,B,C,...)

**Description** TF = isequal(A,B) is true (1) if the categorical arrays A and B are the same class, have the same size and the same sets of levels, and contain the same values, and false (0) otherwise.

TF = isequal(A,B,C,...) is true (1) if all the input arguments are equal.

Elements with undefined levels are not considered equal to each other.

**See Also** getlabels

# categorical.islevel

---

**Purpose** Test for levels

**Syntax** `I = islevel(levels,A)`

**Description** `I = islevel(levels,A)` returns a logical array `I` the same size as the string, cell array of strings, or 2-D character matrix `levels`. `I` is true (1) where the corresponding element of `levels` is the label of a level in the categorical array `A`, even if the level contains no elements. `I` is false (0) otherwise.

**Examples** Display age levels in the data in `hospital.mat`, before and after dropping occupied levels:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
disp(labels')
'0s' '10s' '20s' '30s' '40s' '50s' '60s' '70s' '80s' '90s'

AgeGroup = ordinal(hospital.Age, labels, [], edges);
I = islevel(labels, AgeGroup);
disp(I')
1 1 1 1 1 1 1 1 1 1

AgeGroup = droplevels(AgeGroup);
I = islevel(labels, AgeGroup);
disp(I')
0 0 1 1 1 1 0 0 0 0
```

**See Also** `ismember` | `isundefined`

**Purpose** True for elements of categorical array in set

---

**Note** In a future release, the behavior of `categorical.ismember` will change to be consistent with the MATLAB function `ismember`. This behavior change is optional in R2012a. For a demonstration of using the 'R2012a' flag to preview the future behavior, or the 'legacy' flag to preserve the current behavior in your existing code, see the documentation for `ismember`.

---

**Syntax**

```
TF = ismember(A,B)
[TF,LOCB] = ismember(A,B)
[...] = ismember(A,B,'rows')
[...] = intersect(...,'R2012a')
[...] = intersect(...,'legacy')
```

**Description** `TF = ismember(A,B)` for categorical arrays `A` and `B`, returns a logical array the same size as `A`, containing true (1) where the elements of `A` are in `B`, and false (0) otherwise. `B` can also be a cell array of strings or two-dimensional character array containing level labels.

`[TF,LOCB] = ismember(A,B)` also returns an index array `LOCB` containing the highest absolute index in `B` for each element in `A` which is a member of `B`, and 0 if there is no such index.

`[...] = ismember(A,B,'rows')`, for categorical matrices `A` and `B` with the same number of columns, returns a logical vector containing true (1) where the rows of `A` are also rows of `B`, and false (0) otherwise. The optional output `LOCB` is an index vector containing the highest absolute index in `B` for each row in `A` which is a member of `B` and 0 if there is no such index.

`[...] = intersect(...,'R2012a')` adopts the future behavior of `ismember`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `B`, or 'rows'.

# categorical.ismember

---

[...] = intersect(...,'legacy') preserves the current behavior of ismember. You can specify the flag as the final argument with any previous syntax that accepts A, B, or 'rows'.

## Purpose

Dataset array elements that are members of set

## Syntax

```
LiA = ismember(A,B)  
LiA = ismember(A,B,vars)  
[LiA,LocB] = ismember( ___ )
```

## Description

`LiA = ismember(A,B)` for dataset arrays `A` and `B` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B`, and 0 (false) otherwise.

`LiA = ismember(A,B,vars)` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B` for the variables specified in `vars` only, and 0 (false) otherwise.

`[LiA,LocB] = ismember( ___ )` also returns a vector the same length as `A` containing the index to the first observation in `B` that corresponds to each observation in `A`, or 0 if there is no such observation. You can use any of the previous input arguments.

## Input Arguments

### A

Query dataset array, containing the observations to be found in `B`.

### B

Set dataset array. When an observation in `A` is found in `B`, for all variables or only those variables specified in `vars`, the corresponding element of `LiA` is 1.

### vars

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating which variables to match observations on in `A` and `B`.

# dataset.ismember

---

## Output Arguments

### LiA

Vector of logical values the same length as A. LiA has value 1 (true) when the corresponding observation in A is present in B. Otherwise, LiA has value 0 (false).

If you specify `vars`, LiA has value 1 when the corresponding observation in A is present in B for the variables in `vars` only.

### LocB

Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in `vars`.

## Examples

### Find Observations That Are Members of a Dataset Array

Load sample data.

```
load('hospital')
B = hospital(1:50,1:5);
```

This set dataset array, B, has 50 observations on 5 variables.

Specify a query dataset array.

```
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

A =

## Concepts

- “Dataset Arrays” on page 2-135

**Purpose** Find dataset array elements with missing values

**Syntax**

```
I = ismissing(ds)  
I = ismissing(ds,Name,Value)
```

**Description** `I = ismissing(ds)` returns a logical array that indicates which elements in the dataset array, `ds`, contain a missing value. By default, `ismissing` recognizes NaN as a missing value in numeric variables, '' as a missing value in string variables, and <undefined> as a missing value in categorical arrays.

- `ds2 = ds(~any(I,2),:)` creates a new dataset array containing only the complete observations in `ds`.
- `ds2 = ds(:,~any(I,1))` creates a new dataset array containing only the variables from `ds` with no missing values.

`I = ismissing(ds,Name,Value)` returns missing value indices with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ds**  
dataset array

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'NumericTreatAsMissing'

# dataset.ismissing

---

Vector of numeric values to treat as missing value indicators in floating point `ds` variables. `ismissing` always treats a NaN value as a missing value.

## 'StringTreatAsMissing'

String or cell array of strings to treat as missing value indicators in string `ds` variables. `ismissing` always treats the empty string '' as a missing value.

## Output Arguments

**I**

Logical array indicating which elements in `ds` contain a missing value. `I` is the same size as `ds`, with value 1 for elements that contain a missing value.

## See Also

`dataset` | `isempty` | `isnanisundefined` | `replaceWithMissing` |

## Related Examples

## Concepts

- “Dataset Arrays” on page 2-135

<b>Purpose</b>	True if categorical array is scalar
<b>Syntax</b>	TF = isscalar(A)
<b>Description</b>	TF = isscalar(A) returns true (1) if the categorical array A is a 1-by-1 matrix, and false (0) otherwise.
<b>See Also</b>	isempty   isvector   size

# categorical.isundefined

---

**Purpose** Test for undefined elements

**Syntax** `I = isundefined(A)`

**Description** `I = isundefined(A)` returns a logical array `I` the same size as the categorical array `A`. `I` is true (1) where the corresponding element of `A` is not assigned to any level. `I` is false (0) where the corresponding element of `A` is assigned to a level.

**Examples** Create and display undefined levels in an ordinal array:

```
A = ordinal([1 2 3 2 1],{'lo','med','hi'})
```

```
A =  
    lo      med      hi      med      lo
```

```
A = droplevels(A,{'med','hi'})
```

```
Warning: OLDLEVELS contains categorical levels that  
were present in A, caused some array elements to  
have undefined levels.
```

```
A =  
    lo <undefined> <undefined> <undefined> lo
```

```
I = isundefined(A)
```

```
I =  
    0     1     1     1     0
```

**See Also** `islevel` | `ismember`

**Purpose** Test handle validity

**Syntax** `tf = isvalid(h)`

**Description** `tf = isvalid(h)` performs an element-wise check for validity on the handle elements of `h`. The result is a logical array of the same dimensions as `h`, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

**See Also** `delete` | `grandstream`

# categorical.isvector

---

**Purpose** True if categorical array is vector

**Syntax** TF = isvector(A)

**Description** TF = isvector(A) returns true (1) if the categorical array A is a 1-by-n or n-by-1 vector, where n >= 0, and false (0) otherwise.

**See Also** isempty | isscalar | size

## gmdistribution.Iters property

---

**Purpose** Number of iterations

**Description** The number of iterations of the algorithm.

---

**Note** This property applies only to gmdistribution objects constructed with `fit`.

---

# iwishrnd

---

**Purpose** Inverse Wishart random numbers

**Syntax**  
`W = wishrnd(Tau,df)`  
`W = wishrnd(Tau,df,DI)`  
`[W,DI] = wishrnd(Tau,df)`

**Description** `W = wishrnd(Tau,df)` generates a random matrix `W` from the inverse Wishart distribution with parameters `Tau` and `df`. The inverse of `W` has the Wishart distribution with covariance matrix `Sigma = inv(Tau)` and with `df` degrees of freedom. `Tau` is a symmetric and positive definite matrix.

`W = wishrnd(Tau,df,DI)` expects `DI` to be the transpose of the inverse of the Cholesky factor of `Tau`, so that  $DI' * DI = inv(Tau)$ , where `inv` is the MATLAB inverse function. `DI` is lower-triangular and the same size as `Tau`. If you call `wishrnd` multiple times using the same value of `Tau`, it is more efficient to supply `DI` instead of computing it each time.

`[W,DI] = wishrnd(Tau,df)` returns `DI` so you can use it as an input in future calls to `wishrnd`.

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter `tau` so that the mean of the output matrix is  $Tau / (df - d - 1)$  where `d` is the dimension of `Tau`.

**See Also** `wishrnd`

**How To** • “Inverse Wishart Distribution” on page B-64

**Purpose**

Jackknife sampling

**Syntax**

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

**Description**

`jackstat = jackknife(jackfun,X)` draws jackknife data samples from the  $n$ -by- $p$  data array `X`, computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of `X` as one data sample, so there are  $n$  data samples. Each of the  $n$  rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with `@`. Row  $i$  of `jackstat` contains the results for the sample consisting of `X` with the  $i$ th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If `X` is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set `'Options'` as a structure you create with `statset`. `jackknife` uses the following field in the structure:

'UseParallel' If true and if a parpool of the Parallel Computing Toolbox is open, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is false, or serial computation.

## Examples

Estimate the bias of the MLE variance estimator of random samples taken from the vector  $y$  using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y, 1);
n = length(y);
bias = -sigma^2 / n % known bias formula
jbias = (n - 1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =
    -0.2500

jbias =
    -0.3378
```

**Purpose**

Jarque-Bera test

**Syntax**

```
h = jbtest(x)
h = jbtest(x,alpha)
h = jbtest(x,alpha,mctol)
[h,p] = jbtest( ___ )
[h,p,jbstat,critval] = jbtest( ___ )
```

**Description**

`h = jbtest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test. The alternative hypothesis is that it does not come from such a distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = jbtest(x,alpha)` returns a test decision for the null hypothesis at the significance level specified by `alpha`.

`h = jbtest(x,alpha,mctol)` returns a test decision based on a  $p$ -value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error less than or equal to `mctol`.

`[h,p] = jbtest( ___ )` also returns the  $p$ -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,jbstat,critval] = jbtest( ___ )` also returns the test statistic `jbstat` and the critical value `critval` for the test.

**Input Arguments****`x` - Sample data**

vector

Sample data for the hypothesis test, specified as a vector. `jbtest` treats NaN values in `x` as missing values and ignores them.

## Data Types

single | double

## alpha - Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If alpha is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use `mctol`.

**Example:** 0.01

## Data Types

single | double

## mctol - Maximum Monte Carlo standard error

nonnegative scalar value

Maximum Monte Carlo standard error for the  $p$ -value,  $p$ , specified as a nonnegative scalar value. If you specify a value for `mctol`, `jbtest` computes a Monte Carlo approximation for  $p$  directly, rather than interpolating into a table of precomputed values. `jbtest` chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for  $p$  less than `mctol`.

If you specify a value for `mctol`, you must also specify a value for alpha. You can specify alpha as `[]` to use the default value of 0.05.

**Example:** 0.0001

## Data Types

single | double

## Output Arguments

## h - Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the  $\alpha$  significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the  $\alpha$  significance level.

**p - p-value**

scalar value in the range (0,1)

$p$ -value of the test, returned as a scalar value in the range (0,1).  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

`jbstest` warns when  $p$  is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use `mctol` to compute a more accurate  $p$ -value.

**jbstat - Test statistic**

nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

**critval - Critical value**

nonnegative scalar value

Critical value for the Jarque-Bera test at the  $\alpha$  significance level, returned as a nonnegative scalar value. If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbstest` looks up the critical value for the test in a table of precomputed values. If you use `mctol`, `jbstest` determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when `jbstat > critval`.

## Examples

### Test for a Normal Distribution

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
h = jbtest(MPG)
```

```
h =
```

```
1
```

The returned value of  $h = 1$  indicates that `jbtest` rejects the null hypothesis at the default 5% significance level.

## Test the Hypothesis at a Different Significance Level

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```
[h,p] = jbtest(MPG,0.01)
```

```
h =
```

```
1
```

```
p =
```

```
0.0022
```

The returned value of  $h = 1$ , and the returned  $p$ -value less than  $\alpha = 0.01$  indicate that `jbtest` rejects the null hypothesis.

## Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact  $p$ -value.

```
[h,p,jbstat,critval] = jbstest(MPG,[],0.0001)
```

```
h =
```

```
    1
```

```
p =
```

```
    0.0022
```

```
jbstat =
```

```
    18.2275
```

```
critval =
```

```
    5.8461
```

The returned value of  $h = 1$  indicates that `jbstest` rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, `jbstat`, is larger than the critical value, `critval`, which indicates rejection of the null hypothesis.

## Definitions

### Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

$$JB = \frac{n}{6} \left( s^2 + \frac{(k-3)^2}{4} \right),$$

where  $n$  is the sample size,  $s$  is the sample skewness, and  $k$  is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

### **Monte Carlo Standard Error**

The Monte Carlo standard error is the error due to simulating the  $p$ -value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\hat{p})(1-\hat{p})}{\text{mcreps}}},$$

where  $\hat{p}$  is the estimated  $p$ -value of the hypothesis test, and  $\text{mcreps}$  is the number of Monte Carlo replications performed. `jbtest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for  $\hat{p}$  less than the value specified for `mctol`.

### **Algorithm**

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see `lillietest`) for small samples. `jbtest`, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

## Concepts

- “Generating Data Using the Pearson System” on page 6-28

# johnsrnd

---

**Purpose** Johnson system random numbers

**Syntax**

```
r = johnsrnd(quantiles,m,n)
r = johnsrnd(quantiles)
[r,type] = johnsrnd(...)
[r,type,coefs] = johnsrnd(...)
```

**Description** `r = johnsrnd(quantiles,m,n)` returns an  $m$ -by- $n$  matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by `quantiles`. `quantiles` is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles  $[-1.5 -0.5 0.5 1.5]$ . In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities  $[0.067 0.309 0.691 0.933]$ . `quantiles` may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

---

**Note** Because `r` is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

---

`r = johnsrnd(quantiles)` returns a scalar value.

`r = johnsrnd(quantiles,m,n,...)` or `r = johnsrnd(quantiles,[m,n,...])` returns an  $m$ -by- $n$ -by-... array.

`[r,type] = johnsrnd(...)` returns the type of the specified distribution within the Johnson system. `type` is 'SN', 'SL', 'SB', or 'SU'. Set `m` and `n` to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- 'SN' — Identity transformation (normal distribution)

- 'SL' — Exponential transformation (lognormal distribution)
- 'SB' — Logistic transformation (bounded)
- 'SU' — Hyperbolic sine transformation (unbounded)

`[r,type,coefs] = johnsrnd(...)` returns coefficients `coefs` of the transformation that defines the distribution. `coefs` is `[gamma, eta, epsilon, lambda]`. If `z` is a standard normal random variable and `h` is one of the transformations defined above, `r = lambda*h((z-gamma)/eta)+epsilon` is a random variate from the distribution type corresponding to `h`.

## Examples

Generate random values with longer tails than a standard normal:

```
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);  
qqplot(r);
```

Generate random values skewed to the right:

```
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);  
qqplot(r);
```

Generate random values that match some sample data well in the right-hand tail:

```
load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;q;quantile(r,normcdf(qnorm))]
ans =
    16.7000    18.2086    19.5376    21.7263
    16.8190    18.2474    19.4492    22.4156
```

Determine the distribution type and the coefficients:

```
[r,type,coefs] = johnsrnd([qnorm;q],0)
r =
    []
type =
    SU
coefs =
    1.0920    0.5829    18.4382    1.4494
```

## How To

- “Johnson System” on page B-66

**Purpose**

Merge observations

**Syntax**

```
C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,va11,param2,va12,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)
```

**Description**

`C = join(A,B)` creates a dataset array `C` by merging observations from the two dataset arrays `A` and `B`. `join` performs the merge by first finding *key variables*, that is, pairs of dataset variables, one in `A` and one in `B`, that share the same name. Each observation in `B` must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from `A`. `join` then uses these key variables to define a many-to-one correspondence between observations in `A` and those in `B`. `join` uses this correspondence to replicate the observations in `B` and combine them with the observations in `A` to create `C`.

`C = join(A,B,keys)` performs the merge using the variables specified by `keys` as the key variables in both `A` and `B`. `keys` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

`C` contains one observation for each observation in `A`. Variables in `C` include all of the variables from `A`, as well as one variable corresponding to each variable in `B` (except for the keys from `B`). If `A` and `B` contain variables with identical names, `join` adds the suffix `'_left'` and `'_right'` to the corresponding variables in `C`.

`C = join(A,B,param1,va11,param2,va12,...)` specifies optional parameter name/value pairs to control how the dataset variables in `A` and `B` are used in the merge. Parameters are:

- `'Keys'` — Specifies the variables to use as keys in both `A` and `B`.
- `'LeftKeys'` — Specifies the variables to use as keys in `A`.

## dataset.join

---

- `'RightKeys'` — Specifies the variables to use as keys in B.

You may provide either the `'Keys'` parameter, or both the `'LeftKeys'` and `'RightKeys'` parameters. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing variable names, or a logical vector. `'LeftKeys'` or `'RightKeys'` must both specify the same number of key variables, and `join` pairs the left and right keys in the order specified.

- `'LeftVars'` — Specifies which variables from A to include in C. By default, `join` includes all variables from A.
- `'RightVars'` — Specifies which variables from B to include in C. By default, `join` includes all variables from B except the key variables.

You can use `'LeftVars'` or `'RightVars'` to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

`[C,IB] = join(...)` returns an index vector `IB`, where `join` constructs C by horizontally concatenating `A(:,LeftVars)` and `B(IB,RightVars)`. `join` can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between A and B, and allow unmatched observations in either A or B.

`C = join(A,B,'Type',TYPE,...)` performs the join operation specified by `TYPE`. `TYPE` is one of `'inner'`, `'leftouter'`, `'rightouter'`, `'fullouter'`, or `'outer'` (which is a synonym for `'fullouter'`). For an inner join, C only contains observations corresponding to a combination of key values that occurred in both A and B. For a left (or right) outer join, C also contains observations corresponding to keys in A (or B) that did not match any in B (or A). Variables in C taken from A (or B) contain null values in those observations. A full outer join is equivalent to a left and right outer join. C contains variables corresponding to the key variables from both A and B, and `join` sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. join sorts the observations in the result C by the key values.

`C = join(A,B, 'Type', TYPE, 'MergeKeys', true, ...)` includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, join creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the 'MergeKeys' parameter to true overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to false is equivalent to not passing in the 'MergeKeys' parameter.

`[C, IA, IB] = join(A,B, 'Type', TYPE, ...)` returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, join constructs C by horizontally concatenating `A(IA, LeftVars)` and `B(IB, RightVars)`. For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

## Examples

Create a dataset array from Fisher's iris data:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)', '%-d'));
iris = dataset({nominal(species), 'species'}, ...
               {meas, 'SL', 'SW', 'PL', 'PW'}, ...
               'ObsNames', NameObs);
```

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```
snames = nominal({'setosa'; 'versicolor'; 'virginica'});
CC = dataset({snames, 'species'}, {[38;108;70], 'cc'})
CC =
    species      cc
```

# dataset.join

---

```
setosa      38
versicolor 108
virginica   70
```

---

Broadcast the data in CC to the rows of iris using the key variable species in each dataset:

```
iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =
```

	species	SL	SW	PL	PW	cc
Obs1	setosa	5.1	3.5	1.4	0.2	38
Obs2	setosa	4.9	3	1.4	0.2	38
Obs51	versicolor	7	3.2	4.7	1.4	108
Obs52	versicolor	6.4	3.2	4.5	1.5	108
Obs101	virginica	6.3	3.3	6	2.5	70
Obs102	virginica	5.8	2.7	5.1	1.9	70

---

Create two datasets and join them using the 'MergeKeys' flag:

```
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
    'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'},[4 5 6 7]',...
    'VarNames',{'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')
```

```
% Join a and b, merging the key values as a single variable  
% in the result.
```

```
coutermerge = join(a,b,'key','Key1','Type','outer',...  
  'MergeKeys',true)
```

```
% Join a and b, retaining only observations whose key  
% values match.
```

```
cinner = join(a,b,'key','Key1','Type','inner',...  
  'MergeKeys',true)
```

```
a =
```

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

```
b =
```

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

```
couter =
```

Key1_left	Var1	Key1_right	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	' '	NaN
' '	NaN	'd'	6
'e'	11	'e'	7

# dataset.join

---

```
'h'          17      ''          NaN
```

```
coutermerge =
```

Key1	Var1	Var2
'a'	1	4
'b'	2	5
'c'	3	NaN
'd'	NaN	6
'e'	11	7
'h'	17	NaN

```
cinner =
```

Key1	Var1	Var2
'a'	1	4
'b'	2	5
'e'	11	7

**Superclasses** NeighborSearcher

**Purpose** Nearest neighbors search using *kd*-tree

**Description** A KDTreeSearcher object represents *k*NN (*k*-nearest neighbor) search using a *kd*-tree. Search objects store information about the data used, the distance metric and parameters, and the maximal number of data points in each leaf node. You cannot create this object for sparse input data. The search performance for this object, compared with the ExhaustiveSearcher object, tends to be better for smaller dimensions (10 or fewer) and worse for larger dimensions. For more information on search objects, see “What Are Search Objects?” on page 16-17.

**Construction** `NS = KDTreeSearcher(X, 'Name', Value)` constructs a *kd*-tree based on *X* and saves the information in a KDTreeSearcher object where rows of *X* correspond to observations and columns correspond to variables. You can use this tree to find neighbors in *X* nearest to the query points. See the following section for optional name/value pairs.

`NS = createns(X, 'NSMethod', 'kdtree', 'Name', Value)` creates a *kd*-tree based on *X* using `createns` and saves the information in a KDTreeSearcher object where rows of *X* correspond to observations and columns correspond to variables. You can use this tree to find neighbors in *X* nearest to the query points. See the following section for optional name/value pairs.

### Name-Value Pair Arguments

KDTreeSearcher and createns accept one or more of the following optional name/value pairs as input:

#### ‘Distance’

A string specifying the default distance metric used when you call the `knnsearch` method.

- 'euclidean' — Euclidean distance (default).
- 'cityblock' — City block distance.

# KDTreeSearcher

---

- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance.

For more information on these distance metrics, see “Distance Metrics” on page 16-9.

## **'p'**

A positive scalar indicating the exponent of the Minkowski distance. This parameter is only valid when `Distance` is 'minkowski'. Default is 2.

## **'BucketSize'**

A positive integer, indicating the maximum number of data points in each leaf node of the *kd*-tree. Default is 50.

## **Properties**

### **X**

A matrix used to create the object

### **Distance**

A string specifying a built-in distance metric that you provide when you create the object. This property is the default distance metric used when you call the `knsearch` method to find nearest neighbors for future query points.

### **DistParameter**

Specifies the additional parameter for the chosen distance metric. The value is:

- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance.
- Otherwise: Empty.

## Methods

<code>knnsearch</code>	Find $k$ -nearest neighbors using KDTreeSearcher object
<code>rangesearch</code>	Find all neighbors within specified distance using object

## Examples

Create a KDTreeSearcher object using the constructor:

```
load fisheriris
x = meas(:,3:4);
kdtreeobj = KDTreeSearcher(x,'distance','minkowski')

kdtreeobj =

    KDTreeSearcher

Properties:
    BucketSize: 50
             X: [150x2 double]
    Distance: 'minkowski'
    DistParameter: 2
```

---

Create a KDTreeSearcher object using createns:

```
load fisheriris
x = meas(:,3:4);
kdtreeobj = createns(x,'NsMethod','kdtree',...
    'distance','minkowski')

kdtreeobj =

    KDTreeSearcher

Properties:
    BucketSize: 50
```

# KDTreeSearcher

---

```
X: [150x2 double]
Distance: 'minkowski'
DistParameter: 2
```

For more in-depth examples using the `knnsearch` method, see the method reference page or see “Classifying Query Data Using `knnsearch`” on page 16-18.

# ProbDistKernel.Kernel property

---

**Purpose** Read-only string specifying name of kernel smoothing function for ProbDistKernel object

**Description** Kernel is a read-only property of the ProbDistKernel class. Kernel is a string specifying the name of the kernel smoothing function used to create a ProbDistKernel object.

**Values**

- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

Use this information to view and compare the kernel smoothing function used to create distributions.

**See Also** [ksdensity](#)

# prob.KernelDistribution

---

**Superclasses** TruncatableDistribution

**Purpose** Kernel probability distribution object

**Description** `prob.KernelDistribution` is an object consisting of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution. Create a `prob.KernelDistribution` object using `fitdist` or `dfittool`.

**Construction** `pd = fitdist(x,'Kernel')` creates a probability distribution object by fitting a kernel-smoothing distribution to the data in `x`.

`pd = fitdist(x,'Kernel',Name,Value)` creates a probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can change the kernel function or specify the kernel bandwidth.

## Input Arguments

### **x - Input data**

column vector

Input data to fit with a kernel-smoothing distribution, specified as a column vector of scalar values. `fitdist` ignores NaN values in `x`.

### **Data Types**

single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **Kernel - Kernel smoother type**

'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following kernel smoothing function types:

- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

### Support - Kernel density support

'unbounded' (default) | 'positive' | two-element vector

Kernel density support, specified as the comma-separated pair consisting of 'Support' and a string or two-element vector. The string must be one of the following.

'unbounded'	Density can extend over the whole real line.
'positive'	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

### Data Types

single | double

### Width - Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes.

# prob.KernelDistribution

---

## Data Types

single | double

## Properties

### Kernel

Kernel function type, stored as a valid kernel function type name.

### BandWidth

Bandwidth of the kernel smoothing window, stored as a positive scalar value.

## Data Types

single | double

### DistributionName

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

### InputData

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

single | double

### IsTruncated

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated.

If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

<code>mean</code>	Mean of probability distribution object
<code>negloglik</code>	Negative loglikelihood
<code>std</code>	Standard deviation of probability distribution object
<code>var</code>	Variance of probability distribution object

## Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object
<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
<code>iqr</code>	Interquartile range of probability distribution object
<code>median</code>	Median of probability distribution object

# prob.KernelDistribution

---

pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object

## Definitions Kernel Distribution

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.

Option	Description	Possible Values
Kernel	Kernel function type	normal, box, triangle, epanechnikov
BandWidth	Kernel smoothing parameter	BandWidth > 0

The kernel density estimator is

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right) ; \quad -\infty < x < \infty ,$$

where  $n$  is the sample size,  $K(\square)$  is the kernel function, and  $h$  is the bandwidth.

## Examples Fit a Kernel Distribution Object to Data

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital;  
hist(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.

```
pd_kernel = fitdist(hospital.Weight, 'Kernel')
```

```
pd_kernel =
```

# prob.KernelDistribution

---

```
KernelDistribution

Kernel = normal
Bandwidth = 14.3792
Support = unbounded
```

For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.

```
pd_normal = fitdist(hospital.Weight, 'Normal')
```

```
pd_normal =
```

```
NormalDistribution

Normal distribution
mu = 154 [148.728, 159.272]
sigma = 26.5714 [23.3299, 30.8674]
```

Define the x values and compute the pdf of each distribution.

```
x = 50:1:250;
pdf_kernel = pdf(pd_kernel,x);
pdf_normal = pdf(pd_normal,x);
```

Plot the pdf of each distribution.

```
plot(x,pdf_kernel,'Color','b','LineWidth',2);
hold on;
plot(x,pdf_normal,'Color','r','LineStyle',':', 'LineWidth',2);
legend('Kernel Distribution','Normal Distribution','Location','SouthEast');
hold off;
```

Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

- Class Attributes
- Property Attributes

# ClassificationPartitionedEnsemble.kfoldEdge

---

**Purpose** Classification edge for observations not used for training

**Syntax**  
E = kfoldEdge(obj)  
E = kfoldEdge(obj,Name,Value)

**Description** E = kfoldEdge(obj) returns classification edge (average classification margin) obtained by cross-validated classification ensemble obj. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

E = kfoldEdge(obj,Name,Value) calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

**Input Arguments**

**ens**  
Object of class ClassificationPartitionedEnsemble. Create ens with fitensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create ens from a classification ensemble with crossval.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### **'folds'**

Indices of folds ranging from 1 to ens.KFold. Use only these folds for predictions.

**Default:** 1:ens.KFold

### **'mode'**

# ClassificationPartitionedEnsemble.kfoldEdge

---

String representing the meaning of the output `edge`:

- 'average' — `edge` is a scalar value, the average over all folds.
- 'individual' — `edge` is a vector of length `ens.KFold` with one element per fold.
- 'cumulative' — `edge` is a vector of length `min(ens.NTrainedPerFold)` in which element `J` is obtained by averaging values across all folds for weak learners `1:J` in each fold.

**Default:** 'average'

## Output Arguments

**E**

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

# ClassificationPartitionedEnsemble.kfoldEdge

---

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Compute the k-fold edge for an ensemble trained on the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
E = kfoldEdge(cvens)
```

```
E =
    3.2078
```

# ClassificationPartitionedModel.kfoldEdge

---

- 'individual' — edge is a vector of length `obj.KFold` with one element per fold.

**Default:** 'average'

## Output Arguments

**E**

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are the class probabilities in `obj.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`. A high value of margin indicates a more reliable prediction than a low value.

### Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

### Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

# ClassificationPartitionedModel.kfoldEdge

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

1

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

2

Prune the tree:

```
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')
```

# ClassificationPartitionedModel.kfoldEdge

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

### 3

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0    1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0    1.0000    0.0975  
    0.9059    0.0941    0.2785
```

```
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Compute the k-fold edge for a model trained on the Fisher iris data:

```
load fisheriris
tree = ClassificationTree.fit(meas,species);
cvtree = crossval(tree);
E = kfoldEdge(cvtree)
```

```
E =
    0.8711
```

## See Also

```
kfoldPredict | kfoldMargin | kfoldLoss | kfoldfun
| crossval | ClassificationPartitionedEnsemble |
ClassificationPartitionedModel
```

# ClassificationPartitionedModel.kfoldfun

---

**Purpose** Cross validate function

**Syntax** `vals = kfoldfun(obj,fun)`

**Description** `vals = kfoldfun(obj,fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `obj`. You must pass `fun` as a function handle.

## Input Arguments

### **obj**

Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

### **fun**

A function handle for a cross-validation function. `fun` has the syntax

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the `obj.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` must have the same size across all folds.

## Output Arguments

### **vals**

The arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold-by-N` numeric matrix with one row per fold.

## Examples

Cross validate a classification tree, and obtain the classification error (see `kfoldLoss`):

```
load fisheriris
t = ClassificationTree.fit(meas,species);
rng(0,'twister') % for reproducibility
cv = crossval(t);
L = kfoldLoss(cv)
```

```
L =
    0.0467
```

Examine the result when the error of misclassifying a flower as 'versicolor' is 10, and any other error is 1:

- 1 Write a function file that gives a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)

Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % total differences
averageCost = cost/numel(Ytest); % average error
```

- 2 Save the file as `noversicolor.m` on your MATLAB path.
- 3 Compute the mean misclassification error with the `noversicolor` cost:

```
mean(kfoldfun(cv,@noversicolor))

ans =
    0.1667
```

# ClassificationPartitionedModel.kfoldfun

---

## See Also

`kfoldMargin` | `kfoldLoss` | `crossval`

# RegressionPartitionedModel.kfoldfun

---

## Purpose

Cross validate function

## Syntax

```
vals = kfoldfun(obj,fun)
```

## Description

`vals = kfoldfun(obj,fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `obj`. You must pass `fun` as a function handle.

## Input Arguments

### **obj**

Object of class `RegressionPartitionedModel` or `RegressionPartitionedEnsemble`. Create `obj` with `RegressionTree.fit` or `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

### **fun**

A function handle for a cross-validation function. `fun` has the syntax

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the `obj.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` must have the same size across all folds.

# RegressionPartitionedModel.kfoldfun

---

## Output Arguments

### vals

The arrays of testvals output, concatenated vertically over all folds. For example, if testvals from every fold is a numeric vector of length N, kfoldfun returns a KFold-by-N numeric matrix with one row per fold.

## Examples

Cross validate a regression tree, and obtain the mean squared error (see kfoldLoss):

```
load imports-85
t = RegressionTree.fit(X(:,[4 5]),X(:,16),...
    'predictorname',{'length' 'width'},...
    'response', 'price');
cv = crossval(t);
L = kfoldLoss(cv)
```

```
L =
    1.5489e+007
```

Examine the result of simple averaging of responses instead of using predictions:

```
f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
mean(kfoldfun(cv,f))

ans =
    6.3497e+007
```

# ClassificationPartitionedEnsemble.kfoldLoss

---

## Purpose

Classification loss for observations not used for training

## Syntax

```
L = kfoldLoss(ens)
L = kfoldLoss(ens,Name,Value)
```

## Description

`L = kfoldLoss(ens)` returns loss obtained by cross-validated classification model `ens`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### **ens**

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'folds'**

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

**Default:** `1:ens.KFold`

### **'lossfun'**

# ClassificationPartitionedEnsemble.kfoldLoss

---

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-1538
- 'classiferror' — Fraction of misclassified data
- 'exponential' — See “Loss Functions” on page 21-1538

You can write your own loss function in the syntax described in “Loss Functions” on page 21-1538.

**Default:** 'classiferror'

## **'mode'**

A string for determining the output of `kfoldLoss`:

- 'average' — `L` is a scalar, the loss averaged over all folds.
- 'individual' — `L` is a vector of length `ens.KFold`, where each entry is the loss for a fold.
- 'cumulative' — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

**Default:** 'average'

## **Output Arguments**

**L**

Loss, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

## **Definitions**

### **Loss Functions**

The built-in loss functions are:

# ClassificationPartitionedEnsemble.kfoldLoss

---

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by  $w$ .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of `ens.X`.
- $K$  is the number of classes in `ens`, represented in `ens.ClassNames`.
- $C$  is an  $N$ -by- $K$  logical matrix, with one `true` per row for the true class. The index for each class is its position in `tree.ClassNames`.
- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the `score` output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

# ClassificationPartitionedEnsemble.kfoldLoss

---

## Examples

Find the average cross-validated classification error for an ensemble model of the ionosphere data:

```
load ionosphere
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L =
    0.0826
```

## See Also

[kfoldPredict](#) | [kfoldEdge](#) | [kfoldMargin](#) | [kfoldfun](#) | [crossval](#)

# ClassificationPartitionedModel.kfoldLoss

---

## Purpose

Classification loss for observations not used for training

## Syntax

```
L = kfoldLoss(obj)
L = kfoldLoss(obj,Name,Value)
```

## Description

`L = kfoldLoss(obj)` returns loss obtained by cross-validated classification model `obj`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(obj,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### **obj**

Object of class `ClassificationPartitionedModel`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'folds'**

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

**Default:** `1:obj.KFold`

### **'lossfun'**

Function handle or string representing a loss function. Built-in loss functions:

# ClassificationPartitionedModel.kfoldLoss

---

- 'binodeviance' — See “Loss Functions” on page 21-1543.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-1543.
- 'exponential' — See “Loss Functions” on page 21-1543.
- 'mincost' — Smallest misclassification cost as given by the `obj.Cost` matrix. See “Loss Functions” on page 21-1543.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-1543.

**Default:** 'mincost'

## 'mode'

A string for determining the output of `kfoldLoss`:

- 'average' —  $L$  is a scalar, the loss averaged over all folds.
- 'individual' —  $L$  is a vector of length `obj.KFold`, where each entry is the loss for a fold.

**Default:** 'average'

## Output Arguments

**L**

Loss, by default the fraction of misclassified data.  $L$  can be a vector, and can mean different things, depending on the name-value pair settings.

## Definitions

### Classification Error

The default classification error is the fraction of the data  $X$  that `obj` misclassifies, where  $Y$  are the true classifications.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `obj` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the Cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of X.
- K is the number of classes in the classifier, represented in the ClassNames property.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.
- S is an N-by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.

# ClassificationPartitionedModel.kfoldLoss

---

- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use  $COST = \text{ones}(K) - \text{eye}(K)$ , which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Find the average cross-validated classification error for a model of the ionosphere data:

```
load ionosphere
tree = ClassificationTree.fit(X,Y);
cvtree = crossval(tree);
L = kfoldLoss(cvtree)
```

```
L =
    0.1197
```

## How To

- “Examine the Quality of a KNN Classifier” on page 16-27

# RegressionPartitionedEnsemble.kfoldLoss

---

## Purpose

Cross-validation loss of partitioned regression ensemble

## Syntax

```
L = kfoldLoss(cvens)
L = kfoldLoss(cvens,Name,Value)
```

## Description

`L = kfoldLoss(cvens)` returns the cross-validation loss of `cvens`.

`L = kfoldLoss(cvens,Name,Value)` returns cross-validation loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### `cvens`

Object of class `RegressionPartitionedEnsemble`. Create `obj` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression ensemble with `crossval`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'folds'**

Indices of folds ranging from 1 to `cvens.KFold`. Use only these folds for predictions.

**Default:** `1:cvens.KFold`

### **'lossfun'**

# RegressionPartitionedEnsemble.kfoldLoss

---

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

**Default:** 'mse'

## 'mode'

String representing the meaning of the output `L`:

- 'ensemble' — `L` is a scalar value, the loss for the entire ensemble.
- 'individual' — `L` is a vector with one element per trained learner.
- 'cumulative' — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

**L**

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

## Examples

Find the cross-validation loss for a regression ensemble of the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSboost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

```
L =
    25.6935
```

## See Also

# RegressionPartitionedModel.kfoldLoss

---

**Purpose** Cross-validation loss of partitioned regression model

**Syntax**  
L = kfoldLoss(cvmodel)  
L = kfoldLoss(cvmodel,Name,Value)

**Description** L = kfoldLoss(cvmodel) returns the cross-validation loss of cvmodel.  
L = kfoldLoss(cvmodel,Name,Value) returns cross-validation loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ,NameN,ValueN.

**Input Arguments**

**cvmodel**  
Object of class RegressionPartitionedModel. Create obj with RegressionTree.fit along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create obj from a regression tree with crossval.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

### **'folds'**

Indices of folds ranging from 1 to obj.KFold. Use only these folds for predictions.

**Default:** 1:obj.KFold

### **'lossfun'**

# RegressionPartitionedModel.kfoldLoss

---

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle `fun`, `kfoldLoss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

**Default:** 'mse'

## 'mode'

One of the following strings:

- 'average' — `L` is the average loss over all folds.
- 'individual' — `L` is a vector of the individual losses of in-fold observations trained on out-of-fold data.

**Default:** 'average'

## Output Arguments

**L**

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If `mode` is 'individual', `L` is a vector of the losses. If `mode` is 'average', `L` is the average loss.

## Examples

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

```
load carsmall
```

# RegressionPartitionedModel.kfoldLoss

---

```
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = RegressionTree.fit(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')
```

```
L =
    44.9635
    11.8525
    18.2046
     9.2965
    29.4329
    54.8659
    24.6446
     8.2085
    19.7593
    16.7394
```

## Alternatives

You can avoid constructing a cross-validated tree model by calling `cvLoss` instead of `kfoldLoss`. The cross-validated tree can save time if you are going to examine it more than once.

# ClassificationPartitionedModel.kfoldMargin

---

<b>Purpose</b>	Classification margins for observations not used for training
<b>Syntax</b>	<code>M = kfoldMargin(obj)</code>
<b>Description</b>	<code>M = kfoldMargin(obj)</code> returns classification margins obtained by cross-validated classification model <code>obj</code> . For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.
<b>Input Arguments</b>	<b>obj</b> A partitioned classification model of type <code>ClassificationPartitionedModel</code> or <code>ClassificationPartitionedEnsemble</code> .
<b>Output Arguments</b>	<b>M</b> The classification margin.
<b>Definitions</b>	<b>Margin</b> The classification <i>margin</i> is the difference between the classification <i>score</i> for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix <code>Obj.X</code> . A high value of margin indicates a more reliable prediction than a low value. <b>Score (discriminant analysis)</b> For discriminant analysis, the <i>score</i> of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7. <b>Score (ensemble)</b> For ensembles, a classification <i>score</i> represents the confidence of a classification into a class. The higher the score, the higher the confidence.

# ClassificationPartitionedModel.kfoldMargin

---

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

1

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

# ClassificationPartitionedModel.kfoldMargin

2

Prune the tree:

```
tree1 = prune(tree, 'level', 1);  
view(tree1, 'mode', 'graph')
```

# ClassificationPartitionedModel.kfoldMargin

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

### 3

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0    1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0    1.0000    0.0975  
    0.9059    0.0941    0.2785
```

# ClassificationPartitionedModel.kfoldMargin

---

```
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649
```

Indeed, every value of X (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

## Examples

Find the k-fold margins for an ensemble that classifies the ionosphere data:

```
load ionosphere
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
cvens = crossval(ens);
M = kfoldMargin(cvens);
[min\(M\) mean\(M\) max\(M\)]

ans =
    -7.6394     7.3469    22.4833
```

## See Also

# ClassificationPartitionedModel.kfoldPredict

---

**Purpose** Predict response for observations not used for training

**Syntax**

```
label = kfoldPredict(obj)
[label,score] = kfoldPredict(obj)
[label,score,cost] = kfoldPredict(obj)
```

**Description** `label = kfoldPredict(obj)` returns class labels predicted by `obj`, a cross-validated classification. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations.

`[label,score] = kfoldPredict(obj)` returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.

`[label,score,cost] = kfoldPredict(obj)` returns misclassification costs.

## Input Arguments

**obj**  
Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

## Output Arguments

**label**  
Vector of class labels of the same type as the response data used in training `obj`. Each entry of `label` corresponds to a predicted class label for the corresponding row of `X`.

**score**  
Numeric matrix of size N-by-K, where N is the number of observations (rows) in `obj.X`, and K is the number of classes (in `obj.ClassNames`). `score(i,j)` represents the confidence that row `i` of `obj.X` is of class `j`. For details, see “Definitions” on page 21-1557.

**cost**

Numeric matrix of misclassification costs of size N-by-K.  $\text{cost}(i, j)$  is the average misclassification cost of predicting that row  $i$  of  $\text{obj.X}$  is of class  $j$ .

## Definitions

### Cost (discriminant analysis)

The *average misclassification cost* is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in “Cost” on page 15-8.

### Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

### Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

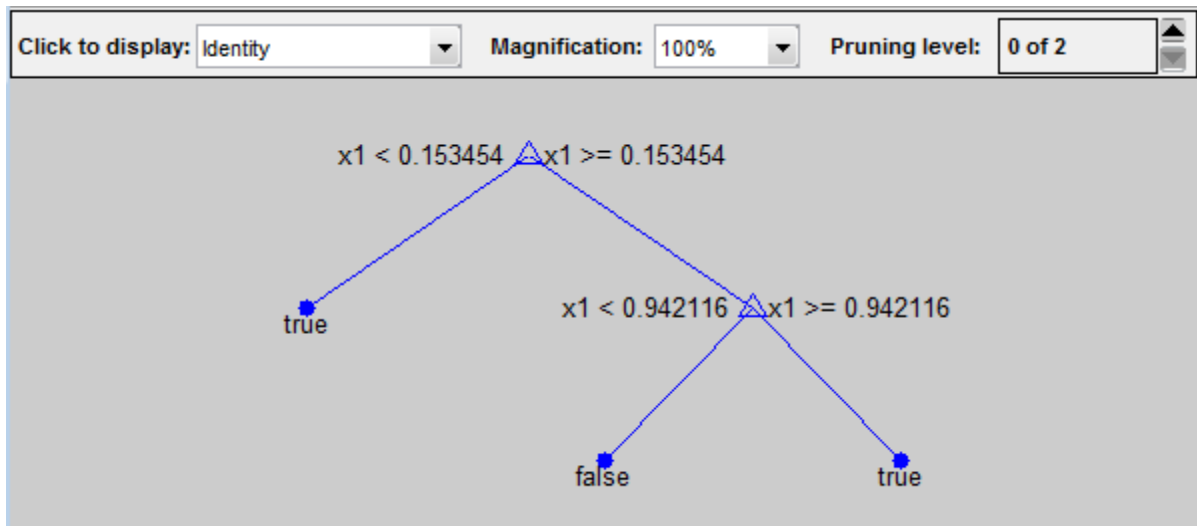

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

# ClassificationPartitionedModel.kfoldPredict

1

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

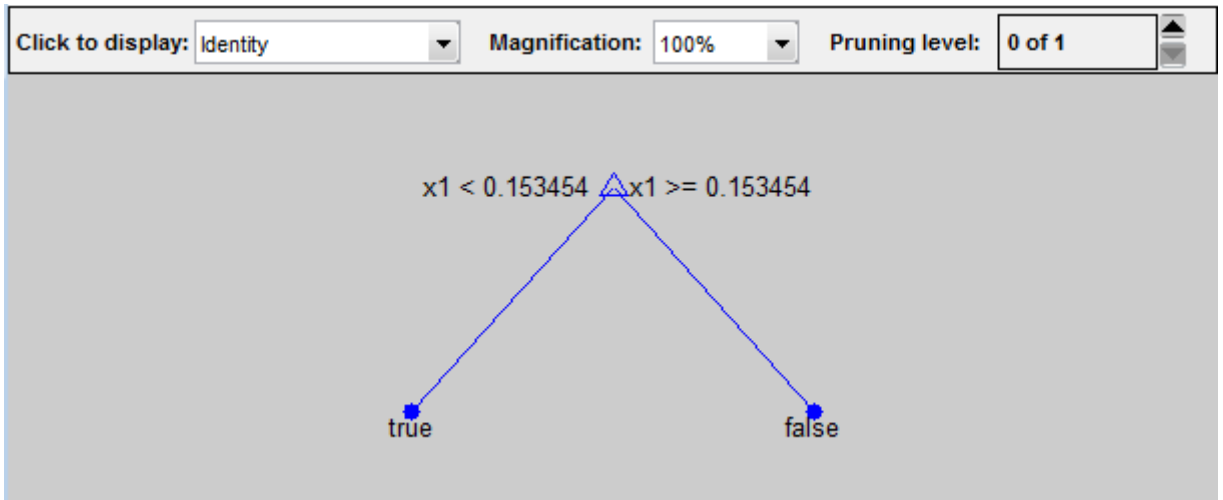

2

Prune the tree:

```
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')
```

# ClassificationPartitionedModel.kfoldPredict

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

### 3

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0    1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0    1.0000    0.0975  
    0.9059    0.0941    0.2785
```

# ClassificationPartitionedModel.kfoldPredict

---

```
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range (.95, 1) instead of the expected 5 observations.

## Examples

Find the cross-validation predictions for a model based on the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
[elabel escore] = kfoldPredict(cvens);
max(escore)
```

```
ans =
    9.3634    8.5624    9.3981
```

```
min(escore)
```

```
ans =
    0.0017    3.7518    0.8911
```

## See Also

[ClassificationPartitionedModel](#) | [kfoldEdge](#) | [kfoldMargin](#) | [kfoldLoss](#) | [kfoldfun](#) | [crossval](#)

# RegressionPartitionedModel.kfoldPredict

---

## Purpose

Predict response for observations not used for training.

## Syntax

```
yfit = kfoldPredict(obj)
```

## Description

`yfit = kfoldPredict(obj)` returns the predicted values for the responses of the training data based on `obj`, an object trained on out-of-fold observations.

## Input Arguments

### **obj**

Object of class `RegressionPartitionedModel`. Create `obj` with `RegressionTree.fit` or `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

## Output Arguments

### **yfit**

A vector of predicted values for the response data based on a model trained on out-of-fold observations.

## Examples

Construct a partitioned regression model, and examine the cross-validation loss. The cross-validation loss is the mean squared error between `yfit` and the true response data:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
tree = RegressionTree.fit(XX,YY);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)

L =
    26.5271

yfit = kfoldPredict(cvmodel);
mean( (yfit - tree.Y).^2 )
```

# RegressionPartitionedModel.kfoldPredict

---

```
ans =  
  26.5271
```

**See Also**      `kfoldLoss`

**Purpose**

*K*-means clustering

**Syntax**

```
IDX = kmeans(X,k)
[IDX,C] = kmeans(X,k)
[IDX,C,sumd] = kmeans(X,k)
[IDX,C,sumd,D] = kmeans(X,k)
[...] = kmeans(...,param1,val1,param2,val2,...)
```

**Description**

`IDX = kmeans(X,k)` partitions the points in the *n*-by-*p* data matrix *X* into *k* clusters. This iterative partitioning minimizes the sum, over all clusters, of the within-cluster sums of point-to-cluster-centroid distances. Rows of *X* correspond to points, columns correspond to variables. `kmeans` returns an *n*-by-1 vector `IDX` containing the cluster indices of each point. By default, `kmeans` uses squared Euclidean distances. When *X* is a vector, `kmeans` treats it as an *n*-by-1 data matrix, regardless of its orientation.

`[IDX,C] = kmeans(X,k)` returns the *k* cluster centroid locations in the *k*-by-*p* matrix `C`.

`[IDX,C,sumd] = kmeans(X,k)` returns the within-cluster sums of point-to-centroid distances in the 1-by-*k* vector `sumd`.

`[IDX,C,sumd,D] = kmeans(X,k)` returns distances from each point to every centroid in the *n*-by-*k* matrix `D`.

`[...] = kmeans(...,param1,val1,param2,val2,...)` enables you to specify optional parameter/value pairs to control the iterative algorithm used by `kmeans`. Valid parameter strings are listed in the following table.

# kmeans

---

Parameter	Value
'distance'	Distance measure, in p-dimensional space. kmeans minimizes with respect to this parameter. kmeans computes centroid clusters differently for the different supported distance measures.
	'sqEuclidean' Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.
	'cityblock' Sum of absolute differences, i.e., the L1 distance. Each centroid is the component-wise median of the points in that cluster.
	'cosine' One minus the cosine of the included angle between points (treated as vectors). Each centroid is the mean of the points in that cluster, after normalizing those points to unit Euclidean length.
	'correlation' One minus the sample correlation between points (treated as sequences of values). Each centroid is the component-wise mean of the points in that cluster, after centering and normalizing those points to zero mean and unit standard deviation.
	'Hamming' Percentage of bits that differ (only suitable for binary data). Each centroid is the component-wise median of points in that cluster.

Parameter	Value	
'emptyaction'	Action to take if a cluster loses all its member observations.	
	'error'	Treat an empty cluster as an error (default).
	'drop'	Remove any clusters that become empty. kmeans sets the corresponding return values in C and D to NaN.
	'singleton'	Create a new cluster consisting of the one point furthest from its centroid.
'onlinephase'	Flag indicating whether kmeans should perform an online update phase in addition to a batch update phase. The online phase can be time consuming for large data sets, but guarantees a solution that is a local minimum of the distance criterion, that is, a partition of the data where moving any single point to a different cluster increases the total sum of distances.	
	'on'	Perform online update (default).
	'off'	Do not perform online update.

# kmeans

Parameter	Value
'options'	Structure specifying options for the iterative algorithm used to minimize the fitting criteria. Create the options structure with <code>statset</code> . Applicable <code>statset</code> parameters are:
Display	Level of display output. Choices are <code>'off'</code> (default), <code>'iter'</code> , and <code>'final'</code> .
MaxIter	Maximum number of iterations allowed. The default is 100.
UseParallel	If true and if a <code>parpool</code> of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel Computing Toolbox is not installed, or a <code>parpool</code> is not open, computation occurs in serial mode. Default is <code>default</code> , meaning serial computation.
UseSubstreams	Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .
Streams	A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code> , <code>kmeans</code> uses the default stream or streams. If you choose to specify <code>Streams</code> , use a single object except in the case: <ul style="list-style-type: none"><li>• You have an open Parallel pool</li><li>• <code>UseParallel</code> is true</li></ul>

Parameter	Value	
	<ul style="list-style-type: none"> <li>UseSubstreams is false</li> </ul> <p>In that case, use a cell array the same size as the Parallel pool. If a Parallel pool is not open, then Streams must supply a single random number stream.</p>	
'replicates'	Number of times to repeat the clustering, each with a new set of initial cluster centroid positions. kmeans returns the solution with the lowest value for sumd. You can supply 'replicates' implicitly by supplying a 3D array as the value for the 'start' parameter.	
'start'	Method used to choose the initial cluster centroid positions, sometimes known as <i>seeds</i> .	
	'sample'	Select k observations from X at random (default).
	'uniform'	Select k points uniformly at random from the range of X. Not valid with Hamming distance.
	'cluster'	Perform a preliminary clustering phase on a random 10% subsample of X. This preliminary phase is itself initialized using 'sample'.
	Matrix	k-by-p matrix of centroid starting locations. In this case, you can pass in [ ] for k, and kmeans infers k from the first dimension of the matrix. You can also supply a 3-D array, implying a value for the

# kmeans

---

Parameter	Value
	'replicates' parameter from the array's third dimension.

## Algorithms

kmeans uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all k clusters:

- 1** The first phase uses *batch updates*, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum, that is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.
- 2** The second phase uses *online updates*, where points are individually reassigned if doing so will reduce the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during the second phase consists of one pass though all the points. The second phase will converge to a local minimum, although there may be other local minima with lower total sum of distances. The problem of finding the global minimum can only be solved in general by an exhaustive (or clever, or lucky) choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.

**Examples**

The following creates two clusters from separated random data:

```
X = [randn(100,2)+ones(100,2);...
      randn(100,2)-ones(100,2)];
opts = statset('Display','final');

[idx,ctrs] = kmeans(X,2,...
                   'Distance','city',...
                   'Replicates',5,...
                   'Options',opts);
5 iterations, total sum of distances = 284.671
4 iterations, total sum of distances = 284.671
4 iterations, total sum of distances = 284.671
3 iterations, total sum of distances = 284.671
3 iterations, total sum of distances = 284.671

plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',12)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',12)
plot(ctrs(:,1),ctrs(:,2),'kx',...
      'MarkerSize',12,'LineWidth',2)
plot(ctrs(:,1),ctrs(:,2),'ko',...
      'MarkerSize',12,'LineWidth',2)
legend('Cluster 1','Cluster 2','Centroids',...
      'Location','NW')
```

# kmeans

[linkage](#) | [clusterdata](#) | [silhouette](#)

**Purpose** Find  $k$ -nearest neighbors using ExhaustiveSearcher object

**Syntax**

```
IDX = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y, 'Name', Value)
```

**Description** `IDX = knnsearch(NS,Y)` finds the nearest neighbor (closest point) in `NS.X` for each point in `Y`. Rows of `Y` correspond to observations and columns correspond to features. `Y` must have the same number of columns as `NS.X`. `IDX` is a column vector with  $n_y$  rows, where  $n_y$  is the number of rows in `Y`. Each row in `IDX` contains the index of observation in `NS.X` which has the smallest distance to the corresponding observation in `Y`.

`[IDX,D] = knnsearch(NS,Y)` returns a column vector `D` containing the distances between each observation in `Y` and the corresponding closest observation in `NS.X`. That is, `D(i)` is the distance between `NS.X(IDX(i),:)` and `Y(i,:)`.

`[IDX,D] = knnsearch(NS,Y, 'Name', Value)` accepts one or more comma-separated argument name/value pairs. Specify *Name* inside single quotes.

## Input Arguments

### Name-Value Pair Arguments

#### 'K'

A positive integer,  $k$ , specifying the number of nearest neighbors in `NS.X` for each point in `Y`. Default is 1. `IDX` and `D` are  $n_y$ -by- $k$  matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the  $k$  closest neighbors in `NS.X` corresponding to the  $k$  smallest distances in `D`.

#### 'IncludeTies'

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the  $K$ th smallest distance. If `IncludeTies` is `true`, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are  $n_y$ -by-1 cell arrays. Each

# ExhaustiveSearcher.knnsearch

---

row in `IDX` and `D` contains a vector with at least `K` numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

**Default:** `false`

## 'Distance'

- `'euclidean'` — Euclidean distance (default).
- `'seuclidean'` — Standardized Euclidean distance. Each coordinate difference between `X` and each query point is scaled by dividing by a scale value `S`. The default value of `S` is `NS.DistanceParameter` if `NS.Distance` is `'seuclidean'`, otherwise the default is the standard deviation computed from `X`, `S=nanstd(X)`. To specify another value for `S`, use the `'Scale'` argument.
- `'cityblock'` — City block distance.
- `'chebychev'` — Chebychev distance (maximum coordinate difference).
- `'minkowski'` — Minkowski distance.
- `'mahalanobis'` — Mahalanobis distance, which is computed using a positive definite covariance matrix `C`. The default value of `C` is `nancov(X)`. To change the value of `C`, use the `Cov` parameter.
- `'cosine'` — One minus the cosine of the included angle between observations (treated as vectors).
- `'correlation'` — One minus the sample linear correlation between observations (treated as sequences of values).
- `'spearman'` — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

- 'hamming' — Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using @ (for example, @distfun). A distance function must be of the form function D2 = distfun(ZI, ZJ), taking as arguments a 1-by- $n$  vector ZI containing a single row of from X or from the query points Y, an  $m2$ -by- $n$  matrix ZJ containing multiple rows of X or Y, and returning an  $m2$ -by-1 vector of distances D2, whose  $j$ th element is the distance between the observations ZI and ZJ( $j$ ,:).

Default is NS.Distance. For more information on these distance metrics, see “Distance Metrics” on page 16-9.

## **'p'**

A positive scalar,  $p$ , indicating the exponent of the Minkowski distance. This parameter is only valid if knnsearch uses the 'minkowski' distance metric. Default is NS.Distance if NS.Distance is 'minkowski' and 2 otherwise.

## **'Cov'**

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when knnsearch uses the 'mahalanobis' distance metric. Default is NS.Distance if NS.Distance is 'mahalanobis', or nancov(X) otherwise.

## **'Scale'**

A vector S with the length equal to the number of columns in X. Each coordinate of X and each query point is scaled by the corresponding element of S when computing the standardized Euclidean distance. This parameter is only valid when Distance is 'seuclidean'. Default is nanstd(X).

# ExhaustiveSearcher.knnsearch

---

## Examples

Create an ExhaustiveSearcher object specifying 'cosine' as the distance metric. Perform a  $k$ -nearest neighbors search on the object using the mahalanobis metric and compare the results:

```
load fisheriris
x = meas(:,3:4);
exhaustiveobj = ExhaustiveSearcher(x,'Distance','cosine')

exhaustiveobj =

    ExhaustiveSearcher

    Properties:
        X: [150x2 double]
        Distance: 'cosine'
        DistParameter: []

% Perform a knnsearch between x and a query point, using
% first cosine then mahalanobis distance metrics:
newpoint = [5 1.45];
[n,d]=knnsearch(exhaustiveobj,newpoint,'k',10);
[nmah,dmah] = knnsearch(exhaustiveobj,newpoint,'k',10,...
    'distance','mahalanobis');

% Visualize the results of the two different nearest
% neighbors searches:

% First plot the training data:
gscatter(x(:,1),x(:,2),species)
% Plot an X for the query point:
line(newpoint(1),newpoint(2),'marker','x','color','k',...
    'markersize',10,'linewidth',2,'linestyle','none')
% Use circles to denote the cosine nearest neighbors:
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
    'linestyle','none','markersize',10)
% Use pentagrams to denote the mahalanobis nearest neighbors:
line(x(nmah,1),x(nmah,2),'color',[.5 .5 .5],'marker','p',...
```

```
'linestyle','none','markersize',10)  
legend('setosa','versicolor','virginica','query point',...  
       'cosine','mahalanobis')  
set(legend,'location','best')
```

## Algorithms

For information on a specific search algorithm, see “Distance Metrics” on page 16-9.

## How To

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-12

# ExhaustiveSearcher.knnsearch

---

- “Distance Metrics” on page 16-9

## Purpose

Find  $k$ -nearest neighbors using KDTreeSearcher object

## Syntax

```
IDX = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y,'Name',Value)
```

## Description

IDX = knnsearch(NS,Y) finds the nearest neighbor (closest point) in NS.X for each point in Y. Rows of Y correspond to observations and columns correspond to features. Y must have the same number of columns as NS.X. IDX is a column vector with  $n_y$  rows, where  $n_y$  is the number of rows in Y. Each row in IDX contains the index of observation in NS.X which has the smallest distance to the corresponding observation in Y.

[IDX,D] = knnsearch(NS,Y) returns a column vector D containing the distances between each observation in Y and the corresponding closest observation in NS.X. That is, D(i) is the distance between NS.X(IDX(i),:) and Y(i,:).

[IDX,D] = knnsearch(NS,Y,'Name',Value) accepts one or more comma-separated name/value pairs. Specify *Name* inside single quotes.

## Input Arguments

### Name-Value Pair Arguments

#### 'K'

A positive integer,  $k$ , specifying the number of nearest neighbors in NS.X for each point in Y. Default is 1. IDX and D are  $n_y$ -by- $k$  matrices. D sorts the distances in each row in ascending order. Each row in IDX contains the indices of the  $k$  closest neighbors in NS.X corresponding to the  $k$  smallest distances in D.

#### 'Distance'

Select one of the following distance algorithms.

- 'euclidean' — Euclidean distance (default).
- 'cityblock' — City block distance.

# KDTreeSearcher.knnsearch

---

- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance.

Default is `NS.Distance`. For more information on these distance metrics, see “Distance Metrics” on page 16-9.

## 'IncludeTies'

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the  $k$ th smallest distance. If `IncludeTies` is `true`, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are  $n_y$ -by-1 cell arrays. Each row in `IDX` and `D` contains a vector with at least  $K$  numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

**Default:** `false`

## 'P'

A positive scalar,  $p$ , indicating the exponent of the Minkowski distance. This parameter is only valid when the `Distance` is 'minkowski'. Default is `NS.DistanceParameter` if `NS.Distance` is 'minkowski' and 2 otherwise.

## Examples

Create a `KDTreeSearcher` object specifying 'minkowski' as the distance metric with an exponent of 5. Perform a  $k$ -nearest neighbors search on the object using the chebychev metric and compare the results:

```
load fisheriris
x = meas(:,3:4);
kdtreeNS = KDTreeSearcher(x,'Distance','minkowski','P',5)

kdtreeNS =

    KDTreeSearcher
```

```
Properties:
    BucketSize: 50
           X: [150x2 double]
           Distance: 'minkowski'
    DistParameter: 5

% Perform a knnsearch between X and a query point, using
% first Minkowski then Chebychev distance metrics:
newpoint = [5 1.45];
[n,d]=knnsearch(kdtreeNS,newpoint,'k',10);
[ncb,dcb] = knnsearch(kdtreeNS,newpoint,'k',10,...
    'distance','chebychev');

% Visualize the results of the two different nearest
% neighbors searches:

% First plot the training data:
gscatter(x(:,1),x(:,2),species)
% Zoom in on the points of interest:
set(gca,'xlim',[4.5 5.5],'ylim',[1 2]); axis square
% Plot an X for the query point:
line(newpoint(1),newpoint(2),'marker','x','color','k',...
    'markersize',10,'linewidth',2,'linestyle','none')
% Use circles to denote the Minkowski nearest neighbors:
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
    'linestyle','none','markersize',10)
% Use pentagrams to denote the Chebychev nearest neighbors:
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...
    'linestyle','none','markersize',10)
legend('setosa','versicolor','virginica','query point',...
    'minkowski','chebychev')
set(legend,'location','best')
```

## How To

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-12

- “Distance Metrics” on page 16-9

# knnsearch

---

**Purpose** Find  $k$ -nearest neighbors using data

**Syntax**  
`IDX = knnsearch(X,Y)`  
`[IDX,D] = knnsearch(X,Y)`  
`[IDX,D] = knnsearch(X,Y, 'Name', Value)`

**Description** `IDX = knnsearch(X,Y)` finds the nearest neighbor in  $X$  for each point in  $Y$ .  $X$  is an  $m_x$ -by- $n$  matrix and  $Y$  is an  $m_y$ -by- $n$  matrix. Rows of  $X$  and  $Y$  correspond to observations and columns correspond to variables. `IDX` is a column vector with  $m_y$  rows. Each row in `IDX` contains the index of nearest neighbor in  $X$  for the corresponding row in  $Y$ .

`[IDX,D] = knnsearch(X,Y)` returns an  $m_y$ -by-1 vector `D` containing the distances between each observation in  $Y$  and the corresponding closest observation in  $X$ . That is, `D(i)` is the distance between  $X(\text{IDX}(i), :)$  and  $Y(i, :)$ .

`[IDX,D] = knnsearch(X,Y, 'Name', Value)` accepts one or more optional comma-separated name/value pairs. Specify *Name* inside single quotes.

`knnsearch` does not save a search object. To create a search object, use `createns`.

**Tips**

- For a fixed positive integer  $K$ , `knnsearch` finds the  $K$  points in  $X$  that are nearest each point in  $Y$ . In contrast, for a fixed positive real value  $r$ , `rangesearch` finds all the points in  $X$  that are within a distance  $r$  of each point in  $Y$ .

**Input Arguments** **Name-Value Pair Arguments**

**'K'**

Positive integer specifying the number of nearest neighbors in  $X$  for each point in  $Y$ . Default is 1. `IDX` and `D` are  $m_y$ -by- $K$  matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the  $K$  closest neighbors in  $X$  corresponding to the  $K$  smallest distances in `D`.

**'IncludeTies'**

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the *K*th smallest distance. If `IncludeTies` is true, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are *m<sub>y</sub>*-by-1 cell arrays. Each row in `IDX` and `D` contains a vector with at least *K* numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

**Default:** false

**'NSMethod'**

Nearest neighbors search method. Value is either:

- `'kdtree'` — Creates and uses a Kd-tree to find nearest neighbors. This is the default value when the number of columns of *X* is less than 10, *X* is not sparse, and the distance measure is one of the following measures. `'kdtree'` is only valid when the distance measure is one of the following:
  - `'euclidean'`
  - `'cityblock'`
  - `'minkowski'`
  - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm by computing the distance values from all the points in *X* to each point in *Y* to find nearest neighbors.

**'Distance'**

A string or a function handle specifying the distance metric. The value can be one of the following:

- `'euclidean'` — Euclidean distance (default).

- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between rows in  $X$  and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from  $X$ ,  $S = \text{nanstd}(X)$ . To specify another value for  $S$ , use the `Scale` argument.
- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' argument.
- 'mahalanobis' — Mahalanobis distance, computed using a positive definite covariance matrix  $C$ . The default value of  $C$  is  $\text{nancov}(X)$ . To change the value of  $C$ , use the `Cov` parameter.
- 'cosine' — 1 minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' — One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman' — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming' — Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using `@` (for example, `@distfun`). A distance function must be of the form function  $D2 = \text{distfun}(ZI, ZJ)$ , taking as arguments a 1-by- $n$  vector  $ZI$  containing a single row of  $X$  or  $Y$ , an  $m2$ -by- $n$  matrix  $ZJ$  containing multiple rows of  $X$  or  $Y$ , and returning an  $m2$ -by-1 vector of distances  $D2$ , whose  $j$ th element is the distance between the observations  $ZI$  and  $ZJ(j,:)$ .

For more information on these distance metrics, see “Distance Metrics” on page 16-9.

**'p'**

A positive scalar,  $p$ , indicating the exponent of the Minkowski distance. This parameter is only valid if the Distance is 'minkowski'. Default is 2.

**'Cov'**

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when Distance is 'mahalanobis'. Default is `nancov(X)`.

**'Scale'**

A vector `S` containing nonnegative values, with length equal to the number of columns in `X`. Each coordinate of `X` and each query point is scaled by the corresponding element of `S` when computing the standardized Euclidean distance. This argument is only valid when Distance is 'seuclidean'. Default is `nanstd(X)`.

**'BucketSize'**

The maximum number of data points in the leaf node of the *kd*-tree. This argument is only meaningful when using the *kd*-tree search method. Default is 50.

**Examples**

Find the 10 nearest neighbors in `x` to each point in `y` using first the 'minkowski' distance metric with a  $p$  value of 5, and then using the 'chebychev' distance metric. Visually compare the results:

```
load fisheriris
x = meas(:,3:4);
y = [5 1.45;6 2;2.75 .75];

% Perform a knnsearch between x and the query points in y,
% using first Minkowski then Chebychev distance metrics.
[n,d]=knnsearch(x,y,'k',10,'distance','minkowski','p',5);
[ncb,dcb] = knnsearch(x,y,'k',10,...
    'distance','chebychev');
```

# knnsearch

---

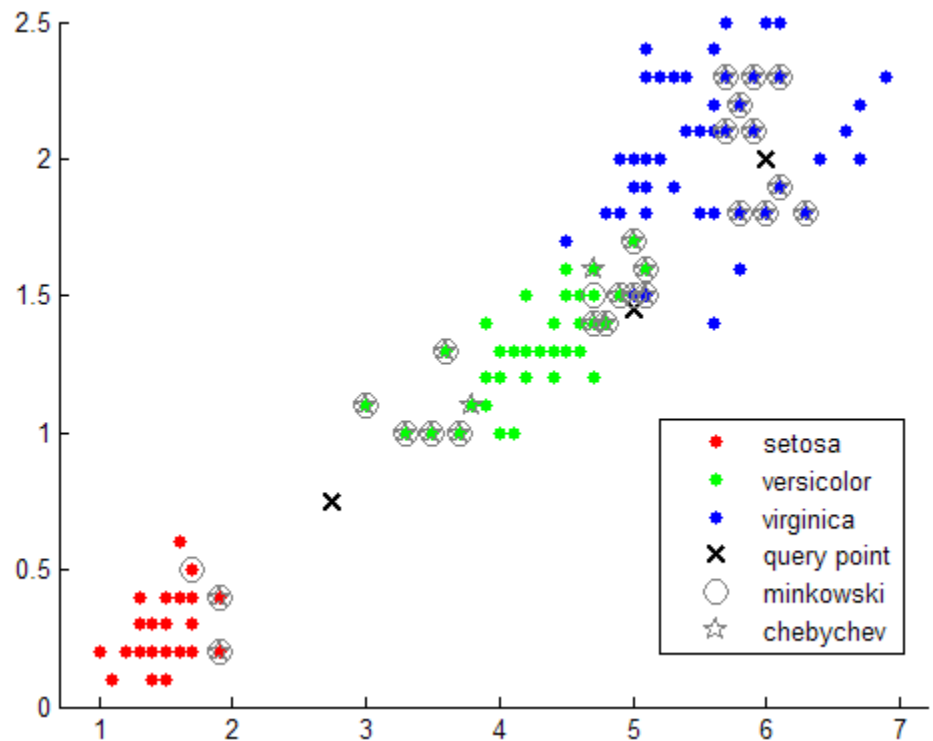

```
% Visualize the results of the two different nearest
% neighbors searches.

% First plot the training data.
gscatter(x(:,1),x(:,2),species)

% Plot an X for the query points.
line(y(:,1),y(:,2),'marker','x','color','k',...
      'markersize',10,'linewidth',2,'linestyle','none')

% Use circles to denote the Minkowski nearest neighbors.
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
      'linestyle','none','markersize',10)

% Use pentagrams to denote the Chebychev nearest neighbors.
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...
      'linestyle','none','markersize',10)
legend('setosa','versicolor','virginica','query point',...
      'minkowski','chebychev')
set(legend,'location','best')
```

## How To

• “*k*-Nearest Neighbor Search and Radius Search” on page 16-12

# kruskalwallis

---

## Purpose

Kruskal-Wallis test

## Syntax

```
p = kruskalwallis(x)
p = kruskalwallis(x,group)
p = kruskalwallis(x,group,displayopt)
[p,tbl,stats] = kruskalwallis( ___ )
```

## Description

`p = kruskalwallis(x)` returns the  $p$ -value for the null hypothesis that the data in each column of the matrix `x` comes from the same distribution, using a Kruskal-Wallis test. The alternative hypothesis is that not all samples come from the same distribution. `kruskalwallis` also returns an ANOVA table and a box plot.

`p = kruskalwallis(x,group)` returns the  $p$ -value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable `group` comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

`p = kruskalwallis(x,group,displayopt)` returns the  $p$ -value of the test and lets you display or suppress the ANOVA table and box plot.

`[p,tbl,stats] = kruskalwallis( ___ )` also returns the ANOVA table as the cell array `tbl` and the structure `stats` containing information about the test statistics.

## Input Arguments

### **x - Sample data**

vector | matrix

Sample data for the hypothesis test, specified as a vector or an  $m$ -by- $n$  matrix. If `x` is an  $m$ -by- $n$  matrix, each of the  $n$  columns represents an independent sample containing  $m$  mutually independent observations.

### **Data Types**

single | double

**group - Grouping variable**

categorical variable | vector | character array | cell array

Grouping variable, specified as a categorical variable, vector, character array, or cell array.

- If `x` is a vector, then each element in `group` identifies the group to which the corresponding element in `x` belongs, and `group` must be a vector of the same length as `x`. If a row of `group` contains an empty cell or empty string, that row and the corresponding observation in `x` are disregarded. NaN values in either `x` or `group` are similarly ignored.
- If `x` is a matrix, then each column in `x` represents a different group, and you can use `group` to specify labels for these columns. The number of elements in `group` and the number of columns in `x` must be equal.

The labels contained in `group` also annotate the box plot.

**Example:**

```
{ 'red', 'blue', 'green', 'blue', 'red', 'blue', 'green', 'green', 'red' }
```

**Data Types**

single | double | char

**displayopt - Display option**

'on' (default) | 'off'

Display option, specified as 'on' or 'off'. If `displayopt` is 'on', `kruskalwallis` displays the following figures:

- An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`.
- A box plot of the data in each column of the data matrix `x`. The box plots are based on the actual data values, rather than on the ranks.

If `displayopt` is 'off', `kruskalwallis` does not display these figures.

If you specify a value for `displayopt`, you must also specify a value for `group`. If you do not have a grouping variable, specify `group` as `[]`.

**Example:** 'off'

# kruskalwallis

---

## Output Arguments

### **p** - **p-value**

scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

### **tbl** - **ANOVA table**

cell array

ANOVA table of test results, returned as a cell array. *tbl* includes the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in *x*, as well as column and row labels.

### **stats** - **Test data**

structure

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of sample medians by using *multcompare*, with *stats* as the input value.

## Examples

### **Test Data Samples for the Same Distribution**

Create two different normal probability distribution objects. The first distribution has *mu* = 0 and *sigma* = 1, and the second distribution has *mu* = 2 and *sigma* = 1.

```
pd1 = makedist('Normal');  
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility  
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of  $x$  contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in  $x$  comes from the same distribution.

```
p = kruskalwallis(x)
```

```
p =
```

```
3.6896e-06
```

Kruskal-Wallis ANOVA Table					
Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	7631.1	2	3815.55	25.02	3.68957e-06
Error	10363.9	57	181.82		
Total	17995	59			

# kruskalwallis

---

The returned value of `p` indicates that `kruskalwallis` rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in `x`.

## Conduct Followup Tests for Unequal Medians

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`. The second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');  
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility  
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution. Suppress the output displays, and generate the structure `stats` to use in further testing.

```
[p,tbl,stats] = kruskalwallis(x,[],'off')
```

```
p =
```

```
3.6896e-06
```

```
tbl =
```

```
Columns 1 through 4
```

'Source'	'SS'	'df'	'MS'
'Columns'	[7.6311e+03]	[ 2]	[3.8155e+03]
'Error'	[1.0364e+04]	[57]	[ 181.8228]
'Total'	[ 17995]	[59]	[ ]

```
Columns 5 through 6
```

'Chi-sq'	'Prob>Chi-sq'
[25.0200]	[ 3.6896e-06]
[ ]	[ ]

# kruskalwallis

---

```
    []          []
```

```
stats =
```

```
    gnames: [3x1 char]
         n: [20 20 20]
    source: 'kruskalwallis'
meanranks: [26.7500 18.9500 45.8000]
    sumt: 0
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure `stats` to perform additional followup testing. The cell array `tbl` contains the same data as the graphical ANOVA table, including column and row labels.

Conduct a followup test to identify which data sample comes from a different distribution.

```
c = multcompare(stats)
```

Note: Intervals can be used for testing but are not simultaneous confidence

```
c =

    2.0000    3.0000  -39.7935  -26.8500  -13.9065
```

The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

## Test for the Same Distribution Across Groups

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, containing strings indicating the type of metal alloy from which the corresponding beam is made.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...  
           78 75 76 77 79 79 77 78 82 79];
```

```
alloy = {'st','st','st','st','st','st','st','st',...  
        'al1','al1','al1','al1','al1','al1',...  
        'al2','al2','al2','al2','al2','al2'};
```

Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

```
p = kruskalwallis(strength,alloy,'off')
```

```
p =
```

```
0.0018
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level.

## Definitions

### Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups. It compares the medians of the groups of data in  $x$  to determine if the samples come from the same population (or, equivalently, from different populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. The  $F$ -statistic used in

classical one-way ANOVA is replaced by a chi-square statistic, and the  $p$ -value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects, and that all observations are mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the stronger assumption that the populations have normal distributions.

# ksdensity

---

**Purpose** Kernel smoothing function estimate

**Syntax**

```
[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity(x,pts,Name,Value)
[f,xi,bw] = ksdensity( ___ )
```

```
ksdensity( ___ )
ksdensity(ax, ___ )
```

**Description** `[f,xi] = ksdensity(x)` returns a probability density estimate, `f`, for the sample in the vector `x`. The estimate is based on a normal kernel function, and is evaluated at 100 equally spaced points, `xi`, that cover the range of the data in `x`.

`ksdensity` works best with continuously distributed samples.

`[f,xi] = ksdensity(x,pts)` returns a probability density estimate, `f`, for the sample in the vector `x`, evaluated at the specified values in vector `pts`. Here, the `xi` and `pts` vectors contain identical values.

`[f,xi] = ksdensity(x,pts,Name,Value)` returns a probability density estimate, `f`, for the sample in the vector `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can define the function type `ksdensity` evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

`[f,xi,bw] = ksdensity( ___ )` also returns the bandwidth of the kernel smoothing window, `bw`. The default bandwidth is the optimal for normal densities.

`ksdensity( ___ )` plots the kernel smoothing function estimate.

`ksdensity(ax, ___)` plots the results using axes with the handle, `ax`, instead of the current axes returned by `gca`.

## Input Arguments

### **x** - Sample data

column vector

Sample data, for which `ksdensity` returns `f` values, specified as a column vector.

**Example:** `[f,xi] = ksdensity(x)`

### Data Types

single | double

### **pts** - Points to evaluate `f`

vector

Points to evaluate `f` at, specified as a vector. `pts` can be a row or column vector. `f` has the same dimensions as `pts`.

**Example:** `pts = (0:1:25); ksdensity(x,pts);`

### Data Types

single | double

### **ax** - Axes handle

handle

Axes handle for the figure `ksdensity` plots to, specified as a handle.

For example, if `h` is a handle for a figure, then `ksdensity` can plot to that figure as follows.

**Example:** `ksdensity(h,x)`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

# ksdensity

---

## Example:

`'censoring',cens,'kernel','triangle','npoints',20,'function','cdf'` specifies that `ksdensity` estimates the cdf by evaluating at 20 equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector `cens`.

## 'censoring' - Logical vector

vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring.

Example: `'censoring',censdata`

## Data Types

logical

## 'kernel' - Type of kernel smoother

`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'` | function handle | string

Type of kernel smoother, specified as the comma-separated pair consisting of `'kernel'` and one of the following.

- `'normal'` (default)
- `'box'`
- `'triangle'`
- `'epanechnikov'`
- You can also specify a custom kernel function, as a function handle or as a string, e.g., `@normpdf` or `'normpdf'`. This calls the function with one argument that is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

When 'function' is 'pdf', this kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when 'function' is 'icdf' returns an error.

If 'support' is 'positive', then `ksdensity` transforms `x` using a log function, estimates the density of the transformed values, and transforms back to the original scale. If 'support' is a vector [L U], then `ksdensity` uses the transformation  $\log((X-L)/(U-X))$ . The width parameter and `bw` outputs are on the scale of the transformed values.

**Example:** 'kernel', 'box'

### Data Types

char | function\_handle

### 'npoints' - Number of equally spaced points

100 (default) | scalar value

Number of equally spaced points in `xi`, specified as the comma-separated pair consisting of 'npoints' and a scalar value.

For instance, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

**Example:** 'npoints', 80

### Data Types

single | double

### 'support' - Support for the density

'unbounded' (default) | 'positive' | two-element vector, [L U]

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

# ksdensity

---

'unbounded'	Default. Allow the density to extend over the whole real line.
'positive'	Restrict the density to positive values.
Two-element vector, [L U]	Give the finite lower and upper bounds for the support of the density.

**Example:** 'support','positive'

**Example:** 'support',[0 10]

## Data Types

single | double | char

## 'weights' - Weights for each x value

vector

Weights for each x value, specified as the comma-separated pair consisting of 'weights' and a vector of the same length as x.

For instance, if the weights for the data values are in vector xw, then you can specify the weights as follows.

**Example:** 'weights',xw

## Data Types

single | double

## 'bandwidth' - Bandwidth of the kernel smoothing window

optimal value for normal densities (default) | scalar value

The bandwidth of the kernel-smoothing window, which is a function of the number of points in x, specified as the comma-separated pair consisting of 'width' and a scalar. The default is optimal for estimating normal densities, but you might want to choose a larger or smaller value to smooth more or less.

**Example:** 'bandwidth',0.8

## Data Types

single | double

**'function' - Function to estimate**`'pdf' (default) | 'cdf' | 'icdf' | 'survivor' | 'cumhazard'`

Function to estimate, specified as the comma-separated pair consisting of 'function' and one of the following.

<code>'pdf'</code>	Default. Probability density function.
<code>'cdf'</code>	Cumulative distribution function.
<code>'icdf'</code>	Inverse cumulative distribution function. For 'icdf', $f = \text{ksdensity}(x, pi, 'function', 'icdf')$ computes
<code>'survivor'</code>	Survivor function.
<code>'cumhazard'</code>	Cumulative hazard function.

**Example:** `'function','icdf'`

**Data Types**

char

**Output Arguments****f - Estimated function values**

vector

Estimated function values, returned as a vector of the same dimension as `xi` or `pts`.

**xi - Evaluation points**

100 equally spaced points (default) | vector

Evaluation points at which `ksdensity` calculates `f`, returned as a vector. Default is 100 equally spaced points that cover the range of data in `x`.

**bw - Bandwidth of smoothing window**

scalar value

Bandwidth of smoothing window, returned as a scalar value.

**Examples****Estimate Density**

Generate a sample data set from a mixture of two normal distributions.

# ksdensity

---

```
rng('default') % for reproducibility  
x = [randn(30,1); 5+randn(30,1)];
```

Plot the estimated density.

```
[f,xi] = ksdensity(x);  
figure()  
plot(xi,f);
```

The density estimate shows the bimodality of the sample.

**Estimate Cumulative Distribution Function at Specified Values**

Load the sample data.

```
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```
pts = (min(hospital.Weight):2:max(hospital.Weight));  
figure()  
ecdf(hospital.Weight)  
hold on  
[f,xi,bw] = ksdensity(hospital.Weight,pts,'support','positive',...  
    'function','cdf');  
plot(xi,f,'-g','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','Location','NorthWest')  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

# ksdensity

`ksdensity` seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.

`bw`

`bw =`

0.1070

Plot the cumulative distribution function estimate using a smaller bandwidth.

```
[f,xi] = ksdensity(hospital.Weight,pts,'support','positive',...  
    'function','cdf','bandwidth',0.05);  
plot(xi,f,'--r','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','kernel-bw:0.05',...  
    'Location','NorthWest')  
hold off
```

# ksdensity

The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

## Plot Estimated Cumulative Density Function for Given Number of Points

Load the sample data.

```
load hospital
```

Plot the estimated cdf evaluated at 50 equally spaced points.

```
figure()  
ksdensity(hospital.Weight,'support','positive','function','cdf',...  
  'npoints',50)  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

### Estimate Survivor and Cumulative Hazard for Censored Failure Data

Generate sample data from an exponential distribution with mean 3.

# ksdensity

---

```
rng('default') % for reproducibility  
x = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```
T = 10;  
cens = (x>10);
```

Compute and plot the estimated density function.

```
figure()  
ksdensity(x,'support','positive','censoring',cens);
```

Compute and plot the survivor function.

```
figure()  
ksdensity(x,'support','positive','censoring',cens,...  
  'function','survivor');
```

# ksdensity

---

Compute and plot the cumulative hazard function.

```
figure()  
ksdensity(x, 'support', 'positive', 'censoring', cens, ...  
  'function', 'cumhazard');
```

### Estimate Inverse Cumulative Distribution Function for Specified Probability Values

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```
rng('default') % for reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
```

# ksdensity

---

```
figure()  
ksdensity(x,pi,'function','icdf');
```

## Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

```
rng('default') % for reproducibility  
x = [randn(30,1); 5+randn(30,1)];
```

Return the bandwidth of the smoothing window for the probability density estimate.

```
[f,xi,bw] = ksdensity(x);  
bw
```

```
bw =
```

```
1.5141
```

The default bandwidth is optimal for normal densities.

Plot the estimated density.

```
figure()  
plot(xi,f);  
xlabel('xi')  
ylabel('f')  
hold on
```

# ksdensity

---

Plot the density using an increased bandwidth value.

```
[f,xi] = ksdensity(x,'width',1.8);  
plot(xi,f,'--r','LineWidth',1.5)
```

A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

```
[f,xi] = ksdensity(x,'width',0.8);  
plot(xi,f,'-.k','LineWidth',1.5)  
legend('bw = default','bw = 1.8','bw = 0.8')  
hold off
```

# ksdensity

A smaller bandwidth smooths the density estimate less, which exaggerate some characteristics of the sample.

# kstest

---

**Purpose** One-sample Kolmogorov-Smirnov test

**Syntax**

```
h = kstest(x)
h = kstest(x,Name,Value)
[h,p] = kstest( ___ )
[h,p,ksstat,cv] = kstest( ___ )
```

**Description** `h = kstest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = kstest(x,Name,Value)` returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.

`[h,p] = kstest( ___ )` also returns the  $p$ -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,ksstat,cv] = kstest( ___ )` also returns the value of the test statistic `ksstat` and the approximate critical value `cv` of the test.

## Input Arguments

### **x - Sample data**

vector

Sample data, specified as a vector.

### **Data Types**

single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'Tail', 'right', 'Alpha', 0.01 specifies a right-tailed hypothesis test at the 1% significance level.

### 'Alpha' - Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

**Example:** 'Alpha', 0.01

### Data Types

single | double

### 'CDF' - cdf of hypothesized continuous distribution

matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of 'CDF' and either a two-column matrix or a continuous probability distribution object. When CDF is a matrix, column 1 contains a set of possible  $x$  values, and column 2 contains the corresponding hypothesized cumulative distribution function values  $G(x)$ . The calculation is most efficient if CDF is specified such that column 1 contains the values in the data vector  $x$ . If there are values in  $x$  not found in column 1 of CDF, `kstest` approximates  $G(x)$  by interpolation. All values in  $x$  must lie in the interval between the smallest and largest values in the first column of CDF. By default, `kstest` tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test  $x$  against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use `lillietest` instead.

## Data Types

single | double

## 'Tail' - Type of alternative hypothesis

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- |           |  |
|-----------|--|
| 'unequal' | Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is not equal to the cdf of the hypothesized distribution. |
| 'larger'  | Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is greater than the cdf of the hypothesized distribution. |
| 'smaller' | Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is less than the cdf of the hypothesized distribution.    |

If the values in the data vector  $x$  tend to be larger than expected from the hypothesized distribution, the empirical distribution function of  $x$  tends to be smaller, and vice versa.

**Example:** 'Tail', 'larger'

## Output Arguments

### **h** - Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p** - p-value

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

**ksstat - Test statistic**

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

**cv - Critical value**

nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

**Examples****Test for a Standard Normal Distribution**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector since, by default, `kstest` tests for a standard normal distribution.

```
x = (test1-75)/10;  
h = kstest(x)
```

```
h =  
0
```

The returned value of  $h = 0$  indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

# kstest

---

Plot the empirical cumulative distribution function (cdf) and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);
F = plot(x_values,f);
set(F,'LineWidth',2);
hold on;
G = plot(x_values,normcdf(x_values,0,1),'r-');
set(G,'LineWidth',2);
legend([F G],...
       'Empirical CDF','Standard Normal CDF',...
       'Location','SE');
```

The plot shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

### **Specify the Hypothesized Distribution Using a Two-Column Matrix**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector  $x$ . Column 2 contains cdf values evaluated at each value in  $x$  for a hypothesized Student's  $t$  distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = [x,cdf('tlocation',x,75,10,1)];
```

Test if the data are from the hypothesized distribution.

```
h = kstest(x,'CDF',test_cdf)
```

```
h =  
1
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

## **Specify the Hypothesized Distribution Using a Probability Distribution Object**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's  $t$  distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocation','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that the data comes from the hypothesized distribution.

```
h = kstest(x,'CDF',test_cdf)
```

```
h =  
    1
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

### Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades.

```
load examgrades;  
test1 = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's  $t$  distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```
[h,p] = kstest(x,'CDF',test_cdf,'Alpha',0.01)
```

```
h =  
    1  
  
p =  
    0.0021
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis at the 1% significance level.

### Conduct a One-Sided Hypothesis Test

Load the sample data. Create a vector containing the third column of the stock return data matrix.

# kstest

---

```
load stockreturns;  
x = stocks(:,3);
```

Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the population cdf of the data is larger than the standard normal cdf.

```
[h,p,k,c] = kstest(x, 'Tail', 'larger')
```

```
h =  
1  
p =  
5.0854e-05  
k =  
0.2197  
c =  
0.1207
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis in favor of the alternative hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);  
J = plot(x_values,f);  
hold on;  
K = plot(x_values,normcdf(x_values), 'r--');  
set(J, 'LineWidth', 2);  
set(K, 'LineWidth', 2);  
legend([J K], 'Empirical CDF', 'Standard Normal CDF', 'Location', 'SE');
```

The plot shows the difference between the empirical cdf of the data vector  $x$  and the cdf of the standard normal distribution.

## Definitions

### One-Sample Kolmogorov-Smirnov Test

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for “unequal” cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not

equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from  $x$  and the hypothesized cdf:

$$D^* = \max_x \left( \left| \hat{F}(x) - G(x) \right| \right),$$

where  $\hat{F}(x)$  is the empirical cdf and  $G(x)$  is the cdf of the hypothesized distribution.

The one-sided test for a “larger” cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf. The test statistic is the maximum amount by which the empirical cdf calculated from  $x$  exceeds the hypothesized cdf:

$$D^* = \max_x \left( \hat{F}(x) - G(x) \right).$$

The one-sided test for a “smaller” cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from  $x$ :

$$D^* = \max_x \left( G(x) - \hat{F}(x) \right).$$

`kstest` computes the critical value `cv` using an approximate formula or by interpolation in a table. The formula and table cover the range  $0.01 \leq \alpha \leq 0.2$  for two-sided tests and  $0.005 \leq \alpha \leq 0.1$  for one-sided tests. `cv` is returned as `NaN` if `alpha` is outside this range.

## Algorithms

`kstest` decides to reject the null hypothesis by comparing the  $p$ -value `p` with the significance level `Alpha`, not by comparing the test statistic `ksstat` with the critical value `cv`. Since `cv` is approximate, comparing `ksstat` with `cv` occasionally leads to a different conclusion than comparing `p` with `Alpha`.

`kstest2` | `lillietest` | `adtest`

# kstest2

---

**Purpose** Two-sample Kolmogorov-Smirnov test

**Syntax**

```
h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2( ___ )
[h,p,ks2stat] = kstest2( ___ )
```

**Description** `h = kstest2(x1,x2)` returns a test decision for the null hypothesis that the data in vectors `x1` and `x2` are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test. The alternative hypothesis is that `x1` and `x2` are from different continuous distributions. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = kstest2(x1,x2,Name,Value)` returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = kstest2( ___ )` also returns the asymptotic  $p$ -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,ks2stat] = kstest2( ___ )` also returns the test statistic `ks2stat`.

## Input Arguments

### **x1 - Sample data**

vector

Sample data from the first sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

### **Data Types**

single | double

### **x2 - Sample data**

vector

Sample data from the second sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

**Data Types**

single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

**Example:**

**'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

**Example:** 'Alpha',0.01

**Data Types**

single | double

**'Tail' - Type of alternative hypothesis**

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'unequal' Test the alternative hypothesis that the empirical cdf of `x1` is unequal to the empirical cdf of `x2`.
- 'larger' Test the alternative hypothesis that the empirical cdf of `x1` is larger than the empirical cdf of `x2`.
- 'smaller' Test the alternative hypothesis that the empirical cdf of `x1` is smaller than the empirical cdf of `x2`.

If the data values in `x1` tend to be larger than those in `x2`, the empirical distribution function of `x1` tends to be smaller than that of `x2`, and vice versa.

**Example:** 'Tail', 'larger'

## Output Arguments

### **h - Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If `h = 1`, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p - Asymptotic p-value**

scalar value in the range (0,1)

Asymptotic *p*-value of the test, returned as a scalar value in the range (0,1). *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic *p*-value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes `n1` and `n2`, such that  $(n1*n2)/(n1 + n2) \geq 4$ .

### **ks2stat - Test statistic**

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

## Examples

### **Test Two Samples for the Same Distribution**

Generate sample data from two different Weibull distributions.

```
rng(1);          % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution.

```
h = kstest2(x1,x2)
```

```
h =  
1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

### **Test the Hypothesis at Different Significance Levels**

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility  
x1 = wblrnd(1,1,1,50);  
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data vectors `x1` and `x2` are from populations with the same distribution at the 1% significance level.

```
[h,p] = kstest2(x1,x2,'Alpha',0.01)
```

```
h =  
0  
p =  
0.0317
```

The returned value of `h = 0` indicates that `kstest` does not reject the null hypothesis at the 1% significance level.

### **One-Sided Hypothesis Test**

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility  
x1 = wblrnd(1,1,1,50);  
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors  $x_1$  and  $x_2$  comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of  $x_1$  is larger than the cdf of the distribution of  $x_2$ .

```
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

```
h =  
  1  
p =  
  0.0158  
k =  
  0.2800
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of  $x_1$  is larger than the cdf of the distribution of  $x_2$ , at the default 5% significance level. The returned value of  $k$  is the test statistic for the two-sample Kolmogorov-Smirnov test.

## Definitions

### Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of  $x$  in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

$$D^* = \max_x (|F_1(x) - F_2(x)|),$$

where  $\hat{F}_1(x)$  is the proportion of  $x_1$  values less than or equal to  $x$  and  $\hat{F}_2(x)$  is the proportion of  $x_2$  values less than or equal to  $x$ .

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

$$D^* = \max_x (F_1(x) - F_2(x)).$$

## Algorithms

In `kstest2`, the decision to reject the null hypothesis is based on comparing the  $p$ -value `p` with the significance level `Alpha`, not by comparing the test statistic `ks2stat` with a critical value.

# kurtosis

---

**Purpose** Kurtosis

**Syntax**  
`k = kurtosis(X)`  
`k = kurtosis(X,flag)`  
`k = kurtosis(X,flag,dim)`

**Description** `k = kurtosis(X)` returns the sample kurtosis of  $X$ . For vectors, `kurtosis(x)` is the kurtosis of the elements in the vector  $x$ . For matrices `kurtosis(X)` returns the sample kurtosis for each column of  $X$ . For  $N$ -dimensional arrays, `kurtosis` operates along the first nonsingleton dimension of  $X$ .

`k = kurtosis(X,flag)` specifies whether to correct for bias (`flag` is 0) or not (`flag` is 1, the default). When  $X$  represents a sample from a population, the kurtosis of  $X$  is biased, that is, it will tend to differ from the population kurtosis by a systematic amount that depends on the size of the sample. You can set `flag` to 0 to correct for this systematic bias.

`k = kurtosis(X,flag,dim)` takes the kurtosis along dimension `dim` of  $X$ .

`kurtosis` treats NaNs as missing values and removes them.

**Algorithms** Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3.

The kurtosis of a distribution is defined as

$$k = \frac{E(x - \mu)^4}{\sigma^4}$$

where  $\mu$  is the mean of  $x$ ,  $\sigma$  is the standard deviation of  $x$ , and  $E(t)$  represents the expected value of the quantity  $t$ . `kurtosis` computes a sample version of this population value.

**Note** Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The kurtosis function does not use this convention.

When you set `flag` to 1, the following equation applies:

$$k_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^4}{\left( \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^2}$$

When you set `flag` to 0, the following equation applies:

$$k_0 = \frac{n-1}{(n-2)(n-3)} ((n+1)k_1 - 3(n-1)) + 3$$

This bias-corrected formula requires that `X` contain at least four elements.

## Examples

```
X = randn([5 4])
X =
  1.1650  1.6961  -1.4462  -0.3600
  0.6268  0.0591  -0.7012  -0.1356
  0.0751  1.7971  1.2460  -1.3493
  0.3516  0.2641  -0.6390  -1.2704
 -0.6965  0.8717  0.5774  0.9846

k = kurtosis(X)
k =
  2.1658  1.2967  1.6378  1.9589
```

values represent elastic net optimization. See “Definitions” on page 21-1645.

**Default:** 1

## **‘CV’**

Method `lasso` uses to estimate mean squared error:

- `K`, a positive integer — `lasso` uses `K`-fold cross validation.
- `cvp`, a `cvpartition` object — `lasso` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lasso`.
- 'resubstitution' — `lasso` uses `X` and `Y` to fit the model and to estimate the mean squared error, without cross validation.

**Default:** 'resubstitution'

## **‘DFmax’**

Maximum number of nonzero coefficients in the model. `lasso` returns results only for `Lambda` values that satisfy this criterion.

**Default:** Inf

## **‘Lambda’**

Vector of nonnegative `Lambda` values. See “Definitions” on page 21-1645.

- If you do not supply `Lambda`, `lasso` calculates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, `lasso` ignores `LambdaRatio` and `NumLambda`.

**Default:** Geometric sequence of `NumLambda` values, the largest just sufficient to produce  $B = 0$

## **‘LambdaRatio’**

Positive scalar, the ratio of the smallest to the largest `Lambda` value when you do not set `Lambda`.

If you set `LambdaRatio = 0`, `lasso` generates a default sequence of `Lambda` values, and replaces the smallest one with 0.

**Default:** 1e-4

### **'MCReps'**

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If CV is 'resubstitution' or a `cvpartition` of type 'resubstitution', `MCReps` must be 1.
- If CV is a `cvpartition` of type 'holdout', `MCReps` must be greater than 1.

**Default:** 1

### **'NumLambda'**

Positive integer, the number of `Lambda` values `lasso` uses when you do not set `Lambda`. `lasso` can return fewer than `NumLambda` fits if the residual error of the fits drops below a threshold fraction of the variance of `Y`.

**Default:** 100

### **'Options'**

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: 'mlfg6331\_64' or 'mrg32k3a'. Default is `false`.

- **Streams** — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lasso` uses the default stream.

### **'PredictorNames'**

Cell array of strings representing names of the predictor variables, in the order in which they appear in `X`.

**Default:** {}

### **'RelTol'**

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the  $L^2$  norm by a relative amount less than `RelTol`.

**Default:** 1e-4

### **'Standardize'**

Boolean value specifying whether `lasso` scales `X` before fitting the models.

**Default:** true

### **'Weights'**

Observation weights, a nonnegative vector of length `n`, where `n` is the number of rows of `X`. `lasso` scales `Weights` to sum to 1.

**Default:** `1/n * ones(n,1)`

## **Output Arguments**

### **B**

Fitted coefficients, a `p`-by-`L` matrix, where `p` is the number of predictors (columns) in `X`, and `L` is the number of `Lambda` values.

### **FitInfo**

Structure containing information about the model fits.

Field in FitInfo	Description
Intercept	Intercept term $\beta_0$ for each linear model, a 1-by-L vector
Lambda	Lambda parameters in ascending order, a 1-by-L vector
Alpha	Value of Alpha parameter, a scalar
DF	Number of nonzero coefficients in B for each value of Lambda, a 1-by-L vector
MSE	Mean squared error (MSE), a 1-by-L vector

If you set the CV name-value pair to cross validate, the FitInfo structure contains additional fields.

Field in FitInfo	Description
SE	The standard error of MSE for each Lambda, as calculated during cross validation, a 1-by-L vector
LambdaMinMSE	The Lambda value with minimum MSE, a scalar
Lambda1SE	The largest Lambda such that MSE is within one standard error of the minimum, a scalar
IndexMinMSE	The index of Lambda with value LambdaMinMSE, a scalar
Index1SE	The index of Lambda with value Lambda1SE, a scalar

## Definitions

### Lasso

For a given value of  $\lambda$ , a nonnegative parameter, lasso solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda \sum_{j=1}^p |\beta_j| \right),$$

where

- $N$  is the number of observations.
- $y_i$  is the response at observation  $i$ .
- $x_i$  is data, a vector of  $p$  values at observation  $i$ .
- $\lambda$  is a nonnegative regularization parameter corresponding to one value of **Lambda**.
- The parameters  $\beta_0$  and  $\beta$  are scalar and  $p$ -vector respectively.

As  $\lambda$  increases, the number of nonzero components of  $\beta$  decreases.

The lasso problem involves the  $L^1$  norm of  $\beta$ , as contrasted with the elastic net algorithm.

## Elastic Net

For an  $\alpha$  strictly between 0 and 1, and a nonnegative  $\lambda$ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left( \frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when  $\alpha = 1$ . As  $\alpha$  shrinks toward 0, elastic net approaches **ridge** regression. For other values of  $\alpha$ , the penalty term  $P_\alpha(\beta)$  interpolates between the  $L^1$  norm of  $\beta$  and the squared  $L^2$  norm of  $\beta$ .

## Examples

### Remove Redundant Predictors

Construct a data set with redundant predictors, and identify those predictors using cross-validated lasso.

Create a matrix  $X$  of 100 five-dimensional normal variables and a response vector  $Y$  from just two components of  $X$ , with small added noise.

```
X = randn(100,5);  
r = [0;2;0;-3;0]; % only two nonzero coefficients  
Y = X*r + randn(100,1)*.1; % small added noise
```

Construct the default lasso fit.

```
B = lasso(X,Y);
```

Find the coefficient vector for the 25th value in  $B$ .

```
B(:,25)
```

```
ans =
```

```
    0  
  1.6093  
    0  
 -2.5865  
    0
```

lasso identifies and removes the redundant predictors.

### Plot a Regularized Fit with Cross Validation

Visually examine the cross-validated error of various levels of regularization.

Load the acetylene data and prepare the data with interactions for fitting.

```
load acetylene  
Xs = [x1 x2 x3];
```

# lasso

```
X = x2fx(Xs,'interaction');  
X(:,1) = []; % No constant term
```

Construct the lasso fit using ten-fold cross validation. Include the FitInfo output so you can plot the result.

```
[B FitInfo] = lasso(X,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');
```

**How To**

- “Lasso and Elastic Net” on page 9-132

# lassoglm

---

**Purpose** Lasso or elastic net regularization for generalized linear model regression

**Syntax**

```
B = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y,distr)
[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)
```

**Description** `B = lassoglm(X,Y)` returns penalized maximum-likelihood fitted coefficients for a generalized linear model of the response `Y` to the data matrix `X`. `Y` are assumed to have a Gaussian probability distribution.

`[B,FitInfo] = lassoglm(X,Y)` returns a structure containing information about the fits.

`[B,FitInfo] = lassoglm(X,Y,distr)` fits the model using the probability distribution type for `Y` as specified in `distr`.

`[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)` fits regularized generalized linear regressions with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **X**

Numeric matrix with `n` rows and `p` columns. Each row represents one observation, and each column represents one predictor (variable).

### **Y**

When `distr` is not `'binomial'`, `Y` is a numeric vector of length `n`, where `n` is the number of rows of `X`. `Y(i)` is the response to row `i` of `X`.

When `distr` is `'binomial'`, `Y` is either a:

- Numeric vector of length `n`, where each entry represents success (1) or failure (0)
- Logical vector of length `n`, where each entry represents success or failure

- Two column numeric matrix, where the first column contains the number of successes for each observation, and the second column contains the total number of trials

**distr**

Distributional family for the nonsystematic variation in the responses, a string. Choices:

- 'normal'
- 'binomial'
- 'poisson'
- 'gamma'
- 'inverse gaussian'

By default, `lassoglm` uses the canonical link function corresponding to `distr`. Specify another link function using the 'link' name-value pair.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'Alpha'**

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso ( $L^1$ ) versus ridge ( $L^2$ ) optimization. `Alpha = 1` represents lasso regression, and other values represent elastic net optimization. `Alpha` close to 0 approaches ridge regression. See “Definitions” on page 21-1645.

**Default:** 1

**'CV'**

Method `lassoglm` uses to estimate deviance:

- `K`, a positive integer — `lassoglm` uses `K`-fold cross validation.
- `cvp`, a `cvpartition` object — `lassoglm` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lassoglm`.
- 'resubstitution' — `lassoglm` uses `X` and `Y` to fit the model and to estimate the deviance, without cross validation.

**Default:** 'resubstitution'

## 'DFmax'

Maximum number of nonzero coefficients in the model. `lassoglm` returns results for `Lambda` values that satisfy this criterion.

**Default:** Inf

## 'Lambda'

Vector of nonnegative `Lambda` values. See "Lasso" on page 21-1658.

- If you do not supply `Lambda`, `lassoglm` estimates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, `lassoglm` ignores `LambdaRatio` and `NumLambda`.

**Default:** Geometric sequence of `NumLambda` values, the largest just sufficient to produce  $B = 0$

## 'LambdaRatio'

Positive scalar, the ratio of the smallest to the largest `Lambda` value when you do not explicitly set `Lambda`.

If you set `LambdaRatio = 0`, `lassoglm` generates a default sequence of `Lambda` values, and replaces the smallest one with 0.

**Default:** `1e-4`

### 'Link'

Specify the mapping between the mean  $\mu$  of the response and the linear predictor  $Xb$ .

Value	Description
'comploglog'	$\log(-\log((1-\mu))) = Xb$
'identity', default for the distribution 'normal'	$\mu = Xb$
'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
'logit', default for the distribution 'binomial'	$\log(\mu/(1-\mu)) = Xb$
'loglog'	$\log(-\log(\mu)) = Xb$
'probit'	$\Phi^{-1}(\mu) = Xb$ , where $\Phi$ is the normal (Gaussian) CDF function
'reciprocal', default for the distribution 'gamma'	$\mu^{-1} = Xb$

Value	Description
$p$ (a number), default for the distribution 'inverse gaussian' (with $p = -2$ )	$\mu^p = Xb$
Cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI). Equivalently, can be a structure of function handles with field Link containing FL, field Derivative containing FD, and field Inverse containing FI.	User-specified link function (see “Custom Link Function” on page 10-16)

### **'MCReps'**

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', MCReps must be 1.
- If CV is a cvpartition of type 'holdout', MCReps must be greater than 1.

**Default:** 1

### **'NumLambda'**

Positive integer, the number of Lambda values lassoglm uses when you do not set Lambda. lassoglm can return fewer than NumLambda fits if the

deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors  $X$ ).

**Default:** 100

### **'Offset'**

Numeric vector with the same number of rows as  $X$ . `lassoglm` uses `Offset` as an additional predictor variable, but keeps its coefficient value fixed at 1.0.

### **'Options'**

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Default is `false`.
- `Streams` — `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lassoglm` uses the default stream.

### **'PredictorNames'**

Cell array of strings representing names of the predictor variables, in the order in which they appear in  $X$ .

**Default:** {}

### **'RelTol'**

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the  $L^2$  norm by a relative amount less than `RelTol`.

# lassoglm

---

**Default:** 1e-4

## 'Standardize'

Boolean value specifying whether `lassoglm` scales X before fitting the models.

**Default:** true

## 'Weights'

Observation weights, a nonnegative vector of length n, where n is the number of rows of X. At least two values must be positive.

**Default:**  $1/n * \text{ones}(n,1)$

## Output Arguments

### B

Fitted coefficients, a p-by-L matrix, where p is the number of predictors (columns) in X, and L is the number of Lambda values.

### FitInfo

Structure containing information about the model fits.

Field in FitInfo	Description
Alpha	Value of Alpha parameter, a scalar.
Deviance	Deviance of the fitted model for each value of Lambda, a 1-by-L vector. If cross validation was performed, the values for Deviance represent the estimated expected deviance of the model applied to new data, as calculated by cross validation. Otherwise, Deviance is the deviance of the fitted model applied to the data used to perform the fit.
DF	Number of nonzero coefficients in B for each Lambda value, a 1-by-L vector.

Field in FitInfo	Description
Intercept	Intercept term $\beta_0$ for each linear model, a 1-by-L vector.
Lambda	Lambda parameters in ascending order, a 1-by-L vector.

If you set the CV name-value pair to cross validate, the `FitInfo` structure contains additional fields.

Field in FitInfo	Description
IndexMinDeviance	Index of Lambda with value <code>LambdaMinDeviance</code> , a scalar.
Index1SE	Index of Lambda with value <code>Lambda1SE</code> , a scalar.
LambdaMinDeviance	Lambda value with minimum expected deviance, as calculated by cross validation, a scalar.
Lambda1SE	Largest Lambda such that Deviance is within one standard error of the minimum, a scalar.
SE	Standard error of Deviance for each Lambda, as calculated during cross validation, a 1-by-L vector.

## Definitions

### Link Function

A link function  $f(\mu)$  maps a distribution with mean  $\mu$  to a linear model with data  $X$  and coefficient vector  $b$  using the formula

$$f(\mu) = Xb.$$

Find the formulas for the link functions in the `Link` name-value pair description. Here, “typical” means a link function that is typically used for the listed distribution.

# lassoglm

Distributional Family	Link Function (typical, {default})
'normal'	{'identity'}
'binomial'	'comploglog', 'loglog', 'probit', {'logit'}
'poisson'	{'log'}
'gamma'	{'reciprocal'}
'inverse gaussian'	{-2}

## Lasso

For a nonnegative value of  $\lambda$ , lasso solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda \sum_{j=1}^p |\beta_j| \right),$$

where

- Deviance is the deviance of the model fit to the responses using intercept  $\beta_0$  and predictor coefficients  $\beta$ . The formula for Deviance depends on the `distr` parameter you supply to `lassoglm`. Minimizing the  $\lambda$ -penalized deviance is equivalent to maximizing the  $\lambda$ -penalized log likelihood.
- $N$  is the number of observations.
- $\lambda$  is a nonnegative regularization parameter corresponding to one value of `Lambda`.
- Parameters  $\beta_0$  and  $\beta$  are scalar and  $p$ -vector respectively.

As  $\lambda$  increases, the number of nonzero components of  $\beta$  decreases.

The lasso problem involves the  $L^1$  norm of  $\beta$ , as contrasted with the elastic net algorithm.

## Elastic Net

For an  $\alpha$  strictly between 0 and 1, and a nonnegative  $\lambda$ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left( \frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when  $\alpha = 1$ . For other values of  $\alpha$ , the penalty term  $P_\alpha(\beta)$  interpolates between the  $L^1$  norm of  $\beta$  and the squared  $L^2$  norm of  $\beta$ . As  $\alpha$  shrinks toward 0, elastic net approaches ridge regression.

## Examples

### Lasso Regularization of a Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors using `lassoglm`.

Create data with 20 predictors, and Poisson responses using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:, [5 10 15]) * [.4; .2; .3] + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```
[B FitInfo] = lassoglm(X,y,'poisson','CV',10);
```

Examine the cross-validation plot to see the effect of the Lambda regularization parameter.

# lassoglm

```
lassoPlot(B,FitInfo,'plotttype','CV');
```

The green circle and dashed line locate the Lambda with minimal cross-validation error. The blue circle and dashed line locate the point with minimal cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```
minpts = find(B(:,FitInfo.IndexMinDeviance))
```

```
min1pts =  
    3  
    5  
    6  
   10  
   11  
   15  
   16  
  
min1pts = find(B(:,FitInfo.Index1SE))  
  
min1pts =  
    5  
   10  
   15
```

The coefficients from the minimal plus one standard error point are exactly those coefficients used to create the data.

<b>Purpose</b>	Trace plot of lasso fit
<b>Syntax</b>	<pre>ax = lassoPlot(B) ax = lassoPlot(B,FitInfo) ax = lassoPlot(B,FitInfo,Name,Value) [ax,figh] = lassoPlot(B,...)</pre>
<b>Description</b>	<p><code>ax = lassoPlot(B)</code> creates a trace plot of the values in <code>B</code> against the <math>L^1</math> norm of <code>B</code>. <code>ax</code> is a handle to the plot axis.</p> <p><code>ax = lassoPlot(B,FitInfo)</code> creates a plot with type depending on the data type of <code>FitInfo</code> and the value, if any, of the <code>plotType</code> name-value pair.</p> <p><code>ax = lassoPlot(B,FitInfo,Name,Value)</code> creates a plot with additional options specified by one or more <code>Name,Value</code> pair arguments.</p> <p><code>[ax,figh] = lassoPlot(B,...)</code> returns a handle to the figure window.</p>
<b>Input Arguments</b>	<p><b>B</b></p> <p>Coefficients of a sequence of regression fits, as returned from the <code>lasso</code> or <code>lassoglm</code> functions. <code>B</code> is a <code>p</code>-by-<code>NLambda</code> matrix, where <code>p</code> is the number of predictors, and each column of <code>B</code> is a set of coefficients <code>lasso</code> calculates using one <code>Lambda</code> penalty value.</p> <p><b>FitInfo</b></p> <p>Information controlling the plot:</p> <ul style="list-style-type: none"><li>• <code>FitInfo</code> is a structure, especially as returned from <code>lasso</code> or <code>lassoglm</code> — <code>lassoPlot</code> creates a plot based on the <code>PlotType</code> name-value pair.</li><li>• <code>FitInfo</code> is a vector — <code>lassoPlot</code> forms the <math>x</math>-axis of the plot from the values in <code>FitInfo</code>. The length of <code>FitInfo</code> must equal the number of columns of <code>B</code>.</li></ul>

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'Parent'

Axis in which to draw the plot.

**Default:** New plot

### 'PlotType'

Choose the plot type when you give a `FitInfo` vector or structure:

FitInfo Type	PlotType	Plot
Vector or Structure	'L1'	<code>plotLasso</code> creates the <i>x</i> -axis from the $L^1$ norm of the coefficients in <code>B</code> . The <i>x</i> -axis at the top of the plot contains the degrees of freedom ( <code>df</code> ), meaning the number of nonzero coefficients of <code>B</code> .
Structure	'Lambda'	<code>plotLasso</code> creates the <i>x</i> -axis from the <code>Lambda</code> field of <code>FitInfo</code> . The <i>x</i> -axis at the top of the plot contains the degrees of freedom ( <code>df</code> ), meaning the number of nonzero coefficients of <code>B</code> .
Cross-Validated Structure	'CV'	<ul style="list-style-type: none"><li>• For each <code>Lambda</code>, plots an estimate of the mean squared prediction error on new data for the model fitted by <code>lasso</code> with that value of <code>Lambda</code>.</li><li>• Plots error bars for the estimates.</li><li>• Plots the value of <code>Lambda</code> with minimum cross-validated MSE.</li></ul>

FitInfo Type	PlotType	Plot
		<ul style="list-style-type: none"> <li>Plots the greatest Lambda that is within one standard error of minimum MSE (so makes the sparsest model within that region).</li> </ul>

**Default:** 'L1'

### 'PredictorNames'

Cell array of strings to label each coefficient of **B**. If the length of **PredictorNames** is less than the number of rows of **B**, the remaining labels are padded with default values.

`lassoPlot` uses the predictor names in **FitInfo** only if:

- You created **FitInfo** with a call to `lasso` that included a **PredictorNames** name-value pair.
- You call `lassoPlot` *without* a **PredictorNames** name-value pair.
- You include **FitInfo** in your `lassoPlot` call.

**Default:** {'B1', 'B2', ...}

### 'XScale'

- 'linear' for linear x-axis
- 'log' for logarithmic scaled x-axis

**Default:** 'linear', except 'log' for the 'CV' plot type

## Output Arguments

### **ax**

Handle to the axis of the plot (see “Setting Axis Parameters”).

### **figh**

Handle to the figure window (see “Graphics Windows — the Figure”).

# lassoPlot

---

## Examples

### Lasso Plot with Default Plot Type

Load the sample data

```
load acetylene
```

Prepare the design matrix for lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');  
D(:,1) = []; % No constant term
```

Fit a regularized model of the data using `lasso`.

```
B = lasso(D,y);
```

Plot the fits with the default plot type.

```
lassoPlot(B);
```

### Lasso Plot with Lambda Plot Type

Load the sample data.

```
load acetylene
```

Prepare the data for lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');
```

# lassoPlot

```
D(:,1) = []; % No constant term  
Fit a regularized model of the data with lasso .  
[B FitInfo] = lasso(D,y);  
Plot the fits with the Lambda plot type and logarithmic scaling.  
lassoPlot(B,FitInfo,'PlotType','Lambda','XScale','log');
```

## Lasso Plot with Cross-Validated Fits

Load the sample data.

```
load acetylene
```

Prepare the design matrix for a lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');  
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with lasso and cross validation.

```
[B FitInfo] = lasso(D,y, 'CV', 10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo, 'PlotType', 'CV');
```

# lassoPlot

## How To

- “Lasso and Elastic Net” on page 9-132

<b>Purpose</b>	Less than or equal relation for handles
<b>Syntax</b>	<code>h1 &lt;= h2</code>
<b>Description</b>	<p>Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.</p> <p><code>h1 &lt;= h2</code> performs element-wise comparisons between handle arrays <code>h1</code> and <code>h2</code>. <code>h1</code> and <code>h2</code> must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise <code>&lt;=</code> result.</p> <p>If one of <code>h1</code> or <code>h2</code> is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.</p> <p><code>tf = le(h1, h2)</code> stores the result in a logical array of the same dimensions.</p>

# grandset.Lean property

---

**Purpose** Interval between points

**Description** Number of points to leap over and omit for each point taken from the sequence. The Leap property of a point set contains a positive integer which specifies the number of points in the sequence to leap over and omit for every point taken. The default Leap value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the Leap values with care; many Leap values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube, and so fail to be a uniform quasi-random point set.

## Choosing Leap Values for Halton Sets

A known rule for choosing Leap values for Halton sets is to set it to  $(P-1)$  where  $P$  is a prime number that has not been used to generate one of the dimensions, i.e. for a  $k$ -dimensional point set  $P$  would be the  $(k+1)$ th or greater prime.

**Examples** Experiment with different leap values:

```
% No leaping produces the standard Halton sequence.
P = haltonset(5);
P(1:5,:)

% Set a leap of 1. The point set now includes every other
% point from the sequence.
P.Lean = 1;
P(1:5,)
```

**See Also** net | grandset | Skip | subsref | haltonset

**Purpose** Length of dataset array

**Syntax** `n = length(A)`

**Description** `n = length(A)` returns the number of observations in the dataset A. `length` is equivalent to `size(A,1)`.

**See Also** `size`

# grandset.length

---

**Purpose** Length of point set

**Syntax** length(p)

**Description** length(p) returns the number of points in the point set p. It is equivalent to size(p, 1).

**See Also** grandset | size

**Purpose** Length of categorical array

**Syntax** `n = length(A)`

**Description** `n = length(A)` returns the size of the longest dimension of the categorical array `A` when `A` is not empty. If `A` is a vector, this is the same as its length. `length` is equivalent to `max(size(x))` for nonempty arrays, and 0 for empty arrays.

**See Also** `isempty` | `isscalar` | `size`

# categorical.levelcounts

---

**Purpose** Element counts by level

**Syntax** `C = levelcounts(A)`  
`C = levelcounts(A,dim)`

**Description** `C = levelcounts(A)` for a categorical vector `A` counts the number of elements in `A` equal to each of the possible levels in `A`. The output is a vector `C` containing those counts, and has as many elements as `A` has levels. For matrix `A`, `C` is a matrix of column counts. For  $N$ -dimensional arrays, `levelcounts` operates along the first nonsingleton dimension. `C = levelcounts(A,dim)` operates along the dimension `dim`.

**Examples** Count the number of patients in each age group in the data in `hospital.mat`:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
disp(labels')
'0s' '10s' '20s' '30s' '40s' '50s' '60s' '70s' '80s' '90s'

AgeGroup = ordinal(hospital.Age, labels, [], edges);
I = islevel(labels, AgeGroup);
disp(I')
0 1 1 1 1 1 1 1 1 1
c = levelcounts(AgeGroup);
disp(c')
0 0 15 41 42 2 0 0 0 0

AgeGroup = droplevels(AgeGroup);
I = islevel(labels, AgeGroup);
disp(I')
0 0 1 1 1 1 0 0 0 0
c = levelcounts(AgeGroup);
disp(c')
15 41 42 2
```

**See Also**     `islevel` | `ismember`

# leverage

---

## Purpose

Leverage

## Syntax

```
h = leverage(data)
h = leverage(data,model)
```

## Description

`h = leverage(data)` finds the leverage of each row (point) in the matrix data for a linear additive regression model.

`h = leverage(data,model)` finds the leverage on a regression, using a specified model type, where *model* can be one of these strings:

- 'linear' - includes constant and linear terms
- 'interaction' - includes constant, linear, and cross product terms
- 'quadratic' - includes interactions and squared terms
- 'purequadratic' - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.

## Algorithms

```
[Q,R] = qr(x2fx(data,'model'));
leverage = (sum(Q' .* Q'))'
```

## Examples

One rule of thumb is to compare the leverage to  $2p/n$  where  $n$  is the number of observations and  $p$  is the number of parameters in the model. For the Hald data set this value is 0.7692.

```
load hald
h = max(leverage(ingredients,'linear'))
h =
    0.7004
```

Since  $0.7004 < 0.7692$ , there are no high leverage points using this rule.

## How To

- regstats

# lhsdesign

---

**Purpose** Latin hypercube sample

**Syntax**

```
X = lhsdesign(n,p)
X = lhsdesign(...,'smooth','off')
X = lhsdesign(...,'criterion',criterion)
X = lhsdesign(...,'iterations',k)
```

**Description** `X = lhsdesign(n,p)` returns an  $n$ -by- $p$  matrix,  $X$ , containing a latin hypercube sample of  $n$  values on each of  $p$  variables. For each column of  $X$ , the  $n$  values are randomly distributed with one from each interval  $(0, 1/n)$ ,  $(1/n, 2/n)$ , ...,  $(1-1/n, 1)$ , and they are randomly permuted.

`X = lhsdesign(...,'smooth','off')` produces points at the midpoints of the above intervals:  $0.5/n$ ,  $1.5/n$ , ...,  $1-0.5/n$ . The default is 'on'.

`X = lhsdesign(...,'criterion',criterion)` iteratively generates latin hypercube samples to find the best one according to the criterion *criterion*, which can be one of the following strings.

Criterion	Description
'none'	No iteration.
'maximin'	Maximize minimum distance between points. This is the default.
'correlation'	Reduce correlation.

`X = lhsdesign(...,'iterations',k)` iterates up to  $k$  times in an attempt to improve the design according to the specified criterion. The default is  $k = 5$ .

**See Also** haltonset | sobolset | lhsnorm | unifrnd

---

<b>Purpose</b>	Latin hypercube sample from normal distribution
<b>Syntax</b>	<pre>X = lhsnorm(mu,sigma,n) X = lhsnorm(mu,sigma,n,flag) [X,Z] = lhsnorm(...)</pre>
<b>Description</b>	<p><code>X = lhsnorm(mu,sigma,n)</code> returns an <math>n</math>-by-<math>p</math> matrix, <math>X</math>, containing a latin hypercube sample of size <math>n</math> from a <math>p</math>-dimensional multivariate normal distribution with mean vector, <math>\mu</math>, and covariance matrix, <math>\sigma</math>.</p> <p><math>X</math> is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.</p> <p><code>X = lhsnorm(mu,sigma,n,flag)</code> controls the amount of smoothing in the sample. If <code>flag</code> is 'off', each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values <math>G(0.5/n)</math>, <math>G(1.5/n)</math>, ..., <math>G(1-0.5/n)</math> where <math>G</math> is the inverse normal cumulative distribution for that column's marginal distribution. If <code>flag</code> is 'on' (the default), each column has points uniformly distributed on the probability scale. For example, in place of <math>0.5/n</math> you use a value having a uniform distribution on the interval <math>(0/n, 1/n)</math>.</p> <p><code>[X,Z] = lhsnorm(...)</code> also returns <math>Z</math>, the original multivariate normal sample before the marginals are adjusted to obtain <math>X</math>.</p>
<b>References</b>	[1] Stein, M. "Large sample properties of simulations using latin hypercube sampling." <i>Technometrics</i> . Vol. 29, No. 2, 1987, pp. 143–151. Correction, Vol. 32, p. 367.

# lillietest

---

**Purpose** Lilliefors test

**Syntax**

```
h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest( __ )
[h,p,kstat,critval] = lillietest( __ )
```

**Description** `h = lillietest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = lillietest(x,Name,Value)` returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the  $p$ -value using a Monte Carlo approximation.

`[h,p] = lillietest( __ )` also returns the  $p$ -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,kstat,critval] = lillietest( __ )` also returns the test statistic `kstat` and the critical value `critval` for the test.

## Input Arguments

### **x - Sample data**

vector

Sample data, specified as a vector.

### **Data Types**

single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'Distr','exp','Alpha',0.01 tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

### **'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

- If MCTol is not used, Alpha must be in the range [0.001,0.50].
- If MCTol is used, Alpha must be in the range (0,1).

**Example:** 'Alpha',0.01

### **Data Types**

single | double

### **'Distr' - Distribution family**

'norm' (default) | 'exp' | 'ev'

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of 'Distr' and one of the following.

'norm'	Normal distribution
'exp'	Exponential distribution
'ev'	Extreme value distribution

**Example:** 'Distr','exp'

### **'MCTol' - Maximum Monte Carlo standard error**

scalar value in the range (0,1)

Maximum Monte Carlo standard error for  $p$ , the  $p$ -value of the test, specified as the comma-separated pair consisting of 'MCTol' and a scalar value in the range (0,1).

**Example:** 'MCTol',0.001

## Data Types

single | double

## Output Arguments

### h - Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### p - p-value

scalar value in the range (0,1)

$p$ -value of the test, returned as a scalar value in the range (0,1).  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

- If MCTol is not used,  $p$  is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. lillietest warns when  $p$  is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If MCTol is used, lillietest conducts a Monte Carlo simulation to compute a more accurate  $p$ -value, and  $p$  is returned as a scalar value in the range (0,1).

### kstat - Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

### **critval - Critical value**

nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

## **Examples**

### **Test for a Normal Distribution**

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
load carbig.mat;
[h,p,k,c] = lillietest(MPG)
```

Warning: P is less than the smallest tabulated value, returning 0.001.

```
h =
    1
p =
 1.0000e-003
k =
    0.0789
c =
    0.0451
```

The test statistic  $k$  is greater than the critical value  $c$ , so `lillietest` returns a result of  $h = 1$  to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates that the returned  $p$ -value is the smallest value in the table of precomputed values. To find a more accurate  $p$ -value, use `MCTol` to run a Monte Carlo approximation.

### **Test the Hypothesis at Different Significance Levels**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

```
[h,p] = lillietest(x,'Alpha',0.01)
```

```
h =  
0  
p =  
0.0348
```

The returned value of  $h = 0$  indicates that `lillietest` does not reject the null hypothesis at the 1% significance level.

## Test for an Exponential Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows an exponential distribution across different makes of cars.

```
load carbig.mat;  
h = lillietest(MPG,'Distr','exp')
```

```
h =  
1
```

The returned value of  $h = 1$  indicates that `lillietest` rejects the null hypothesis at the default 5% significance level.

## Determine the $p$ -value Using Monte Carlo Approximation

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Determine the  $p$ -value using a Monte Carlo approximation with a maximum Monte Carlo standard error of  $1e-4$ .

```
load carbig.mat;  
[h,p] = lillietest(MPG,'MCTol',1e-4)
```

```

h =
  1
p =
  0

```

The returned value of `h = 1` indicates that `lillietest` rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

## Definitions

### Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

$$D^* = \max_x |F(x) - G(x)|,$$

where  $\hat{F}(x)$  is the empirical cdf of the sample data and  $G(x)$  is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

`lillietest` can be used to test whether the data vector  $\mathbf{x}$  has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test  $\mathbf{x}$  for a lognormal distribution, test if  $\exp(\mathbf{x})$  has a normal distribution.
- To test  $\mathbf{x}$  for a Weibull distribution, test if  $\log(\mathbf{x})$  has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

## **Monte Carlo Standard Error**

The Monte Carlo standard error is the error due to simulating the  $p$ -value.

The Monte Carlo standard error is calculated as:

$$SE = \sqrt{\frac{(\hat{p})(1-\hat{p})}{\text{mcreps}}},$$

where  $\hat{p}$  is the estimated  $p$ -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, `mcreps`, is determined such that the Monte Carlo standard error for  $\hat{p}$  less than the value specified for `MCTol`.

## **Algorithms**

To compute the critical value for the hypothesis test, `lillietest` interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by `lillietest` is larger and more accurate than the table originally introduced by Lilliefors. If a more accurate  $p$ -value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the `MCTol` input argument can be used to run a Monte Carlo simulation to calculate the  $p$ -value more exactly.

When the computed value of the test statistic is greater than the critical value, `lillietest` rejects the null hypothesis at significance level `Alpha`.

`lillietest` treats NaN values in `x` as missing values and ignores them.

# LinearModel

---

**Purpose** Linear regression model class

**Description** An object comprising training data, model description, diagnostic information, and fitted coefficients for a linear regression. Predict model responses with the `predict` or `feval` methods.

**Construction** `mdl = fitlm(ds)` or `mdl = fitlm(X,y)` create a linear model of a dataset array `ds`, or of the responses `y` to a data matrix `X`. For details, see `fitlm`.

`mdl = stepwiselm(ds)` or `mdl = stepwiselm(X,y)` create a linear model of a dataset array `ds`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiselm`.

## Input Arguments

### **ds** - Input data

dataset array

Input data, specified as a dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### **Data Types**

single | double | logical

### **X** - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

### Data Types

single | double | logical

### **y** - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### Data Types

single | double

## Properties

### CoefficientCovariance

Covariance matrix of coefficient estimates.

### CoefficientNames

Cell array of strings containing a label for each coefficient.

### Coefficients

Table of coefficient values in a dataset array. **Coefficients** has one row for each coefficient and these columns:

- Estimate — Estimated coefficient value
- SE — Standard error of the estimate
- tStat —  $t$  statistic for a test that the coefficient is zero
- pValue —  $p$ -value for the  $t$  statistic

# LinearModel

---

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

## DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

## Diagnostics

Dataset array with the same number of rows as the input data (`ds` or `X`). `Diagnostics` contains diagnostics helpful in finding outliers and influential observations. Many diagnostics describe the effect on the fit of deleting single observations. `Diagnostics` contains the following fields.

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	<code>Leverage</code> indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with <code>P</code> coefficients and <code>N</code> observations, the average value of <code>Leverage</code> is <code>P/N</code> . An observation with <code>Leverage</code> larger than <code>2*P/N</code> can be regarded as having high leverage.
<code>CooksDistance</code>	Cook's measure of scaled change in fitted values	<code>CooksDistance</code> is a measure of scaled change in fitted values. An observation with <code>CooksDistance</code> larger than three times the mean Cook's distance can be an outlier.

Field	Meaning	Utility
Dffits	Delete-1 scaled differences in fitted values vs. observation number	Dffits is the scaled change in the fitted values for each observation that would result from excluding that observation from the fit. Values with an absolute value larger than $2 \cdot \sqrt{P/N}$ may be considered influential.
S2_i	Delete-1 variance vs. observation number	S2_i is a set of residual variance estimates obtained by deleting each observation in turn. These can be compared with the value of the MSE property.
CovRatio	Delete-1 ratio of determinant of covariance vs. observation number	CovRatio is the ratio of the determinant of the coefficient covariance matrix with each observation deleted in turn to the determinant of the covariance matrix for the full model. Values larger than $1 + 3 \cdot P/N$ or smaller than $1 - 3 \cdot P/N$ indicate influential points.
Dfbetas	Delete-1 scaled differences in covariance estimates vs. observation number	Dfbetas is an N-by-P matrix of the scaled change in the coefficient estimates that would result from excluding each observation in turn. Values larger than $3 / \sqrt{N}$ in absolute value indicate that the observation has a large influence on the corresponding coefficient.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an N-by-N matrix such that $\text{Fitted} = \text{HatMatrix} \cdot Y$ , where Y is the response vector and Fitted is the vector of fitted response values.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exception: Delete-1 diagnostics refer to the statistic with and without that observation (row) included in the fit. These diagnostics help identify important observations.

# LinearModel

---

## **Fitted**

Predicted response to the input data by using the model. Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

## **Formula**

Object containing information about the model.

## **LogLikelihood**

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

## **ModelCriterion**

AIC and other information criteria for comparing models. A structure with fields:

- `AIC` — Akaike information criterion
- `AICc` — Akaike information criterion corrected for sample size
- `BIC` — Bayesian information criterion
- `CAIC` — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

## **MSE**

Mean squared error (residuals),  $SSE/DFE$ .

## **NumCoefficients**

Number of coefficients in the model, a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

## NumEstimatedCoefficients

Number of estimated coefficients in the model, a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

## NumObservations

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original dataset or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

## NumPredictors

Number of variables `fitlm` used as predictors for fitting.

## NumVariables

Number of variables in the data. `NumVariables` is the number of variables in the original dataset when the fit is based on a dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

## ObservationInfo

Dataset with the same number of rows as the input data (`ds` or `X`).

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.

# LinearModel

---

Field	Description
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

## ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

## PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

## Residuals

Dataset array containing a table of residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
Pearson	Raw residuals divided by RMSE.

Field	Description
Standardized	Raw residuals divided by their estimated standard deviation.
Studentized	Residual divided by an independent estimate of the residual standard deviation. The residual for observation $i$ is divided by an estimate of the error standard deviation based on all observations except for observation $i$ .

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

## **ResponseName**

String giving naming the response variable.

## **RMSE**

Root mean squared error (residuals),  $\sqrt{\text{MSE}}$ .

## **Robust**

# LinearModel

---

Structure that is empty unless `fitlm` constructed the model using robust regression.

Field	Description
WgtFun	Robust weighting function, such as 'bisquare' (see <code>robustfit</code> )
Tune	Value specified for tuning parameter (can be [ ])
Weights	Vector of weights used in final iteration of robust fit

## **Rsquared**

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}.$$

Rsquared is a structure with two fields:

- Ordinary — Ordinary (unadjusted) R-squared
- Adjusted — R-squared adjusted for the number of coefficients

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

$$r2 = \text{mdl.Rsquared.Adjusted}$$

## **SSE**

Sum of squared errors (residuals).

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

## SSR

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## SST

Total sum of squares, the sum of squared deviations of  $y$  from  $\text{mean}(y)$ .

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## Steps

Structure that is empty unless `stepwiselm` constructed the model.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model
Upper	Formula representing the upper bound model, model cannot contain more terms than Upper
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Dataset representing the steps taken in the fit

The `History` dataset has one row for each step including the initial fit, and the following variables (columns).

# LinearModel

---

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"><li>'Start' — First step</li><li>'Add' — A term is added</li><li>'Remove' — A term is removed</li></ul>
TermName	<ul style="list-style-type: none"><li>'Start' step: The starting model specification</li><li>'Add' or 'Remove' steps: The term moved in that step</li></ul>
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code> )
DF	Regression degrees of freedom after this step
delDF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step
FStat	$F$ statistic that led to this step
PValue	$p$ -value of the $F$ statistic

## VariableInfo

Dataset array containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"><li>• Continuous variable — Two-element vector <math>[min, max]</math>, the minimum and maximum values</li><li>• Categorical variable — Cell array of distinct variable values</li></ul>
InModel	Logical vector, where true indicates the variable is in the model
IsCategorical	Logical vector, where true indicates a categorical variable

## VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a dataset, this property provides the names of the variables in that dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

## Variables

Dataset array containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a dataset array, `Variables` is a copy of that dataset. Otherwise, `Variables` is a dataset created from the input data matrix  $X$  and response vector  $y$ .

# LinearModel

---

## Methods

<code>addTerms</code>	Add terms to linear regression model
<code>anova</code>	Analysis of variance for linear model
<code>coefCI</code>	Confidence intervals of coefficient estimates of linear model
<code>coefTest</code>	Linear hypothesis test on linear regression model coefficients
<code>disp</code>	Display linear regression model
<code>dwtest</code>	Durbin-Watson test of linear model
<code>feval</code>	Evaluate linear regression model prediction
<code>fit</code>	Create linear regression model
<code>plot</code>	Scatter plot or added variable plot of linear model
<code>plotAdded</code>	Added variable plot or leverage plot for linear model
<code>plotAdjustedResponse</code>	Adjusted response plot for linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of linear regression model
<code>plotEffects</code>	Plot main effects of each predictor in linear regression model
<code>plotInteraction</code>	Plot interaction effects of two predictors in linear regression model
<code>plotResiduals</code>	Plot residuals of linear regression model

plotSlice	Plot of slices through fitted linear regression surface
predict	Predict response of linear regression model
random	Simulate responses for linear regression model
removeTerms	Remove terms from linear model
step	Improve linear regression model by adding or removing terms
stepwise	Create linear regression model by stepwise regression

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$ :

$$H = X(X^T X)^{-1} X^T.$$

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

### Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the

number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance,  $D_i$ , of observation  $i$  is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- $\hat{y}_j$  is the  $j$ th fitted response value.
- $\hat{y}_{j(i)}$  is the  $j$ th fitted response value, where the fit does not include observation  $i$ .
- $\text{MSE}$  is the mean squared error.
- $p$  is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left( \frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where  $r_i$  is the  $i$ th residual, and  $h_{ii}$  is the  $i$ th leverage value.

`CooksDistance` is an  $n$ -by-1 column vector in the `Diagnostics` dataset array of the `LinearModel` object.

## Examples

### Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
```

Linear regression model:

$$y \sim 1 + x_1 + x_2 + x_3 + x_4$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.45

R-squared: 0.982, Adjusted R-Squared 0.974

F-statistic vs. constant model: 111, p-value = 4.76e-07

### Linear Regression with Categorical Predictor and Nonlinear Model

Fit a model of a dataset array that contains a categorical predictor.  
Use a nonlinear response formula.

Load the carsmall data.

# LinearModel

---

```
load carsmall
```

Construct a dataset containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
ds = dataset(MPG,Weight);  
ds.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight2`. (You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight2`. For details, see "Formula" on page 21-938.)

```
mdl = fitlm(ds,'MPG ~ Year + Weight^2')
```

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ 1 + Weight + Year + Weight^2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 2.78
```

```
R-squared: 0.885, Adjusted R-Squared 0.88
```

```
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year (for more information on

dummy variables see “Dummy Indicator Variables” on page 2-55). The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164Weight + 2.0887(Year\_76) + 8.1864(Year\_82) + 1.557e - 06Weight^2$$

## Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
```

```
y ~ 1 + x1 + x2 + x3 + x4
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

```
Number of observations: 13, Error degrees of freedom: 8
```

```
Root Mean Squared Error: 2.65
```

```
R-squared: 0.979, Adjusted R-Squared 0.969
```

```
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

# LinearModel

---

## Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

## Alternatives

To remove redundant predictors in linear regression using lasso or elastic net, use the `lasso` function.

To regularize a regression with correlated terms using ridge regression, use the `ridge` or `lasso` functions.

To regularize a regression with correlated terms using partial least squares, use the `plsregress` function.

## How To

- “Linear Regression” on page 9-12

## Purpose

Linear mixed-effects model class

## Description

A `LinearMixedModel` object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

## Construction

You can fit a linear mixed-effects model using `fitlme(ds, formula)` if your data is in a `dataset` array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X, y, Z, G)`.

## Input Arguments

### **ds - Input data**

`dataset` array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a `dataset` array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-51). You must specify the model for the variables using `formula`.

### **Data Types**

`single` | `double` | `char` | `cell`

### **formula - Formula for model specification**

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see “Formula” on page 21-1722.

**Example:** `'y ~ treatment +(1|block)'`

# LinearMixedModel

---

## **X - Fixed-effects design matrix**

*n*-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of X corresponds to one observation, and each column of X corresponds to one variable.

### **Data Types**

single | double

## **y - Response values**

*n*-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

### **Data Types**

single | double

## **Z - Random-effects design**

*n*-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then Z must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then Z must be a cell array of length *R*. Each cell of Z contains an *n*-by-*q*(*r*) design matrix Z{*r*}, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, Z{*r*}.

### **Data Types**

single | double | cell

## **G - Grouping variable or variables**

*n*-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then  $G$  must be an  $n$ -by-1 vector corresponding to a single grouping variable with  $M$  levels or groups.

$G$  can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then  $G$  must be a cell array of length  $R$ . Each cell of  $G$  contains a grouping variable  $G\{r\}$ ,  $r = 1, 2, \dots, R$ , with  $M(r)$  levels.

$G\{r\}$  can be a categorical vector, numeric vector, character array, or cell array of strings.

## Data Types

single | double | char | cell

## Properties

### Coefficients

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

Name	Name of the term.
Estimate	Estimated value of the coefficient.
SE	Standard error of the coefficient.
tStat	$t$ -statistics for testing the null hypothesis that the coefficient is equal to zero.

# LinearMixedModel

---

DF	Degrees of freedom for the <i>t</i> -test. Method to compute DF is specified by the 'DFMethod' name-value pair argument. <code>Coefficients</code> always uses the 'Residual' method for 'DFMethod'.
pValue	<i>p</i> -value for the <i>t</i> -test.
Lower	Lower limit of the confidence interval for coefficient. <code>Coefficients</code> always uses the 95% confidence level, i.e. 'alpha' is 0.05.
Upper	Upper limit of confidence interval for coefficient. <code>Coefficients</code> always uses the 95% confidence level, i.e. 'alpha' is 0.05.

You can change 'DFMethod' and 'alpha' while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the `coefCI` and `coefTest` methods.

## **CoefficientCovariance**

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a *p*-by-*p* matrix, where *p* is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the `covarianceParameters` method.

## **Data Types**

double

## **CoefficientNames**

1-by- $p$  cell array of strings containing the names of the fixed-effects coefficients of a linear mixed-effects model.

## Data Types

cell

## DFE

Residual degrees of freedom, stored as a positive integer value.  $DFE = n - p$ , where  $n$  is the number of observations, and  $p$  is the number of fixed-effects coefficients.

This corresponds to the 'Residual' method of calculating degrees of freedom in the `fixedEffects` and `randomEffects` methods.

## Data Types

double

## FitMethod

Method used to fit the linear mixed-effects model, stored as either of the following strings.

- ML, if the fitting method is maximum likelihood
- REML, if the fitting method is restricted maximum likelihood

## Data Types

char

## Formula

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see “Formula” on page 21-1722.

## LogLikelihood

# LinearMixedModel

---

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

## Data Types

double

## ModelCriterion

Model criterion that can be used to compare fitted linear mixed-effects models, stored as a dataset with the following columns.

AIC	Akaike Information Criterion
BIC	Bayesian Information Criterion
Loglikelihood	Log likelihood value of the model
Deviance	-2 times the log likelihood of the model

If  $n$  is the number of observations used in fitting the model, and  $p$  is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is  $nc + p + 1$ , where  $nc$  is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
  - $n$ , when the fitting method is maximum likelihood (ML)
  - $n - p$ , when the fitting method is restricted maximum likelihood (REML)

## MSE

ML or REML estimate, based on the fitting method used for estimating  $\sigma^2$ , stored as a positive scalar value.  $\sigma^2$  is the residual variance or variance of the observation error term of the linear mixed-effects model.

**Data Types**

double

**NumCoefficients**

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

**Data Types**

double

**NumEstimatedCoefficients**

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

**Data Types**

double

**NumObservations**

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the dataset array, or the design matrices minus the excluded rows or rows with NaN values.

**Data Types**

double

**NumPredictors**

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

**Data Types**

double

**NumVariables**

# LinearMixedModel

---

Total number of variables including the response and predictors, stored as a positive integer value.

- If the sample data is in a dataset array `ds`, `NumVariables` is the total number of variables in `ds` including the response variable.
- If the fit is based on matrix input, `NumVariables` is the total number of columns in the predictor matrix or matrices, and response vector.

`NumVariables` includes variables, if there are any, that are not used as predictors or as the response.

## Data Types

double

## ObservationInfo

Information about the observations used in the fit, stored as a dataset array.

`ObservationInfo` has one row for each observation and the following four columns.

Weights	The value of the weighted variable for that observation. Default value is 1.
Excluded	true, if the observation was excluded from the fit using the 'Exclude' name-value pair argument, false, otherwise. 1 stands for true and 0 stands for false.

Missing

true, if the observation was excluded from the fit because any response or predictor value is missing, false, otherwise. Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <undefined> value for categorical arrays.

Subset

true, if the observation was used in the fit, false, if it was not used because it is missing or excluded.

## ObservationNames

Names of observations used in the fit, stored as a cell array of strings.

- If the data is in a dataset array, `ds`, containing observation names, `ObservationNames` has those names.
- If the data is provided in matrices or a dataset array without observation names, then `ObservationNames` is an empty cell array.

## Data Types

cell

## PredictorNames

Names of the variables that you use as predictors in the fit, stored as a cell array of strings that has the same length as `NumPredictors`.

## Data Types

cell

# LinearMixedModel

---

## ResponseName

Name of the variable used as the response variable in the fit, stored as a character string.

## Data Types

char

## Rsquared

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. Rsquared has two fields.

Ordinary

R-squared value, stored as a scalar value in a structure.  
Rsquared.Ordinary = 1 - SSE./SST

Adjusted

R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure.  
Rsquared.Adjusted = 1 - (SSE./SST)\*(DFT./DFE),  
where DFE = n - p, DFT = n - 1, and n is the total number of observations, p is the number of fixed-effects coefficients.

## Data Types

struct

## SSE

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

$SSE = \sum (y - F)^2$ , where  $y$  is the response vector, and  $F$  is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

## Data Types

double

## SSR

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar value. It is the sum of squared deviations of the conditional fitted values from their mean.

$SSR = \sum (F - \text{mean}(F))^2$ , where  $F$  is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

## Data Types

double

## SST

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

$SST = \sum (y - \text{mean}(y))^2 = SSR + SSE$ , where  $y$  is the response vector.

## Data Types

double

## Variables

Variables, stored as a dataset array.

- If the fit is based on a dataset array `ds`, then `Variables` is identical to `ds`.

# LinearMixedModel

---

- If the fit is based on matrix input, then `Variables` is a dataset array containing all the variables in the predictor matrix or matrices, and response variable.

## VariableInfo

Information about the variables used in the fit, stored as a dataset array.

`VariableInfo` has one row for each variable and contains the following four columns.

<code>Class</code>	Class of the variable ('double', 'cell', 'nominal', and so on).
<code>Range</code>	Value range of the variable. <ul style="list-style-type: none"><li>• For a numerical variable, it is a two-element vector of the form <code>[min,max]</code>.</li><li>• For a cell or categorical variable, it is a cell or categorical array containing all unique values of the variable.</li></ul>
<code>InModel</code>	<code>true</code> , if the variable is a predictor in the fitted model. <code>false</code> , if the variable is not in the fitted model.
<code>IsCategorical</code>	<code>true</code> , if the variable has a type that is treated as a categorical predictor, such as cell, logical, or categorical, or if it is specified as categorical by the 'Categorical' name-value pair argument of the fit

method.false, if it is a continuous predictor.

## VariableNames

Names of the variables used in the fit, stored as a cell array of strings.

- If sample data is in a dataset array `ds`, `VariableNames` contains the names of the variables in `ds`.
- If sample data is in matrix format, then `VariableInfo` includes variable names you supply while fitting the model. If you do not supply the variable names, then `VariableInfo` contains the default names.

## Data Types

cell

## Methods

<code>anova</code>	Analysis of variance for linear mixed-effects model
<code>coefCI</code>	Confidence intervals for coefficients of linear mixed-effects model
<code>coefTest</code>	Hypothesis test on fixed and random effects of linear mixed-effects model
<code>compare</code>	Compare linear mixed-effects models
<code>covarianceParameters</code>	Extract covariance parameters of linear mixed-effects model
<code>designMatrix</code>	Fixed- and random-effects design matrices

# LinearMixedModel

---

<code>disp</code>	Display linear mixed-effects model
<code>fit</code>	Fit linear mixed-effects model using dataset arrays
<code>fitmatrix</code>	Fit linear mixed-effects model using design matrices
<code>fitted</code>	Fitted responses from a linear mixed-effects model
<code>fixedEffects</code>	Estimates of fixed effects and related statistics
<code>plotResiduals</code>	Plot residuals of linear mixed-effects model
<code>predict</code>	Predict response of linear mixed-effects model
<code>random</code>	Generate random responses from fitted linear mixed-effects model
<code>randomEffects</code>	Estimates of random effects and related statistics
<code>residuals</code>	Residuals of fitted linear mixed-effects model
<code>response</code>	Response vector of the linear mixed-effects model

## Definitions

### Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms. Suppose a dataset array `ds` contains the following:

- A response variable,  $y$
- Predictor variables,  $X_j$ , which can be continuous or grouping variables
- Grouping variables,  $g_1, g_2, \dots, g_R$ ,

where the grouping variables in  $X_j$  and  $g_r$  can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, ' $y \sim \text{fixed} + (\text{random}_1 | g_1) + \dots + (\text{random}_R | g_R)$ ', the term `fixed` corresponds to a specification of the fixed-effects design matrix  $X$ , `random1` is a specification of the random-effects design matrix  $Z_1$  corresponding to grouping variable  $g_1$ , and similarly `randomR` is a specification of the random-effects design matrix  $Z_R$  corresponding to grouping variable  $g_R$ . You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$X^k$ , where $k$ is a positive integer	$X, X^2, \dots, X^k$
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$ )
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

# LinearMixedModel

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	Fixed effects for X1 and X2. The implicit intercept term is suppressed by including <code>-1</code> .
'y ~ 1 + (1   g1)'	Intercept plus random effect for each level of the grouping variable <code>g1</code> .
'y ~ X1 + (1   g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1   g1)'	Random intercept and slope, with possible correlation between them.
'y ~ X1 + (1   g1) + (-1 + X1   g1)'	Independent random intercept and slope.
'y ~ 1 + (1   g1) + (1   g2) + (1   g1:g2)'	Random intercept model with independent main effects for <code>g1</code> and <code>g2</code> , plus an independent interaction effect.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Random Intercept Model with Categorical Predictor

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...
            'IndVarName', 'Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

Because region is a nominal variable, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example,  $I[MidAtl]$  is the dummy variable representing the region `MidAtl`. For details, see “Dummy Indicator Variables” on page 2-55.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[MidAtl]_i + \beta_2 I[ENCentral]_i + \beta_3 I[WNCentral]_i + \beta_4 I[SAtl]_i \\ + \beta_5 I[ESCentral]_i + \beta_6 I[WSCentral]_i + \beta_7 I[Mtn]_i + \beta_8 I[Pac]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable `Date`,  $\beta_j$ ,  $j = 0, 1, \dots, 8$ , are the fixed-effects coefficients,  $b_{0m}$  is the random effect for level  $m$  of the grouping variable `Date`, and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b \sim N(0, \sigma_b^2)$  and the error term has the distribution,  $\varepsilon \sim N(0, \sigma_\varepsilon^2)$ .

# LinearMixedModel

---

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	9
Random effects coefficients	52
Covariance parameters	2

Formula:

```
FluRate ~ 1 + Region + (1|Date)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
318.71	364.35	-148.36	296.71

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF
'(Intercept)'	1.2233	0.096678	12.654	459
'Region_MidAtl'	0.010192	0.052221	0.19518	459
'Region_ENCentral'	0.051923	0.052221	0.9943	459
'Region_WNCentral'	0.23687	0.052221	4.5359	459
'Region_SAtl'	0.075481	0.052221	1.4454	459
'Region_ESCentral'	0.33917	0.052221	6.495	459
'Region_WSCentral'	0.069	0.052221	1.3213	459
'Region_Mtn'	0.046673	0.052221	0.89377	459
'Region_Pac'	-0.16013	0.052221	-3.0665	459

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	0.6443	0.588	0.701

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The  $p$ -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term,  $\sigma_b^2$ , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
```

```
y_hat =
    1.2884
```

You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =
```

# LinearMixedModel

---

```
1.2884
```

Compute the fitted marginal response for region WNCentral in week 10/9/2005.

```
F = fitted(lme, 'Conditional', false);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =
```

```
1.4602
```

## Linear Mixed-Effects Model with a Random Slope

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left( \mathbf{0}, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where  $D(\theta)$  is the covariance matrix.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];  
Z = [ones(406,1) Acceleration];  
Model_Year = nominal(Model_Year);
```

```
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Use the 'fminunc' optimization algorithm.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...  
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...  
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'},...  
'FitMethod','REML')
```

```
lme =
```

```
Linear mixed-effects model fit by REML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

```
Formula:
```

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
2202.9	2230.7	-1094.5	2188.9

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	p
'Intercept'	50.064	2.3176	21.602	389	1.0e-04
'Acceleration'	-0.57897	0.13843	-4.1825	389	3.0e-05
'Horsepower'	-0.16958	0.0073242	-23.153	389	3.0e-05

```
Random effects covariance parameters (95% CIs):
```

```
Group: Model_Year (13 Levels)
```

Name1	Name2	Type	Estimate
-------	-------	------	----------

# LinearMixedModel

---

```
'Intercept'          'Intercept'          'std'          3.72
'Acceleration'       'Intercept'          'corr'         -0.8769
'Acceleration'       'Acceleration'       'std'          0.3593
```

Group: Error

```
Name          Estimate    Lower    Upper
'Res Std'     3.6913     3.4331   3.9688
```

The fixed effects coefficients display includes the estimate, standard errors (SE), and the 95% confidence interval limits (Lower and Upper). The  $p$ -values for (pValue) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the `compare` method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

```
lme.CoefficientCovariance
```

```
ans =
```

```
 5.3711  -0.2809  -0.0126
-0.2809   0.0192   0.0005
-0.0126   0.0005   0.0001
```

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is `sqrt(5.3711)`.

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is  $-0.2809$  and the correlation between acceleration and horsepower is 0.0005.

Display the coefficient of determination for the model.

```
lme.Rsquared
```

```
ans =
```

```
  Ordinary: 0.7826
```

```
  Adjusted: 0.7815
```

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

```

# linhpytest

---

**Purpose** Linear hypothesis test

**Syntax** `p = linhpytest(beta,COVB,c,H,dfe)`  
`[p,t,r] = linhpytest(...)`

**Description** `p = linhpytest(beta,COVB,c,H,dfe)` returns the  $p$  value  $p$  of a hypothesis test on a vector of parameters. `beta` is a vector of  $k$  parameter estimates. `COVB` is the  $k$ -by- $k$  estimated covariance matrix of the parameter estimates. `c` and `H` specify the null hypothesis in the form  $H*b = c$ , where `b` is the vector of unknown parameters estimated by `beta`. `dfe` is the degrees of freedom for the `COVB` estimate, or `Inf` if `COVB` is known rather than estimated.

`beta` is required. The remaining arguments have default values:

- `COVB = eye(k)`
- `c = zeros(k,1)`
- `H = eye(K)`
- `dfe = Inf`

If `H` is omitted, `c` must have  $k$  elements and it specifies the null hypothesis values for the entire parameter vector.

---

**Note** The following functions return outputs suitable for use as the `COVB` input argument to `linhpytest`: `nlinfit`, `coxphfit`, `glmfit`, `mnrfit`, `regstats`, `robustfit`. `nlinfit` returns `COVB` directly; the other functions return `COVB` in `stats.covb`.

---

`[p,t,r] = linhpytest(...)` also returns the test statistic `t` and the rank `r` of the hypothesis matrix `H`. If `dfe` is `Inf` or is not given, `t*r` is a chi-square statistic with `r` degrees of freedom. If `dfe` is specified as a finite value, `t` is an  $F$  statistic with `r` and `dfe` degrees of freedom.

`linhpytest` performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation

procedure for which the parameter covariances are available, such as `regstats` or `glmfit`. For linear regression, the  $p$ -values are exact. For other procedures, the  $p$ -values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

## Examples

Fit a multiple linear model to the data in `hald.mat`:

```
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
beta =
    62.4054
     1.5511
     0.5102
     0.1019
    -0.1441
```

Perform an  $F$ -test that the last two coefficients are both 0:

```
SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhpytest(beta,SIGMA,c,H,dfe)
p =
    0.4668
F =
    0.8391
```

## See Also

`regstats` | `glmfit` | `robustfit` | `mnrfit` | `nlinfit` | `coxphfit`

# linkage

---

## Purpose

Agglomerative hierarchical cluster tree

## Syntax

```
Z = linkage(X)
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X,method,pdist_inputs)
Z = linkage(X,method,metric,'savememory',value)
Z = linkage(Y)
Z = linkage(Y,method)
```

## Description

`Z = linkage(X)` returns a matrix `Z` that encodes a tree of hierarchical clusters of the rows of the real matrix `X`.

`Z = linkage(X,method)` creates the tree using the specified *method*, where *method* describes how to measure the distance between clusters.

`Z = linkage(X,method,metric)` performs clustering using the distance measure *metric* to compute distances between the rows of `X`.

`Z = linkage(X,method,pdist_inputs)` passes parameters to the `pdist` function, which is the function that computes the distance between rows of `X`.

`Z = linkage(X,method,metric,'savememory',value)` uses a memory-saving algorithm when *value* is 'true', and uses the standard algorithm when *value* is 'false'.

`Z = linkage(Y)` uses a vector representation `Y` of a distance matrix. `Y` can be a distance matrix as computed by `pdist`, or a more general dissimilarity matrix conforming to the output format of `pdist`.

`Z = linkage(Y,method)` creates the tree using the specified *method*, where *method* describes how to measure the distance between clusters.

## Tips

- Computing `linkage(Y)` can be slow when `Y` is a vector representation of the distance matrix. For the 'centroid', 'median', and 'ward' methods, `linkage` checks whether `Y` is a Euclidean distance. Avoid this time-consuming check by passing in `X` instead of `Y`.

- The centroid and median methods can produce a cluster tree that is not monotonic. This occurs when the distance from the union of two clusters,  $r$  and  $s$ , to a third cluster is less than the distance between  $r$  and  $s$ . In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this, use another method. The following image shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. This leads to a nonmonotonic tree.

- You can provide the output  $Z$  to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

## Input Arguments

### **X**

Matrix with two or more rows. The rows represent observations, the columns represent categories or dimensions.

### **method**

# linkage

---

Algorithm for computing distance between clusters.

Method	Description
'average'	Unweighted average distance (UPGMA)
'centroid'	Centroid distance (UPGMC), appropriate for Euclidean distances only
'complete'	Furthest distance
'median'	Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only
'single'	Shortest distance
'ward'	Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only
'weighted'	Weighted average distance (WPGMA)

**Default:** 'single'

## **metric**

Any distance metric that the `pdist` function accepts.

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>X</code> is scaled by dividing by the corresponding element of the standard deviation <code>S=nanstd(X)</code> . To specify another value for <code>S</code> , use <code>D=pdist(X, 'seuclidean', S)</code> .
'cityblock'	City block metric.

Metric	Description
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use <code>D = pdist(X, 'minkowski', P)</code> , where <code>P</code> is a scalar
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of <code>X</code> as computed by <code>nancov</code> . To compute the distance with a different covariance, use <code>D = pdist(X, 'mahalanobis', C)</code> , where the matrix <code>C</code> is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
custom distance function	<p>A distance function specified using <code>@</code>:</p> $D = \text{pdist}(X, @\text{distfun})$ <p>A distance function must be of form</p> $d2 = \text{distfun}(XI, XJ)$ <p>taking as arguments a 1-by-<math>n</math> vector <math>XI</math>, corresponding to a single row of <math>X</math>, and an <math>m2</math>-by-<math>n</math> matrix <math>XJ</math>, corresponding to multiple rows of <math>X</math>. <code>distfun</code> must accept a matrix <math>XJ</math></p>

# linkage

---

Metric	Description
	with an arbitrary number of rows. <code>distfun</code> must return an $m2$ -by-1 vector of distances <code>d2</code> , whose $k$ th element is the distance between $XI$ and $XJ(k, :)$ .

**Default:** 'euclidean'

## **pdist\_inputs**

A cell array of parameters accepted by the `pdist` function. For example, to set the *metric* to `minkowski` and use an exponent of 5, set `pdist_inputs` to {'minkowski', 5}.

## **savememory**

A string, either 'on' or 'off'. When applicable, the 'on' setting causes `linkage` to construct clusters without computing the distance matrix. `savememory` is applicable when:

- `linkage` is 'centroid', 'median', or 'ward'
- `distance` is 'euclidean' (default)

When `savememory` is 'on', `linkage` run time is proportional to the number of dimensions (number of columns of  $X$ ). When `savememory` is 'off', `linkage` memory requirement is proportional to  $N^2$ , where  $N$  is the number of observations. So choosing the best (least-time) setting for `savememory` depends on the problem dimensions, number of observations, and available memory. The default `savememory` setting is a rough approximation of an optimal setting.

**Default:** 'on' when  $X$  has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix; otherwise 'off'

## **Y**

A vector of distances with the same format as the output of the `pdist` function:

- A row vector of length  $m(m-1)/2$ , corresponding to pairs of observations in a matrix  $X$  with  $m$  rows
- Distances arranged in the order  $(2,1)$ ,  $(3,1)$ , ...,  $(m,1)$ ,  $(3,2)$ , ...,  $(m,2)$ , ...,  $(m,m-1)$

$Y$  can be a more general dissimilarity matrix conforming to the output format of `pdist`.

## Output Arguments

### Z

$Z$  is a  $(m-1)$ -by-3 matrix, where  $m$  is the number of observations in the original data. Columns 1 and 2 of  $Z$  contain cluster indices linked in pairs to form a binary tree. The leaf nodes are numbered from 1 to  $m$ . Leaf nodes are the singleton clusters from which all higher clusters are built. Each newly-formed cluster, corresponding to row  $Z(I, :)$ , is assigned the index  $m+I$ .  $Z(I, 1:2)$  contains the indices of the two component clusters that form cluster  $m+I$ . There are  $m-1$  higher clusters which correspond to the interior nodes of the clustering tree.  $Z(I, 3)$  contains the linkage distances between the two clusters merged in row  $Z(I, :)$ .

For example, suppose there are 30 initial nodes and at step 12 cluster 5 and cluster 7 are combined. Suppose their distance at that time is 1.5. Then  $Z(12, :)$  will be  $[5, 7, 1.5]$ . The newly formed cluster will have index  $12 + 30 = 42$ . If cluster 42 appears in a later row, it means the cluster created at step 12 is being combined into some larger cluster.

## Definitions

### Linkages

The following notation is used to describe the linkages used by the various methods:

- Cluster  $r$  is formed from clusters  $p$  and  $q$ .
- $n_r$  is the number of objects in cluster  $r$ .
- $x_{ri}$  is the  $i$ th object in cluster  $r$ .

# linkage

---

- *Single linkage*, also called *nearest neighbor*, uses the smallest distance between objects in the two clusters:

$$d(r, s) = \min(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Complete linkage*, also called *furthest neighbor*, uses the largest distance between objects in the two clusters:

$$d(r, s) = \max(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Average linkage* uses the average distance between all pairs of objects in any two clusters:

$$d(r, s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \text{dist}(x_{ri}, x_{sj})$$

- *Centroid linkage* uses the Euclidean distance between the centroids of the two clusters:

$$d(r, s) = \|\bar{x}_r - \bar{x}_s\|_2$$

where

$$\bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri}$$

- *Median linkage* uses the Euclidean distance between weighted centroids of the two clusters,

$$d(r, s) = \|\tilde{x}_r - \tilde{x}_s\|_2$$

where  $\tilde{x}_r$  and  $\tilde{x}_s$  are weighted centroids for the clusters  $r$  and  $s$ . If cluster  $r$  was created by combining clusters  $p$  and  $q$ ,  $\tilde{x}_r$  is defined recursively as

$$\tilde{x}_r = \frac{1}{2}(\tilde{x}_p + \tilde{x}_q)$$

- *Ward's linkage* uses the incremental sum of squares; that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares measure is equivalent to the following distance measure  $d(r,s)$ , which is the formula linkage uses:

$$d(r,s) = \sqrt{\frac{2n_r n_s}{(n_r + n_s)}} \|\bar{x}_r - \bar{x}_s\|_2,$$

where

- $\|\cdot\|_2$  is Euclidean distance
- $\bar{x}_r$  and  $\bar{x}_s$  are the centroids of clusters  $r$  and  $s$
- $n_r$  and  $n_s$  are the number of elements in clusters  $r$  and  $s$

In some references the Ward linkage does not use the factor of 2 multiplying  $n_r n_s$ . The linkage function uses this factor so the distance between two singleton clusters is the same as the Euclidean distance.

- *Weighted average linkage* uses a recursive definition for the distance between two clusters. If cluster  $r$  was created by combining clusters  $p$  and  $q$ , the distance between  $r$  and another cluster  $s$  is defined as the average of the distance between  $p$  and  $s$  and the distance between  $q$  and  $s$ :

$$d(r,s) = \frac{(d(p,s) + d(q,s))}{2}$$

# linkage

---

## Examples

Compute four clusters of the Fisher iris data using Ward linkage and ignoring species information, and see how the cluster assignments correspond to the three species.

```
load fisheriris
Z = linkage(meas,'ward','euclidean');
c = cluster(Z,'maxclust',4);
crosstab(c,species)
firstfive = Z(1:5,:) % first 5 rows of Z
dendrogram(Z)
```

```
ans =
     0     25     1
     0     24    14
     0      1    35
    50      0     0
```

```
firstfive =
 102.0000  143.0000         0
   8.0000   40.0000    0.1000
   1.0000   18.0000    0.1000
  10.0000   35.0000    0.1000
 129.0000  133.0000    0.1000
```

Create a hierarchical cluster tree for a data with 20000 observations using Ward's linkage. If you set `savememory` to `'off'`, you can get an out-of-memory error if your machine doesn't have enough memory to hold the distance matrix. Cluster the data into four groups and plot the result.

```
X = rand(20000,3);  
Z = linkage(X,'ward','euclidean','savememory','on');  
c = cluster(Z,'maxclust',4);  
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```

# linkage

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Logistic probability distribution object

**Description** prob.LogisticDistribution is an object consisting of parameters, a model description, and sample data for a logistic probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Logistic')` creates a logistic probability distribution object using the default parameter values.

`pd = makedist('Logistic','mu',mu,'sigma',sigma)` creates a logistic probability distribution object using the specified parameter values.

### Input Arguments

#### **mu - Mean**

0 (default) | scalar value

Mean of the logistic distribution, specified as a scalar value.

#### **Data Types**

single | double

#### **sigma - Scale parameter**

1 (default) | nonnegative scalar value

Scale parameter of the logistic distribution, specified as a nonnegative scalar value.

#### **Data Types**

single | double

**Properties** **mu**

Mean of the logistic distribution, stored as a scalar value.

# prob.LogisticDistribution

---

## Data Types

single | double

## **sigma**

Scale parameter of the logistic distribution, stored as a nonnegative scalar value.

## Data Types

single | double

## **DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## **InputData**

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

single | double

## **IsTruncated**

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## **NumParameters**

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## **Data Types**

single | double

## **ParameterCovariance**

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## **Data Types**

single | double

## **ParameterDescription**

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## **Data Types**

char

## **ParameterIsFixed**

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

## **Data Types**

logical

## **ParameterNames**

# prob.LogisticDistribution

### Logistic Distribution

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

The logistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

The probability density function (pdf) is

# prob.LogisticDistribution

---

$$f(x | \mu, \sigma) = \frac{\exp\left\{\frac{x - \mu}{\sigma}\right\}}{\sigma \left(1 + \exp\left\{\frac{x - \mu}{\sigma}\right\}\right)^2} ; \quad -\infty < x < \infty.$$

## Examples

## Definitions **Loglogistic Distribution**

The loglogistic distribution is closely related to the logistic distribution. If  $x$  is distributed loglogistically with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed logistically with mean and standard deviation. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease.

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$\mu > 0$
sigma	Log scale parameter	$\sigma > 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma} \frac{1}{x} \frac{e^z}{(1 + e^z)^2} ; \quad x \geq 0,$$

where  $z = \frac{\log(x) - \mu}{\sigma}$ .

## Examples

### Create a Loglogistic Distribution Object Using Default Parameters

Create a loglogistic distribution object using the default parameter values.

```
pd = makedist('Loglogistic')
```

```
pd =
```

```
LoglogisticDistribution
```

```
Log-Logistic distribution
```

```
mu = 0
```

```
sigma = 1
```

### Create a Loglogistic Distribution Object Using Specified Parameters

Create a loglogistic distribution object by specifying the parameter values.

# prob.LoglogisticDistribution

---

```
pd = makedist('Loglogistic','mu',5,'sigma',2)
```

```
pd =
```

```
LoglogisticDistribution
```

```
Log-Logistic distribution
```

```
mu = 5
```

```
sigma = 2
```

Generate random numbers from the loglogistic distribution and compute their log values.

```
rng(19) % for reproducibility
```

```
x = random(pd,10000,1);
```

```
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m =
```

```
4.9828
```

The mean of the log of  $x$  is equal to the  $\mu$  parameter of  $x$ , since  $x$  has a loglogistic distribution.

Plot  $\log x$ .

```
hist(logx,50)
```

The plot shows that the log values of  $x$  have a logistic distribution.

## Concepts

- “Loglogistic Distribution” on page B-78
- Class Attributes
- Property Attributes

# logncdf

---

**Purpose** Lognormal cumulative distribution function

**Syntax**

```
p = logncdf(x,mu,sigma)
[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = logncdf( __ , 'upper' )
```

**Description** `p = logncdf(x,mu,sigma)` returns values at `x` of the lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies 100(1 - `alpha`)% confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = logncdf( __ , 'upper' )` returns the complement of the lognormal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use 'upper' with any of the previous syntaxes.

`logncdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{x - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal cdf is

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}}}{t} dt$$

**Examples****Compute Lognormal Distribution CDF**

```
x = (0:0.2:10);  
y = logncdf(x,0,1);  
plot(x,y);  
grid;  
xlabel('x');  
ylabel('p');
```

# logncdf

## How To

- “Lognormal Distribution” on page B-80

**Purpose**

Lognormal parameter estimates

**Syntax**

```
parmhat = lognfit(data)
[parmhat,parmci] = lognfit(data)
[parmhat,parmci] = lognfit(data,alpha)
[...] = lognfit(data,alpha,censoring)
[...] = lognfit(data,alpha,censoring,freq)
[...] = lognfit(data,alpha,censoring,freq,options)
```

**Description**

`parmhat = lognfit(data)` returns a vector of maximum likelihood estimates `parmhat(1) = mu` and `parmhat(2) = sigma` of parameters for a lognormal distribution fitting data. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution.

`[parmhat,parmci] = lognfit(data)` returns 95% confidence intervals for the parameter estimates `mu` and `sigma` in the 2-by-2 matrix `parmci`. The first column of the matrix contains the lower and upper confidence bounds for parameter `mu`, and the second column contains the confidence bounds for parameter `sigma`.

`[parmhat,parmci] = lognfit(data,alpha)` returns  $100(1 - \alpha)\%$  confidence intervals for the parameter estimates, where `alpha` is a value in the range (0 1) specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = lognfit(data,alpha,censoring)` accepts a Boolean vector `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = lognfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = lognfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The lognormal fit function accepts an `options`

# lognfit

---

structure which can be created using the function `statset`. Enter `statset('lognfit')` to see the names and default values of the parameters that `lognfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

---

**Note** With no censoring, `lognfit` computes `sigma` using the square root of the unbiased estimator of the variance. With censoring, `sigma` is the maximum likelihood estimate.

---

## Examples

This example generates 100 independent samples of lognormally distributed data with  $\mu = 0$  and  $\sigma = 3$ . `parmhat` estimates  $\mu$  and  $\sigma$  and `parmci` gives 99% confidence intervals around `parmhat`. Notice that `parmci` contains the true values of  $\mu$  and  $\sigma$ .

```
data = lognrnd(0,3,100,1);
[parmhat,parmci] = lognfit(data,0.01)
parmhat =
    -0.2480    2.8902
parmci =
    -1.0071    2.4393
     0.5111    3.5262
```

## See Also

`mle` | `lognlike` | `lognpdf` | `logncdf` | `logninv` | `lognstat` | `lognrnd`

## How To

- “Lognormal Distribution” on page B-80

**Purpose**

Lognormal inverse cumulative distribution function

**Syntax**

```
X = logninv(P,mu,sigma)
[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)
```

**Description**

`X = logninv(P,mu,sigma)` returns values at `P` of the inverse lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)` returns confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies  $100(1 - \alpha)\%$  confidence bounds. The default value of `alpha` is 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

`logninv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where  $q$  is the  $P$ th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal inverse function is defined in terms of the lognormal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x : F(x | \mu, \sigma) = p\}$$

where

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}} dt$$

## Examples

```
p = (0.005:0.01:0.995);  
crit = logninv(p,1,0.5);  
plot(p,crit)  
xlabel('Probability'); ylabel('Critical Value'); grid
```

# prob.LognormalDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Lognormal probability distribution object

**Description** prob.LognormalDistribution is an object consisting of parameters, a model description, and sample data for a lognormal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Lognormal')` creates a lognormal probability distribution object using the default parameter values.

`pd = makedist('Lognormal','mu',mu,'sigma',sigma)` creates a lognormal probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Log mean**

0 (default) | scalar value

Log mean for the lognormal distribution, specified as a scalar value. `mu` is the mean of the log of  $x$ , when  $x$  has a lognormal distribution.

### **Data Types**

single | double

### **sigma - Log standard deviation**

1 (default) | nonnegative scalar value

Log standard deviation for the lognormal distribution, specified as a nonnegative scalar value. `sigma` is the standard deviation of the log of  $x$ , when  $x$  has a lognormal distribution.

### **Data Types**

single | double

## Properties

### **mu**

Log mean for the lognormal distribution, stored as a scalar value.

### **Data Types**

single | double

### **sigma**

Log standard deviation for the lognormal distribution, stored as a nonnegative scalar value.

### **Data Types**

single | double

### **DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

### **Data Types**

char

### **InputData**

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

### **Data Types**

single | double

### **IsTruncated**

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated.

# prob.LognormalDistribution

---

If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

### Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object

# prob.LognormalDistribution

---

pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions **Lognormal Distribution**

The lognormal distribution is closely related to the normal distribution. If  $x$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ . The lognormal distribution is applicable when the quantity of interest must be positive, since  $\log(x)$  exists only when  $x$  is positive.

The lognormal distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$-\infty < \mu < \infty$
sigma	Log standard deviation	$\sigma \geq 0$

The probability density function (pdf) of the lognormal distribution is

$$f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{-\frac{(\ln x - \mu)^2}{2\sigma^2}\right\} ; \quad x > 0.$$

## Examples

### Create a Lognormal Distribution Object Using Default Parameters

Create a lognormal distribution object using the default parameter values.

```
pd = makedist('Lognormal')
```

```
pd =
```

```
LognormalDistribution
```

```
Lognormal distribution
```

```
mu = 0
```

```
sigma = 1
```

### Create a Lognormal Distribution Object Using Specified Parameters

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal','mu',5,'sigma',2)
```

```
pd =
```

# prob.LognormalDistribution

---

```
LognormalDistribution
```

```
Lognormal distribution  
mu = 5  
sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)
```

```
ans =
```

```
1.0966e+03
```

The mean of the lognormal distribution is not equal to the mu parameter.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng(47); % for reproducibility  
x = random(pd,10000,1);  
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m =
```

```
4.9999
```

The mean of the log of x is equal to the mu parameter of x, since x has a lognormal distribution.

Plot logx.

```
hist(logx,50)
```

The plot shows that the log values of  $x$  are normally distributed with a mean equal to 5 and a standard deviation equal to 2.

# lognpdf

---

**Purpose** Lognormal probability density function

**Syntax** `Y = lognpdf(X,mu,sigma)`

**Description** `Y = lognpdf(X,mu,sigma)` returns values at `X` of the lognormal pdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

The lognormal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{(\ln x - \mu)^2}{2\sigma^2}}$$

The normal and lognormal distributions are closely related. If  $X$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(X)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ .

The mean  $m$  and variance  $v$  of a lognormal random variable are functions of  $\mu$  and  $\sigma$  that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$

$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean  $m$  and variance  $v$  has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$

$$\sigma = \sqrt{\log\left(v / m^2 + 1\right)}$$

The lognormal distribution is applicable when the quantity of interest must be positive, since  $\log(X)$  exists only when  $X$  is positive.

## Examples

```
x = (0:0.02:10);  
y = lognpdf(x,0,1);  
plot(x,y); grid;  
xlabel('x'); ylabel('p')
```

## How To

- “Lognormal Distribution” on page B-80

# lognrnd

---

**Purpose** Lognormal random numbers

**Syntax**  
`R = lognrnd(mu,sigma)`  
`R = lognrnd(mu,sigma,m,n,...)`  
`R = lognrnd(mu,sigma,[m,n,...])`

**Description** `R = lognrnd(mu,sigma)` returns an array of random numbers generated from the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = lognrnd(mu,sigma,m,n,...)` or `R = lognrnd(mu,sigma,[m,n,...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

The normal and lognormal distributions are closely related. If  $X$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(X)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ .

The mean  $m$  and variance  $v$  of a lognormal random variable are functions of  $\mu$  and  $\sigma$  that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean  $m$  and variance  $v$  has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log\left(v / m^2 + 1\right)}$$

**Examples**

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;  
v = 2;  
mu = log((m^2)/sqrt(v+m^2));  
sigma = sqrt(log(v/(m^2)+1));
```

```
[M,V]= lognstat(mu,sigma)
```

```
M =  
    1  
V =  
    2.0000
```

```
X = lognrnd(mu,sigma,1,1e6);
```

```
MX = mean(X)
```

```
MX =  
    0.9974
```

```
VX = var(X)
```

```
VX =  
    1.9776
```

**How To**

- “Lognormal Distribution” on page B-80

# lognstat

---

**Purpose** Lognormal mean and variance

**Syntax** `[M,V] = lognstat(mu,sigma)`

**Description** `[M,V] = lognstat(mu,sigma)` returns the mean of and variance of the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

The normal and lognormal distributions are closely related. If  $X$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(X)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ .

The mean  $m$  and variance  $v$  of a lognormal random variable are functions of  $\mu$  and  $\sigma$  that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean  $m$  and variance  $v$  has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log\left(v / m^2 + 1\right)}$$

**Examples** Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;  
v = 2;
```

```
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

[M,V]= lognstat(mu,sigma)
M =
    1
V =
    2.0000

X = lognrnd(mu,sigma,1,1e6);

MX = mean(X)
MX =
    0.9974
VX = var(X)
VX =
    1.9776
```

**How To**

• “Lognormal Distribution” on page B-80

# CompactClassificationDiscriminant.logP

---

**Purpose** Log of the unconditional probability density

**Syntax** `lp = logP(obj, Xnew)`

**Description** `lp = logP(obj, Xnew)` returns the log of the unconditional probability density of each row of `Xnew`, computed using the discriminant analysis model `obj`.

**Input Arguments**

**obj**  
Discriminant analysis classifier, produced using `ClassificationDiscriminant.fit`.

**Xnew**  
Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `Xnew` must equal the number of predictors in `obj`.

**Output Arguments**

**lp**  
Column vector with the same number of rows as `Xnew`. Each entry is the logarithm of the unconditional probability density of the corresponding row of `Xnew`.

## Definitions **Unconditional Probability Density**

The unconditional probability density of a point  $x$  of a discriminant analysis model is

$$P(x) = \sum_{k=1}^K P(x, k),$$

where  $P(x, k)$  is the conditional density of the model at  $x$  for class  $k$ , when the total number of classes is  $K$ .

The conditional density  $P(x, k)$  is

$$P(x,k) = P(k)P(x|k),$$

where  $P(k)$  is the prior probability of class  $k$ , and  $P(x|k)$  is the conditional density of  $x$  given class  $k$ . The conditional density function of the multivariate normal with mean  $\mu_k$  and covariance  $\Sigma_k$  at a point  $x$  is

$$P(x|k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x-\mu_k)^T \Sigma_k^{-1}(x-\mu_k)\right),$$

where  $|\Sigma_k|$  is the determinant of  $\Sigma_k$ , and  $\Sigma_k^{-1}$  is the inverse matrix.

## Examples

### logP Calculation

Construct a discriminant analysis classifier for the Fisher iris data, and examine its prediction for an average measurement.

Load the Fisher iris data and construct a default discriminant analysis classifier.

```
load fisheriris
mdl = ClassificationDiscriminant.fit(meas,species);
```

Find the log probability of the discriminant model applied to an average iris.

```
logpaverage = logP(mdl,mean(meas))
```

```
logpaverage =
```

```
-1.7254
```

# ClassificationKNN.loss

---

**Purpose** Loss of  $k$ -nearest neighbor classifier

**Syntax**  
`L = loss(md1,X,Y)`  
`L = loss(md1,X,Y,Name,Value)`

**Description** `L = loss(md1,X,Y)` returns a scalar representing how well `md1` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `md1`.

`L = loss(md1,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**md1**  
*k*-nearest neighbor classifier, created by `ClassificationKNN.fit`.

**X**  
Matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

**Y**  
A numeric vector, vector of categorical variables (nominal or ordinal), logical vector, character array, or cell array of strings, with the same number of rows as `X`. Each row of `Y` represents the classification of the corresponding row of `X`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'lossfun'**

Function handle or string representing a loss function. The built-in loss functions are:

- 'binodeviance' — See “Loss Functions” on page 21-1786.
- 'exponential' — See “Loss Functions” on page 21-1786.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-1786.
- 'mincost' — Smallest misclassification cost as given by the `mdl.Cost` matrix. See “Loss Functions” on page 21-1786.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-1786.

**Default:** 'mincost'

## 'weights'

Numeric vector of length  $N$ , where  $N$  is the number of rows of  $X$ . `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

**Default:** `ones(N,1)`

## Output Arguments

**L**

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-1791.

## Definitions

### Classification Error

The default classification error is the fraction of data  $X$  that `mdl` misclassifies, where  $Y$  represents the true classifications.

# ClassificationKNN.loss

---

The weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `mdl` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of  $X$ .
- $K$  is the number of classes in the classifier, represented in the `ClassNames` property.
- $C$  is an  $N$ -by- $K$  logical matrix, with one true per row for the true class. The index for each class is its position in the `ClassNames` property.

- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use  $COST = \text{ones}(K) - \text{eye}(K)$ , which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `ClassificationKNN.fit`.  $Cost(i, j)$  is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default,  $Cost(i, j) = 1$  if  $i \neq j$ , and  $Cost(i, j) = 0$  if  $i = j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have  $K$  classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

# ClassificationKNN.loss

---

returns, among other outputs, a `cost` matrix of size `Nobs-by-K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{new}(n))$  is the posterior probability of class  $i$  for observation  $X_{new}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Examples

### Loss Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = ClassificationKNN.fit(meas,species,'NumNeighbors',5);
```

Examine the loss of the classifier for a mean observation classified 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
L = loss(mdl,X,Y)
```

```
L =
```

0

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

## Concepts

- “Classification Using Nearest Neighbors” on page 16-9

# CompactClassificationDiscriminant.loss

---

**Purpose** Classification error

**Syntax**  
`L = loss(obj,X,Y)`  
`L = loss(obj,X,Y,Name,Value)`

**Description** `L = loss(obj,X,Y)` returns a scalar representing how well `obj` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `obj`.

`L = loss(obj,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**obj**  
Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `ClassificationDiscriminant.fit`.

**X**  
Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

**Y**  
Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-1792.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-1792.
- 'exponential' — See “Loss Functions” on page 21-1792.
- 'mincost' — Smallest misclassification cost as given by the `obj.Cost` matrix. See “Loss Functions” on page 21-1792.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-1792.

**Default:** 'mincost'

## 'weights'

Numeric vector of length  $N$ , where  $N$  is the number of rows of  $X$ . `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

**Default:** `ones(N,1)`

## Output Arguments

**L**

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-1791.

## Definitions

### Classification Error

The default classification error is the fraction of data  $X$  that `obj` misclassifies, where  $Y$  represents the true classifications.

# CompactClassificationDiscriminant.loss

---

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when obj misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `COST` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of  $X$ .
- $K$  is the number of classes in the classifier, represented in the `ClassNames` property.
- $C$  is an  $N$ -by- $K$  logical matrix, with one true per row for the true class. The index for each class is its position in the `ClassNames` property.

- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use  $COST = \text{ones}(K) - \text{eye}(K)$ , which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Posterior Probability

The posterior probability that a point  $z$  belongs to class  $j$  is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean  $\mu_j$  and covariance  $\Sigma_j$  at a point  $z$  is

$$P(x | k) = \frac{1}{(2\pi |\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where  $|\Sigma_k|$  is the determinant of  $\Sigma_k$ , and  $\Sigma_k^{-1}$  is the inverse matrix.

Let  $P(k)$  represent the prior probability of class  $k$ . Then the posterior probability that an observation  $x$  is of class  $k$  is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where  $P(x)$  is a normalization constant, the sum over  $k$  of  $P(x | k)P(k)$ .

## Prior Probability

The prior probability is one of three choices:

# CompactClassificationDiscriminant.loss

---

- 'uniform' — The prior probability of class  $k$  is one over the total number of classes.
- 'empirical' — The prior probability of class  $k$  is the number of training samples of class  $k$  divided by the total number of training samples.
- Custom — The prior probability of class  $k$  is the  $k$ th element of the prior vector. See `ClassificationDiscriminant.fit`.

After creating a classifier `obj`, you can set the prior by dot addressing:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

## Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

## Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = ClassificationDiscriminant.fit(meas,species);
L = loss(obj,meas,species)
```

```
L =
    0.0200
```

## See Also

## How To

- “Discriminant Analysis” on page 15-3

# CompactClassificationEnsemble.loss

---

## Purpose

Classification error

## Syntax

```
L = loss(ens,X,Y)
L = loss(ens,X,Y,Name,Value)
```

## Description

`L = loss(ens,X,Y)` returns the classification error for ensemble `ens` computed using matrix of predictors `X` and true class labels `Y`.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `ens`.

`L = loss(ens,X,Y,Name,Value)` computes classification error with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

### **X**

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `ens`. `X` should have the same number of rows as the number of elements in `Y`.

### **Y**

Classification of `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `X`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

# CompactClassificationEnsemble.loss

---

specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## 'learners'

Indices of weak learners in the ensemble ranging from 1 to ens.NTrained. loss uses only these learners for calculating loss.

**Default:** 1:NTrained

## 'lossfun '

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-1797
- 'classiferror' — Fraction of misclassified data
- 'exponential' — See “Loss Functions” on page 21-1797

You can write your own loss function in the syntax described in “Loss Functions” on page 21-1797.

**Default:** 'classiferror'

## 'mode'

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## 'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When `UseObsForLearner(i, j)` is true, learner j is used in predicting the class of row i of X.

**Default:** `true(N,T)`

## 'weights'

Vector of observation weights, with nonnegative entries. The length of `weights` must equal the number of rows in X. When you specify weights, `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class.

**Default:** `ones(size(X,1),1)`

## Output Arguments

### L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

## Definitions

### Classification Error

The default classification error is the fraction of the data X that ens misclassifies, where Y are the true classifications.

Weighted classification error is the sum of weight *i* times the Boolean value that is 1 when `tree` misclassifies the *i*th row of X, divided by the sum of the weights.

### Loss Functions

The built-in loss functions are:

# CompactClassificationEnsemble.loss

---

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by  $w$ .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of `ens.X`.
- $K$  is the number of classes in `ens`, represented in `ens.ClassNames`.
- $C$  is an  $N$ -by- $K$  logical matrix, with one true per row for the true class. The index for each class is its position in `tree.ClassNames`.
- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the `score` output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Create a compact classification ensemble for the ionosphere data, and find the fraction of training data that the ensemble misclassifies:

```
load ionosphere
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
adb = compact(ada);
L = loss(adb,X,Y)
```

```
L =
    0.0085
```

## See Also

[loss](#) | [edge](#) | [margin](#) | [predict](#)

# CompactClassificationTree.loss

---

**Purpose** Classification error

**Syntax**

```
L = loss(tree,X,Y)
L = loss(tree,X,Y,Name,Value)
L = loss(tree,X,Y,'subtrees',subtreevector)
[L,se] = loss(tree,X,Y,'subtrees',subtreevector)
[L,se,NLeaf] = loss(tree,X,Y,'subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = loss(tree,X,Y,'subtrees',
    subtreevector)
[L,...] =
loss(tree,X,Y,'subtrees',subtreevector,Name,Value)
```

**Description** `L = loss(tree,X,Y)` returns a scalar representing how well tree classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `tree`.

`L = loss(tree,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

`L = loss(tree,X,Y,'subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = loss(tree,X,Y,'subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

---

**Note** `loss` returns `se` and further outputs only when the `lossfun` name-value pair is the default `'classiferror'`.

---

`[L,se,NLeaf] = loss(tree,X,Y,'subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = loss(tree,X,Y,'subtrees', subtreevector)` returns the best pruning level as defined in the `treesize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = loss(tree,X,Y,'subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

A classification tree or compact classification tree constructed by `ClassificationTree.fit` or `compact`.

### **X**

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` should have the same number of rows as the number of elements in `Y`.

### **Y**

Classification of `X`. `Y` should be of the same type as the classification used to train `tree`, and its number of elements should equal the number of rows of `X`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'lossfun'**

Function handle or string representing a loss function. Built-in loss functions:

# CompactClassificationTree.loss

---

- 'binodeviance' — See “Loss Functions” on page 21-1804
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-1804.
- 'exponential' — See “Loss Functions” on page 21-1804
- 'mincost' — Smallest misclassification cost as given by the `tree.Cost` matrix. See “Loss Functions” on page 21-1804.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-1804.

**Default:** 'mincost'

## 'weights'

A numeric vector of length  $N$ , where  $N$  is the number of rows of  $X$ . `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

**Default:** `ones(N,1)`

Name, Value arguments associated with pruning subtrees:

## 'subtrees'

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`. You can set subtrees to 'all', meaning the entire pruning sequence.

**Default:** 0

## 'treesize'

One of the following strings:

- 'se' — loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- 'min' — loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Output Arguments

**L**

Classification error, a vector the length of subtrees. The meaning of the error depends on the values in `weights` and `lossfun`; see “Classification Error” on page 21-1803.

**se**

Standard error of loss, a vector the length of subtrees.

**NLeaf**

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

**bestlevel**

A scalar whose value depends on `treesize`:

- `treesize = 'se'` — loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- `treesize = 'min'` — loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Definitions

### Classification Error

The default classification error is the fraction of data  $X$  that `tree` misclassifies, where  $Y$  represents the true classifications.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `tree` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

# CompactClassificationTree.loss

---

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `COST` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of `X`.
- `K` is the number of classes in the classifier, represented in the `ClassNames` property.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.

- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use  $COST = \text{ones}(K) - \text{eye}(K)$ , which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `ClassificationTree.fit` method.  $Cost(i, j)$  is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default,  $Cost(i, j)=1$  if  $i \neq j$ , and  $Cost(i, j)=0$  if  $i=j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have  $K$  classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by- $K$ . Each row of `CE` contains the expected (average) cost of classifying the observation into each of the  $K$  classes.  $CE(n, k)$  is

# CompactClassificationTree.loss

---

$$\sum_{i=1}^K \hat{P}(i | X_{new(n)}) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{new(n)})$  is the posterior probability of class  $i$  for observation  $X_{new(n)}$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

1

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

# CompactClassificationTree.loss

2

Prune the tree:

```
tree1 = prune(tree, 'level', 1);  
view(tree1, 'mode', 'graph')
```

# CompactClassificationTree.loss

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

### 3

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0    1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0    1.0000    0.0975  
    0.9059    0.0941    0.2785
```

0.9059	0.0941	0.5469
0.9059	0.0941	0.9575
0.9059	0.0941	0.9649

Indeed, every value of  $X$  (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Compute the resubstituted classification error for the ionosphere data:

```
load ionosphere
tree = ClassificationTree.fit(X,Y);
L = loss(tree,X,Y)
```

```
L =
    0.0114
```

## See Also

[margin](#) | [edge](#) | [predict](#)

# CompactRegressionEnsemble.loss

---

**Purpose** Regression error

**Syntax**  
`L = loss(ens,X,Y)`  
`L = loss(ens,X,Y,Name,Value)`

**Description** `L = loss(ens,X,Y)` returns the mean squared error between the predictions of `ens` to the data in `X`, compared to the true responses `Y`.  
`L = loss(ens,X,Y,Name,Value)` computes the error in prediction with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A regression ensemble created with `fitensemble`, or the compact method.

### **X**

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

NaN values in `X` are taken to be missing values. Observations with all missing values for `X` are not used in the calculation of loss.

### **Y**

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

NaN values in `Y` are taken to be missing values. Observations with missing values for `Y` are not used in the calculation of loss.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NTrained`. `oobEdge` uses only these learners for calculating loss.

**Default:** `1:NTrained`

## 'lossfun'

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

**Default:** `'mse'`

## 'mode'

String representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

# CompactRegressionEnsemble.loss

---

**Default:** 'ensemble'

## 'UseObsForLearner'

A logical matrix of size N-by-NTrained, where N is the number of observations in `ens.X`, and NTrained is the number of weak learners. When `UseObsForLearner(I,J)` is true, `predict` uses learner J in predicting observation I.

**Default:** `true(N,NTrained)`

## 'weights'

Numeric vector of observation weights with the same number of elements as Y. The formula for loss with weights is in “Weighted Mean Squared Error” on page 21-1812.

**Default:** `ones(size(Y))`

## Output Arguments

**L**

Weighted mean squared error of predictions. The formula for loss is in “Weighted Mean Squared Error” on page 21-1812.

## Definitions

### Weighted Mean Squared Error

Let  $n$  be the number of rows of data,  $x_j$  be the  $j$ th row of data,  $y_j$  be the true response to  $x_j$ , and let  $f(x_j)$  be the response prediction of `ens` to  $x_j$ . Let  $w$  be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one:  $w \rightarrow w/\sum w$ . The mean squared error  $L$  is

$$L = \sum_{j=1}^n w_j (f(x_j) - y_j)^2.$$

## Examples

Find the loss of an ensemble predictor of the `carsmall` data to find MPG as a function of engine displacement, horsepower, and vehicle weight:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
L = loss(ens,X,MPG)
```

```
L =
    4.3904
```

## See Also

[predict](#) | [fitensemble](#)

# CompactRegressionTree.loss

---

**Purpose** Regression error

**Syntax**

```
L = loss(tree,X,Y)
[L,se] = loss(tree,X,Y)
[L,se,NLeaf] = loss(tree,X,Y)
[L,se,NLeaf,bestlevel] = loss(tree,X,Y)
L = loss(tree,X,Y,Name,Value)
```

**Description**

`L = loss(tree,X,Y)` returns the mean squared error between the predictions of `tree` to the data in `X`, compared to the true responses `Y`.

`[L,se] = loss(tree,X,Y)` returns the standard error of the loss.

`[L,se,NLeaf] = loss(tree,X,Y)` returns the number of leaves (terminal nodes) in the tree.

`[L,se,NLeaf,bestlevel] = loss(tree,X,Y)` returns the optimal pruning level for `tree`.

`L = loss(tree,X,Y,Name,Value)` computes the error in prediction with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

Regression tree created with `RegressionTree.fit`, or the `compact` method.

### **X**

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

### **Y**

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## **'lossfun'**

Function handle for loss, or the string 'mse' representing mean-squared error. If you pass a function handle fun, loss calls fun as:

```
fun(Y,Yfit,W)
```

- Y is the vector of true responses.
- Yfit is the vector of predicted responses.
- W is the observation weights. If you pass W, the elements are normalized to sum to 1.

All the vectors have the same number of rows as Y.

**Default:** 'mse'

## **'subtrees'**

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`. You can set subtrees to 'all', meaning the entire pruning sequence.

**Default:** 0

## **'treesize'**

A string, either:

- 'se' — loss returns `bestlevel` that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.

# CompactRegressionTree.loss

---

- 'min' — loss returns `bestlevel` that corresponds to the minimal MSE tree.

## 'weights'

Numeric vector of observation weights with the same number of elements as `Y`.

**Default:** `ones(size(Y))`

## Output Arguments

### **L**

Classification error, a vector the length of `subtrees`. The error for each tree is the mean squared error, weighted with `weights`. If you include `lossfun`, `L` reflects the loss calculated with `lossfun`.

### **se**

Standard error of loss, a vector the length of `subtrees`.

### **Nleaf**

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `subtrees`.

### **bestlevel**

A scalar whose value depends on `treesize`:

- `treesize = 'se'` — loss returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `subtrees`).
- `treesize = 'min'` — loss returns the element of `subtrees` with smallest loss, usually the smallest element of `subtrees`.

## Definitions

### **Mean Squared Error**

The mean squared error  $m$  of the predictions  $f(X_n)$  with weight vector  $w$  is

$$m = \frac{\sum w_n (f(X_n) - Y_n)^2}{\sum w_n}.$$

## Examples

Find the loss of a regression tree predictor of the carsmall data to find MPG as a function of engine displacement, horsepower, and vehicle weight:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
L = loss(tree,X,MPG)
```

```
L =
    4.8952
```

---

Find the pruning level that gives the optimal level of loss for the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
[L,se,NLeaf,bestlevel] = loss(tree,X,MPG,'Subtrees','all');
bestlevel
```

```
bestlevel =
    4
```

## See Also

predict

# paretotails.lowerparams

---

**Purpose** Lower Pareto tails parameters

**Syntax** `params = lowerparams(obj)`

**Description** `params = lowerparams(obj)` returns the 2-element vector `params` of shape and scale parameters, respectively, of the lower tail of the Pareto tails object `obj`. `lowerparams` does not return a location parameter.

**Examples** Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);  
obj = paretotails(t,0.1,0.9);
```

```
lowerparams(obj)  
ans =  
    -0.1901    1.1898  
upperparams(obj)  
ans =  
    0.3646    0.5103
```

**See Also** `paretotails` | `upperparams`

**Purpose** Less than relation for handles

**Syntax** `h1 < h2`

**Description** `h1 < h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = lt(h1, h2)` stores the result in a logical array of the same dimensions.

**See Also** `grandstream | eq | ge | gt | le | ne`

# lsline

---

**Purpose** Add least-squares line to scatter plot

**Syntax** `lsline`  
`h = lsline`

**Description** `lsline` superimposes a least-squares line on each scatter plot in the current axes. Scatter plots are produced by the MATLAB `scatter` and `plot` functions. Data points connected with solid, dashed, or dash-dot lines ('-', '--', or '-.') are not considered to be scatter plots by `lsline`, and are ignored.

`h = lsline` returns a column vector of handles `h` to the least-squares lines.

**Examples** Use `lsline` together with scatter plots produced by `scatter` and various line styles of `plot`:

```
x = 1:10;  
  
y1 = x + randn(1,10);  
scatter(x,y1,25,'b','*')  
hold on  
  
y2 = 2*x + randn(1,10);  
plot(x,y2,'mo')  
  
y3 = 3*x + randn(1,10);  
plot(x,y3,'rx:')  
  
y4 = 4*x + randn(1,10);  
plot(x,y4,'g+--')  
  
lsline
```

**See Also**

scatter | plot | refline | refcurve | gline

# mad

---

**Purpose** Mean or median absolute deviation

**Syntax**

```
y = mad(X)
Y = mad(X,1)
Y = mad(X,0)
```

**Description** `y = mad(X)` returns the mean absolute deviation of the values in `X`. For vector input, `y` is `mean(abs(X-mean(X)))`. For a matrix input, `y` is a row vector containing the mean absolute deviation of each column of `X`. For  $N$ -dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,1)` returns the median absolute deviation of the values in `X`. For vector input, `y` is `median(abs(X-median(X)))`. For a matrix input, `y` is a row vector containing the median absolute deviation of each column of `X`. For  $N$ -dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,0)` is the same as `mad(X)`, and returns the mean absolute deviation of the values in `X`.

`mad(X,flag,dim)` computes absolute deviations along the dimension `dim` of `X`. `flag` is 0 or 1 to indicate mean or median absolute deviation, respectively.

`mad` treats NaNs as missing values and removes them.

For normally distributed data, multiply `mad` by one of the following factors to obtain an estimate of the normal scale parameter  $\sigma$ :

- `sigma = 1.253*mad(X,0)` — For mean absolute deviation
- `sigma = 1.4826*mad(X,1)` — For median absolute deviation

**Examples** The following compares the robustness of different scale estimates for normally distributed data in the presence of outliers:

```
x = normrnd(0,1,1,50);
xo = [x 10]; % Add outlier
```

```
r1 = std(xo)/std(x)
r1 =
    1.7385
```

```
r2 = mad(xo,0)/mad(x,0)
r2 =
    1.2306
```

```
r3 = mad(xo,1)/mad(x,1)
r3 =
    1.0602
```

std | range | iqr

# mahal

---

**Purpose** Mahalanobis distance

**Syntax** `d = mahal(Y,X)`

**Description** `d = mahal(Y,X)` computes the Mahalanobis distance (in squared units) of each observation in `Y` from the reference sample in matrix `X`. If `Y` is  $n$ -by- $m$ , where  $n$  is the number of observations and  $m$  is the dimension of the data, `d` is  $n$ -by-1. `X` and `Y` must have the same number of columns, but can have different numbers of rows. `X` must have more rows than columns.

For observation `I`, the Mahalanobis distance is defined by  $d(I) = (Y(I,:) - \mu) * \text{inv}(\text{SIGMA}) * (Y(I,:) - \mu)'$ , where `mu` and `SIGMA` are the sample mean and covariance of the data in `X`. `mahal` performs an equivalent, but more efficient, computation.

**Examples** Generate some correlated bivariate data in `X` and compare the Mahalanobis and squared Euclidean distances of observations in `Y`:

```
X = mvnrnd([0;0],[1 .9;.9 1],100);
Y = [1 1;1 -1;-1 1;-1 -1];

d1 = mahal(Y,X) % Mahalanobis
d1 =
    1.3592
   21.1013
   23.8086
    1.4727

d2 = sum((Y-repmat(mean(X),4,1)).^2, 2) % Squared Euclidean
d2 =
    1.9310
    1.8821
    2.1228
    2.0739

scatter(X(:,1),X(:,2))
```

```
hold on
scatter(Y(:,1),Y(:,2),100,d1,'*', 'LineWidth',2)
hb = colorbar;
ylabel(hb,'Mahalanobis Distance')
legend('X','Y','Location','NW')
```

The observations in Y with equal coordinate values are much closer to X in Mahalanobis distance than observations with opposite coordinate values, even though all observations are approximately equidistant from the mean of X in Euclidean distance. The Mahalanobis distance, by considering the covariance of the data and the scales of the different variables, is useful for detecting outliers in such cases.

## See Also

`pdist` | `mahal`

# CompactClassificationDiscriminant.mahal

---

**Purpose** Mahalanobis distance to class means

**Syntax** `M = mahal(obj,X)`  
`M = mahal(obj,X,Name,Value)`

**Description** `M = mahal(obj,X)` returns the squared Mahalanobis distances from observations in `X` to the class means in `obj`.  
`M = mahal(obj,X,Name,Value)` computes the squared Mahalanobis distance with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **obj**

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `ClassificationDiscriminant.fit`.

### **X**

Numeric matrix of size `n-by-p`, where `p` is the number of predictors in `obj`, and `n` is any positive integer.  `mahal`  computes the Mahalanobis distances from the rows of `X` to each of the `K` means of the classes in `obj`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'ClassLabels'**

Class labels consisting of `n` elements of `obj.Y`, where `n` is the number of rows of `X`.

## Output Arguments

**M**

Size and meaning of output **M** depends on whether the **ClassLabels** name-value pair is present:

- No **ClassLabels** — **M** is a numeric matrix of size  $n$ -by- $K$ , where  $K$  is the number of classes in **obj**, and  $n$  is the number of rows in **X**.  $M(i, j)$  is the squared Mahalanobis distance from the  $i$ th row of **X** to the mean of class  $j$ .
- **ClassLabels** exists — **M** is a column vector with  $n$  elements.  $M(i)$  is the squared Mahalanobis distance from the  $i$ th row of **X** to the mean for the class of the  $i$ th element of **ClassLabels**.

## Definitions

### Mahalanobis Distance

The Mahalanobis distance  $d(x,y)$  between  $n$ -dimensional points  $x$  and  $y$ , with respect to a given  $n$ -by- $n$  covariance matrix  $S$ , is

$$d(x,y) = \sqrt{(x-y)^T S^{-1} (x-y)}.$$

## Examples

Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```
load fisheriris
obj = ClassificationDiscriminant.fit(meas,species,...
    'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))

mahadist =
    220.0667    5.0254    30.5804
```

## See Also

CompactClassificationDiscriminant | mahal | gmdistribution

## How To

- “Discriminant Analysis” on page 15-3

# gmdistribution.mahal

---

**Purpose** Mahalanobis distance to component means

**Syntax** `D = mahal(obj,X)`

**Description** `D = mahal(obj,X)` computes the Mahalanobis distance (in squared units) of each observation in `X` to the mean of each of the  $k$  components of the Gaussian mixture distribution defined by `obj`. `obj` is an object created by `gmdistribution` or `fit`. `X` is an  $n$ -by- $d$  matrix, where  $n$  is the number of observations and  $d$  is the dimension of the data. `D` is  $n$ -by- $k$ , with `D(I,J)` the distance of observation `I` from the mean of component `J`.

**Examples** Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function:

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];
```

```
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Fit a two-component Gaussian mixture model:

```
obj = gmdistribution.fit(X,2);  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

# gmdistribution.mahal

Compute the Mahalanobis distance of each point in  $X$  to the mean of each component of  $obj$ :

```
D = mahal(obj,X);
```

```
delete(h)  
scatter(X(:,1),X(:,2),10,D(:,1),'.')  
hb = colorbar;  
ylabel(hb,'Mahalanobis Distance to Component 1')
```

## See Also

[gmdistribution](#) | [cluster](#) | [posterior](#) | [mahal](#)

# maineffectsplot

---

**Purpose** Main effects plot for grouped data

**Syntax** `maineffectsplot(Y, GROUP)`  
`maineffectsplot(Y, GROUP, param1, val1, param2, val2, ...)`  
`[figh, AXESH] = maineffectsplot(...)`

**Description** `maineffectsplot(Y, GROUP)` displays main effects plots for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The display has one subplot per grouping variable, with each subplot showing the group means of `Y` as a function of one grouping variable.

`maineffectsplot(Y, GROUP, param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`, ... .
- `'statistic'` — String values that indicate whether the group mean or the group standard deviation should be plotted. Use `'mean'` or `'std'`. The default is `'mean'`. If the value is `'std'`, `Y` is required to have multiple columns.
- `'parent'` — A handle to the figure window for the plots. The default is the current figure window.

`[figh, AXESH] = maineffectsplot(...)` returns the handle `figh` to the figure window and an array of handles `AXESH` to the subplot axes.

## Examples

Display main effects plots for car weight with two grouping variables, model year and number of cylinders:

```
load carsmall;  
maineffectsplot(Weight,{Model_Year,Cylinders}, ...  
                'varnames',{'Model Year','# of Cylinders'})
```

## See Also

[interactionplot](#) | [multivarichart](#)

## How To

- “Grouping Variables” on page 2-51

# ClassificationDiscriminant.make

---

**Purpose** Construct discriminant analysis classifier from parameters

**Syntax**  
`cobj = ClassificationDiscriminant.make(Mu, Sigma)`  
`cobj = ClassificationDiscriminant.make(Mu, Sigma, Name, Value)`

**Description** `cobj = ClassificationDiscriminant.make(Mu, Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`.

`cobj = ClassificationDiscriminant.make(Mu, Sigma, Name, Value)` constructs a compact classifier with additional options specified by one or more `Name, Value` pair arguments.

**Tips**

- You can change the discriminant type using dot addressing after constructing `cobj`:

```
cobj.DiscrimType = 'discrimType'
```

where *discrimType* is one of 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', or 'pseudoQuadratic'. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

- `cobj` is a linear classifier when `Sigma` is a matrix. `cobj` is a quadratic classifier when `Sigma` is a three-dimensional array.

## Input Arguments

### **Mu**

Matrix of class means of size  $K$ -by- $p$ , where  $K$  is the number of classes, and  $p$  is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

### **Sigma**

Within-class covariance matrix or matrices.

- For a linear discriminant, `Sigma` is a symmetric, positive semidefinite matrix of size `p-by-p`, where `p` is the number of predictors.
- For a quadratic discriminant, `Sigma` is an array of size `p-by-p-by-K`, where `K` is the number of classes. For each `i`, `Sigma(:, :, i)` is a symmetric, positive semidefinite matrix.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'ClassNames'

Array of class names. Use any data type for a grouping variable: a numeric vector, vector of categorical variables (nominal or ordinal), logical vector, character array, or cell array of strings.

`ClassNames` names the classes, as ordered in `Mu`.

**Default:** `1:K`, where `K` is the number of classes (the number of rows of `Mu`)

### 'Cost'

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

**Default:** `Cost(i, j)=1` if `i~=j`, and `Cost(i, j)=0` if `i=j`

### 'PredictorNames'

# ClassificationDiscriminant.make

---

Cell array of names for the predictor variables, in the order in which they appear in X.

**Default:** {'x1', 'x2', ...}

## 'prior'

Prior probabilities for each class. Specify as one of:

- 'uniform', a string meaning all class prior probabilities are equal
- A vector (one scalar value for each class)
- A structure S with two fields:
  - S.ClassNames containing the class names as a variable of the same type as ClassNames
  - S.ClassProbs containing a vector of corresponding probabilities

**Default:** 'uniform'

## 'ResponseName'

Name of the response variable Y, a string.

**Default:** 'Y'

## Output Arguments

### cobj

Discriminant analysis classifier, of class CompactClassificationDiscriminant.

## Examples

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data:

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
```

```
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
    ResponseName: 'Y'
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    DiscrimType: 'linear'
    Mu: [3x4 double]
    Coeffs: [3x3 struct]
```

## How To

- “Discriminant Analysis” on page 15-3

# makedist

---

**Purpose** Create probability distribution object

**Syntax**  
`pd = makedist(distname)`  
`pd = makedist(distname,Name,Value)`

**Description** `pd = makedist(distname)` creates a probability distribution object for the distribution `distname`, using the default parameter values.

`pd = makedist(distname,Name,Value)` creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

## Input Arguments

### **distname - Distribution name**

string

Distribution name, specified as one of the following strings. The distribution specified by `distname` determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta'	Beta distribution	prob.BetaDistribution
'Binomial'	Binomial distribution	prob.BinomialDistribution
'BirnbaumSaunders'	Birnbaum-Saunders distribution	prob.BirnbaumSaundersDistribution
'Burr'	Burr distribution	prob.BurrDistribution
'Exponential'	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma'	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueDistribution

<b>Distribution Name</b>	<b>Description</b>	<b>Distribution Class</b>
'GeneralizedPareto'	Generalized Pareto distribution	prob.GeneralizedParetoDistrib
'InverseGaussian'	Inverse Gaussian distribution	prob.InverseGaussianDistribut
'Logistic'	Logistic distribution	prob.LogisticDistribution
'Loglogistic'	Loglogistic distribution	prob.LoglogisticDistribution
'Lognormal'	Lognormal distribution	prob.LognormalDistribution
'Multinomial'	Multinomial distribution	prob.MultinomialDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistribu
'Normal'	Normal distribution	prob.NormalDistribution
'PiecewiseLinear'	Piecewise Linear distribution	prob.PiecewiseLinearDistribut
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution
'Rician'	Rician distribution	prob.RicianDistribution
'tLocationScale'	$t$ Location-Scale distribution	prob.tLocationScaleDistributi
'Triangular'	Triangular distribution	prob.TriangularDistribution
'Uniform'	Uniform distribution	prob.UniformDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `makedist('Normal','mu',10)` specifies a normal distribution with parameter `mu` equal to 10, and parameter `sigma` equal to the default value of 1.

## Beta Distribution

### 'a' - First shape parameter

1 (default) | nonnegative scalar value

**Example:** `'a',3`

### Data Types

single | double

### 'b' - Second shape parameter

1 (default) | nonnegative scalar value

**Example:** `'b',5`

### Data Types

single | double

## Binomial Distribution

### 'N' - Number of trials

1 (default) | positive integer value

**Example:** `'N',25`

### Data Types

single | double

### 'p' - Probability of success

0.5 (default) | scalar value in the range [0,1]

**Example:** 'p',0.25

**Data Types**

single | double

**Birnbaum-Saunders Distribution**

**'beta' - Scale parameter**

1 (default) | positive scalar value

**Example:** 'beta',2

**Data Types**

single | double

**'gamma' - Shape parameter**

1 (default) | nonnegative scalar value

**Example:** 'gamma',0

**Data Types**

single | double

**Burr Distribution**

**'alpha' - Scale parameter**

1 (default) | positive scalar value

**Example:** 'alpha',2

**Data Types**

single | double

**'c' - First shape parameter**

1 (default) | positive scalar value

**Example:** 'c',2

**Data Types**

single | double

## **'k' - Second shape parameter**

1 (default) | positive scalar value

Example: 'k',5

### **Data Types**

single | double

## **Exponential Distribution**

### **'mu' - Mean parameter**

1 (default) | positive scalar value

Example: 'mu',5

### **Data Types**

single | double

## **Extreme Value Distribution**

### **'mu' - Location parameter**

0 (default) | scalar value

Example: 'mu',-2

### **Data Types**

single | double

### **'sigma' - Scale parameter**

1 (default) | nonnegative scalar value

Example: 'sigma',2

### **Data Types**

single | double

## **Gamma Distribution**

### **'a' - Shape parameter**

1 (default) | positive scalar value

**Example:** 'a',2

**Data Types**

single | double

**'b' - Scale parameter**

1 (default) | nonnegative scalar value

**Example:** 'b',0

**Data Types**

single | double

**Generalized Extreme Value Distribution**

**'k' - Shape parameter**

0 (default) | scalar value

**Example:** 'k',0

**Data Types**

single | double

**'sigma' - Scale parameter**

1 (default) | nonnegative scalar value

**Example:** 'sigma',2

**Data Types**

single | double

**'mu' - Location parameter**

0 (default) | scalar value

**Example:** 'mu',1

**Data Types**

single | double

**Generalized Pareto Distribution**

**'k' - Shape parameter**

1 (default) | scalar value

Example: 'k',0

**Data Types**

single | double

**'sigma' - Scale parameter**

1 (default) | nonnegative scalar value

Example: 'sigma',2

**Data Types**

single | double

**'theta' - Location parameter**

1 (default) | scalar value

Example: 'theta',2

**Data Types**

single | double

**Inverse Gaussian Distribution****'mu' - Scale parameter**

1 (default) | positive scalar value

Example: 'mu',2

**Data Types**

single | double

**'lambda' - Shape parameter**

1 (default) | positive scalar value

Example: 'lambda',4

**Data Types**

single | double

### Logistic Distribution

**'mu' - Mean**

0 (default) | scalar value

Example: 'mu',2

**Data Types**

single | double

**'sigma' - Scale parameter**

1 (default) | nonnegative scalar value

Example: 'sigma',4

**Data Types**

single | double

### Loglogistic Distribution

**'mu' - Log mean**

0 (default) | scalar value

Example: 'mu',2

**Data Types**

single | double

**'sigma' - Log scale parameter**

1 (default) | nonnegative scalar value

Example: 'sigma',4

**Data Types**

single | double

### Lognormal Distribution

**'mu' - Log mean**

0 (default) | scalar value

**Example:** 'mu',2

## **Data Types**

single | double

## **'sigma' - Log standard deviation**

1 (default) | nonnegative scalar value

**Example:** 'sigma',2

## **Data Types**

single | double

## **Multinomial Distribution**

### **'probabilities' - Outcome probabilities**

[0.500 0.500] (default) | vector of scalar values in the range [0,1]

**Example:** 'probabilities',[0.1 0.2 0.5 0.2]

## **Data Types**

single | double

## **Nakagami Distribution**

### **'mu' - Shape parameter**

1 (default) | positive scalar value

**Example:** 'mu',5

## **Data Types**

single | double

### **'omega' - Scale parameter**

1 (default) | positive scalar value

**Example:** 'omega',5

## **Data Types**

single | double

## Negative Binomial Distribution

### **'R' - Number of successes**

1 (default) | positive scalar value

Example: 'R',5

### **Data Types**

single | double

### **'p' - Probability of success**

0.5 (default) | scalar value in the range (0,1]

Example: 'p',0.1

### **Data Types**

single | double

## Normal Distribution

### **'mu' - Mean**

0 (default) | scalar value

Example: 'mu',2

### **Data Types**

single | double

### **'sigma' - Standard deviation**

1 (default) | nonnegative scalar value

Example: 'sigma',2

### **Data Types**

single | double

## Piecewise Linear Distribution

### **'x' - Data values**

1 (default) | vector of scalar values

**Example:** 'x',[1 2 3]

## **Data Types**

single | double

## **'Fx' - cdf values**

1 (default) | vector of scalar values

**Example:** 'Fx',[.2 .5 1]

## **Data Types**

single | double

## **Poisson Distribution**

### **'lambda' - Mean**

1 (default) | nonnegative scalar value

**Example:** 'lambda',5

## **Data Types**

single | double

## **Rayleigh Distribution**

### **'b' - Defining parameter**

1 (default) | positive scalar value

**Example:** 'b',3

## **Data Types**

single | double

## **Rician Distribution**

### **'s' - Noncentrality parameter**

1 (default) | nonnegative scalar value

**Example:** 's',0

**Data Types**

single | double

**'sigma' - Scale parameter**

1 (default) | positive scalar value

Example: 'sigma',2

**Data Types**

single | double

***t* Location-Scale Distribution****'mu' - Location parameter**

0 (default) | scalar value

Example: 'mu',-2

**Data Types**

single | double

**'sigma' - Scale parameter**

1 (default) | positive scalar value

Example: 'sigma',2

**Data Types**

single | double

**'nu' - Degrees of freedom**

5 (default) | positive scalar value

Example: 'nu',20

**Data Types**

single | double

**Triangular Distribution****'a' - Lower limit**

0 (default) | scalar value

**Example:** 'a', -2

**Data Types**

single | double

**'b' - Peak location**

0.5 (default) | scalar value greater than or equal to a

**Example:** 'b', 1

**Data Types**

single | double

**'c' - Upper limit**

1 (default) | scalar value greater than or equal to b

**Example:** 'c', 5

**Data Types**

single | double

**Uniform Distribution**

**'lower' - Lower parameter**

0 (default) | scalar value

**Example:** 'lower', -4

**Data Types**

single | double

**'upper' - Upper parameter**

1 (default) | scalar value greater than lower

**Example:** 'upper', 2

**Data Types**

single | double

**Weibull Distribution**

**'a' - Scale parameter**

1 (default) | positive scalar value

Example: 'a',2

**Data Types**

single | double

**'b' - Shape parameter**

1 (default) | positive scalar value

Example: 'b',5

**Data Types**

single | double

**Output Arguments****pd - Probability distribution**

probability distribution object

Probability distribution, returned as a probability distribution object of the type specified by `distname`.

**Examples****Create a Normal Distribution Object**

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =  
1.3490
```

## Create a Gamma Distribution Object

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')  
pd =  
GammaDistribution  
  
Gamma distribution  
a = 1  
b = 1
```

Compute the mean of the gamma distribution.

```
mean = mean(pd)  
mean =  
1
```

## Specify Parameters for a Normal Distribution Object

Create a normal distribution object with parameter values  $\mu = 75$  and  $\sigma = 10$ .

```
pd = makedist('Normal','mu',75,'sigma',10)  
pd =  
NormalDistribution  
  
Normal distribution  
mu = 75  
sigma = 10
```

## Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value  $a = 3$  and the default value  $b = 1$ .

```
pd = makedist('Gamma','a',3)
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 3
```

```
  b = 1
```

## Alternative Functionality

### App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

# manova1

---

**Purpose** One-way multivariate analysis of variance

**Syntax**  
`d = manova1(X,group)`  
`d = manova1(X,group,alpha)`  
`[d,p] = manova1(...)`  
`[d,p,stats] = manova1(...)`

**Description** `d = manova1(X,group)` performs a one-way Multivariate Analysis of Variance (MANOVA) for comparing the multivariate means of the columns of `X`, grouped by `group`. `X` is an  $m$ -by- $n$  matrix of data values, and each row is a vector of measurements on  $n$  variables for a single observation. `group` is a grouping variable defined as a categorical variable, vector, string array, or cell array of strings. Two observations are in the same group if they have the same value in the `group` array. The observations in each group represent a sample from a population.

The function returns `d`, an estimate of the dimension of the space containing the group means. `manova1` tests the null hypothesis that the means of each group are the same  $n$ -dimensional multivariate vector, and that any difference observed in the sample `X` is due to random chance. If `d = 0`, there is no evidence to reject that hypothesis. If `d = 1`, then you can reject the null hypothesis at the 5% level, but you cannot reject the hypothesis that the multivariate means lie on the same line. Similarly, if `d = 2` the multivariate means may lie on the same plane in  $n$ -dimensional space, but not on the same line.

`d = manova1(X,group,alpha)` gives control of the significance level, `alpha`. The return value `d` will be the smallest dimension having  $p > \alpha$ , where  $p$  is a  $p$ -value for testing whether the means lie in a space of that dimension.

`[d,p] = manova1(...)` also returns a `p`, a vector of  $p$ -values for testing whether the means lie in a space of dimension 0, 1, and so on. The largest possible dimension is either the dimension of the space, or one less than the number of groups. There is one element of `p` for each dimension up to, but not including, the largest.

If the  $i$ th  $p$ -value is near zero, this casts doubt on the hypothesis that the group means lie on a space of  $i-1$  dimensions. The choice of a

critical  $p$ -value to determine whether the result is judged statistically significant is left to the researcher and is specified by the value of the input argument `alpha`. It is common to declare a result significant if the  $p$ -value is less than 0.05 or 0.01.

`[d,p,stats] = manova1(...)` also returns `stats`, a structure containing additional MANOVA results. The structure contains the following fields.

Field	Contents
W	Within-groups sum of squares and cross-products matrix
B	Between-groups sum of squares and cross-products matrix
T	Total sum of squares and cross-products matrix
dfW	Degrees of freedom for W
dfB	Degrees of freedom for B
dfT	Degrees of freedom for T
lambda	Vector of values of Wilk's lambda test statistic for testing whether the means have dimension 0, 1, etc.
chisq	Transformation of lambda to an approximate chi-square distribution
chisqdf	Degrees of freedom for chisq
eigenval	Eigenvalues of $W^{-1}B$
eigenvec	Eigenvectors of $W^{-1}B$ ; these are the coefficients for the canonical variables C, and they are scaled so the within-group variance of the canonical variables is 1
canon	Canonical variables C, equal to $XC * \text{eigenvec}$ , where XC is X with columns centered by subtracting their means

Field	Contents
mdist	A vector of Mahalanobis distances from each point to the mean of its group
gmdist	A matrix of Mahalanobis distances between each pair of group means

The canonical variables  $C$  are linear combinations of the original variables, chosen to maximize the separation between groups. Specifically,  $C(:, 1)$  is the linear combination of the  $X$  columns that has the maximum separation between groups. This means that among all possible linear combinations, it is the one with the most significant  $F$  statistic in a one-way analysis of variance.  $C(:, 2)$  has the maximum separation subject to it being orthogonal to  $C(:, 1)$ , and so on.

You may find it useful to use the outputs from `manova1` along with other functions to supplement your analysis. For example, you may want to start with a grouped scatter plot matrix of the original variables using `gplotmatrix`. You can use `gscatter` to visualize the group separation using the first two canonical variables. You can use `manovacluster` to graph a dendrogram showing the clusters among the group means.

## Assumptions

The MANOVA test makes the following assumptions about the data in  $X$ :

- The populations for each group are normally distributed.
- The variance-covariance matrix is the same for each population.
- All observations are mutually independent.

## Examples

you can use `manova1` to determine whether there are differences in the averages of four car characteristics, among groups defined by the country where the cars were made.

```
load carbig
[d,p] = manova1([MPG Acceleration Weight Displacement],...
```

```
Origin)
d =
  3
p =
  0
  0.0000
  0.0075
  0.1934
```

There are four dimensions in the input matrix, so the group means must lie in a four-dimensional space. `manova1` shows that you cannot reject the hypothesis that the means lie in a 3-D subspace.

## How To

- “Grouping Variables” on page 2-51

# manovacluster

---

**Purpose** Dendrogram of group mean clusters following MANOVA

**Syntax**  
`manovacluster(stats)`  
`manovacluster(stats,method)`  
`H = manovacluster(stats,method)`

**Description** `manovacluster(stats)` generates a dendrogram plot of the group means after a multivariate analysis of variance (MANOVA). `stats` is the output `stats` structure from `manova1`. The clusters are computed by applying the single linkage method to the matrix of Mahalanobis distances between group means.

See `dendrogram` for more information on the graphical output from this function. The dendrogram is most useful when the number of groups is large.

`manovacluster(stats,method)` uses the specified method in place of single linkage. `method` can be any of the following character strings that identify ways to create the cluster hierarchy. (See `linkage` for additional information.)

<b>Method</b>	<b>Description</b>
'single'	Shortest distance (default)
'complete'	Largest distance
'average'	Average distance
'centroid'	Centroid distance
'ward'	Incremental sum of squares

`H = manovacluster(stats,method)` returns a vector of handles to the lines in the figure.

**Examples** Let's analyze the larger car data set to determine which countries produce cars with the most similar characteristics.

```
load carbig
```

```
X = [MPG Acceleration Weight Displacement];  
[d,p,stats] = manova1(X,Origin);  
manovacluster(stats)
```

# ClassificationKNN.margin

---

<b>Purpose</b>	Margin of $k$ -nearest neighbor classifier
<b>Syntax</b>	<code>m = margin mdl,X,Y</code>
<b>Description</b>	<code>m = margin mdl,X,Y</code> returns the classification margins for the matrix of predictors $X$ and class labels $Y$ . For the definition, see “Margin” on page 21-1860.
<b>Input Arguments</b>	<b>mdl</b> $k$ -nearest neighbor classifier, created by <code>ClassificationKNN.fit</code> . <b>X</b> Matrix of predictor values. Each column of $X$ represents one variable, and each row represents one observation. <b>Y</b> A numeric vector, vector of categorical variables (nominal or ordinal), logical vector, character array, or cell array of strings, with the same number of rows as $X$ . Each row of $Y$ represents the classification of the corresponding row of $X$ .
<b>Output Arguments</b>	<b>m</b> Numeric column vector of length <code>size(X,1)</code> . Each entry in $m$ represents the margin for the corresponding rows of $X$ and (true class) $Y$ , computed using <code>mdl</code> .
<b>Definitions</b>	<b>Margin</b> The classification <i>margin</i> is the difference between the classification <i>score</i> for the true class and maximal classification score for the false classes. <b>Score</b> The <i>score</i> of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more

detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-2608.

## Examples

### Margin Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = ClassificationKNN.fit(meas,species,'NumNeighbors',5);
```

Examine the margin of the classifier for a mean observation classified 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
m = margin(mdl,X,Y)
```

```
m =
```

```
1
```

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

## Concepts

- “Classification Using Nearest Neighbors” on page 16-9

# CompactClassificationDiscriminant.margin

---

<b>Purpose</b>	Classification margins
<b>Syntax</b>	<code>m = margin(obj,X,Y)</code>
<b>Description</b>	<code>m = margin(obj,X,Y)</code> returns the classification margins for the matrix of predictors <i>X</i> and class labels <i>Y</i> . For the definition, see “Definitions” on page 21-1862.
<b>Input Arguments</b>	<b>obj</b> Discriminant analysis classifier of class <code>ClassificationDiscriminant</code> or <code>CompactClassificationDiscriminant</code> , typically constructed with <code>ClassificationDiscriminant.fit</code> . <b>X</b> Matrix where each row represents an observation, and each column represents a predictor. The number of columns in <i>X</i> must equal the number of predictors in <i>obj</i> . <b>Y</b> Class labels, with the same data type as exists in <i>obj</i> . The number of elements of <i>Y</i> must equal the number of rows of <i>X</i> .
<b>Output Arguments</b>	<b>m</b> Numeric column vector of length <code>size(X,1)</code> . Each entry in <i>m</i> represents the margin for the corresponding rows of <i>X</i> and (true class) <i>Y</i> , computed using <i>obj</i> .
<b>Definitions</b>	<b>Margin</b> The classification <i>margin</i> is the difference between the classification <i>score</i> for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix <i>X</i> . A high value of margin indicates a more reliable prediction than a low value.

## Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

## Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = ClassificationDiscriminant.fit(X,species);
M = margin(obj,X,species);
M(end-10:end)
```

```
ans =
    0.6551
    0.4838
    0.6551
   -0.5127
    0.5659
    0.4611
    0.4949
    0.1024
    0.2787
   -0.1439
   -0.4444
```

The classifier trained on all the data is better:

```
obj = ClassificationDiscriminant.fit(meas,species);
M = margin(obj,meas,species);
M(end-10:end)
```

```
ans =
    0.9983
    1.0000
```

# CompactClassificationDiscriminant.margin

## How To

- “Discriminant Analysis” on page 15-3

# CompactClassificationEnsemble.margin

---

## Purpose

Classification margins

## Syntax

```
M = margin(ens,X,Y)
M = margin(ens,X,Y,Name,Value)
```

## Description

`M = margin(ens,X,Y)` returns the classification margin for the predictions of `ens` on data `X`, when the true classifications are `Y`.

`M = margin(ens,X,Y,Name,Value)` calculates margin with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

### **X**

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `ens`. `X` should have the same number of rows as the number of elements in `Y`.

### **Y**

Classification of `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `X`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

# CompactClassificationEnsemble.margin

---

Indices of weak learners in the ensemble ranging from 1 to `ens.NTrained`. `oobEdge` uses only these learners for calculating loss.

**Default:** `1:NTrained`

## 'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in `ens`.

When `UseObsForLearner(i, j)` is `true`, learner `j` is used in predicting the class of row `i` of X.

**Default:** `true(N,T)`

## Output Arguments

**M**

A numeric column vector with the same number of rows as X. Each row of M gives the classification margin for that row of X.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Find the margin for classifying an average flower from the Fisheriris data as 'versicolor':

```
load fisheriris % X = meas, Y = species
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
flower = mean(meas);
predict(ens,flower)
```

```
ans =
    'versicolor'
```

```
margin(ens,mean(meas),'versicolor')
```

```
ans =
    3.2140
```

# CompactClassificationTree.margin

---

**Purpose** Classification margins

**Syntax** `m = margin(tree,X,Y)`

**Description** `m = margin(tree,X,Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`. For the definition, see “Margin” on page 21-1868.

## Input Arguments

### **tree**

A classification tree created by `ClassificationTree.fit`, or a compact classification tree created by `compact`.

### **X**

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `tree`.

### **Y**

Class labels, with the same data type as exists in `tree`.

## Output Arguments

### **m**

A numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `tree`.

## Definitions

### **Margin**

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `X`.

### **Score (tree)**

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that

# CompactClassificationTree.margin

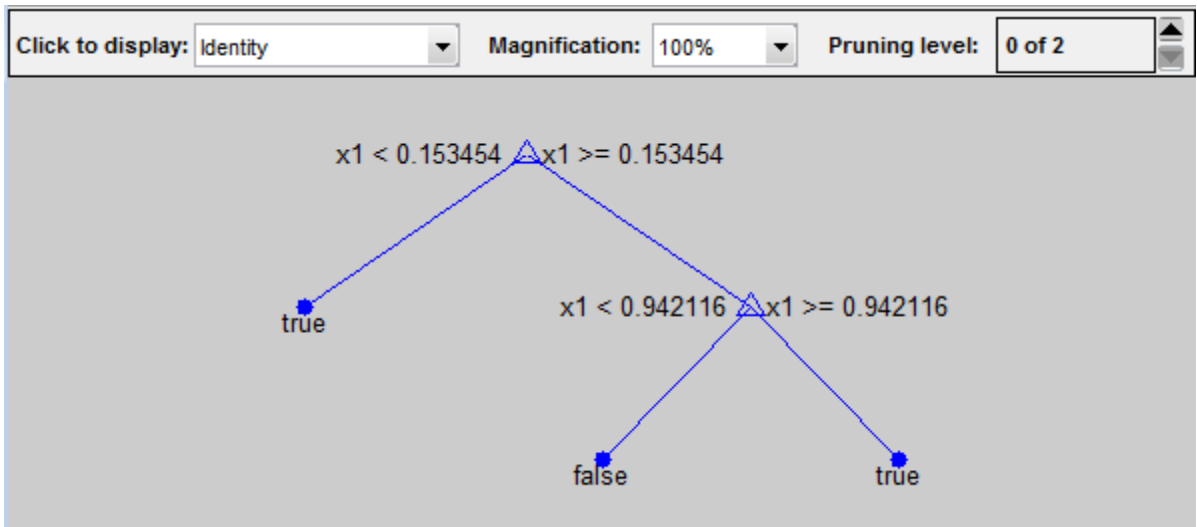

lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

1

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = ClassificationTree.fit(X,Y);
view(tree,'mode','graph')
```

2

Prune the tree:

```
tree1 = prune(tree,'level',1);
view(tree1,'mode','graph')
```

# CompactClassificationTree.margin

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

### 3

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
0.9059    0.0941    0.8147  
0.9059    0.0941    0.9058  
0         1.0000    0.1270  
0.9059    0.0941    0.9134  
0.9059    0.0941    0.6324  
0         1.0000    0.0975  
0.9059    0.0941    0.2785
```

0.9059	0.0941	0.5469
0.9059	0.0941	0.9575
0.9059	0.0941	0.9649

Indeed, every value of  $X$  (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
tree = ClassificationTree.fit(X,species);
M = margin(tree,X,species);
M(end-10:end)

ans =
    0.1111
    0.1111
    0.1111
   -0.2857
    0.6364
    0.6364
    0.1111
    0.7500
    1.0000
    0.6364
    0.2000
```

The classification tree trained on all the data is better:

```
tree = ClassificationTree.fit(meas,species);
M = margin(tree,meas,species);
M(end-10:end)
```

# CompactClassificationTree.margin

---

```
ans =  
  0.9565  
  0.9565  
  0.9565  
  0.9565  
  0.9565  
  0.9565  
  0.9565  
  0.9565  
  0.9565  
  0.9565  
  0.9565
```

## Purpose

Classification margin

## Syntax

```
mar = margin(B,X,Y)
mar = margin(B,X,Y, 'param1',val1, 'param2',val2, ...)
```

## Description

`mar = margin(B,X,Y)` computes the classification margins for predictors  $X$  given true response  $Y$ . The  $Y$  can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `mar` is a numeric array of size `Nobs`-by-`NTrees`, where `Nobs` is the number of rows of  $X$  and  $Y$ , and `NTrees` is the number of trees in the ensemble  $B$ . For observation  $I$  and tree  $J$ , `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,X,Y, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

- 'mode' String indicating how the method computes errors. If set to 'cumulative' (default), `margin` computes cumulative errors and `mar` is an `Nobs`-by-`NTrees` matrix, where the first column gives error from `trees(1)`, second column gives error from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to 'individual', `mar` is a `Nobs`-by-`NTrees` matrix, where each element is an error from each tree in the ensemble. If set to 'ensemble', `mar` a single column of length `Nobs` showing the cumulative margins for the entire ensemble.
- 'trees' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length `NTrees` for 'cumulative' and 'individual' modes, where `NTrees` is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element

## CompactTreeBagger.margin

---

gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.

'useifort' Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`CompactTreeBagger.margin`

**Purpose** Convert matrix to dataset array

**Syntax**  
`ds = mat2dataset(X)`  
`ds = mat2dataset(X,Name,Value)`

**Description** `ds = mat2dataset(X)` converts a matrix to a dataset array.

`ds = mat2dataset(X,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **X - Input matrix**

matrix

Input matrix to convert to a dataset array, specified as an  $M$ -by- $N$  numeric matrix. Each column of  $X$  becomes a variable in the output  $M$ -by- $N$  dataset array.

### **Data Types**

single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'NumCols',[1,1,2,1]` specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

### **'VarNames' - Variable names for output dataset array**

cell array of strings

Variable names for the output dataset array, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings. You must provide a variable name for each variable in `ds`. The names must be valid MATLAB identifiers, and must be unique.

**Example:** 'VarNames', {'myVar1', 'myVar2', 'myVar3'}

## **'ObsNames' - Observation names for output dataset array**

cell array of strings

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a cell array of strings. The names do not need to be valid MATLAB identifiers, but they must be unique.

## **'NumCols' - Number of columns for each variable**

vector of nonnegative integers

Number of columns for each variable in `ds`, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `mat2dataset` combines multiple columns in `X` into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(X,2)`.

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1,1,3,1,2].

## **Output Arguments**

### **ds - Output dataset array**

dataset array

Output dataset array, returned by default with a variable for each column of `X`, and an observation for each row of `X`. If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

## **Examples**

### **Convert Matrix to Dataset Array**

Convert a matrix to a dataset array using the default options.

Load sample data.

```
load('fisheriris')
X = meas;
```

```
size(X)
```

```
ans =
```

```
    150     4
```

Convert the matrix to a dataset array.

```
ds = mat2dataset(X);
```

```
size(ds)
```

```
ans =
```

```
    150     4
```

```
ds(1:5,:)
```

```
ans =
```

X1	X2	X3	X4
5.1	3.5	1.4	0.2
4.9	3	1.4	0.2
4.7	3.2	1.3	0.2
4.6	3.1	1.5	0.2
5	3.6	1.4	0.2

When you do not specify variable names, `mat2dataset` uses the matrix name and column numbers to create default variable names.

## Convert Matrix to Dataset Array with Variable Names

Load sample data.

```
load('fisheriris')
```

```
X = meas;
```

```
size(X)
```

```
ans =
```

# mat2dataset

---

```
150    4
```

Convert the matrix to a dataset array, providing a variable name for each of the four column of X.

```
ds = mat2dataset(X, 'VarNames', {'SLength', ...  
'SWidth', 'PLength', 'PWidth'});  
size(ds)
```

```
ans =
```

```
150    4
```

```
ds(1:5,:)
```

```
ans =
```

SWidth	SLength	PWidth	PLength
5.1	3.5	1.4	0.2
4.9	3	1.4	0.2
4.7	3.2	1.3	0.2
4.6	3.1	1.5	0.2
5	3.6	1.4	0.2

## Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.

Load sample data.

```
load('fisheriris')  
X = meas;  
size(X)
```

```
ans =
```

```
150    4
```

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named `SepalMeas`, and the petal measurements (third and fourth columns) into one variable names `PetalMeas`.

```
ds = mat2dataset(X,'NumCols',[2,2],...
'VarNames',{'SepalMeas','PetalMeas'});
ds(1:5,:)
```

```
ans =
```

SepalMeas		PetalMeas	
5.1	3.5	1.4	0.2
4.9	3	1.4	0.2
4.7	3.2	1.3	0.2
4.6	3.1	1.5	0.2
5	3.6	1.4	0.2

The output dataset array has 150 observations and 2 variables.

```
size(ds)
```

```
ans =
```

```
150    2
```

# mdscale

---

**Purpose** Nonclassical multidimensional scaling

**Syntax**

```
Y = mdscale(D,p)
[Y,stress] = mdscale(D,p)
[Y,stress,disparities] = mdscale(D,p)
[...] = mdscale(D,p,'Name',value)
```

**Description** `Y = mdscale(D,p)` performs nonmetric multidimensional scaling on the  $n$ -by- $n$  dissimilarity matrix  $D$ , and returns  $Y$ , a configuration of  $n$  points (rows) in  $p$  dimensions (columns). The Euclidean distances between points in  $Y$  approximate a monotonic transformation of the corresponding dissimilarities in  $D$ . By default, `mdscale` uses Kruskal's normalized stress1 criterion.

You can specify  $D$  as either a full  $n$ -by- $n$  matrix, or in upper triangle form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. `mdscale` treats NaNs in  $D$  as missing values, and ignores those elements. `Inf` is not accepted.

You can also specify  $D$  as a full similarity matrix, with ones along the diagonal and all other elements less than one. `mdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in  $Y$  approximate  $\sqrt{1-D}$ . To use a different transformation, transform the similarities prior to calling `mdscale`.

`[Y,stress] = mdscale(D,p)` returns the minimized stress, i.e., the stress evaluated at  $Y$ .

`[Y,stress,disparities] = mdscale(D,p)` returns the disparities, that is, the monotonic transformation of the dissimilarities  $D$ .

`[...] = mdscale(D,p,'Name',value)` specifies one or more optional parameter name/value pairs that control further details of `mdscale`. Specify *Name* in single quotes. Available parameters are

- **Criterion**— The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that mdscale performs. Choices for non-metric scaling are:
  - 'stress' — Stress normalized by the sum of squares of the inter-point distances, also known as stress1. This is the default.
  - 'sstress' — Squared stress, normalized with the sum of 4th powers of the inter-point distances.

Choices for metric scaling are:

- 'metricstress' — Stress, normalized with the sum of squares of the dissimilarities.
  - 'metricsstress' — Squared stress, normalized with the sum of 4th powers of the dissimilarities.
  - 'sammon' — Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
  - 'strain' — A criterion equivalent to that used in classical multidimensional scaling.
- **Weights** — A matrix or vector the same size as D, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of D in computing and minimizing stress. Elements of D corresponding to zero weights are effectively ignored.

---

**Note** When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of D do not enter into the stress calculation.

---

- **Start** — Method used to choose the initial configuration of points for Y. The choices are

# mdscale

---

- 'cmdscale' — Use the classical multidimensional scaling solution. This is the default. 'cmdscale' is not valid when there are zero weights.
- 'random' — Choose locations randomly from an appropriately scaled  $p$ -dimensional normal distribution with uncorrelated coordinates.
- An  $n$ -by- $p$  matrix of initial locations, where  $n$  is the size of the matrix  $D$  and  $p$  is the number of columns of the output matrix  $Y$ . In this case, you can pass in `[]` for  $p$  and `mdscale` infers  $p$  from the second dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.
- Replicates — Number of times to repeat the scaling, each with a new initial configuration. The default is 1.
- Options — Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by `statset`. For example,

```
opts = statset(param1, val1, param2, val2, ...);  
[...] = mdscale(..., 'Options', opts)
```

The choices of `statset` parameters are

- 'Display' — Level of display output. The choices are 'off' (the default), 'iter', and 'final'.
- 'MaxIter' — Maximum number of iterations allowed. The default is 200.
- 'TolFun' — Termination tolerance for the stress criterion and its gradient. The default is  $1e-4$ .
- 'TolX' — Termination tolerance for the configuration location step size. The default is  $1e-4$ .

## Examples

```
load cereal.mat  
X = [Calories Protein Fat Sodium Fiber ...
```

```
Carbo Sugars Shelf Potass Vitamins];

% Take a subset from a single manufacturer.
X = X(strcmp('K',cellstr(Mfg)),:);

% Create a dissimilarity matrix.
dissimilarities = pdist(X);

% Use non-metric scaling to recreate the data in 2D,
% and make a Shepard plot of the results.
[Y, stress, disparities] = mdscale(dissimilarities, 2);
distances = pdist(Y);
[dum, ord] = sortrows([disparities(:) dissimilarities(:)]);
plot(dissimilarities, distances, 'bo', ...
dissimilarities(ord), disparities(ord), 'r.-');
xlabel('Dissimilarities'); ylabel('Distances/Disparities')
legend({'Distances' 'Disparities'}, 'Location', 'NW');
```

# mdscale

```
% Do metric scaling on the same dissimilarities.  
figure  
[Y, stress] = ...  
mdscale(dissimilarities, 2, 'criterion', 'metricsstress');  
distances = pdist(Y);  
plot(dissimilarities, distances, 'bo', ...  
[0 max(dissimilarities)], [0 max(dissimilarities)], 'r.-');  
xlabel('Dissimilarities'); ylabel('Distances')
```

**See Also** `cmdscale` | `pdist` | `statset`

# CompactTreeBagger.mdsProx

---

**Purpose** Multidimensional scaling of proximity matrix

**Syntax** `[SC,EIGEN] = mdsProx(B,X)`  
`[SC,EIGEN] = mdsProx(B,X,'param1',val1,'param2',val2,...)`

**Description** `[SC,EIGEN] = mdsProx(B,X)` applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix `X`, and returns scaled coordinates `SC` and eigenvalues `EIGEN` of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as `1-prox`, where `prox` is the proximity matrix returned by the proximity method.

You can supply the proximity matrix directly by using the `'data'` parameter.

`[SC,EIGEN] = mdsProx(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

- `'data'` Flag indicating how the method treats the `X` input argument. If set to `'predictors'` (default), `mdsProx` assumes `X` to be a matrix of predictors and used for computation of the proximity matrix. If set to `'proximity'`, the method treats `X` as a proximity matrix returned by the proximity method.
- `'colors'` If you supply this argument, `mdsProx` makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, `mdsProx` only plots the first `C` classes, where `C` is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in `X`.

- 'labels' Vector of true class labels for a classification ensemble. True class labels can be either a numeric vector, character matrix, or cell array of strings. If supplied, this vector must have as many elements as there are observations (rows) in X. This argument has no effect unless you also supply the 'colors' argument.
- 'mdscoords' Indices of the two scaled coordinates to plot. By default, mdsProx makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'colors' argument.

# TreeBagger.mdsProx

---

**Purpose** Multidimensional scaling of proximity matrix

**Syntax** `[S,E] = mdsProx(B)`  
`[S,E] = mdsProx(B, 'param1', val1, 'param2', val2, ...)`

**Description** `[S,E] = mdsProx(B)` returns scaled coordinates, S, and eigenvalues, E, for the proximity matrix in the ensemble B. An earlier call to `fillProximities(B)` must create the proximity matrix.

`[S,E] = mdsProx(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

- 'keep' Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to 'all'. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues.
- 'colors' If you supply this argument, `mdsProx` makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, `mdsProx` only plots the first C classes, where C is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in X.
- 'mdscoords' Indices of the two scaled coordinates to plot. By default, `mdsProx` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'colors' argument.

# prob.ParametricTruncatableDistribution.mean

---

<b>Purpose</b>	Mean of probability distribution object
<b>Syntax</b>	<code>m = mean(pd)</code>
<b>Description</b>	<code>m = mean(pd)</code> returns the mean <code>m</code> of the probability distribution <code>pd</code> .
<b>Input Arguments</b>	<b>pd - Probability distribution</b> probability distribution object  Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using <code>makedist</code> .
<b>Output Arguments</b>	<b>m - Mean</b> scalar value  Mean of the probability distribution, returned as a scalar value.

## Examples **Mean of a Uniform Distribution**

Create a uniform distribution object

```
pd = makedist('Uniform','lower',-3,'upper',5)
```

```
pd =
```

```
UniformDistribution
```

```
Uniform distribution
```

```
Lower = -3
```

```
Upper = 5
```

Compute the mean of the distribution.

```

# prob.ToolboxFittableParametricDistribution.mean

---

**Purpose** Mean of probability distribution object

**Syntax** `m = mean(pd)`

**Description** `m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

**Input Arguments** **pd - Probability distribution**  
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

**Output Arguments** **m - Mean**  
scalar value

Mean of the probability distribution, returned as a scalar value.

## Examples **Mean of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75.0083 [73.4321, 76.5846]
```

```
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)
```

```
m =
```

```
75.0083
```

The mean of the normal distribution is equal to the parameter  $\mu$ .

## Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 5
```

```
B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean =
```

```
4.4311
```

# CompactTreeBagger.meanMargin

---

**Purpose** Mean classification margin

**Syntax**  
`mar = meanMargin(B,X,Y)`  
`mar = meanMargin(B,X,Y, 'param1',val1, 'param2',val2,...)`

**Description** `mar = meanMargin(B,X,Y)` computes average classification margins for predictors `X` given true response `Y`. The `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `meanMargin` averages the margins over all observations (rows) in `X` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B,X,Y, 'param1',val1, 'param2',val2,...)` specifies optional parameter name/value pairs:

`'mode'` String indicating how `meanMargin` computes errors. If set to `'cumulative'` (default), is a vector of length `NTrees` where the first element gives mean margin from `trees(1)`, second column gives mean margins from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `mar` is a vector of length `NTrees`, where each element is a mean margin from each tree in the ensemble. If set to `'ensemble'`, `mar` is a scalar showing the cumulative mean margin for the entire ensemble.

`'trees'` Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes, where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element

gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.

'`treeweights`' Vector of tree weights. This vector must have the same length as the '`trees`' vector. `meanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the '`individual`' mode.

# classregtree.meansurrvarassoc

---

**Purpose** Mean predictive measure of association for surrogate splits in decision tree

**Syntax** MA = meansurrvarassoc(T)  
MA = meansurrvarassoc(T,N)

**Description** MA = meansurrvarassoc(T) returns a  $p$ -by- $p$  matrix, MA, with predictive measures of association for  $p$  predictors. Element MA( $i,j$ ) is the predictive measure of association averaged over surrogate splits on predictor  $j$  for which predictor  $i$  is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor  $i$  and surrogate splits on predictor  $j$  and dividing by the total number of optimal splits on predictor  $i$ , including splits for which the predictive measure of association between predictors  $i$  and  $j$  is negative.

MA = meansurrvarassoc(T,N) takes an array N of node numbers and returns the predictive measure of association averaged over the specified nodes.

# CompactClassificationTree.meanSurrVarAssoc

---

<b>Purpose</b>	Mean predictive measure of association for surrogate splits in decision tree
<b>Syntax</b>	<code>ma = meanSurrVarAssoc(tree)</code> <code>ma = meanSurrVarAssoc(tree,N)</code>
<b>Description</b>	<code>ma = meanSurrVarAssoc(tree)</code> returns a matrix of predictive measures of association for the predictors in <code>tree</code> . <code>ma = meanSurrVarAssoc(tree,N)</code> returns a matrix of predictive measures of association averaged over the nodes in vector <code>N</code> .
<b>Input Arguments</b>	<b>tree</b> A classification tree constructed with <code>ClassificationTree.fit</code> , or a compact regression tree constructed with <code>compact</code> . <b>N</b> Vector of node numbers in <code>tree</code> .
<b>Output Arguments</b>	<b>ma</b> <ul style="list-style-type: none"><li><code>ma = meanSurrVarAssoc(tree)</code> returns a P-by-P matrix, where P is the number of predictors in <code>tree</code>. <code>ma(i,j)</code> is the predictive measure of association between the optimal split on variable <code>i</code> and a surrogate split on variable <code>j</code>. See “Predictive Measure of Association” on page 21-1903.</li><li><code>ma = meanSurrVarAssoc(tree,N)</code> returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector <code>N</code>. <code>N</code> contains node numbers from 1 to <code>max(tree.NumNodes)</code>.</li></ul>
<b>Definitions</b>	<b>Predictive Measure of Association</b> The predictive measure of association between the optimal split on variable <code>i</code> and a surrogate split on variable <code>j</code> is:

# CompactClassificationTree.meanSurrVarAssoc

---

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- $P_L$  and  $P_R$  are the node probabilities for the optimal split of node  $i$  into Left and Right nodes respectively.
- $P_{L_i L_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Left.
- $P_{R_i R_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Right.

Clearly,  $\lambda_{i,j}$  lies from  $-\infty$  to 1. Variable  $j$  is a worthwhile surrogate split for variable  $i$  if  $\lambda_{i,j} > 0$ .

Element  $ma(i, j)$  is the predictive measure of association averaged over surrogate splits on predictor  $j$  for which predictor  $i$  is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor  $i$  and surrogate splits on predictor  $j$  and dividing by the total number of optimal splits on predictor  $i$ , including splits for which the predictive measure of association between predictors  $i$  and  $j$  is negative.

## Examples

Find the mean predictive measure of association between the variables in the Fisher iris data:

```
load fisheriris
obj = ClassificationTree.fit(meas,species,'surrogate','on');
msva = meanSurrVarAssoc(obj)
```

```
msva =
    1.0000         0         0         0
         0    1.0000         0         0
    0.4633    0.2500    1.0000    0.5000
```

# CompactClassificationTree.meanSurrVarAssoc

---

```
0.2065    0.1413    0.4022    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in obj:

```
N = 1:2:obj.NumNodes;  
msva = meanSurrVarAssoc(obj,N)
```

```
msva =  
    1.0000         0         0         0  
         0    1.0000         0         0  
    0.7600    0.5000    1.0000    1.0000  
    0.4130    0.2826    0.8043    1.0000
```

# CompactRegressionTree.meanSurrVarAssoc

---

**Purpose** Mean predictive measure of association for surrogate splits in decision tree

**Syntax** `ma = meanSurrVarAssoc(tree)`  
`ma = meanSurrVarAssoc(tree,N)`

**Description** `ma = meanSurrVarAssoc(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.  
`ma = meanSurrVarAssoc(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

**Input Arguments** **tree**  
A regression tree constructed with `RegressionTree.fit`, or a compact regression tree constructed with `compact`.

**N**  
Vector of node numbers in `tree`.

**Output Arguments** **ma**

- `ma = meanSurrVarAssoc(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association between the optimal split on variable `i` and a surrogate split on variable `j`. See “Predictive Measure of Association” on page 21-1906.
- `ma = meanSurrVarAssoc(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector `N`. `N` contains node numbers from 1 to `max(tree.NumNodes)`.

## **Definitions Predictive Measure of Association**

The predictive measure of association between the optimal split on variable `i` and a surrogate split on variable `j` is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- $P_L$  and  $P_R$  are the node probabilities for the optimal split of node  $i$  into Left and Right nodes respectively.
- $P_{L_i L_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Left.
- $P_{R_i R_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Right.

Clearly,  $\lambda_{i,j}$  lies from  $-\infty$  to 1. Variable  $j$  is a worthwhile surrogate split for variable  $i$  if  $\lambda_{i,j} > 0$ .

Element  $\text{ma}(i, j)$  is the predictive measure of association averaged over surrogate splits on predictor  $j$  for which predictor  $i$  is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor  $i$  and surrogate splits on predictor  $j$  and dividing by the total number of optimal splits on predictor  $i$ , including splits for which the predictive measure of association between predictors  $i$  and  $j$  is negative.

## Examples

Find the mean predictive measure of association between the Displacement, Horsepower, and Weight variables in the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG, 'surrogate', 'on');
ma = meanSurrVarAssoc(tree)

ma =
    1.0000    0.2708    0.3854
    0.4764    1.0000    0.4568
```

# CompactRegressionTree.meanSurrVarAssoc

---

```
0.3472    0.2326    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in tree:

```
N = 1:2:tree.NumNodes;  
ma = meanSurrVarAssoc(tree,N)
```

```
ma =  
    1.0000    0.2500    0.3750  
    0.5910    1.0000    0.5861  
    0.5000    0.2361    1.0000
```

# ProbDistUnivParam.median

---

**Purpose** Return median of ProbDistUnivParam object

**Syntax**  $M = \text{median}(PD)$

**Description**  $M = \text{median}(PD)$  returns  $M$ , the median of the ProbDistUnivParam object  $PD$ .

**Input Arguments**  $PD$  An object of the class ProbDistUnivParam.

**Output Arguments**  $M$  The median of the ProbDistUnivParam object  $PD$ .

**See Also** median

<b>Purpose</b>	Median of probability distribution object
<b>Syntax</b>	<code>m = median(pd)</code>
<b>Description</b>	<code>m = median(pd)</code> returns the median <code>m</code> for the probability distribution <code>pd</code> .
<b>Input Arguments</b>	<b>pd - Probability distribution</b> probability distribution object  Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using <code>makedist</code> . Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using <code>fitdist</code> or the Distribution Fitting app.
<b>Output Arguments</b>	<b>m - Median</b> scalar value  Median of the probability distribution, returned as a scalar value. The value of <code>m</code> is the 50th percentile of the probability distribution.
<b>Examples</b>	<b>Median of a Fitted Distribution</b>  Load the sample data. Create a vector containing the first column of students' exam grade data.  <pre>load examgrades; x = grades(:,1);</pre> Create a normal distribution object by fitting it to the data. <pre>pd = fitdist(x,'Normal')</pre> <pre>pd =  NormalDistribution</pre>

# prob.TruncatableDistribution.median

---

```
Normal distribution
  mu = 75.0083 [73.4321, 76.5846]
  sigma = 8.7202 [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)
```

```
m =
```

```
75.0083
```

For a symmetrical distribution such as the normal distribution, the median will be equal to the mean,  $\mu$ .

## Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 5
```

```
B = 2
```

Compute the median of the distribution.

```
m = median(pd)
```

```
m =
```

```
4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean =  
    4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];  
pdf = pdf(pd,x);  
plot(x,pdf)
```

# prob.TruncatableDistribution.median

# TreeBagger.MergeLeaves property

---

- Purpose** Flag to merge leaves that do not improve risk
- Description** The MergeLeaves property is true if decision trees have their leaves with the same parent merged for splits that do not decrease the total risk, and false otherwise. The default value is false.
- See Also** `classregtree`

# categorical.mergelevels

---

**Purpose** Merge levels

**Syntax** B = mergelevels(A,oldlevels,newlevel)  
B = mergelevels(A,oldlevels)

**Description** B = mergelevels(A,oldlevels,newlevel) merges two or more levels of the categorical array A into a single new level. oldlevels is a cell array of strings or a 2-D character matrix that specifies the levels to be merged. Any elements of A that have levels in oldlevels are assigned the new level in the corresponding elements of B. newlevel is a character string that specifies the label for the new level. For ordinal arrays, the levels of A specified by oldlevels must be consecutive, and mergelevels inserts the new level to preserve the order of the levels.

B = mergelevels(A,oldlevels) merges two or more levels of A. For nominal arrays, mergelevels uses the first label in oldlevels as the label for the new level. For ordinal arrays, mergelevels uses the label corresponding to the lowest level in oldlevels as the label for the new level.

## **Examples Merge Levels in Nominal Array**

Load the sample data. Create a nominal array containing the iris species data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a nominal array containing the iris species data. Display the levels in the nominal array.

```
species = nominal(species);  
getlevels(species)
```

```
ans =
```

```
setosa    versicolor    virginica
```

Merge the 'setosa' and 'virginica' levels into a single new level called 'parent'.

```
species = mergelevels(species,...  
                       {'setosa','virginica'}, 'parent');
```

Display the new level labels.

```
getlabels(species)
```

```
ans =  
    'parent'    'versicolor'
```

# categorical.mergelevels

---

## Merge Levels in Ordinal Array

Create an ordinal array.

```
A = ordinal([1 2 3 2 1], {'lo', 'med', 'hi'})
```

```
A =  
    lo      med      hi      med      lo
```

Merge the 'lo' and 'med' levels into a single new level labeled 'bad'.

```
A = mergelevels(A, {'lo', 'med'}, 'bad')
```

```
A =  
    bad      bad      hi      bad      bad
```

Any element previous belonging to the levels 'lo' or 'med' now belongs to the level 'bad'.

# TreeBagger.Method property

---

**Purpose**

Method used by trees (classification or regression)

**Description**

The Method property is 'classification' for classification ensembles and 'regression' for regression ensembles.

# mhsample

---

## Purpose

Metropolis-Hastings sample

## Syntax

```
smp1 = mhsample(start, nsamples, 'pdf', pdf, 'proppdf', proppdf,
               'proprnd', proprnd)
smp1 = mhsample(..., 'symmetric', sym)
smp1 = mhsample(..., 'burnin', K)
smp1 = mhsample(..., 'thin', m)
smp1 = mhsample(..., 'nchain', n)
[smp1, accept] = mhsample(...)
```

## Description

`smp1 = mhsample(start, nsamples, 'pdf', pdf, 'proppdf', proppdf, 'proprnd', proprnd)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm.

`start` is a row vector containing the start value of the Markov Chain, `nsamples` is an integer specifying the number of samples to be generated, and `pdf`, `proppdf`, and `proprnd` are function handles created using `@`. `proppdf` defines the proposal distribution density, and `proprnd` defines the random number generator for the proposal distribution. `pdf` and `proprnd` take one argument as an input with the same type and size as `start`. `proppdf` takes two arguments as inputs with the same type and size as `start`.

`smp1` is a column vector or matrix containing the samples. If the log density function is preferred, `'pdf'` and `'proppdf'` can be replaced with `'logpdf'` and `'logproppdf'`. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.

The proposal distribution  $q(x,y)$  gives the probability density for choosing  $x$  as the next point when  $y$  is the current point. It is sometimes written as  $q(x|y)$ .

If the `proppdf` or `logproppdf` satisfies  $q(x,y) = q(y,x)$ , that is, the proposal distribution is symmetric, `mhsample` implements Random Walk Metropolis-Hastings sampling. If the `proppdf` or `logproppdf` satisfies  $q(x,y) = q(x)$ , that is, the proposal distribution is independent of current values, `mhsample` implements Independent Metropolis-Hastings sampling.

`smp1 = mhsample(..., 'symmetric', sym)` draws `nsamples` random samples from a target stationary distribution pdf using the Metropolis-Hastings algorithm. `sym` is a logical value that indicates whether the proposal distribution is symmetric. The default value is false, which corresponds to the asymmetric proposal distribution. If `sym` is true, for example, the proposal distribution is symmetric, `proppdf` and `logproppdf` are optional.

`smp1 = mhsample(..., 'burnin', K)` generates a Markov chain with values between the starting point and the  $k^{\text{th}}$  point omitted in the generated sequence. Values beyond the  $k^{\text{th}}$  point are kept. `k` is a nonnegative integer with default value of 0.

`smp1 = mhsample(..., 'thin', m)` generates a Markov chain with `m-1` out of `m` values omitted in the generated sequence. `m` is a positive integer with default value of 1.

`smp1 = mhsample(..., 'nchain', n)` generates `n` Markov chains using the Metropolis-Hastings algorithm. `n` is a positive integer with a default value of 1. `smp1` is a matrix containing the samples. The last dimension contains the indices for individual chains.

`[smp1, accept] = mhsample(...)` also returns `accept`, the acceptance rate of the proposed distribution. `accept` is a scalar if a single chain is generated and is a vector if multiple chains are generated.

## Examples

Estimate the second order moment of a Gamma distribution using the Independent Metropolis-Hastings sampling.

```
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); %target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
    exprnd(floor(alpha)/alpha,floor(alpha),1));
nsamples = 5000;
smp1 = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...
    'proppdf',proppdf);
xxhat = cumsum(smp1.^2)./(1:nsamples)';
```

# mhsample

```
plot(1:nsamples,xxhat)
```

Generate random samples from  $N(0,1)$  using the Random Walk Metropolis-Hastings sampling.

```
delta = .5;
pdf = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);
histfit(x,50)
h = get(gca,'Children');
set(h(2),'FaceColor',[.8 .8 1])
```

**See Also**

`slicesample` | `rand`

# TreeBagger.MinLeaf property

---

**Purpose** Minimum number of observations per tree leaf

**Description** The MinLeaf property specifies the minimum number of observations per tree leaf. The default values are 1 for classification and 5 for regression. For `classregtree` training, the 'minparent' value is set to  $2 * \text{MinLeaf}$ .

**See Also** `classregtree`

**Purpose**

Maximum likelihood estimates

**Syntax**

```
phat = mle(data)
phat = mle(data, 'distribution', dist)

phat = mle(data, 'pdf', pdf, 'start', start)
phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)

phat = mle(data, 'logpdf', logpdf, 'start', start)
phat =
mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)

phat = mle(data, 'nloglf', nloglf, 'start', start)

phat = mle( __, Name, Value)
[phat, pci] = mle( __ )
```

**Description**

`phat = mle(data)` returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector `data`.

`phat = mle(data, 'distribution', dist)` returns parameter estimates for a distribution specified by `dist`.

`phat = mle(data, 'pdf', pdf, 'start', start)` returns parameter estimates for a custom distribution specified by the probability density function `pdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)` returns parameter estimates for a custom distribution specified by the probability density function `pdf` and custom cumulative distribution function `cdf`.

`phat = mle(data, 'logpdf', logpdf, 'start', start)` returns parameter estimates for a custom distribution specified by the log

probability density function `logpdf`. You must also specify the initial parameter values, `start`.

```
phat =  
mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf) returns  
parameter estimates for a custom distribution specified by  
the log probability density function logpdf and custom log  
survival function logsf.
```

```
phat = mle(data, 'nloglf', nloglf, 'start', start) returns  
parameter estimates for the custom distribution specified by the  
negative loglikelihood function nloglf. You must also specify the initial  
parameter values, start.
```

```
phat = mle( ___, Name, Value) also returns the parameter estimates  
with additional options specified by one or more name-value pair  
arguments. You can use any of the input arguments in the previous  
syntaxes.
```

```
[phat, pci] = mle( ___ ) also returns the 95% confidence intervals  
for the parameters.
```

## Input Arguments

### **data** - Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

### **Data Types**

single | double

### **dist** - Distribution type

'normal' (default) | string

Distribution type to estimate parameters for, specified as one of the following.

<b>dist</b>	<b>Description</b>	<b>Parameter 1</b>	<b>Parameter 2</b>	<b>Parameter 3</b>
'bernoulli'	“Bernoulli Distribution” on page B-3	p: probability of success for each trial	—	—
'beta' or 'Beta'	“Beta Distribution” on page B-5	a	b	—
'bino' or 'Binomial'	“Binomial Distribution” on page B-9	n: number of trials	p: probability of success for each trial	—
'birnbaumsaunders'	“Birnbaum-Saunders Distribution” on page B-13	$\beta$ : scale	$\gamma$ : shape	—
'burr' or 'Burr'	“Burr Type XII Distribution” on page B-15	$\alpha$ : scale	c: first shape	k: second shape
'Discrete Uniform' or 'unid'	“Uniform Distribution (Discrete)” on page B-139	N: maximum observable value	—	—
'exp' or 'Exponential'	“Exponential Distribution” on page B-32	$\mu$ : mean	—	—
'ev' or 'Extreme Value'	“Extreme Value Distribution” on page B-35	$\mu$ : location	$\sigma$ : scale	—
'gam' or 'Gamma'	“Gamma Distribution” on page B-43	a: shape	b: scale	—
'gev' or 'Generalized Extreme Value'	“Generalized Extreme Value Distribution” on page B-48	k: shape	$\sigma$ : scale	$\mu$ : location

dist	Description	Parameter 1	Parameter 2	Parameter 3
'gp' or 'Generalized Pareto'	“Generalized Pareto Distribution” on page B-53	k: tail index (shape)	$\sigma$ : scale	$\theta$ : threshold
'geo' or 'Geometric'	“Geometric Distribution” on page B-57	p: probability	—	—
'inversegaussian'	“Inverse Gaussian Distribution” on page B-63	$\mu$ : scale	$\lambda$ : shape	—
'logistic'	“Logistic Distribution” on page B-76	$\mu$ : location	$\sigma$ : scale	—
'loglogistic'	“Loglogistic Distribution” on page B-78	$\mu$ : log location	$\sigma$ : log scale	—
'logn' or 'Lognormal'	“Lognormal Distribution” on page B-80	$\mu$ : log location	$\sigma$ : log scale	—
'nakagami'	“Nakagami Distribution” on page B-97	$\mu$ : shape	$\omega$ : scale	—
'nbin' or 'Negative Binomial'	“Negative Binomial Distribution” on page B-98	r: number of successes	p: probability of success in a single trial	—
'norm' or 'Normal'	“Normal Distribution” on page B-110	$\mu$ : location (mean)	$\sigma$ : scale (standard deviation)	—
'poiss' or 'Poisson'	“Poisson Distribution” on page B-118	$\lambda$ : mean	—	—
'rayl' or 'Rayleigh'	“Rayleigh Distribution” on page B-121	b: scale	—	—

dist	Description	Parameter 1	Parameter 2	Parameter 3
'rician'	“Rician Distribution” on page B-123	s: noncentrality	$\sigma$ : scale	—
'tlocationscale'	“t Location-Scale Distribution” on page B-126	$\mu$ : location	$\sigma$ : scale	$\nu$ : degrees of freedom
'unif' or 'Uniform'	“Uniform Distribution (Continuous)” on page B-133	a: lower endpoint (minimum)	b: upper endpoint (maximum)	—
'wbl' or 'Weibull'	“Weibull Distribution” on page B-141	a: scale	b: shape	—

**Example:** 'rician'

### pdf - Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is newpdf, then you can specify the function handle in mle as follows.

**Example:** @newpdf

### Data Types

function\_handle

### cdf - Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mle` as follows.

**Example:** `@newcdf`

### **Data Types**

`function_handle`

### **logpdf - Custom log probability density function**

`function handle`

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mle` as follows.

**Example:** `@customlogpdf`

### **Data Types**

`function_handle`

### **logsf - Custom log survival function**

`function handle`

Custom log survival function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define logsf with logpdf if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify logsf while using logpdf.

For example, if the name of the custom log survival function is logsurvival, then you can specify the function handle in mle as follows.

**Example:** @logsurvival

### Data Types

function\_handle

### nloglf - Custom negative loglikelihood function

function handle

Custom negative loglikelihood function, specified as a function handle created using @.

This custom function accepts the following input arguments.

params	Vector of distribution parameter values. mle detects the number of parameters from the number of
data	Vector of data.
cens	Boolean vector of censored values.
freq	Vector of integer data frequencies.

nloglf must accept all four arguments even if you do not use the 'censoring' or 'frequency' name-value pair arguments. You can write 'nloglf' to ignore cens and freq arguments in that case.

nloglf returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'options').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mle` as follows.

**Example:** `@negloglik`

### Data Types

`function_handle`

### start - Initial parameter values

`scalar` | `vector`

Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use `start` when you fit custom distributions, that is, when you use `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

**Example:** `0.05`

**Example:** `[100,2]`

### Data Types

`single` | `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'censoring',Cens,'alpha',0.01,'options',Opt` specifies that `mle` estimates the parameters for the distribution of censored data specified by array `Cens`, computes the 99% confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure `Opt`.

### 'censoring' - Indicator for censoring

`array of 0s (default)` | `array of 0s and 1s`

Indicator for censoring, specified as the comma-separated pair consisting of 'censoring' and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

Censoring is not supported for all distributions.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

**Example:** 'censoring',`Censored`

### Data Types

logical

### 'frequency' - Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of 'frequency' and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

**Example:** 'frequency',`Freq`

### Data Types

single | double

### 'alpha' - Confidence level

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of parameter estimates, `pci`, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range (0,1). The confidence level of `pci` is  $100(1-\alpha)\%$ . The default is 0.05 for 95% confidence.

For example, for 99% confidence limits, you can specify the confidence level as follows.

**Example:** 'alpha',0.01

## **Data Types**

single | double

## **'ntrials' - Number of trials**

scalar value | vector

Number of trials for the corresponding element of data, specified as the comma-separated pair consisting of 'ntrials' and a scalar or a vector of the same size as data.

Applies only to binomial distribution.

**Example:** 'ntrials',total

## **Data Types**

single | double

## **'options' - Fitting algorithm control parameters**

structure

Fitting algorithm control parameters, specified as the comma-separated pair consisting of 'options' and a structure returned by `statset`.

Not applicable to all distributions.

Use the 'options' name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and default values, type `statset('mlecustom')`. You can set the options under a new name and use that in the name-value pair argument. `mle` interprets the following `statset` parameters for custom distribution fitting.

Parameter	Value
'GradObj'	<p>Default is 'off'.</p> <p>'on' or 'off', indicating whether or not <code>fmincon</code> can expect the custom function provided with the <code>nloglf</code> input argument to return the gradient vector of the negative log-likelihood as a second output.</p>
'DerivStep'	<p>Default is <math>\text{eps}^{(1/3)}</math>.</p> <p>The relative difference, specified as a scalar or a vector the same size as <code>start</code>, used in finite difference derivative approximations when using <code>fmincon</code>, and 'GradObj' is 'off'.</p> <p><code>mle</code> ignores 'DerivStep' when using <code>fminsearch</code>.</p>
'FunValCheck'	<p>Default is 'on'.</p> <p>'on' or 'off', indicating whether or not <code>mle</code> should check the values returned by the custom distribution functions for validity.</p> <p>A poor choice of starting point can sometimes cause these functions to return NaNs, infinite values, or out-of-range values if they are written without suitable error checking.</p>
'TolBnd'	<p>Default is <math>1\text{e-}6</math>. An offset for upper and lower bounds when using <code>fmincon</code>.</p> <p><code>mle</code> treats upper and lower bounds as strict inequalities, that is, open bounds. With <code>fmincon</code>, this is approximated by creating closed bounds inset from the specified upper and lower bounds by <code>TolBnd</code>.</p>

Example: `'options', statset('mlecustom')`

**Data Types**  
struct

## **'lowerbound' - Lower bounds for distribution parameters**

$-\infty$  (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of 'lowerbound' and a vector the same size as **start**.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logcdf, or nloglf input arguments.

**Example:** 'lowerbound',0

### **Data Types**

single | double

## **'upperbound' - Upper bounds for distribution parameters**

$\infty$  (default) | vector

Upper bounds for distribution parameters, specified as the comma-separated pair consisting of 'upperbound' and a vector the same size as **start**.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

**Example:** 'upperbound',1

### **Data Types**

single | double

## **'optimfun' - Optimization function**

'fminsearch' (default) | 'fmincon'

Optimization function mle uses in maximizing the likelihood, specified as the comma-separated pair consisting of 'optimfun' and either 'fminsearch' or 'fmincon'.

Default is 'fminsearch'.

You can only specify 'fmincon' if Optimization Toolbox is available.

The 'optimfun' name-value pair argument is valid only when you fit custom distributions, that is, when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

**Example:** 'optimfun', 'fmincon'

## Output Arguments

### **phat** - Parameter estimates

scalar value | row vector

Parameter estimates, returned as a scalar value or a row vector.

### **pci** - Confidence intervals for parameter estimates

2-by- $k$  matrix

Confidence intervals for parameter estimates, returned as a column vector or a matrix depending on the number of parameters, hence the size of phat.

pci is a 2-by- $k$  matrix, where  $k$  is the number of parameters mle estimates. The first and second rows of the pci show the upper and lower confidence limits, respectively.

## Examples

### **Estimate Parameters of Burr Distribution**

Load the sample data.

```
load carbig
```

The variable MPG has the miles per gallon for different models of cars.

Draw a histogram of MPG data.

```
hist(MPG)
```

# mle

---

The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the MPG data.

```
phat = mle(MPG, 'distribution', 'burr')
```

```
phat =
```

```
34.6447    3.7898    3.5722
```

The maximum likelihood estimates for the scale parameter  $\alpha$  is 34.6447. The estimates for the two shape parameters  $c$  and  $k$  of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

### Fit Custom Distribution to Censored Data

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

```
custpdf = @(data,lambda) lambda*exp(-lambda*data);
custcdf = @(data,lambda) 1-exp(-lambda*data);
```

Estimate the parameter, `lambda`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'pdf',custpdf,...
'cdf',custcdf,'start',0.05,'Censoring',Censored)
phat
```

```
phat =
```

```
0.1096
```

## Fit Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...
             +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
           'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)
```

```
phat =
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

## Fit Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf=@(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =
```

```
0.1462
```

### **Estimate Probability of Success**

Generate 100 random observations from a binomial distribution with the number of trials,  $n = 20$ , and the probability of success,  $p = 0.75$ .

```
data = binornd(20,0.75,100,1);
```

Estimate the probability of success and 95% confidence limits using the simulated sample data.

```
[phat,pci] = mle(data,'distribution','binomial',...
                'alpha',.05,'ntrials',20)
```

```
phat =
```

```
0.7370
```

```
pci =
```

```
0.7171
```

0.7562

The estimate of probability of success is 0.737 and the lower and upper limits of the 95% confidence interval are 0.7171 and 0.7562. This interval covers the true value used to simulate the data.

## Definitions **Survival Function**

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function,  $F(t)$ , is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution,  $S(t)$ , is the complement of the cumulative distribution function:  $S(t) = 1 - F(t)$ .

## Tips

When you supply distribution functions, `mle` computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause `mle` to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

## See Also

`fitdist` | `mlecov` | `statset`

## Concepts

- “What Is Survival Analysis?” on page 12-2

**Purpose**

Asymptotic covariance of maximum likelihood estimators

**Syntax**

```
acov = mlecov(params,data,'pdf',pdf)
acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)

acov = mlecov(params,data,'logpdf',logpdf)
acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)

acov = mlecov(params,data,'nloglf',nloglf)

acov = mlecov( ____,Name,Value)
```

**Description**

`acov = mlecov(params,data,'pdf',pdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf`.

`mlecov` computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates `params`, given the observed data, and returns the negative inverse of that Hessian.

`acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf` and cumulative distribution function `cdf`.

`acov = mlecov(params,data,'logpdf',logpdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function `logpdf`.

`acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution

specified by the custom log probability density function `logpdf` and custom log survival function `logsf`.

`acov = mlecov(params,data,'nloglf',nloglf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom negative loglikelihood function `nloglf`.

`acov = mlecov( ___,Name,Value)` also returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

## Input Arguments

### **params - Parameter estimates**

scalar value | vector

Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by `mle`.

### **Data Types**

single | double

### **data - Sample data**

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

### **Data Types**

single | double

### **pdf - Custom probability density function**

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@newpdf`

### Data Types

function\_handle

### **cdf - Custom cumulative distribution function**

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@newcdf`

### Data Types

function\_handle

### **logpdf - Custom log probability density function**

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@customlogpdf`

### **Data Types**

`function_handle`

### **logsf - Custom log survival function**

`function handle`

Custom log survival function, specified as a function handle created using `@`.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@logsurvival`

### **Data Types**

`function_handle`

### **nloglf - Custom negative loglikelihood function**

`function handle`

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

params	Vector of distribution parameter values
data	Vector of data
cens	Boolean vector of censored values
freq	Vector of integer data frequencies

`nloglf` must accept all four arguments even if you do not use the 'censoring' or 'frequency' name-value pair arguments. You can write 'nloglf' to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'options').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@negloglik`

### Data Types

`function_handle`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** 'censoring', `cens`, 'options', `opt` specifies that `mlecov` reads the censored data information from the vector `cens` and performs according to the new options structure `opt`.

### 'censoring' - Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'censoring' and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use `cdf` with `pdf`, or `logsf` with `logpdf`, or `nloglf` must be defined to account for censoring.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

**Example:** 'censoring',Censored

### Data Types

logical

### 'frequency' - Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of 'frequency' and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

**Example:** 'frequency',Freq

### Data Types

single | double

### 'options' - Numerical options

structure

Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of 'options' and a structure returned by `statset`.

You can set the options under a new name and use it in the name-value pair argument. The applicable `statset` parameters are as follows.

Parameter	Value
'GradObj'	Default is 'off'.  'on' or 'off', indicating whether or not the function provided with the nloglf input argument can return the gradient vector of the negative log-likelihood as a second output.
'DerivStep'	Default is $\text{eps}^{(1/4)}$ .  Relative step size used in finite difference for Hessian calculations. It can be a scalar, or the same size as <code>params</code> . A smaller value than the default might be appropriate if 'GradObj' is 'on'.

**Example:** `'options', statset('mlecov')`

**Data Types**  
struct

## Output Arguments

**acov - Approximation to asymptotic covariance matrix**  
*p*-by-*p* matrix

Approximation to asymptotic covariance matrix, returned as a *p*-by-*p* matrix, where *p* is the number of parameters in `params`.

## Examples

### Custom Probability Density Function

Load the sample data.

```
load carbig
```

The vector `Weight` shows the weights of 406 cars.

In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as `lognormpdf.m`.

```
function newpdf = lognormpdf(data,mu,sigma)
```

```
newpdf = exp((- (log(data) - mu).^2) / (2*sigma^2)) ./ (data*sigma*sqrt(2*pi));
```

Estimate the parameters, mu and sigma, of the custom-defined distribution.

```
phat = mle(Weight, 'pdf', @lognormpdf, 'start', [4.5 0.3])
```

```
phat =
```

```
    7.9600    0.2804
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat, Weight, 'pdf', @lognormpdf)
```

```
acov =
```

```
    1.0e-03 *  
    0.1937    -0.0000  
   -0.0000    0.0968
```

Estimate the standard errors of estimates.

```
se = sqrt(diag(acov))
```

```
se =
```

```
    0.0139  
    0.0098
```

The standard error of the estimates of mu and sigma are 0.0139 and 0.0098, respectively.

## Custom Log Probability Density Function

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as `betalogpdf.m`.

```
function logpdf = betalogpdf(x,a,b)
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-betaIn(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```
rng('default')
x = betarnd(1.23,3.45,25,1);
phat = mle(x,'dist','beta')
```

```
phat =

    1.1213    2.7182
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,x,'logpdf',@betalogpdf)
```

```
acov =

    0.0810    0.1646
    0.1646    0.6074
```

## Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...  
             +(k-1)*log(data)-(data/lambda).^k;  
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...  
          'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)
```

```
phat =  
  
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,ReadmissionTime,...  
             'logpdf',custlogpdf,'logsf',custlogsf,'Censoring',Censored)
```

```
acov =  
  
    0.5653    0.0102  
    0.0102    0.0163
```

## Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =
```

```
0.1462
```

Compute the variance of the parameter estimate.

```
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)
```

```
acov =
```

```
2.1374e-04
```

Compute the standard error.

```
sqrt(acov)
```

```
ans =
```

0.0146

## **Definitions**      **Survival Function**

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function,  $F(t)$ , is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution,  $S(t)$ , is the complement of the cumulative distribution function:  $S(t) = 1 - F(t)$ .

## **See Also**      mle

## **Concepts**      • “What Is Survival Analysis?” on page 12-2

<b>Purpose</b>	Multinomial probability density function
<b>Syntax</b>	<code>Y = mnpdf(X,PROB)</code>
<b>Description</b>	<code>Y = mnpdf(X,PROB)</code> returns the pdf for the multinomial distribution with probabilities <code>PROB</code> , evaluated at each row of <code>X</code> . <code>X</code> and <code>PROB</code> are $m$ -by- $k$ matrices or 1-by- $k$ vectors, where $k$ is the number of multinomial bins or categories. Each row of <code>PROB</code> must sum to one, and the sample sizes for each observation (rows of <code>X</code> ) are given by the row sums <code>sum(X,2)</code> . <code>Y</code> is an $m$ -by- $k$ matrix, and <code>mnpdf</code> computes each row of <code>Y</code> using the corresponding rows of the inputs, or replicates them if needed.

**Examples**

```
% Compute the distribution
p = [1/2 1/3 1/6]; % Outcome probabilities
n = 10; % Sample size
x1 = 0:n;
x2 = 0:n;
[X1,X2] = meshgrid(x1,x2);
X3 = n - (X1+X2);
Y = mnpdf([X1(:),X2(:),X3(:)],repmat(p,(n+1)^2,1));

% Plot the distribution
Y = reshape(Y,n+1,n+1);
bar3(Y)
set(gca,'XTickLabel',0:n)
set(gca,'YTickLabel',0:n)
xlabel('x_1')
ylabel('x_2')
zlabel('Probability Mass')
title('Trinomial Distribution')
```

Note that the visualization does not show  $x_3$ , which is determined by the constraint  $x_1 + x_2 + x_3 = n$ .

mnrnd

**How To**

- “Multinomial Distribution” on page B-83

**Purpose** Multinomial logistic regression

**Syntax**

```
B = mnrfit(X,Y)
B = mnrfit(X,Y,Name,Value)
[B,dev,stats] = mnrfit( ___ )
```

**Description** `B = mnrfit(X,Y)` returns a matrix, `B`, of coefficient estimates for a multinomial logistic regression of the nominal responses in `Y` on the predictors in `X`.

`B = mnrfit(X,Y,Name,Value)` returns a matrix, `B`, of coefficient estimates for a multinomial model fit with additional options specified by one or more `Name,Value` pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.

`[B,dev,stats] = mnrfit( ___ )` also returns the deviance of the fit, `dev`, and the structure `stats` for any of the previous input arguments. `stats` contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

## Input Arguments

### **X - Observations on predictor variables**

*n*-by-*p* matrix

Observations on predictor variables, specified as an *n*-by-*p* matrix. `X` contains *n* observations for *p* predictors.

---

**Note** `mnrfit` automatically includes a constant term (intercept) in all models. Do not include a column of 1s in `X`.

---

### **Data Types**

single | double

## **Y - Response values**

*n*-by-*k* matrix | *n*-by-1 column vector

Response values, specified as a column vector or a matrix. Y can be one of the following:

- An *n*-by-*k* matrix, where  $Y(i,j)$  is the number of outcomes of the multinomial category *j* for the predictor combinations given by  $X(i,:)$ . In this case, the number of observations are made at each predictor combination.
- An *n*-by-1 column vector of scalar integers from 1 to *k* indicating the value of the response for each observation. In this case, all sample sizes are 1.

## **Data Types**

single | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:** 'model', 'ordinal', 'link', 'probit' specifies an ordinal model with a probit link function.

## **'model' - Type of model to fit**

'nominal' (default) | 'ordinal' | 'hierarchical'

Type of model to fit, specified as the comma-separated pair consisting of 'model' and one of the following.

'nominal'	Default. There is no ordering among the response categories.
'ordinal'	There is a natural ordering among the response categories.
'hierarchical'	The choice of response category is sequential/nested.

**Example:** 'model', 'ordinal'

### 'interactions' - Indicator for interaction between multinomial categories and coefficients

'on' | 'off'

Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of 'interactions' and one of the following.

'on'	Default for nominal and hierarchical models. Fit a model with different coefficients across categories.
'off'	Default for ordinal models. Fit a model with a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or the <i>proportional odds model</i> .

In all cases, the model has different intercepts across categories. The choice of 'interactions' determines the dimensions of the output array B.

**Example:** 'interactions', 'off'

### Data Types

logical

### 'link' - Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1 - \gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comloglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors,  $X\beta$ . The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model,  $\gamma$  represents the cumulative probability of being in categories 1 to  $j$  and the model with a logit link function as follows:

$$\ln\left(\frac{\gamma}{1 - \gamma}\right) = \ln\left(\frac{\pi_1 + \pi_2 + \dots + \pi_j}{\pi_{j+1} + \dots + \pi_k}\right) = \beta_{0j} + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p,$$

where  $k$  represents the last category.

You cannot specify the 'link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1} X_{j1} + \beta_{j2} X_{j2} + \dots + \beta_{jp} X_{jp}, \quad j = 1, \dots, k - 1,$$

where  $\pi$  stands for a categorical probability, and  $r$  corresponds to the reference category. mnrfit uses the last category as the reference category for nominal models.

**Example:** 'link', 'loglog'

**'estdisp' - Indicator for estimating dispersion parameter**

'off' (default) | 'on'

Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of 'estdisp' and one of the following.

'off'	Default. Use the theoretical dispersion value of 1.
'on'	Estimate a dispersion parameter for the multinomial distribution in computing standard errors.

**Example:** 'estdisp', 'on'

## Output Arguments

### **B - Coefficient estimates**

vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in  $Y$ , returned as a vector or a matrix.

- If 'interaction' is 'off', then  $B$  is a  $k - 1 + p$  vector. The first  $k - 1$  rows of  $B$  correspond to the intercept terms, one for each  $k - 1$  multinomial categories, and the remaining  $p$  rows correspond to the predictor coefficients, which are common for all of the first  $k - 1$  categories.
- If 'interaction' is 'on', then  $B$  is a  $(p + 1)$ -by- $(k - 1)$  matrix. Each column of  $B$  corresponds to the estimated intercept term and predictor coefficients, one for each of the first  $k - 1$  multinomial categories.

The estimates for the  $k$ th category are taken to be zero as `mnrfit` takes the last category as the reference category.

### **dev - Deviance of the fit**

scalar value

Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

$$dev = 2 * \sum_i^n \sum_j^k y_{ij} * \log \left( \frac{y_{ij}}{\pi_{ij} * m_i} \right) = \sum_i^n rd_i,$$

where  $rd_i$  are the deviance residuals. For deviance residuals see `stats`.

## stats - Model statistics

structure

Model statistics, returned as a structure that contains the following fields.

beta	The coefficient estimates. These are the same as B.
dfc	Degrees of freedom for error <ul style="list-style-type: none"> <li>• If 'interactions' is 'off', then degrees of freedom is <math>n*(k - 1) - (k - 1 + p)</math>.</li> <li>• If 'interactions' is 'on', then degrees of freedom is <math>(n - p + 1)*(k - 1)</math>.</li> </ul>
sfit	Estimated dispersion parameter.
s	Theoretical or estimated dispersion parameter. <ul style="list-style-type: none"> <li>• If estdisp is 'off', then s is the theoretical dispersion parameter, 1.</li> <li>• If estdisp is 'on', then s is equal to the estimated dispersion parameter, sfit.</li> </ul>
estdisp	Indicator for a theoretical or estimated dispersion parameter.
se	Standard errors of coefficient estimates, B.
coeffcorr	Estimated correlation matrix for B.
covb	Estimated covariance matrix for B.
t	<i>t</i> statistics for B.
p	<i>p</i> -values for B.

resid	<p>Raw residuals. Observed minus fitted values,</p> $r_{ij} = y_{ij} - \hat{\pi}_{ij} * m_i, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k \end{cases}$ <p>where <math>\pi_{ij}</math> is the categorical, cumulative or conditional probability, and <math>m_i</math> is the corresponding sample size.</p>
residp	<p>Pearson residuals, which are the raw residuals scaled by the estimated standard deviation:</p> $rp_{ij} = \frac{r_{ij}}{\hat{\sigma}_{ij}} = \frac{y_{ij} - \hat{\pi}_{ij} * m_i}{\sqrt{\hat{\pi}_{ij} * (1 - \hat{\pi}_{ij}) * m_i}}, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k \end{cases}$ <p>where <math>\pi_{ij}</math> is the categorical, cumulative, or conditional probability, and <math>m_i</math> is the corresponding sample size.</p>
residd	<p>Deviance residuals:</p> $rd_i = 2 * \sum_j^k y_{ij} * \log \left( \frac{y_{ij}}{\pi_{ij} * m_i} \right), \quad i = 1, \dots, n.$ <p>where <math>\pi_{ij}</math> is the categorical, cumulative, or conditional probability, and <math>m_i</math> is the corresponding sample size.</p>

## Examples

### Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);  
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a multinomial regression model to predict the species using the measurements.

```
[B,dev,stats] = mnrfity(meas,sp);  
B
```

B =

13.3860	15.4492
2.4623	1.8196
5.2948	2.5700
-7.4916	-4.3714
-8.9322	-7.6467

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of `meas`. The first row of `B` contains the intercept terms for the relative risk of the first two response categories, `setosa` and `versicolor` versus the reference category, `virginica`. The last four rows contain the slopes for the models for the first two categories. `mnrfit` accepts the third category as the reference category.

The models for the relative risk of an iris flower being a setosa versus a virginica, and the relative risk of an iris flower being a versicolor species versus a virginica species are respectively

$$\ln\left(\frac{\pi_{setosa}}{\pi_{virginica}}\right) = 13.38 + 2.46X_1 + 5.29X_2 - 7.49X_3 - 8.93X_4$$

and

$$\ln\left(\frac{\pi_{versicolor}}{\pi_{virginica}}\right) = 15.45 + 1.82X_1 + 2.57X_2 - 4.37X_3 - 7.65X_4.$$

The coefficients express the effects of the predictor variables on the relative risk or the log odds of being in one category versus the reference category.

For example, the estimated coefficient 2.46 indicates that the probability of being species 1 (setosa) compared to the probability of being species 3 (virginica) (the relative risk of being a setosa versus a virginica) increases  $\exp(2.46)$  times for each unit increase in  $X_1$ , the first measurement, given all else equal.

In terms of log odds, you can say that the relative log odds of being a setosa versus a virginica increases 2.46 times with a one-unit increase in  $X_1$  given all else is equal.

Check the statistical significance of the model coefficients.

```
stats.p
```

```
ans =
```

0.2457	0.0031
0.4543	0.1048
0.0773	0.0815
0.0258	0.0007
0.1856	0.0002

The  $p$ -value of 0.0258 indicates that the third measure is significant on the relative risk of being a setosa versus a virginica (species 1 compared to species 3). The  $p$ -values of 0.0007 and 0.0002 indicate that the third and fourth measures are significant on the relative risk of being a versicolor versus a virginica (species 2 compared to species 3).

Request the standard errors of coefficient estimates.

```
stats.se
```

```
ans =
```

```
    11.5316    5.2201
     3.2905    1.1218
     2.9976    1.4753
     3.3609    1.2869
     6.7474    2.0846
```

Calculate the 95% confidence limits for the coefficients.

```
LL = stats.beta - 1.96.*stats.se;
UL = stats.beta + 1.96.*stats.se;
```

Display the confidence intervals for the coefficients of the model for the relative risk of being a setosa versus a virginica (the first column of coefficients in B).

```
[LL(:,1) UL(:,1)]
```

```
ans =
```

```
   -9.2160   35.9880
   -3.9869    8.9116
   -0.5805   11.1701
  -14.0790   -0.9043
  -22.1570    4.2926
```

Find the confidence intervals for the coefficients of the model for the relative risk of being a versicolor versus a virginica (the second column of coefficients in B).

```
[LL(:,2) UL(:,2)]
```

```
ans =
```

```
    5.2177    25.6807
   -0.3791     4.0184
   -0.3216     5.4615
   -6.8938    -1.8490
  -11.7324    -3.5610
```

### Multinomial Regression for Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```
load('carbig.mat')
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg by labeling the response values in the range 9–19 as 1, 20–29 as 2, 30–39 as 3, and 40–48 as 4.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
miles = double(miles);
```

Fit an ordinal response model for the response variable miles.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
B
```

```
B =  
  
-16.6895  
-11.7208  
-8.0606  
0.1048  
0.0103  
0.0645  
0.0017
```

The first three elements of **B** are the intercept terms for the models, and the last four elements of **B** are the coefficients of the covariates, assumed common across all categories. This model corresponds to *parallel regression*, which is also called the *proportional odds* model, where there is a different intercept but common slopes among categories. You can specify this using the 'interactions', 'off' name-value pair argument, which is the default for ordinal models.

```
[B(1:3)'; repmat(B(4:end),1,3)]
```

```
ans =  
-16.6895 -11.7208 -8.0606  
0.1048 0.1048 0.1048  
0.0103 0.0103 0.0103  
0.0645 0.0645 0.0645  
0.0017 0.0017 0.0017
```

The link function in the model is logit ('link', 'logit'), which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

$$\ln\left(\frac{P(\text{mpg} \leq 19)}{P(\text{mpg} > 19)}\right) = -16.6895 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(\text{mpg} \leq 29)}{P(\text{mpg} > 29)}\right) = -11.7208 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(\text{mpg} \leq 39)}{P(\text{mpg} > 39)}\right) = -8.0606 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19, or being less than or equal to 29 versus greater than 29, or being less than or equal to 39 versus greater than 39, by a factor of  $\exp(0.1048)$  given all else is equal.

Assess the significance of the coefficients.

```
stats.p
```

```
ans =
```

```
0.0000
0.0000
0.0000
0.1899
0.0350
0.0000
0.0118
```

The  $p$ -values of 0.035, 0.0000, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

## **Hierarchical Multinomial Regression Model**

Fit a hierarchical multinomial regression model.

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load smoking
```

The data set `smoking` contains five variables: `sex`, `age`, `weight`, and `systolic` and `diastolic` blood pressure. `Sex` is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

```
Y = nominal(smoking.Smoker);
Y = double(Y);
```

The data in `Smoker` has four categories:

- 0: Nonsmoker, 0 cigarettes a day
- 1: Smoker, 1–5 cigarettes a day
- 2: Smoker, 6–10 cigarettes a day
- 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

```
X = [smoking.Sex smoking.Age smoking.Weight...
     smoking.SystolicBP smoking.DiastolicBP];
```

Fit a hierarchical multinomial model.

```
[B,dev,stats] = mnrfity(X,Y,'model','hierarchical');
B
```

B =

43.8148	5.9571	44.0712
1.8709	-0.0230	0.0662
0.0188	0.0625	0.1335
0.0046	-0.0072	-0.0130
-0.2170	0.0416	-0.0324
-0.2273	-0.1449	-0.4824

The first column of **B** includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking 1–5 cigarettes a day versus more than five cigarettes a day given that a person is a smoker. Finally, the third column includes the parameter estimates for modeling the log odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the 'interactions', 'on' name-value pair argument, which is the default for hierarchical models. So, the model in this example is

$$\ln\left(\frac{P(y=0)}{P(y>0)}\right) = 43.8148 + 1.8709X_S + 0.0188X_A + 0.0046X_W - 0.2170X_{SBP} - 0.2273X_{DBP}$$

$$\ln\left(\frac{P(1 \leq y \leq 5)}{P(y > 5)}\right) = 5.9571 - 0.0230X_S + 0.0625X_A + 0.0072X_W + 0.0416X_{SBP} - 0.1449X_{DBP}$$

$$\ln\left(\frac{P(6 \leq y \leq 10)}{P(y > 10)}\right) = 44.0712 + 0.0662X_S + 0.1335X_A - 0.0130X_W - 0.0324X_{SBP} - 0.4824X_{DBP}$$

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by  $\exp(1.8709) = 6.49$  times as the gender changes from female to male given everything else held constant.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =
```

```
0.0000    0.5363    0.2149
0.3549    0.9912    0.9835
0.6850    0.2676    0.2313
0.9032    0.8523    0.8514
0.0009    0.5187    0.8165
0.0004    0.0483    0.0545
```

Sex, age, or weight don't appear significant on any level. The  $p$ -values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The  $p$ -value of 0.0483 shows that only diastolic blood pressure is significant on the odds of a person smoking 0–5 cigarettes a day versus more than 5 cigarettes a day. Similarly, the  $p$ -value of 0.0545 indicates that diastolic blood pressure is significant on the odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```
figure()
gscatter(smoking.Age,smoking.Weight,smoking.Sex)
legend('Male','Female')
xlabel('Age')
ylabel('Weight')
```

The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

```
X = double([smoking.Sex smoking.SystolicBP...
```

```
smoking.DiastolicBP]);  
[B,dev,stats] = mnrfits(X,Y,'model','hierarchical');  
B
```

```
B =
```

```
    44.8456    5.3230    25.0248  
    1.6045    0.2330    0.4982  
   -0.2161    0.0497    0.0179  
   -0.2222   -0.1358   -0.3092
```

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by  $\exp(1.6045) = 4.97$  times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an  $\exp(-.2161) = 0.8056$  decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an  $\exp(-.2222) = 0.8007$  decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =
```

```
    0.0000    0.4715    0.2325  
    0.0210    0.7488    0.6362  
    0.0010    0.4107    0.8899  
    0.0003    0.0483    0.0718
```

The  $p$ -values of 0.0210, 0.0010, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the  $p$ -value of 0.0483, diastolic blood pressure appears significant on the relative risk of a person smoking 1–5 cigarettes versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the  $p$ -values on the third column are less than 0.05,

you can say that none of the variables are statistically significant on the relative risk of a person smoking from 6–10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

## Algorithms

mnrfit treats NaNs in either X or Y as missing values, and ignores them.

# mnrnd

---

**Purpose** Multinomial random numbers

**Syntax**  
 $r = \text{mnrnd}(n, p)$   
 $R = \text{mnrnd}(n, p, m)$   
 $R = \text{mnrnd}(N, P)$

**Description**  $r = \text{mnrnd}(n, p)$  returns random values  $r$  from the multinomial distribution with parameters  $n$  and  $p$ .  $n$  is a positive integer specifying the number of trials (sample size) for each multinomial outcome.  $p$  is a 1-by- $k$  vector of multinomial probabilities, where  $k$  is the number of multinomial bins or categories.  $p$  must sum to one. (If  $p$  does not sum to one,  $r$  consists entirely of NaN values.)  $r$  is a 1-by- $k$  vector, containing counts for each of the  $k$  multinomial bins.

$R = \text{mnrnd}(n, p, m)$  returns  $m$  random vectors from the multinomial distribution with parameters  $n$  and  $p$ .  $R$  is a  $m$ -by- $k$  matrix, where  $k$  is the number of multinomial bins or categories. Each row of  $R$  corresponds to one multinomial outcome.

$R = \text{mnrnd}(N, P)$  generates outcomes from different multinomial distributions.  $P$  is a  $m$ -by- $k$  matrix, where  $k$  is the number of multinomial bins or categories and each of the  $m$  rows contains a different set of multinomial probabilities. Each row of  $P$  must sum to one. (If any row of  $P$  does not sum to one, the corresponding row of  $R$  consists entirely of NaN values.)  $N$  is a  $m$ -by-1 vector of positive integers or a single positive integer (replicated by `mnrnd` to a  $m$ -by-1 vector).  $R$  is a  $m$ -by- $k$  matrix. Each row of  $R$  is generated using the corresponding rows of  $N$  and  $P$ .

**Examples** Generate 2 random vectors with the same probabilities:

```
n = 1e3;  
p = [0.2, 0.3, 0.5];  
R = mnrd(n, p, 2)  
R =  
    215    282    503  
    194    303    503
```

Generate 2 random vectors with different probabilities:

```
n = 1e3;  
P = [0.2, 0.3, 0.5; ...  
     0.3, 0.4, 0.3;];  
R = mnrnd(n,P)  
R =  
    186    290    524  
    290    389    321
```

**How To**

- “Multinomial Distribution” on page B-83

# mnrval

---

**Purpose** Multinomial logistic regression values

**Syntax**

```
pihat = mnrvl(B,X)
[pihat,dlow,dhi] = mnrvl(B,X,stats)
[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)

yhat = mnrvl(B,X,ssize)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)
```

**Description** `pihat = mnrvl(B,X)` returns the predicted probabilities for the multinomial logistic regression model with predictors,  $X$ , and the coefficient estimates,  $B$ .

`pihat` is an  $n$ -by- $k$  matrix of predicted probabilities for each multinomial category.  $B$  is the vector or matrix that contains the coefficient estimates returned by `mnrfit`. And  $X$  is an  $n$ -by- $p$  matrix which contains  $n$  observations for  $p$  predictors.

---

**Note** `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in  $X$ .

---

`[pihat,dlow,dhi] = mnrvl(B,X,stats)` also returns 95% error bounds on the predicted probabilities, `pihat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `pihat` are `pihat` minus `dlow` and `pihat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

`[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)` returns the predicted probabilities and 95% error bounds on the predicted probabilities `pihat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of probabilities to return.

`yhat = mnrvl(B,X,ssize)` returns the predicted category counts for sample sizes, `ssize`.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)` also computes 95% error bounds on the predicted counts `yhat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `yhat` are `yhat` minus `dlo` and `yhat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)` returns the predicted category counts and 95% error bounds on the predicted counts `yhat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

## Input Arguments

### **B - Coefficient estimates**

vector or matrix returned by `mnrfit`

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by `mnrfit`. It is a vector or matrix depending on the model and interactions.

**Example:** `B = mnrfit(X,y); pihat = mnrvl(B,X)`

### **Data Types**

single | double

### **X - Sample data**

matrix

Sample data on predictors, specified as an  $n$ -by- $p$ .  $X$  contains  $n$  observations for  $p$  predictors.

---

**Note** `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in  $X$ .

---

**Example:** `pihat = mnrfval(B,X)`

### Data Types

single | double

### stats - Model statistics

structure returned by `mnrfit`

Model statistics, specified as a structure returned by `mnrfit`. You must use the `stats` input argument in `mnrval` to compute the lower and upper error bounds on the category probabilities and counts.

**Example:** `[B,dev,stats] = mnrfval(X,y);[pihat,dlo,dhi] = mnrfval(B,X,stats)`

### ssize - Sample sizes

column vector of positive integers

Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an  $n$ -by-1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is  $y_1$ ,  $y_2$ , and  $y_3$ , respectively, then the sample size,  $m$ , for that observation is  $m = y_1 + y_2 + y_3$ .

If the sample sizes for  $n$  observations are in vector `sample`, then you can enter the sample sizes as follows.

**Example:** `yhat = mnrfval(B,X,sample)`

**Data Types**

single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:**

`'model', 'ordinal', 'link', 'probit', 'type', 'cumulative'` specifies that `mnrval` returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

**'model' - Type of multinomial model**

'nominal' (default) | 'ordinal' | 'hierarchical'

Type of multinomial model fit by `mnrfit`, specified as the comma-separated pair consisting of `'model'` and one of the following.

'nominal'	Default. Specify when there is no ordering among the response categories.
'ordinal'	Specify when there is a natural ordering among the response categories.
'hierarchical'	Specify when the choice of response category is sequential.

**Example:** `'model', 'ordinal'`

**'interactions' - Indicator for interaction between multinomial categories and coefficients**

'on' | 'off'

Indicator for an interaction between the multinomial categories and coefficients in the model fit by `mnrfit`, specified as the comma-separated pair consisting of `'interactions'` and one of the following.

'on'	Default for nominal and hierarchical models. Specify to fit a model with different intercepts and coefficients across categories.
'off'	Default for ordinal models. Specify to fit a model with different intercepts, but a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or <i>proportional odds model</i> .

**Example:** 'interactions','off'

## Data Types

logical

## 'link' - Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function `mnrfit` uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1 - \gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors,  $X\beta$ .

$\gamma$  might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the 'link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \cdots + \beta_{jp}X_{jp}, \quad j = 1, \dots, k-1,$$

where  $\pi$  stands for a categorical probability, and  $r$  corresponds to the reference category,  $k$  is the total number of response categories,  $p$  is the number of predictor variables. `mnrfit` uses the last category as the reference category for nominal models.

**Example:** `'link','loglog'`

### 'type' - Type of probabilities or counts to estimate

`'category'` (default) | `'cumulative'` | `'conditional'`

Type of probabilities or counts to estimate, specified as the comma-separated pair including `'type'` and one of the following.

<code>'category'</code>	Default. Specify to return predictions and error bounds for the probabilities (or counts) of the $k$ multinomial categories.
<code>'cumulative'</code>	Specify to return predictions and confidence bounds for the cumulative probabilities (or counts) of the first $k - 1$ multinomial categories, as an $n$ -by- $(k - 1)$ matrix. The predicted cumulative probability for the $k$ th category is always 1.
<code>'conditional'</code>	Specify to return predictions and error bounds in terms of the first $k - 1$ conditional category probabilities (counts), i.e., the probability (count) for category $j$ , given an outcome in category $j$ or higher. When <code>'type'</code> is <code>'conditional'</code> , and you supply the sample size argument <code>ssize</code> , the predicted counts at each row of $X$ are conditioned on the corresponding element of <code>ssize</code> , across all categories.

**Example:** `'type','cumulative'`

## Output Arguments

### 'confidence' - Confidence level

0.95 (default) | Scalar value in the range (0,1)

Confidence level for the error bounds, specified as the comma-separated pair consisting of 'confidence' and a scalar value in the range (0,1).

For example, for 99% error bounds, you can specify the confidence as follows:

**Example:** 'confidence',0.99

### Data Types

single | double

### pihat - Probability estimates

$n$ -by- $(k - 1)$  matrix

Probability estimates for each multinomial category, returned as an  $n$ -by- $(k - 1)$  matrix, where  $n$  is the number of observations, and  $k$  is the number of response categories.

### yhat - Count estimates

$n$ -by- $k - 1$  matrix

Count estimates for the number in each response category, returned as an  $n$ -by- $k - 1$  matrix, where  $n$  is the number of observations, and  $k$  is the number of response categories.

### dlow - Lower error bound

column vector

Lower error bound to compute the lower confidence bound for pihat or yhat, returned as a column vector.

The lower confidence bound for pihat is pihat minus dlow. Similarly, the lower confidence bound for yhat is yhat minus dlow. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

### dhi - Upper error bound

column vector

Upper error bound to compute the upper confidence bound for `pihat` or `yhat`, returned as a column vector.

The upper confidence bound for `pihat` is `pihat` plus `dhi`. Similarly, the upper confidence bound for `yhat` is `yhat` plus `dhi`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

## Examples

### Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);  
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2, 3.7, 5.8, 0.2];
```

```
pihat = mnrvl(B,meas);  
pihat  
  
pihat =  
  
    0.0017    0.9982    0.0001
```

The probability of an iris flower having the measurements (6.2, 3.7, 5.8, 0.2) being a setosa is 0.0017, a versicolor is 0.9982, and a virginica is 0.0001.

## **Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses**

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.

```
load('carbig.mat')  
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (MPG).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);  
miles = double(miles);
```

Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48, respectively.

Fit a multinomial regression model for the response variable miles. For an ordinal model, the default 'link' is logit and the default 'interactions' is 'off'.

```
[B,dev,stats] = mnrfits(X,miles,'model','ordinal');
```

Compute the probability estimates and 95% error bounds for probability confidence intervals for miles per gallon of a car with  $x = (12, 113, 110, 2670)$ .

```
x = [12,113,110,2670];
[pihat,dlow,hi] = mnrval(B,x,stats,'model','ordinal');
pihat
```

```
pihat =
```

```
    0.0615    0.8426    0.0932    0.0027
```

Calculate the confidence bounds for the category probability estimates.

```
LL = pihat - dlow;
UL = pihat + hi;
[LL;UL]
```

```
ans =
```

```
    0.0073    0.7829    0.0283   -0.0003
    0.1157    0.9022    0.1580    0.0057
```

### **Estimate Category Counts and Error Bounds for Nominal Responses**

Fit a multinomial regression for nominal outcomes and estimate the category counts.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);  
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```
[B,dev,stats] = mnrfit(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2,3.7,5.8,0.2];  
yhat = mnrvl(B,x,18)
```

```
yhat =
```

```
    0.0314    17.9671    0.0016
```

Estimate the error bounds for the counts.

```
[yhat,dlow,hi] = mnrvl(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```
LL = yhat - dlow;  
UL = yhat + hi;  
[LL;UL]
```

```
ans =
```

```
-0.7084    17.2272   -0.0115
 0.7711    18.7069    0.0146
```

### Plot the Count Estimates

Create sample data with one predictor variable and a categorical response variable with three categories.

```
x = [-3 -2 -1 0 1 2 3]';
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10; ...
     5 14 6; 7 13 5; 8 11 6];
[Y x]
```

```
ans =
```

```
 1    11    13    -3
 2     9    14    -2
 6    14     5    -1
 5    10    10     0
 5    14     6     1
 7    13     5     2
 8    11     6     3
```

There are observations on seven different values of the predictor variable  $x$ . The response variable  $Y$  has three categories and the data shows how many of the 25 individuals are in each category of  $Y$  for each observation of  $x$ . For example, when  $x$  is  $-3$ , 1 of 25 individuals is observed in category 1, 11 observed in category 2, and 13 observed in category 3. Similarly, when  $x$  is 1, 5 of the individuals are observed in category 1, 14 are observed in category 2, and 6 are observed in category 3.

Plot the number in each category versus the  $x$  values, on a stacked bar graph.

```
bar(x,Y,'stacked');
ylim([0 25]);
```

# mnrval

Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable,  $x$ , for each category.

```
betaHatNom = mnrfity(x,Y,'model','nominal',...  
                    'interactions','on')
```

```
betaHatNom =
```

```
-0.6028    0.3832  
 0.4068    0.1948
```

The first row of `betaHatNom` contains the intercept terms for the first two response categories. The second row contains the slopes. `mnrfit` accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

Compute the predicted probabilities for the three response categories.

```
xx = linspace(-4,4)';  
piHatNom = mnrfval(betaHatNom,xx,'model','nominal',...  
    'interactions','on');
```

The probability of being in the third category is simply  $1 - P(y = 1) - P(y = 2)$ .

Plot the estimated cumulative number in each category on the bar graph.

```
line(xx,cumsum(25*piHatNom,2),'LineWidth',2);
```

The cumulative probability for the third category is always 1.

Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable,  $x$ , across all categories:

```
betaHatOrd = mnrfits(x,Y,'model','ordinal',...  
                    'interactions','off')
```

```
betaHatOrd =
```

```
-1.5001  
0.7266  
0.2642
```

The first two elements of `betaHatOrd` are the intercept terms for the first two response categories. The last element of `betaHatOrd` is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1.

```
piHatOrd = mnrvl(betaHatOrd,xx,'type','cumulative',...  
                'model','ordinal','interactions','off');
```

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

```
figure()  
bar(x,cumsum(Y,2),'grouped');  
ylim([0 25]);  
line(xx,25*piHatOrd,'LineWidth',2);
```

# moment

---

**Purpose** Central moments

**Syntax** `m = moment(X,order)`  
`moment(X,order,dim)`

**Description** `m = moment(X,order)` returns the central sample moment of  $X$  specified by the positive integer order. For vectors, `moment(x,order)` returns the central moment of the specified order for the elements of  $x$ . For matrices, `moment(X,order)` returns central moment of the specified order for each column. For  $N$ -dimensional arrays, `moment` operates along the first nonsingleton dimension of  $X$ .

`moment(X,order,dim)` takes the moment along dimension `dim` of  $X$ .

**Tips** Note that the central first moment is zero, and the second central moment is the variance computed using a divisor of  $n$  rather than  $n - 1$ , where  $n$  is the length of the vector  $x$  or the number of rows in the matrix  $X$ .

The central moment of order  $k$  of a distribution is defined as

$$m_k = E(x - \mu)^k$$

where  $E(x)$  is the expected value of  $x$ .

## Examples

```
X = randn([6 5])
X =

# gmdistribution.mu property

---

**Purpose**            Input matrix of means  $\mu$

**Description**     Input matrix of means  $\mu$ .

**Purpose** Multiple comparison test

**Syntax**

```
c = multcompare(stats)
c = multcompare(stats,param1,va11,param2,va12,...)
[c,m] = multcompare(...)
[c,m,h] = multcompare(...)
[c,m,h,gnames] = multcompare(...)
```

**Description** `c = multcompare(stats)` performs a multiple comparison test using the information in the `stats` structure, and returns a matrix `c` of pairwise comparison results. It also displays an interactive graph of the estimates with comparison intervals around them. See “Examples” on page 21-2004.

In a one-way analysis of variance, you compare the means of several groups to test the hypothesis that they are all the same, against the general alternative that they are not all the same. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A test that can provide such information is called a *multiple comparison procedure*.

When you perform a simple t-test of one group mean against another, you specify a significance level that determines the cutoff value of the t statistic. For example, you can specify the value `alpha = 0.05` to insure that when there is no real difference, you will incorrectly find a significant difference no more than 5% of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary t-test in this situation, the alpha value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that *any* comparison will be incorrectly found significant.

The output `c` contains the results of the test in the form of a five-column matrix. Each row of the matrix represents one test, and there is one row for each pair of groups. The entries in the row indicate the means being compared, the estimated difference in means, and a confidence interval for the difference.

# multcompare

---

For example, suppose one row contains the following entries.

2.0000 5.0000 1.9442 8.2206 14.4971

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206, and a 95% confidence interval for the true difference of the means is [1.9442, 14.4971].

In this example the confidence interval does not contain 0.0, so the difference is significant at the 0.05 level. If the confidence interval did contain 0.0, the difference would not be significant at the 0.05 level.

The `multcompare` function also displays a graph with each group mean represented by a symbol and an interval around the symbol. Two means are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. You can use the mouse to select any group, and the graph will highlight any other groups that are significantly different from it.

`c = multcompare(stats,param1,va11,param2,va12,...)` specifies one or more of the parameter name/value pairs described in the following table.

Parameter	Values
'alpha'	Scalar between 0 and 1 that determines the confidence levels of the intervals in the matrix <code>c</code> and in the figure (default is 0.05). The confidence level is $100(1 - \alpha)\%$ .
'display'	Either 'on' (the default) to display a graph of the estimates with comparison intervals around them, or 'off' to omit the graph. See “Examples” on page 21-2004.
'ctype'	Specifies the type of critical value to use for the multiple comparison. “Values of <code>ctype</code> ” on page 21-2002 describes the allowed values for <code>ctype</code> .

Parameter	Values
'dimension'	A vector specifying the dimension or dimensions over which the population marginal means are to be calculated. Use only if you create <b>stats</b> with the function <b>anovan</b> . The default is 1 to compute over the first dimension. See “Dimension Parameter” on page 21-2004 for more information.
'estimate'	Specifies the estimate to be compared. The allowable values of estimate depend on the function that was the source of the <b>stats</b> structure, as described in “Values of estimate” on page 21-2003

`[c,m] = multcompare(...)` returns an additional matrix **m**. The first column of **m** contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.

`[c,m,h] = multcompare(...)` returns a handle **h** to the comparison graph. Note that the title of this graph contains instructions for interacting with the graph, and the *x*-axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit the title and the *x*-axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

```
title('')
xlabel('')
```

`[c,m,h,gnames] = multcompare(...)` returns **gnames**, a cell array with one row for each group, containing the names of the groups.

The intervals shown in the graph are computed so that to a very close approximation, two estimates being compared are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. (This is exact for multiple comparison of means from

anova1, if all means are based on the same sample size.) You can click on any estimate to see which means are significantly different from it.

## Values of ctype

The following table describes the allowed values for the parameter ctype.

Value	Description
'hsd' or 'tukey-kramer'	Use Tukey's honestly significant difference criterion. This is the default, and it is based on the Studentized range distribution. It is optimal for balanced one-way ANOVA and similar procedures with equal sample sizes. It has been proven to be conservative for one-way ANOVA with different sample sizes. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.
'lsd'	Use Tukey's least significant difference procedure. This procedure is a simple t-test. It is reasonable if the preliminary test (say, the one-way ANOVA $F$ statistic) shows a significant difference. If it is used unconditionally, it provides no protection against multiple comparisons.
'bonferroni'	Use critical values from the t distribution, after a Bonferroni adjustment to compensate for multiple comparisons. This procedure is conservative, but usually less so than the Scheffé procedure.

Value	Description
'dunn-sidak'	Use critical values from the t distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. This procedure is similar to, but less conservative than, the Bonferroni procedure.
'scheffe'	Use critical values from Scheffé's S procedure, derived from the F distribution. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative for comparisons of simple differences of pairs.

### Values of estimate

The allowable values of the parameter 'estimate' depend on the function that was the source of the stats structure, according to the following table.

Source	Values
'anova1'	Ignored. Always compare the group means.
'anova2'	Either 'column' (the default) or 'row' to compare column or row means.
'anovan'	Ignored. Always compare the population marginal means as specified by the dim argument.
'aoctool'	Either 'slope', 'intercept', or 'pmm' to compare slopes, intercepts, or population marginal means. If the analysis of covariance model did not include separate slopes, then 'slope' is not allowed. If it did not include separate intercepts, then no comparisons are possible.

Source	Values
'friedman'	Ignored. Always compare average column ranks.
'kruskalwallis'	Ignored. Always compare average group ranks.

## Dimension Parameter

The dimension parameter is a vector specifying the dimension or dimensions over which the population marginal means are to be calculated. For example, if `dim = 1`, the estimates that are compared are the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If `dim = [1 3]`, population marginal means are computed for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value `NaN`.

Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by `dim`, and averaging out the effects of other factors as if each factor combination occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means ignoring other factors. For surveys and other studies where the number of observations at each combination does have meaning, population marginal means may be harder to interpret.

## Examples

### Example 1

The following example performs a 1-way analysis of variance (ANOVA) and displays group means with their names.

```
load carsmall
```

```
[p,t,st] = anova1(MPG,Origin,'off');
[c,m,h,nms] = multcompare(st,'display','off');
[nms num2cell(m)]
ans =
    'USA'      [21.1328]  [0.8814]
    'Japan'    [31.8000]  [1.8206]
    'Germany'  [28.4444]  [2.3504]
    'France'   [23.6667]  [4.0711]
    'Sweden'   [22.5000]  [4.9860]
    'Italy'    [28.0000]  [7.0513]
```

multcompare also displays the following graph of the estimates with comparison intervals around them.

You can click the graphs of each country to compare its mean to those of other countries.

## Example 2

The following continues the example described in the `anova1` reference page, which is related to testing the material strength in structural beams. From the `anova1` output you found significant evidence that the three types of beams are not equivalent in strength. Now you can determine where those differences lie. First you create the data arrays and you perform one-way ANOVA.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...  
            78 75 76 77 79 79 77 78 82 79];  
alloy = {'st','st','st','st','st','st','st','st',...  
         'al1','al1','al1','al1','al1','al1',...  
         'al2','al2','al2','al2','al2','al2'};  
[p,a,s] = anova1(strength,alloy);
```

Among the outputs is a structure that you can use as input to `multcompare`.

```
[c,m,h,nms] = multcompare(s);  
[nms num2cell(c)]  
ans =  
    'st'    [1]    [2]    [ 3.6064]    [ 7]    [10.3936]  
    'al1'   [1]    [3]    [ 1.6064]    [ 5]    [ 8.3936]  
    'al2'   [2]    [3]   [-5.6280]   [-2]    [ 1.6280]
```

The third row of the output matrix shows that the differences in strength between the two alloys is not significant. A 95% confidence interval for the difference is  $[-5.6, 1.6]$ , so you cannot reject the hypothesis that the true difference is zero.

The first two rows show that both comparisons involving the first group (steel) have confidence intervals that do not include zero. In other words, those differences are significant. The graph shows the same information.

**Superclasses** ParametricTruncatableDistribution

**Purpose** Multinomial probability distribution object

**Description** `prob.MultinomialDistribution` is an object consisting of parameters and a model description for a multinomial probability distribution. Create a probability distribution object with specified parameters using `makedist`.

**Construction** `pd = makedist('Multinomial')` creates a multinomial probability distribution object using the default parameter values.

`pd = makedist('Multinomial','Probabilities',probabilities)` creates a multinomial distribution object using the specified parameter value.

## Input Arguments

### **probabilities - outcome probabilities**

[0.500 0.500] (default) | vector of scalar values in the range [0,1]

Outcome probabilities, specified as a vector of scalar values in the range [0,1]. Each vector element is the probability that a multinomial trial has a particular corresponding outcome. The values in `probabilities` must sum to 1.

### **Data Types**

single | double

## Properties

### **probabilities**

Outcome probabilities for the multinomial distribution, stored as a vector of scalar values in the range [0,1]. The values in `probabilities` must sum to 1.

### **Data Types**

single | double

### **DistributionName**

# prob.MultinomialDistribution

---

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## IsTruncated

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

# prob.MultinomialDistribution

---

mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions **Multinomial Distribution**

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of “successes” in  $n$  independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in  $n$  independent trials of a  $k$ -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities  $p_1, \dots, p_k$ .

The multinomial distribution uses the following parameters.

Parameter	Description	Support
probabilities	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$

The probability density function (pdf) is

$$f(x | n, p) = \frac{n!}{x_1! \dots x_k!} p_1^{x_1} \dots p_k^{x_k} \quad ; \quad \sum_1^k x_i = n, \sum_1^k p_i = 1,$$

where  $x = (x_1, \dots, x_k)$  gives the number of each  $k$  outcome in  $n$  trials of a process with fixed probabilities  $p = (p_1, \dots, p_k)$  of individual outcomes in any one trial.

## Examples

### Create a Multinomial Distribution Object Using Default Parameters

Create a multinomial distribution object using the default parameter values.

```
pd = makedist('Multinomial')
```

```
pd =
```

```
    MultinomialDistribution
```

```
    Probabilities:
```

```
    0.5000    0.5000
```

### Create a Multinomial Distribution Object Using Specified Parameters

Create a multinomial distribution object for a distribution with three possible outcomes. Outcome 1 has a probability of 1/2, outcome 2 has a probability of 1/3, and outcome 3 has a probability of 1/6.

```
pd = makedist('Multinomial','probabilities',[1/2 1/3 1/6])
```

```
pd =
```

```
    MultinomialDistribution
```

```
    Probabilities:
```

```
    0.5000    0.3333    0.1667
```

Generate a random outcome from the distribution.

```
rng('default'); % for reproducibility
```

```
r = random(pd)
```

```
r =
```

```
    2
```

# prob.MultinomialDistribution

---

The result of this trial is outcome 2. By default, the number of trials in each experiment,  $n$ , equals 1.

Generate random outcomes from the distribution when the number of trials in each experiment,  $n$ , equals 1, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
r = random(pd,10,1)
```

```
r =
```

```
2
3
1
3
2
1
1
2
3
3
```

Each element in the array is the outcome of an individual experiment that contains one trial.

Generate random outcomes from the distribution when the number of trials in each experiment,  $n$ , equals 5, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
r = random(pd,10,5)
```

```
r =
```

```
2    1    2    2    1
3    3    1    1    1
```

1	3	3	1	2
3	1	3	1	2
2	2	2	1	1
1	1	2	2	1
1	1	2	2	1
2	3	1	1	2
3	2	2	3	2
3	3	1	1	2

Each element in the resulting matrix is the outcome of one trial. The columns correspond to the five trials in each experiment, and the rows correspond to the ten experiments. For example, in the first experiment (corresponding to the first row), 2 of the 5 trials resulted in outcome 1, and 3 of the 5 trials resulted in outcome 2.

# multivarichart

---

**Purpose** Multivari chart for grouped data

**Syntax**  
`multivarichart(y, GROUP)`  
`multivarichart(Y)`  
`multivarichart(..., param1, val1, param2, val2, ...)`  
`[charthandle, AXESH] = multivarichart(...)`

**Description** `multivarichart(y, GROUP)` displays the multivari chart for the vector `y` grouped by entries in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of elements as `y`. The number of grouping variables must be 2, 3, or 4.

Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The *x*-axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position (*i*,*j*) is the multivari chart for the subset of `y` at the *i*th level of the third grouping variable and the *j*th level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.

`multivarichart(Y)` displays the multivari chart for a matrix `Y`. The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.

`multivarichart(..., param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- 'varnames' — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are 'X1', 'X2', ... .
- 'plotorder' — A string with the value 'sorted' or a vector containing a permutation of the integers from 1 to the number of grouping variables.

If 'plotorder' is a string with value 'sorted', the grouping variables are rearranged in descending order according to the number of levels in each variable.

If 'plotorder' is a vector, it indicates the order in which each grouping variable should be plotted. For example, [2,3,1,4] indicates that the second grouping variable should be used as the x-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.

[charthandle,AXESH] = multivarichart(...) returns a handle charthandle to the figure window and a matrix AXESH of handles to the subplot axes.

## Examples

Display a multivari chart for data with two grouping variables:

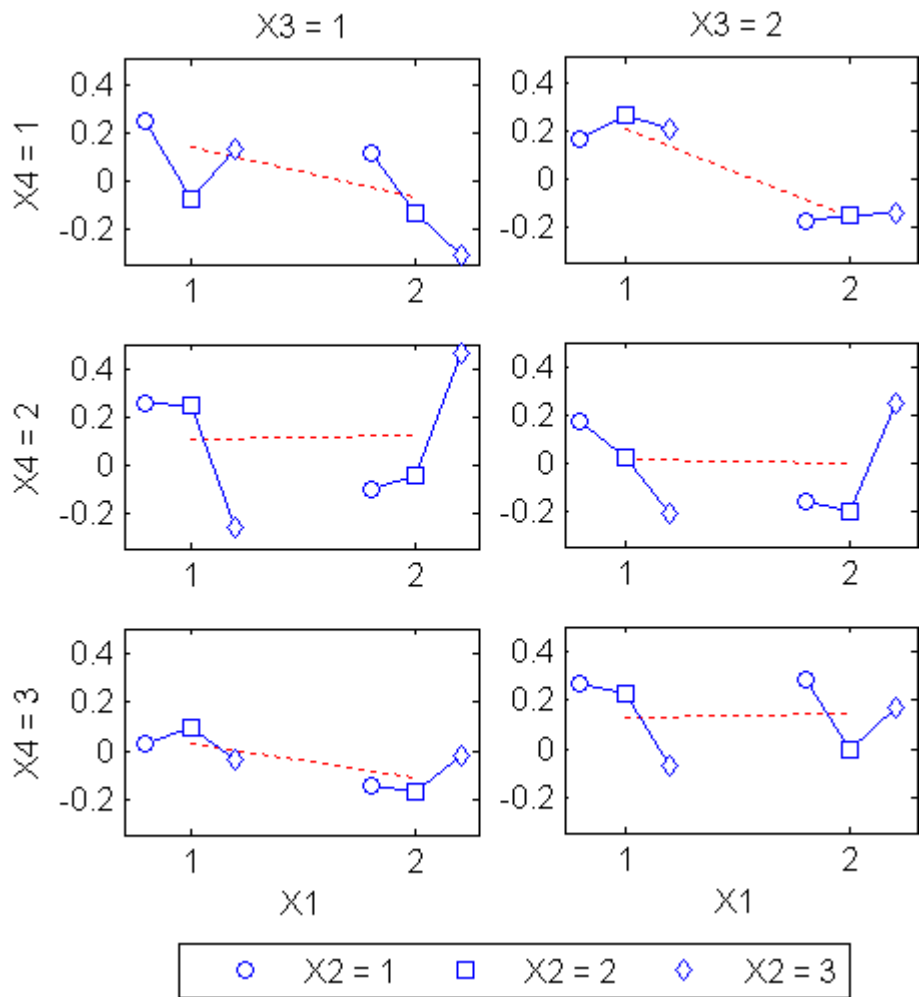

```
y = randn(100,1); % response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
```

# multivarichart

Display a multivari chart for data with four grouping variables:

```
y = randn(1000,1); % response
group = {ceil(2*rand(1000,1)),ceil(3*rand(1000,1)), ...
        ceil(2*rand(1000,1)),ceil(3*rand(1000,1))};
multivarichart(y,group)
```

# mvncdf

---

**Purpose** Multivariate normal cumulative distribution function

**Syntax**

```
y = mvncdf(X)
y = mvncdf(X,mu,SIGMA)
y = mvncdf(xl,xu,mu,SIGMA)
[y,err] = mvncdf(...)
[...] = mvncdf(...,options)
```

**Description** `y = mvncdf(X)` returns the cumulative probability of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of  $X$ . Rows of the  $n$ -by- $d$  matrix  $X$  correspond to observations or points, and columns correspond to variables or coordinates.  $y$  is an  $n$ -by-1 vector.

`y = mvncdf(X,mu,SIGMA)` returns the cumulative probability of the multivariate normal distribution with mean  $\mu$  and covariance  $\text{SIGMA}$ , evaluated at each row of  $X$ .  $\mu$  is a 1-by- $d$  vector, and  $\text{SIGMA}$  is a  $d$ -by- $d$  symmetric, positive definite matrix.  $\mu$  can also be a scalar value, which `mvncdf` replicates to match the size of  $X$ . If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal,  $\text{SIGMA}$  may also be specified as a 1-by- $d$  vector containing just the diagonal. Pass in the empty matrix `[]` for  $\mu$  to use as its default value when you want to only specify  $\text{SIGMA}$ .

The multivariate normal cumulative probability at  $X$  is defined as the probability that a random vector  $V$ , distributed as multivariate normal, will fall within the semi-infinite rectangle with upper limits defined by  $X$ , for example,  $\Pr\{V(1) \leq X(1), V(2) \leq X(2), \dots, V(d) \leq X(d)\}$ .

`y = mvncdf(xl,xu,mu,SIGMA)` returns the multivariate normal cumulative probability evaluated over the rectangle with lower and upper limits defined by  $x_l$  and  $x_u$ , respectively.

`[y,err] = mvncdf(...)` returns an estimate of the error in  $y$ . For bivariate and trivariate distributions, `mvncdf` uses adaptive quadrature on a transformation of the  $t$  density, based on methods developed by Drezner and Wesolowsky and by Genz, as described in the references. The default absolute error tolerance for these cases is  $1e-8$ . For four or more dimensions, `mvncdf` uses a quasi-Monte Carlo integration

algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is  $1e-4$ .

`[...] = mvncdf(...,options)` specifies control parameters for the numerical integration used to compute `y`. This argument can be created by a call to `statset`. Choices of `statset` parameters:

- `'TolFun'` — Maximum absolute error tolerance. Default is  $1e-8$  when  $d < 4$ , or  $1e-4$  when  $d \geq 4$ .
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when  $d \geq 4$ . Default is  $1e7$ . `'MaxFunEvals'` is ignored when  $d < 4$ .
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when  $d < 4$ .

## Examples

```
mu = [1 -1]; SIGMA = [.9 .4; .4 .3];  
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');  
X = [X1(:) X2(:)];  
p = mvncdf(X,mu,SIGMA);  
surf(X1,X2,reshape(p,25,25));
```

**How To**

- “Multivariate Normal Distribution” on page B-86

# mvnpdf

---

**Purpose** Multivariate normal probability density function

**Syntax**

```
y = mvnpdf(X)
y = mvnpdf(X,MU)
y = mvnpdf(X,MU,SIGMA)
```

**Description** `y = mvnpdf(X)` returns the  $n$ -by-1 vector `y`, containing the probability density of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the  $n$ -by- $d$  matrix `X`. Rows of `X` correspond to observations and columns correspond to variables or coordinates.

`y = mvnpdf(X,MU)` returns the density of the multivariate normal distribution with mean `mu` and identity covariance matrix, evaluated at each row of `X`. `MU` is a 1-by- $d$  vector, or an  $n$ -by- $d$  matrix. If `MU` is a matrix, the density is evaluated for each row of `X` with the corresponding row of `MU`. `MU` can also be a scalar value, which `mvnpdf` replicates to match the size of `X`.

`y = mvnpdf(X,MU,SIGMA)` returns the density of the multivariate normal distribution with mean `MU` and covariance `SIGMA`, evaluated at each row of `X`. `SIGMA` is a  $d$ -by- $d$  matrix, or a  $d$ -by- $d$ -by- $n$  array, in which case the density is evaluated for each row of `X` with the corresponding page of `SIGMA`, i.e., `mvnpdf` computes `y(i)` using `X(i,:)` and `SIGMA(:,:,i)`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a 1-by- $d$  vector or a 1-by- $d$ -by- $n$  array, containing just the diagonal. Specify `[]` for `MU` to use its default value when you want to specify only `SIGMA`.

If `X` is a 1-by- $d$  vector, `mvnpdf` replicates it to match the leading dimension of `mu` or the trailing dimension of `SIGMA`.

**Examples**

```
mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
X = mvnrnd(mu,SIGMA,10);
p = mvnpdf(X,mu,SIGMA);
```

- “Multivariate Normal Distribution” on page B-86

# mvregress

---

**Purpose** Multivariate linear regression

**Syntax**

```
beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress( ___ )
[beta,Sigma,E,CovB,logL] = mvregress( ___ )
```

**Description** `beta = mvregress(X,Y)` returns the estimated coefficients for a multivariate normal regression of the  $d$ -dimensional responses in  $Y$  on the design matrices in  $X$ .

`beta = mvregress(X,Y,Name,Value)` returns the estimated coefficients using additional options specified by one or more name-value pair arguments. For example, you can specify the estimation algorithm, initial estimate values, or maximum number of iterations for the regression.

`[beta,Sigma] = mvregress( ___ )` also returns the estimated  $d$ -by- $d$  variance-covariance matrix of  $Y$ , using any of the input arguments from the previous syntaxes.

`[beta,Sigma,E,CovB,logL] = mvregress( ___ )` also returns a matrix of residuals  $E$ , estimated variance-covariance matrix of the regression coefficients  $CovB$ , and the value of the log likelihood objective function after the last iteration  $logL$ .

## Input Arguments

**X - Design matrices**  
matrix | cell array of matrices

Design matrices for the multivariate regression, specified as a matrix or cell array of matrices.  $n$  is the number of observations in the data,  $K$  is the number of regression coefficients to estimate,  $p$  is the number of predictor variables, and  $d$  is the number of dimensions in the response variable matrix  $Y$ .

- If  $d = 1$ , then specify  $X$  as a single  $n$ -by- $K$  design matrix.

- If  $d > 1$  and all  $d$  dimensions have the same design matrix, then you can specify  $X$  as a single  $n$ -by- $p$  design matrix (not in a cell array).
- If  $d > 1$  and all  $n$  observations have the same design matrix, then you can specify  $X$  as a cell array containing a single  $d$ -by- $K$  design matrix.
- If  $d > 1$  and all  $n$  observations do not have the same design matrix, then specify  $X$  as a cell array of length  $n$  containing  $d$ -by- $K$  design matrices.

To include a constant term in the regression model, each design matrix should contain a column of ones.

`mvregress` treats NaN values in  $X$  as missing values, and ignores rows in  $X$  with missing values.

### Data Types

single | double | cell

### Y - Response variables

matrix

Response variables, specified as an  $n$ -by- $d$  matrix.  $n$  is the number of observations in the data, and  $d$  is the number of dimensions in the response. When  $d = 1$ , `mvregress` treats the values in  $Y$  like  $n$  independent response values.

`mvregress` treats NaN values in  $Y$  as missing values, and handles them according to the estimation algorithm specified using the name-value pair argument `algorithm`.

### Data Types

single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** 'algorithm', 'cwls', 'covar0', C specifies covariance-weighted least squares estimation using the covariance matrix C.

## 'algorithm' - Estimation algorithm

'mvn' | 'ecm' | 'cwls'

Estimation algorithm, specified as the comma-separated pair consisting of 'algorithm' and one of the following.

'mvn'	Ordinary multivariate normal maximum likelihood estimation.
'ecm'	Maximum likelihood estimation via the ECM algorithm.
'cwls'	Covariance-weighted least squares estimation.

The default algorithm depends on the presence of missing data.

- For complete data, the default is 'mvn'.
- If there are any missing responses (indicated by NaN), the default is 'ecm', provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is 'cwls'.

---

**Note** If algorithm has the value 'mvn', then mvregress removes observations with missing response values before estimation.

---

**Example:** 'algorithm', 'ecm'

## 'beta0' - Initial estimates for regression coefficients

vector

Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of 'beta0' and a vector with  $K$  elements. The default value is a vector of 0s.

The `beta0` argument is not used if the estimation algorithm is `'mvn'`.

### **'covar0' - Initial estimate for variance-covariance matrix**

matrix

Initial estimate for the variance-covariance matrix, `Sigma`, specified as the comma-separated pair consisting of `'covar0'` and a symmetric, positive definite,  $d$ -by- $d$  matrix. The default value is the identity matrix.

If the estimation algorithm is `'cqls'`, then `mvregress` uses `covar0` as the weighting matrix at each iteration, without changing it.

### **'covtype' - Type of variance-covariance matrix**

`'full'` (default) | `'diagonal'`

Type of variance-covariance matrix to estimate for `Y`, specified as the comma-separated pair consisting of `'covtype'` and one of the following.

<code>'full'</code>	Estimate all $d(d + 1)/2$ variance-covariance elements.
<code>'diagonal'</code>	Estimate only the $d$ diagonal elements of the variance-covariance matrix.

**Example:** `'covtype','diagonal'`

### **'maxiter' - Maximum number of iterations**

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of `'maxiter'` and a positive integer.

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

**Example:** `'maxiter',50`

## **'outputfcn' - Function to evaluate each iteration**

function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of 'outputfcn' and a function handle. The function must return a logical true or false. At each iteration, `mvregress` evaluates the function. If the result is true, iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns true if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates
- Structure containing these three fields:

<code>Covar</code>	Current value of the variance-covariance matrix
<code>iteration</code>	Current iteration number
<code>fval</code>	Current value of the loglikelihood objective function

- Text string that takes these three values:

<code>'init'</code>	When the function is called during initialization
<code>'iter'</code>	When the function is called after an iteration
<code>'done'</code>	When the function is called after completion

## **'tolbeta' - Convergence tolerance for regression coefficients**

`sqrt(eps)` (default) | positive scalar value

Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of 'tolbeta' and a positive scalar value.

Let  $\mathbf{b}^t$  denote the estimate of the coefficient vector at iteration  $t$ , and  $\tau_\beta$  be the tolerance specified by `tolbeta`. The convergence criterion for regression coefficient estimation is

$$\|\mathbf{b}^t - \mathbf{b}^{t-1}\| < \tau_\beta \sqrt{K} (1 + \|\mathbf{b}^t\|),$$

where  $K$  is the length of  $\mathbf{b}^t$  and  $\|\mathbf{v}\|$  is the norm of a vector  $\mathbf{v}$ .

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

**Example:** `'tolbeta', 1e-5`

### **'tolobj' - Convergence tolerance for loglikelihood objective function**

`eps^(3/4)` (default) | positive scalar value

Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of `'tolobj'` and a positive scalar value.

Let  $L^t$  denote the value of the loglikelihood objective function at iteration  $t$ , and  $\tau_\ell$  be the tolerance specified by `tolobj`. The convergence criterion for the objective function is

$$|L^t - L^{t-1}| < \tau_\ell (1 + |L^t|).$$

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

**Example:** `'tolobj', 1e-5`

## **'varformat' - Format for parameter estimate variance-covariance matrix**

'beta' (default) | 'full'

Format for the parameter estimate variance-covariance matrix, `COVB`, specified as the comma-separated pair consisting of 'varformat' and one of the following.

'beta'	Return the variance-covariance matrix for only the regression coefficient estimates, <code>beta</code> .
'full'	Return the variance-covariance matrix for both the regression coefficient estimates, <code>beta</code> , and the variance-covariance matrix estimate, <code>Sigma</code> .

**Example:** 'varformat', 'full'

## **'vartype' - Type of variance-covariance matrix for parameter estimates**

'hessian' (default) | 'fisher'

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of 'vartype' and either 'hessian' or 'fisher'.

- If the value is 'hessian', then `mvregress` uses the Hessian, or observed information, matrix to compute `COVB`.
- If the value is 'fisher', then `mvregress` uses the complete-data Fisher, or expected information, matrix to compute `COVB`.

The 'hessian' method takes into account the increase uncertainties due to missing data, while the 'fisher' method does not.

**Example:** 'vartype', 'fisher'

## Output Arguments

### **beta** - Estimated regression coefficients

column vector | matrix

Estimated regression coefficients, returned as a column vector or matrix.

- If you specify  $X$  as a single  $n$ -by- $K$  design matrix, then `mvregress` returns **beta** as a column vector of length  $K$ . For example, if  $X$  is a 20-by-5 design matrix, then **beta** is a 5-by-1 column vector.
- If you specify  $X$  as a cell array containing one or more  $d$ -by- $K$  design matrices, then `mvregress` returns **beta** as a column vector of length  $K$ . For example, if  $X$  is a cell array containing 2-by-10 design matrices, then **beta** is a 10-by-1 column vector.
- If you specify  $X$  as a single  $n$ -by- $p$  design matrix (not in a cell array), and  $Y$  has dimension  $d > 1$ , then `mvregress` returns **beta** as a  $p$ -by- $d$  matrix. For example, if  $X$  is a 20-by-5 design matrix, and  $Y$  has two dimensions such that  $d = 2$ , then **beta** is a 5-by-2 matrix, and the fitted  $Y$  values are  $X \times \text{beta}$ .

### **Sigma** - Estimated variance-covariance matrix

square matrix

Estimated variance-covariance matrix for the responses in  $Y$ , returned as a  $d$ -by- $d$  square matrix.

---

**Note** The estimated variance-covariance matrix, **Sigma**, is not the sample covariance matrix of the residual matrix, **E**.

---

### **E** - Residuals

matrix

Residuals for the fitted regression model, returned as an  $n$ -by- $d$  matrix.

If `algorithm` has the value 'ecm' or 'cwlsl', then `mvregress` computes the residual values corresponding to missing values in  $Y$  as

the difference between the conditionally imputed values and the fitted values.

---

**Note** If `algorithm` has the value 'mvn', then `mvregress` removes observations with missing response values before estimation.

---

## **CovB - Parameter estimate variance-covariance matrix**

square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If `varformat` has the value 'beta' (default), then `CovB` is the estimated variance-covariance matrix of the coefficient estimates in `beta`.
- If `varformat` has the value 'full', then `CovB` is the estimated variance-covariance matrix of the combined estimates in `beta` and `Sigma`.

## **logL - Loglikelihood objective function value**

scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

## **Examples**

### **Multivariate Regression Model for Panel Data with Different Intercepts**

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.

Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google query data.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));  
[n,d] = size(Y);  
x = flu.WtdILI;
```

The responses in  $Y$  are the nine regional flu estimates. Observations exist for every week over a one-year period, so  $n = 52$ . The dimension of the responses corresponds to the regions, so  $d = 9$ . The predictors in  $x$  are the weekly national flu estimates.

Plot the flu data, grouped by region.

```
figure;  
regions = flu.Properties.VarNames(2:end-1);  
plot(x,Y,'x')  
legend(regions,'Location','NorthWest')
```

# mvregress

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$\text{COV}(\varepsilon_{ij}, \varepsilon_{ij'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are  $K = 10$  regression coefficients to estimate: nine intercept terms and a common slope. The input argument  $X$  should be an  $n$ -element cell array of  $d$ -by- $K$  design matrices.

```
X = cell(n,1);  
for i=1:n  
    X{i} = [eye(d) repmat(x(i),d,1)];
```

```
end
[beta,Sigma] = mvregress(X,Y);
```

beta contains estimates of the  $K$ -dimensional coefficient vector

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta)'$$

Sigma contains estimates of the  $d$ -by- $d$  variance-covariance matrix for the between-region concurrent correlations

$$\begin{pmatrix} \sigma_{11} & \cdots & \sigma_{1,9} \\ \vdots & \ddots & \vdots \\ \sigma_{9,1} & \cdots & \sigma_{9,9} \end{pmatrix}.$$

Plot the fitted regression model.

```
B = [beta(1:d)'; repmat(beta(end),1,d)];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end
legend(regions,'Location','NorthWest');
```

The plot shows that each regression line has a different intercept but the same slope. Upon visual inspection, some regression lines appear to fit the data better than others.

## Multivariate Regression for Panel Data with Different Slopes

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```

Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;

```

The responses in  $Y$  are the nine regional flu estimates. Observations exist for every week over a one-year period, so  $n = 52$ . The dimension of the responses corresponds to the regions, so  $d = 9$ . The predictors in  $x$  are the weekly national flu estimates.

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{ij'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are  $K = 18$  regression coefficients to estimate: nine intercept terms, and nine slope terms.  $X$  is an  $n$ -element cell array of  $d$ -by- $K$  design matrices.

```

X = cell(n,1);
for i=1:n
    X{i} = [eye(d) x(i)*eye(d)];
end
[beta,Sigma] = mvregress(X,Y,'algorithm','cwlsl');

```

$\beta$  contains estimates of the  $K$ -dimensional coefficient vector,

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta_1, \beta_2, \dots, \beta_9)'$$

Plot the fitted regression model.

```

B = [beta(1:d)';beta(d+1:end)'];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

```

# mvregress

```
figure;  
h = plot(x,Y,'x',xx,fits,'-');  
for i = 1:d  
    set(h(d+i),'color',get(h(i),'color'));  
end  
  
regions = flu.Properties.VarNames(2:end-1);  
legend(regions,'Location','NorthWest');
```

The plot shows that each regression line has a different intercept and slope.

## Multivariate Regression With a Single Design Matrix

Fit a multivariate regression model using a single  $n$ -by- $P$  design matrix for all response dimensions.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in  $Y$  are the nine regional flu estimates. Observations exist for every week over a one-year period, so  $n = 52$ . The dimension of the responses corresponds to the regions, so  $d = 9$ . The predictors in  $x$  are the weekly national flu estimates.

Create an  $n$ -by- $P$  design matrix  $X$ . Add a column of ones to include a constant term in the regression.

```
X = [ones(size(x)), x];
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{ij'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are 18 regression coefficients to estimate: nine intercept terms, and nine slope terms.

```
[beta, Sigma, E, CovB, logL] = mvregress(X, Y);
```

`beta` contains estimates of the  $P$ -by- $d$  coefficient matrix. `Sigma` contains estimates of the  $d$ -by- $d$  variance-covariance matrix for the between-region concurrent correlations. `E` is a matrix of the residuals.

## mvregress

---

CovB is the estimated variance-covariance matrix of the regression coefficients. logL is the value of the log likelihood objective function after the last iteration.

Plot the fitted regression model.

```
B = beta;
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x', xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest');
```

The plot shows that each regression line has a different intercept and slope.

## Definitions **Multivariate Normal Regression**

Multivariate normal regression is the regression of a  $d$ -dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated.

The model is

$$\mathbf{y}_i = \mathbf{X}_i\boldsymbol{\beta} + \mathbf{e}_i, \quad i = 1, \dots, n,$$

where

- $\mathbf{y}_i$  is a  $d$ -dimensional vector of responses.
- $\mathbf{X}_i$  is a design matrix of predictor variables.
- $\boldsymbol{\beta}$  is vector or matrix of regression coefficients.
- $\mathbf{e}_i$  is a  $d$ -dimensional vector of error terms, with multivariate normal distribution

$$\mathbf{e}_i \sim MVN_d(\mathbf{0}, \Sigma).$$

## Conditionally Imputed Values

The expectation/conditional maximization ('ecm') and covariance-weighted least squares ('cwlsl') estimation algorithms include imputation of missing response values.

Let  $\tilde{\mathbf{y}}$  denote missing observations. The conditionally imputed values are the expected value of the missing observation given the observed data,  $E(\tilde{\mathbf{y}} | \mathbf{y})$ .

The joint distribution of the missing and observed responses is a multivariate normal distribution,

$$\begin{pmatrix} \tilde{\mathbf{y}} \\ \mathbf{y} \end{pmatrix} \sim MVN \left\{ \begin{pmatrix} \tilde{\mathbf{X}}\boldsymbol{\beta} \\ \mathbf{X}\boldsymbol{\beta} \end{pmatrix}, \begin{pmatrix} \Sigma_{\tilde{\mathbf{y}}} & \Sigma_{\tilde{\mathbf{y}}\mathbf{y}} \\ \Sigma_{\mathbf{y}\tilde{\mathbf{y}}} & \Sigma_{\mathbf{y}} \end{pmatrix} \right\}.$$

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

$$E(\tilde{\mathbf{y}} | \mathbf{y}) = \tilde{\mathbf{X}}\boldsymbol{\beta} + \Sigma_{\tilde{\mathbf{y}}\mathbf{y}}\Sigma_{\mathbf{y}}^{-1}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta}).$$

---

**Note** mvregress only imputes missing response values. Observations with missing values in the design matrix are removed.

---

# mvregresslike

---

**Purpose** Negative log-likelihood for multivariate regression

**Syntax**  
`nlogL = mvregresslike(X,Y,b,SIGMA,alg)`  
`[nlogL,COVB] = mvregresslike(...)`  
`[nlogL,COVB] = mvregresslike(...,type,format)`

**Description** `nlogL = mvregresslike(X,Y,b,SIGMA,alg)` computes the negative log-likelihood `nlogL` for a multivariate regression of the  $d$ -dimensional multivariate observations in the  $n$ -by- $d$  matrix `Y` on the predictor variables in the matrix or cell array `X`, evaluated for the  $p$ -by-1 column vector `b` of coefficient estimates and the  $d$ -by- $d$  matrix `SIGMA` specifying the covariance of a row of `Y`. If  $d = 1$ , `X` can be an  $n$ -by- $p$  design matrix of predictor variables. For any value of  $d$ , `X` can also be a cell array of length  $n$ , with each cell containing a  $d$ -by- $p$  design matrix for one multivariate observation. If all observations have the same  $d$ -by- $p$  design matrix, `X` can be a single cell.

NaN values in `X` or `Y` are taken as missing. Observations with missing values in `X` are ignored. Treatment of missing values in `Y` depends on the algorithm specified by `alg`.

`alg` should match the algorithm used by `mvregress` to obtain the coefficient estimates `b`, and must be one of the following:

- 'ecm' — ECM algorithm
- 'cwlsl' — Least squares conditionally weighted by `SIGMA`
- 'mvm' — Multivariate normal estimates computed after omitting rows with any missing values in `Y`

`[nlogL,COVB] = mvregresslike(...)` also returns an estimated covariance matrix `COVB` of the parameter estimates `b`.

`[nlogL,COVB] = mvregresslike(...,type,format)` specifies the type and format of `COVB`.

`type` is either:

- 'hessian' — To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- 'fisher' — To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.

*format* is either:

- 'beta' — To compute COVB for b only. This is the default.
- 'full' — To compute COVB for both b and SIGMA.

## How To

- “Multivariate Normal Distribution” on page B-86

# mvnrnd

---

**Purpose** Multivariate normal random numbers

**Syntax**  
`R = mvnrnd(MU,SIGMA)`  
`r = mvnrnd(MU,SIGMA,cases)`

**Description** `R = mvnrnd(MU,SIGMA)` returns an  $n$ -by- $d$  matrix `R` of random vectors chosen from the multivariate normal distribution with mean `MU`, and covariance `SIGMA`. `MU` is an  $n$ -by- $d$  matrix, and `mvnrnd` generates each row of `R` using the corresponding row of `mu`. `SIGMA` is a  $d$ -by- $d$  symmetric positive semi-definite matrix, or a  $d$ -by- $d$ -by- $n$  array. If `SIGMA` is an array, `mvnrnd` generates each row of `R` using the corresponding page of `SIGMA`, i.e., `mvnrnd` computes `R(i,:)` using `MU(i,:)` and `SIGMA(:,:,i)`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a 1-by- $d$  vector or a 1-by- $d$ -by- $n$  array, containing just the diagonal. If `MU` is a 1-by- $d$  vector, `mvnrnd` replicates it to match the trailing dimension of `SIGMA`.

`r = mvnrnd(MU,SIGMA,cases)` returns a cases-by- $d$  matrix `R` of random vectors chosen from the multivariate normal distribution with a common 1-by- $d$  mean vector `MU`, and a common  $d$ -by- $d$  covariance matrix `SIGMA`.

**Examples**

```
mu = [2 3];  
SIGMA = [1 1.5; 1.5 3];  
r = mvnrnd(mu,SIGMA,100);  
plot(r(:,1),r(:,2),'+')
```

**See Also**

[mvnpdf](#) | [mvncdf](#) | [normrnd](#)

**How To**

- “Multivariate Normal Distribution” on page B-86

# mvtcdf

---

**Purpose** Multivariate  $t$  cumulative distribution function

**Syntax**

```
y = mvtcdf(X,C,DF)
y = mvtcdf(x1,xu,C,DF)
[y,err] = mvtcdf(...)
[...] = mvntdf(...,options)
```

**Description** `y = mvtcdf(X,C,DF)` returns the cumulative probability of the multivariate  $t$  distribution with correlation parameters **C** and degrees of freedom **DF**, evaluated at each row of **X**. Rows of the  $n$ -by- $d$  matrix **X** correspond to observations or points, and columns correspond to variables or coordinates. **y** is an  $n$ -by-1 vector.

**C** is a symmetric, positive definite,  $d$ -by- $d$  matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtcdf` scales **C** to correlation form. `mvtcdf` does not rescale **X**. **DF** is a scalar, or a vector with  $n$  elements.

The multivariate  $t$  cumulative probability at **X** is defined as the probability that a random vector **T**, distributed as multivariate  $t$ , will fall within the semi-infinite rectangle with upper limits defined by **X**, i.e.,  $\Pr\{T(1) \leq X(1), T(2) \leq X(2), \dots, T(d) \leq X(d)\}$ .

`y = mvtcdf(x1,xu,C,DF)` returns the multivariate  $t$  cumulative probability evaluated over the rectangle with lower and upper limits defined by **x1** and **xu**, respectively.

`[y,err] = mvtcdf(...)` returns an estimate of the error in **y**. For bivariate and trivariate distributions, `mvtcdf` uses adaptive quadrature on a transformation of the  $t$  density, based on methods developed by Genz, as described in the references. The default absolute error tolerance for these cases is  $1e-8$ . For four or more dimensions, `mvtcdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is  $1e-4$ .

`[...] = mvntdf(...,options)` specifies control parameters for the numerical integration used to compute **y**. This argument can be created by a call to `statset`. Choices of `statset` parameters are:

- 'TolFun' — Maximum absolute error tolerance. Default is  $1e-8$  when  $d < 4$ , or  $1e-4$  when  $d \geq 4$ .
- 'MaxFunEvals' — Maximum number of integrand evaluations allowed when  $d \geq 4$ . Default is  $1e7$ . 'MaxFunEvals' is ignored when  $d < 4$ .
- 'Display' — Level of display output. Choices are 'off' (the default), 'iter', and 'final'. 'Display' is ignored when  $d < 4$ .

## Examples

```
C = [1 .4; .4 1]; df = 2;
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
p = mvtcdf(X,C,df);
surf(X1,X2,reshape(p,25,25));
```

**How To**      • “Multivariate  $t$  Distribution” on page B-91

# mvtpdf

---

**Purpose** Multivariate  $t$  probability density function

**Syntax** `y = mvtpdf(X,C,df)`

**Description** `y = mvtpdf(X,C,df)` returns the probability density of the multivariate  $t$  distribution with correlation parameters `C` and degrees of freedom `df`, evaluated at each row of `X`. Rows of the  $n$ -by- $d$  matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `C` is a symmetric, positive definite,  $d$ -by- $d$  matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtpdf` scales `C` to correlation form. `mvtcdf` does not rescale `X`. `df` is a scalar, or a vector with  $n$  elements. `y` is an  $n$ -by-1 vector.

**Examples** Visualize a multivariate  $t$  distribution:

```
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
C = [1 .4; .4 1];
df = 2;
p = mvtpdf(X,C,df);
surf(X1,X2,reshape(p,25,25))
```

**See Also**

[mvtcdf](#) | [mvtrnd](#)

**How To**

- “Multivariate  $t$  Distribution” on page B-91

# mvtrnd

---

**Purpose** Multivariate  $t$  random numbers

**Syntax** `R = mvtrnd(C,df,cases)`  
`R = mvtrnd(C,df)`

**Description** `R = mvtrnd(C,df,cases)` returns a matrix of random numbers chosen from the multivariate  $t$  distribution, where `C` is a correlation matrix. `df` is the degrees of freedom and is either a scalar or is a vector with `cases` elements. If `p` is the number of columns in `C`, then the output `R` has `cases` rows and `p` columns.

Let `t` represent a row of `R`. Then the distribution of `t` is that of a vector having a multivariate normal distribution with mean 0, variance 1, and covariance matrix `C`, divided by an independent chi-square random value having `df` degrees of freedom. The rows of `R` are independent.

`C` must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if `C` is a covariance matrix rather than a correlation matrix), `mvtrnd` rescales `C` to transform it to a correlation matrix before generating the random numbers.

`R = mvtrnd(C,df)` returns a single random number from the multivariate  $t$  distribution.

**Examples**

```
SIGMA = [1 0.8;0.8 1];  
R = mvtrnd(SIGMA,3,100);  
plot(R(:,1),R(:,2),'+')
```

# cvpartition.N property

---

**Purpose**            Number of observations (including observations with missing group values)

**Description**        Number of observations (including observations with missing group values).

<b>Purpose</b>	Naive Bayes classifier	
<b>Description</b>	A NaiveBayes object defines a Naive Bayes classifier. A Naive Bayes classifier assigns a new observation to the most probable class, assuming the features are conditionally independent given the class value.	
<b>Construction</b>	NaiveBayes	Create NaiveBayes object
<b>Methods</b>	disp	Display NaiveBayes classifier object
	display	Display NaiveBayes classifier object
	fit	Create Naive Bayes classifier object by fitting training data
	posterior	Compute posterior probability of each class for test data
	predict	Predict class label for test data
	subsasgn	Subscripted reference for NaiveBayes object
	subsref	Subscripted reference for NaiveBayes object
<b>Properties</b>	CIIsNonEmpty	Flag for non-empty classes
	ClassLevels	Class levels
	Dist	Distribution names
	NClasses	Number of classes

# NaiveBayes

---

NDims	Number of dimensions
Params	Parameter estimates
Prior	Class priors

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

Predict the class label using the Naive Bayes classifier:

```
load fisheriris
```

Use the default Gaussian distribution and a confusion matrix:

```
O1 = NaiveBayes.fit(meas,species);  
C1 = O1.predict(meas);  
cMat1 = confusionmat(species,C1)
```

This returns:

```
cMat1 =  
  
    50     0     0  
     0    47     3  
     0     3    47
```

Use the Gaussian distribution for features 1 and 3 and use the kernel density estimation for features 2 and 4:

```
O2 = NaiveBayes.fit(meas,species,'dist',...  
{'normal','kernel','normal','kernel'});  
C2 = O2.predict(meas);  
cMat2 = confusionmat(species,C2)
```

This returns:

```
cMat2 =
```

50	0	0
0	47	3
0	3	47

# NaiveBayes

---

**Purpose** Create NaiveBayes object

**Description** You cannot create a NaiveBayes classifier by calling the constructor. Use `NaiveBayes.fit` to create a NaiveBayes classifier by fitting the object to training data.

**See Also** `fit`

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Nakagami probability distribution object

**Description** `prob.NakagamiDistribution` is an object consisting of parameters, a model description, and sample data for a Nakagami probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Nakagami')` creates a Nakagami probability distribution object using the default parameter values.

`pd = makedist('Nakagami','mu',mu,'omega',omega)` creates a Nakagami probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Shape parameter**

1 (default) | positive scalar value

Shape parameter for the Nakagami distribution, specified as a positive scalar value.

### **Data Types**

single | double

### **omega - Scale parameter**

1 (default) | positive scalar value

Scale parameter for the Nakagami distribution, specified as a positive scalar value.

### **Data Types**

single | double

# prob.NakagamiDistribution

---

## Properties

### **mu**

Shape parameter for the Nakagami distribution, stored as a positive scalar value.

### **Data Types**

single | double

### **omega**

Scale parameter for the Nakagami distribution, stored as a positive scalar value.

### **Data Types**

single | double

### **DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

### **Data Types**

char

### **InputData**

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

### **Data Types**

single | double

### **IsTruncated**

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated.

If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

# prob.NakagamiDistribution

---

## Data Types

logical

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object

pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Nakagami Distribution

The Nakagami distribution is commonly used in communication theory to model scattered signals that reach a receiver using multiple paths.

The Nakagami distribution uses the following parameters.

Parameter	Description	Support
mu	Shape parameter	$\mu > 0$
omega	Scale parameter	$\omega > 0$

# prob.NakagamiDistribution

---

The probability density function (pdf) is

$$f(x | \mu, \omega) = 2 \left( \frac{\mu^\mu}{\omega} \right) \frac{1}{\Gamma(\mu)} x^{(2\mu-1)} \exp\left\{ \frac{-\mu}{\omega} x^2 \right\} ; \quad x > 0,$$

where  $\Gamma(\cdot)$  is the Gamma function.

## Examples

### Create a Nakagami Distribution Object Using Default Parameters

Create a Nakagami distribution object using the default parameter values.

```
pd = makedist('Nakagami')
```

```
pd =
```

```
NakagamiDistribution
```

```
Nakagami distribution
```

```
mu = 1
```

```
omega = 1
```

### Create a Nakagami Distribution Object Using Specified Parameters

Create a Nakagami distribution object by specifying parameter values.

```
pd = makedist('Nakagami','mu',5,'omega',2)
```

```
pd =
```

```
NakagamiDistribution
```

```
Nakagami distribution
```

```
mu = 5
```

```
omega = 2
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
1.3794
```

## Concepts

- “Nakagami Distribution” on page B-97
- Class Attributes
- Property Attributes

# nancov

---

**Purpose** Covariance ignoring NaN values

**Syntax**  
`Y = nancov(X)`  
`Y = nancov(X1,X2)`  
`Y = nancov(...,1)`  
`Y = nancov(...,'pairwise')`

**Description** `Y = nancov(X)` is the covariance cov of `X`, computed after removing observations with NaN values.

For vectors `x`, `nancov(x)` is the sample variance of the remaining elements, once NaN values are removed. For matrices `X`, `nancov(X)` is the sample covariance of the remaining observations, once observations (rows) containing any NaN values are removed.

`Y = nancov(X1,X2)`, where `X1` and `X2` are matrices with the same number of elements, is equivalent to `nancov(X)`, where `X = [X1(:) X2(:)]`.

`nancov` removes the mean from each variable (column for matrix `X`) before calculating `Y`. If `n` is the number of remaining observations after removing observations with NaN values, `nancov` normalizes `Y` by either  $n - 1$  or  $n$ , depending on whether  $n > 1$  or  $n = 1$ , respectively. To specify normalization by  $n$ , use `Y = nancov(...,1)`.

`Y = nancov(...,'pairwise')` computes `Y(i,j)` using rows with no NaN values in columns `i` or `j`. The result `Y` may not be a positive definite matrix.

**Examples** Generate random data for two variables (columns) with random missing values:

```
X = rand(10,2);
p = randperm(numel(X));
X(p(1:5)) = NaN
X =
    0.8147    0.1576
         NaN         NaN
    0.1270    0.9572
```

```

0.9134      NaN
0.6324      NaN
0.0975     0.1419
0.2785     0.4218
0.5469     0.9157
0.9575     0.7922
0.9649      NaN

```

Establish a correlation between a third variable and the other two variables:

```

X(:,3) = sum(X,2)
X =

```

```

0.8147     0.1576     0.9723
      NaN      NaN      NaN
0.1270     0.9572     1.0842
0.9134      NaN      NaN
0.6324      NaN      NaN
0.0975     0.1419     0.2394
0.2785     0.4218     0.7003
0.5469     0.9157     1.4626
0.9575     0.7922     1.7497
0.9649      NaN      NaN

```

Compute the covariance matrix for the three variables after removing observations (rows) with NaN values:

```

Y = nancov(X)
Y =

```

```

0.1311     0.0096     0.1407
0.0096     0.1388     0.1483
0.1407     0.1483     0.2890

```

## See Also

NaN | cov | var | nanvar

# nanmax

---

**Purpose** Maximum ignoring NaN values

**Syntax**

```
y = nanmax(X)
Y = nanmax(X1,X2)
y = nanmax(X,[],dim)
[y,indices] = nanmax(...)
```

**Description** `y = nanmax(X)` is the maximum max of `X`, computed after removing NaN values.

For vectors `x`, `nanmax(x)` is the maximum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmax(X)` is a row vector of column maxima, once NaN values are removed. For multidimensional arrays `X`, `nanmax` operates along the first nonsingleton dimension.

`Y = nanmax(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmax(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmax(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmax(...)` also returns the row indices of the maximum values for each column in the vector `indices`.

**Examples** Find column maxima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
[y,indices] = nanmax(X)
y =
     4     5    NaN
indices =
     3     2     1
```

**See Also** NaN | max | nanmin

**Purpose** Mean ignoring NaN values

**Syntax**  
`y = nanmean(X)`  
`y = nanmean(X,dim)`

**Description** `y = nanmean(X)` is the mean of `X`, computed after removing NaN values. For vectors `x`, `nanmean(x)` is the mean of the remaining elements, once NaN values are removed. For matrices `X`, `nanmean(X)` is a row vector of column means, once NaN values are removed. For multidimensional arrays `X`, `nanmean` operates along the first nonsingleton dimension. `y = nanmean(X,dim)` takes the mean along dimension `dim` of `X`.

---

**Note** If `X` contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0. Since the mean involves division by 0, its value is NaN. The output NaN is not a mean of NaN values.

---

**Examples** Find column means for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanmean(X)
y =
    3.5000    3.0000    NaN
```

**See Also** NaN | mean | nanmedian

# nanmedian

---

**Purpose** Median ignoring NaN values

**Syntax** `y = nanmedian(X)`  
`y = nanmedian(X,dim)`

**Description** `y = nanmedian(X)` is the median of `X`, computed after removing NaN values.

For vectors `x`, `nanmedian(x)` is the median of the remaining elements, once NaN values are removed. For matrices `X`, `nanmedian(X)` is a row vector of column medians, once NaN values are removed. For multidimensional arrays `X`, `nanmedian` operates along the first nonsingleton dimension.

`y = nanmedian(X,dim)` takes the mean along dimension `dim` of `X`.

**Examples** Find column medians for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanmedian(X)
y =
    3.5000    3.0000    NaN
```

**See Also** `NaN` | `median` | `nanmean`

**Purpose** Minimum ignoring NaN values

**Syntax**

```
y = nanmin(X)
Y = nanmin(X1,X2)
y = nanmin(X,[],dim)
[y,indices] = nanmin(...)
```

**Description** `y = nanmin(X)` is the minimum min of `X`, computed after removing NaN values.

For vectors `x`, `nanmin(x)` is the minimum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmin(X)` is a row vector of column minima, once NaN values are removed. For multidimensional arrays `X`, `nanmin` operates along the first nonsingleton dimension.

`Y = nanmin(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmin(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmin(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmin(...)` also returns the row indices of the minimum values for each column in the vector `indices`.

**Examples** Find column minima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
[y,indices] = nanmin(X)
y =
     3     1    NaN
indices =
     2     1     1
```

**See Also** NaN | min | nanmax

# nanstd

---

**Purpose** Standard deviation ignoring NaN values

**Syntax**  
`y = nanstd(X)`  
`y = nanstd(X,1)`  
`y = nanstd(X,flag,dim)`

**Description** `y = nanstd(X)` is the standard deviation `std` of `X`, computed after removing NaN values.

For vectors `x`, `nanstd(x)` is the sample standard deviation of the remaining elements, once NaN values are removed. For matrices `X`, `nanstd(X)` is a row vector of column sample standard deviations, once NaN values are removed. For multidimensional arrays `X`, `nanstd` operates along the first nonsingleton dimension.

If  $n$  is the number of remaining observations after removing observations with NaN values, `nanstd` normalizes `y` by  $n-1$ . To specify normalization by  $n$ , use `y = nanstd(X,1)`.

`y = nanstd(X,flag,dim)` takes the standard deviation along the dimension `dim` of `X`. The `flag` is 0 or 1 to specify normalization by  $n-1$  or  $n$ , respectively, where  $n$  is the number of remaining observations after removing observations with NaN values.

**Examples** Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanstd(X)
y =
    0.7071    2.8284    NaN
```

**See Also** [NaN](#) | [std](#) | [nanvar](#) | [nanmean](#)

**Purpose** Sum ignoring NaN values

**Syntax**  
`y = nansum(X)`  
`y = nansum(X,dim)`

**Description** `y = nansum(X)` is the sum of `X`, computed after removing NaN values. For vectors `x`, `nansum(x)` is the sum of the remaining elements, once NaN values are removed. For matrices `X`, `nansum(X)` is a row vector of column sums, once NaN values are removed. For multidimensional arrays `X`, `nansum` operates along the first nonsingleton dimension. `y = nansum(X,dim)` takes the sum along dimension `dim` of `X`.

---

**Note** If `X` contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0. The output 0 is not a sum of NaN values.

---

**Examples** Find column sums for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nansum(X)
y =
     7     6     0
```

**See Also** NaN | sum

**Purpose** Variance, ignoring NaN values

**Syntax**

```
y = nanvar(X)
y = nanvar(X,1)
y = nanvar(X,w)
y = nanvar(X,w,dim)
```

**Description** `y = nanvar(X)` is the variance `var` of `X`, computed after removing NaN values.

For vectors `x`, `nanvar(x)` is the sample variance of the remaining elements, once NaN values are removed. For matrices `X`, `nanvar(X)` is a row vector of column sample variances, once NaN values are removed. For multidimensional arrays `X`, `nanvar` operates along the first nonsingleton dimension.

`nancov` removes the mean from each variable (column for matrix `X`) before calculating `Y`. If  $n$  is the number of remaining observations after removing observations with NaN values, `nanvar` normalizes `y` by either  $n - 1$  or  $n$ , depending on whether  $n > 1$  or  $n = 1$ , respectively. To specify normalization by  $n$ , use `y = nanvar(X,1)`.

`y = nanvar(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `nanvar` operates, and its elements must be nonnegative. Elements of `X` corresponding to NaN values of `w` are ignored.

`y = nanvar(X,w,dim)` takes the variance along the dimension `dim` of `X`. Set `w` to `[]` to use the default normalization by  $n - 1$ .

**Examples** Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanvar(X)
```

```
y =  
0.5000 8.0000 NaN
```

[NaN](#) | [var](#) | [nanstd](#) | [nanmean](#)

# nbincdf

---

**Purpose** Negative binomial cumulative distribution function

**Syntax**  
`y = nbincdf(x,R,p)`  
`y = nbincdf(x,R,p, 'upper')`

**Description** `y = nbincdf(x,R,p)` computes the negative binomial cdf at each of the values in `x` using the corresponding number of successes, `R` and probability of success in a single trial, `p`. `x`, `R`, and `p` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `y`. A scalar input for `x`, `R`, or `p` is expanded to a constant array with the same dimensions as the other inputs.

`y = nbincdf(x,R,p, 'upper')` returns the complement of the negative binomial cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The negative binomial cdf is

$$y = F(x | r, p) = \sum_{i=0}^x \binom{r+i-1}{i} p^r q^i I_{(0,1,\dots)}(i)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `p` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

$$\frac{\Gamma(r+i)}{\Gamma(r)\Gamma(i+1)}$$

**Examples**      **Compute Negative Binomial Distribution CDF**

`x = (0:15);`

```
p = nbincdf(x,3,0.5);  
stairs(x,p)
```

**How To**

- “Negative Binomial Distribution” on page B-98

# nbinfit

---

**Purpose** Negative binomial parameter estimates

**Syntax**

```
parmhat = nbinfit(data)
[parmhat,parmci] = nbinfit(data,alpha)
[...] = nbinfit(data,alpha,options)
```

**Description** `parmhat = nbinfit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector `data`.

`[parmhat,parmci] = nbinfit(data,alpha)` returns MLEs and 100(1-alpha) percent confidence intervals. By default, `alpha = 0.05`, which corresponds to 95% confidence intervals.

`[...] = nbinfit(data,alpha,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an `options` structure which you can create using the function `statset`. Enter `statset('nbinfit')` to see the names and default values of the parameters that `nbinfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

---

**Note** The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in `data` is less than its sample mean, `nbinfit` cannot compute MLEs. You should use the `poissfit` function instead.

---

**How To**

- “Negative Binomial Distribution” on page B-98

<b>Purpose</b>	Negative binomial inverse cumulative distribution function
<b>Syntax</b>	$X = \text{nbininv}(Y, R, P)$
<b>Description</b>	<p><math>X = \text{nbininv}(Y, R, P)</math> returns the inverse of the negative binomial cdf with corresponding number of successes, <math>R</math> and probability of success in a single trial, <math>P</math>. Since the binomial distribution is discrete, <code>nbininv</code> returns the least integer <math>X</math> such that the negative binomial cdf evaluated at <math>X</math> equals or exceeds <math>Y</math>. <math>Y</math>, <math>R</math>, and <math>P</math> can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of <math>X</math>. A scalar input for <math>Y</math>, <math>R</math>, or <math>P</math> is expanded to a constant array with the same dimensions as the other inputs.</p> <p>The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability <math>P</math> of success. The number of <i>extra</i> trials you must perform in order to observe a given number <math>R</math> of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, <code>nbininv</code> allows <math>R</math> to be any positive value, including nonintegers.</p>
<b>Examples</b>	<p>How many times would you need to flip a fair coin to have a 99% probability of having observed 10 heads?</p> <pre>flips = nbininv(0.99, 10, 0.5) + 10 flips =     33</pre> <p>Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10.</p>
<b>See Also</b>	<code>icdf</code>   <code>nbincdf</code>   <code>nbinpdf</code>   <code>nbinstat</code>   <code>nbinfit</code>   <code>nbinrnd</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Negative Binomial Distribution” on page B-98</li></ul>

# nbinpdf

---

**Purpose** Negative binomial probability density function

**Syntax** `Y = nbinpdf(X,R,P)`

**Description** `Y = nbinpdf(X,R,P)` returns the negative binomial pdf at each of the values in `X` using the corresponding number of successes, `R` and probability of success in a single trial, `P`. `X`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in `X` are integers.

The negative binomial pdf is

$$y = f(x | r, p) = \binom{r+x-1}{x} p^r q^x I_{(0,1,\dots)}(x)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinpdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)}$$

**Examples**

```
x = (0:10);  
y = nbinpdf(x,3,0.5);  
plot(x,y, '+')  
set(gca, 'Xlim', [-0.5,10.5])
```

**See Also**

**How To**

- “Negative Binomial Distribution” on page B-98

# nbinrnd

---

**Purpose** Negative binomial random numbers

**Syntax**  
RND = nbinrnd(R,P)  
RND = nbinrnd(R,P,m,n,...)  
RND = nbinrnd(R,P,[m,n,...])

**Description** RND = nbinrnd(R,P) is a matrix of random numbers chosen from a negative binomial distribution with corresponding number of successes, R and probability of success in a single trial, P. R and P can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of RND. A scalar input for R or P is expanded to a constant array with the same dimensions as the other input.

RND = nbinrnd(R,P,m,n,...) or RND = nbinrnd(R,P,[m,n,...]) generates an m-by-n-by-... array. The R, P parameters can each be scalars or arrays of the same size as R.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability P of success. The number of *extra* trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, nbinrnd allows R to be any positive value, including nonintegers.

**Examples** Suppose you want to simulate a process that has a defect probability of 0.01. How many units might Quality Assurance inspect before finding three defective items?

```
r = nbinrnd(3,0.01,1,6)+3  
r =  
    496    142    420    396    851    178
```

**See Also** random | nbinpdf | nbincdf | nbininv | nbinstat | nbinfit

**How To** • “Negative Binomial Distribution” on page B-98

**Purpose** Negative binomial mean and variance

**Syntax** `[M,V] = nbinstat(R,P)`

**Description** `[M,V] = nbinstat(R,P)` returns the mean of and variance for the negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters  $r$  and  $p$  is  $rq / p$ , where  $q = 1 - p$ . The variance is  $rq / p^2$ .

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinstat` allows `R` to be any positive value, including nonintegers.

## Examples

```
p = 0.1:0.2:0.9;
r = 1:5;
[R,P] = meshgrid(r,p);
[M,V] = nbinstat(R,P)

## How To

- “Negative Binomial Distribution” on page B-98

**Purpose**

Noncentral  $F$  cumulative distribution function

**Syntax**

```
p = ncfcdf(x,nu1,nu2,delta)
p = ncfcdf(x,nu1,nu2,delta,'upper')
```

**Description**

`p = ncfcdf(x,nu1,nu2,delta)` computes the noncentral  $F$  cdf at each value in `x` using the corresponding numerator degrees of freedom in `nu1`, denominator degrees of freedom in `nu2`, and positive noncentrality parameters in `delta`. `nu1`, `nu2`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu1`, `nu2`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncfcdf(x,nu1,nu2,delta,'upper')` returns the complement of the noncentral  $F$  cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The noncentral  $F$  cdf is

$$F(x | v_1, v_2, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{v_1 \cdot x}{v_2 + v_1 \cdot x} \middle| \frac{v_1}{2} + j, \frac{v_2}{2}\right)$$

where  $I(x | a, b)$  is the incomplete beta function with parameters  $a$  and  $b$ .

**Examples****Compute Noncentral F Distribution cdf**

Compare the noncentral  $F$  cdf with  $\delta = 10$  to the  $F$  cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';
p1 = ncfcdf(x,5,20,10);
p = fcdf(x,5,20);
plot(x,p,'-',x,p1,'-')
```

## How To

• “Noncentral F Distribution” on page B-106

**Purpose** Noncentral  $F$  probability density function

**Syntax**  $Y = \text{ncfpdf}(X, \text{NU1}, \text{NU2}, \text{DELTA})$

**Description**  $Y = \text{ncfpdf}(X, \text{NU1}, \text{NU2}, \text{DELTA})$  computes the noncentral  $F$  pdf at each of the values in  $X$  using the corresponding numerator degrees of freedom in  $\text{NU1}$ , denominator degrees of freedom in  $\text{NU2}$ , and positive noncentrality parameters in  $\text{DELTA}$ .  $X$ ,  $\text{NU1}$ ,  $\text{NU2}$ , and  $\text{DELTA}$  can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of  $Y$ . A scalar input for  $\text{NU1}$ ,  $\text{NU2}$ , or  $\text{DELTA}$  is expanded to a constant array with the same dimensions as the other inputs.

The  $F$  distribution is a special case of the noncentral  $F$  where  $\delta = 0$ . As  $\delta$  increases, the distribution flattens like the plot in the example.

**Examples** Compare the noncentral  $F$  pdf with  $\delta = 10$  to the  $F$  pdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';
p1 = ncfpdf(x,5,20,10);
p = fpdf(x,5,20);
plot(x,p,'-',x,p1,'-')
```

**References** [1] Johnson, N., and S. Kotz. *Distributions in Statistics: Continuous Univariate Distributions-2*. Hoboken, NJ: John Wiley & Sons, Inc., 1970, pp. 189–200.

## **How To**

- “Noncentral F Distribution” on page B-106

**Purpose**

Noncentral  $F$  random numbers

**Syntax**

```
R = ncfrnd(NU1,NU2,DELTA)
R = ncfrnd(NU1,NU2,DELTA,m,n,...)
R = ncfrnd(NU1,NU2,DELTA,[m,n,...])
```

**Description**

`R = ncfrnd(NU1,NU2,DELTA)` returns a matrix of random numbers chosen from the noncentral  $F$  distribution with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant matrix with the same dimensions as the other inputs.

`R = ncfrnd(NU1,NU2,DELTA,m,n,...)` or `R = ncfrnd(NU1,NU2,DELTA,[m,n,...])` generates an `m`-by-`n`-by-... array. The `NU1`, `NU2`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

**Examples**

Compute six random numbers from a noncentral  $F$  distribution with 10 numerator degrees of freedom, 100 denominator degrees of freedom and a noncentrality parameter,  $\delta$ , of 4.0. Compare this to the  $F$  distribution with the same degrees of freedom.

```
r = ncfrnd(10,100,4,1,6)
r =
    2.5995    0.8824    0.8220    1.4485    1.4415    1.4864
```

```
r1 = frnd(10,100,1,6)
r1 =

## **How To**

- “Noncentral F Distribution” on page B-106

**Purpose**

Noncentral  $F$  mean and variance

**Syntax**

$[M, V] = \text{ncfstat}(NU1, NU2, DELTA)$

**Description**

$[M, V] = \text{ncfstat}(NU1, NU2, DELTA)$  returns the mean of and variance for the noncentral  $F$  pdf with corresponding numerator degrees of freedom in  $NU1$ , denominator degrees of freedom in  $NU2$ , and positive noncentrality parameters in  $DELTA$ .  $NU1$ ,  $NU2$ , and  $DELTA$  can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of  $M$  and  $V$ . A scalar input for  $NU1$ ,  $NU2$ , or  $DELTA$  is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral  $F$  distribution with parameters  $\nu_1$ ,  $\nu_2$ , and  $\delta$  is

$$\frac{\nu_2(\delta + \nu_1)}{\nu_1(\nu_2 - 2)}$$

where  $\nu_2 > 2$ .

The variance is

$$2 \left( \frac{\nu_2}{\nu_1} \right)^2 \left[ \frac{(\delta + \nu_1)^2 + (2\delta + \nu_1)(\nu_2 - 2)}{(\nu_2 - 2)^2(\nu_2 - 4)} \right]$$

where  $\nu_2 > 4$ .

**Examples**

```
[m,v]= ncfstat(10,100,4)
m =
    1.4286
v =
    0.4252
```

## How To

- “Noncentral F Distribution” on page B-106

# NaiveBayes.NClasses property

---

**Purpose**

Number of classes

**Description**

The NClasses property specifies the number of classes in the grouping variable used to create the Naive Bayes classifier.

# gmdistribution.NComponents property

---

**Purpose**            Number  $k$  of mixture components

**Description**      The number  $k$  of mixture components.

**Purpose** Noncentral  $t$  cumulative distribution function

**Syntax**

```
p = nctcdf(x,nu,delta)
p = nctcdf(x,nu,delta,'upper')
```

**Description** `p = nctcdf(x,nu,delta)` computes the noncentral  $t$  cdf at each value in `x` using the corresponding degrees of freedom in `nu` and noncentrality parameters in `delta`. `x`, `nu`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = nctcdf(x,nu,delta,'upper')` returns the complement of the noncentral  $t$  cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

### Examples **Compute Noncentral $t$ Distribution cdf**

Compare the noncentral  $t$  cdf with `DELTA = 1` to the  $t$  cdf with the same number of degrees of freedom (10).

```
x = (-5:0.1:5)';
p1 = nctcdf(x,10,1);
p = tcdf(x,10);
plot(x,p,'-',x,p1,':')
```

**How To**

- “Noncentral t Distribution” on page B-108

# nctinv

---

**Purpose** Noncentral  $t$  inverse cumulative distribution function

**Syntax** `X = nctinv(P,NU,DELTA)`

**Description** `X = nctinv(P,NU,DELTA)` returns the inverse of the noncentral  $t$  cdf with `NU` degrees of freedom and noncentrality parameter `DELTA` for the corresponding probabilities in `P`. `P`, `NU`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `NU`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

**Examples**

```
x = nctinv([0.1 0.2],10,1)
x =
    -0.2914    0.1618
```

<b>How To</b>	• “Noncentral $t$ Distribution” on page B-108

# nctstat

---

**Purpose** Noncentral  $t$  mean and variance

**Syntax** `[M,V] = nctstat(NU,DELTA)`

**Description** `[M,V] = nctstat(NU,DELTA)` returns the mean of and variance for the noncentral  $t$  pdf with  $NU$  degrees of freedom and noncentrality parameter  $DELTA$ .  $NU$  and  $DELTA$  can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of  $M$  and  $V$ . A scalar input for  $NU$  or  $DELTA$  is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral  $t$  distribution with parameters  $\nu$  and  $\delta$  is

$$\frac{\delta(\nu/2)^{1/2}\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}$$

where  $\nu > 1$ .

The variance is

$$\frac{\nu}{(\nu-2)}(1+\delta^2) - \frac{\nu}{2}\delta^2 \left[ \frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)} \right]^2$$

where  $\nu > 2$ .

**Examples** `[m,v] = nctstat(10,1)`

`m =`  
`1.0837`

`v =`  
`1.3255`

**How To**

- “Noncentral t Distribution” on page B-108

**Purpose** Noncentral chi-square cumulative distribution function

**Syntax**  
`p = ncx2cdf(x,v,delta)`  
`p = ncx2cdf(x,v,delta,'upper')`

**Description** `p = ncx2cdf(x,v,delta)` computes the noncentral chi-square cdf at each value in `x` using the corresponding degrees of freedom in `v` and positive noncentrality parameters in `delta`. `x`, `v`, and `delta` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `p`. A scalar input for `x`, `v`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncx2cdf(x,v,delta,'upper')` returns the complement of the noncentral chi-square cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

The noncentral chi-square cdf is

$$F(x | v, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr[\chi_{v+2j}^2 \leq x]$$

## Examples **Compute Noncentral Chi-Square cdf**

Compare the noncentral chi-square cdf with `DELTA = 2` to the chi-square cdf with the same number of degrees of freedom (4):

```
x = (0:0.1:10)';  
ncx2 = ncx2cdf(x,4,2);  
chi2 = chi2cdf(x,4);  
  
plot(x,ncx2,'b-','LineWidth',2)
```

```
hold on
plot(x,chi2,'g--','LineWidth',2)
legend('ncx2','chi2','Location','NW')
```

## How To

- “Noncentral Chi-Square Distribution” on page B-104

# ncx2rnd

---

**Purpose** Noncentral chi-square random numbers

**Syntax**  
R = ncx2rnd(V,DELTA)  
R = ncx2rnd(V,DELTA,m,n,...)  
R = ncx2rnd(V,DELTA,[m,n,...])

**Description** R = ncx2rnd(V,DELTA) returns a matrix of random numbers chosen from the noncentral chi-square distribution using the corresponding degrees of freedom in V and positive noncentrality parameters in DELTA. V and DELTA can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of R. A scalar input for V or DELTA is expanded to a constant array with the same dimensions as the other input.

R = ncx2rnd(V,DELTA,m,n,...) or R = ncx2rnd(V,DELTA,[m,n,...]) generates an m-by-n-by-... array. The V, DELTA parameters can each be scalars or arrays of the same size as R.

**Examples**

```
ncx2rnd(4,2,6,3)
ans =
    6.8552    5.9650   11.2961
    5.2631    4.2640    5.9495
    9.1939    6.7162    3.8315

# categorical.ndim

---

**Purpose**            Number of dimensions of categorical array

**Syntax**            `n = ndims(A)`

**Description**        `n = ndims(A)` returns the number of dimensions in the categorical array `A`. The number of dimensions in an array is always greater than or equal to 2. Trailing singleton dimensions are ignored. Put simply, `ndims(A)` is `length(size(A))`.

**See Also**            `size`

# gmdistribution.NDimensions property

---

**Purpose** Dimension  $d$  of multivariate Gaussian distributions

**Description** The dimension  $d$  of the multivariate Gaussian distributions.

# dataset.ndims

---

**Purpose**            Number of dimensions of dataset array

**Syntax**            `n = ndims(A)`

**Description**        `n = ndims(A)` returns the number of dimensions in the dataset A. The number of dimensions in an array is always 2.

**See Also**            `size`

**Purpose** Number of dimensions in matrix

**Syntax** `n = ndims(p)`

**Description** `n = ndims(p)` returns the number of dimensions in the matrix that is created by the syntax `p(:, :)`. Since this is always a 2-D matrix, `n` is always equal to 2.

**See Also** `grandset` | `size`

# NaiveBayes.NDims property

---

**Purpose**            Number of dimensions

**Description**        The NDims property specifies the number of dimensions, which is equal to the number of features in the training data used to create the Naive Bayes classifier.

---

<b>Purpose</b>	Not equal relation for handles
<b>Syntax</b>	<code>h1 ~= h2</code>
<b>Description</b>	<p>Handles are equal if they are handles for the same object and are unequal otherwise.</p> <p><code>h1 ~= h2</code> performs element-wise comparisons between handle arrays <code>h1</code> and <code>h2</code>. <code>h1</code> and <code>h2</code> must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise <code>~=</code> result.</p> <p>If one of <code>h1</code> or <code>h2</code> is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.</p> <p><code>tf = ne(h1, h2)</code> stores the result in a logical array of the same dimensions.</p>

# prob.NegativeBinomialDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Negative binomial distribution object

**Description** prob.NegativeBinomialDistribution is an object consisting of parameters, a model description, and sample data for a negative binomial probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('NegativeBinomial')` creates a negative binomial probability distribution object using the default parameter values.

`pd = makedist('NegativeBinomial', 'R', r, 'p', p)` creates a negative binomial probability distribution object using the specified parameter values.

## Input Arguments

### **r - Number of successes**

1 (default) | positive scalar value

Number of successes for the negative binomial distribution, specified as a positive scalar value.

### **Data Types**

single | double

### **p - Probability of success**

0.5 (default) | positive scalar value in the range (0,1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

### **Data Types**

single | double

## Properties

**r**

Number of successes for the negative binomial distribution, stored as a positive scalar value.

### Data Types

single | double

**p**

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

### Data Types

single | double

### DistributionName

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

### Data Types

char

### InputData

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

### Data Types

single | double

### IsTruncated

# prob.NegativeBinomialDistribution

---

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames`

# prob.NegativeBinomialDistribution

---

array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

### Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object

# prob.NegativeBinomialDistribution

---

median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Negative Binomial Distribution

The negative binomial distribution models the number of failures  $x$  before a specified number of successes is reached in a series of independent, identical trials. This distribution can also model count data, in which case  $r$  does not need to be an integer value.

The negative binomial distribution uses the following parameters.

# prob.NegativeBinomialDistribution

Parameter	Description	Support
R	Number of successes	$r > 0$
p	Probability of success	$0 < p \leq 1$

The probability density function (pdf) when  $r$  is an integer is

$$f(x|r,p) = \binom{r+x-1}{x} p^r q^x \quad ; \quad x = 1, 2, \dots, \infty,$$

where  $q = 1 - p$  and  $\binom{r+x-1}{x}$  is the binomial coefficient.

When  $r$  is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)},$$

where  $\Gamma(\cdot)$  is the Gamma function.

## Examples

### Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')
```

```
pd =
```

```
NegativeBinomialDistribution
```

```
Negative Binomial distribution
```

```
R = 1
```

```
P = 0.5
```

# prob.NegativeBinomialDistribution

---

## Create a Negative Binomial Distribution Object Using Specified Parameters

Create a negative binomial distribution object by specifying the parameter values.

```
pd = makedist('NegativeBinomial','r',5,'p',.1)
```

```
pd =
```

```
    NegativeBinomialDistribution
```

```
    Negative Binomial distribution
```

```
    R =    5
```

```
    P = 0.1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
    45
```

**Purpose** Nearest neighbor search object

**Description** NeighborSearcher is an abstract class used for nearest neighbor search. You cannot create instances of this class directly. Instead, create an instance of a derived class such as ExhaustiveSearcher or KDTreeSearcher either by calling the derived class constructor or by calling the function createns.

**Construction** NeighborSearcher is an abstract class. You cannot create instances of this class directly. You can construct an object in a subclass, such as KDTreeSearcher or ExhaustiveSearcher, either by calling the subclass constructors or by using the createns function.

**Properties** **x**

A matrix used to create the object.

**Distance**

A string specifying a built-in distance metric (applies to both ExhaustiveSearcher and KDTreeSearcher) or a function handle (only applies to ExhaustiveSearcher) that you provide when you create the object. This property is the default distance metric used when you call the knnsearch method to find nearest neighbors for future query points.

**DistParameter**

Specifies the additional parameter for the chosen distance metric. The value is:

- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance. (Applies for both ExhaustiveSearcher and KDTreeSearcher.)
- If 'Distance' is 'mahalanobis': A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance. (Only applies for ExhaustiveSearcher.)

# NeighborSearcher

---

- If 'Distance' is 'seuclidean': A vector representing the scale value of the data when computing the 'seuclidean' distance. (Only applies for ExhaustiveSearcher.)
- Otherwise: Empty.

<b>Purpose</b>	Generate quasi-random point set
<b>Syntax</b>	<code>X = net(p,n)</code>
<b>Description</b>	<p><code>X = net(p,n)</code> returns the first <math>n</math> points <math>X</math> from the point set <math>p</math> of the <code>grandset</code> class. <math>X</math> is <math>n</math>-by-<math>d</math>, where <math>d</math> is the dimension of the point set.</p> <p>Objects <math>p</math> of the <code>@grandset</code> class encapsulate properties of a specified quasi-random sequence. Values of the point set are not generated and stored in memory until <math>p</math> is accessed using <code>net</code> or parenthesis indexing.</p>
<b>Examples</b>	<p>Use <code>haltonset</code> to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:</p> <pre>p = haltonset(3,'Skip',1e3,'Leap',1e2) p =     Halton point set in 3 dimensions (8.918019e+013 points)     Properties:         Skip : 1000         Leap : 100         ScrambleMethod : none</pre> <p>Use <code>scramble</code> to apply reverse-radix scrambling:</p> <pre>p = scramble(p,'RR2') p =     Halton point set in 3 dimensions (8.918019e+013 points)     Properties:         Skip : 1000         Leap : 100         ScrambleMethod : RR2</pre> <p>Use <code>net</code> to generate the first four points:</p> <pre>X0 = net(p,4) X0 =     0.0928    0.6950    0.0029     0.6958    0.2958    0.8269</pre>

```
0.3013    0.6497    0.4141
0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

# CompactClassificationDiscriminant.nLinearCoeffs

---

<b>Purpose</b>	Number of nonzero linear coefficients
<b>Syntax</b>	<code>ncoeffs = nLinearCoeffs(obj)</code> <code>ncoeffs = nLinearCoeffs(obj,delta)</code>
<b>Description</b>	<code>ncoeffs = nLinearCoeffs(obj)</code> returns the number of nonzero linear coefficients in the linear discriminant model <code>obj</code> . <code>ncoeffs = nLinearCoeffs(obj,delta)</code> returns the number of nonzero linear coefficients for threshold parameter <code>delta</code> .
<b>Input Arguments</b>	<b>obj</b> Discriminant analysis classifier, produced using <code>ClassificationDiscriminant.fit</code> . <b>delta</b> Scalar or vector value of the Delta parameter. See “Gamma and Delta” on page 21-2139.
<b>Output Arguments</b>	<b>ncoeffs</b> Nonnegative integer, the number of nonzero coefficients in the discriminant analysis model <code>obj</code> . If you call <code>nLinearCoeffs</code> with a <code>delta</code> argument, <code>ncoeffs</code> is the number of nonzero linear coefficients for threshold parameter <code>delta</code> . If <code>delta</code> is a vector, <code>ncoeffs</code> is a vector with the same number of elements. If <code>obj</code> is a quadratic discriminant model, <code>ncoeffs</code> is the number of predictors in <code>obj</code> .
<b>Definitions</b>	<b>Gamma and Delta</b> Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, $\gamma$ and $\delta$ , that control regularization as follows. <code>cvshrink</code> helps you select appropriate values of the parameters.

# Compact Classification Discriminant.nLinear Coeffs

---

Let  $\Sigma$  represent the covariance matrix of the data  $X$ , and let  $\hat{X}$  be the centered data (the data  $X$  minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T * \hat{X}).$$

The regularized covariance matrix  $\tilde{\Sigma}$  is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever  $\gamma \geq \text{MinGamma}$ ,  $\tilde{\Sigma}$  is nonsingular.

Let  $\mu_k$  be the mean vector for those elements of  $X$  in class  $k$ , and let  $\mu_0$  be the global mean vector (the mean of the rows of  $X$ ). Let  $C$  be the correlation matrix of the data  $X$ , and let  $\tilde{C}$  be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where  $I$  is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point  $x$  is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = [(x - \mu_0)^T D^{-1/2}] [\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)].$$

The parameter  $\delta$  enters into this equation as a threshold on the final term in square brackets. Each component of the vector

$[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)]$  is set to zero if it is smaller in magnitude than the threshold  $\delta$ . Therefore, for class  $k$ , if component  $j$  is thresholded to zero, component  $j$  of  $x$  does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When  $\delta \geq \text{DeltaPredictor}(i)$ , all classes  $k$  have

$$|\tilde{C}^{-1}D^{-1/2}(\mu_k - \mu_0)| \leq \delta.$$

Therefore, when  $\delta \geq \text{DeltaPredictor}(i)$ , the regularized classifier does not use predictor  $i$ .

## Examples

### Find the Number of Nonzero Coefficients in a Discriminant Analysis Classifier

Find the number of nonzero coefficients in a discriminant analysis classifier for various `Delta` values.

Create a discriminant analysis classifier from the `fishseriris` data.

```
load fisheriris
obj = ClassificationDiscriminant.fit(meas,species);
```

Find the number of nonzero coefficients in `obj`.

```
ncoeffs = nLinearCoeffs(obj)
```

```
ncoeffs =
```

```
4
```

Find the number of nonzero coefficients for `delta = 1, 2, 4, and 8`.

```
delta = [1 2 4 8];
ncoeffs = nLinearCoeffs(obj,delta)
```

```
ncoeffs =
```

```
4
```

```
4
```

```
3
```

```
0
```

The `DeltaPredictor` property gives the values of `delta` where the number of nonzero coefficients changes.

# CompactClassificationDiscriminant.nLinearCoeffs

---

```
ncoeffs2 = nLinearCoeffs(obj,obj.DeltaPredictor)
```

```
ncoeffs2 =
```

```
4
```

```
3
```

```
1
```

```
2
```

## Concepts

- “Discriminant Analysis” on page 15-3

**Purpose**

Nonlinear regression

**Syntax**

```
beta = nlinfit(X,Y,modelfun,beta0)
beta = nlinfit(X,Y,modelfun,beta0,options)
beta = nlinfit(___,Name,Value)
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(___)
```

**Description**

`beta = nlinfit(X,Y,modelfun,beta0)` returns a vector of estimated coefficients for the nonlinear regression of the responses in `Y` on the predictors in `X` using the model specified by `modelfun`. The coefficients are estimated using iterative least squares estimation, with initial values specified by `beta0`.

`beta = nlinfit(X,Y,modelfun,beta0,options)` fits the nonlinear regression using the algorithm control parameters in the structure `options`. You can return any of the output arguments in the previous syntaxes.

`beta = nlinfit(___,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify observation weights or a nonconstant error model. You can use any of the input arguments in the previous syntaxes.

`[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(___)` additionally returns the residuals, `R`, the Jacobian of `modelfun`, `J`, the estimated variance-covariance matrix for the estimated coefficients, `CovB`, an estimate of the variance of the error term, `MSE`, and a structure containing details about the error model, `ErrorModelInfo`.

**Input Arguments****X - Predictor variables**

matrix

Predictor variables for the nonlinear regression function, specified as a matrix. Typically, `X` is a design matrix of predictor (independent

variable) values, with one row for each value in Y, and one column for each coefficient. However, X can be any array that `modelfun` can accept.

### Data Types

`single` | `double`

### Y - Response values

vector

Response values (dependent variable) for fitting the nonlinear regression function, specified as a vector with the same number of rows as X.

### Data Types

`single` | `double`

### modelfun - Nonlinear regression model function

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array X—in that order—and return a vector of fitted response values.

For example, to specify the hougen nonlinear regression function, use the function handle `@hougen`.

### Data Types

function\_handle

### beta0 - Initial coefficient values

vector

Initial coefficient values for the least squares estimation algorithm, specified as a vector.

---

**Note** Poor starting values can lead to a solution with large residual error.

---

## Data Types

single | double

## options - Estimation algorithm options

structure created using `statset`

Estimation algorithm options, specified as a structure you create using `statset`. The following `statset` parameters are applicable to `nlinfit`.

## DerivStep - Relative difference for finite difference gradient

$\text{eps}^{(1/3)}$  (default) | positive scalar value | vector

Relative difference for the finite difference gradient calculation, specified as a positive scalar value, or a vector the same size as `beta`. Use a vector to specify a different relative difference for each coefficient.

## Display - Level of output display

'off' (default) | 'iter' | 'final'

Level of output display during estimation, specified as one of 'off', 'iter', or 'final'. If you specify 'iter', output is displayed at each iteration. If you specify 'final', output is displayed after the final iteration.

## FunValCheck - Indicator for whether to check for invalid values

'on' (default) | 'off'

Indicator for whether to check for invalid values such as NaN or Inf from the objective function, specified as 'on' or 'off'.

## MaxIter - Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as a positive integer. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

## RobustWgtFun - Weight function

string | function handle | []

Weight function for robust fitting, specified as a valid string or function handle.

**Note** RobustWgtFun must have value [] when you use observation weights, W.

The following table describes the possible string values. Let  $r$  denote normalized residuals and  $w$  denote robust weights. The indicator function  $I[x]$  is equal to 1 if the expression  $x$  is true, and 0 otherwise.

Weight Function	Equation	Default Tuning Constant
' ' (default)	No robust fitting	—
'andrews'	$w = I[ r  < \pi] \times \sin(r) / r$	1.339
'bisquare'	$w = I[ r  < 1] \times (1 - r^2)^2$	4.685
'cauchy'	$w = \frac{1}{(1 + r^2)}$	2.385
'fair'	$w = \frac{1}{(1 +  r )}$	1.400

Weight Function	Equation	Default Tuning Constant
'huber'	$w = \frac{1}{\max(1,  r )}$	1.345
'logistic'	$w = \frac{\tanh(r)}{r}$	1.205
'talwar'	$w = I[ r  < 1]$	2.795
'welsch'	$w = \exp\{-r^2\}$	2.985

You can alternatively specify a function handle that accepts a vector of normalized residuals as input, and returns a vector of robust weights as output. If you use a function handle, you must provide a `Tune` constant.

### **Tune - Tuning constant**

positive scalar value

Tuning constant for robust fitting, specified as a positive scalar value. The tuning constant is used to normalize residuals before applying a robust weight function. The default tuning constant depends on the function specified by `RobustWgtFun`.

If you use a function handle to specify `RobustWgtFun`, then you must specify a value for `Tune`.

### **TolFun - Termination tolerance on residual sum of squares**

1e-8 (default) | positive scalar value

Termination tolerance for the residual sum of squares, specified as a positive scalar value. Iterations continue until estimates are within the

convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

### **TolX - Termination tolerance on estimated coefficients**

1e-8 (default) | positive scalar value

Termination tolerance on the estimated coefficients, `beta`, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

### **Robust - Indicator for robust fitting**

'off' (default) | 'on'

Indicator for robust fitting, specified as 'off' or 'on'.

---

**Note** Robust will be removed in a future software release. Use `RobustWgtFun` for robust fitting.

---

### **WgtFun - Weight function for robust fitting**

string | function handle

Weight function for robust fitting, specified as a string indicating a weight function, or a function handle. `WgtFun` is valid only when `Robust` has value 'on'.

---

**Note** `WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

---

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'ErrorModel', 'proportional', 'ErrorParameters', 0.5` specifies a proportional error model, with initial value 0.5 for the error parameter estimation

### 'ErrorModel' - Form of error term

`'constant'` (default) | `'proportional'` | `'combined'`

Form of the error term, specified as the comma-separated pair consisting of `'ErrorModel'` and one of the following strings indicating the error model. Each model defines the error using a standard mean-zero and unit-variance variable  $e$  in combination with independent components: the function value  $f$ , and one or two parameters  $a$  and  $b$ .

<code>'constant'</code> (default)	$y = f + ae$
<code>'proportional'</code>	$y = f + bfe$
<code>'combined'</code>	$y = f + (a + b f )e$

The only allowed error model when using `Weights` is `'constant'`.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

---

### 'ErrorParameters' - Initial estimates for error model parameters

1 or `[1, 1]` (default) | scalar value | two-element vector

Initial estimates for the error model parameters in the chosen `ErrorModel`, specified as the comma-separated pair consisting of `'ErrorParameters'` and a scalar value or two-element vector.

Error Model	Parameters	Default Values
'constant'	$a$	1
'proportional'	$b$	1
'combined'	$a, b$	[1,1]

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for  $a$  and the starting value 2 for  $b$  as follows.

**Example:** 'ErrorParameters', [1,2]

You can only use the 'constant' error model when using **Weights**.

---

**Note** options.RobustWgtFun must have value [] when using an error model other than 'constant'.

---

## Data Types

double | single

## 'Weights' - Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of real positive weights or a function handle. You can use observation weights to down-weight the observations that you want to have less influence on the fitted model.

- If  $W$  is a vector, then it must be the same size as  $Y$ .
- If  $W$  is a function handle, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

---

**Note** options.RobustWgtFun must have value [] when you use observation weights.

---

## Output Arguments

### Data Types

double | single | function\_handle

### beta - Estimated regression coefficients

vector

Estimated regression coefficients, returned as a vector. The number of elements in `beta` equals the number of elements in `beta0`.

Let  $f(X_i, \mathbf{b})$  denote the nonlinear function specified by `modelfun`, where  $\mathbf{x}_i$  are the predictors for observation  $i$ ,  $i = 1, \dots, N$ , and  $\mathbf{b}$  are the regression coefficients. The vector of coefficients returned in `beta` minimizes the weighted least squares equation,

$$\sum_{i=1}^N w_i [y_i - f(\mathbf{x}_i, \mathbf{b})]^2.$$

For unweighted nonlinear regression, all of the weight terms are equal to 1.

### R - Residuals

vector

Residuals for the fitted model, returned as a vector.

- If you specify observation weights using the name-value pair argument `Weights`, then `R` contains weighted residuals.
- If you specify an error model other than 'constant' using the name-value pair argument `ErrorModel`, then you can no longer interpret `R` as model fit residuals.

### J - Jacobian

matrix

Jacobian of the nonlinear regression model, `modelfun`, returned as an  $N$ -by- $p$  matrix, where  $N$  is the number of observations and  $p$  is the number of estimated coefficients.

- If you specify observation weights using the name-value pair argument `Weights`, then `J` is the weighted model function Jacobian.
- If you specify an error model other than 'constant' using the name-value pair argument `ErrorModel`, then you can no longer interpret `J` as the model function Jacobian.

## **CovB - Estimated variance-covariance matrix**

matrix

Estimated variance-covariance matrix for the fitted coefficients, `beta`, returned as a  $p$ -by- $p$  matrix, where  $p$  is the number of estimated coefficients. If the model Jacobian, `J`, has full column rank, then  $\text{CovB} = \text{inv}(J' * J) * \text{MSE}$ , where `MSE` is the mean squared error.

## **MSE - Mean squared error**

scalar value

Mean squared error (MSE) of the fitted model, returned as a scalar value. MSE is an estimate of the variance of the error term. If the model Jacobian, `J`, has full column rank, then  $\text{MSE} = (R' * R) / (N - p)$ , where  $N$  is the number of observations, and  $p$  is the number of estimated coefficients.

## **ErrorModelInfo - Information about error model fit**

structure

Information about the error model fit, returned as a structure with the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an $N$ -by- $p$ matrix, <code>X</code> , and returns an $N$ -by-1 vector of error variances using the estimated error model

MSE	Mean squared error
ScheffeSimPred	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
WeightFunction	Logical with value true if you used a custom weight function previously in nlinfit
FixedWeights	Logical with value true if you used fixed weights previously in nlinfit
RobustWeightFunction	Logical with value true if you used robust fitting previously in

## Examples

### Nonlinear Regression Model Using Default Options

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
beta = nlinfit(X,y,@hougen,beta0)
```

```
beta =  
  
    1.2526  
    0.0628  
    0.0400  
    0.1124  
    1.1914
```

## Nonlinear Regression Using Robust Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.1.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options.

```
beta0 = [2;2;2];  
beta = nlinfit(x,y,modelfun,beta0,opts)
```

```
beta =  
  
    1.0041  
    3.0997  
    2.1483
```

## Nonlinear Regression Using Observation Weights

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;
```

```
beta0 = S.beta;
```

Specify a vector of known observation weights.

```
W = [8 2 1 6 12 9 12 10 10 12 2 10 8]';
```

Fit the Hougen-Watson model to the rate data using the specified observation weights.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',W);  
beta
```

```
beta =  
  
    2.2068  
    0.1077  
    0.0766  
    0.1818  
    0.6516
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))
```

```
ans =  
  
    2.5721  
    0.1251  
    0.0950

## **Nonlinear Regression Using Weights Function Handle**

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;
```

```
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);  
beta
```

```
beta =  
  
    0.8308  
    0.0409  
    0.0251  
    0.0801  
    1.8261
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))  
  
ans =  
  
    0.5822  
    0.0297  
    0.0197  
    0.0578  
    1.2810
```

## **Nonlinear Regression Using Nonconstant Error Model**

Load sample data.

```
S = load('reaction');
```

```
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error model.

```
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(X,y,@hougen,beta0,'ErrorModelInfo',beta)
```

```
beta =
```

```
    1.2526
    0.0628
    0.0400
    0.1124
    1.1914
```

Display the error model information.

```
ErrorModelInfo
```

```
ErrorModelInfo =
```

```
    ErrorModel: 'combined'
    ErrorParameters: [0.1517 5.6783e-08]
    ErrorVariance: @(x)mse*(errorparam(1)+errorparam(2)*abs(mod
    MSE: 1.6245
    ScheffeSimPred: 6
    WeightFunction: 0
    FixedWeights: 0
    RobustWeightFunction: 0
```

## Tips

- To produce error estimates on predictions, use the optional output arguments R, J, CovB, or MSE as inputs to `nlpredci`.
- To produce error estimates on the estimated coefficients, beta, use the optional output arguments R, J, CovB, or MSE as inputs to `nlparci`.

- If you use the robust fitting option, `RobustWgtFun`, you must use `CovB`—and might need `MSE`—as inputs to `nlpredci` or `nlparci` to ensure that the confidence intervals take the robust fit properly into account.

## Algorithms

- `nlinfit` treats NaN values in `Y` or `modelfun(beta0,X)` as missing data, and ignores the corresponding observations.
- For nonrobust estimation, `nlinfit` uses the Levenberg-Marquardt nonlinear least squares algorithm [1].
- For robust estimation, `nlinfit` uses an iterative reweighted least squares algorithm ([2], [3]). At each iteration, the robust weights are recalculated based on each observation's residual from the previous iteration. These weights downweight outliers, so that their influence on the fit is decreased. Iterations continue until the weights converge.
- When you specify a function handle for observation weights, the weights depend on the fitted model. In this case, `nlinfit` uses an iterative generalized least squares algorithm to fit the nonlinear regression model.

## Definitions

### Weighted Residuals

A *weighted residual* is a residual multiplied by the square root of the corresponding observation weight.

Given estimated regression coefficients,  $\mathbf{b}$ , the residual for observation  $i$  is

$$r_i = y_i - f(\mathbf{x}_i, \mathbf{b}),$$

where  $y_i$  is the observed response and  $f(\mathbf{x}_i, \mathbf{b})$  is the fitted response at predictors  $\mathbf{x}_i$ .

When you fit a weighted nonlinear regression with weights  $w_i$ ,  $i = 1, \dots, N$ , `nlinfit` returns the weighted residuals,

$$r_i^* = \sqrt{w_i} (y_i - f(\mathbf{x}_i, \mathbf{b})).$$

## Weighted Model Function Jacobian

The *weighted model function Jacobian* is the nonlinear model Jacobian multiplied by the square root of the observation weight matrix.

Given estimated regression coefficients,  $\mathbf{b}$ , the estimated model Jacobian,  $\mathbf{J}$ , for the nonlinear function  $f(\mathbf{x}_i, \mathbf{b})$  has elements

$$\mathbf{J}_{ij} = \frac{\partial f(\mathbf{x}_i, \mathbf{b})}{\partial b_j},$$

where  $b_j$  is the  $j$ th element of  $\mathbf{b}$ .

When you fit a weighted nonlinear regression with diagonal weights matrix  $\mathbf{W}$ , nlinfit returns the weighted Jacobian matrix,

$$\mathbf{J}^* = \mathbf{W}^{1/2}\mathbf{J}.$$

## **Concepts**

- “Nonlinear Regression” on page 11-2

---

<b>Purpose</b>	Interactive nonlinear regression
<b>Syntax</b>	<pre>nlintool(X,y,fun,beta0) nlintool(X,y,fun,beta0,alpha) nlintool(X,y,fun,beta0,alpha,'xname','yname')</pre>
<b>Description</b>	<p><code>nlintool(X,y,fun,beta0)</code> is a graphical user interface to the <code>nlinfit</code> function, and uses the same input arguments. The interface displays plots of the fitted response against each predictor, with the other predictors held fixed. The fixed values are in the text boxes below each predictor axis. Change the fixed values by typing in a new value or by dragging the vertical lines in the plots to new positions. When you change the value of a predictor, all plots update to display the model at the new point in predictor space. Dashed red curves show 95% simultaneous confidence bands for the function.</p> <p><code>nlintool(X,y,fun,beta0,alpha)</code> shows <math>100(1-\alpha)\%</math> confidence bands. These are simultaneous confidence bounds for the function value. Using the <b>Bounds</b> menu you can switch between simultaneous and non-simultaneous bounds, and between bounds on the function and bounds for predicting a new observation.</p> <p><code>nlintool(X,y,fun,beta0,alpha,'xname','yname')</code> labels the plots using the string matrix <code>'xname'</code> for the predictors and the string <code>'yname'</code> for the response.</p>
<b>Examples</b>	<p>The data in <code>reaction.mat</code> are partial pressures of three chemical reactants and the corresponding reaction rates. The function <code>hougen</code> implements the nonlinear Hougen-Watson model for reaction rates. The following fits the model to the data:</p> <pre>load reaction nlintool(reactants,rate,@hougen,beta,0.01,xn,yn)</pre>

# nlintool

**See Also** [nlinfit](#) | [polytool](#) | [rstool](#)

**Purpose**

Nonlinear mixed-effects estimation

**Syntax**

```
beta = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',
    value)
```

**Description**

`beta = nlmefit(X,y,group,V,fun,beta0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in `beta`. By default, `nlmefit` fits a model in which each parameter is the sum of a fixed and a random effect, and the random effects are uncorrelated (their covariance matrix is diagonal).

`X` is an  $n$ -by- $h$  matrix of  $n$  observations on  $h$  predictors.

`y` is an  $n$ -by-1 vector of responses.

`group` is a grouping variable indicating  $m$  groups in the observations. `group` is a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings. For more information on grouping variables, see “Grouping Variables” on page 2-51.

`V` is an  $m$ -by- $g$  matrix or cell array of  $g$  group-specific predictors. These are predictors that take the same value for all observations in a group. The rows of `V` are assigned to groups using `grp2idx`, according to the order specified by `grp2idx(group)`. Use a cell array for `V` if group predictors vary in size across groups. Use `[]` for `V` if there are no group-specific predictors.

`fun` is a handle to a function that accepts predictor values and model parameters and returns fitted values. `fun` has the form

```
yfit = modelfun(PHI,XFUN,VFUN)
```

The arguments are:

- `PHI` — A 1-by- $p$  vector of model parameters.

- XFUN — A  $k$ -by- $h$  array of predictors, where:
  - $k = 1$  if XFUN is a single row of X.
  - $k = n_i$  if XFUN contains the rows of X for a single group of size  $n_i$ .
  - $k = n$  if XFUN contains all rows of X.
- VFUN — Group-specific predictors given by one of:
  - A 1-by- $g$  vector corresponding to a single group and a single row of V.
  - An  $n$ -by- $g$  array, where the  $j$ th row is  $V(I,:)$  if the  $j$ th observation is in group I.

If V is empty, nlmefit calls modelfun with only two inputs.

- yfit — A  $k$ -by-1 vector of fitted values

When either PHI or VFUN contains a single row, it corresponds to all rows in the other two input arguments.

---

**Note** If modelfun can compute yfit for more than one vector of model parameters per call, use the 'Vectorization' parameter (described later) for improved performance.

---

beta0 is a  $q$ -by-1 vector with initial estimates for  $q$  fixed effects. By default,  $q$  is the number of model parameters  $p$ .

nlmefit fits the model by maximizing an approximation to the marginal likelihood with random effects integrated out, assuming that:

- Random effects are multivariate normally distributed and independent between groups.
- Observation errors are independent, identically normally distributed, and independent of the random effects.

`[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)` also returns `PSI`, an  $r$ -by- $r$  estimated covariance matrix for the random effects. By default,  $r$  is equal to the number of model parameters  $p$ .

`[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)` also returns `stats`, a structure with fields:

- `dfe` — The error degrees of freedom for the model
- `logl` — The maximized loglikelihood for the fitted model
- `rmse` — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion, calculated as  $\text{aic} = -2 * \text{logl} + 2 * \text{numParam}$ , where `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model, and `logl` is a field in the `stats` structure
- `bic` — The Bayesian information criterion, calculated as  $\text{bic} = -2 * \text{logl} + \log(M) * \text{numParam}$ 
  - `M` is the number of groups.
  - `numParam` and `logl` are defined as in `aic`.Note that some literature suggests that the computation of `bic` should be ,  $\text{bic} = -2 * \text{logl} + \log(N) * \text{numParam}$ , where `N` is the number of observations.
- `covb` — The estimated covariance matrix of the parameter estimates
- `sebeta` — The standard errors for `beta`
- `ires` — The population residuals ( $y - y_{\text{population}}$ ), where `y_population` is the individual predicted values
- `pres` — The population residuals ( $y - y_{\text{population}}$ ), where `y_population` is the population predicted values
- `iwres` — The individual weighted residuals

- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)` also returns `B`, an  $r$ -by- $m$  matrix of estimated random effects for the  $m$  groups. By default,  $r$  is equal to the number of model parameters  $p$ .

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)` specifies one or more optional parameter name/value pairs. Specify *Name* inside single quotes.

Use the following parameters to fit a model different from the default. (The default model is obtained by setting both `FEConstDesign` and `REConstDesign` to `eye(p)`, or by setting both `FEPARAMSSelect` and `REPARAMSSelect` to `1:p`.) Use at most one parameter with an 'FE' prefix and one parameter with an 'RE' prefix. The `nlmefit` function requires you to specify at least one fixed effect and one random effect.

Parameter	Value
<code>FEPARAMSSelect</code>	A vector specifying which elements of the parameter vector <code>PHI</code> include a fixed effect, given as a numeric vector of indices from 1 to $p$ or as a 1-by- $p$ logical vector. If $q$ is the specified number of elements, then the model includes $q$ fixed effects.
<code>FEConstDesign</code>	A $p$ -by- $q$ design matrix <code>ADESIGN</code> , where <code>ADESIGN*beta</code> are the fixed components of the $p$ elements of <code>PHI</code> .
<code>FEGroupDesign</code>	A $p$ -by- $q$ -by- $m$ array specifying a different $p$ -by- $q$ fixed-effects design matrix for each of the $m$ groups.
<code>FEObsDesign</code>	A $p$ -by- $q$ -by- $n$ array specifying a different $p$ -by- $q$ fixed-effects design matrix for each of the $n$ observations.

Parameter	Value
REParamsSelect	A vector specifying which elements of the parameter vector PHI include a random effect, given as a numeric vector of indices from 1 to $p$ or as a 1-by- $p$ logical vector. The model includes $r$ random effects, where $r$ is the specified number of elements.
REConstDesign	A $p$ -by- $r$ design matrix BDESIGN, where BDESIGN*B are the random components of the $p$ elements of PHI.
REGroupDesign	A $p$ -by- $r$ -by- $m$ array specifying a different $p$ -by- $r$ random-effects design matrix for each of $m$ groups.
REObsDesign	A $p$ -by- $r$ -by- $n$ array specifying a different $p$ -by- $r$ random-effects design matrix for each of $n$ observations.

Use the following parameters to control the iterative algorithm for maximizing the likelihood:

Parameter	Value
RefineBeta0	Determines whether nlmefit makes an initial refinement of beta0 by first fitting modelfun without random effects and replacing beta0 with beta. Choices are 'on' and 'off'. The default value is 'on'.
ErrorModel	A string specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable $e$ , the function value $f$ , and one or two parameters $a$ and $b$ . Choices are: <ul style="list-style-type: none"> <li>'constant': <math>y = f + a*e</math></li> </ul>

Parameter	Value
	<ul style="list-style-type: none"> <li>• 'proportional': <math>y = f + b \cdot f^a \cdot e</math></li> <li>• 'combined': <math>y = f + (a + b \cdot f)^a \cdot e</math></li> <li>• 'exponential': <math>y = f \cdot \exp(a \cdot e)</math>, or equivalently <math>\log(y) = \log(f) + a \cdot e</math></li> </ul> <p>If this parameter is given, the output <code>stats.errorparam</code> field has the value</p> <ul style="list-style-type: none"> <li>• <math>a</math> for 'constant' and 'exponential'</li> <li>• <math>b</math> for 'proportional'</li> <li>• <math>[a \ b]</math> for 'combined'</li> </ul>
ApproximationType	<p>The method used to approximate the likelihood of the model. Choices are:</p> <ul style="list-style-type: none"> <li>• 'LME' — Use the likelihood for the linear mixed-effects model at the current conditional estimates of <code>beta</code> and <code>B</code>. This is the default.</li> <li>• 'RELME' — Use the restricted likelihood for the linear mixed-effects model at the current conditional estimates of <code>beta</code> and <code>B</code>.</li> <li>• 'FO' — First-order Laplacian approximation without random effects.</li> <li>• 'FOCE' — First-order Laplacian approximation at the conditional estimates of <code>B</code>.</li> </ul>

Parameter	Value
Vectorization	<p data-bbox="805 319 1277 409">Indicates acceptable sizes for the PHI, XFUN, and VFUN input arguments to <code>modelfun</code>. Choices are:</p> <ul data-bbox="805 447 1332 1407" style="list-style-type: none"><li data-bbox="805 447 1332 795">• 'SinglePhi' — <code>modelfun</code> can only accept a single set of model parameters at a time, so PHI must be a single row vector in each call. <code>nlmefit</code> calls <code>modelfun</code> in a loop, if necessary, with a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. This is the default.</li><li data-bbox="805 815 1332 1072">• 'SingleGroup' — <code>modelfun</code> can only accept inputs corresponding to a single group in the data, so XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group or a matrix with one row for each observation. VFUN is a single row.</li><li data-bbox="805 1093 1332 1407">• 'Full' — <code>modelfun</code> can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN or a matrix with rows corresponding to rows in XFUN. This option can improve performance by reducing the number of calls to <code>modelfun</code>, but may require <code>modelfun</code> to perform singleton expansion on PHI or V.</li></ul>

Parameter	Value
CovParameterization	Specifies the parameterization used internally for the scaled covariance matrix. Choices are 'chol' for the Cholesky factorization or 'logm' the matrix logarithm. The default is 'logm'.
CovPattern	<p>Specifies an <math>r</math>-by-<math>r</math> logical or numeric matrix <math>P</math> that defines the pattern of the random-effects covariance matrix <math>\Psi</math>. <code>nlmefit</code> estimates the variances along the diagonal of <math>\Psi</math> and the covariances specified by nonzeros in the off-diagonal elements of <math>P</math>. Covariances corresponding to zero off-diagonal elements in <math>P</math> are constrained to be zero. If <math>P</math> does not specify a row-column permutation of a block diagonal matrix, <code>nlmefit</code> adds nonzero elements to <math>P</math> as needed. The default value of <math>P</math> is <math>\text{eye}(r)</math>, corresponding to uncorrelated random effects.</p> <p>Alternatively, <math>P</math> may be a 1-by-<math>r</math> vector containing values in <math>1:r</math>, with equal values specifying groups of random effects. In this case, <code>nlmefit</code> estimates covariances only within groups, and constrains covariances across groups to be zero.</p>

Parameter	Value
ParamTransform	<p>A vector of <math>p</math>-values specifying a transformation function <math>f()</math> for each of the <math>P</math> parameters: <math>XB = ADESIGN*BETA + BDESIGN*B</math> <math>PHI = f(XB)</math>. Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of <math>PHI</math>:</p> <ul style="list-style-type: none"> <li>• 0: <math>PHI = XB</math> (default for all parameters)</li> <li>• 1: <math>\log(PHI) = XB</math></li> <li>• 2: <math>\text{probit}(PHI) = XB</math></li> <li>• 3: <math>\text{logit}(PHI) = XB</math></li> </ul>
Options	<p>A structure of the form returned by <code>statset</code>. <code>nlmefit</code> uses the following <code>statset</code> parameters:</p> <ul style="list-style-type: none"> <li>• 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters <math>p</math>. The default is <math>\text{eps}^{(1/3)}</math>.</li> <li>• 'Display' — Level of iterative display during estimation. Choices are: <ul style="list-style-type: none"> <li>▪ 'off' (default) — Displays no information</li> <li>▪ 'final' — Displays information after the final iteration</li> <li>▪ 'iter' — Displays information at each iteration</li> </ul> </li> <li>• 'FunValCheck' — Check for invalid values, such as NaN or Inf, from</li> </ul>

Parameter	Value
	<p>modelfun. Choices are 'on' and 'off'. The default is 'on'.</p> <ul style="list-style-type: none"> <li>• 'MaxIter' — Maximum number of iterations allowed. The default is 200.</li> <li>• 'OutputFcn' — Function handle specified using @, a cell array with function handles or an empty array (default). The solver calls all output functions after each iteration.</li> <li>• 'TolFun' — Termination tolerance on the loglikelihood function. The default is 1e-4.</li> <li>• 'TolX' — Termination tolerance on the estimated fixed and random effects. The default is 1e-4.</li> </ul>
OptimFun	<p>Specifies the optimization function used in maximizing the likelihood. Choices are 'fminsearch' to use fminsearch or 'fminunc' to use fminunc. The default is 'fminsearch'. You can specify 'fminunc' only if Optimization Toolbox software is installed.</p>

## Examples

### Nonlinear Mixed-Effects Model

Enter and display data on the growth of five orange trees.

```
CIRC = [30 58 87 115 120 142 145;
        33 69 111 156 172 203 203;
        30 51 75 108 115 139 140;
        32 62 112 167 179 209 214;
        30 49 81 125 142 174 177];
time = [118 484 664 1004 1231 1372 1582];
```

```
h = plot(time,CIRC','o','LineWidth',2);
xlabel('Time (days)')
ylabel('Circumference (mm)')
title('\bf Orange Tree Growth')
legend([repmat('Tree ',5,1),num2str((1:5)')],...
       'Location','NW')
grid on
hold on
```

Use an anonymous function to specify a logistic growth model.

```
model = @(PHI,t)(PHI(:,1))./(1+exp(-(t-PHI(:,2))./PHI(:,3))));
```

Fit the model using `nlmefit` with default settings (that is, assuming each parameter is the sum of a fixed and a random effect, with no correlation among the random effects):

```
TIME = repmat(time,5,1);  
NUMS = repmat((1:5)',size(time));  
  
beta0 = [100 100 100];  
[beta1,PSI1,stats1] = nlmefit(TIME(:),CIRC(:),NUMS(:),...  
                             [],model,beta0)
```

```
beta1 =
```

```
191.3189  
723.7608  
346.2517
```

```
PSI1 =
```

```
962.1534    0    0  
    0    0.0000    0  
    0    0    297.9879
```

```
stats1 =
```

```
    dfe: 28  
    logl: -131.5457  
    mse: 59.7882  
    rmse: 7.9016  
    errorparam: 7.7323
```

```
aic: 277.0913
bic: 274.3574
covb: [3x3 double]
sebeta: [15.2249 33.1579 26.8235]
ires: [35x1 double]
pres: [35x1 double]
iwres: [35x1 double]
pwres: [35x1 double]
cwres: [35x1 double]
```

The negligible variance of the second random effect,  $\text{PSI1}(2,2)$ , suggests that it can be removed to simplify the model.

```
[beta2,PSI2,stats2,b2] = nlmefit(TIME(:),CIRC(:),...
    NUMS(:),[],model,beta0,'REParamsSelect',[1 3])
```

```
beta2 =
```

```
191.3193
723.7627
346.2529
```

```
PSI2 =
```

```

      0 297.9475
```

```
stats2 =
```

```
dfc: 29
logl: -131.5456
mse: 59.7850
rmse: 7.7642
```

```
errorparam: 7.7321
      aic: 275.0913
      bic: 272.7479
      covb: [3x3 double]
      sebeta: [15.2270 33.1574 26.8228]
      ires: [35x1 double]
      pres: [35x1 double]
      iwres: [35x1 double]
      pwres: [35x1 double]
      cwres: [35x1 double]
```

b2 =

```
-28.5263   31.6066  -36.5079   39.0750  -5.6473
   9.9967  -0.7622   6.0038  -9.4567  -5.7816
```

The loglikelihood `logl` is unaffected, and both the Akaike and Bayesian information criteria ( `aic` and `bic` ) are reduced, supporting the decision to drop the second random effect from the model.

Use the estimated fixed effects in `beta2` and the estimated random effects for each tree in `b2` to plot the model through the data.

```
PHI = repmat(beta2,1,5) + ...           % Fixed effects
      [b2(1,:);zeros(1,5);b2(2,:)];    % Random effects

colors = get(h,'Color');
tplot = 0:0.1:1600;
for I = 1:5
    fitted_model=@(t)(PHI(1,I))./(1+exp(-(t-PHI(2,I))./ ...
    PHI(3,I)));
    plot(tplot,fitted_model(tplot),'Color',colors{I}, ...
        'LineWidth',2)
end
```

## How To

- “Mixed-Effects Models” on page 11-23
- “Grouping Variables” on page 2-51

**Purpose**

Fit nonlinear mixed-effects model with stochastic EM algorithm

**Syntax**

```
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,
    'Name',Value)
```

**Description**

[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0) fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in BETA. By default, nlmefitsa fits a model where each model parameter is the sum of a corresponding fixed and random effect, and the covariance matrix of the random effects is diagonal, i.e., uncorrelated random effects.

The BETA, PSI, and other values this function returns are the result of a random (Monte Carlo) simulation designed to converge to the maximum likelihood estimates of the parameters. Because the results are random, it is advisable to examine the plot of simulation to results to be sure that the simulation has converged. It may also be helpful to run the function multiple times, using multiple starting values, or use the 'Replicates' parameter to perform multiple simulations.

[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0, 'Name',Value) accepts one or more comma-separated parameter name/value pairs. Specify *Name* inside single quotes.

**Input Arguments****Definitions:**

In the following list of arguments, the following variable definitions apply:

- *n* — number of observations
- *h* — number of predictor variables
- *m* — number of groups
- *g* — number of group-specific predictor variables
- *p* — number of parameters
- *f* — number of fixed effects

## **X**

An  $n$ -by- $h$  matrix of  $n$  observations on  $h$  predictor variables.

## **Y**

An  $n$ -by-1 vector of responses.

## **GROUP**

A grouping variable indicating to which of  $m$  groups each observation belongs. **GROUP** can be a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings.

## **V**

An  $m$ -by- $g$  matrix of  $g$  group-specific predictor variables for each of the  $m$  groups in the data. These are predictor values that take on the same value for all observations in a group. Rows of **V** are ordered according to `GRP2IDX(GROUP)`. Use an  $m$ -by- $g$  cell array for **V** if any of the group-specific predictor values vary in size across groups. Specify `[]` for **V** if there are no group predictors.

## **MODELFUN**

A handle to a function that accepts predictor values and model parameters, and returns fitted values. **MODELFUN** has the form `YFIT = MODELFUN(PHI, XFUN, VFUN)` with input arguments

- **PHI** — A 1-by- $p$  vector of model parameters.
- **XFUN** — An  $l$ -by- $h$  array of predictor variables where
  - $l$  is 1 if **XFUN** is a single row of **X**
  - $l$  is  $n_i$  if **XFUN** contains the rows of **X** for a single group of size  $n_i$
  - $l$  is  $n$  if **XFUN** contains all rows of **X**.
- **VFUN** — Either
  - A 1-by- $g$  vector of group-specific predictors for a single group, corresponding to a single row of **V**

- An  $n$ -by- $g$  matrix, where the  $k$ -th row of VFUN is  $V(i,:)$  if the  $k$ -th observation is in group  $i$ .

If  $V$  is empty, nlmefitsa calls MODELFUN with only two inputs.

MODELFUN returns an  $l$ -by-1 vector of fitted values YFIT. When either PHI or VFUN contains a single row, that one row corresponds to all rows in the other two input arguments. For improved performance, use the 'Vectorization' parameter name/value pair (described below) if MODELFUN can compute YFIT for more than one vector of model parameters in one call.

### **BETA0**

An  $f$ -by-1 vector with initial estimates for the  $f$  fixed effects. By default,  $f$  is equal to the number of model parameters  $p$ . BETA0 can also be an  $f$ -by-REPS matrix, and the estimation is repeated REPS times using each column of BETA0 as a set of starting values.

### **Name-Value Pair Arguments**

By default, nlmefitsa fits a model where each model parameter is the sum of a corresponding fixed and random effect. Use the following parameter name/value pairs to fit a model with a different number of or dependence on fixed or random effects. Use at most one parameter name with an 'FE' prefix and one parameter name with an 'RE' prefix. Note that some choices change the way nlmefitsa calls MODELFUN, as described further below.

#### **'FEParamsSelect'**

A vector specifying which elements of the model parameter vector PHI include a fixed effect, as a numeric vector with elements in  $1:p$ , or as a 1-by- $p$  logical vector. The model will include  $f$  fixed effects, where  $f$  is the specified number of elements.

#### **'FEConstDesign'**

A  $p$ -by- $f$  design matrix ADESIGN, where ADESIGN\*BETA are the fixed components of the  $p$  elements of PHI.

## **'FEGroupDesign'**

A  $p$ -by- $f$ -by- $m$  array specifying a different  $p$ -by- $f$  fixed effects design matrix for each of the  $m$  groups.

## **'REParamsSelect'**

A vector specifying which elements of the model parameter vector PHI include a random effect, as a numeric vector with elements in  $1:p$ , or as a 1-by- $p$  logical vector. The model will include  $r$  random effects, where  $r$  is the specified number of elements.

## **'REConstDesign'**

A  $p$ -by- $r$  design matrix BDESIGN, where BDESIGN\*B are the random components of the  $p$  elements of PHI. This matrix must consist of 0s and 1s, with at most one 1 per row.

The default model is equivalent to setting both FEConstDesign and REConstDesign to  $\text{eye}(p)$ , or to setting both FEParamsSelect and REParamsSelect to  $1:p$ .

Additional optional parameter name/value pairs control the iterative algorithm used to maximize the likelihood:

## **'CovPattern'**

Specifies an  $r$ -by- $r$  logical or numeric matrix PAT that defines the pattern of the random effects covariance matrix PSI. nlmefitsa computes estimates for the variances along the diagonal of PSI as well as covariances that correspond to non-zeroes in the off-diagonal of PAT. nlmefitsa constrains the remaining covariances, i.e., those corresponding to off-diagonal zeroes in PAT, to be zero. PAT must be a row-column permutation of a block diagonal matrix, and nlmefitsa adds non-zero elements to PAT as needed to produce such a pattern. The default value of PAT is  $\text{eye}(r)$ , corresponding to uncorrelated random effects.

Alternatively, specify PAT as a 1-by- $r$  vector containing values in  $1:r$ . In this case, elements of PAT with equal values define groups of random

effects, `nlmefitsa` estimates covariances only within groups, and constrains covariances across groups to be zero.

#### **'Cov0'**

Initial value for the covariance matrix `PSI`. Must be an  $r$ -by- $r$  positive definite matrix. If empty, the default value depends on the values of `BETA0`.

#### **'ComputeStdErrors'**

`true` to compute standard errors for the coefficient estimates and store them in the output `STATS` structure, or `false` (default) to omit this computation.

#### **'ErrorModel'**

A string specifying the form of the error term. Default is `'constant'`. Each model defines the error using a standard normal (Gaussian) variable  $e$ , the function value  $f$ , and one or two parameters  $a$  and  $b$ . Choices are

- `'constant'` —  $y = f + a*e$
- `'proportional'` —  $y = f + b*f*e$
- `'combined'` —  $y = f + (a+b*f)*e$
- `'exponential'` —  $y = f*\exp(a*e)$ , or equivalently  $\log(y) = \log(f) + a*e$

If this parameter is given, the output `STATS.errorparam` field has the value

- $a$  for `'constant'` and `'exponential'`
- $b$  for `'proportional'`
- $[a\ b]$  for `'combined'`

#### **'ErrorParameters'**

A scalar or two-element vector specifying starting values for parameters of the error model. This specifies the  $a$ ,  $b$ , or  $[a\ b]$  values depending on the `ErrorModel` parameter.

### **'LogLikMethod'**

Specifies the method for approximating the loglikelihood. Choices are:

- 'is' — Importance sampling
- 'gq' — Gaussian quadrature
- 'lin' — Linearization
- 'none' — Omit the loglikelihood approximation (default)

### **'NBurnIn'**

Number of initial burn-in iterations during which the parameter estimates are not recomputed. Default is 5.

### **'NChains'**

Number  $c$  of "chains" simulated. Default is 1. Setting  $c > 1$  causes  $c$  simulated coefficient vectors to be computed for each group during each iteration. Default depends on the data, and is chosen to provide about 100 groups across all chains.

### **'NIterations'**

Number of iterations. This can be a scalar or a three-element vector. Controls how many iterations are performed for each of three phases of the algorithm:

- 1** simulated annealing
- 2** full step size
- 3** reduced step size

Default is [150 150 100]. A scalar is distributed across the three phases in the same proportions as the default.

### **'NMCIterations'**

Number of Markov Chain Monte Carlo (MCMC) iterations. This can be a scalar or a three-element vector. Controls how many of three different types of MCMC updates are performed during each phase of the main iteration:

- 1** full multivariate update
- 2** single coordinate update
- 3** multiple coordinate update

Default is [2 2 2]. A scalar value is treated as a three-element vector with all elements equal to the scalar.

### **'OptimFun'**

Either 'fminsearch' or 'fminunc', specifying the optimization function to be used during the estimation process. Default is 'fminsearch'. Use of 'fminunc' requires Optimization Toolbox.

### **'Options'**

A structure created by a call to `statset`. `nlmefitsa` uses the following `statset` parameters:

- 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters  $p$ . The default is  $\text{eps}^{(1/3)}$ .
- Display — Level of display during estimation.
  - 'off' (default) — Displays no information
  - 'final' — Displays information after the final iteration of the estimation algorithm

- 'iter' — Displays information at each iteration
- FunValCheck
  - 'on' (sdefault) — Check for invalid values (such as NaN or Inf) from MODELFUN
  - 'off' — Skip this check
- OutputFcn — Function handle specified using @, a cell array with function handles or an empty array. nlmefitsa calls all output functions after each iteration. See nlmefitoutputfcn.m (the default output function for nlmefitsa) for an example of an output function.

### **'ParamTransform'**

A vector of  $p$ -values specifying a transformation function  $f()$  for each of the  $p$  parameters:

$$XB = ADESIGN*BETA + BDESIGN*B$$
$$PHI = f(XB)$$

Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:

- 0:  $PHI = XB$  (default for all parameters)
- 1:  $\log(PHI) = XB$
- 2:  $\text{probit}(PHI) = XB$
- 3:  $\text{logit}(PHI) = XB$

### **'Replicates'**

Number REPS of estimations to perform starting from the starting values in the vector BETA0. If BETA0 is a matrix, REPS must match the number of columns in BETA0. Default is the number of columns in BETA0.

### **'Vectorization'**

Determines the possible sizes of the PHI, XFUN, and VFUN input arguments to MODELFUN. Possible values are:

- 'SinglePhi' — MODELFUN is a function (such as an ODE solver) that can only compute YFIT for a single set of model parameters at a time, i.e., PHI must be a single row vector in each call. nlmefitsa calls MODELFUN in a loop if necessary using a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN.
- 'SingleGroup' — MODELFUN can only accept inputs corresponding to a single group in the data, i.e., XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group, or a matrix with one row for each observation. VFUN is a single row.
- 'Full' — MODELFUN can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. Using this option can improve performance by reducing the number of calls to MODELFUN, but may require MODELFUN to perform singleton expansion on PHI or V.

The default for 'Vectorization' is 'SinglePhi'. In all cases, if V is empty, nlmefitsa calls MODELFUN with only two inputs.

## Output Arguments

### BETA

Estimates of the fixed effects

### PSI

An  $r$ -by- $r$  estimated covariance matrix for the random effects. By default,  $r$  is equal to the number of model parameters  $p$ .

### STATS

A structure with the following fields:

- logl — The maximized loglikelihood for the fitted model; empty if the LogLikMethod parameter has its default value of 'none'

- `rmse` — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion (empty if `logl` is empty), calculated as  $\text{aic} = -2 * \text{logl} + 2 * \text{numParam}$ , where
  - `logl` is the maximized loglikelihood.
  - `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model.
- `bic` — The Bayesian information criterion (empty if `logl` is empty), calculated as  $\text{bic} = -2 * \text{logl} + \log(M) * \text{numParam}$ 
  - `M` is the number of groups.
  - `logl` and `numParam` are defined as in `aic`.  
Note that some literature suggests that the computation of `bic` should be ,  $\text{bic} = -2 * \text{logl} + \log(N) * \text{numParam}$ , where `N` is the number of observations. To adjust the value of the output you can redefine `bic` as follows:  $\text{bic} = \text{bic} - \text{numel}(\text{unique}(\text{group})) + \text{numel}(Y)$
- `sebeta` — The standard errors for BETA (empty if the `ComputeStdErrors` parameter has its default value of false)
- `covb` — The estimated covariance of the parameter estimates (empty if `ComputeStdErrors` is false)
- `dfe` — The error degrees of freedom
- `pres` — The population residuals ( $y - y_{\text{population}}$ ), where `y_population` is the population predicted values
- `ires` — The population residuals ( $y - y_{\text{population}}$ ), where `y_population` is the individual predicted values
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals
- `iwres` — The individual weighted residuals

**Examples****Nonlinear Mixed-Effects Model with Stochastic EM Algorithm**

Load the sample data.

```
load indomethacin
```

Fit a model to data on concentrations of the drug indomethacin in the bloodstream of six subjects over eight hours.

```
model = @(phi,t)(phi(:,1).*exp(-phi(:,2).*t)+phi(:,3).*exp(-phi(:,4).*t));
phi0 = [1 1 1 1];
xform = [0 1 0 1]; % log transform for 2nd and 4th parameters
[beta,PSI,stats,br] = nlmefitsa(time,concentration,...
    subject,[],model,phi0,'ParamTransform',xform)
```

```
beta =
```

Plot the data along with an overall population fit

```
clf
phi = [beta(1), exp(beta(2)), beta(3), exp(beta(4))];
h = gscatter(time,concentration,subject);
xlabel('Time (hours)')
ylabel('Concentration (mcg/ml)')
title('{\bf Indomethacin Elimination}')
xx = linspace(0,8);
line(xx,model(phi,xx),'linewidth',2,'color','k')
```

Plot individual curves based on random-effect estimates.

```
for j=1:6
    phir = [beta(1)+br(1,j), exp(beta(2)+br(2,j)), ...
            beta(3)+br(3,j), exp(beta(4)+br(4,j))];
    line(xx,model(phir,xx),'color',get(h(j),'color'))
end
```

## Algorithms

In order to estimate the parameters of a nonlinear mixed effects model, we would like to choose the parameter values that maximize a likelihood function. These values are called the maximum likelihood estimates. The likelihood function can be written in the form

$$p(y | \beta, \sigma^2, \Sigma) = \int p(y | \beta, b, \sigma^2) p(b | \Sigma) db$$

where

- $y$  is the response data
- $\beta$  is the vector of population coefficients
- $\sigma^2$  is the residual variance
- $\Sigma$  is the covariance matrix for the random effects
- $b$  is the set of unobserved random effects

Each  $p()$  function on the right-hand-side is a normal (Gaussian) likelihood function that may depend on covariates.

Since the integral does not have a closed form, it is difficult to find parameters that maximize it. Delyon, Lavielle, and Moulines [1] proposed to find the maximum likelihood estimates using an Expectation-Maximization (EM) algorithm in which the E step is replaced by a stochastic procedure. They called their algorithm SAEM, for Stochastic Approximation EM. They demonstrated that this algorithm has desirable theoretical properties, including convergence under practical conditions and convergence to a local maximum of the likelihood function. Their proposal involves three steps:

- 1** Simulation: Generate simulated values of the random effects  $b$  from the posterior density  $p(b | \Sigma)$  given the current parameter estimates.
- 2** Stochastic approximation: Update the expected value of the loglikelihood function by taking its value from the previous step, and moving part way toward the average value of the loglikelihood calculated from the simulated random effects.
- 3** Maximization step: Choose new parameter estimates to maximize the loglikelihood function given the simulated values of the random effects.

# gmdistribution.NlogL property

---

**Purpose** Negative of log-likelihood

**Description** The negative of the log-likelihood of the data.

---

**Note** This property applies only to gmdistribution objects constructed with `fit`.

---

# ProbDistParametric.NLogL property

---

<b>Purpose</b>	Read-only value specifying negative log likelihood for input data to ProbDistParametric object
<b>Description</b>	NLogL is a read-only property of the ProbDistParametric class. NLogL is a value specifying the negative log likelihood for input data used to fit a distribution represented by a ProbDistParametric object.
<b>Values</b>	The value is a numeric scalar for a distribution fit to input data, that is, a distribution created using the <code>fitdist</code> function. This property is empty for distributions created without fitting to data, that is, by using the <code>ProbDistUnivParam.ProbDistUnivParam</code> constructor. Use this information to view and compare the negative log likelihood for input data supplied to create distributions.

# ProbDistUnivKernel.NLogL property

---

<b>Purpose</b>	Read-only value specifying negative log likelihood for input data to ProbDistUnivKernel object
<b>Description</b>	NLogL is a read-only property of the ProbDistUnivKernel class. NLogL is a value specifying the negative log likelihood for input data used to fit a distribution represented by a ProbDistUnivKernel object.
<b>Values</b>	The value is a numeric scalar for a distribution fit to input data, that is, a distribution created using the <code>fitdist</code> function. Use this information to view and compare the negative log likelihood for input data used to create distributions.

**Purpose**

Nonlinear regression parameter confidence intervals

**Syntax**

```
ci = nlparci(beta,resid,'covar',sigma)
ci = nlparci(beta,resid,'jacobian',J)
ci = nlparci(...,'alpha',alpha)
```

**Description**

`ci = nlparci(beta,resid,'covar',sigma)` returns the 95% confidence intervals `ci` for the nonlinear least squares parameter estimates `beta`. Before calling `nlparci`, use `nlinfit` to fit a nonlinear regression model and get the coefficient estimates `beta`, residuals `resid`, and estimated coefficient covariance matrix `sigma`.

`ci = nlparci(beta,resid,'jacobian',J)` is an alternative syntax that also computes 95% confidence intervals. `J` is the Jacobian computed by `nlinfit`. If the `'robust'` option is used with `nlinfit`, use the `'covar'` input rather than the `'jacobian'` input so that the required `sigma` parameter takes the robust fitting into account.

`ci = nlparci(...,'alpha',alpha)` returns  $100(1-\alpha)\%$  confidence intervals.

`nlparci` treats NaNs in `resid` or `J` as missing values, and ignores the corresponding observations.

The confidence interval calculation is valid for systems where the length of `resid` exceeds the length of `beta` and `J` has full column rank. When `J` is ill-conditioned, confidence intervals may be inaccurate.

**Examples****Fit to exponential decay**

Suppose you have data, and want to fit a model of the form

$$y_i = a_1 + a_2 \exp(-a_3 x_i) + \varepsilon_i.$$

Here the  $a_i$  are the parameters you want to estimate,  $x_i$  are the data points, the  $y_i$  are the responses, and the  $\varepsilon_i$  are noise terms.

**1** Write a function handle that represents the model:

```
mdl = @(a,x)(a(1) + a(2)*exp(-a(3)*x));
```

- 2** Generate synthetic data with parameters  $a = [1;3;2]$ , with the  $x$  data points distributed exponentially with parameter 2, and normally distributed noise with standard deviation 0.1:

```
rng(9845,'twister') % for reproducibility
a = [1;3;2];
x = exprnd(2,100,1);
epsn = normrnd(0,0.1,100,1);
y = mdl(a,x) + epsn;
```

- 3** Fit the model to data starting from the arbitrary guess  $a_0 = [2;2;2]$ :

```
a0 = [2;2;2];
[ahat,r,J,cov,mse] = nlinfit(x,y,mdl,a0);
ahat
```

```
ahat =
    1.0153
    3.0229
    2.1070
```

- 4** Check whether  $[1;3;2]$  is in a 95% confidence interval using the Jacobian argument in `nlparci`:

```
ci = nlparci(ahat,r,'Jacobian',J)
```

```
ci =
    0.9869    1.0438
    2.9401    3.1058
    1.9963    2.2177
```

- 5** You can obtain the same result using the covariance argument:

```
ci = nlparci(ahat,r,'covar',cov)
```

```
ci =
    0.9869    1.0438
```

2.9401    3.1058  
1.9963    2.2177

**See Also**    `nlinfit` | `nlpredci`

# nlpredci

---

## Purpose

Nonlinear regression prediction confidence intervals

## Syntax

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)
[Ypred,delta] =
nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,
        Value)
```

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)
[Ypred,delta] =
nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,
        Value)
```

## Description

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB) returns predictions, Ypred, and 95% confidence interval half-widths, delta, for the nonlinear regression model modelfun at input values X. Before calling nlpredci, use nlinfit to fit modelfun and get the estimated coefficients, beta, residuals, R, and variance-covariance matrix, CovB.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name, Value) uses additional options specified by one or more name-value pair arguments.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J) returns predictions, Ypred, and 95% confidence interval half-widths, delta, for the nonlinear regression model modelfun at input values X. Before calling nlpredci, use nlinfit to fit modelfun and get the estimated coefficients, beta, residuals, R, and Jacobian, J.

If you use a robust option with nlinfit, then you should use the Covar syntax rather than the Jacobian syntax. The variance-covariance matrix, CovB, is required to properly take the robust fitting into account.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name, Value) uses additional options specified by one or more name-value pair arguments.

## Input Arguments

### **modelfun - Nonlinear regression model function**

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array  $X$ —in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

### **Data Types**

function\_handle

### **X - Input values for predictions**

matrix

Input values for predictions, specified as a matrix. `nlpredci` makes a prediction for the covariates in each row of  $X$ . There should be a column in  $X$  for each coefficient in the model.

### **Data Types**

single | double

### **beta - Estimated regression coefficients**

vector returned by `nlinfit`

Estimated regression coefficients, specified as the vector of fitted coefficients returned by a previous call to `nlinfit`.

### **Data Types**

single | double

### **R - Residuals**

vector returned by `nlinfit`

Residuals for the fitted `modelfun`, specified as the vector of residuals returned by a previous call to `nlinfit`.

### **CovB - Estimated variance-covariance matrix**

matrix returned by `nlinfit`

Estimated variance-covariance matrix for the fitted coefficients, `beta`, specified as the variance-covariance matrix returned by a previous call to `nlinf`.

## **J - Estimated Jacobian**

matrix returned by `nlinf`

Estimated Jacobian of the nonlinear regression model, `modelfun`, specified as the Jacobian matrix returned by a previous call to `nlinf`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Alpha', 0.1, 'PredOpt', 'observation'` specifies 90% prediction intervals for new observations.

## **'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). If `Alpha` has value  $\alpha$ , then `nlpredci` returns intervals with  $100 \times (1 - \alpha)\%$  confidence level.

The default confidence level is 95% ( $\alpha = 0.05$ ).

**Example:** `'Alpha', 0.1`

## **Data Types**

single | double

## **'ErrorModelInfo' - Information about error model fit**

structure returned by `nlinf`

Information about the error model fit, specified as the comma-separated pair consisting of 'ErrorModelInfo' and a structure returned by a previous call to `nlinfit`.

`ErrorModelInfo` only has an effect on the returned prediction interval when `PredOpt` has the value 'observation'. If you do not use `ErrorModelInfo`, then `nlpredci` assumes the error variance model is 'constant'.

The error model structure returned by `nlinfit` has the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an $N$ -by- $p$ matrix, $X$ , and returns an $N$ -by-1 vector of error variances using the estimated error model
<code>MSE</code>	Mean squared error
<code>ScheffeSimPred</code>	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
<code>WeightFunction</code>	Logical with value <code>true</code> if you used a custom weight function previously in <code>nlinfit</code>
<code>FixedWeights</code>	Logical with value <code>true</code> if you used fixed weights previously in <code>nlinfit</code>
<code>RobustWeightFunction</code>	Logical with value <code>true</code> if you used robust fitting previously in

### 'MSE' - Mean squared error

MSE returned by `nlinfit`

Mean squared error (MSE) for the fitted nonlinear regression model, specified as the comma-separated pair consisting of 'MSE' and the MSE value returned by a previous call to `nlinfit`.

If you use a robust option with `nlinfit`, then you must specify the MSE when predicting new observations to properly take the robust fitting into account. If you do not specify the MSE, then `nlpredci` computes the MSE from the residuals, `R`, and does not take the robust fitting into account.

For example, if `mse` is the MSE value returned by `nlinfit`, then you can specify `'MSE',mse`.

### Data Types

`single` | `double`

### 'PredOpt' - Prediction interval to compute

`'curve'` (default) | `'observation'`

Prediction interval to compute, specified as the comma-separated pair consisting of `'PredOpt'` and either `'curve'` or `'observation'`.

- If you specify the value `'curve'`, then `nlpredci` returns confidence intervals for the estimated curve (function value) at the observations `X`.
- If you specify the value `'observation'`, then `nlpredci` returns prediction intervals for new observations at `X`.

If you specify `'observation'` after using a robust option with `nlinfit`, then you must also specify a value for MSE to provide the robust estimate of the mean squared error.

**Example:** `'PredOpt','observation'`

### Data Types

`char`

### 'SimOpt' - Indicator for specifying simultaneous bounds

`'off'` (default) | `'on'`

Indicator for specifying simultaneous bounds, specified as the comma-separated pair consisting of `'SimOpt'` and either `'off'` or `'on'`. Use the value `'off'` to compute nonsimultaneous bounds, and `'on'` for simultaneous bounds.

**'Weights' - Observation weights**

vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of positive scalar values or a function handle. The default is no weights.

- If you specify a vector of weights, then it must have the same number of elements as the number of observations (rows) in X.
- If you specify a function handle for the weights, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W, nlpredci estimates the error variance at observation i by  $mse * (1/W(i))$ , where mse is the mean squared error value specified using MSE.

**Example:** 'Weights',@WFun

**Data Types**

double | single | function\_handle

**Output Arguments****Ypred - Predicted responses**

vector

Predicted responses, returned as a vector with the same number of rows as X.

**delta - Confidence interval half-widths**

vector

Confidence interval half-widths, returned as a vector with the same number of rows as X. By default, delta contains the half-widths for nonsimultaneous 95% confidence intervals for modelfun at the observations in X. You can compute the lower and upper bounds of the confidence intervals as Ypred-delta and Ypred+delta, respectively.

If 'PredOpt' has value 'observation', then delta contains the half-widths for prediction intervals of new observations at the values in X.

## Examples

### Confidence Interval for Nonlinear Regression Curve

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% confidence interval half-width for the value of the curve at average reactant levels.

```
[ypred,delta] = nlpredci(@hougen,mean(X),beta,R,'Jacobian',J)
```

```
ypred =
```

```
5.4622
```

```
delta =
```

```
0.1921
```

Compute the 95% confidence interval for the value of the curve.

```
[ypred-delta,ypred+delta]
```

```
ans =
```

```
5.2702 5.6543
```

### Prediction Interval for New Observation

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% prediction interval half-width for a new observation with reactant levels [100,100,100].

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
                        'PredOpt','observation')
```

```
ypred =
```

```
    1.8346
```

```
delta =
```

```
    0.5101
```

Compute the 95% prediction interval for the new observation.

```
[ypred-delta,ypred+delta]
```

```
ans =
```

```
    1.3245    2.3447
```

### **Simultaneous Confidence Intervals for Robust Fit Curve**

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';  
beta0 = [2;2;2];  
[beta,R,J,CovB,MSE] = nlinfit(x,y,modelfun,beta0,opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = min(x):.01:max(x);  
[ypred,delta] = nlpredci(modelfun,xrange,beta,R,'Covar',CovB,...  
                        'MSE',MSE,'SimOpt','on');  
lower = ypred - delta;  
upper = ypred + delta;  
  
figure()  
plot(x,y,'ko') % observed data  
hold on  
plot(xrange,ypred,'k','LineWidth',2)  
plot(xrange,[lower;upper],'r--','LineWidth',1.5)
```

### Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);  
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
```

# nlpredci

---

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the observation weight function.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...  
                        'PredOpt','observation','Weights',weights);  
[ypred-delta,ypred+delta]
```

```
ans =
```

```
    1.5264    2.1033
```

## Confidence Interval Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
[beta,R,J,CovB,MSE,S] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined')
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the fitted error variance model.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...  
                        'PredOpt','observation','ErrorModelInfo',S);  
[ypred-delta,ypred+delta]
```

```
ans =
```

```
    1.3245    2.3447
```

## Algorithms

- `nlpredci` treats NaN values in the residuals, R, or the Jacobian, J, as missing values, and ignores the corresponding observations.

- If the Jacobian,  $J$ , does not have full column rank, then some of the model parameters might be nonidentifiable. In this case, `nlpredci` tries to construct confidence intervals for estimable predictions, and returns NaN for those that are not.
- To compute confidence intervals for complex parameters or data, you need to split the problem into its real and imaginary parts. When calling `nlinfit`:
  - 1 Define your parameter vector `beta` as the concatenation of the real and imaginary parts of the original parameter vector.
  - 2 Concatenate the real and imaginary parts of the response vector `Y` as a single vector.
  - 3 Modify your model function `modelfun` to accept `X` and the purely real parameter vector, and return a concatenation of the real and imaginary parts of the fitted values.

With the problem formulated this way, `nlinfit` computes real estimates, and confidence intervals are feasible.

## Definitions

### Confidence Intervals for Estimable Predictions

When the estimated model Jacobian is not of full rank, then it might not be possible to construct sensible confidence intervals at all prediction points. In this case, `nlpredci` still tries to construct confidence intervals for any *estimable* prediction points.

For example, suppose you fit the linear function

$f(\mathbf{x}_i, \beta) = \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$  at the points in the design matrix

$$\mathbf{X} = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \end{pmatrix}.$$

The estimated Jacobian at the values in  $\mathbf{X}$  is the design matrix itself,  $\mathbf{J} = \mathbf{X}$ . Thus, the Jacobian is not of full rank:

```
rng('default') % For reproducibility
y = randn(6,1);

linfun = @(b,x) x*b;
beta0 = [1;1;1];
X = [repmat([1 1 0],3,1); repmat([1 0 1],3,1)];

[beta,R,J] = nlinfit(X,y,linfun,beta0);
```

```
Warning: The Jacobian at the solution is ill-conditioned, and
some model parameters may not be estimated well (they are not
identifiable). Use caution in making predictions.
> In nlinfit at 283
```

In this example, `nlpredci` can only compute prediction intervals at points that satisfy the linear relationship

$$x_{i1} = x_{i2} + x_{i3}.$$

If you try to compute confidence intervals for predictions at nonidentifiable points, `nlpredci` returns NaN for the corresponding interval half-widths:

```
xpred = [1 1 1;0 1 -1;2 1 1];
[ypred,delta] = nlpredci(linfun,xpred,beta,R,'Jacobian',J)

ypred =

    -0.0035
     0.0798
    -0.0047

delta =
```

```
      NaN  
      3.8102  
      3.8102
```

Here, the first element of `delta` is NaN because the first row in `xpred` does not satisfy the required linear dependence, and is therefore not an estimable contrast.

# nnmf

---

**Purpose** Nonnegative matrix factorization

**Syntax**  
 $[W,H] = \text{nnmf}(A,k)$   
 $[W,H] = \text{nnmf}(A,k,param1,val1,param2,val2,...)$   
 $[W,H,D] = \text{nnmf}(...)$

**Description**  $[W,H] = \text{nnmf}(A,k)$  factors the nonnegative  $n$ -by- $m$  matrix  $A$  into nonnegative factors  $W$  ( $n$ -by- $k$ ) and  $H$  ( $k$ -by- $m$ ). The factorization is not exact;  $W*H$  is a lower-rank approximation to  $A$ . The factors  $W$  and  $H$  are chosen to minimize the root-mean-squared residual  $D$  between  $A$  and  $W*H$ :

$$D = \sqrt{\text{norm}(A-W*H, 'fro') / (N*M)}$$

The factorization uses an iterative method starting with random initial values for  $W$  and  $H$ . Because the root-mean-squared residual  $D$  may have local minima, repeated factorizations may yield different  $W$  and  $H$ . Sometimes the algorithm converges to a solution of lower rank than  $k$ , which may indicate that the result is not optimal.

$W$  and  $H$  are normalized so that the rows of  $H$  have unit length. The columns of  $W$  are ordered by decreasing length.

$[W,H] = \text{nnmf}(A,k,param1,val1,param2,val2,...)$  specifies optional parameter name/value pairs from the following table.

Parameter	Value
'algorithm'	Either 'als' (the default) to use an alternating least-squares algorithm, or 'mult' to use a multiplicative update algorithm.  In general, the 'als' algorithm converges faster and more consistently. The 'mult' algorithm is more sensitive to initial values, which makes it a

Parameter	Value
	good choice when using 'replicates' to find W and H from multiple random starting values.
'w0'	An $n$ -by- $k$ matrix to be used as the initial value for W.
'h0'	A $k$ -by- $m$ matrix to be used as the initial value for H.
'options'	<p>An options structure as created by the <code>statset</code> function. <code>nnmf</code> uses the following fields of the options structure:</p> <ul style="list-style-type: none"> <li>• <b>Display</b> — Level of display. Choices: <ul style="list-style-type: none"> <li>▪ 'off' (default) — No display</li> <li>▪ 'final' — Display final result</li> <li>▪ 'iter' — Iterative display of intermediate results</li> </ul> </li> <li>• <b>MaxIter</b> — Maximum number of iterations. Default is 100. Unlike in optimization settings, reaching <b>MaxIter</b> iterations is treated as convergence.</li> <li>• <b>TolFun</b> — Termination tolerance on change in size of the residual. Default is <math>1e-4</math>.</li> <li>• <b>TolX</b> — Termination tolerance on relative change in the elements of W and H. Default is <math>1e-4</math>.</li> <li>• <b>UseParallel</b> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>.</li> <li>• <b>UseSubstreams</b> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <b>Streams</b></li> </ul>

Parameter	Value
	<p>to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</p> <ul style="list-style-type: none"> <li>Streams — A RandStream object or cell array of such objects. If you do not specify Streams, nnmf uses the default stream or streams. If you choose to specify Streams, use a single object except in the case <ul style="list-style-type: none"> <li>You have an open Parallel pool</li> <li>UseParallel is true</li> <li>UseSubstreams is false</li> </ul> </li> </ul> <p>In that case, use a cell array the same size as the Parallel pool.</p>
'replicates'	<p>The number of times to repeat the factorization, using new random starting values for W and H, except at the first replication if 'w0' and 'h0' are given. This is most beneficial with the 'mult' algorithm. The default is 1.</p>

[W,H,D] = nnmf(...) also returns D, the root mean square residual.

## Examples

### Example 1

Compute a nonnegative rank-two approximation of the measurements of the four variables in Fisher's iris data:

```
load fisheriris
[W,H] = nnmf(meas,2);
H
H =
    0.6852    0.2719    0.6357    0.2288
    0.8011    0.5740    0.1694    0.0087
```

The first and third variables in meas (sepal length and petal length, with coefficients 0.6852 and 0.6357, respectively) provide relatively

strong weights to the first column of  $W$ . The first and second variables in `meas` (sepal length and sepal width, with coefficients 0.8011 and 0.5740) provide relatively strong weights to the second column of  $W$ .

Create a biplot of the data and the variables in `meas` in the column space of  $W$ :

```
biplot(H', 'scores', W, 'varlabels', {'sl', 'sw', 'pl', 'pw'});  
axis([0 1.1 0 1.1])  
xlabel('Column 1')  
ylabel('Column 2')
```

## Example 2

Starting from a random array  $X$  with rank 20, try a few iterations at several replicates using the multiplicative algorithm:

```
X = rand(100,20)*rand(20,50);
opt = statset('MaxIter',5,'Display','final');
[WO,H0] = nnmf(X,5,'replicates',10,...
               'options',opt,...
               'algorithm','mult');
```

rep	iteration	rms resid	delta x
1	5	0.560887	0.0245182
2	5	0.66418	0.0364471
3	5	0.609125	0.0358355
4	5	0.608894	0.0415491
5	5	0.619291	0.0455135
6	5	0.621549	0.0299965
7	5	0.640549	0.0438758
8	5	0.673015	0.0366856
9	5	0.606835	0.0318931
10	5	0.633526	0.0319591

Final root mean square residual = 0.560887

Continue with more iterations from the best of these results using alternating least squares:

```
opt = statset('Maxiter',1000,'Display','final');
[W,H] = nnmf(X,5,'w0',WO,'h0',H0,...
              'options',opt,...
              'algorithm','als');
```

rep	iteration	rms resid	delta x
1	80	0.256914	9.78625e-005

Final root mean square residual = 0.256914

# classregtree.nodeclass

---

**Purpose** Class values of nodes of classification tree

**Syntax** NAME=nodeclass(T)  
NAME=nodeclass(T,J)  
[NAME,ID]=nodeclass(...)

**Description** NAME=nodeclass(T) returns an  $n$ -element cell array with the names of the most probable classes in each node of the tree T, where  $n$  is the number of nodes in the tree. Every element of this array is a string equal to one of the class names returned by `classname(T)`. For regression trees, `nodeclass` returns an empty cell array.

NAME=nodeclass(T,J) takes an array J of node numbers and returns the class names for the specified nodes.

[NAME,ID]=nodeclass(...) also returns a numeric array with the class index for each node. The class index is determined by the order of classes `classname` returns.

**See Also** classregtree | classname | numnodes

**Purpose** Return vector of node errors

**Syntax**  
`e = nodeerr(t)`  
`e = nodeerr(t,nodes)`

**Description** `e = nodeerr(t)` returns an  $n$ -element vector `e` of the errors of the nodes in the tree `t`, where  $n$  is the number of nodes. For a regression tree, the error `e(i)` for node `i` is the variance of the observations assigned to node `i`. For a classification tree, `e(i)` is the misclassification probability for node `i`.

`e = nodeerr(t,nodes)` takes a vector `nodes` of node numbers and returns the errors for the specified nodes.

The error `e` is the so-called *resubstitution error* computed by applying the tree to the same data used to create the tree. This error is likely to under estimate the error you would find if you applied the tree to new data. The `test` function provides options to compute the error (or cost) using cross-validation or a test sample.

**Examples** Create a classification tree for Fisher's iris data:

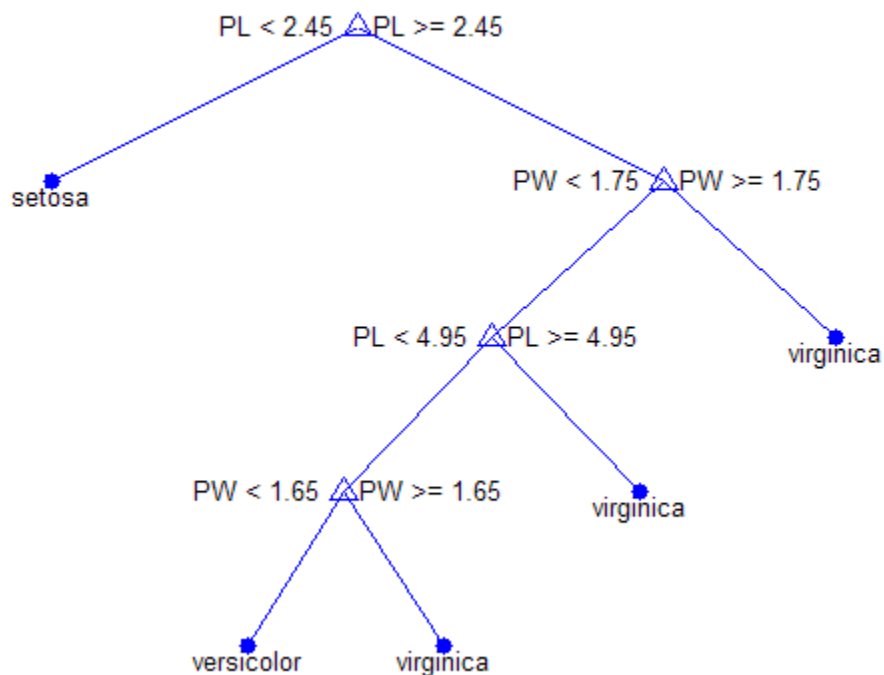

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica
```

# classregtree.nodeerr

view(t)

Click to display:  Magnification:  Pruning level:

e = nodeerr(t)

e =

# classregtree.nodemean

---

**Purpose** Mean values of nodes of regression tree

**Syntax** NM = nodemean(T)  
NM = nodemean(T,J)

**Description** NM = nodemean(T) returns an  $n$ -element numeric array with mean values in each node of the tree T, where  $n$  is the number of nodes in the tree. Every element of this array is computed by averaging true Y values over all observations in the node. For classification trees, nodemean returns an empty numeric array.

NM = nodemean(T,J) takes an array J of node numbers and returns the mean values for the specified nodes.

**See Also** classregtree | numnodes

## Purpose

Node probabilities

## Syntax

```
p = nodeprob(t)
p = nodeprob(t,nodes)
```

## Description

`p = nodeprob(t)` returns an  $n$ -element vector `p` of the probabilities of the nodes in the tree `t`, where  $n$  is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. For a classification tree, this proportion is adjusted for any prior probabilities assigned to each class.

`p = nodeprob(t,nodes)` takes a vector `nodes` of node numbers and returns the probabilities for the specified nodes.

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification

# classregtree.nodesize

---

**Purpose** Return node size

**Syntax** `sizes = nodesize(t)`  
`sizes = nodesize(t,nodes)`

**Description** `sizes = nodesize(t)` returns an  $n$ -element vector `sizes` of the sizes of the nodes in the tree `t`, where  $n$  is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

`sizes = nodesize(t,nodes)` takes a vector `nodes` of node numbers and returns the sizes for the specified nodes.

**Examples** Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =

classregtree | numnodes

**Purpose** Notify listeners of event

**Syntax** `notify(h, 'eventname')`  
`notify(h, 'eventname', data)`

**Description** `notify(h, 'eventname')` notifies listeners added to the event named `eventname` on handle object array `h` that the event is taking place. `h` is the array of handles to objects triggering the event, and `eventname` must be a string.

`notify(h, 'eventname', data)` provides a way of encapsulating information about an event which can then be accessed by each registered listener. `data` must belong to the `event.EventData` class.

**See Also** `addlistener` | `event.EventData` | `events` | `grandstream`

# nominal

---

**Superclasses**    categorical

**Purpose**    Arrays for nominal categorical data

**Description**    Nominal arrays are used to store discrete values that are not numeric and that do not have an ordering. A nominal array provides efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values. Nominal arrays are often used as grouping variables.

You can subscript, concatenate, reshape, etc. nominal arrays much like ordinary numeric arrays. You can test equality between elements of two nominal arrays, or between a nominal array and a single string representing a nominal value.

**Construction**    Use the `nominal` constructor to create a nominal array from a numeric, logical, or character array, or from a cell array of strings.

<code>nominal</code>	Construct nominal categorical array
----------------------	-------------------------------------

**Methods**    Each nominal array carries along a list of possible values that it can store, known as its levels. The list is created when you create a nominal array, and you can access it using the `getlevels` method, or modify it using the `addlevels`, `mergelevels`, or `droplevels` methods. Assignment to the array will also add new levels automatically if the values assigned are not already levels of the array.

You can change the order of the list of levels for a nominal array using the `reorderlevels` method, however, that order has no significance for the values in the array. The order is used only for display purposes, or when you convert the nominal array to numeric values using methods such as `double` or `subsindex`, or compare two arrays using `isequal`. If you need to work with values that have a mathematical ordering, you should use an `ordinal` array instead.

The following table lists operations available for nominal arrays.

---

summary	Summary statistics for nominal array
---------	--------------------------------------

### Inherited Methods

Methods in the following table are inherited from `categorical`.

addlevels	Add levels to categorical array
cat	Concatenate categorical arrays
cellstr	Convert categorical array to cell array of strings
char	Convert categorical array to character array
circshift	Shift categorical array circularly
ctranspose	Transpose categorical matrix
disp	Display categorical array
display	Display categorical array
double	Convert categorical array to double array
droplevels	Drop levels
end	Last index in indexing expression for categorical array
flipdim	Flip categorical array along specified dimension
fliplr	Flip categorical matrix in left/right direction
flipud	Flip categorical matrix in up/down direction
getlabels	Access categorical array labels
getlevels	Get categorical array levels

# nominal

---

hist	Plot histogram of categorical data
horzcat	Horizontal concatenation for categorical arrays
int16	Convert categorical array to signed 16-bit integer array
int32	Convert categorical array to signed 32-bit integer array
int64	Convert categorical array to signed 64-bit integer array
int8	Convert categorical array to signed 8-bit integer array
intersect	Set intersection for categorical arrays
ipermute	Inverse permute dimensions of categorical array
isempty	True for empty categorical array
isequal	True if categorical arrays are equal
islevel	Test for levels
ismember	True for elements of categorical array in set
isscalar	True if categorical array is scalar
isundefined	Test for undefined elements
isvector	True if categorical array is vector
length	Length of categorical array
levelcounts	Element counts by level
mergelevels	Merge levels

---

<code>ndims</code>	Number of dimensions of categorical array
<code>numel</code>	Number of elements in categorical array
<code>permute</code>	Permute dimensions of categorical array
<code>reorderlevels</code>	Reorder levels
<code>repmat</code>	Replicate and tile categorical array
<code>reshape</code>	Resize categorical array
<code>rot90</code>	Rotate categorical matrix 90 degrees
<code>setdiff</code>	Set difference for categorical arrays
<code>setlabels</code>	Label levels
<code>setxor</code>	Set exclusive-or for categorical arrays
<code>shiftdim</code>	Shift dimensions of categorical array
<code>single</code>	Convert categorical array to single array
<code>size</code>	Size of categorical array
<code>squeeze</code>	Squeeze singleton dimensions from categorical array
<code>subsasgn</code>	Subscripted assignment for categorical array
<code>subsindex</code>	Subscript index for categorical array

# nominal

---

suboref	Subscripted reference for categorical array
times	Product of categorical arrays
transpose	Transpose categorical matrix
uint16	Convert categorical array to unsigned 16-bit integers
uint32	Convert categorical array to unsigned 32-bit integers
uint64	Convert categorical array to unsigned 64-bit integers
uint8	Convert categorical array to unsigned 8-bit integers
union	Set union for categorical arrays
unique	Unique values in categorical array
vertcat	Vertical concatenation for categorical arrays

## Properties

## Inherited Properties

Properties in the following table are inherited from `categorical`.

labels	Text labels for levels
undeflabel	Text label for undefined levels

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Create and Compare Nominal Arrays

Create a nominal array from string data in a cell array.

```
colors = nominal({'r' 'b' 'g';'g' 'r' 'b';'b' 'r' 'g'},...  
                {'blue' 'green' 'red'})
```

```
colors =
```

red	blue	green
green	red	blue
blue	red	green

Identify the elements in `colors` that are members of the level 'red'.

```
colors == 'red'
```

```
ans =
```

1	0	0
0	1	0
0	1	0

A value of 1 in the resulting array `ans` indicates that the corresponding element of `colors` is a member of 'red'.

Identify the elements of `colors` that are members of either 'red' or 'blue'.

```
ismember(colors,{'red' 'blue'})
```

```
ans =
```

1	1	0
0	1	1
1	1	0

A value of 1 in the resulting array `ans` indicates that the corresponding element of `colors` is a member of either 'red' or 'blue'.

Create a second nominal array `colors2` by flipping `colors` from left to right.

# nominal

---

```
colors2 = fliplr(colors)
```

```
colors2 =
```

```
    green    blue    red  
    blue    red    green  
    green    red    blue
```

Compare the elements of `colors` and `colors2`.

```
colors == colors2
```

```
ans =
```

```
    0    1    0  
    0    1    0  
    0    1    0
```

A value of 1 in the resulting array `ans` indicates that the corresponding element of `colors` is a member of the same level as the corresponding element of `colors2`.

## See Also

`histc` | `ordinal`

**Purpose**

Construct nominal categorical array

**Syntax**

```
B = nominal(A)
B = nominal(A,labels)
B = nominal(A,labels,levels)
B = nominal(A,labels,[],edges)
```

**Description**

`B = nominal(A)` creates a nominal array `B` from the array `A`. `A` can be numeric, logical, character, categorical, or a cell array of strings. `nominal` creates the levels of `B` from the sorted unique values in `A`, and creates default labels for them.

`B = nominal(A,labels)` labels the levels in `B` using the character array or cell array of strings `labels`. `nominal` assigns labels to levels in `B` in order according to the sorted unique values in `A`.

`B = nominal(A,labels,levels)` creates a nominal array with possible levels defined by `levels`. `levels` is a vector whose values can be compared to those in `A` using the equality operator. `nominal` assigns labels to each level from the corresponding elements of `labels`. If `A` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined.

`B = nominal(A,labels,[],edges)` creates a nominal array by binning the numeric array `A` with bin edges given by the numeric vector `edges`. The uppermost bin includes values equal to the right-most edge. `nominal` assigns labels to each level in `B` from the corresponding elements of `labels`. `edges` must have one more element than `labels`.

By default, an element of `B` is undefined if the corresponding element of `A` is NaN (when `A` is numeric), an empty string (when `A` is character), or undefined (when `A` is categorical). `nominal` treats such elements as “undefined” or “missing” and does not include entries for them among the possible levels for `B`. To create an explicit level for such elements instead of treating them as undefined, you must use the `levels` input, and include NaN, the empty string, or an undefined element.

You may include duplicate labels in `labels` in order to merge multiple values in `A` into a single level in `B`.

# nominal

---

## Examples

### Create and Label Nominal Arrays

Load the sample data.

```
load fisheriris;
```

Create a nominal array and display a summary of the data.

```
species = nominal(species);  
summary(species)
```

```
      setosa      50  
versicolor      50  
virginica        50
```

Create a nominal array from characters, and provide explicit labels.

```
colors1 = nominal({'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}, ...  
                 {'blue' 'green' 'red'})
```

```
colors1 =
```

```
      red      blue      green  
green      red      blue  
blue       red      green
```

Create a nominal array from characters, and provide both explicit labels and an explicit order for display.

```
colors2 = nominal({'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}, ...  
                 {'red' 'green' 'blue'}, {'r' 'g' 'b'})
```

```
colors2 =
```

```
      red      blue      green  
green      red      blue  
blue       red      green
```

Create a nominal array from integer data, merging odd and even values into only two nominal levels. Provide explicit labels.

```
toss = nominal(randi([1 4],5,2),{'odd' 'even' 'odd' 'even'},1:4)
```

```
toss =
```

```

    even    odd
    even    even
    odd     odd
    even    even
    odd     even

```

### Change Nominal Array Levels

Load the sample data.

```
load hospital;
```

Make the {0,1}-valued variable `Smoker` nominal, and change the labels to 'No' and 'Yes'.

```
hospital.Smoker = nominal(hospital.Smoker,{'No','Yes'});
```

Add new levels to `Smoker` as placeholders for more detailed histories of smokers.

```
hospital.Smoker = addlevels(hospital.Smoker,...
    {'0-5 Years','5-10 Years','LongTerm'});
```

Assuming the nonsmokers have never smoked, relabel the 'No' level.

```
hospital.Smoker = setlabels(hospital.Smoker,'Never','No');
```

Drop the undifferentiated 'Yes' level from `Smoker`.

```
hospital.Smoker = droplevels(hospital.Smoker,'Yes');
```

Note that smokers now have an undefined level.

# nominal

---

Set each smoker to one of the new levels, by observation name.

```
hospital.Smoker('YPL-320') = '5-10 Years';
```

## See Also

[histc](#) | [ordinal](#)

**Purpose**

Nonlinear regression model class

**Description**

An object comprising training data, model description, diagnostic information, and fitted coefficients for a nonlinear regression. Predict model responses with the `predict` or `feval` methods.

**Construction**

`nlm = fitnlm(ds,modelfun,beta0)` or `nlm = fitnlm(X,y,modelfun,beta0)` create a nonlinear model of a dataset array `ds`, or of the responses `y` to a data matrix `X`. For details, see `fitnlm`.

**Input Arguments****ds - Input data**

dataset array

Input data, specified as a dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-51). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

**Data Types**

single | double | logical

**X - Predictor variables**

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor

# NonLinearModel

---

variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## **y** - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## **modelfun** - Functional form of the model

function handle | string of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - $b$  is a coefficient vector with the same number of elements as `beta0`.
  - $x$  is a matrix with the same number of columns as  $X$  or the number of predictor variable columns of `ds`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as  $x$ . Each row of the vector is the result of evaluating `modelfun` on the corresponding row of  $x$ . In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call.

- String of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ ', where  $f$  represents a scalar function of the scalar coefficient variables  $b_1, \dots, b_j$  and the scalar data variables  $x_1, \dots, x_k$ .

## **beta0 - Coefficients**

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. NonLinearModel starts its search for optimal coefficients from beta0.

## **Data Types**

single | double

## **Properties**

### **CoefficientCovariance**

Covariance matrix of coefficient estimates.

### **CoefficientNames**

Cell array of strings containing a label for each coefficient.

### **Coefficients**

Table of coefficient values in a dataset array. Coefficients has one row for each coefficient and these columns:

- Estimate — Estimated coefficient value
- SE — Standard error of the estimate
- tStat —  $t$  statistic for a test that the coefficient is zero
- pValue —  $p$ -value for the  $t$  statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in mdl the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use coefTest to perform other tests on the coefficients.

### **Diagnostics**

# NonLinearModel

---

Dataset array with diagnostics helpful in finding outliers and influential observations. The structure contains the following fields.

Field	Meaning	Utility
Leverage	Diagonal elements of HatMatrix	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of Leverage is P/N. An observation with Leverage larger than $2 \cdot P/N$ can be regarded as having high leverage.
CooksDistance	Cook's measure of scaled change in fitted values	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an N-by-N matrix such that $Fitted = HatMatrix \cdot Y$ , where Y is the response vector and Fitted is the vector of fitted response values.

## DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

## Fitted

Vector of predicted values based on the training data. `fitnlm` attempts to make Fitted as close as possible to the response data.

## Formula

Object that represents the mathematical form of the model.

## **Iterative**

Structure with information about the fitting process. Fields:

- `InitialCoefs` — Initial coefficient values (the `beta0` vector)
- `IterOpts` — Options included in the `Options` name-value pair argument for `fitnlm`.

## **LogLikelihood**

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

## **ModelCriterion**

AIC and other information criteria for comparing models. A structure with fields:

- `AIC` — Akaike information criterion
- `AICc` — Akaike information criterion corrected for sample size
- `BIC` — Bayesian information criterion
- `CAIC` — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

## **MSE**

Mean squared error, a scalar that is an estimate of the variance of the error term in the model.

## **NumCoefficients**

# NonLinearModel

---

Number of coefficients in the fitted model, a scalar. `NumCoefficients` is the same as `NumEstimatedCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

## **NumEstimatedCoefficients**

Number of estimated coefficients in the fitted model, a scalar. `NumEstimatedCoefficients` is the same as `NumCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

## **NumPredictors**

Number of variables `fitnlm` used as predictors for fitting.

## **NumVariables**

Number of variables in the data. `NumVariables` is the number of variables in the original dataset when the fit is based on a dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

## **ObservationInfo**

Dataset with the same number of rows as the input data (`ds` or `X`).

<b>Field</b>	<b>Description</b>
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

## ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

## PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

## Residuals

Dataset array containing a table of residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
Pearson	Raw residuals divided by RMSE.
Standardized	Raw residuals divided by their estimated standard deviation.
Studentized	Residual divided by an independent estimate of the residual standard deviation. The residual for observation $i$ is divided by an estimate of the error standard deviation based on all observations except for observation $i$ .

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

# NonLinearModel

---

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

## ResponseName

String giving naming the response variable.

## RMSE

Root mean squared error, a scalar that is an estimate of the standard deviation of the error term in the model.

## Robust

Structure that is empty unless `fitnlm` constructed the model using robust regression.

Field	Description
WgtFun	Robust weighting function, such as 'bisquare' (see <code>robustfit</code> )
Tune	Value specified for tuning parameter (can be [ ])
Weights	Vector of weights used in final iteration of robust fit

## Rsquared

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$Rsquared = SSR/SST = 1 - SSE/SST.$$

Rsquared is a structure with two fields:

- Ordinary — Ordinary (unadjusted) R-squared
- Adjusted — R-squared adjusted for the number of coefficients

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

## **SSE**

Sum of squared errors (residuals).

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## **SSR**

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## **SST**

Total sum of squares, the sum of squared deviations of  $y$  from  $\text{mean}(y)$ .

The Pythagorean theorem implies

# NonLinearModel

---

$$\text{SST} = \text{SSE} + \text{SSR}.$$

## VariableInfo

Dataset array containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"><li>• Continuous variable — Two-element vector <math>[min, max]</math>, the minimum and maximum values</li><li>• Categorical variable — Cell array of distinct variable values</li></ul>
InModel	Logical vector, where true indicates the variable is in the model
IsCategorical	Logical vector, where true indicates a categorical variable

## VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a dataset, this property provides the names of the variables in that dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

## Variables

Dataset array containing the data, both observations and responses, that the fitting function used to construct the fit. If

the fit is based on a dataset array, `Variables` is a copy of that dataset. Otherwise, `Variables` is a dataset created from the input data matrix  $X$  and response vector  $y$ .

## Methods

<code>coefCI</code>	Confidence intervals of coefficient estimates of nonlinear regression model
<code>coefTest</code>	Linear hypothesis test on nonlinear regression model coefficients
<code>disp</code>	Display nonlinear regression model
<code>feval</code>	Evaluate nonlinear regression model prediction
<code>fit</code>	Fit nonlinear regression model
<code>plotDiagnostics</code>	Plot diagnostics of nonlinear regression model
<code>plotResiduals</code>	Plot residuals of nonlinear regression model
<code>plotSlice</code>	Plot of slices through fitted nonlinear regression surface
<code>predict</code>	Predict response of nonlinear regression model
<code>random</code>	Simulate responses for nonlinear regression model

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$  and the Jacobian matrix  $J$ :

# NonLinearModel

---

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here  $f$  is the nonlinear model function, and  $\beta$  is the vector of model coefficients.

The Hat Matrix  $H$  is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$
$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

## Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

The Cook's distance  $D_i$  of observation  $i$  is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- $\hat{y}_j$  is the  $j$ th fitted response value.
- $\hat{y}_{j(i)}$  is the  $j$ th fitted response value, where the fit does not include observation  $i$ .
- $MSE$  is the mean squared error.
- $p$  is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{pMSE} \left( \frac{h_{ii}}{(1-h_{ii})^2} \right),$$

where  $e_i$  is the  $i$ th residual.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Nonlinear Model

Create a nonlinear model for auto mileage based on the carbig data. Predict the mileage of an average car.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
```

# NonLinearModel

---

```
Nonlinear regression model:  
y ~ b1 + b2*x1^b3 + b4*x2^b5
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```
Number of observations: 392, Error degrees of freedom: 387  
Root Mean Squared Error: 3.96  
R-Squared: 0.745, Adjusted R-Squared 0.743  
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using `nanmean`.

```
Xnew = nanmean(X)
```

```
Xnew =  
1.0e+03 *  
0.1051    2.9794
```

```
MPGnew = predict mdl, Xnew)
```

```
MPGnew =  
  
21.8073
```

# prob.NormalDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Normal probability distribution object

**Description** `prob.NormalDistribution` is an object consisting of parameters, a model description, and sample data for a normal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction**

`pd = makedist('Normal')` creates a normal probability distribution object using the default parameter values.

`pd = makedist('Normal','mu',mu,'sigma',sigma)` creates a normal distribution object using the specified parameter values.

## Input Arguments

### **mu - Mean**

0 (default) | scalar value

Mean of the normal distribution, specified as a scalar value.

### **Data Types**

single | double

### **sigma - Standard deviation**

1 (default) | nonnegative scalar value

Standard deviation of the normal distribution, specified as a nonnegative scalar value.

### **Data Types**

single | double

**Properties** `mu`

Mean of the normal distribution, stored as a scalar value.

**Data Types**

single | double

**sigma**

Standard deviation of the normal distribution, stored as a nonnegative scalar value.

**Data Types**

single | double

**DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

**Data Types**

char

**InputData**

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

**Data Types**

single | double

**IsTruncated**

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

**Data Types**

logical

# prob.NormalDistribution

---

## **NumParameters**

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## **Data Types**

single | double

## **ParameterCovariance**

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## **Data Types**

single | double

## **ParameterDescription**

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## **Data Types**

char

## **ParameterIsFixed**

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

## **Data Types**

logical

## **ParameterNames**

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

### Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object

negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Normal Distribution

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

The normal distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Standard deviation	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad -\infty < x < \infty.$$

## Examples

### Create a Normal Distribution Object Using Default Parameters

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

### Create a Normal Distribution Object Using Specified Parameters

Create a normal distribution object by specifying the parameter values.

```
pd = makedist('Normal', 'mu', 75, 'sigma', 10)
```

```
pd =
```

```
NormalDistribution
```

# prob.NormalDistribution

---

```
Normal distribution
  mu = 75
  sigma = 10
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

```
13.4898
```

## Fit a Normal Distribution Object

Load the sample data. Create a vector containing the first column of students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
  mu = 75.0083    [73.4321, 76.5846]
  sigma =  8.7202    [7.7391, 9.98843]
```

## See Also

[makedist](#) | [fitdist](#) | [dfittool](#)

## Concepts

- “Normal Distribution” on page B-110
- Class Attributes
- Property Attributes

**Purpose**

Normal cumulative distribution function

**Syntax**

```
p = normcdf(x)
p = normcdf(x,mu,sigma)
[p,plo,pup] = normcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = normcdf( __ , 'upper' )
```

**Description**

`p = normcdf(x)` returns the standard normal cdf at each value in `x`. The standard normal distribution has parameters `mu = 0` and `sigma = 1`. `x` can be a vector, matrix, or multidimensional array.

`p = normcdf(x,mu,sigma)` returns the normal cdf at each value in `x` using the specified values for the mean `mu` and standard deviation `sigma`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive.

`[p,plo,pup] = normcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies  $100(1 - \alpha)\%$  confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = normcdf( __ , 'upper' )` returns the complement of the normal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use 'upper' with any of the previous syntaxes.

The function `normcdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{X - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller

# normcdf

---

samples other methods of computing the confidence bounds might be more accurate.

The normal cdf is

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt$$

The result,  $p$ , is the probability that a single observation from a normal distribution with parameters  $\mu$  and  $\sigma$  will fall in the interval  $(-\infty, x]$ .

The *standard normal* distribution has  $\mu = 0$  and  $\sigma = 1$ .

## Examples

### Compute Normal Distribution cdf

What is the probability that an observation from a standard normal distribution will fall on the interval  $[-1, 1]$ ?

```
p = normcdf([-1 1]);  
p(2) - p(1)
```

```
ans =  
    0.6827
```

More generally, about 68% of the observations from a normal distribution fall within one standard deviation,  $\sigma$ , of the mean,  $\mu$ .

## How To

- “Normal Distribution” on page B-110

**Purpose**

Normal parameter estimates

**Syntax**

```
[muhat,sigmahat] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)
[...] = normfit(data,alpha,censoring)
[...] = normfit(data,alpha,censoring,freq)
[...] = normfit(data,alpha,censoring,freq,options)
```

**Description**

`[muhat,sigmahat] = normfit(data)` returns an estimate of the mean  $\mu$  in `muhat`, and an estimate of the standard deviation  $\sigma$  in `sigmahat`, of the normal distribution given the data in `data`.

`[muhat,sigmahat,muci,sigmaci] = normfit(data)` returns 95% confidence intervals for the parameter estimates on the mean and standard deviation in the arrays `muci` and `sigmaci`, respectively. The first row of `muci` contains the lower bounds of the confidence intervals for  $\mu$  the second row contains the upper bounds. The first row of `sigmaci` contains the lower bounds of the confidence intervals for  $\sigma$ , and the second row contains the upper bounds.

`[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)` returns  $100(1 - \alpha)$  % confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = normfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = normfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

# normfit

---

[...] = normfit(data,alpha,censoring,freq,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The normal fit function accepts an options structure which you can create using the function statset. Enter statset('normfit') to see the names and default values of the parameters that normfit accepts in the options structure. See the reference page for statset for more information about these options.

---

**Note** With no censoring, normfit computes muhat using the sample mean and sigmahat using the square root of the unbiased estimator of the variance. With censoring, both muhat and sigmahat are the maximum likelihood estimates.

---

## Examples

In this example the data is a two-column random normal matrix. Both columns have  $\mu = 10$  and  $\sigma = 2$ . Note that the confidence intervals below contain the "true values."

```
data = normrnd(10,2,100,2);
[mu,sigma,muci,sigmaci] = normfit(data)
mu =
    10.1455    10.0527
sigma =
    1.9072    2.1256
muci =
    9.7652    9.6288
    10.5258    10.4766
sigmaci =
    1.6745    1.8663
    2.2155    2.4693
```

## See Also

mle | normlike | normpdf | normcdf | norminv | normstat | normrnd

## How To

- “Normal Distribution” on page B-110

**Purpose**

Normal inverse cumulative distribution function

**Syntax**

```
X = norminv(P,mu,sigma)
[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)
```

**Description**

`X = norminv(P,mu,sigma)` computes the inverse of the normal cdf using the corresponding mean `mu` and standard deviation `sigma` at the corresponding probabilities in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive, and the values in `P` must lie in the interval `[0 1]`.

`[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)` produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies `100(1 - alpha)%` confidence bounds. The default value of `alpha` is `0.05`. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `norminv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where  $q$  is the  $P$ th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds may be more accurate.

The normal inverse function is defined in terms of the normal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x : F(x | \mu, \sigma) = p\}$$

where

# norminv

---

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt$$

The result,  $x$ , is the solution of the integral equation above where you supply the desired probability,  $p$ .

## Examples

Find an interval that contains 95% of the values from a standard normal distribution.

```
x = norminv([0.025 0.975],0,1)
x =
-1.9600  1.9600
```

Note that the interval  $x$  is not the only such interval, but it is the shortest.

```
x1 = norminv([0.01 0.96],0,1)
x1 =
-2.3263  1.7507
```

The interval  $x1$  also contains 95% of the probability, but it is longer than  $x$ .

<b>How To</b>	<ul style="list-style-type: none"><li>• “Normal Distribution” on page B-110</li></ul>

# normpdf

---

**Purpose** Normal probability density function

**Syntax**  
`Y = normpdf(X,mu,sigma)`  
`Y = normpdf(X)`  
`Y = normpdf(X,mu)`

**Description** `Y = normpdf(X,mu,sigma)` computes the pdf at each of the values in `X` using the normal distribution with mean `mu` and standard deviation `sigma`. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive.

The normal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

The *likelihood function* is the pdf viewed as a function of the parameters. Maximum likelihood estimators (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of `x`.

The *standard normal* distribution has  $\mu = 0$  and  $\sigma = 1$ .

If `x` is standard normal, then `xσ + μ` is also normal with mean  $\mu$  and standard deviation  $\sigma$ . Conversely, if `y` is normal with mean  $\mu$  and standard deviation  $\sigma$ , then `x = (y-μ) / σ` is standard normal.

`Y = normpdf(X)` uses the standard normal distribution (`mu = 0`, `sigma = 1`).

`Y = normpdf(X,mu)` uses the normal distribution with unit standard deviation (`sigma = 1`).

## Examples

```
mu = [0:0.1:2];  
[y i] = max(normpdf(1.5,mu,1));  
MLE = mu(i)  
MLE =
```

1.5000

pdf | normcdf | norminv | normstat | normfit | normlike | normrnd  
| mvnpdf

**How To**

- “Normal Distribution” on page B-110

# normplot

---

**Purpose** Normal probability plot

**Syntax** `h = normplot(X)`

**Description** `h = normplot(X)` displays a normal probability plot of the data in `X`. For matrix `X`, `normplot` displays a line for each column of `X`. `h` is a handle to the plotted lines.

The plot has the sample data displayed with the plot symbol '+' . Superimposed on the plot is a line joining the first and third quartiles of each column of `X` (a robust linear fit of the sample order statistics.) This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

The purpose of a normal probability plot is to graphically assess whether the data in `X` could come from a normal distribution. If the data are normal the plot will be linear. Other distribution types will introduce curvature in the plot. `normplot` uses midpoint probability plotting positions. Use `probplot` when the data included censored observations.

## **Examples** **Generate a Normal Probability Plot**

This example shows how to generate a normal probability plot using sample data.

Generate random sample data from a normal distribution with  $\mu = 10$  and  $\sigma = 1$ .

```
rng('default'); % For reproducibility
x = normrnd(10,1,25,1);
```

Create a normal probability plot of the sample data.

```
normplot(x)
```

The plot indicates that the data follows a normal distribution.

### How To

- “Normal Distribution” on page B-110

# normrnd

---

**Purpose** Normal random numbers

**Syntax**  
`R = normrnd(mu,sigma)`  
`R = normrnd(mu,sigma,m,n,...)`  
`R = normrnd(mu,sigma,[m,n,...])`

**Description** `R = normrnd(mu,sigma)` generates random numbers from the normal distribution with mean parameter `mu` and standard deviation parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = normrnd(mu,sigma,m,n,...)` or `R = normrnd(mu,sigma,[m,n,...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

**Examples**

```
n1 = normrnd(1:6,1./(1:6))
n1 =
    2.1650    2.3134    3.0250    4.0879    4.8607    6.2827

n2 = normrnd(0,1,[1 5])
n2 =
    0.0591    1.7971    0.2641    0.8717   -1.4462

n3 = normrnd([1 2 3;4 5 6],0.1,2,3)
n3 =
    0.9299    1.9361    2.9640
    4.1246    5.0577    5.9864
```

**See Also** `random` | `normpdf` | `normcdf` | `norminv` | `normstat` | `normfit` | `normlike` | `mvnrnd` | `lognrnd`

**How To** • “Normal Distribution” on page B-110

**Purpose** Normal density plot between specifications

**Syntax**

```
normspec(specs)
normspec(specs,mu,sigma)
normspec(specs,mu,sigma,region)
p = normspec(...)
[p,h] = normspec(...)
```

**Description**

`normspec(specs)` plots the standard normal density, shading the portion inside the specification limits given by the two-element vector `specs`. Set `specs(1)` to `-Inf` if there is no lower limit; set `specs(2)` to `Inf` if there is no upper limit.

`normspec(specs,mu,sigma)` shades the portion inside the specification limits of a normal density with parameters `mu` and `sigma`. The defaults are `mu = 0` and `sigma = 1`.

`normspec(specs,mu,sigma,region)` shades the *region* either 'inside' or 'outside' the specification limits. The default is 'inside'.

`p = normspec(...)` also returns the probability, `p`, of the shaded area.

`[p,h] = normspec(...)` also returns a handle `h` to the line objects.

**Examples**

A production process fills cans of paint. The average amount of paint in any can is 1 gallon, but variability in the process produces a standard deviation of 2 ounces (2/128 gallons). What is the probability that cans will be filled under specification by 3 or more ounces?

```
p = normspec([1-3/128,Inf],1,2/128,'outside')
p =
    0.0668
```

## See Also

`capaplot` | `histfit`

## How To

- “Normal Distribution” on page B-110

**Purpose** Normal mean and variance

**Syntax** `[M,V] = normstat(mu,sigma)`

**Description** `[M,V] = normstat(mu,sigma)` returns the mean of and variance for the normal distribution using the corresponding mean `mu` and standard deviation `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

The mean of the normal distribution with parameters  $\mu$  and  $\sigma$  is  $\mu$ , and the variance is  $\sigma^2$ .

**Examples**

```
n = 1:5;
[m,v] = normstat(n'*n,n'*n)
m =
     1     2     3     4     5
     2     4     6     8    10

**How To** • “Normal Distribution” on page B-110

# piecewisedistribution.nsegments

---

**Purpose**            Number of segments

**Syntax**            `n = nsegments(obj)`

**Description**        `n = nsegments(obj)` returns the number of segments `n` in the piecewise distribution object `obj`.

**Examples**            Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);  
obj = paretotails(t,0.1,0.9);
```

```
n = nsegments(obj)  
n =  
    3
```

**See Also**            `paretotails` | `boundary` | `segment`

<b>Purpose</b>	Number of decision trees in ensemble
<b>Description</b>	The NTrees property is a scalar equal to the number of decision trees in the ensemble.

# ProbDistParametric.NumParams property

---

<b>Purpose</b>	Read-only value specifying number of parameters of ProbDistParametric object
<b>Description</b>	NumParams is a read-only property of the ProbDistParametric class. NumParams is a value specifying the number of parameters of a distribution represented by a ProbDistParametric object.
<b>Values</b>	This value is an integer that counts both the specified parameters and parameters that are fit to the data. Use this information to view and compare the number of parameters supplied to create distributions.

**Purpose** Number of elements in dataset array

**Syntax** `n = numel(A)`  
`n = numel(A, varargin)`

**Description** `n = numel(A)` returns 1. To find the number of elements, `n`, in the dataset array `A`, use `prod(size(A))` or `numel(A, ':', ':')`.  
`n = numel(A, varargin)` returns the number of subscripted elements, `n`, in `A(index1, index2, ..., indexn)`, where `varargin` is a cell array whose elements are `index1, index2, ..., indexn`.

**See Also** `length` | `size`

# categorical.numel

classregtree

# cvpartition.NumTestSets property

---

**Purpose**

Number of test sets

**Description**

Value is the number of folds in partitions of type 'kfold' and 'leaveout'.

Value is 1 in partitions of type 'holdout' and 'resubstitution'.

# TreeBagger.NVarToSample property

---

**Purpose** Number of variables for random feature selection

**Description** The `NVarToSample` property specifies the number of predictor or feature variables to select at random for each decision split. By default, it is set to the square root of the total number of variables for classification and one third of the total number of variables for regression. Setting this argument to any valid value except 'all' invokes Breiman's "random forest" algorithm.

**See Also** `classregtree`

# dataset.ObsNames property

---

**Purpose**

Cell array of nonempty, distinct strings giving names of observations in data set

**Description**

A cell array of nonempty, distinct strings giving the names of the observations in the data set. This property may be empty, but if not empty, the number of strings must equal the number of observations.

# optimalleaforder

---

**Purpose** Optimal leaf ordering for hierarchical clustering

**Syntax** `leafOrder = optimalleaforder(tree,D)`  
`leafOrder = optimalleaforder(tree,D,Name,Value)`

**Description** `leafOrder = optimalleaforder(tree,D)` returns an optimal leaf ordering for the hierarchical binary cluster tree, `tree`, using the distances, `D`. An optimal leaf ordering of a binary tree maximizes the sum of the similarities between adjacent leaves by flipping tree branches without dividing the clusters.

`leafOrder = optimalleaforder(tree,D,Name,Value)` returns the optimal leaf ordering using one or more name-value pair arguments.

## Input Arguments

### **tree - Hierarchical binary cluster tree**

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an  $(M - 1)$ -by-3 matrix that you generate using `linkage`, where  $M$  is the number of leaves.

### **D - Distances**

matrix | vector

Distances for determining similarities between leaves, specified as a matrix or vector of distances. For example, you can generate distances using `pdist`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Criteria', 'group', 'Transformation', 'inverse'` specifies that the sum of similarities be maximized between every leaf

and all other leaves in adjacent clusters, using an inverse similarity transformation.

## 'Criteria' - Optimization criterion

'adjacent' (default) | 'group'

Optimization criterion for determining an optimal leaf ordering, specified as the comma-separated pair consisting of 'criteria' and one of these strings:

'adjacent'	Maximize the sum of similarities between adjacent leaves.
'group'	Maximize the sum of similarities between every leaf and all other leaves in the adjacent clusters at the same level of the dendrogram.

**Example:** 'Criteria', 'group'

## Data Types

char

## 'Transformation' - Method for transforming distances to similarities

'linear' (default) | 'inverse' | function handle

Method for transforming distances to similarities, specified as the comma-separated pair consisting of 'Transformation' and one of 'linear', 'inverse', or a function handle.

Let  $d_{i,j}$  and  $Sim_{i,j}$  denote the distance and similarity between leaves  $i$  and  $j$ , respectively. The included similarity transformations are:

'linear'	$Sim_{i,j} = \max_{i,j} (d_{i,j}) - d_{i,j}$
'inverse'	$Sim_{i,j} = 1/d_{i,j}$

To use a custom transformation function, specify a handle to a function that accepts a matrix of distances, D, and returns a matrix of similarities, S. The function should be monotonic decreasing in the

# optimalleaforder

---

range of distance values.  $S$  must have the same size as  $D$ , with  $S(i, j)$  being the similarity computed based on  $D(i, j)$ .

**Example:** 'Transformation',@myTransform

## Data Types

char | function\_handle

## Output Arguments

### leafOrder - Optimal leaf order

vector

Optimal leaf order, returned as a length- $M$  vector, where  $M$  is the number of leaves. `leafOrder` is a permutation of the vector  $1:M$ , giving an optimal leaf ordering based on the specified distances and similarity transformation.

## Examples

### Plot Dendrogram With Optimal Leaf Order

Create a hierarchical binary cluster tree using `linkage`. Then, compare the dendrogram plot with the default ordering to a dendrogram with an optimal leaf ordering.

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree. Use the distances and clustering tree to determine an optimal leaf order.

```
D = pdist(X);
tree = linkage(D, 'average');
leafOrder = optimalleaforder(tree,D);
```

Plot the dendrogram with the default ordering and the dendrogram with the optimal leaf ordering.

```
figure()
subplot(2,1,1)
dendrogram(tree)
```

```
title('Default Leaf Order')  
  
subplot(2,1,2)  
dendrogram(tree,'reorder',leafOrder)  
title('Optimal Leaf Order')
```

The order of the leaves in the bottom figure corresponds to the elements in `leafOrder`.

`leafOrder`

# optimalleaforder

---

```
leafOrder =  
    1    4    9   10    2    5    8    3    7    6
```

## Optimal Leaf Order Using Inverse Distance Similarity

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree.

```
D = pdist(X);  
tree = linkage(D,'average');
```

Use the inverse distance similarity transformation to determine an optimal leaf order.

```
leafOrder = optimalleaforder(tree,D,'Transformation','inverse')
```

```
leafOrder =  
    1    4    9   10    2    5    8    3    7    6
```

**Purpose** Out-of-bag classification edge

**Syntax**  
edge = oobEdge(ens)  
edge = oobEdge(ens,Name,Value)

**Description**  
edge = oobEdge(ens) returns out-of-bag classification edge for ens.  
edge = oobEdge(ens,Name,Value) computes classification edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

**Input Arguments**  
**ens**  
A classification bagged ensemble, constructed with fitensemble.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

#### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to ens.NTrained. oobEdge uses only these learners for calculating loss.

**Default:** 1:NTrained

#### **'mode'**

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.

# ClassificationBaggedEnsemble.oobEdge

---

- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

### edge

Classification edge, a weighted average of the classification margin.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed

prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Examples

Find the out-of-bag edge for a bagged ensemble from the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
edge = oobEdge(ens)

edge =
    0.8730
```

## See Also

[oobMargin](#) | [oobPredict](#) | [oobLoss](#)

# TreeBagger.oobError

---

**Purpose** Out-of-bag error

**Syntax**  
`err = oobError(B)`  
`err = oobError(B, 'param1', val1, 'param2', val2, ...)`

**Description** `err = oobError(B)` computes the misclassification probability (for classification trees) or mean squared error (for regression trees) for out-of-bag observations in the training data, using the trained bagger `B`. `err` is a vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`err = oobError(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

`'mode'` String indicating how `oobError` computes errors. If set to `'cumulative'` (default), the method computes cumulative errors and `err` is a vector of length `NTrees`, where the first element gives error from `trees(1)`, second element gives error from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `err` is a vector of length `NTrees`, where each element is an error from each tree in the ensemble. If set to `'ensemble'`, `err` is a scalar showing the cumulative error for the entire ensemble.

`'trees'` Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes, where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the

first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobError` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

## See Also

`CompactTreeBagger.error`

# TreeBagger.OOBIndices property

---

**Purpose** Indicator matrix for out-of-bag observations

**Description** The `OOBIndices` property is a logical array of size `Nobs-by-NTrees` where `Nobs` is the number of observations in the training data and `NTrees` is the number of trees in the ensemble. The  $(I, J)$  element is true if observation `I` is out-of-bag for tree `J` and false otherwise. In other words, a true value means observation `I` was not selected for the training data used to grow tree `J`.

**See Also** `classregtree`

# TreeBagger.OOBInstanceWeight property

---

**Purpose**

Count of out-of-bag trees for each observation

**Description**

The `OOBInstanceWeight` property is a numeric array of size `Nobs-by-1` containing the number of trees used for computing out-of-bag response for each observation. `Nobs` is the number of observations in the training data used to create the ensemble.

# ClassificationBaggedEnsemble.oobLoss

---

**Purpose** Out-of-bag classification error

**Syntax**  
L = oobloss(ens)  
L = oobloss(ens,Name,Value)

**Description** L = oobloss(ens) returns the classification error for ens computed for out-of-bag data.

L = oobloss(ens,Name,Value) computes error with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

## Input Arguments

**ens**  
A classification bagged ensemble, constructed with fitensemble.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

#### 'learners'

Indices of weak learners in the ensemble ranging from 1 to NTrained. oobLoss uses only these learners for calculating loss.

**Default:** 1:NTrained

#### 'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-2306
- 'classiferror' — Fraction of misclassified data

- 'exponential' — See “Loss Functions” on page 21-2306

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2306.

**Default:** 'classiferror'

## 'mode'

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

**L**

Classification error of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

## Definitions

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

# ClassificationBaggedEnsemble.oobLoss

---

Drawing  $N$  out of  $N$  observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by  $w$ .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of  $X$ .
- $K$  is the number of classes in `tree`, represented in `tree.ClassNames`.
- $C$  is an  $N$ -by- $K$  logical matrix, with one true per row for the true class. The index for each class is its position in `tree.ClassNames`.

# ClassificationBaggedEnsemble.oobLoss

---

- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. The default `'classiferror'` cost function uses a cost of 0 for correct classification, and 1 for misclassification. In other words, `'classiferror'` uses  $COST = \text{ones}(K) - \text{eye}(K)$ .
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Find the out-of-bag error for a bagged ensemble from the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
L = oobLoss(ens)

L =
    0.0467
```

## See Also

`loss` | `oobEdge` | `oobMargin` | `oobPredict`

# RegressionBaggedEnsemble.oobLoss

---

**Purpose** Out-of-bag regression error

**Syntax**  
L = oobLoss(ens)  
L = oobLoss(ens,Name,Value)

**Description** L = oobLoss(ens) returns the mean squared error for ens computed for out-of-bag data.

L = oobLoss(ens,Name,Value) computes error with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

## Input Arguments

**ens**  
A regression bagged ensemble, constructed with fitensemble.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

### 'learners'

Indices of weak learners in the ensemble ranging from 1 to NTrained. oobLoss uses only these learners for calculating loss.

**Default:** 1:NTrained

### 'lossfun'

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle fun, oobLoss calls it as

FUN(Y,Yfit,W)

where  $Y$ ,  $Y_{fit}$ , and  $W$  are numeric vectors of the same length.  $Y$  is the observed response,  $Y_{fit}$  is the predicted response, and  $W$  is the observation weights.

**Default:** 'mse'

## 'mode'

String representing the meaning of the output  $L$ :

- 'ensemble' —  $L$  is a scalar value, the loss for the entire ensemble.
- 'individual' —  $L$  is a vector with one element per trained learner.
- 'cumulative' —  $L$  is a vector in which element  $J$  is obtained by using learners  $1:J$  from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

### $L$

Mean squared error of the out-of-bag observations, a scalar.  $L$  can be a vector, or can represent a different quantity, depending on the name-value settings.

## Definitions

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting  $N$  observations out of  $N$  with replacement, where  $N$  is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing  $N$  out of  $N$  observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag"

# RegressionBaggedEnsemble.oobLoss

---

observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Examples

Compute the out-of-bag error for the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
L = oobLoss(ens)

L =
    17.0665
```

`oobPredict` | `oobLoss` | `oobEdge` | `margin`

## Purpose

Out-of-bag margins

## Syntax

```
mar = oobMargin(B)
mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)
```

## Description

`mar = oobMargin(B)` computes an `Nobs`-by-`NTrees` matrix of classification margins for out-of-bag observations in the training data, using the trained bagger `B`.

`mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

'mode'	String indicating how <code>oobMargin</code> computes errors. If set to 'cumulative' (default), the method computes cumulative margins and <code>mar</code> is an <code>Nobs</code> -by- <code>NTrees</code> matrix, where the first column gives margins from <code>trees(1)</code> , second column gives margins from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is an <code>Nobs</code> -by- <code>NTrees</code> matrix, where each column gives margins from each tree in the ensemble. If set to 'ensemble', <code>mar</code> is a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
'trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns an <code>Nobs</code> -by- <code>NTrees</code> matrix for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a single column for 'ensemble' mode. For example, in the 'cumulative' mode, the first column gives

# TreeBagger.oobMargin

---

margins from `trees(1)`, the second column gives margins from `trees(1:2)` etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

## See Also

`CompactTreeBagger.margin`

## Purpose

Out-of-bag mean margins

## Syntax

```
mar = oobMeanMargin(B)
mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)
```

## Description

`mar = oobMeanMargin(B)` computes average classification margins for out-of-bag observations in the training data, using the trained bagger `B`. `oobMeanMargin` averages the margins over all out-of-bag observations. `mar` is a row-vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

- 'mode' String indicating how `oobMargin` computes errors. If set to 'cumulative' (default), is a vector of length `NTrees` where the first element gives mean margin from `trees(1)`, second column gives mean margins from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to 'individual', `mar` is a vector of length `NTrees`, where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', `mar` is a scalar showing the cumulative mean margin for the entire ensemble.
- 'trees' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length `NTrees` for 'cumulative' and 'individual' modes, where `NTrees` is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.
- 'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobMeanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

# TreeBagger.OOBPermutedVarCountRaiseMargin property

---

**Purpose**

Variable importance for raising margin

**Description**

The `OOBPermutedVarCountRaiseMargin` property is a numeric array of size 1-by-Nvars containing a measure of variable importance for each predictor. For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

# TreeBagger.OOBPermutedVarDeltaError property

---

**Purpose** Variable importance for prediction error

**Description** The OOBPermutedVarDeltaError property is a numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

# TreeBagger.OOBPermutedVarDeltaMeanMargin property

---

**Purpose** Variable importance for classification margin

**Description** The `OOBPermutedVarDeltaMeanMargin` property is a numeric array of size 1-by-Nvars containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

# ClassificationBaggedEnsemble.oobPredict

---

<b>Purpose</b>	Predict out-of-bag response of ensemble
<b>Syntax</b>	<pre>[label,score] = oobPredict(ens) [label,score] = oobPredict(ens,Name,Value)</pre>
<b>Description</b>	<p>[label,score] = oobPredict(ens) returns class labels and scores for ens for out-of-bag data.</p> <p>[label,score] = oobPredict(ens,Name,Value) computes labels and scores with additional options specified by one or more Name,Value pair arguments.</p>

<b>Output Arguments</b>	<p><b>label</b></p> <p>Classification labels of the same data type as the training data Y. There are N elements or rows, where N is the number of training observations. The label is the class with the highest score. In case of a tie, the label is earliest in ens.ClassNames.</p> <p><b>score</b></p>

An N-by-K numeric matrix for N observations and K classes. A high score indicates that an observation is likely to come from this class. Scores are in the range 0 to 1.

## Definitions

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

# ClassificationBaggedEnsemble.oobPredict

---

## Examples

Find the out-of-bag predictions and scores for the Fisher iris data. Find the scores in the range (0.2,0.8); these are the scores where there is notable uncertainty in the resulting classifications.

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
[label score] = oobPredict(ens);
unsure = ( (score > .2) & (score < .8));
sum(sum(unsure)) % How many uncertain predictions?

ans =
    16
```

## See Also

[oobMargin](#) | [oobPredict](#) | [oobLoss](#) | [oobEdge](#) | [predict](#)

**Purpose** Predict out-of-bag response of ensemble

**Syntax**  
`Yfit = oobPredict(ens)`  
`Yfit = oobPredict(ens,Name,Value)`

**Description** `Yfit = oobPredict(ens)` returns the predicted responses for the out-of-bag data in `ens`.

`Yfit = oobPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ens**

A regression bagged ensemble, constructed with `fitensemble`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'learners'

Indices of weak learners in the ensemble ranging from 1 to `NTrained`. `oobLoss` uses only these learners for calculating loss.

**Default:** `1:NTrained`

## Output Arguments

**Yfit**

A vector of predicted responses for out-of-bag data. `Yfit` has `size(ens.X,1)` elements.

You can find the indices of out-of-bag observations for weak learner `L` with the command

`~ens.UseObsForLearner(:,L)`

# RegressionBaggedEnsemble.oobPredict

---

## Definitions

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting  $N$  observations out of  $N$  with replacement, where  $N$  is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing  $N$  out of  $N$  observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Examples

Compute out-of-bag predictions for the `carsmall` data. Look at the first three terms of the fit:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
Yfit = oobPredict(ens);
Yfit(1:3) % first three terms

ans =
    15.7964
    14.7162
    14.8062
```

## See Also

`oobLoss` | `predict`

**Purpose** Ensemble predictions for out-of-bag observations

**Syntax** `Y = oobPredict(B)`  
`Y = oobPredict(B, 'param1', val1, 'param2', val2, ...)`

**Description** `Y = oobPredict(B)` computes predicted responses using the trained bagger `B` for out-of-bag observations in the training data. The output has one prediction for each observation in the training data. The returned `Y` is a cell array of strings for classification and a numeric array for regression.

`Y = oobPredict(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

`'trees'` Array of tree indices to use for computation of responses. Default is `'all'`.

`'treeweights'` Array of `N`Tree weights for weighting votes from the specified trees.

# ordinal

---

**Superclasses**    categorical

**Purpose**    Arrays for ordinal categorical data

**Description**    Ordinal arrays are used to store discrete values that have an ordering but are not numeric. An ordinal array provides efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values. Ordinal arrays are often used as grouping variables.

Like a numerical array, an ordinal array can have any size or dimension. You can subscript, concatenate, reshape, sort, etc. ordinal arrays, much like ordinary numeric arrays. You can make comparisons between elements of two ordinal arrays, or between an ordinal array and a single string representing a ordinal value.

**Construction**    Use the `ordinal` constructor to create an ordinal array from a numeric, logical, or character array, or from a cell array of strings.

<code>ordinal</code>	Construct ordinal categorical array
----------------------	-------------------------------------

**Methods**    Each ordinal array carries along a list of possible values that it can store, known as its levels. The list is created when you create an ordinal array, and you can access it using the `getlevels` method, or modify it using the `addlevels`, `mergelevels`, or `droplevels` methods. Assignment to the array will also add new levels automatically if the values assigned are not already levels of the array. The ordering on values stored in an ordinal array is defined by the order of the list of levels. You can change that order using the `reorderlevels` method.

The following table lists operations available for ordinal arrays.

sort	Sort elements of ordinal array
sortrows	Sort rows
summary	Summary statistics for ordinal array

### Inherited Methods

Methods in the following table are inherited from categorical.

addlevels	Add levels to categorical array
cat	Concatenate categorical arrays
cellstr	Convert categorical array to cell array of strings
char	Convert categorical array to character array
circshift	Shift categorical array circularly
ctranspose	Transpose categorical matrix
disp	Display categorical array
display	Display categorical array
double	Convert categorical array to double array
droplevels	Drop levels
end	Last index in indexing expression for categorical array
flipdim	Flip categorical array along specified dimension
fliplr	Flip categorical matrix in left/right direction
flipud	Flip categorical matrix in up/down direction

<code>getlabels</code>	Access categorical array labels
<code>getlevels</code>	Get categorical array levels
<code>hist</code>	Plot histogram of categorical data
<code>horzcat</code>	Horizontal concatenation for categorical arrays
<code>int16</code>	Convert categorical array to signed 16-bit integer array
<code>int32</code>	Convert categorical array to signed 32-bit integer array
<code>int64</code>	Convert categorical array to signed 64-bit integer array
<code>int8</code>	Convert categorical array to signed 8-bit integer array
<code>intersect</code>	Set intersection for categorical arrays
<code>ipermute</code>	Inverse permute dimensions of categorical array
<code>isempty</code>	True for empty categorical array
<code>isequal</code>	True if categorical arrays are equal
<code>islevel</code>	Test for levels
<code>ismember</code>	True for elements of categorical array in set
<code>isscalar</code>	True if categorical array is scalar
<code>isundefined</code>	Test for undefined elements
<code>isvector</code>	True if categorical array is vector
<code>length</code>	Length of categorical array
<code>levelcounts</code>	Element counts by level

---

<code>mergelevels</code>	Merge levels
<code>ndims</code>	Number of dimensions of categorical array
<code>numel</code>	Number of elements in categorical array
<code>permute</code>	Permute dimensions of categorical array
<code>reorderlevels</code>	Reorder levels
<code>repmat</code>	Replicate and tile categorical array
<code>reshape</code>	Resize categorical array
<code>rot90</code>	Rotate categorical matrix 90 degrees
<code>setdiff</code>	Set difference for categorical arrays
<code>setlabels</code>	Label levels
<code>setxor</code>	Set exclusive-or for categorical arrays
<code>shiftdim</code>	Shift dimensions of categorical array
<code>single</code>	Convert categorical array to single array
<code>size</code>	Size of categorical array
<code>squeeze</code>	Squeeze singleton dimensions from categorical array
<code>subsasgn</code>	Subscripted assignment for categorical array
<code>subsindex</code>	Subscript index for categorical array

# ordinal

---

suboref	Subscripted reference for categorical array
times	Product of categorical arrays
transpose	Transpose categorical matrix
uint16	Convert categorical array to unsigned 16-bit integers
uint32	Convert categorical array to unsigned 32-bit integers
uint64	Convert categorical array to unsigned 64-bit integers
uint8	Convert categorical array to unsigned 8-bit integers
union	Set union for categorical arrays
unique	Unique values in categorical array
vertcat	Vertical concatenation for categorical arrays

## Properties

## Inherited Properties

Properties in the following table are inherited from `categorical`.

labels	Text labels for levels
undeflabel	Text label for undefined levels

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Create and Compare Ordinal Arrays

Create an ordinal array from integer data.

```
quality = ordinal([1 2 3; 3 2 1; 2 1 3],{'low' 'medium' 'high'})
```

```
quality =
```

low	medium	high
high	medium	low
medium	low	high

Identify the elements in `quality` that are members of a level that is greater than or equal to `'medium'`.

```
quality >= 'medium'
```

```
ans =
```

0	1	1
1	1	0
1	0	1

A value of 1 in the resulting array `ans` indicates that the corresponding element of `quality` is a member of a level that is greater than or equal to `'medium'`.

Identify the elements of `quality` that are members of either `'low'` or `'high'`.

```
ismember(quality,{'low' 'high'})
```

```
ans =
```

1	0	1
1	0	1
0	1	1

A value of 1 in the resulting array `ans` indicates that the corresponding element of `quality` is a member of either `'low'` or `'high'`.

Create a second nominal array `quality2` by flipping `quality` from left to right.

# ordinal

---

```
quality2 = fliplr(quality)
```

```
quality2 =
```

```
      high      medium      low
low      medium      high
high      low      medium
```

Compare the elements of `quality` and `quality2`.

```
quality == quality2
```

```
ans =
```

```
      0      1      0
      0      1      0
      0      1      0
```

A value of 1 in the resulting array `ans` indicates that the corresponding element of `quality` is a member of the same level as the corresponding element of `quality2`.

## See Also

`histc` | `nominal`

**Purpose**

Construct ordinal categorical array

**Syntax**

```
B = ordinal(A)
B = ordinal(A,labels)
B = ordinal(A,labels,levels)
B = ordinal(A,labels,[],edges)
```

**Description**

`B = ordinal(A)` creates an ordinal array `B` from the array `A`. `A` can be numeric, logical, character, categorical, or a cell array of strings. `ordinal` creates the levels of `B` from the sorted unique values in `A`, and creates default labels for them.

`B = ordinal(A,labels)` labels the levels in `B` using the character array or cell array of strings `labels`. `ordinal` assigns labels to levels in `B` in order according to the sorted unique values in `A`.

`B = ordinal(A,labels,levels)` creates an ordinal array with possible levels defined by `levels`. `levels` is a vector whose values can be compared to those in `A` using the equality operator. `ordinal` assigns labels to each level from the corresponding elements of `labels`. If `A` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined. Use `[]` for `labels` to allow `ordinal` to create default labels.

`B = ordinal(A,labels,[],edges)` creates an ordinal array by binning the numeric array `A`, with bin edges given by the numeric vector `edges`. The uppermost bin includes values equal to the right-most edge. `ordinal` assigns labels to each level in `B` from the corresponding elements of `labels`. `edges` must have one more element than `labels`.

By default, an element of `B` is undefined if the corresponding element of `A` is NaN (when `A` is numeric), an empty string (when `A` is character), or undefined (when `A` is categorical). `ordinal` treats such elements as “undefined” or “missing” and does not include entries for them among the possible levels for `B`. To create an explicit level for such elements instead of treating them as undefined, you must use the `levels` input, and include NaN, the empty string, or an undefined element.

# ordinal

---

You may include duplicate labels in `labels` in order to merge multiple values in A into a single level in B.

## Examples **Create and Label Ordinal Arrays**

Create an ordinal array from integer data, and provide explicit labels.

```
quality1 = ordinal([1 2 3; 3 2 1; 2 1 3],...  
                  {'low' 'medium' 'high'})
```

```
quality1 =
```

```
      low      medium      high  
high      medium      low  
medium      low      high
```

Create an ordinal array from integer data, and provide both explicit labels and an explicit order.

```
quality2 = ordinal([1 2 3; 3 2 1; 2 1 3],...  
                  {'high' 'medium' 'low'},[3 2 1])
```

```
quality2 =
```

```
      low      medium      high  
high      medium      low  
medium      low      high
```

Create an ordinal array by binning floating point values.

```
size = ordinal(rand(5,2),{'small' 'medium' 'large'},...  
                [],[0 1/3 2/3 1])
```

```
size =
```

```
      small      small  
      large      medium  
      large      large
```

```
    medium    large
    large     large
```

## Create Ordinal Array Using Sample Data

Load the sample data.

```
load fisheriris;
```

Create an ordinal array from the measurements in Fisher's iris data, ignoring decimal lengths.

```
m = floor(min(meas(:)));
M = floor(max(meas(:)));
labels = num2str((m:M)');
edges = m:M+1;
cms = ordinal(meas,labels,[],edges);
```

Display the first five rows of `meas`, which contains actual flower measurements.

```
meas(1:5,:)
```

```
ans =
```

```
    5.1000    3.5000    1.4000    0.2000
    4.9000    3.0000    1.4000    0.2000
    4.7000    3.2000    1.3000    0.2000
    4.6000    3.1000    1.5000    0.2000
    5.0000    3.6000    1.4000    0.2000
```

Display the first five rows of the ordinal array `cms`.

```
cms(1:5,:)
```

```
ans =
```

```
    5     3     1     0
    4     3     1     0
```

# ordinal

---

```
4     3     1     0
4     3     1     0
5     3     1     0
```

## Create Groups in Ordinal Array

Load the sample data.

```
load hospital;
```

Create an age group ordinal array from the patients' age data.

```
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
AgeGroup = ordinal(hospital.Age, labels, [], edges);
```

Display the first five elements of the ordinal array AgeGroup.

```
AgeGroup(1:5)
```

```
ans =
```

```
30s
40s
30s
40s
40s
```

## Purpose

Outlier measure for data

## Syntax

```
out = outlierMeasure(B,X)
out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)
```

## Description

`out = outlierMeasure(B,X)` computes outlier measures for predictors `X` using trees in the ensemble `B`. The method computes the outlier measure for a given observation by taking an inverse of the average squared proximity between this observation and other observations. `outlierMeasure` then normalizes these outlier measures by subtracting the median of their distribution, taking the absolute value of this difference, and dividing by the median absolute deviation. A high value of the outlier measure indicates that this observation is an outlier.

You can supply the proximity matrix directly by using the `'data'` parameter.

`out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

<code>'data'</code>	Flag indicating how to treat the <code>X</code> input argument. If set to <code>'predictors'</code> (default), the method assumes <code>X</code> is a matrix of predictors and uses it for computation of the proximity matrix. If set to <code>'proximity'</code> , the method treats <code>X</code> as a proximity matrix returned by the <code>proximity</code> method. If you do not supply the proximity matrix, <code>outlierMeasure</code> computes it internally. If you use the <code>proximity</code> method to compute a proximity matrix, supplying it as input to <code>outlierMeasure</code> reduces computing time.
<code>'labels'</code>	Vector of true class labels. True class labels can be either a numeric vector, character matrix, or cell array of strings. When you supply this parameter, the method performs the outlier calculation for any observations using only other observations from the same class. This parameter must specify one label for each observation (row) in <code>X</code> .

# CompactTreeBagger.outlierMeasure

---

## See Also

`proximity`

# TreeBagger.OutlierMeasure property

---

**Purpose** Measure for determining outliers

**Description** The OutlierMeasure property is a numeric array of size Nobs-by-1, where Nobs is the number of observations in the training data, containing outlier measures for each observation.

**See Also** CompactTreeBagger.outlierMeasure

# parallelcoords

---

**Purpose** Parallel coordinates plot

**Syntax**

```
parallelcoords(X)
parallelcoords(X,...,'Standardize','on')
parallelcoords(X,...,'Standardize','PCA')
parallelcoords(X,...,'Standardize','PCAStd')
parallelcoords(X,...,'Quantile',alpha)
parallelcoords(X,...,'Group',group)
parallelcoords(X,...,'Labels',labels)
parallelcoords(X,...,PropertyName,PropertyValue,...)
h = parallelcoords(X,...)
parallelcoords(axes,...)
```

**Description** `parallelcoords(X)` creates a parallel coordinates plot of the multivariate data in the  $n$ -by- $p$  matrix  $X$ . Rows of  $X$  correspond to observations, columns to variables. A parallel coordinates plot is a tool for visualizing high dimensional data, where each observation is represented by the sequence of its coordinate values plotted against their coordinate indices. `parallelcoords` treats NaNs in  $X$  as missing values and does not plot those coordinate values.

`parallelcoords(X,...,'Standardize','on')` scales each column of  $X$  to have mean 0 and standard deviation 1 before making the plot.

`parallelcoords(X,...,'Standardize','PCA')` creates a parallel coordinates plot from the principal component scores of  $X$ , in order of decreasing eigenvalues. `parallelcoords` removes rows of  $X$  containing missing values (NaNs) for principal components analysis (PCA) standardization.

`parallelcoords(X,...,'Standardize','PCAStd')` creates a parallel coordinates plot using the standardized principal component scores.

`parallelcoords(X,...,'Quantile',alpha)` plots only the median and the  $\alpha$  and  $1-\alpha$  quantiles of  $f(t)$  at each value of  $t$ . This is useful if  $X$  contains many observations.

`parallelcoords(X,...,'Group',group)` plots the data in different groups with different colors. Groups are defined by `group`, a numeric

array containing a group index for each observation. `group` can also be a categorical variable, character matrix, or cell array of strings, containing a group name for each observation.

`parallelcoords(X,...,'Labels',labels)` labels the coordinate tick marks along the horizontal axis using `labels`, a character array or cell array of strings.

`parallelcoords(X,...,PropertyName,PropertyValue,...)` sets properties to the specified property values for all line graphics objects created by `parallelcoords`.

`h = parallelcoords(X,...)` returns a column vector of handles to the line objects created by `parallelcoords`, one handle per row of `X`. If you use the `'Quantile'` input argument, `h` contains one handle for each of the three lines objects created. If you use both the `'Quantile'` and the `'Group'` input arguments, `h` contains three handles for each group.

`parallelcoords(axes,...)` plots into the axes with handle axes.

## Examples

```
% Make a grouped plot of the raw data
load fisheriris
labels = {'Sepal Length','Sepal Width',...
         'Petal Length','Petal Width'};
parallelcoords(meas,'group',species,'labels',labels);
```

```
% Plot only the median and quartiles of each group
parallelcoords(meas,'group',species,'labels',labels,...
              'quantile',.25);
```

## How To

- “Grouping Variables” on page 2-51

# ProbDistUnivParam.paramci

---

**Purpose** Return parameter confidence intervals of ProbDistUnivParam object

**Syntax** CI = paramci(PD)  
CI = paramci(PD, Alpha)

**Description** CI = paramci(PD) returns CI, a 2-by-N array containing 95% confidence intervals for the parameters of the ProbDistUnivParam object PD. N is the number of parameters in the distribution. When you create PD by specifying parameters (such as using the ProbDistUnivParam.ProbDistUnivParam constructor or using the fitdist function and specifying a 'binomial' or 'generalized pareto' distribution) rather than by fitting to data, the confidence intervals have a width of 0 because the parameters are viewed as estimates of an unknown parameter.

CI = paramci(PD, Alpha) returns 100\*(1 - Alpha)% confidence intervals. Default Alpha is 0.05, which specifies 95% confidence intervals.

---

**Note** If you create PD with a distribution that does not support confidence intervals, then CI contains NaN values.

---

**Input Arguments**

PD	An object of the class ProbDistUnivParam.
Alpha	A value between 0 and 1 that specifies a confidence interval. Default is 0.05, which specifies 95% confidence intervals.

**Output Arguments**

CI	A 2-by-N array containing 100*(1 - Alpha)% confidence intervals for the parameters of the ProbDistUnivParam object PD. N is the number of parameters in the distribution.
----	---

**See Also**     `fitdist`

# prob.ToolboxFittableParametricDistribution.paramci

---

**Purpose** Confidence intervals for probability distribution parameters

**Syntax**  
`ci = paramci(pd)`  
`ci = paramci(pd,Name,Value)`

**Description**  
`ci = paramci(pd)` returns the array `ci` containing the lower and upper boundaries of the 95% confidence interval for each parameter in probability distribution `pd`.  
`ci = paramci(pd,Name,Value)` returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

## Input Arguments

**pd - Probability distribution**  
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Alpha',0.01` specifies a 99% confidence interval.

## 'Alpha' - Alpha level

0.05 (default) | scalar value in the range (0,1)

Alpha level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value

in the range (0,1). The default value 0.05 corresponds to a 95% confidence interval.

**Example:** 'Alpha',0.01

## Data Types

single | double

## 'Parameter' - Parameter list

vector | cell array of strings

Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of 'Parameter' and a vector or a cell array of strings containing the parameter names. By default, paramci computes confidence intervals for all distribution parameters.

**Example:** 'Parameter', 'mu'

## Data Types

char

## 'Type' - Computation method

'exact' | 'Wald' | 'lr'

Computation method for the confidence intervals, specified as the comma-separated pair consisting of 'Type' and 'exact', 'Wald', or 'lr'.

'exact' computes the confidence intervals using an exact method, and is available for the following distributions.

Binomial	Compute using the Clopper-Pearson method based on exact probability calculations. This method does not provide exact coverage probabilities.
Exponential	Compute using a method based on a chi-square distribution. This method provides exact coverage for complete and Type 2 censored samples.

# prob.ToolboxFittableParametricDistribution.paramci

---

Normal	Computation method based on $t$ and chi-square distributions for uncensored samples provides exact coverage for uncensored samples. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Lognormal	Computation method based on $t$ and chi-square distributions for uncensored samples provides exact coverage. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Poisson	Computation method based on a chi-square distribution provides exact coverage. For large degrees of freedom, the chi-square is approximated by a normal distribution for numerical efficiency.
Rayleigh	Computation method based on a chi-square distribution provides exact coverage probabilities.

'exact' is the default when it is available. Alternatively, you can specify 'Wald' to compute the confidence intervals using the Wald method, or 'lr' to compute the confidence intervals using the likelihood ratio method.

**Example:** 'Type', 'Wald'

## 'LogFlag' - Boolean flag for log scale

vector

Boolean flag for the log scale, specified as the comma-separated pair consisting of 'LogFlag' and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.

**Example:** 'LogFlag', [0, 1]

## Data Types

logical

## Output Arguments

### ci - Confidence interval

array

Confidence interval, returned as a  $p$ -by-2 array containing the lower and upper bounds of the  $(1 - \text{Alpha})\%$  confidence interval for each distribution parameter.  $p$  is the number of distribution parameters.

## Examples

### Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the 95% confidence interval for the distribution parameters.

```
ci = paramci(pd)
```

```
ci =
```

```
73.4321 7.7391  
76.5846 9.9884
```

# prob.ToolboxFittableParametricDistribution.paramci

---

Column 1 of `ci` contains the lower and upper 95% confidence interval boundaries for the `mu` parameter, and column 2 contains the boundaries for the `sigma` parameter.

## Change Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')  
  
pd =  
  
NormalDistribution  
  
Normal distribution  
    mu = 75.0083    [73.4321, 76.5846]  
    sigma =  8.7202    [7.7391, 9.98843]
```

Compute the 99% confidence interval for the distribution parameters.

```
ci = paramci(pd,'Alpha',.01)  
  
ci =  
  
    72.9245    7.4627  
    77.0922   10.4403
```

Column 1 of `ci` contains the lower and upper 99% confidence interval boundaries for the `mu` parameter, and column 2 contains the boundaries for the `sigma` parameter.

# ProbDistParametric.ParamCov property

---

<b>Purpose</b>	Read-only covariance matrix of parameter estimates of ProbDistParametric object
<b>Description</b>	ParamCov is a read-only property of the ProbDistParametric class. ParamCov is a covariance matrix containing the parameter estimates of a distribution represented by a ProbDistParametric object. ParamCov has a size of NumParams-by-NumParams.
<b>Values</b>	This covariance matrix includes estimates for both the specified parameters and parameters that are fit to the data. For specified parameters, the covariance is 0, indicating the parameter is known exactly. Use this information to view and compare the descriptions of parameters supplied to create distributions.

# ProbDistParametric.ParamDescription property

---

<b>Purpose</b>	Read-only cell array specifying descriptions of parameters of ProbDistParametric object
<b>Description</b>	ParamDescription is a read-only property of the ProbDistParametric class. ParamDescription is a cell array of strings specifying the descriptions or meanings of the parameters of a distribution represented by a ProbDistParametric object. ParamDescription has a length of NumParams.
<b>Values</b>	This cell array includes a brief description of the meaning of both the specified parameters and parameters that are fit to the data. The description is the same as the parameter name when no further description information is available. Use this information to view and compare the descriptions of parameters used to create distributions.

# ProbDistParametric.ParamIsFixed property

---

<b>Purpose</b>	Read-only logical array specifying fixed parameters of ProbDistParametric object
<b>Description</b>	ParamIsFixed is a read-only property of the ProbDistParametric class. ParamIsFixed is a logical array specifying the fixed parameters of a distribution represented by a ProbDistParametric object. ParamIsFixed has a length of NumParams.
<b>Values</b>	This array specifies a 1 (true) for fixed parameters, and a 0 (false) for parameters that are estimated from the input data. Use this information to view and compare the fixed parameters used to create distributions.

# ProbDistParametric.ParamNames property

---

<b>Purpose</b>	Read-only cell array specifying names of parameters of ProbDistParametric object
<b>Description</b>	ParamNames is a read-only property of the ProbDistParametric class. ParamNames is a cell array of strings specifying the names of the parameters of a distribution represented by a ProbDistParametric object. ParamNames has a length of NumParams.
<b>Values</b>	This cell array includes the names of both the specified parameters and parameters that are fit to the data. Use this information to view and compare the names of parameters used to create distributions.

## Purpose

Parameter estimates

## Description

The Params property is an NClasses-by-NDims cell array containing the parameter estimates, excluding the class priors. Params(i, j) contains the parameter estimates for the jth feature in the ith class. Params(i, j) is an empty cell if the ith class is empty.

The entry in Params(i, j) depends on the distribution type used for the jth feature, as follows:

'normal'	A vector of length two. The first element is the mean, and the second element is standard deviation.
'kernel'	A ProbDistUnivKernel object
'mvmn'	A vector containing the probability for each possible value of the jth feature in the ith class. The order of the probabilities is decided by the sorted order of all the unique values of the jth feature.
'mn'	A scalar representing the probability the jth token appearing in the ith class, Prob(token j   class i). It is estimated as $(1 + \text{the number of occurrence of token J in class I}) / (\text{NDims} + \text{the total number of token occurrence in class I})$ .

# ProbDistParametric.Params property

---

<b>Purpose</b>	Read-only array specifying values of parameters of ProbDistParametric object
<b>Description</b>	Params is a read-only property of the ProbDistParametric class. Params is an array of values specifying the values of the parameters of a distribution represented by a ProbDistParametric object. Params has a length of NumParams.
<b>Values</b>	This array includes the values of both the specified parameters and parameters that are fit to the data. Use this information to view and compare the values of parameters used to create distributions.

# prob.ParametricTruncatableDistribution

---

<b>Superclasses</b>	TruncatableDistribution	
<b>Purpose</b>	Parametric truncatable probability distribution object	
<b>Description</b>	Create a probability distribution object with specified parameter values using <code>makedist</code> .	
<b>Methods</b>	<code>mean</code>	Mean of probability distribution object
	<code>std</code>	Standard deviation of probability distribution object
	<code>var</code>	Variance of probability distribution object
	<b>Inherited Methods</b>	
	<code>cdf</code>	Cumulative distribution function of probability distribution object
	<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
	<code>iqr</code>	Interquartile range of probability distribution object
	<code>median</code>	Median of probability distribution object
	<code>pdf</code>	Probability density function of probability distribution object
	<code>random</code>	Generate random numbers from probability distribution object
	<code>truncate</code>	Truncate probability distribution object

# prob.ParametricTruncatableDistribution

- Property Attributes

## Purpose

Parent node

## Syntax

```
p = parent(t)
p = parent(t,nodes)
```

## Description

`p = parent(t)` returns an  $n$ -element vector `p` containing the number of the parent node for each node in the tree `t`, where  $n$  is the number of nodes. The parent of the root node is 0.

`p = parent(t,nodes)` takes a vector `nodes` of node numbers and returns the parent nodes for the specified nodes.

## Examples

Create a classification tree for Fisher's iris data:

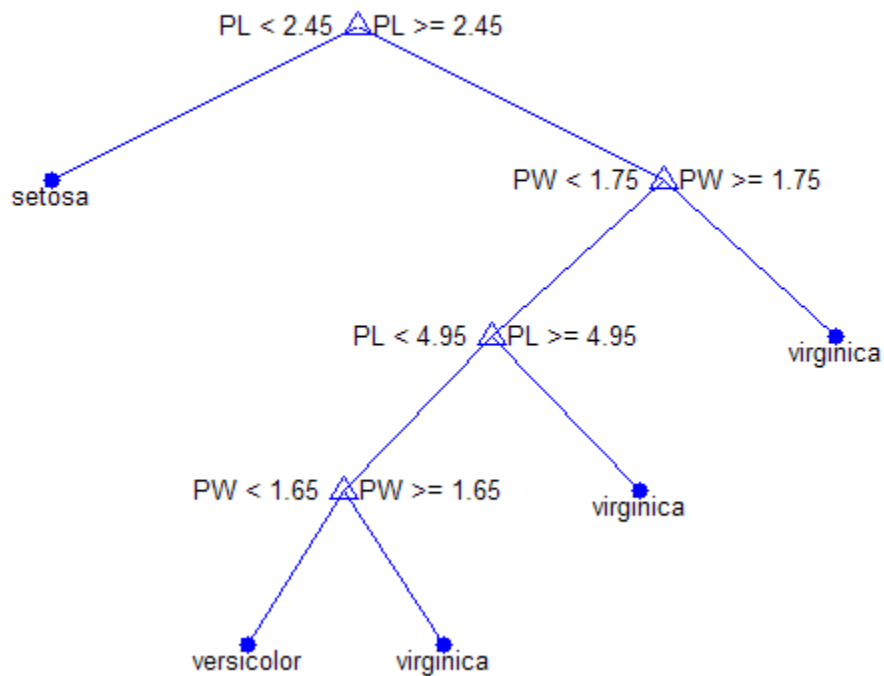

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 else node 3
2  class = setosa
3  if PW<1.75 then node 4 else node 5
4  if PL<4.95 then node 6 else node 7
5  class = virginica
6  if PW<1.65 then node 8 else node 9
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```

# classregtree.parent

Click to display:  Magnification:  Pruning level:

p = parent(t)

p =  
0  
1  
1  
3  
3  
4  
4  
6

6

# paretotails

---

<b>Superclasses</b>	piecewisedistribution	
<b>Purpose</b>	Empirical distributions with Pareto tails	
<b>Construction</b>	paretotails	Construct Pareto tails object
<b>Methods</b>	lowerparams upperparams	Lower Pareto tails parameters Upper Pareto tails parameters

## Inherited Methods

Methods in the following table are inherited from `piecewisedistribution`.

boundary	Piecewise distribution boundaries
cdf	Cumulative distribution function for piecewise distribution
disp	Display <code>piecewisedistribution</code> object
display	Display <code>piecewisedistribution</code> object
icdf	Inverse cumulative distribution function for piecewise distribution
nsegments	Number of segments
pdf	Probability density function for piecewise distribution
random	Random numbers from piecewise distribution
segment	Segments containing values

## **Properties**

Objects of the `paretotails` class have no properties accessible by dot indexing, `get` methods, or `set` methods. To obtain information about a `paretotails` object, use the appropriate method.

## **Copy Semantics**

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## **How To**

- “Generalized Pareto Distribution” on page B-53

# paretotails

---

**Purpose** Construct Pareto tails object

**Syntax**  
`obj = paretotails(x,p1,pu)`  
`obj = paretotails(x,p1,pu,cdf_fun)`

**Description** `obj = paretotails(x,p1,pu)` creates an object `obj` defining a distribution consisting of the empirical distribution of `x` in the center and Pareto distributions in the tails. `x` is a real-valued vector of data values whose extreme observations are fit to generalized Pareto distributions (GPDs). `p1` and `pu` identify the lower- and upper-tail cumulative probabilities such that  $100 \cdot p1$  and  $100 \cdot (1 - pu)$  percent of the observations in `x` are, respectively, fit to a GPD by maximum likelihood. If `p1` is 0, or if there are not at least two distinct observations in the lower tail, then no lower Pareto tail is fit. If `pu` is 1, or if there are not at least two distinct observations in the upper tail, then no upper Pareto tail is fit.

`obj = paretotails(x,p1,pu,cdf_fun)` uses `cdf_fun` to estimate the cdf of `x` between the lower and upper tail probabilities. `cdf_fun` may be any of the following:

- 'ecdf' — Uses an interpolated empirical cdf, with data values as the midpoints in the vertical steps in the empirical cdf, and computed by linear interpolation between data values. This is the default.
- 'kernel' — Uses a kernel-smoothing estimate of the cdf.
- @fun — Uses a handle to a function of the form `[p,xi] = fun(x)` that accepts the input data vector `x` and returns a vector `p` of cdf values and a vector `xi` of evaluation points. Values in `xi` must be sorted and distinct but need not equal the values in `x`.

`cdf_fun` is used to compute the quantiles corresponding to `p1` and `pu` by inverse interpolation, and to define the fitted distribution between these quantiles.

The output object `obj` is a Pareto tails object with methods to evaluate the cdf, inverse cdf, and other functions of the fitted distribution. These methods are well-suited to copula and other Monte Carlo simulations.

The pdf method in the tails is the GPD density, but in the center it is computed as the slope of the interpolated cdf.

The `paretotails` class is a subclass of the `piecewisedistribution` class, and many of its methods are derived from that class.

## Examples

Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj);

x = linspace(-5,5);
plot(x,cdf(obj,x),'b-','LineWidth',2)
hold on
plot(x,tcdf(x,3),'r:','LineWidth',2)
plot(q,p,'bo','LineWidth',2,'MarkerSize',5)
legend('Pareto Tails Object','t Distribution',...
       'Location','NW')
```

# paretotails

[cdf](#) | [ecdf](#) | [gpfit](#) | [icdf](#) | [ksdensity](#)

**Purpose** Linear or rank partial correlation coefficients

**Syntax**

```
rho = partialcorr(x)
rho = partialcorr(x,z)
rho = partialcorr(x,y,z)
rho = partialcorr( __ ,Name,Value)
[rho,pval] = partialcorr( __ )
```

**Description** `rho = partialcorr(x)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the remaining variables in `x`.

`rho = partialcorr(x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the variables in `z`.

`rho = partialcorr(x,y,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x` and `y`, controlling for the variables in `z`.

`rho = partialcorr( __ ,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorr( __ )` also returns a matrix `pval` of  $p$ -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

# partialcorr

---

## Input Arguments

### **x - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_x$  matrix. The rows of  $x$  correspond to observations, and the columns correspond to variables.

### **Data Types**

single | double

### **y - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_y$  matrix. The rows of  $y$  correspond to observations, and the columns correspond to variables.

### **Data Types**

single | double

### **z - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_z$  matrix. The rows of  $z$  correspond to observations, and columns correspond to variables.

### **Data Types**

single | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:** 'Type', 'Spearman', 'Rows', 'complete' computes Spearman partial correlations using only the data in rows that contain no missing values.

### **'Type' - Type of partial correlations**

'Pearson' (default) | 'Spearman'

Type of partial correlations to compute, specified as the comma-separated pair consisting of 'Type' and one of the following.

'Pearson'	Compute Pearson (linear) partial correlations.
'Spearman'	Compute Spearman (rank) partial correlations.

**Example:** 'Type', 'Spearman'

**'Rows' - Rows to use in computation**

'all' (default) | 'complete' | 'pairwise'

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of the following.

'all'	Use all rows regardless of missing (NaN) values.
'complete'	Use only rows with no missing values.
'pairwise'	Compute $\rho(i, j)$ using rows with no missing values in column $i$ or $j$ .

Using 'pairwise' can produce a  $\rho$  that is not positive definite. 'complete' always produces a positive definite  $\rho$ , but when data is missing, the estimates are generally based on fewer observations.

**Example:** 'Rows', 'complete'

**'Tail' - Alternative hypothesis**

'both' (default) | 'right' | 'left'

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternative hypothesis that the correlation is not 0.
'right'	Test the alternative hypothesis that the correlation is greater than 0.
'left'	Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail', 'right'

## Output Arguments

### **rho** - Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a matrix.

- If you input only an  $\mathbf{x}$  matrix,  $\mathbf{rho}$  is a symmetric  $p_x$ -by- $p_x$  matrix. The  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ -th and  $j$ -th columns in  $\mathbf{x}$ .
- If you input  $\mathbf{x}$  and  $\mathbf{z}$  matrices,  $\mathbf{rho}$  is a symmetric  $p_x$ -by- $p_x$  matrix. The  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ th and  $j$ th columns in  $\mathbf{x}$ , controlled for the variables in  $\mathbf{z}$ .
- If you input  $\mathbf{x}$ ,  $\mathbf{y}$ , and  $\mathbf{z}$  matrices,  $\mathbf{rho}$  is a  $p_x$ -by- $p_y$  matrix, where the  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ th column in  $\mathbf{x}$  and the  $j$ th column in  $\mathbf{y}$ , controlled for the variables in  $\mathbf{z}$ .

If the covariance matrix of  $[\mathbf{x}, \mathbf{z}]$  is

$$S = \begin{pmatrix} S_{xx} & S_{xz} \\ S_{xz}^T & S_{zz} \end{pmatrix},$$

then the partial correlation matrix of  $\mathbf{x}$ , controlling for  $\mathbf{z}$ , can be defined formally as a normalized version of the covariance matrix  $S_{xy} = S_{xx} - (S_{xz} S_{zz}^{-1} S_{xz}^T)$

### **pval** - p-values

matrix

$p$ -values, returned as a matrix. Each element of `pval` is the  $p$ -value for the corresponding element of `rho`.

If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from 0.

`partialcorr` computes  $p$ -values for linear and rank partial correlations using a Student's  $t$  distribution for a transformation of the correlation. This is exact for linear partial correlation when  $x$  and  $z$  are normal, but is a large-sample approximation otherwise.

## Examples

### Compute Partial Correlation Coefficients

Compute partial correlation coefficients between pairs of variables in the input matrix.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create an input matrix containing the sample data.

```
x = [hospital.SexID hospital.Age hospital.Smoker hospital.Weight];
```

Each row in `x` contains a patient's gender, age, smoking status, and weight.

Compute partial correlation coefficients between pairs of variables in `x`, while controlling for the effects of the remaining variables in `x`.

```
rho = partialcorr(x)
```

```
rho =
```

```

    1.0000    -0.0105    0.0273    0.9421
   -0.0105     1.0000    0.0419    0.0369
    0.0273     0.0419     1.0000    0.0451
    0.9421     0.0369     0.0451     1.0000
```

The matrix `rho` indicates, for example, a correlation of 0.9421 between gender and weight after controlling for all other variables in `x`. You can return the  $p$ -values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames', {'SexID', 'Age', 'Smoker', 'Weight'}, ...  
    'RowNames', {'SexID', 'Age', 'Smoker', 'Weight'});
```

```
disp('Partial Correlation Coefficients')  
disp(rho)
```

```
Partial Correlation Coefficients  
                SexID      Age      Smoker      Weight  
-----  
SexID           1      -0.01052    0.027324    0.9421  
Age      -0.01052           1      0.041945    0.036873  
Smoker    0.027324    0.041945           1      0.045106  
Weight    0.9421      0.036873    0.045106           1
```

## Test for Partial Correlations with Controlled Variables

Test for partial correlation between pairs of variables in the input matrix, while controlling for the effects of a second set of variables.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;  
hospital.SexID = grp2idx(hospital.Sex);
```

Create two matrices containing the sample data.

```
x = [hospital.Age hospital.BloodPressure];  
z = [hospital.SexID hospital.Smoker hospital.Weight];
```

The `x` matrix contains the variables to test for partial correlation. The `z` matrix contains the variables to control for. The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,z)
```

```
rho =
```

```
    1.0000    0.1300    0.0462
    0.1300    1.0000    0.0012
    0.0462    0.0012    1.0000
```

```
pval =
```

```
    0    0.2044    0.6532
    0.2044    0    0.9903
    0.6532    0.9903    0
```

The large values in `pval` indicate that there is no significant correlation between age and either blood pressure measurement after controlling for gender, smoking status, and weight.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Age','BPTop','BPBottom'},...
    'RowNames',{'SexID','Smoker','Weight'});
```

```
pval = array2table(pval, ...
```

```
'VariableNames',{ 'Age', 'BPTop', 'BPBottom'}, ...  
'RowNames',{ 'SexID', 'Smoker', 'Weight'});
```

```
disp('Partial Correlation Coefficients')  
disp(rho)  
disp('p-values')  
disp(pval)
```

```
Partial Correlation Coefficients
```

	Age	BPTop	BPBottom
SexID	1	0.13	0.046202
Smoker	0.13	1	0.0012475
Weight	0.046202	0.0012475	1

```
p-values
```

	Age	BPTop	BPBottom
SexID	0	0.20438	0.65316
Smoker	0.20438	0	0.99032
Weight	0.65316	0.99032	0

## Test for Paired Partial Correlation Coefficients

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of a third set of variables.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;  
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];  
y = [hospital.Weight hospital.Age];  
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x` and `y`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,y,z)
```

```
rho =
```

```
   -0.0257    0.1289  
    0.0292    0.0472
```

```
pval =
```

```
    0.8018    0.2058  
    0.7756    0.6442
```

The results in `pval` indicate that, after controlling for gender and smoking status, there is no significant correlation between either of a patient's blood pressure measurements and that patient's weight or age.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames',{'BPTop','BPBottom'},...  
    'RowNames',{'Weight','Age'});
```

```
pval = array2table(pval, ...  
    'VariableNames',{'BPTop','BPBottom'},...
```

```
'RowNames',{'Weight','Age'});  
  
disp('Partial Correlation Coefficients')  
disp(rho)  
disp('p-values')  
disp(pval)
```

```
Partial Correlation Coefficients  
                BPTop      BPBottom  
-----  
Weight          -0.02568    0.12893  
Age             0.029168    0.047226
```

```
p-values  
                BPTop      BPBottom  
-----  
Weight          0.80182     0.2058  
Age             0.77556     0.64424
```

## One-Tailed Partial Correlation Test

Test the hypothesis that pairs of variables have no correlation, against the alternative hypothesis that the correlation is greater than 0.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;  
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];  
y = [hospital.Weight hospital.Age];  
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender

and smoking status). The measurements for BloodPressure are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Compute the correlation coefficients using a right-tailed test.

```
[rho,pval] = partialcorr(x,y,z,'Tail','right')
```

```
rho =
```

```
   -0.0257    0.1289  
    0.0292    0.0472
```

```
pval =
```

```
   0.5991    0.1029  
   0.3878    0.3221
```

The results in `pval` indicate that `partialcorr` does not reject the null hypothesis of nonzero correlations between the variables in `x` and `y`, after controlling for the variables in `z`, when the alternative hypothesis is that the correlations are greater than 0.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames',{'BPTop','BPBottom'},...  
    'RowNames',{'Weight','Age'});
```

```
pval = array2table(pval, ...  
    'VariableNames',{'BPTop','BPBottom'},...  
    'RowNames',{'Weight','Age'});
```

```
disp('Partial Correlation Coefficients')  
disp(rho)
```

# partialcorr

---

```
disp('p-values')  
disp(pval)
```

```

## See Also

`corr` | `tiedrank` | `corrcoef` | `partialcorri`

## Purpose

Partial correlation coefficients adjusted for internal variables

## Syntax

```
rho = partialcorri(y,x)
rho = partialcorri(y,x,z)
rho = partialcorri( ___,Name,Value)
[rho,pval] = partialcorri( ___ )
```

## Description

`rho = partialcorri(y,x)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`.

`rho = partialcorri(y,x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`, after first controlling both `x` and `y` for the variables in `z`.

`rho = partialcorri( ___,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorri( ___ )` also returns a matrix `pval` of  $p$ -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

## Input Arguments

### **x** - Data matrix

matrix

Data matrix, specified as an  $n$ -by- $p_x$  matrix. The rows of `x` correspond to observations, and the columns correspond to variables.

### Data Types

single | double

## **y - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_y$  matrix. The rows of  $y$  correspond to observations, and the columns correspond to variables.

### **Data Types**

single | double

## **z - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_z$  matrix. The rows of  $z$  correspond to observations, and the columns correspond to variables.

### **Data Types**

single | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:** 'Type', 'Spearman', 'Rows', 'complete' computes Spearman partial correlations using only the data in rows that contain no missing values.

## **'Type' - Type of partial correlations**

'Pearson' (default) | 'Spearman'

Type of partial correlations to compute, specified as the comma-separated pair consisting of 'Type' and either 'Pearson' or 'Spearman'. Pearson computes the Pearson (linear) partial correlations. Spearman computes the Spearman (rank) partial correlations.

**Example:** 'Type', 'Spearman'

**'Rows' - Rows to use in computation**`'all' (default) | 'complete' | 'pairwise'`

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of the following.

<code>'all'</code>	Use all rows regardless of missing (NaN) values.
<code>'complete'</code>	Use only rows with no missing values.
<code>'pairwise'</code>	Use all available values in each column of $y$ when computing the partial correlation coefficients and $p$ -values corresponding to that column. For each column of $y$ , rows will be dropped corresponding to missing values in $x$ (and/or $z$ , if supplied). However, remaining rows with valid values in that column of $y$ are used, even if there are missing values in other columns of $y$ .

**Example:** `'Rows', 'complete'`

**'Tail' - Alternative hypothesis**`'both' (default) | 'right' | 'left'`

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

<code>'both'</code>	Test the alternative hypothesis that the correlation is not zero.
<code>'right'</code>	Test the alternative hypothesis that the correlation is greater than 0.
<code>'left'</code>	Test the alternative hypothesis that the correlation is less than 0.

**Example:** `'Tail', 'right'`

## Output Arguments

### **rho - Sample linear partial correlation coefficients**

matrix

Sample linear partial correlation coefficients, returned as a  $p_y$ -by- $p_x$  matrix.

- If you input  $x$  and  $y$  matrices, the  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ th column in  $y$  and the  $j$ th column in  $x$ , controlled for all the columns of  $x$  except column  $j$ .
- If you input  $x$ ,  $y$ , and  $z$  matrices, the  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ th column in  $y$  and the  $j$ th column in  $x$ , adjusted for all the columns of  $x$  except column  $j$ , after first controlling both  $x$  and  $y$  for the variables in  $z$ .

### **pval - p-values**

matrix

$p$ -values, returned as a matrix. Each element of `pval` is the  $p$ -value for the corresponding element of `rho`. If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from zero.

`partialcorri` computes  $p$ -values for linear and rank partial correlations using a Student's  $t$  distribution for a transformation of the correlation. This is exact for linear partial correlation when  $x$  and  $z$  are normal, but is a large-sample approximation otherwise.

## Examples

### **Compute Partial Correlation Coefficients**

Compute partial correlation coefficients for each pair of variables in the  $x$  and  $y$  input matrices, while controlling for the effects of the remaining variables in  $x$ .

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes MPG and Acceleration as performance measures, and Displacement, Horsepower, and Weight as design

variables. Acceleration is the time required to accelerate from 0 to 60 miles per hour, so a high value for Acceleration corresponds to a vehicle with low acceleration.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
```

Compute the correlation coefficients. Include only rows with no missing values in the computation.

```
rho = partialcorri(y,x,'Rows','complete')
```

```
rho =
```

```
    -0.0537    -0.1520    -0.4856
    -0.3994    -0.4008     0.4912
```

The results suggest, for example, a 0.4912 correlation between weight and acceleration after controlling for the effects of displacement and horsepower. You can return the *p*-values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});
```

```
disp('Partial Correlation Coefficients')
disp(rho)
```

```
Partial Correlation Coefficients
                Displacement    Horsepower    Weight
                -----
```

MPG	-0.053684	-0.15199	-0.48563
Acceleration	-0.39941	-0.40075	0.49123

## Test Partial Correlations While Controlling for Additional Variables

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of the remaining variables in x plus additional variables in matrix z.

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes MPG and Acceleration as performance measures, and Displacement, Horsepower, and Weight as design variables. Acceleration is the time required to accelerate from 0 to 60 miles per hour, so a high value for Acceleration corresponds to a vehicle with low acceleration.

Create a new variable Headwind, and randomly generate data to represent the notion of an average headwind along the performance measurement route.

```
rng('default'); % For reproducibility  
Headwind = (10:-0.2:-9.8)' + 5*randn(100,1);
```

Since headwind can affect the performance measures, control for its effects when testing for partial correlation between the remaining variables.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables. The z matrix contains additional variables to control for when computing the partial correlations, such as headwind.

```
y = [MPG,Acceleration];  
x = [Displacement,Horsepower,Weight];
```

```
z = Headwind;
```

Compute the partial correlation coefficients. Include only rows with no missing values in the computation.

```
[rho,pval] = partialcorri(y,x,z,'Rows','complete')
```

```
rho =
```

```
    0.0572    -0.1055    -0.5736
   -0.3845   -0.3966     0.4674
```

```
pval =
```

```
    0.5923    0.3221    0.0000
    0.0002    0.0001    0.0000
```

The small returned *p*-value of 0.001 in *pval* indicates, for example, a significant negative correlation between horsepower and acceleration, after controlling for displacement, weight, and headwind.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});
```

```
pval = array2table(pval, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});
```

```
disp('Partial Correlation Coefficients, Accounting for Headwind')
disp(rho)
disp('p-values, Accounting for Headwind')
disp(pval)
```

```
Partial Correlation Coefficients, Accounting for Headwind
```

# partialcorri

Acceleration	0.00018272	0.00010902	3.4091e-06

## See Also

`partialcorr` | `corr`

**Purpose**

Principal component analysis of raw data

**Syntax**

```
coeff = pca(X)
coeff = pca(X,Name,Value)
[coeff,score,latent] = pca( ___ )
[coeff,score,latent,tsquared] = pca( ___ )
[coeff,score,latent,tsquared,explained,mu] = pca( ___ )
```

**Description**

`coeff = pca(X)` returns the principal component coefficients for the  $n$ -by- $p$  data matrix  $X$ . Rows of  $X$  correspond to observations and columns correspond to variables. The coefficient matrix is  $p$ -by- $p$ . Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. By default, `pca` centers the data and uses the singular value decomposition (SVD) algorithm.

`coeff = pca(X,Name,Value)` returns any of the output arguments in the previous syntaxes using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of principal components `pca` returns or an algorithm other than SVD to use.

`[coeff,score,latent] = pca( ___ )` also returns the principal component scores in `score` and the principal component variances in `latent`. You can use any of the input arguments in the previous syntaxes.

Principal component scores are the representations of  $X$  in the principal component space. Rows of `score` correspond to observations, and columns correspond to components.

The principal component variances are the eigenvalues of the covariance matrix of  $X$ .

`[coeff,score,latent,tsquared] = pca( ___ )` also returns the Hotelling's T-squared statistic for each observation in  $X$ .

`[coeff,score,latent,tsquared,explained,mu] = pca( ___ )` also returns `explained`, the percentage of the total variance explained by each principal component and `mu`, the estimated mean of each variable in  $X$ .

## Input Arguments

### **X - Input data**

matrix

Input data for which to compute the principal components, specified as an  $n$ -by- $p$  matrix. Rows of  $X$  correspond to observations and columns to variables.

### **Data Types**

single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

### **Example:**

`'Algorithm','eig','Centered',false,'Rows','all','NumComponents',3` specifies that `pca` uses eigenvalue decomposition algorithm, not center the data, use all of the observations, and return only the first three principal components.

### **'Algorithm' - Principal component algorithm**

`'svd' (default) | 'eig' | 'als'`

Principal component algorithm that `pca` uses to perform the principal component analysis, specified as the comma-separated pair consisting of `'Algorithm'` and one of the following.

'svd'	Default. Singular value decomposition (SVD) of $X$ .
'eig'	Eigenvalue decomposition (EIG) of the covariance matrix. The EIG algorithm is faster than SVD when the number of observations, $n$ , exceeds the number of variables, $p$ , but is less accurate because the condition number of the covariance is the square of the condition number of $X$ .
'als'	Alternating least squares (ALS) algorithm. This algorithm finds the best rank- $k$ approximation by factoring $X$ into a $n$ -by- $k$ left factor matrix, $L$ , and a $p$ -by- $k$ right factor matrix, $R$ , where $k$ is the number of principal components. The factorization uses an iterative method starting with random initial values. ALS is designed to better handle missing values. It is preferable to pairwise deletion ('Rows', 'pairwise') and deals with missing values without listwise deletion ('Rows', 'complete'). It can work well for data sets with a small percentage of missing data at random, but might not perform well on sparse data sets.

Example: 'Algorithm', 'eig'

### Data Types

char

### 'Centered' - Indicator for centering columns

true (default) | false

Indicator for centering the columns, specified as the comma-separated pair consisting of 'Centered' and one of these logical expressions.

true	Default. <code>pca</code> centers $X$ by subtracting column means before computing singular value decomposition or eigenvalue decomposition. If $X$ contains NaN missing values, <code>nanmean</code> is used to find the mean with any available data. You can reconstruct the centered data using <code>score*coeff</code> .
false	In this case <code>pca</code> does not center the data. You can reconstruct the original data using <code>score*coeff</code> .

**Example:** 'Centered', false

### Data Types

logical

### 'Economy' - Indicator for economy size output

true (default) | false

Indicator for the economy size output when the degrees of freedom,  $d$ , is smaller than the number of variables,  $p$ , specified as the comma-separated pair consisting of 'Economy' and one of these logical expressions.

true	Default. <code>pca</code> returns only the first $d$ elements of latent and the corresponding columns of <code>coeff</code> and <code>score</code> .  This option can be significantly faster when the number of variables $p$ is much larger than $d$ .
false	<code>pca</code> returns all elements of latent. The columns of <code>coeff</code> and <code>score</code> corresponding to zero elements in latent are zeros.

Note that when  $d < p$ , `score(:, d+1:p)` and `latent(d+1:p)` are necessarily zero, and the columns of `coeff(:, d+1:p)` define directions that are orthogonal to  $X$ .

**Example:** 'Economy', false

### Data Types

logical

### 'NumComponents' - Number of components requested

number of variables (default) | scalar integer

Number of components requested, specified as the comma-separated pair consisting of 'NumComponents' and a scalar integer  $k$  satisfying  $0 < k \leq p$ , where  $p$  is the number of original variables in  $X$ . When specified, `pca` returns the first  $k$  columns of `coeff` and `score`.

**Example:** 'NumComponents', 3

**Data Types**

single | double

**'Rows' - Action to take for NaN values**

'complete' (default) | 'pairwise' | 'all'

Action to take for NaN values in the data matrix  $X$ , specified as the comma-separated pair consisting of 'Rows' and one of the following.

'complete'	Default. Observations with NaN values are removed before calculation. Rows of NaNs are reinserted into score and tsquared at the corresponding locations.
'pairwise'	<p>This option only applies when the algorithm is 'eig'. If you don't specify the algorithm along with 'pairwise', then <code>pca</code> sets it to 'eig'. If you specify 'svd' as the algorithm, along with the option 'Rows', 'pairwise', then <code>pca</code> returns a warning message, sets the algorithm to 'eig' and continues.</p> <p>When you specify the 'Rows', 'pairwise' option, <code>pca</code> computes the <math>(i,j)</math> element of the covariance matrix using the rows with no NaN values in the columns <math>i</math> or <math>j</math> of <math>X</math>.</p> <p>Note that the resulting covariance matrix might not be positive definite. In that case, <code>pca</code> terminates with an error message.</p>
'all'	$X$ is expected to have no missing values. <code>pca</code> uses all of the data and terminates if any NaN value is found.

**Example:** 'Rows', 'pairwise'

**Data Types**

char

**'Weights' - Observation weights**

ones (default) | row vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$  containing all positive elements.

**Data Types**

single | double

**'VariableWeights' - Variable weights**

row vector | 'variance'

Variable weights, specified as the comma-separated pair consisting of 'VariableWeights' and one of the following.

---

Vector of length  $p$  containing all positive elements.

The string 'variance'. The variable weights are the inverse of sample variance. If you also assign weights to observations using 'Weights', then the variable weights become the inverse of weighted sample variance.

If 'Centered' is set to true at the same time, the data matrix  $X$  is centered and standardized. In this case, pca returns the principal components based on the correlation matrix.

---

**Example:** 'VariableWeights', 'variance'

**Data Types**

single | double | char

**'Coeff0' - Initial value for coefficients**

matrix of random values (default) |  $p$ -by- $k$  matrix

Initial value for the coefficient matrix `coeff`, specified as the comma-separated pair consisting of 'Coeff0' and a  $p$ -by- $k$  matrix, where  $p$  is the number of variables, and  $k$  is the number of principal components requested.

---

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

---

**Data Types**

single | double

**'Score0' - Initial value for scores**matrix of random values (default) |  $k$ -by- $m$  matrix

Initial value for scores matrix `score`, specified as a comma-separated pair consisting of 'Score0' and an  $n$ -by- $k$  matrix, where  $n$  is the number of observations and  $k$  is the number of principal components requested.

---

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

---

**Data Types**

single | double

**'Options' - Options for iterations**

structure

Options for the iterations, specified as a comma-separated pair consisting of 'Options' and a structure created by the `statset` function. `pca` uses the following fields in the options structure.

'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number steps allowed. The default is 100. Unlike in optimization settings, reaching the MaxIter value is regarded as convergence.
'TolFun'	Positive number giving the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive number giving the convergence threshold for the relative change in the elements of the left and right factor matrices, L and R, in the ALS algorithm. The default is 1e-6.

---

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

---

You can change the values of these fields and specify the new structure in `pca` using the 'Options' name-value pair argument.

**Example:** `opt = statset('pca'); opt.MaxIter = 2000; coeff = pca(X, 'Options', opt);`

### Data Types

struct

## Output Arguments

### **coeff** - Principal component coefficients

matrix

Principal component coefficients, returned as a  $p$ -by- $p$  matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, `latent`.

### **score** - Principal component scores

matrix

Principal component scores, returned as a matrix. Rows of `score` correspond to observations, and columns to components.

### **latent** - Principal component variances

column vector

Principal component variances, that is the eigenvalues of the covariance matrix of `X`, returned as a column vector.

### **tsquared** - Hotelling's T-squared statistic

column vector

"Hotelling's T-Squared Statistic" on page 21-2406, which is the sum of squares of the standardized scores for each observation, returned as a column vector.

**explained - Percentage of total variance explained**

column vector

Percentage of the total variance explained by each principal component, returned as a column vector.

**mu - Estimated means**

row vector

Estimated means of the variables in X, returned as a row vector. When 'algorithm' is 'als', this is estimated by ALS algorithm. When 'algorithm' is not 'als', mu is equal to the sample mean of X.

**Examples****Principal Components of a Data Set**

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal components for the ingredients data.

```
coeff = pca(ingredients)
```

```
coeff =
```

```

-0.0678   -0.6460    0.5673    0.5062
-0.6785   -0.0200   -0.5440    0.4933
 0.0290    0.7553    0.4036    0.5156
 0.7309   -0.1085   -0.4684    0.4844
```

The rows of `coeff` contain the coefficients for the four ingredient variables, and its columns correspond to four principal components.

**PCA in the Presence of Missing Data**

Find the principal component coefficients when there are missing values in a data set.

Load the sample data set.

```
load imports-85
```

Data matrix  $X$  has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform principal component analysis.

```
coeff = pca(X(:,3:15));
```

By default, `pca` performs the action specified by the 'Rows', 'complete' name-value pair argument. This option removes the observations with NaN values before calculation. Rows of NaNs are reinserted into `score` and `tsquared` at the corresponding locations, namely rows 56 to 59, 131, and 132.

Use 'pairwise' to perform the principal component analysis.

```
coeff = pca(X(:,3:15), 'Rows', 'pairwise');
```

In this case, `pca` computes the  $(i,j)$  element of the covariance matrix using the rows with no NaN values in the columns  $i$  or  $j$  of  $X$ . Note that the resulting covariance matrix might not be positive definite. This option applies when the algorithm `pca` uses is eigenvalue decomposition. When you don't specify the algorithm, as in this example, `pca` sets it to 'eig'. If you require 'svd' as the algorithm, with the 'pairwise' option, then `pca` returns a warning message, sets the algorithm to 'eig' and continues.

If you use the 'Rows', 'all' name-value pair argument, `pca` terminates because this option assumes there are no missing values in the data set.

```
coeff = pca(X(:,3:15), 'Rows', 'all');
```

Error using pca (line 180)

Raw data contains NaN missing value while 'Rows' option is set to 'all'

## Weighted PCA

Use the inverse variable variances as weights while performing the principal components analysis.

Load the sample data set.

```
load hald
```

Perform the principal component analysis using the inverse of variances of the ingredients as variable weights.

```
[wcoeff,~,latent,~,explained] = pca(ingredients,...  
'VariableWeights','variance')
```

```
wcoeff =
```

-2.7998	2.9940	-3.9736	1.4180
-8.7743	-6.4411	4.8927	9.9863
2.5240	-3.8749	-4.0845	1.7196
9.1714	7.5529	3.2710	11.3273

```
latent =
```

2.2357
1.5761
0.1866
0.0016

```
explained =
```

55.8926
39.4017
4.6652
0.0406

Note that the coefficient matrix, `wcoeff`, is not orthonormal.

Calculate the orthonormal coefficient matrix.

```
coefforth = inv(diag(std(ingredients))) * wcoeff
```

```
coefforth =
```

```
-0.4760    0.5090   -0.6755    0.2411  
-0.5639   -0.4139    0.3144    0.6418  
 0.3941   -0.6050   -0.6377    0.2685  
 0.5479    0.4512    0.1954    0.6767
```

Check orthonormality of the new coefficient matrix, `coefforth`.

```
coefforth*coefforth'
```

```
ans =
```

```
 1.0000    0.0000   -0.0000   -0.0000  
 0.0000    1.0000   -0.0000   -0.0000  
-0.0000   -0.0000    1.0000         0  
-0.0000   -0.0000         0    1.0000
```

### PCA Using ALS for Missing Data

Find the principal components using the alternating least squares (ALS) algorithm when there are missing values in the data.

Load the sample data.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff,score,latent,tsquared,explained] = pca(ingredients);  
coeff
```

```
coeff =
    -0.0678    -0.6460     0.5673     0.5062
    -0.6785    -0.0200    -0.5440     0.4933
     0.0290     0.7553     0.4036     0.5156
     0.7309    -0.1085    -0.4684     0.4844
```

Introduce missing values randomly.

```
y = ingredients;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.30;
y(ix) = NaN
```

```
y =
     7     26     6  NaN
     1     29    15   52
    NaN  NaN     8   20
    11    31  NaN   47
     7    52     6   33
    NaN   55  NaN  NaN
    NaN   71  NaN    6
     1    31  NaN   44
     2  NaN  NaN   22
    21   47     4   26
    NaN   40   23   34
    11   66     9  NaN
    10   68     8   12
```

Approximately 30% of the data has missing values now, indicated by NaN.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff1,score1,latent,tsquared,explained,mu1] = pca(y,...
'algorithm','als');
```

coeff1

coeff1 =

-0.0362	0.8215	-0.5252	0.2190
-0.6831	-0.0998	0.1828	0.6999
0.0169	0.5575	0.8215	-0.1185
0.7292	-0.0657	0.1261	0.6694

Display the estimated mean.

mu1

mu1 =

8.9956	47.9088	9.0451	28.5515
--------	---------	--------	---------

Reconstruct the observed data.

t = score1\*coeff1' + repmat(mu1,13,1)

t =

7.0000	26.0000	6.0000	51.5250
1.0000	29.0000	15.0000	52.0000
10.7819	53.0230	8.0000	20.0000
11.0000	31.0000	13.5500	47.0000
7.0000	52.0000	6.0000	33.0000
10.4818	55.0000	7.8328	17.9362
3.0982	71.0000	11.9491	6.0000
1.0000	31.0000	-0.5161	44.0000
2.0000	53.7914	5.7710	22.0000
21.0000	47.0000	4.0000	26.0000
21.5809	40.0000	23.0000	34.0000
11.0000	66.0000	9.0000	5.7078
10.0000	68.0000	8.0000	12.0000

The ALS algorithm estimates the missing values in the data.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors. Find the angle between the coefficients found for complete data and data with missing values using ALS.

```
subspace(coeff,coeff1)
```

```
ans =
```

```
2.2925e-16
```

This is a small value. It indicates that the results if you use `pca` with `'Rows','complete'` name-value pair argument when there is no missing data and if you use `pca` with `'algorithm','als'` name-value pair argument when there is missing data are close to each other.

Perform the principal component analysis using `'Rows','complete'` name-value pair argument and display the component coefficients.

```
[coeff2,score2,latent,tsquared,explained,mu2] = pca(y,...
'Rows','complete');
coeff2
```

```
coeff2 =
```

```
-0.2054    0.8587    0.0492
-0.6694   -0.3720    0.5510
 0.1474   -0.3513   -0.5187
 0.6986   -0.0298    0.6518
```

In this case, `pca` removes the rows with missing values, and `y` has only four rows with no missing values. `pca` returns only three principal components. You cannot use the `'Rows','pairwise'` option because the covariance matrix is not positive semidefinite and `pca` returns an error message.

Find the angle between the coefficients found for complete data and data with missing values using listwise deletion (when `'Rows','complete'`).

```
subspace(coeff(:,1:3),coeff2)
```

```
ans =
```

```
0.3576
```

The angle between the two spaces is substantially larger. This indicates that these two results are differ.

Display the estimated mean.

```
mu2
```

```
mu2 =
```

```
7.8889 46.9091 9.8750 29.6000
```

In this case, the mean is just the sample mean of y.

Reconstruct the observed data.

```
score2*coeff2'
```

```
ans =
```

```
NaN NaN NaN NaN
-7.5162 -18.3545 4.0968 22.0056
NaN NaN NaN NaN
NaN NaN NaN NaN
-0.5644 5.3213 -3.3432 3.6040
NaN NaN NaN NaN
NaN NaN NaN NaN
NaN NaN NaN NaN
NaN NaN NaN NaN
12.8315 -0.1076 -6.3333 -3.7758
NaN NaN NaN NaN
NaN NaN NaN NaN
1.4680 20.6342 -2.9292 -18.0043
```

This shows that deleting rows containing NaN values does not work as well as the ALS algorithm. Using ALS is better when the data has too many missing values.

### Principal Component Coefficients, Scores, and Variances

Find the coefficients, scores, and variances of the principal components.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal component coefficients, scores, and variances of the components for the ingredients data.

```
[coeff,score,latent] = pca(ingredients)
```

```
coeff =
```

-0.0678	-0.6460	0.5673	0.5062
-0.6785	-0.0200	-0.5440	0.4933
0.0290	0.7553	0.4036	0.5156
0.7309	-0.1085	-0.4684	0.4844

```
score =
```

36.8218	-6.8709	-4.5909	0.3967
29.6073	4.6109	-2.2476	-0.3958
-12.9818	-4.2049	0.9022	-1.1261
23.7147	-6.6341	1.8547	-0.3786
-0.5532	-4.4617	-6.0874	0.1424
-10.8125	-3.6466	0.9130	-0.1350
-32.5882	8.9798	-1.6063	0.0818
22.6064	10.7259	3.2365	0.3243
-9.2626	8.9854	-0.0169	-0.5437
-3.2840	-14.1573	7.0465	0.3405

```
    9.2200    12.3861    3.4283    0.4352
   -25.5849   -2.7817   -0.3867    0.4468
   -26.9032   -2.9310   -2.4455    0.4116
```

latent =

```
517.7969
 67.4964
 12.4054
  0.2372
```

Each column of `score` corresponds to one principal component. The vector, `latent`, stores the variances of the four principal components.

Reconstruct the centered ingredients data.

```
Xcentered = score*coeff'
```

Xcentered =

```
-0.4615  -22.1538  -5.7692  30.0000
-6.4615  -19.1538   3.2308  22.0000
 3.5385   7.8462  -3.7692 -10.0000
 3.5385  -17.1538  -3.7692  17.0000
-0.4615   3.8462  -5.7692   3.0000
 3.5385   6.8462  -2.7692  -8.0000
-4.4615  22.8462   5.2308 -24.0000
-6.4615  -17.1538  10.2308  14.0000
-5.4615   5.8462   6.2308  -8.0000
13.5385  -1.1538  -7.7692  -4.0000
-6.4615  -8.1538  11.2308   4.0000
 3.5385  17.8462  -2.7692 -18.0000
 2.5385  19.8462  -3.7692 -18.0000
```

The new data in `Xcentered` is the original ingredients data centered by subtracting the column means from corresponding columns.

## T-Squared Statistic

Find the Hotelling's T-squared statistic values.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform the principal component analysis and request the T-squared values.

```
[coeff,score,latent,tsquared] = pca(ingredients);  
tsquared
```

```
tsquared =
```

```
    5.6803  
    3.0758  
    6.0002  
    2.6198  
    3.3681  
    0.5668  
    3.4818  
    3.9794  
    2.6086  
    7.4818  
    4.1830  
    2.2327  
    2.7216
```

Request only the first two principal components and compute the T-squared values in the reduced space of requested principal components.

```
[coeff,score,latent,tsquared] = pca(ingredients,'NumComponents',2);  
tsquared
```

```
tsquared =  
  
    5.6803  
    3.0758  
    6.0002  
    2.6198  
    3.3681  
    0.5668  
    3.4818  
    3.9794  
    2.6086  
    7.4818  
    4.1830  
    2.2327  
    2.7216
```

Note that even when you specify a reduced component space, `pca` computes the T-squared values in the full space, using all four components.

The T-squared value in the reduced space corresponds to the Mahalanobis distance in the reduced space.

```
tsqreduced = mahal(score, score)
```

```
tsqreduced =  
  
    3.3179  
    2.0079  
    0.5874  
    1.7382  
    0.2955  
    0.4228  
    3.2457  
    2.6914  
    1.3619  
    2.9903
```

```

2.4371
1.3788
1.5251

```

Calculate the T-squared values in the discarded space by taking the difference of the T-squared values in the full space and Mahalanobis distance in the reduced space.

```
tsqdiscarded = tsquared - tsqreduced
```

```
tsqdiscarded =
```

```

2.3624
1.0679
5.4128
0.8816
3.0726
0.1440
0.2362
1.2880
1.2467
4.4915
1.7459
0.8539
1.1965

```

### **Percent Variability Explained by Principal Components**

Find the percent variability explained by the principal components.

Load the sample data set.

```
load imports-85
```

Data matrix  $X$  has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg.

Find the percent variability explained by principal components of these variables.

```
[coeff,score,latent,tsquared,explained] = pca(X(:,3:15));
```

```
explained
```

```
explained =
```

```
64.3429  
35.4484  
0.1550  
0.0379  
0.0078  
0.0048  
0.0013  
0.0011  
0.0005  
0.0002  
0.0002  
0.0000  
0.0000
```

The first two components explain 99.79% of all variability.

To skip any of the outputs, you can use ~ instead in the corresponding element. For example, if you don't want to get the T-squared values, specify

```
[coeff,score,latent,~,explained] = pca(X(:,3:15));
```

## **Definitions**

### **Hotelling's T-Squared Statistic**

Hotelling's T-squared statistic is a statistical measure of the multivariate distance of each observation from the center of the data set.

Even when you request fewer components than the number of variables, `pca` uses all principal components to compute the T-squared statistic

(computes it in the full space). If you want the T-squared statistic in the reduced or the discarded space, do one of the following:

- For the T-squared statistic in the reduced space, use `mahal(score, score)`.
- For the T-squared statistic in the discarded space, first compute the T-squared statistic using `[coeff, score, latent, tsquared] = pca(X, 'NumComponents', k, ...)`, compute the T-squared statistic in the reduced space using `tsqreduced = mahal(score, score)`, and then take the difference: `tsquared - tsqreduced`.

### Degrees of Freedom

The degrees of freedom,  $d$ , is equal to  $n - 1$ , if data is centered and  $n$  otherwise, where:

- $n$  is the number of rows without any NaNs if you use `'Rows', 'complete'`.
- $n$  is the number of rows without any NaNs in the column pair that has the maximum number of rows without NaNs if you use `'Rows', 'pairwise'`.

### Variable Weights

Note that when variable weights are used, the coefficient matrix is not orthonormal. Suppose the variable weights vector you used is called `varwei`, and the principal component coefficients vector `pca` returned is `wcoeff`. You can then calculate the orthonormal coefficients using the transformation `diag(sqrt(varwei))*wcoeff`.

<b>Purpose</b>	Principal component analysis on covariance matrix
<b>Syntax</b>	<pre>COEFF = pcacov(V) [COEFF,latent] = pcacov(V) [COEFF,latent,explained] = pcacov(V)</pre>
<b>Description</b>	<p>COEFF = pcacov(V) performs principal components analysis on the p-by-p covariance matrix V and returns the principal component coefficients, also known as loadings. COEFF is a p-by-p matrix, with each column containing coefficients for one principal component. The columns are in order of decreasing component variance.</p> <p>pcacov does not standardize V to have unit variances. To perform principal components analysis on standardized variables, use the correlation matrix <math>R = V ./ (SD * SD')</math>, where <math>SD = \text{sqrt}(\text{diag}(V))</math>, in place of V. To perform principal components analysis directly on the data matrix, use <code>pca</code>.</p> <p>[COEFF,latent] = pcacov(V) returns latent, a vector containing the principal component variances, that is, the eigenvalues of V.</p> <p>[COEFF,latent,explained] = pcacov(V) returns explained, a vector containing the percentage of the total variance explained by each principal component.</p>
<b>Examples</b>	<pre>load hald covx = cov(ingredients); [COEFF,latent,explained] = pcacov(covx) COEFF =     0.0678 -0.6460  0.5673 -0.5062     0.6785 -0.0200 -0.5440 -0.4933    -0.0290  0.7553  0.4036 -0.5156    -0.7309 -0.1085 -0.4684 -0.4844  latent =     517.7969      67.4964      12.4054</pre>

**Purpose**

Residuals from principal component analysis

**Syntax**

```
residuals = pcares(X,ndim)
[residuals,reconstructed] = pcares(X,ndim)
```

**Description**

`residuals = pcares(X,ndim)` returns the residuals obtained by retaining `ndim` principal components of the `n`-by-`p` matrix `X`. Rows of `X` correspond to observations, columns to variables. `ndim` is a scalar and must be less than or equal to `p`. `residuals` is a matrix of the same size as `X`. Use the data matrix, *not* the covariance matrix, with this function.

`pcares` does not normalize the columns of `X`. To perform the principal components analysis based on standardized variables, that is, based on correlations, use `pcares(zscore(X), ndim)`. You can perform principal components analysis directly on a covariance or correlation matrix, but without constructing residuals, by using `pcacov`.

`[residuals,reconstructed] = pcares(X,ndim)` returns the reconstructed observations; that is, the approximation to `X` obtained by retaining its first `ndim` principal components.

**Examples**

This example shows the drop in the residuals from the first row of the Hald data as the number of component dimensions increases from one to three.

```
load hald
r1 = pcares(ingredients,1);
r2 = pcares(ingredients,2);
r3 = pcares(ingredients,3);

r11 = r1(1,:)
r11 =
    2.0350    2.8304   -6.8378    3.0879

r21 = r2(1,:)
r21 =
   -2.4037    2.6930   -1.6482    2.3425
```

```
r31 = r3(1,:)
r31 =
    0.2008    0.1957    0.2045    0.1921
```

factoran | pcacov | pca

**Purpose**

Probabilistic principal component analysis

**Syntax**

```
[coeff,score,pcvar] = ppca(Y,K)
[coeff,score,pcvar] = ppca(Y,K,Name,Value)
[coeff,score,pcvar,mu] = ppca(____)
[coeff,score,pcvar,mu,v,S] = ppca(____)
```

**Description**

`[coeff,score,pcvar] = ppca(Y,K)` returns the principal component coefficients for the  $n$ -by- $p$  data matrix  $Y$  based on a probabilistic principal component analysis (PPCA). It also returns the principal component scores, which are the representations of  $Y$  in the principal component space, and the principal component variances, which are the eigenvalues of the covariance matrix of  $Y$ , in `pcvar`.

Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. Rows of `score` correspond to observations, and columns correspond to components. Rows of  $Y$  correspond to observations and columns correspond to variables.

Probabilistic principle component analysis might be preferable to other algorithms that handle missing data, such as the alternating least squares algorithm when any data vector has one or more missing values. It assumes that the values are missing at random through the data set. An expectation-maximization algorithm is used for both complete and missing data.

`[coeff,score,pcvar] = ppca(Y,K,Name,Value)` returns the principal component coefficients, scores, and variances using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can introduce initial values for the residual variance, `v`, or change the termination criteria.

[coeff, score, pcvar, mu] = ppca( \_\_\_ ) also returns the estimated mean of each variable in  $Y$ . You can use any of the input arguments in the previous syntaxes.

[coeff, score, pcvar, mu, v, S] = ppca( \_\_\_ ) also returns the isotropic residual variance in  $v$  and the final results at convergence in structure  $S$ .

## Input Arguments

### **Y - Input data**

*n*-by-*p* matrix

Input data for which to compute the principal components, specified as an *n*-by-*p* matrix. Rows of  $Y$  correspond to observations and columns correspond to variables.

### **Data Types**

single | double

### **K - Number of principal components**

positive integer value less than rank

Number of principal components to return, specified as an integer value less than the rank of data. The maximum possible rank is  $\min(n,p)$ , where  $n$  is the number of observations and  $p$  is the number of variables. However, if the data is correlated, the rank might be smaller than  $\min(n,p)$ .

ppca orders the components based on their variance.

If  $K$  is  $\min(n,p)$ , ppca sets  $K$  equal to  $\min(n,p) - 1$ , and 'W0' is truncated to  $\min(p,n) - 1$  columns if you specify a *p*-by-*p*  $W0$  matrix.

For example, you can request only the first three components, based on the component variance as follows.

**Example:** coeff = ppca(Y,3)

### **Data Types**

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'W0', init, 'Options', opt` specifies that the initial values for `'W0'` are in matrix `init` and `ppca` uses the options defined by `opt`.

### 'W0' - Initial value of $W$

matrix of random values (default) |  $p$ -by- $k$  matrix

Initial value of  $W$  in the probabilistic principal component analysis algorithm, specified as a comma-separated pair consisting of `'W0'` and a  $p$ -by- $k$  matrix.

#### Data Types

single | double

### 'v0' - Initial value of residual variance

random number (default) | positive scalar value

Initial value of residual variance, specified as the comma-separated pair consisting of `'v0'` and a positive scalar value.

#### Data Types

single | double

### 'Options' - Options for iterations

structure

Options for the iterations, specified as a comma-separated pair `'Options'` and a structure created by the `statset` function. `ppca` uses the following fields in the options structure.

'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number of steps allowed. The default is 1000. Unlike in optimization settings, reaching the MaxIter value is regarded as convergence.
'TolFun'	Positive integer stating the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive integer stating the convergence threshold for the relative change in the elements of $W$ . The default is 1e-6.

You can change the values of these fields and specify the new structure in ppca using the 'Options' name-value pair argument.

**Example:** `opt = statset('ppca'); opt.MaxIter = 2000; coeff = ppca(Y,3,'Options',opt);`

**Data Types**

struct

**Output Arguments**

**coeff - Principal component coefficients**

*p*-by-*k* matrix

Principal component coefficients, returned as a *p*-by-*k* matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, `pcvar`.

**score - Principal component scores**

*n*-by-*k* matrix

Principal component scores, returned as an *n*-by-*k* matrix. Rows of `score` correspond to observations, and columns correspond to components.

**pcvar - Principal component variances**

column vector

Principal component variances, which are the eigenvalues of the covariance matrix of  $Y$ , returned as a column vector.

### **$\mu$ - Estimated mean**

row vector

Estimated mean of each variable in  $Y$ , returned as a row vector.

### **$v$ - Isotropic residual variance**

scalar value

Isotropic residual variance, returned as a scalar value.

### **$S$ - Final results at convergence**

structure

Final results at convergence, returned as a structure containing the following fields.

$W$	$W$ at convergence.
Xexp	Conditional expectation of the estimated latent variable $x$ .
Recon	Reconstructed observations using $k$ principle components. This is a low dimension approximation of the input data $Y$ , and is equal to $\mu + \text{score} * \text{coeff}'$ .
$v$	Residual variance.
RMSResid	Root mean square of residuals.
NumIter	Number of iteration counts.
nloglk	Negative loglikelihood function value.

## Examples

### Perform Probabilistic Principal Component Analysis

Load the sample data.

```
load fisheriris
```

The double matrix `meas` consists of four types of measurements on the flowers, which, respectively, are the length and width of sepals and petals.

Introduce missing values randomly.

```
y = meas;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.20;
y(ix) = NaN;
```

Now, approximately 20% of the data is missing, indicated by NaN.

Perform probabilistic principal component analysis and request the component coefficients and variances.

```
[coeff,score,pcvar,mu] = ppca(y,3);
coeff
```

```
coeff =
```

```
    0.3562    0.6709   -0.5518
   -0.0765    0.7121    0.6332
    0.8592   -0.1596    0.0596
    0.3592   -0.1318    0.5395
```

```
pcvar
```

```
pcvar =
```

```
    4.0912
    0.2126
    0.0617
```

Perform principal component analysis using the alternating least squares algorithm and request the component coefficients and variances.

```
[coeff2,score2,pcvar2,mu2] = pca(y,'algorithm','als',...
```

```
'NumComponents',3);
coeff2

coeff2 =

    0.3376    0.4955    0.7404
   -0.0731    0.8607   -0.4479
    0.8657   -0.1169   -0.1231
    0.3623   -0.0087   -0.4859
```

```
pcvar2
```

```
pcvar2 =

    4.0734
    0.2651
    0.1221
```

The coefficients and the variances of the first two principal components are similar.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors.

```
subspace(coeff,coeff2)

ans =

    0.0881
```

The angle between the two spaces is pretty small. This indicates that these two results are close to each other.

### **Change the Termination Criteria for Probabilistic Principal Component Analysis**

Load the sample data set.

```
load imports-85
```

Data matrix  $X$  has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform probabilistic principal component analysis and display the first three principal components.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3);
```

```
Warning: Maximum number of iterations 1000 reached'.  
> In ppca at 249
```

Change the termination tolerance for the cost function to 0.01.

```
opt = statset('ppca');  
opt.TolFun = 0.01;
```

Perform probabilistic principal component analysis.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3,'Options',opt);
```

ppca now terminates before the maximum number of iterations is reached because it meets the tolerance for the cost function.

## Reconstruct Observations

Load the sample data.

```
load hald  
y = ingredients;
```

The ingredients data has 13 observations for 4 variables.

Introduce missing values to the data.

```
y(2:16:end) = NaN;
```

Every 16th value is NaN. This corresponds to 7.69% of the data.

Find the first three principal components of data using PPCA and display the reconstructed observations.

```
[coeff,score,pcvar,mu,v,S] = ppca(y,3);
S.Recon
```

```
ans =
```

```

    6.8533    25.8675    5.8388    59.8755
    1.0431    28.9690   14.9652    51.9758
   11.5770   56.5080    8.6352   20.5062
   11.0833   31.0707    8.0920   47.0764
    7.0684   52.2539    6.0753   33.0597
   11.0486   55.0442    9.0534   22.0410
    2.8494   70.8719   16.8338    5.8624
    1.0331   31.0267   19.6906   44.0321
    2.0401   54.0364   18.0440   22.0337
   20.7823   46.8096    3.7603   25.8075
    0.9540   39.9590   22.9495   31.1540
   10.8251   65.8498    8.8072   11.8420
    9.9174   67.9309    7.9087   11.9230
```

You can also reconstruct the observations using the principle components and the estimated mean.

```
t = score*coeff' + repmat(mu,13,1);
```

## Results at Convergence

Load the sample data.

```
load hald
```

Here, `ingredients` is a real-valued matrix of predictor variables.

Perform the probabilistic principal components analysis and display coefficients.

```
[coeff,score,pcvariance,mu,v,S] = ppca(ingredients,3);  
coeff
```

```
coeff =
```

```
   -0.0693   -0.6459    0.5673  
   -0.6786   -0.0184   -0.5440  
    0.0308    0.7552    0.4036  
    0.7306   -0.1102   -0.4684
```

Display the algorithm results at convergence of the PPCA.

```
S
```

```
S =
```

```
           W: [4x3 double]  
          Xexp: [13x3 double]  
         Recon: [13x4 double]  
           v: 0.2372  
    NumIter: 1000  
   RMSResid: 0.2340  
     nloglk: 149.3388
```

Display the matrix W.

```
S.W
```

```
ans =
```

```
    0.5624    2.0279    5.4075  
    4.8320   -10.3894    5.9202  
   -3.7521   -3.0555   -4.1552  
   -1.5144   11.7122   -7.2564
```

Orthogonalizing W recovers the coefficients.

orth(S.W)

ans =

-0.0693	0.6459	0.5673
-0.6786	0.0184	-0.5440
0.0308	-0.7552	0.4036
0.7306	0.1102	-0.4684

## Definitions

### Probabilistic Principal Component Analysis

Probabilistic principle component analysis (PPCA) is a method to estimate the principal axes when any data vector has one or more missing values.

PPCA is based on an isotropic error model. It seeks to relate a  $p$ -dimensional observation vector  $y$  to a corresponding  $k$ -dimensional vector of latent (or unobserved) variable  $x$ , which is normal with mean zero and covariance  $I(k)$ . The relationship is

$$y^T = W * x^T + \mu + \varepsilon,$$

where  $y$  is the row vector of observed variable,  $x$  is the row vector of latent variables, and  $\varepsilon$  is the isotropic error term.  $\varepsilon$  is Gaussian with mean zero and covariance of  $v * I(k)$ , where  $v$  is the residual variance. Here,  $k$  needs to be smaller than the rank for the residual variance to be greater than 0 ( $v > 0$ ). Standard principal component analysis, where the residual variance is zero, is the limiting case of PPCA. The observed variables,  $y$ , are conditionally independent given the values of the latent variables,  $x$ . So, the latent variables explain the correlations between the observation variables and the error explains the variability unique to a particular  $y_i$ . The  $p$ -by- $k$  matrix  $W$  relates the latent and observation variables, and the vector  $\mu$  permits the model to have a nonzero mean. PPCA assumes that the values are missing at random through the data set. This means that whether a data value is missing or not does not depend on the latent variable given the observed data values.

Under this model,

$$y \sim N\left(\mu, W * W^T + v * I(k)\right).$$

There is no closed-form analytical solution for  $W$  and  $v$ , so their estimates are determined by iterative maximization of the corresponding loglikelihood using an expectation-maximization (EM) algorithm. This EM algorithm handles missing values by treating them as additional latent variables. At convergence, the columns of  $W$  spans the subspace, but they are not orthonormal. `ppca` obtains the orthonormal coefficients, `coeff`, for the components by orthogonalization of  $W$ .

# gmdistribution.PComponents property

---

**Purpose** Input vector of mixing proportions

**Description** Optional input vector of mixing proportions  $p$ , or its default value.

**Purpose** Probability density functions

**Syntax**  
 $Y = \text{pdf}(\text{name}, X, A)$   
 $Y = \text{pdf}(\text{name}, X, A, B)$   
 $Y = \text{pdf}(\text{name}, X, A, B, C)$

**Description**  $Y = \text{pdf}(\text{name}, X, A)$  computes the probability density function for the one-parameter family of distributions specified by `name`. Parameter values for the distribution are given in `A`. Densities are evaluated at the values in `X` and returned in `Y`.

If `X` and `A` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`. If `A` is a scalar, it is expanded to a constant matrix the same size as `X`.

`Y` is the common size of `X` and `A` after any necessary scalar expansion.

$Y = \text{pdf}(\text{name}, X, A, B)$  computes the probability density function for two-parameter families of distributions, where parameter values are given in `A` and `B`.

If `X`, `A`, and `B` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A` and `B`. If either `A` or `B` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, and `B` after any necessary scalar expansion.

$Y = \text{pdf}(\text{name}, X, A, B, C)$  computes the probability density function for three-parameter families of distributions, where parameter values are given in `A`, `B`, and `C`.

If `X`, `A`, `B`, and `C` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`, `B`, and `C`. If any of `A`, `B` or `C` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, `B` and `C` after any necessary scalar expansion.

## Examples

Compute the pdf of the normal distribution with mean 0 and standard deviation 1 at inputs  $-2, -1, 0, 1, 2$ :

```
p1 = pdf('Normal', -2:2, 0, 1)
p1 =
    0.0540    0.2420    0.3989    0.2420    0.0540
```

The order of the parameters is the same as for `normpdf`.

Compute the pdfs of Poisson distributions with rate parameters 0, 1, ..., 4 at inputs 1, 2, ..., 5, respectively:

```
p2 = pdf('Poisson', 0:4, 1:5)
```

---

```
p2 =  
  0.3679  0.2707  0.2240  0.1954  0.1755
```

The order of the parameters is the same as for `poisspdf`.

`cdf` | `icdf` | `mle` | `random`

# gmdistribution.pdf

---

**Purpose** Probability density function for Gaussian mixture distribution

**Syntax** `y = pdf(obj,X)`

**Description** `y = pdf(obj,X)` returns a vector `y` of length  $n$  containing the values of the probability density function (`pdf`) for the `gmdistribution` object `obj`, evaluated at the  $n$ -by- $d$  data matrix `X`, where  $n$  is the number of observations and  $d$  is the dimension of the data. `obj` is an object created by `gmdistribution` or `fit`. `y(I)` is the pdf of observation `I`.

**Examples** Create a `gmdistribution` object defining a two-component mixture of bivariate Gaussian distributions:

```
MU = [1 2;-3 -5];
SIGMA = cat(3,[2 0;0 .5],[1 0;0 1]);
p = ones(1,2)/2;
obj = gmdistribution(MU,SIGMA,p);

ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

**See Also**

`gmdistribution` | `fit` | `cdf` | `mvnpdf`

# piecewisedistribution.pdf

---

**Purpose** Probability density function for piecewise distribution

**Syntax** `P = pdf(obj,X)`

**Description** `P = pdf(obj,X)` returns an array `P` of values of the probability density function for the piecewise distribution object `obj`, evaluated at the values in the array `X`.

---

**Note** For a Pareto tails object, the pdf is computed using the generalized Pareto distribution in the tails. In the center, the pdf is computed using the slopes of the cdf, which are interpolated between a set of discrete values. Therefore the pdf in the center is piecewise constant. It is noisy for a *cdf* specified in *paretotails* via the 'ecdf' option, and somewhat smoother for the 'kernel' option, but generally not a good estimate of the underlying density of the original data.

---

## Examples

Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432

pdf(obj,q)
ans =
    0.2367
    0.1960
```

# ProbDist.pdf

---

<b>Purpose</b>	Return probability density function (PDF) for ProbDist object	
<b>Syntax</b>	$Y = \text{pdf}(PD, X)$	
<b>Description</b>	$Y = \text{pdf}(PD, X)$ returns $Y$ , an array containing the probability density function (PDF) for the ProbDist object $PD$ , evaluated at values in $X$ .	
<b>Input Arguments</b>	$PD$	An object of the class ProbDistUnivParam or ProbDistUnivKernel.
	$X$	A numeric array of values where you want to evaluate the PDF.
<b>Output Arguments</b>	$Y$	An array containing the probability density function (PDF) for the ProbDist object $PD$ .
<b>See Also</b>	pdf	

<b>Purpose</b>	Probability density function of probability distribution object
<b>Syntax</b>	<code>y = pdf(pd,x)</code>
<b>Description</b>	<code>y = pdf(pd,x)</code> returns the probability density function (pdf) of the continuous probability distribution <code>pd</code> at the values in <code>x</code> . For discrete distributions, <code>pdf</code> returns the probability mass function.
<b>Input Arguments</b>	<p><b>pd - Probability distribution</b> probability distribution object</p> <p>Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using <code>makedist</code>. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using <code>fitdist</code> or the Distribution Fitting app.</p> <p><b>x - Values at which to calculate pdf</b> array</p> <p>Values at which to calculate pdf, specified as an array.</p> <p><b>Data Types</b> single   double</p>
<b>Output Arguments</b>	<p><b>y - Probability density function</b> array</p> <p>Probability density function of <code>pd</code>, evaluated at the values in data vector <code>x</code>, returned as a array. <code>y</code> has the same dimensions as input <code>x</code>.</p>
<b>Examples</b>	<p><b>Plot the pdf of a Standard Normal Distribution</b></p> <p>Create a standard normal distribution object.</p> <pre>pd = makedist('Normal')</pre> <pre>pd =</pre>

# pdist

---

**Purpose** Pairwise distance between pairs of objects

**Syntax**  
`D = pdist(X)`  
`D = pdist(X,distance)`

**Description** `D = pdist(X)` computes the Euclidean distance between pairs of objects in  $m$ -by- $n$  data matrix  $X$ . Rows of  $X$  correspond to observations, and columns correspond to variables.  $D$  is a row vector of length  $m(m-1)/2$ , corresponding to pairs of observations in  $X$ . The distances are arranged in the order  $(2,1)$ ,  $(3,1)$ , ...,  $(m,1)$ ,  $(3,2)$ , ...,  $(m,2)$ , ...,  $(m,m-1)$ .  $D$  is commonly used as a dissimilarity matrix in clustering or multidimensional scaling.

To save space and computation time,  $D$  is formatted as a vector. However, you can convert this vector into a square matrix using the `squareform` function so that element  $i, j$  in the matrix, where  $i < j$ , corresponds to the distance between objects  $i$  and  $j$  in the original data set.

`D = pdist(X,distance)` computes the distance between objects in the data matrix,  $X$ , using the method specified by `distance`, which can be any of the following character strings.

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in $X$ is scaled by dividing by the corresponding element of the standard deviation <code>S=nanstd(X)</code> . To specify another value for $S$ , use <code>D=pdist(X, 'seuclidean', S)</code> .
'cityblock'	City block metric.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use <code>D = pdist(X, 'minkowski', P)</code> , where $P$ is a scalar positive value of the exponent.

<b>Metric</b>	<b>Description</b>
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of X as computed by nancov. To compute the distance with a different covariance, use <code>D = pdist(X, 'mahalanobis', C)</code> , where the matrix C is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
custom distance function	<p>A distance function specified using @:  <code>D = pdist(X,@distfun)</code></p> <p>A distance function must be of form</p> $d2 = \text{distfun}(XI, XJ)$ <p>taking as arguments a 1-by-<i>n</i> vector XI, corresponding to a single row of X, and an <i>m2</i>-by-<i>n</i> matrix XJ, corresponding to multiple rows of X. <code>distfun</code> must accept a matrix XJ with an arbitrary number of rows. <code>distfun</code> must return an <i>m2</i>-by-1 vector of distances d2, whose <i>k</i>th element is the distance between XI and XJ(<i>k</i>, :).</p>

The output  $D$  is arranged in the order of  $((2,1),(3,1),\dots,(m,1),(3,2),\dots(m,2),\dots(m,m-1))$ , i.e. the lower left triangle of the full  $m$ -by- $m$  distance matrix in column order. To get the distance between the  $i$ th and  $j$ th observations ( $i < j$ ), either use the formula  $D((i-1)*(m-i/2)+j-i)$ , or use the helper function  $Z = \text{squareform}(D)$ , which returns an  $m$ -by- $m$  square symmetric matrix, with the  $(i,j)$  entry equal to distance between observation  $i$  and observation  $j$ .

### Metrics

Given an  $m$ -by- $n$  data matrix  $X$ , which is treated as  $m$  (1-by- $n$ ) row vectors  $x_1, x_2, \dots, x_m$ , the various distances between the vector  $x_s$  and  $x_t$  are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - x_t)(x_s - x_t)'$$

Notice that the Euclidean distance is a special case of the Minkowski metric, where  $p = 2$ .

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - x_t)V^{-1}(x_s - x_t)'$$

where  $V$  is the  $n$ -by- $n$  diagonal matrix whose  $j$ th diagonal element is  $S(j)^2$ , where  $S$  is the vector of standard deviations.

- Mahalanobis distance

$$d_{st}^2 = (x_s - x_t)C^{-1}(x_s - x_t)'$$

where  $C$  is the covariance matrix.

- City block metric

$$d_{st} = \sum_{j=1}^n |x_{sj} - x_{tj}|$$

Notice that the city block distance is a special case of the Minkowski metric, where  $p=1$ .

- Minkowski metric

$$d_{st} = \sqrt[p]{\sum_{j=1}^n |x_{sj} - x_{tj}|^p}$$

Notice that for the special case of  $p = 1$ , the Minkowski metric gives the city block metric, for the special case of  $p = 2$ , the Minkowski metric gives the Euclidean distance, and for the special case of  $p = \infty$ , the Minkowski metric gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - x_{tj}|\}$$

Notice that the Chebychev distance is a special case of the Minkowski metric, where  $p = \infty$ .

- Cosine distance

$$d_{st} = 1 - \frac{x_s x_t'}{\sqrt{(x_s x_s')(x_t x_t')}}}$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(x_t - \bar{x}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)' (x_t - \bar{x}_t)(x_t - \bar{x}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj} \quad \text{and} \quad \bar{x}_t = \frac{1}{n} \sum_j x_{tj}$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq x_{tj}) / n)$$

- Jaccard distance

$$d_{st} = \frac{\#[(x_{sj} \neq x_{tj}) \cap ((x_{sj} \neq 0) \cup (x_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (x_{tj} \neq 0)]}$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'} \sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- $r_{sj}$  is the rank of  $x_{sj}$  taken over  $x_{1j}, x_{2j}, \dots, x_{mj}$ , as computed by `tiedrank`
- $r_s$  and  $r_t$  are the coordinate-wise rank vectors of  $x_s$  and  $x_t$ , i.e.,  
 $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$

$$\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$$

$$\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$$

## Examples

Generate random data and find the unweighted Euclidean distance and then find the weighted distance using two different methods:

```
% Compute the ordinary Euclidean distance.
X = randn(100, 5);
D = pdist(X, 'euclidean'); % euclidean distance
```

```
% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation.
```

```
Dstd = pdist(X,'seuclidean');

% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1];      % coordinate weights
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist(X, @(Xi,Xj) weuc(Xi,Xj,Wgts));
```

# pdist2

---

## Purpose

Pairwise distance between two sets of observations

## Syntax

```
D = pdist2(X,Y)
D = pdist2(X,Y,distance)
D = pdist2(X,Y,'minkowski',P)
D = pdist2(X,Y,'mahalanobis',C)
D = pdist2(X,Y,distance,'Smallest',K)
D = pdist2(X,Y,distance,'Largest',K)
[D,I] = pdist2(X,Y,distance,'Smallest',K)
[D,I] = pdist2(X,Y,distance,'Largest',K)
```

## Description

`D = pdist2(X,Y)` returns a matrix `D` containing the Euclidean distances between each pair of observations in the  $mx$ -by- $n$  data matrix `X` and  $my$ -by- $n$  data matrix `Y`. Rows of `X` and `Y` correspond to observations, columns correspond to variables. `D` is an  $mx$ -by- $my$  matrix, with the  $(i,j)$  entry equal to distance between observation  $i$  in `X` and observation  $j$  in `Y`. The  $(i,j)$  entry will be NaN if observation  $i$  in `X` or observation  $j$  in `Y` contain NaNs.

`D = pdist2(X,Y,distance)` computes `D` using `distance`. Choices are:

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>X</code> and <code>Y</code> is scaled by dividing by the corresponding element of the standard deviation computed from <code>X</code> , <code>S=nanstd(X)</code> . To specify another value for <code>S</code> , use <code>D = PDIST2(X,Y,'seuclidean',S)</code> .
'cityblock'	City block metric.
'minkowski'	Minkowski distance. The default exponent is 2. To compute the distance with a different exponent, use <code>D = pdist2(X,Y,'minkowski',P)</code> , where the exponent <code>P</code> is a scalar positive value.

<b>Metric</b>	<b>Description</b>
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of X as computed by nancov. To compute the distance with a different covariance, use $D = \text{pdist2}(X,Y, \text{'mahalanobis'}, C)$ where the matrix C is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations, treated as sequences of values.
'hamming'	Hamming distance, the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
function	<p>A distance function specified using @:  <math>D = \text{pdist2}(X,Y,@\text{distfun})</math>.</p> <p>A distance function must be of the form</p> <pre>function D2 = distfun(ZI, ZJ)</pre> <p>taking as arguments a 1-by-n vector ZI containing a single observation from X or Y, an m2-by-n matrix ZJ containing multiple observations from X or Y, and returning an m2-by-1 vector of distances D2, whose Jth element is the distance between the observations ZI and ZJ(J, :).</p>

Metric	Description
	If your data is not sparse, generally it is faster to use a built-in distance than to use a function handle.

$D = \text{pdist2}(X,Y,\text{distance},\text{'Smallest'},K)$  returns a  $K$ -by- $m_y$  matrix  $D$  containing the  $K$  smallest pairwise distances to observations in  $X$  for each observation in  $Y$ .  $\text{pdist2}$  sorts the distances in each column of  $D$  in ascending order.  $D = \text{pdist2}(X,Y,\text{distance},\text{'Largest'},K)$  returns the  $K$  largest pairwise distances sorted in descending order. If  $K$  is greater than  $m_x$ ,  $\text{pdist2}$  returns an  $m_x$ -by- $m_y$  distance matrix. For each observation in  $Y$ ,  $\text{pdist2}$  finds the  $K$  smallest or largest distances by computing and comparing the distance values to all the observations in  $X$ .

$[D,I] = \text{pdist2}(X,Y,\text{distance},\text{'Smallest'},K)$  returns a  $K$ -by- $m_y$  matrix  $I$  containing indices of the observations in  $X$  corresponding to the  $K$  smallest pairwise distances in  $D$ .  $[D,I] = \text{pdist2}(X,Y,\text{distance},\text{'Largest'},K)$  returns indices corresponding to the  $K$  largest pairwise distances.

## Metrics

Given an  $m_x$ -by- $n$  data matrix  $X$ , which is treated as  $m_x$  (1-by- $n$ ) row vectors  $x_1, x_2, \dots, x_{m_x}$ , and  $m_y$ -by- $n$  data matrix  $Y$ , which is treated as  $m_y$  (1-by- $n$ ) row vectors  $y_1, y_2, \dots, y_{m_y}$ , the various distances between the vector  $x_s$  and  $y_t$  are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - y_t)(x_s - y_t)'$$

Notice that the Euclidean distance is a special case of the Minkowski metric, where  $p=2$ .

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)'$$

where  $V$  is the  $n$ -by- $n$  diagonal matrix whose  $j$ th diagonal element is  $S(j)^2$ , where  $S$  is the vector of standard deviations.

- Mahalanobis distance

$$d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)'$$

where  $C$  is the covariance matrix.

- City block metric

$$d_{st} = \sum_{j=1}^n |x_{sj} - y_{tj}|$$

Notice that the city block distance is a special case of the Minkowski metric, where  $p=1$ .

- Minkowski metric

$$d_{st} = \sqrt[p]{\sum_{j=1}^n |x_{sj} - y_{tj}|^p}$$

Notice that for the special case of  $p = 1$ , the Minkowski metric gives the City Block metric, for the special case of  $p = 2$ , the Minkowski metric gives the Euclidean distance, and for the special case of  $p=\infty$ , the Minkowski metric gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - y_{tj}|\}$$

Notice that the Chebychev distance is a special case of the Minkowski metric, where  $p=\infty$ .

- Cosine distance

$$d_{st} = \left( 1 - \frac{x_s y_t'}{\sqrt{(x_s x_s')(y_t y_t')}} \right)$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj} \quad \text{and}$$
$$\bar{y}_t = \frac{1}{n} \sum_j y_{tj}$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq y_{tj}) / n)$$

- Jaccard distance

$$d_{st} = \frac{\#[(x_{sj} \neq y_{tj}) \cap ((x_{sj} \neq 0) \cup (y_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (y_{tj} \neq 0)]}$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- $r_{sj}$  is the rank of  $x_{sj}$  taken over  $x_{1j}, x_{2j}, \dots, x_{mx,j}$ , as computed by `tiedrank`
- $r_{tj}$  is the rank of  $y_{tj}$  taken over  $y_{1j}, y_{2j}, \dots, y_{my,j}$ , as computed by `tiedrank`
- $r_s$  and  $r_t$  are the coordinate-wise rank vectors of  $x_s$  and  $y_t$ , i.e.  $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$  and  $r_t = (r_{t1}, r_{t2}, \dots, r_{tn})$
- $\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$
- $\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$

## Examples

Generate random data and find the unweighted Euclidean distance, then find the weighted distance using two different methods:

```
% Compute the ordinary Euclidean distance
X = randn(100, 5);
Y = randn(25, 5);
D = pdist2(X,Y,'euclidean'); % euclidean distance

% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation
Dstd = pdist2(X,Y,'seuclidean');

% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1];
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist2(X,Y, @(Xi,Xj) weuc(Xi,Xj,Wgts));
```

## See Also

`pdist` | `createns` | `knnsearch` | `KDTreeSearcher` | `ExhaustiveSearcher`

# pearsrnd

---

## Purpose

Pearson system random numbers

## Syntax

```
r = pearsrnd(mu,sigma,skew,kurt,m,n)
r = pearsrnd(mu,sigma,skew,kurt)
r = pearsrnd(mu,sigma,skew,kurt,m,n,...)
r = pearsrnd(mu,sigma,skew,kurt,[m,n,...])
[r,type] = pearsrnd(...)
[r,type,coefs] = pearsrnd(...)
```

## Description

`r = pearsrnd(mu,sigma,skew,kurt,m,n)` returns an  $m$ -by- $n$  matrix of random numbers drawn from the distribution in the Pearson system with mean `mu`, standard deviation `sigma`, skewness `skew`, and kurtosis `kurt`. The parameters `mu`, `sigma`, `skew`, and `kurt` must be scalars.

---

**Note** Because `r` is a random sample, its sample moments, especially the skewness and kurtosis, typically differ somewhat from the specified distribution moments.

`pearsrnd` uses the definition of kurtosis for which a normal distribution has a kurtosis of 3. Some definitions of kurtosis subtract 3, so that a normal distribution has a kurtosis of 0. The `pearsrnd` function does not use this convention.

---

Some combinations of moments are not valid; in particular, the kurtosis must be greater than the square of the skewness plus 1. The kurtosis of the normal distribution is defined to be 3.

`r = pearsrnd(mu,sigma,skew,kurt)` returns a scalar value.

`r = pearsrnd(mu,sigma,skew,kurt,m,n,...)` or `r = pearsrnd(mu,sigma,skew,kurt,[m,n,...])` returns an  $m$ -by- $n$ -by-... array.

`[r,type] = pearsrnd(...)` returns the type of the specified distribution within the Pearson system. `type` is a scalar integer from 0

to 7. Set `m` and `n` to 0 to identify the distribution type without generating any random values.

The seven distribution types in the Pearson system correspond to the following distributions:

- 0 — Normal distribution
- 1 — Four-parameter beta distribution
- 2 — Symmetric four-parameter beta distribution
- 3 — Three-parameter gamma distribution
- 4 — Not related to any standard distribution. The density is proportional to:

$$(1 + ((x - a)/b)^2)^{-c} \exp(-d \arctan((x - a)/b)).$$

- 5 — Inverse gamma location-scale distribution
- 6 —  $F$  location-scale distribution
- 7 — Student's  $t$  location-scale distribution

`[r,type,coefs] = pearsrnd(...)` returns the coefficients `coefs` of the quadratic polynomial that defines the distribution via the differential equation

$$\frac{d}{dx} \log(p(x)) = \frac{-(a+x)}{c(0) + c(1)x + c(2)x^2}.$$

## Examples

Generate random values from the standard normal distribution:

```
r = pearsrnd(0,1,0,3,100,1); % Equivalent to randn(100,1)
```

Determine the distribution type:

```
[r,type] = pearsrnd(0,1,1,4,0,0);
r =
    []
```

# pearsrnd

---

type =  
1

## Purpose

Compute Receiver Operating Characteristic (ROC) curve or other performance curve for classifier output

## Syntax

```
[X,Y] = perfcurve(labels,scores,posclass)
[X,Y] = perfcurve(labels,scores,posclass,'Name',value)
[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,
    posclass)
[X,Y,T,AUC] = perfcurve(labels,scores,posclass)
```

## Description

`[X,Y] = perfcurve(labels,scores,posclass)` computes a ROC curve for a vector of classifier predictions `scores` given true class labels, `labels`. `labels` can be a numeric vector, logical vector, character matrix, cell array of strings or categorical vector. `scores` is a numeric vector of scores returned by a classifier for some data. `posclass` is the positive class label (scalar), either numeric (for numeric labels), logical (for logical labels), or char. The returned values `X` and `Y` are coordinates for the performance curve and can be visualized with `plot(X,Y)`. For more information on `labels`, `scores`, and `posclass`, see “Input Arguments” on page 21-2459 . For more information on `X` and `Y`, see “Output Arguments” on page 21-2463.

`[X,Y] = perfcurve(labels,scores,posclass,'Name',value)` specifies one or more optional parameter name/value pairs, with `Name` in single quotes. See “Input Arguments” on page 21-2459 for a list of inputs, parameter name/value pairs, and respective explanations.

See “Grouping Variables” on page 2-51 for more information on grouping variables.

`[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores, posclass)` returns:

- An array of thresholds on classifier scores for the computed values of `X` and `Y` (`T`).
- The area under curve (AUC) for the computed values of `X` and `Y`.
- The optimal operating point of the ROC curve (`OPTROCPT`).
- An array of `Y` values for negative subclasses (`SUBY`).

- A cell array of negative class names (SUBYNAMES).

For more information on each output, see “Output Arguments” on page 21-2463.

`[X,Y,T,AUC] = perfcurve(labels,scores,posclass)` also returns pointwise confidence bounds for the computed values X, Y, T, and AUC if you supply cell arrays for `labels` and `scores` or set `NBoot` (see “Input Arguments” on page 21-2459 ) to a positive integer. To compute the confidence bounds, `perfcurve` uses either vertical averaging (VA) or threshold averaging (TA). The returned values Y are an  $m$ -by-3 array in which the 1st element in every row gives the mean value, the 2nd element gives the lower bound and the 3rd element gives the upper bound. The returned AUC is a row-vector with 3 elements following the same convention. For VA, the returned values T are an  $m$ -by-3 array and X is a column-vector. For TA, the returned values X are an  $m$ -by-3 matrix and T is a column-vector.

`perfcurve` computes confidence bounds using either cross validation or bootstrap. If you supply cell arrays for `labels` and `scores`, `perfcurve` uses cross validation and treats elements in the cell arrays as cross validation folds. `labels` can be a cell array of numeric vectors, logical vectors, character matrices, cell arrays of strings or categorical vectors. All elements in `labels` must have the same type. `scores` is a cell array of numeric vectors. The cell arrays for `labels` and `scores` must have the same number of elements, and the number of labels in cell  $k$  must be equal to the number of scores in cell  $k$  for any  $k$  in the range from 1 to the number of elements in `scores`.

If you set `NBoot` to a positive integer, `perfcurve` generates `nboot` bootstrap replicas to compute pointwise confidence bounds. You cannot supply cell arrays for `labels` and `scores` and set `NBoot` to a positive integer at the same time.

`perfcurve` returns pointwise confidence bounds. It does not return a simultaneous confidence band for the entire curve.

If you use 'XCrit' or 'YCrit' options described below to set the criterion for X or Y to an anonymous function, `perfcurve` can only compute confidence bounds by bootstrap.

## Input Arguments

labels	labels can be a numeric vector, logical vector, character matrix, cell array of strings or categorical vector.
scores	scores is a numeric vector of scores returned by a classifier for some data. This vector must have as many elements as labels does.
posclass	posclass is the positive class label (scalar), either numeric (for numeric labels) or char. The specified positive class must be in the array of input labels.

## Name-Value Pair Arguments

### Name

### Value and Description

negClass

List of negative classes. Can be either a numeric array or an array of chars or a cell array of strings. By default, negClass is set to 'all' and all classes found in the input array of labels that are not the positive class are considered negative. If negClass is a subset of the classes found in the input array of labels, instances with labels that do not belong to either positive or negative classes are discarded.

xCrit

Criterion to compute for X. This criterion must be a monotone function of the positive class score. perfcurve supports the following criteria:

- TP — Number of true positive instances.
- FN — Number of false negative instances.
- FP — Number of false positive instances.
- TN — Number of true negative instances.
- TP+FP — Sum of TP and FP.

## Name

## Value and Description

- RPP — Rate of positive predictions.  
 $RPP = (TP + FP) / (TP + FN + FP + TN)$
- RNP — Rate of negative predictions.  
 $RNP = (TN + FN) / (TP + FN + FP + TN)$
- accu — Accuracy.  $accu = (TP + TN) / (TP + FN + FP + TN)$
- TPR, sens, reca — True positive rate, sensitivity, recall.  $TPR, sens, reca = TP / (TP + FN)$
- FNR, miss — False negative rate, miss.  $FNR, miss = FN / (TP + FN)$
- FPR, fall — False positive rate, fallout.  $FPR, fall = FP / (TN + FP)$
- TNR, spec — True negative rate, specificity.  $TNR, spec = TN / (TN + FP)$
- PPV, prec — Positive predictive value, precision.  $PPV, prec = TP / (TP + FP)$
- NPV — Negative predictive value.  $NPV = TN / (TN + FN)$
- ecost — Expected cost.  
 $ecost = (TP * COST(P|P) + FN * COST(N|P) + FP * COST(P|N) + TN * COST(N|N)) / (TP + FN + FP + TN)$

In addition, you can define an arbitrary criterion by supplying an anonymous function of three arguments, `(C, scale, cost)`, where `C` is a 2-by-2 confusion matrix, `scale` is a 2-by-1 array of class scales, and `cost` is a 2-by-2 misclassification cost matrix.

---

**Caution** Some of these criteria return NaN values at one of the two special thresholds, 'reject all' and 'accept all'.

---

<b>Name</b>	<b>Value and Description</b>
yCrit	Criterion to compute for Y. perfcurve supports the same criteria as for X. This criterion does not have to be a monotone function of the positive class score.
XVals	Values for the X criterion. The default value for xVals is 'all' and perfcurve computes X and Y values for all scores. If the value for xVals is not 'all', it must be a numeric array. In this case, perfcurve computes X and Y only for the specified xVals.
TVals	Thresholds for the positive class score. By default, TVals is unset and perfcurve computes X, Y, and T values for all scores. You can set TVals to either 'all' or a numeric array. If TVals is set to 'all' or unset and XVals is unset, perfcurve returns X, Y, and T values for all scores and computes pointwise confidence bounds for Y and X using threshold averaging. If TVals is set to a numeric array, perfcurve returns X, Y, and T values for the specified thresholds and computes pointwise confidence bounds for Y and X at these thresholds using threshold averaging. You cannot set XVals and TVals at the same time.
UseNearest	'on' to use nearest values found in the data instead of the specified numeric XVals or TVals and 'off' otherwise. If you specify numeric XVals and set UseNearest to 'on', perfcurve returns nearest unique values X found in the data, as well as corresponding values of Y and T. If you specify numeric XVals and set UseNearest to 'off', perfcurve returns these XVals sorted. By default this parameter is set to 'on'. If you compute confidence bounds by cross validation or bootstrap, this parameter is always 'off'.

Name	Value and Description
ProcessNaN	Specifies how perfcurve processes NaN scores. The default value is 'ignore' and perfcurve removes observations with NaN scores from the data. If you set the parameter to 'addtofalse', perfcurve adds instances with NaN scores to false classification counts in the respective class. That is, perfcurve always counts instances from the positive class as false negative (FN), and always counts instances from the negative class as false positive (FP).
Prior	Either string or array with two elements. It represents prior probabilities for the positive and negative class, respectively. Default is 'empirical', that is, perfcurve derives prior probabilities from class frequencies. If set to 'uniform', perfcurve sets all prior probabilities equal.
Cost	A 2-by-2 matrix of misclassification costs $[C(P P) \ C(N P); C(P N) \ C(N N)]$ where $C(I J)$ is the cost of misclassifying class $J$ as class $I$ . By default set to $[0 \ 0.5; \ 0.5 \ 0]$ .
Alpha	A numeric value between 0 and 1. perfcurve returns $100*(1-Alpha)$ percent pointwise confidence bounds for X, Y, T and AUC. By default set to 0.05 for 95% confidence interval.
Weights	A numeric vector of nonnegative observation weights. This vector must have as many elements as scores or labels do. If you supply cell arrays for scores and labels and you need to supply weights, you must supply them as a cell array too. In this case, every element in weights must be a numeric vector with as many elements as the corresponding element in scores: <code>numel(weights{1})==numel(scores{1})</code> etc. To compute X, Y and T or to compute confidence bounds by cross validation, perfcurve uses these observation weights instead of observation counts. To compute confidence bounds by bootstrap, perfcurve samples $N$ out of $N$ with replacement using these weights as multinomial sampling probabilities.

Name	Value and Description	
NBoot	Number of bootstrap replicas for computation of confidence bounds. Must be a positive integer. By default this parameter is set to zero, and bootstrap confidence bounds are not computed. If you supply cell arrays for <code>labels</code> and <code>scores</code> , this parameter must be set to zero because <code>perfcurve</code> cannot use both cross validation and bootstrap to compute confidence bounds.	
BootType	Confidence interval type <code>bootci</code> uses to compute confidence bounds. You can specify any type supported by <code>bootci</code> . By default set to <code>'bca'</code> .	
BootArg	Optional input arguments for <code>bootci</code> used to compute confidence bounds. You can specify all arguments <code>bootci</code> supports. Empty by default.	
<b>Output Arguments</b>	X	<i>x</i> -coordinates for the performance curve. By default, X is false positive rate, FPR, (equivalently, fallout, or 1-specificity). To change this output, use the <code>'xCrit'</code> name/value input. For accepted criterion, see <code>'xCrit'</code> in “Input Arguments” on page 21-2459 for more information.
	Y	<i>y</i> -coordinates for the performance curve. By default, Y is true positive rate, TPR, (equivalently, recall, or sensitivity). To change this output, use the <code>'yCrit'</code> input. For accepted criterion, see <code>'xCrit'</code> in “Input Arguments” on page 21-2459 for more information.

**T** An array of thresholds on classifier scores for the computed values of X and Y. It has the same number of rows as X and Y. For each threshold, TP is the count of true positive observations with scores greater or equal to this threshold, and FP is the count of false positive observations with scores greater or equal to this threshold. `perfcurve` defines negative counts, TN and FN, in a similar way then sorts the thresholds in the descending order which corresponds to the ascending order of positive counts.

For the M distinct thresholds found in the array of scores, `perfcurve` returns the X, Y and T arrays with M+1 rows. `perfcurve` sets elements T(2:M+1) to the distinct thresholds, and T(1) replicates T(2). By convention, T(1) represents the highest 'reject all' threshold and `perfcurve` computes the corresponding values of X and Y for TP=0 and FP=0. T(end) is the lowest 'accept all' threshold for which TN=0 and FN=0.

**AUC** The area under curve (AUC) for the computed values of X and Y. If you set `xVals` to 'all' (the default), `perfcurve` computes AUC using the returned X and Y values. If `xVals` is a numeric array, `perfcurve` computes AUC using X and Y values found from all distinct scores in the interval specified by the smallest and largest elements of `xVals`. More precisely, `perfcurve` finds X values for all distinct thresholds as if `xVals` were set to 'all', then uses a subset of these (with corresponding Y values) between `min(xVals)` and `max(xVals)` to compute AUC. The function uses trapezoidal approximation to estimate the area. If the first or last value of X or Y are NaNs, `perfcurve` removes them to allow calculation of AUC. This takes care of criteria that produce NaNs for the special 'reject all' or 'accept all' thresholds, for example, positive predictive value (PPV) or negative predictive value (NPV).

**OPTROCPPT** The optimal operating point of the ROC curve as an array of size 1-by-2 with FPR and TPR values for the optimal ROC operating point. `perfcurve` computes `optrocppt` only for the standard ROC curve and sets to NaNs otherwise. To obtain the optimal operating point for the ROC curve, `perfcurve` first finds the slope,  $S$ , using

$$S = \frac{\text{cost}(P | N) - \text{cost}(N | N) * \frac{N}{P}}{\text{cost}(N | P) - \text{cost}(P | P)}$$

where  $\text{cost}(I | J)$  is the cost of assigning an instance of class  $J$  to class  $I$ , and  $P=TP+FN$  and  $N=TN+FP$  are the total instance counts in the positive and negative class, respectively. `perfcurve` then finds the optimal operating point by moving the straight line with slope  $S$  from the upper left corner of the ROC plot (FPR=0, TPR=1) down and to the right until it intersects the ROC curve.

**SUBY** An array of  $Y$  values for negative subclasses. If you only specify one negative class, `SUBY` is identical to  $Y$ . Otherwise `SUBY` is a matrix of size  $M$ -by- $K$ , where  $M$  is the number of returned values for  $X$  and  $Y$ , and  $K$  is the number of negative classes. `perfcurve` computes  $Y$  values by summing counts over all negative classes. `SUBY` gives values of the  $Y$  criterion for each negative class separately. For each negative class, `perfcurve` places a new column in `SUBY` and fills it with  $Y$  values for  $TN$  and  $FP$  counted just for this class.

**SUBYNAMES** A cell array of negative class names. If you provide an input array, `negClass`, of negative class names, `perfcurve` copies it into `SUBYNAMES`. If you do not provide `negClass`, `perfcurve` extracts `SUBYNAMES` from input labels. The order of `SUBYNAMES` is the same as the order of columns in `SUBY`, that is, `SUBY(:, 1)` is for negative class `SUBYNAMES{1}` etc.

## Examples

Plot the ROC curve for classification by logistic regression:

```
load fisheriris
x = meas(51:end,1:2);
% iris data, 2 classes and 2 features
y = (1:100) '>50';
% versicolor=0, virginica=1
b = glmfit(x,y,'binomial');
% logistic regression
p = glmval(b,x,'logit');
% fit probabilities for scores
[X,Y,T,AUC] = perfcurve(species(51:end,:),p,'virginica');
plot(X,Y)
xlabel('False positive rate'); ylabel('True positive rate')
title('ROC for classification by logistic regression')
```

Obtain errors on TPR by vertical averaging

```
[X,Y] = perfcurve(species(51:end,:),p,'virginica',...
    'nboot',1000,'xvals','all');
% plot errors
```

```
errorbar(X,Y(:,1),Y(:,2)-Y(:,1),Y(:,3)-Y(:,1));
```

- “Plotting a Classification Performance Curve” on page 16-143

# perms

---

**Purpose** Enumeration of permutations

**Syntax** `P = perms(v)`

**Description** `P = perms(v)`, where `v` is a row vector of length `n`, creates a matrix whose rows consist of all possible permutations of the `n` elements of `v`. The matrix `P` contains `n!` rows and `n` columns.

`perms` is only practical when `n` is less than about 11 (for `n = 11`, the output takes over 3 gigabytes).

**Examples** `perms([2 4 6])`

`ans =`

```
6 4 2
6 2 4
4 6 2
4 2 6
2 4 6
2 6 4
```

**See Also**

`combnk`

**Purpose** Permute dimensions of categorical array

**Syntax** `B = permute(A,order)`

**Description** `B = permute(A,order)` rearranges the dimensions of the categorical array `A` so that they are in the order specified by the vector `order`. The array produced has the same values as `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. The elements of `order` must be a rearrangement of the numbers from 1 to `n`.

# piecewisedistribution

---

<b>Purpose</b>	Piecewise-defined distributions	
<b>Construction</b>	piecewisedistribution is an abstract class. To construct a piecewisedistribution object, use the subclass constructor, paretotails.	
<b>Methods</b>	boundary	Piecewise distribution boundaries
	cdf	Cumulative distribution function for piecewise distribution
	disp	Display piecewisedistribution object
	display	Display piecewisedistribution object
	icdf	Inverse cumulative distribution function for piecewise distribution
	nsegments	Number of segments
	pdf	Probability density function for piecewise distribution
	random	Random numbers from piecewise distribution
	segment	Segments containing values
<b>Properties</b>	Objects of the piecewisedistribution class have no properties accessible by dot indexing, get methods, or set methods. To obtain information about a piecewisedistribution object, use the appropriate method.	
<b>Copy Semantics</b>	Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.	

**Purpose** Create piecewise distribution object

**Description** `piecewisedistribution` is an abstract class, and you cannot create instances of it directly. You can create `paretotails` objects that are derived from this class.

**See Also** `paretotails`

# prob.PiecewiseLinearDistribution

---

**Superclasses** ParametricTruncatableDistribution

**Purpose** Piecewise linear probability distribution object

**Description** `prob.PiecewiseLinearDistribution` is an object consisting of a model description for a piecewise linear probability distribution. Create a probability distribution object with specified parameters using `makedist`.

**Construction** `pd = makedist('PiecewiseLinear')` creates a piecewise linear probability distribution object using the default parameter values.

`pd = makedist('PiecewiseLinear', 'x', x, 'Fx', Fx)` creates a piecewise linear probability distribution object using the specified values.

## Input Arguments

### **x - Data values**

1 (default) | vector of scalar values

Data values at which the cumulative distribution function (cdf) changes slope, specified as a vector of scalar values.

### **Data Types**

single | double

### **Fx - cdf value**

1 (default) | vector of scalar values

cdf value at each value in `x`, specified as a vector of scalar values. `x` and `Fx` must be the same size. The first value in the vector `Fx` must be 0, and the last element must be 1. `Fx` increases linearly between `x(j)` and `x(j+1)`, for all `j`.

### **Data Types**

single | double

## Properties

**x**

Data values at which the cumulative distribution function (cdf) changes slope, stored as a vector of scalar values.

### Data Types

single | double

**Fx**

cdf value at each value in x, stored as a vector of scalar values.

### Data Types

single | double

**DistributionName**

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

### Data Types

char

**IsTruncated**

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

### Data Types

logical

**NumParameters**

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

### Data Types

single | double

**ParameterDescription**

# prob.PiecewiseLinearDistribution

---

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

### Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object

iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Piecewise Linear Distribution

The piecewise linear distribution is a nonparametric probability distribution created using a piecewise linear representation of the cumulative distribution function (cdf). The options specified for the piecewise linear distribution specify the form of the cdf. The probability density function (pdf) is a step function.

## Examples

### Create a Piecewise Linear Distribution Object Using Default Parameters

Create a piecewise linear distribution object using the default parameter values.

```
pd = makedist('PiecewiseLinear')
```

# prob.PiecewiseLinearDistribution

---

```
pd =  
  
    PiecewiseLinearDistribution  
  
F(0) = 0  
F(1) = 1
```

## **Create a Piecewise Linear Distribution Object Using Specified Parameters**

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital;  
hist(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Compute the empirical cumulative distribution function (ecdf) for the data.

```
[f,x] = ecdf(hospital.Weight);
```

Construct a piecewise linear approximation to the ecdf and plot both functions.

# prob.PiecewiseLinearDistribution

---

```
f = f(1:5:end); % keep a less dense grid of points
x = x(1:5:end);

figure;
ecdf(hospital.Weight)
hold on
plot(x,f,'ro','MarkerFace','r') % overlay grid
plot(x,f,'k') % show interpolation
```

# prob.PiecewiseLinearDistribution

---

Create a piecewise linear probability distribution object using the piecewise approximation of the ecdf.

```
pd = makedist('PiecewiseLinear','x',x,'Fx',f)
```

```
pd =
```

```
    PiecewiseLinearDistribution
```

```
F(111) = 0
F(118) = 0.05
F(124) = 0.13
F(130) = 0.25
F(135) = 0.37
F(142) = 0.5
F(163) = 0.55
F(171) = 0.61
F(178) = 0.7
F(183) = 0.82
F(189) = 0.94
F(202) = 1
```

Generate 100 random numbers from the distribution.

```
rw = random(pd,100,1);
```

Plot the random numbers to visually compare their distribution to the original data.

```
figure;
hist(rw)
```

# prob.PiecewiseLinearDistribution

---

The random numbers generated from the piecewise linear distribution have the same bimodal distribution as the original data.

**See Also** `makedist`

## Concepts

- “Piecewise Linear Distribution” on page B-115
- Class Attributes
- Property Attributes

<b>Purpose</b>	Plot clustering evaluation object criterion values
<b>Syntax</b>	<pre>plot(eva) h = plot(eva)</pre>
<b>Description</b>	<p><code>plot(eva)</code> displays a plot of the criterion values versus the number of clusters, based on the values stored in the clustering evaluation object <code>eva</code>.</p> <p><code>h = plot(eva)</code> returns a handle to the plot line.</p>
<b>Input Arguments</b>	<p><b>eva - Clustering evaluation data</b> clustering evaluation object</p> <p>Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using <code>evalclusters</code>.</p>
<b>Output Arguments</b>	<p><b>h - Handle to plot line</b> scalar value</p> <p>Handle to the plot line, returned as a scalar value.</p>
<b>Examples</b>	<p><b>Plot the Clustering Evaluation Criterion Values</b></p> <p>Plot the criterion values versus the number of clusters for each clustering solution stored in a clustering evaluation object.</p> <p>Load the sample data.</p> <pre>load fisheriris;</pre> <p>The data contains length and width measurements from the sepals and petals of three species of iris flowers.</p> <p>Create a clustering evaluation object. Cluster the data using <code>kmeans</code>, and evaluate the optimal number of clusters using the Calinski-Harabasz criterion.</p> <pre>rng('default'); % For reproducibility</pre>

# clustering.evaluation.ClusterCriterion.plot

---

```
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6]);
```

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```
figure;  
plot(eva);
```

The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

**See Also** `evalclusters`

# LinearModel.plot

---

**Purpose** Scatter plot or added variable plot of linear model

**Syntax**  
`plot mdl)`  
`h = plot(mdl)`

**Description** `plot(mdl)` creates a plot of the fitted linear model. The plot type depends on the number of predictor variables.

- If there is just one predictor variable, `plot` creates a scatter plot of the data along with a fitted curve and confidence bounds.
- If there are multiple predictor variables, `plot` creates an added variable plot.
- If there are no predictors, `plot` creates a histogram of the residuals.

`h = plot(mdl)` returns handles to the lines in the plot.

**Input Arguments** **mdl**  
Linear model, as constructed by `fitlm` or `stepwiselm`.

**Output Arguments** **h**  
Vector of handles to lines or patches in the plot.

**Definitions** **Added Variable Plot, Adjusted Response**

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

**Examples** **Create an Added Variable Plot**

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the carsmall data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create an added variable plot.

```
plot(mdl)
```

The plot illustrates that the model is significant—a horizontal line does not fit between the confidence bounds.

# LinearModel.plot

---

**Alternatives**    Use `plotAdded` to select particular predictors for an added variable plot.

**See Also**        `LinearModel` | `plotAdded`

**How To**            • “Linear Regression” on page 9-12

## Purpose

Added variable plot or leverage plot for linear model

## Syntax

```
plotAdded mdl
plotAdded mdl,coef
h = plotAdded mdl,...
h = plotAdded mdl,coef,Name,Value
```

## Description

`plotAdded(mdl)` produces a generalized added variable plot for all terms in `mdl` except the constant term.

`plotAdded(mdl,coef)` produces an added variable plot for the `coef` terms in `mdl`, after adjusting for all other terms.

`h = plotAdded(mdl,...)` returns handles to the lines in the plot.

`h = plotAdded(mdl,coef,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

## Tips

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **coef**

Coefficients in `mdl`. Represent as:

- String giving a single coefficient name
- Vector of coefficient numbers in the `mdl.CoefficientNames` property

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

# LinearModel.plotAdded

---

specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

## **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

## **'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

## **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

## **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

## **'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

## **'MarkerSize'**

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Added Variable Plot, Adjusted Response

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

## Examples

### Create an Added Variable Plot

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create an added variable plot.

```
plotAdded(mdl)
```

# LinearModel.plotAdded

The plot illustrates that the model is significant—a horizontal line does not fit between the confidence bounds.

## Create an Added Variable Plot for Particular Variables

Create a model of car mileage as a function of weight and model year. Then create a plot to see the effect of the weight terms (Weight and Weight<sup>2</sup>).

Create a linear model of mileage from the carsmall data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Find the terms in the model corresponding to the Weight and Weight<sup>2</sup>.

```
mdl.CoefficientNames
```

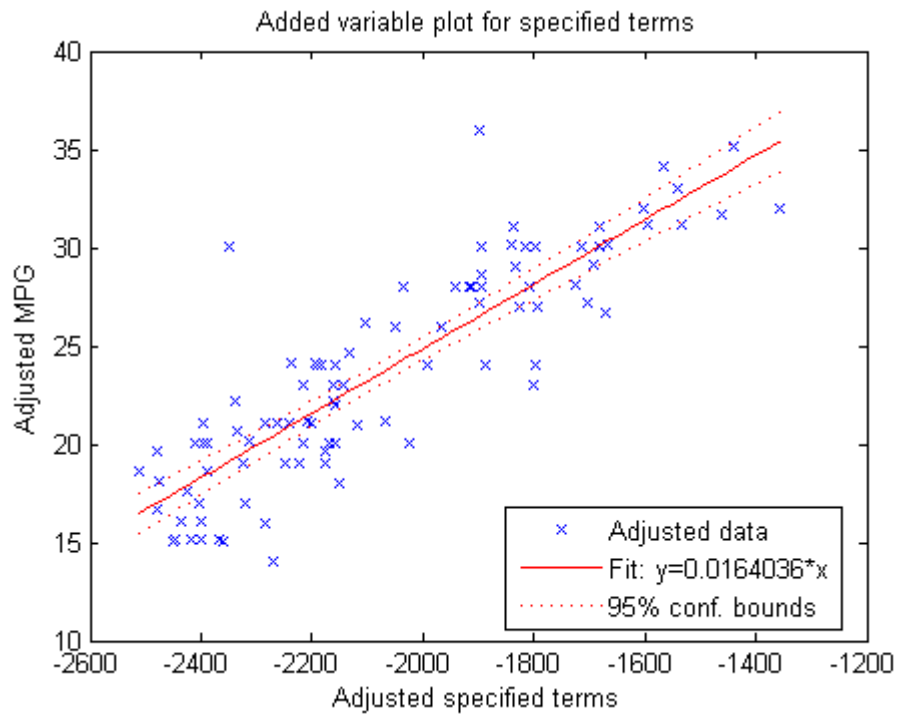

```
ans =
```

```
'(Intercept)' 'Weight' 'Year_76' 'Year_82' 'Weight^2'
```

The weight terms are 2 and 5.

Create an added variable plot with the weight terms.

```
coef = [2 5];  
plotAdded(mdl,coef)
```

# LinearModel.plotAdded

---

The plot illustrates that the weight terms are significant—a horizontal line does not fit between the confidence bounds.

# LinearModel.plotAdjustedResponse

---

## Purpose

Adjusted response plot for linear regression model

## Syntax

```
plotAdjustedResponse mdl, var)
h = plotAdjustedResponse mdl, var)
h = plotAdjustedResponse mdl, var, Name, Value)
```

## Description

`plotAdjustedResponse(mdl, var)` gives an adjusted response plot for the variable `var` in the `mdl` regression model.

`h = plotAdjustedResponse(mdl, var)` returns handles to the lines in the plot.

`h = plotAdjustedResponse(mdl, var, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

## Tips

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **var**

Variable name, or scalar index of variable in `mdl.CoefficientNames`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

# LinearModel.plotAdjustedResponse

---

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

**'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

**'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

**'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

**'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

**'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

**'MarkerSize'**

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

**Output Arguments**

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Adjusted Response Plot

The adjusted response plot shows the fitted response as a function of var, with the other predictors averaged out by averaging the fitted values over the data used in the fit. Adjusted data points are computed by adding the residual to the adjusted fitted value for each observation.

## Examples

### Plot Adjusted Responses

Plot the adjusted responses of a fitted linear model.

Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Plot the effect of 'Weight' averaged over Year values.

```
plotAdjustedResponse(mdl,'Weight')
```

# LinearModel.plotAdjustedResponse

Plot the effect of Year averaged over 'Weight' values. Include the h output.

```
h = plotAdjustedResponse(md1, 'Year');
```

# LinearModel.plotAdjustedResponse

Change the adjusted data to black x instead of red o.

```
set(h(1), 'Marker', 'x', 'Color', 'k')
```

# LinearModel.plotAdjustedResponse

## How To

- “Linear Regression” on page 9-12

# GeneralizedLinearModel.plotDiagnostics

---

**Purpose** Plot diagnostics of generalized linear regression model

**Syntax**

```
plotDiagnostics mdl
plotDiagnostics mdl,plottype
h = plotDiagnostics(...)
h = plotDiagnostics mdl,plottype,Name,Value
```

**Description**

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics from the `mdl` generalized linear model in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

### **plottype**

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

**Default:** 'leverage'

# GeneralizedLinearModel.plotDiagnostics

---

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### **'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerSize'**

# GeneralizedLinearModel.plotDiagnostics

---

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$  and a diagonal weight matrix  $W$ :

$$H = X(X^T W X)^{-1} X^T W^T.$$

$W$  has diagonal elements  $w_i$ :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- $g$  is the link function mapping  $y_i$  to  $x_i b$ .
- $g'$  is the derivative of the link function  $g$ .
- $V$  is the variance function.
- $\mu_i$  is the  $i$ th mean.

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

# GeneralizedLinearModel.plotDiagnostics

---

## Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

The Cook's distance  $D_i$  of observation  $i$  is

$$D_i = w_i \frac{e_i^2}{p\hat{\phi}} \frac{h_{ii}}{(1-h_{ii})^2},$$

where

- $\hat{\phi}$  is the dispersion parameter (estimated or theoretical).
- $e_i$  is the linear predictor residual,  $g(y_i) - x_i\hat{\beta}$ , where
  - $g$  is the link function.
  - $y_i$  is the observed response.
  - $x_i$  is the observation.
  - $\hat{\beta}$  is the estimated coefficient vector.
- $p$  is the number of coefficients in the regression model.
- $h_{ii}$  is the  $i$ th diagonal element of the Hat Matrix  $H$ .

## Examples

### Diagnostic Plots for Generalized Linear Models

Create leverage and Cook's distance plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors  $X(1)$  and  $X(2)$ .

# GeneralizedLinearModel.plotDiagnostics

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,...
    'y ~ x1 + x2','distr','poisson');
```

Create a leverage plot.

```
plotDiagnostics(mdl)
```

# GeneralizedLinearModel.plotDiagnostics

Create a contour plot with Cook's distance.

```
plotDiagnostics(md1, 'contour')
```

## References

## Related Examples

- “Diagnostic Plots” on page 10-26

## Concepts

- “Generalized Linear Models” on page 10-12

**Purpose** Plot diagnostics of linear regression model

**Syntax**

```
plotDiagnostics mdl
plotDiagnostics mdl,plottype
h = plotDiagnostics(...)
h = plotDiagnostics mdl,plottype,Name,Value
```

**Description**

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using scaled delete-1 fitted values.

`plotDiagnostics(mdl,plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **plottype**

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'covratio'	Delete-1 ratio of determinant of covariance
'dfbetas'	Scaled delete-1 coefficient estimates

# LinearModel.plotDiagnostics

---

'dffits'	Scaled delete-1 fitted values
'leverage'	Leverage
's2_i'	Delete-1 variance estimate

Delete-1 means compute a new model without the current observation. If the delete-1 calculation differs significantly from the model using all observations, then the observation is influential.

**Default:** 'leverage'

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### 'Color'

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### 'LineStyle'

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### 'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

## 'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see `linespec`.

## 'MarkerFaceColor'

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see `linespec`.

## 'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$ :

$$H = X(X^T X)^{-1} X^T.$$

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

### Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the

# LinearModel.plotDiagnostics

---

number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance,  $D_i$ , of observation  $i$  is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- $\hat{y}_j$  is the  $j$ th fitted response value.
- $\hat{y}_{j(i)}$  is the  $j$ th fitted response value, where the fit does not include observation  $i$ .
- $\text{MSE}$  is the mean squared error.
- $p$  is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left( \frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where  $r_i$  is the  $i$ th residual, and  $h_{ii}$  is the  $i$ th leverage value.

`CooksDistance` is an  $n$ -by-1 column vector in the `Diagnostics` dataset array of the `LinearModel` object.

## Examples

### Leverage Plot of Linear Model

Plot the leverage values of observations in a fitted model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Plot the leverage values.

```
plotDiagnostics(mdl)
```

# LinearModel.plotDiagnostics

---

Plot the Cook's distance.

```
plotDiagnostics(md1, 'cookd')
```

The two diagnostic plots give different results.

## Purpose

Plot diagnostics of nonlinear regression model

## Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl,plottype
h = plotDiagnostics(...)
h = plotDiagnostics mdl,plottype,Name,Value
```

## Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

## Tips

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

### **plottype**

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

**Default:** 'leverage'

# NonLinearModel.plotDiagnostics

---

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### **'LineStyle'**

### **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerSize'**

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$  and the Jacobian matrix  $J$ :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here  $f$  is the nonlinear model function, and  $\beta$  is the vector of model coefficients.

The Hat Matrix  $H$  is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

### Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

# NonLinearModel.plotDiagnostics

---

## Cook's Distance

The Cook's distance  $D_i$  of observation  $i$  is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- $\hat{y}_j$  is the  $j$ th fitted response value.
- $\hat{y}_{j(i)}$  is the  $j$ th fitted response value, where the fit does not include observation  $i$ .
- $\text{MSE}$  is the mean squared error.
- $p$  is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left( \frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where  $e_i$  is the  $i$ th residual.

## Examples

### Nonlinear Model Leverage Plot

Create a leverage plot of a fitted nonlinear model, and find the points with high leverage.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

# NonLinearModel.plotDiagnostics

Create a leverage plot of the fitted model.

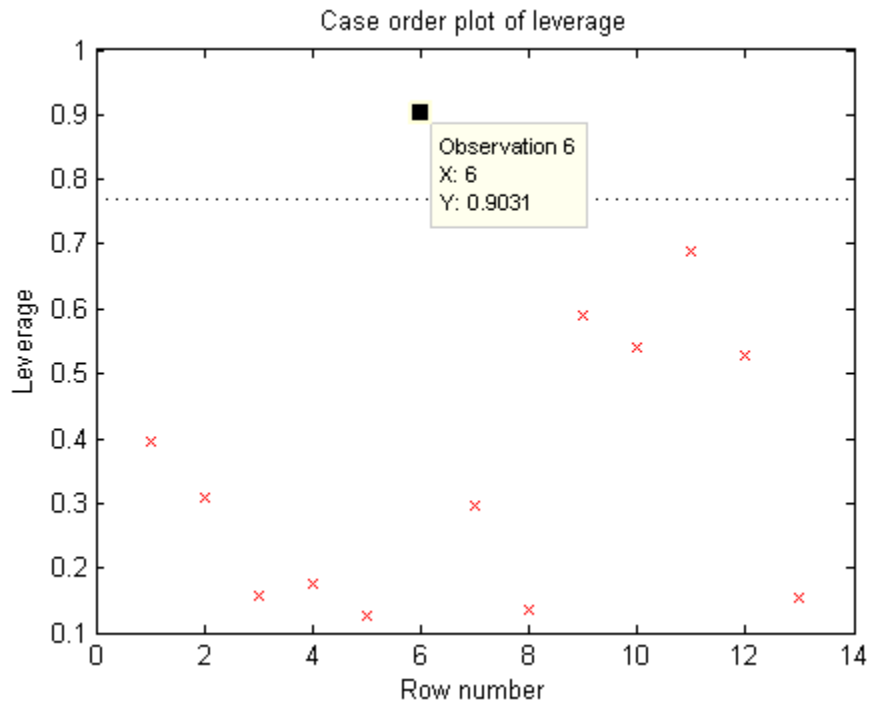

```
plotDiagnostics(md1)
```

To examine the observation with high leverage, activate the Data Cursor and click the observation.

# NonLinearModel.plotDiagnostics

Alternatively, find the high-leverage observation at the command line.

```
find(md1.Diagnostics.Leverage > 0.8)
```

```
ans =
```

```
6
```

<b>Input Arguments</b>	<p><b>mdl</b></p> <p>Linear model, as constructed by <code>fitlm</code> or <code>stepwiselm</code>.</p>
<b>Output Arguments</b>	<p><b>h</b></p> <p>Vector of handles to lines or patches in plot. <code>h(1)</code> is a handle to the circles that represent the main effect estimates. <code>h(j+1)</code> is a handle to the line that defines the confidence interval for the effect of predictor <math>j</math>.</p>
<b>Examples</b>	<p><b>Effects Plot</b></p> <p>Plot the effects of two predictors in a fitted linear model.</p> <p>Load the <code>carsmall</code> data and fit a linear model of the mileage as a function of model year, weight, and weight squared.</p> <pre>load carsmall ds = dataset(MPG,Weight); ds.Year = ordinal(Model_Year);</pre>

```
mdl = fitlm(ds, 'MPG ~ Year + Weight^2');
```

Create an effects plot.

```
plotEffects(mdl)
```

The width of each horizontal line in the figure shows a confidence interval for the effect on the response of the listed change in each predictor. The estimated effect of changing Year from 70 to 82 is an increase of about 8, and is between 6 and 10 with 95% confidence.

## Alternatives

Use `plotInteraction` for an effects plot of the interactions of two specified variables.

# LinearModel.plotEffects

---

## **See Also**

LinearModel | plotAdjustedResponse | plotInteraction

## **Tutorials**

- “Plots to Understand Predictor Effects” on page 9-30

## **How To**

- “Linear Regression” on page 9-12

**Purpose** Plot interaction effects of two predictors in linear regression model

**Syntax**

```
plotInteraction(md1,var1,var2)
plotInteraction(md1,var1,var2,ptype)
h = plotInteraction(...)
```

**Description** `plotInteraction(md1,var1,var2)` creates a plot of the interaction effects of the predictors `var1` and `var2` in `md1`. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. The plot also shows the estimated effect with the other predictor fixed at certain values. `plotInteraction` chooses values to produce a relatively large effect on the response. The plot lets you examine whether the effect of one predictor depends on the value of the other predictor.

`plotInteraction(md1,var1,var2,ptype)` returns a plot of the type specified in `ptype`.

`h = plotInteraction(...)` returns handles to the lines in the plot.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

## Input Arguments

### **md1**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **var1**

String naming the variable for plot. `plotInteraction` chooses values of `var1` to create relatively large changes in the response. When you set `ptype = 'predictions'`, the plot shows curves as a function of `var2` with various fixed values of `var1`.

### **var2**

String naming the variable for plot. `plotInteraction` chooses values of `var2` to create relatively large changes in the response.

# LinearModel.plotInteraction

---

When you set `ptype = 'predictions'`, the plot shows curves as a function of `var2` various fixed values of `var1`.

## **ptype**

String naming the plot type.

- 'effects' — The plot shows each effect as a circle, with a horizontal bar showing the confidence interval for the estimated effect. `plotInteraction` computes the effect values from the adjusted response curve, as shown by the `plotAdjustedResponse` function.
- 'predictions' — The plot shows the adjusted response curve as a function of `var2`, with `var1` fixed at certain values.

**Default:** 'effects'

## **Output Arguments**

### **h**

Vector of handles to lines or patches in the plot.

## **Examples**

### **Interaction Plot**

Create a model of car mileage as a function of weight and model year. Then create a plot to see if the predictors have interactions.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = fitlm(ds,'MPG ~ Year * Weight^2');
```

Create an interaction plot.

```
plotInteraction(mdl,var1,var2)
```

The plot might show an interaction, because the groups of points are not perfectly vertical. But the error bars seem large enough that a vertical line could pass within all of the confidence intervals for each group, possibly indicating no interaction.

## Prediction Curve Interaction Plot

Create a model of car mileage as a function of weight and model year. Then create an interaction curve plot to see if the predictors have interactions.

Create a linear model of mileage from the carsmall data.

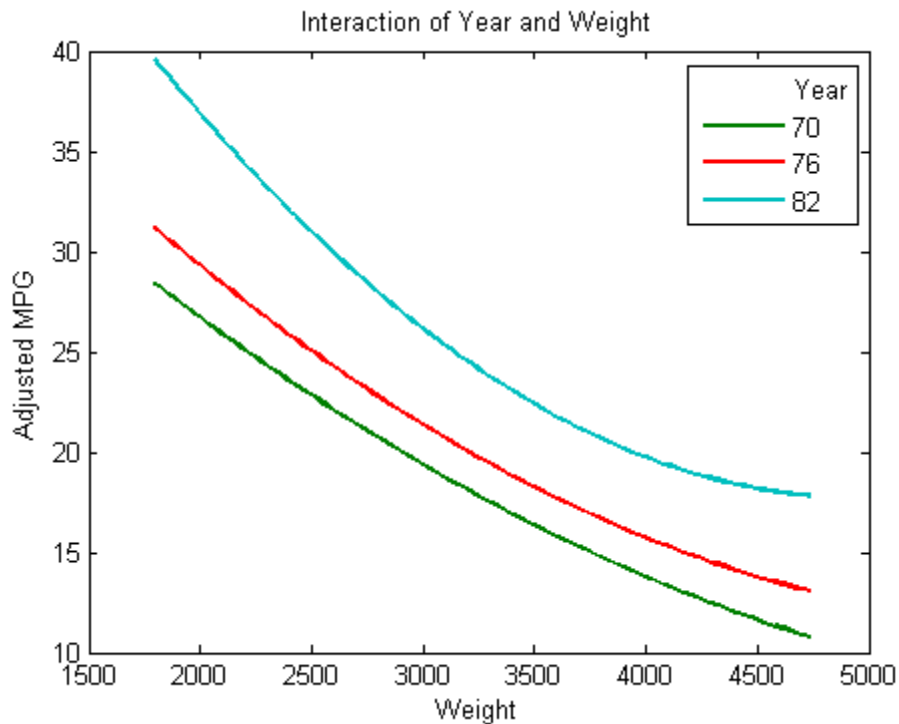

```
load carsmall
```

# LinearModel.plotInteraction

```
ds = dataset(MPG,Weight);  
ds.Year = ordinal(Model_Year);  
var1 = 'Year';  
var2 = 'Weight';  
mdl = fitlm(ds,'MPG ~ Year * Weight^2');
```

Create an interaction plot with type 'predictions'.

```
plotInteraction(mdl,var1,var2,'predictions')
```

The curves are not parallel. This indicates interactions between the predictors. The effect is subtle enough not to definitively indicate a interaction.

**Alternatives** Use `plotEffects` for an effects plot showing separate effects for all predictors.

**See Also** `LinearModel` | `plotAdjustedResponse` | `plotEffects`

**Tutorials** • “Plots to Understand Predictor Effects” on page 9-30

**How To** • “Linear Regression” on page 9-12

# GeneralizedLinearModel.plotResiduals

---

**Purpose** Plot residuals of generalized linear regression model

**Syntax**

```
plotResiduals mdl
plotResiduals mdl,plottype
h = plotResiduals(...)
h = plotResiduals mdl,plottype,Name,Value)
```

**Description**

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

### **plottype**

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ( $r(t)$ vs. $r(t-1)$ )

# GeneralizedLinearModel.plotResiduals

---

'probability'	Normal probability plot
'symmetry'	Symmetry plot

**Default:** 'histogram'

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### 'Color'

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### 'LineStyle'

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### 'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### 'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

# GeneralizedLinearModel.plotResiduals

---

## 'MarkerFaceColor'

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see `linespec`.

## 'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## 'ResidualType'

String giving type of residual used in the plot.

'Raw'	Observed minus fitted values
'LinearPredictor'	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors
'Pearson'	Raw residuals divided by RMSE
'Anscombe'	Residuals defined on transformed data with the transformation chosen to remove skewness
'Deviance'	Residuals based on the contribution of each observation to the deviance

**Default:** 'Raw'

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Deviance

*Deviance* is twice the log likelihood of the model. Because this overall log likelihood is a sum of log likelihoods for each observation, the residual plot of deviance type shows the log likelihood per observation.

## Examples

### Residual Plots for Generalized Linear Models

Create residual plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors  $X(1)$  and  $X(2)$ .

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create a default residuals plot.

```
plotResiduals(mdl)
```

# GeneralizedLinearModel.plotResiduals

---

Create a probability plot.

```
plotResiduals mdl, 'probability'
```

# GeneralizedLinearModel.plotResiduals

The residuals do not match a normal distribution in the tails—they are more spread out.

Create a plot of the fitted residuals of Anscombe type.

# GeneralizedLinearModel.plotResiduals

**See Also** [GeneralizedLinearModel |](#)

## Purpose

Plot residuals of linear regression model

## Syntax

```
plotResiduals mdl
plotResiduals mdl,plottype
h = plotResiduals(...)
h = plotResiduals mdl,plottype,Name,Value
```

## Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` linear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

## Tips

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **plottype**

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ( $r(t)$ vs. $r(t-1)$ )
'probability'	Normal probability plot
'symmetry'	Symmetry plot

# LinearModel.plotResiduals

---

**Default:** 'histogram'

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### **'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

## 'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## 'ResidualType'

Type of residual used in the plot:

'Raw'	Observed minus fitted values
'Pearson'	Raw residuals divided by RMSE
'Standardized'	Raw residuals divided by their estimated standard deviation
'Studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

**Default:** 'Raw'

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Examples

### Linear Residuals Plot

Plot the residuals of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Plot the raw residuals.

```
plotResiduals(mdl)
```

# LinearModel.plotResiduals

---

## Residual Probability Plot

Create a normal probability plot of the residuals of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
X = [Weight,Model_Year];
mdl = fitlm(X,MPG,...
    'y ~ x2 + x1^2','Categorical',2);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

## Alternatives

The `mdl.Residuals` dataset array contains the information in residual plots.

# LinearModel.plotResiduals

---

## How To

- “Linear Regression” on page 9-12

# LinearMixedModel.plotResiduals

---

**Purpose** Plot residuals of linear mixed-effects model

**Syntax** `plotResiduals(lme,plottype)`  
`plotResiduals(lme,plottype,Name,Value)`

`h = plotResiduals( ___ )`

**Description** `plotResiduals(lme,plottype)` plots the raw conditional residuals of the linear mixed-effects model `lme` in a plot of the type specified by `plottype`.

`plotResiduals(lme,plottype,Name,Value)` also plots the residuals of the linear mixed-effects model `lme` with additional options specified by one or more name-value pair arguments. For example, you can specify the residual type to plot.

`plotResiduals` also accepts some other name-value pair arguments that specify the properties of the primary line in the plot. For those name-value pairs, see `plot`.

`h = plotResiduals( ___ )` returns a handle, `h`, to the lines or patches in the plot of residuals.

## Input Arguments

### **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **plottype - Type of residual plot**

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Type of residual plot, specified as one of the following strings.

# LinearMixedModel.plotResiduals

---

'histogram'	Default. Histogram of residuals
'caseorder'	Residuals versus case (row) order
'fitted'	Residuals versus fitted values
'lagged'	Residuals versus lagged residual ( $r(t)$ versus $r(t - 1)$ )
'probability'	Normal probability plot
'symmetry'	Symmetry plot

**Example:** `plotResiduals(lme, 'lagged')`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'Conditional' - Indicator for conditional residuals**

True (default) | False

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

**Example:** `'Conditional', 'False'`

## **'ResidualType' - Residual type**

# LinearMixedModel.plotResiduals

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

Residual Type	Conditional	Marginal
'Raw'	$r_i^C = [y - X\hat{\beta} - Zb]_i$	$r_i^M = [y - X\hat{\beta}]_i$
'Pearson'	$pr_i^C = \frac{r_i^C}{\sqrt{[\text{Var}_{y,b}(y - X\hat{\beta} - Zb)]_{ii}}}$	$pr_i^M = \frac{r_i^M}{\sqrt{[\text{Var}_y(y - X\hat{\beta})]_{ii}}}$
'Standardized'	$st_i^C = \frac{r_i^C}{\sqrt{[\text{Var}_y(r^C)]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{[\text{Var}_y(r^M)]_{ii}}}$

Example: 'ResidualType', 'Standardized'

## Output Arguments

### h - Handle to residual plot

handle

Handle to the residual plot, returned as a handle.

## Examples

### Examine Residuals

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

# LinearMixedModel.plotResiduals

---

weight contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a dataset array. Define Subject and Program as categorical variables.

```
ds = dataset(InitialWeight,Program,Subject,Week,y);  
ds.Subject = nominal(ds.Subject);  
ds.Program = nominal(ds.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(ds,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Plot the histogram of the raw residuals.

```
plotResiduals(lme)
```

# LinearMixedModel.plotResiduals

Plot the residuals versus the fitted values.

```
figure();  
plotResiduals(lme, 'fitted')
```

# LinearMixedModel.plotResiduals

---

There is no obvious pattern, so there are no immediate signs of heteroscedasticity.

Create the normal probability plot of residuals.

```
figure();  
plotResiduals(lme, 'probability')
```

# LinearMixedModel.plotResiduals

Data appears to be normal.

Find the observation number for the data that appears to be an outlier to the right of the plot.

```
find(residuals(lme)>0.25)
```

```
ans =
```

```
101
```

# LinearMixedModel.plotResiduals

---

Create a box plot of the raw, Pearson, and standardized residuals.

```
r = residuals(lme);  
pr = residuals(lme, 'ResidualType', 'Pearson');  
st = residuals(lme, 'ResidualType', 'Standardized');  
X = [r pr st];  
boxplot(X, 'labels', {'Raw', 'Pearson', 'Standardized'});
```

All three box plots point out the outlier on the right tail of the distribution. The box plots of raw and Pearson residuals also point

out a second possible outlier on the left tail. Find the corresponding observation number.

```
find(pr<-2)
```

```
ans =
```

```
10
```

Plot the raw residuals versus lagged residuals.

```
plotResiduals(lme, 'lagged')
```

# LinearMixedModel.plotResiduals

There is no obvious pattern in the graph. The residuals do not appear to be correlated.

## Definitions

### Conditional and Marginal Residuals

Conditional residuals include contributions from both fixed and random effects, whereas marginal residuals include contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an  $n$ -by- $p$  fixed-effects design matrix  $X$  and an  $n$ -by- $q$  random-effects design matrix  $Z$ . Also,

suppose the  $p$ -by-1 estimated fixed-effects vector is  $\hat{\beta}$ , and the  $q$ -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is  $\hat{b}$ . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

`residuals` can return three types of residuals: raw, Pearson, and standardized. For any type, you can compute the conditional or the marginal residuals. For example, the conditional raw residual is

$$r_{Cond} = y - X\hat{\beta} - Z\hat{b},$$

and the marginal raw residual is

$$r_{Mar} = y - X\hat{\beta}.$$

For more information on other types of residuals, see the `ResidualType` name-value pair argument.

## See Also

`LinearMixedModel` | `residuals` | `fitted` |

# NonLinearModel.plotResiduals

---

**Purpose** Plot residuals of nonlinear regression model

**Syntax**

```
plotResiduals mdl
plotResiduals mdl,plottype
h = plotResiduals(...)
h = plotResiduals mdl,plottype,Name,Value)
```

**Description**

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

### **plottype**

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ( $r(t)$ vs. $r(t-1)$ )
'probability'	Normal probability plot
'symmetry'	Symmetry plot

**Default:** 'histogram'

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### **'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

# NonLinearModel.plotResiduals

---

## 'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## 'ResidualType'

Type of residual used in the plot:

'Raw'	Observed minus fitted values
'Pearson'	Raw residuals divided by RMSE
'Standardized'	Raw residuals divided by their estimated standard deviation
'Studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

**Default:** 'Raw'

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Examples

### Residual Plot

Plot the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Plot the residuals of the fitted model.

```
plotResiduals(mdl)
```

## Residual Probability Plot

Create a normal probability plot of the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

# LinearModel.plotSlice

---

**Purpose** Plot of slices through fitted linear regression surface

**Syntax** `plotSlice mdl`  
`h = plotSlice(mdl)`

**Description** `plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

- Tips**
- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
  - The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

**Input Arguments** **mdl**  
Linear model, as constructed by `fitlm` or `stepwiselm`.

**Output Arguments** **h**  
Vector of handles to lines or patches in the plot.

## Examples

### Slice Plot

Plot the slices through a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create a slice plot.

```
plotSlice mdl
```

Drag the Weight prediction line to the right and observe the change in the predicted MPG and the response curve for Year.

- “Nonlinear Regression Workflow” on page 11-16

## Concepts

- “Nonlinear Regression” on page 11-2

## Purpose

Partial least-squares regression

## Syntax

```
[XL,YL] = plsregress(X,Y,ncomp)
[XL,YL,XS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA] = PLSREGRESS(X,Y,ncomp,...)
[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(...,param1,val1,
    param2,val2,...)
[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = PLSREGRESS(X,Y,ncomp,
    ...)
```

## Description

`[XL,YL] = plsregress(X,Y,ncomp)` computes a partial least-squares (PLS) regression of  $Y$  on  $X$ , using  $ncomp$  PLS components, and returns the predictor and response loadings in  $XL$  and  $YL$ , respectively.  $X$  is an  $n$ -by- $p$  matrix of predictor variables, with rows corresponding to observations and columns to variables.  $Y$  is an  $n$ -by- $m$  response matrix.  $XL$  is a  $p$ -by- $ncomp$  matrix of predictor loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original predictor variables.  $YL$  is an  $m$ -by- $ncomp$  matrix of response loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original response variables.

`[XL,YL,XS] = plsregress(X,Y,ncomp)` returns the predictor scores  $XS$ , that is, the PLS components that are linear combinations of the variables in  $X$ .  $XS$  is an  $n$ -by- $ncomp$  orthonormal matrix with rows corresponding to observations and columns to components.

`[XL,YL,XS,YS] = plsregress(X,Y,ncomp)` returns the response scores  $YS$ , that is, the linear combinations of the responses with which the PLS components  $XS$  have maximum covariance.  $YS$  is an  $n$ -by- $ncomp$  matrix with rows corresponding to observations and columns to components.  $YS$  is neither orthogonal nor normalized.

`plsregress` uses the SIMPLS algorithm, first centering  $X$  and  $Y$  by subtracting off column means to get centered variables  $X0$  and  $Y0$ .

However, it does not rescale the columns. To perform PLS with standardized variables, use `zscore` to normalize `X` and `Y`.

If `ncomp` is omitted, its default value is `min(size(X,1)-1,size(X,2))`.

The relationships between the scores, loadings, and centered variables `X0` and `Y0` are:

$$XL = (XS \setminus X0)' = X0' * XS,$$

$$YL = (XS \setminus Y0)' = Y0' * XS,$$

`XL` and `YL` are the coefficients from regressing `X0` and `Y0` on `XS`, and `XS*XL'` and `XS*YL'` are the PLS approximations to `X0` and `Y0`.

`plsregress` initially computes `YS` as:

$$YS = Y0 * YL = Y0 * Y0' * XS,$$

By convention, however, `plsregress` then orthogonalizes each column of `YS` with respect to preceding columns of `XS`, so that `XS' * YS` is lower triangular.

`[XL, YL, XS, YS, BETA] = PLSREGRESS(X, Y, ncomp, ...)` returns the PLS regression coefficients `BETA`. `BETA` is a  $(p+1)$ -by- $m$  matrix, containing intercept terms in the first row:

$$Y = [\text{ones}(n, 1), X] * BETA + Y_{\text{residuals}},$$

`Y0 = X0 * BETA(2:end, :) + Y_{\text{residuals}}`. Here `Y_{\text{residuals}}` is the vector of response residuals.

`[XL, YL, XS, YS, BETA, PCTVAR] = plsregress(X, Y, ncomp)` returns a 2-by-`ncomp` matrix `PCTVAR` containing the percentage of variance explained by the model. The first row of `PCTVAR` contains the percentage of variance explained in `X` by each PLS component, and the second row contains the percentage of variance explained in `Y`.

`[XL, YL, XS, YS, BETA, PCTVAR, MSE] = plsregress(X, Y, ncomp)` returns a 2-by- $(ncomp+1)$  matrix `MSE` containing estimated mean-squared errors for PLS models with 0:`ncomp` components. The first row of `MSE` contains mean-squared errors for the predictor variables in `X`, and the second row contains mean-squared errors for the response variable(s) in `Y`.

# plsregress

`[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(...,param1,va11, param2,va12,...)` specifies optional parameter name/value pairs from the following table to control the calculation of MSE.

Parameter	Value
'cv'	<p>The method used to compute MSE.</p> <ul style="list-style-type: none"> <li>• When the value is a positive integer <i>k</i>, <code>plsregress</code> uses <i>k</i>-fold cross-validation.</li> <li>• When the value is an object of the <code>cvpartition</code> class, other forms of cross-validation can be specified.</li> <li>• When the value is 'resubstitution', <code>plsregress</code> uses <i>X</i> and <i>Y</i> both to fit the model and to estimate the mean-squared errors, without cross-validation.</li> </ul> <p>The default is 'resubstitution'.</p>
'mcreps'	<p>A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is 1. The value must be 1 if the value of 'cv' is 'resubstitution'.</p>
options	<p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the <code>options</code> structure with <code>statset</code>. Option fields:</p> <ul style="list-style-type: none"> <li>• <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>.</li> <li>• <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</li> <li>• <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>plsregress</code> uses the default stream.</li> </ul>

`[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = PLSREGRESS(X,Y,ncomp,...)` returns a structure `stats` with the following fields:

- $W$  — A  $p$ -by- $n_{\text{comp}}$  matrix of PLS weights so that  $XS = X0*W$ .
- $T^2$  — The  $T^2$  statistic for each point in  $XS$ .
- $X_{\text{residuals}}$  — The predictor residuals, that is,  $X0 - XS*XL'$ .
- $Y_{\text{residuals}}$  — The response residuals, that is,  $Y0 - XS*YL'$ .

## Examples

Load data on near infrared (NIR) spectral intensities of 60 samples of gasoline at 401 wavelengths, and their octane ratings:

```
load spectra
X = NIR;
y = octane;
```

Perform PLS regression with ten components:

```
[XL,y1,XS,YS,beta,PCTVAR] = plsregress(X,y,10);
```

Plot the percent of variance explained in the response variable as a function of the number of components:

```
plot(1:10,cumsum(100*PCTVAR(2,:)),'-bo');
xlabel('Number of PLS components');
ylabel('Percent Variance Explained in y');
```

# plsregress

Compute the fitted response and display the residuals:

```
yfit = [ones(size(X,1),1) X]*beta;  
residuals = y-yfit;
```

```
stem(residuals)  
xlabel('Observation');  
ylabel('Residual');
```

# sobolset.PointOrder property

---

**Purpose** Point generation method

**Description** The `PointOrder` property contains a string that specifies the order in which the Sobol sequence points are produced. The property value must be one of 'standard' or 'graycode'. When set to 'standard' the points produced match the original Sobol sequence implementation. When set to 'graycode', the sequence is generated using an implementation that uses the Gray code of the index instead of the index itself.

**Purpose** Point set from which stream is drawn

**Description** The PointSet property contains a copy of the point set from which the stream is providing points. The point set is specified during construction of a quasi-random stream and cannot subsequently be altered.

## Examples

```
Q = grandstream('sobol', 5, 'Skip', 8);  
% Create a new stream based on the same sequence as that in Q  
Q2 = grandstream(Q.PointSet);  
u1 = rand(Q, 10)  
u2 = rand(Q2, 10) % contains exactly the same values as u1
```

# poisscdf

---

**Purpose** Poisson cumulative distribution function

**Syntax**  
`p = poisscdf(x,lambda)`  
`p = poisscdf(x,lambda,'upper')`

**Description** `p = poisscdf(x,lambda)` returns the Poisson cdf at each value in `x` using the corresponding mean parameters in `lambda`. `x` and `lambda` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `lambda` must be positive.

`p = poisscdf(x,lambda,'upper')` returns the complement of the Poisson cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Poisson cdf is

$$p = F(x | \lambda) = e^{-\lambda} \sum_{i=0}^{\text{floor}(x)} \frac{\lambda^i}{i!}$$

## Examples **Compute Poisson Distribution cdf**

For example, consider a Quality Assurance department that performs random tests of individual hard disks. Their policy is to shut down the manufacturing process if an inspector finds more than four bad sectors on a disk. What is the probability of shutting down the process if the mean number of bad sectors ( $\lambda$ ) is two?

```
probability = 1-poisscdf(4,2)
```

```
probability =  
    0.0527
```

About 5% of the time, a normally functioning manufacturing process produces more than four flaws on a hard disk.

Suppose the average number of flaws ( $\lambda$ ) increases to four. What is the probability of finding fewer than five flaws on a hard drive?

```
probability = poisscdf(4,4)
```

```
probability =  
    0.6288
```

This means that this faulty manufacturing process continues to operate after this first inspection almost 63% of the time.

# poissfit

---

**Purpose** Poisson parameter estimates

**Syntax**  
`lambdahat = poissfit(data)`  
`[lambdahat,lambdaci] = poissfit(data)`  
`[lambdahat,lambdaci] = poissfit(data,alpha)`

**Description** `lambdahat = poissfit(data)` returns the maximum likelihood estimate (MLE) of the parameter of the Poisson distribution,  $\lambda$ , given the data `data`.

`[lambdahat,lambdaci] = poissfit(data)` also gives 95% confidence intervals in `lambdaci`.

`[lambdahat,lambdaci] = poissfit(data,alpha)` gives  $100(1 - \alpha)\%$  confidence intervals. For example `alpha = 0.001` yields 99.9% confidence intervals.

The sample mean is the MLE of  $\lambda$ .

$$\hat{\lambda} = \frac{1}{n} \sum_{i=1}^n x_i$$

**Examples**

```
r = poissrnd(5,10,2);  
[l,lci] = poissfit(r)  
l =  
    7.4000    6.3000  
lci =  
    5.8000    4.8000  
    9.1000    7.9000
```

**See Also** `mle` | `poisspdf` | `poisscdf` | `poissinv` | `poisstat` | `poissrnd`

**How To** • “Poisson Distribution” on page B-118

**Purpose** Poisson inverse cumulative distribution function

**Syntax** `X = poissinv(P,lambda)`

**Description** `X = poissinv(P,lambda)` returns the smallest value  $X$  such that the Poisson cdf evaluated at  $X$  equals or exceeds  $P$ , using mean parameters in `lambda`. `P` and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input.

**Examples** If the average number of defects ( $\lambda$ ) is two, what is the 95th percentile of the number of defects?

```
poissinv(0.95,2)
ans =
     5
```

What is the median number of defects?

```
median_defects = poissinv(0.50,2)
median_defects =
     2
```

# prob.PoissonDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Poisson probability distribution object

**Description** `prob.PoissonDistribution` is an object consisting of parameters, a model description, and sample data for a Poisson probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Poisson')` creates a Poisson probability distribution object using the default parameter values.

`pd = makedist('Poisson','lambda',lambda)` creates a Poisson distribution object using the specified parameter value.

## Input Arguments

### lambda - Mean

1 (default) | nonnegative scalar value

Mean of the Poisson distribution, specified as a nonnegative scalar value.

### Data Types

single | double

## Properties

### lambda

Mean of the Poisson distribution, stored as a nonnegative scalar value.

### Data Types

single | double

### DistributionName

Name of the probability distribution, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## InputData

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

single | double

## IsTruncated

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the

# prob.PoissonDistribution

---

estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription

Descriptions of distribution parameters, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames

Names of distribution parameters, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues

Values of distribution parameters, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters

# prob.PoissonDistribution

---

proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions **Poisson Distribution**

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

The Poisson distribution uses the following parameters.

Parameter	Description	Support
lambda	Mean	$\lambda \geq 0$

The probability density function of the Poisson distribution is

$$f(x | \lambda) = \frac{\lambda^x}{x!} e^{-\lambda} \quad ; \quad x = 0, 1, 2, \dots, \infty .$$

## Examples

### Create a Poisson Distribution Object Using Default Parameters

Create a Poisson distribution object using the default parameter values.

```
pd = makedist('Poisson')
```

```
pd =
```

```
PoissonDistribution
```

```
Poisson distribution  
lambda = 1
```

## Create a Poisson Distribution Object Using Specified Parameters

Create a Poisson distribution object by specifying the parameter values.

```
pd = makedist('Poisson','lambda',5)
```

```
pd =
```

```
PoissonDistribution
```

```
Poisson distribution  
lambda = 5
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v =
```

```
5
```

For the Poisson distribution, both the mean and variance are equal to the parameter lambda.

## Concepts

- “Poisson Distribution” on page B-118
- Class Attributes
- Property Attributes

# poisspdf

---

**Purpose** Poisson probability density function

**Syntax** `Y = poisspdf(X,lambda)`

**Description** `Y = poisspdf(X,lambda)` computes the Poisson pdf at each of the values in `X` using mean parameters in `lambda`. `X` and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `lambda` must all be positive.

The Poisson pdf is

$$f(x | \lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty.$$

The density function is zero unless  $x$  is an integer.

## Examples

A computer hard disk manufacturer has observed that flaws occur randomly in the manufacturing process at the average rate of two flaws in a 4 GB hard disk and has found this rate to be acceptable. What is the probability that a disk will be manufactured with no defects?

In this problem,  $\lambda = 2$  and  $x = 0$ .

```
p = poisspdf(0,2)
p =
    0.1353
```

<b>How To</b>	• “Poisson Distribution” on page B-118

# poisstat

---

**Purpose** Poisson mean and variance

**Syntax** `M = poisstat(lambda)`  
`[M,V] = poisstat(lambda)`

**Description** `M = poisstat(lambda)` returns the mean of the Poisson distribution using mean parameters in `lambda`. The size of `M` is the size of `lambda`.  
`[M,V] = poisstat(lambda)` also returns the variance `V` of the Poisson distribution.  
For the Poisson distribution with parameter  $\lambda$ , both the mean and variance are equal to  $\lambda$ .

**Examples** Find the mean and variance for the Poisson distribution with  $\lambda = 2$ .

```
[m,v] = poisstat([1 2; 3 4])  
m =  
    1    2  
    3    4  
v =  
    1    2  
    3    4
```

**See Also** `poisspdf` | `poisscdf` | `poissinv` | `poissfit` | `poissrnd`

**How To** • “Poisson Distribution” on page B-118

**Purpose** Polynomial confidence intervals

**Syntax**

```
Y = polyconf(p,X)
[Y,DELTA] = polyconf(p,X,S)
[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)
```

**Description**

`Y = polyconf(p,X)` evaluates the polynomial `p` at the values in `X`. `p` is a vector of coefficients in descending powers.

`[Y,DELTA] = polyconf(p,X,S)` takes outputs `p` and `S` from `polyfit` and generates 95% prediction intervals `Y - DELTA` for new observations at the values in `X`.

`[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs chosen from the following list.

Parameter	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 * (1 - \text{alpha})\%$ . The default is 0.05.
'mu'	A two-element vector containing centering and scaling parameters. With this option, <code>polyconf</code> uses $(X - \text{mu}(1)) / \text{mu}(2)$ in place of <code>X</code> .
'predopt'	Either 'observation' (the default) to compute prediction intervals for new observations at the values in <code>X</code> , or 'curve' to compute confidence intervals for the fit evaluated at the values in <code>X</code> . See below.
'simopt'	Either 'off' (the default) for nonsimultaneous bounds, or 'on' for simultaneous bounds. See below.

The 'predopt' and 'simopt' parameters can be understood in terms of the following functions:

- $p(x)$  — the unknown mean function estimated by the fit
- $l(x)$  — the lower confidence bound

- $u(x)$  — the upper confidence bound

Suppose you make a new observation  $y_{n+1}$  at  $x_{n+1}$ , so that

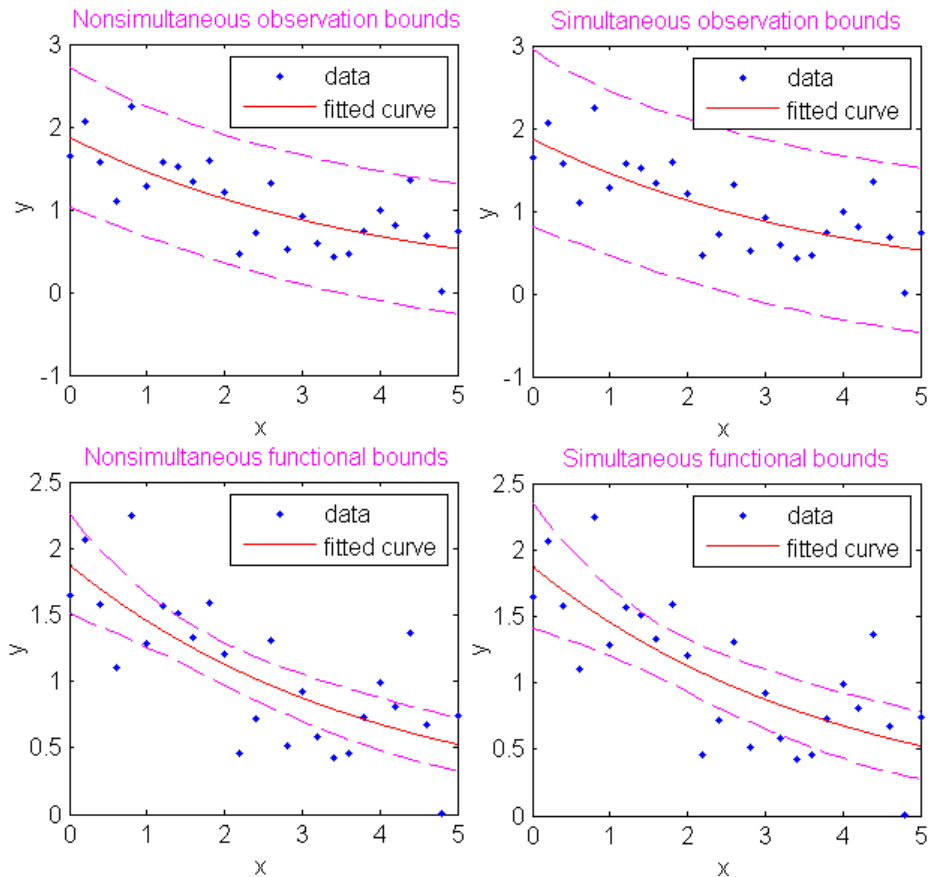

$$y_{n+1}(x_{n+1}) = p(x_{n+1}) + \varepsilon_{n+1}$$

By default, the interval  $[l_{n+1}(x_{n+1}), u_{n+1}(x_{n+1})]$  is a 95% confidence bound on  $y_{n+1}(x_{n+1})$ .

The following combinations of the 'predopt' and 'simopt' parameters allow you to specify other bounds.

'simopt'	'predopt'	Bounded Quantity
'off'	'observation'	$y_{n+1}(x_{n+1})$ (default)
'off'	'curve'	$p(x_{n+1})$
'on'	'observation'	$y_{n+1}(x)$ , for all $x$
'on'	'curve'	$p(x)$ , for all $x$

In general, 'observation' intervals are wider than 'curve' intervals, because of the additional uncertainty of predicting a new response value (the curve plus random errors). Likewise, simultaneous intervals are wider than nonsimultaneous intervals, because of the additional uncertainty of bounding values for all predictors  $x$ .

## Examples

This example uses code from the documentation example function `polydemo`, and calls the documentation example function `polystr` to convert the coefficient vector `p` into a string for the polynomial expression displayed in the figure title. It combines the functions `polyfit`, `polyval`, `roots`, and `polyconf` to produce a formatted display of data with a polynomial fit.

---

**Note** Statistics Toolbox documentation example files are located in the `\help\toolbox\stats\examples` subdirectory of your MATLAB root folder (`matlabroot`). This subdirectory is not on the MATLAB path at installation. To use the files in this subdirectory, either add the subdirectory to the MATLAB path (`addpath`) or make the subdirectory your current working folder (`cd`).

---

Display simulated data with a quadratic trend, a fitted quadratic polynomial, and 95% prediction intervals for new observations:

```
xdata = -5:5;
ydata = x.^2 - 5*x - 3 + 5*randn(size(x));

degree = 2; % Degree of the fit
alpha = 0.05; % Significance level

% Compute the fit and return the structure used by
% POLYCONF.
[p,S] = polyfit(xdata,ydata,degree);

% Compute the real roots and determine the extent of the
% data.
r = roots(p)'; % Roots as a row vector.
real_r = r(imag(r) == 0); % Real roots.

% Assure that the data are row vectors.
xdata = reshape(xdata,1,length(xdata));
ydata = reshape(ydata,1,length(ydata));

% Extent of the data.
mx = min([real_r,xdata]);
Mx = max([real_r,xdata]);
my = min([ydata,0]);
My = max([ydata,0]);
```

```

% Scale factors for plotting.
sx = 0.05*(Mx-mx);
sy = 0.05*(My-my);

% Plot the data, the fit, and the roots.
hdata = plot(xdata,ydata,'md','MarkerSize',5,...
    'LineWidth',2);
hold on
xfit = mx-sx:0.01:Mx+sx;
yfit = polyval(p,xfit);
hfit = plot(xfit,yfit,'b-','LineWidth',2);

**Syntax**

```
polytool
polytool(x,y)
polytool(x,y,n)
polytool(x,y,n,alpha)
polytool(x,y,n,alpha,xname,yname)
h = polytool(...)
```

**Description**

`polytool`

`polytool(x,y)` fits a line to the vectors `x` and `y` and displays an interactive plot of the result in a graphical interface. You can use the interface to explore the effects of changing the parameters of the fit and to export fit results to the workspace.

`polytool(x,y,n)` initially fits a polynomial of degree `n`. The default is 1, which produces a linear fit.

`polytool(x,y,n,alpha)` initially plots  $100(1 - \alpha)\%$  confidence intervals on the predicted values. The default is 0.05 which results in 95% confidence intervals.

`polytool(x,y,n,alpha,xname,yname)` labels the `x` and `y` values on the graphical interface using the strings `xname` and `yname`. Specify `n` and `alpha` as `[]` to use their default values.

`h = polytool(...)` outputs a vector of handles, `h`, to the line objects in the plot. The handles are returned in the degree: data, fit, lower bounds, upper bounds.

## Examples **Interactive polynomial fitting**

This example shows how to start an interactive fitting session with `polytool`.

Generate data from a quadratic curve with added noise.

```
rng('default') % for reproducibility
x = -5:5;
```

# polytool

```
y = x.^2 - 5*x - 3 + 5*randn(size(x));
```

Fit a quadratic (degree-2) model with 0.90 confidence intervals.

```
n = 2;  
alpha = 0.1;  
polytool(x,y,n,alpha)
```

**See Also** [polyfit](#) | [polyval](#) | [polyconf](#) | [invpred](#)

## Purpose

Posterior probabilities of components

## Syntax

```
P = posterior(obj,X)
[P,nlogl] = posterior(obj,X)
```

## Description

`P = posterior(obj,X)` returns the posterior probabilities of each of the  $k$  components in the Gaussian mixture distribution defined by `obj` for each observation in the data matrix  $X$ .  $X$  is  $n$ -by- $d$ , where  $n$  is the number of observations and  $d$  is the dimension of the data. `obj` is an object created by `gmdistribution` or `fit`.  $P$  is  $n$ -by- $k$ , with  $P(I,J)$  the probability of component  $J$  given observation  $I$ .

`posterior` treats NaN values as missing data. Rows of  $X$  with NaN values are excluded from the computation.

`[P,nlogl] = posterior(obj,X)` also returns `nlogl`, the negative log-likelihood of the data.

## Examples

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function:

```
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];

scatter(X(:,1),X(:,2),10,'.')
hold on
```

# gmdistribution.posterior

---

Fit a two-component Gaussian mixture model:

```
obj = gmdistribution.fit(X,2);  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Compute posterior probabilities of the components:

```
P = posterior(obj,X);  
  
delete(h)  
scatter(X(:,1),X(:,2),10,P(:,1),'o')  
hb = colorbar;  
ylabel(hb,'Component 1 Probability')
```

# gmdistribution.posterior

## See Also

`gmdistribution` | `fit` | `cluster` | `mahal`

## Purpose

Compute posterior probability of each class for test data

## Syntax

```
post = posterior(nb,test)
[post,cpre] = posterior(nb,test)
[post,cpre,logp] = posterior(nb,test)
[...] = posterior(..., 'HandleMissing',val)
```

## Description

`post = posterior(nb,test)` returns the posterior probability of the observations in `test` according to the `NaiveBayes` object `nb`. `test` is a `N-by-nb.ndims` matrix, where `N` is the number of observations in the test data. Rows of `test` correspond to points, columns of `test` correspond to features. `post` is a `N-by-nb.nclasses` matrix containing the posterior probability of each observation for each class. `post(i,j)` is the posterior probability of point `I` belonging to class `j`. Classes are ordered the same as `nb.clevels`, i.e., column `j` of `post` corresponds to the `j`th class in `nb.clevels`. The posterior probabilities corresponding to any empty classes are `NaN`.

`[post,cpre] = posterior(nb,test)` returns `cpre`, an `N-by-1` vector, containing the class to which each row of `test` has been assigned. `cpre` has the same type as `nb.CLevels`.

`[post,cpre,logp] = posterior(nb,test)` returns `logp`, an `N-by-1` vector containing estimates of the log of the probability density function (PDF). `logp(i)` is the log of the PDF of point `i`. The PDF value of point `i` is the sum of  $\text{Prob}(\text{point } I \mid \text{class } J) * \text{Pr}\{\text{class } J\}$  taken over all classes.

`[...] = posterior(..., 'HandleMissing',val)` specifies how `posterior` treats `NaN` (missing values). `val` can be one of the following:

# NaiveBayes.posterior

---

'off' (default)	Observations with NaN in any of the columns are not classified into any class. The corresponding rows in <code>post</code> and <code>logp</code> are NaN. The corresponding rows in <code>cpre</code> are NaN (if <code>obj.clevels</code> is numeric or logical), empty strings (if <code>obj.clevels</code> is char or cell array of strings) or (if <code>obj.clevels</code> is categorical).
'on'	For observations having NaN in some (but not all) columns, <code>post</code> and <code>cpre</code> are computed using the columns with non-NaN values. Corresponding <code>logp</code> values are NaN.

## Data Types

double | single

## dim - Dimension

1 (default) | positive integer

Dimension along which the percentiles of  $X$  are required, specified as a positive integer. For example, for a matrix  $X$ , when  $\text{dim} = 1$ , `prctile` returns the quantile(s) of the columns of  $X$  and when  $\text{dim} = 2$ , `prctile` returns the quantile(s) of the rows of  $X$ . For a multidimensional array  $X$ , the length of the  $\text{dim}$ th dimension of  $Y$  is equal to the length of  $p$ .

## Data Types

double

## Output Arguments

### Y - Percentiles

scalar | array

Percentiles of a data vector or array, specified as a scalar or array for one or more percentage values.

- If  $X$  is a vector, then  $Y$  is a scalar or a vector with the same length as the number of percentiles required (`length(p)`).  $Y(i)$  contains the  $p(i)$ th percentile.
- If  $X$  is a matrix, then  $Y$  is a vector or a matrix with the length of the  $\text{dim}$ th dimension equal to the number percentiles required (`length(p)`). When  $\text{dim} = 1$ , for example, the  $i$ th row of  $Y$  contains the  $p(i)$ th percentiles of columns of  $X$ .
- If  $X$  is an array of dimension  $d$ , then  $Y$  is an array with the length of the  $\text{dim}$ th dimension equal to the number of percentiles required (`length(p)`).

## Definitions

### Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if  $X$  is a 1-by-3-by-4 array, then  $X$  is a 3-D array.

## Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if  $X$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $X$ .

## Linear Interpolation

Linear interpolation uses linear polynomials to find  $y_i = f(x_i)$ , the values of the underlying function  $Y = f(X)$  at the points in the vector or array  $x$ . Given the data points  $(x_1, y_1)$  and  $(x_2, y_2)$ , where  $y_1 = f(x_1)$  and  $y_2 = f(x_2)$ , linear interpolation finds  $y = f(x)$  for a given  $x$  between  $x_1$  and  $x_2$  as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the  $100(1.5/n)$ th percentile is  $y_{1.5/n}$  and the  $100(2.5/n)$ th percentile is  $y_{2.5/n}$ , then linear interpolation finds the  $100(2.3/n)$ th percentile,  $y_{2.3/n}$  as:

$$\frac{y_{2.3}}{n} = \frac{y_{1.5}}{n} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)} \left(\frac{y_{2.5}}{n} - \frac{y_{1.5}}{n}\right).$$

## Algorithms

For an  $n$ -element vector  $X$ , `prctile` returns percentiles as follows:

- 1 The sorted values in  $X$  are taken as the  $100(0.5/n)$ th,  $100(1.5/n)$ th, ...,  $100([n - 0.5]/n)$ th percentiles. For example:
  - For a data vector of five elements such as  $\{6, 3, 2, 10, 1\}$ , the sorted elements  $\{1, 2, 3, 6, 10\}$  respectively correspond to the 10th, 30th, 50th, 70th, and 90th percentiles.
  - For a data vector of six elements such as  $\{6, 3, 2, 10, 8, 1\}$ , the sorted elements  $\{1, 2, 3, 6, 8, 10\}$  respectively correspond to the

(50/6)th, (150/6)th, (250/6)th, (350/6)th, (450/6)th, and (550/6)th percentiles.

- 2** `prctile` uses linear interpolation to compute percentiles for percentages between  $100(0.5/n)$  and  $100([n - 0.5]/n)$ .
- 3** `prctile` assigns the minimum or maximum values in `X` to the percentiles corresponding to the percentages outside that range.

`prctile` treats NaNs as missing values and removes them.

## Examples

### Percentiles of a Data Vector

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(5,2,1,10)
```

```
x =
    6.0753    8.6678    0.4823    6.7243    5.6375    2.3846    4.1328
```

Calculate the 42nd percentile.

```
Y = prctile(X,42)
```

```
Y =
    5.6709
```

### Percentiles of a Data Matrix

Calculate the percentiles along the columns and rows of a data matrix for specified percentages.

Generate a 5-by-5 data matrix.

```
X = (1:5)'*(2:6)
```

```
X =
```

2	3	4	5	6
4	6	8	10	12
6	9	12	15	18
8	12	16	20	24
10	15	20	25	30

Calculate the 25th, 50th, and 75th percentiles along the columns of X.

```
Y = prctile(X,[25 50 75],1)
```

```
Y =
    3.5000    5.2500    7.0000    8.7500   10.5000
    6.0000    9.0000   12.0000   15.0000   18.0000
    8.5000   12.7500   17.0000   21.2500   25.5000
```

The rows of Y correspond to the percentiles of columns of X. For example, the 25th, 50th, and 75th percentiles of the third column of X with elements (4, 8, 12, 16, 20) are 7, 12, and 17, respectively. `Y = prctile(X,[25 50 75])` returns the same percentile matrix.

Calculate the 25th, 50th, and 75th percentiles along the rows of X.

```
Y = prctile(X,[25 50 75],2)
```

```
Y =
    2.7500    4.0000    5.2500
    5.5000    8.0000   10.5000
    8.2500   12.0000   15.7500
   11.0000   16.0000   21.0000
   13.7500   20.0000   26.2500
```

The rows of Y correspond to the percentiles of rows of X. For example, the 25th, 50th, and 75th percentiles of the first row of X with elements (2, 3, 4, 5, 6) are 2.75, 4, and 5.25, respectively.

See “Posterior Probability” on page 21-2608.</p> <p><b>cost</b></p>

# ClassificationKNN.predict

---

Matrix of expected costs of size N-by-K, where N is the number of observations (rows) in  $X_{\text{new}}$ , and K is the number of classes (in  $\text{mdl.ClassNames}$ ).  $\text{cost}(i, j)$  is the cost of classifying row  $i$  of  $X$  as class  $j$ . See “Expected Cost” on page 21-2609.

## Definitions

### Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.
- $\hat{P}(k | x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y | k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

### Posterior Probability

For a vector (single query point)  $X_{\text{new}}$  and model  $\text{mdl}$ , let:

- $K$  be the number of nearest neighbors used in prediction,  $\text{mdl.NumNeighbors}$
- $\text{nbd}(\text{mdl}, X_{\text{new}})$  be the  $K$  nearest neighbors to  $X_{\text{new}}$  in  $\text{mdl.X}$
- $Y(\text{nbd})$  be the classifications of the points in  $\text{nbd}(\text{mdl}, X_{\text{new}})$ , namely  $\text{mdl.Y}(\text{nbd})$
- $W(\text{nbd})$  be the weights of the points in  $\text{nbd}(\text{mdl}, X_{\text{new}})$
- $\text{prior}$  be the priors of the classes in  $\text{mdl.Y}$

If there is a vector of prior probabilities, then the observation weights  $W$  are normalized by class to sum to the priors. This might involve a calculation for the point  $X_{\text{new}}$ , because weights can depend on the distance from  $X_{\text{new}}$  to the points in  $\text{mdl.X}$ .

The posterior probability  $p(j | X_{\text{new}})$  is

$$p(j | X_{\text{new}}) = \frac{\sum_{i \in \text{nd}} W(i) 1_{Y(X(i)=j)}}{\sum_{i \in \text{nd}} W(i)}.$$

Here,  $1_{Y(X(i)=j)}$  means 1 when  $\text{mdl.Y}(i) = j$ , and 0 otherwise.

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `ClassificationKNN.fit`. `Cost(i,j)` is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default, `Cost(i,j)=1` if  $i \neq j$ , and `Cost(i,j)=0` if  $i=j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

# ClassificationKNN.predict

---

returns, among other outputs, a `cost` matrix of size `Nobs-by-K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{new}(n))$  is the posterior probability of class  $i$  for observation  $X_{new}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Examples

### KNN Classification Predictions

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ . Evaluate some model predictions on new data.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5);
```

Predict the classifications for flowers with minimum, mean, and maximum characteristics.

```
Xnew = [min(X);mean(X);max(X)];
[label,score,cost] = predict(mdl,Xnew)
```

```
label =
  'setosa'
  'versicolor'
  'virginica'

score =
  1    0    0
  0    1    0
  0    0    1

cost =
  0    1    1
  1    0    1
  1    1    0
```

The classifications have binary values for the score and cost matrices, meaning all five nearest neighbors of each of the three points have identical classifications.

# CompactClassificationDiscriminant.predict

---

<b>Purpose</b>	Predict classification
<b>Syntax</b>	<pre>label = predict(obj,X) [label,score] = predict(obj,X) [label,score,cost] = predict(obj,X)</pre>
<b>Description</b>	<p><code>label = predict(obj,X)</code> returns a vector of predicted class labels for a matrix <code>X</code>, based on <code>obj</code>, a trained full or compact classifier.</p> <p><code>[label,score] = predict(obj,X)</code> returns a matrix of scores (posterior probabilities).</p> <p><code>[label,score,cost] = predict(obj,X)</code> returns a matrix of costs; <code>label</code> is the vector of minimal costs for each row of <code>cost</code>.</p>
<b>Input Arguments</b>	<p><b>obj</b></p> <p>Discriminant analysis classifier of class <code>ClassificationDiscriminant</code> or <code>CompactClassificationDiscriminant</code>, typically constructed with <code>ClassificationDiscriminant.fit</code>.</p> <p><b>X</b></p> <p>Matrix where each row represents an observation, and each column represents a predictor. The number of columns in <code>X</code> must equal the number of predictors in <code>obj</code>.</p>
<b>Output Arguments</b>	<p><b>label</b></p> <p>Vector of class labels of the same type as the response data used in training <code>obj</code>. Each entry of <code>labels</code> corresponds to a predicted class label for the corresponding row of <code>X</code>; see “Predicted Class Label” on page 21-2614.</p> <p><b>score</b></p> <p>Numeric matrix of size N-by-K, where N is the number of observations (rows) in <code>X</code>, and K is the number of classes (in</p>

obj.ClassNames). score(i, j) is the posterior probability that row i of X is of class j; see "Posterior Probability" on page 21-2613.

## cost

Matrix of expected costs of size N-by-K. cost(i, j) is the cost of classifying row i of X as class j. See "Cost" on page 21-2614.

## Definitions

### Posterior Probability

The posterior probability that a point  $z$  belongs to class  $j$  is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean  $\mu_j$  and covariance  $\Sigma_j$  at a point  $z$  is

$$P(x | k) = \frac{1}{(2\pi |\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where  $|\Sigma_k|$  is the determinant of  $\Sigma_k$ , and  $\Sigma_k^{-1}$  is the inverse matrix.

Let  $P(k)$  represent the prior probability of class  $k$ . Then the posterior probability that an observation  $x$  is of class  $k$  is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where  $P(x)$  is a normalization constant, the sum over  $k$  of  $P(x | k)P(k)$ .

### Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class  $k$  is one over the total number of classes.
- 'empirical' — The prior probability of class  $k$  is the number of training samples of class  $k$  divided by the total number of training samples.

# CompactClassificationDiscriminant.predict

---

- Custom — The prior probability of class  $k$  is the  $k$ th element of the prior vector. See `ClassificationDiscriminant.fit`.

After creating a classifier `obj`, you can set the prior by dot addressing:

```
obj.Prior = v;
```

where  $v$  is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

## Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

## Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k|x) C(y|k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.
- $\hat{P}(k|x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y|k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

## Examples

Examine predictions for a few rows in the Fisher iris data:

```
load fisheriris
obj = ClassificationDiscriminant.fit(meas,species);
X = meas(99:102,:); % take four rows
```

# CompactClassificationDiscriminant.predict

---

```
[label score cost] = predict(obj,X)
```

```
label =
```

```
    'versicolor'  
    'versicolor'  
    'virginica'  
    'virginica'
```

```
score =

## How To

- “Discriminant Analysis” on page 15-3

# CompactClassificationEnsemble.predict

---

**Purpose** Predict classification

**Syntax**  
`labels = predict(ens,X)`  
`[labels,score] = predict(ens,X)`  
`[labels,...] = predict(ens,X,Name,Value)`

**Description** `labels = predict(ens,X)` returns a vector of predicted class labels for a matrix `X`, based on `ens`, a trained full or compact classification ensemble.  
`[labels,score] = predict(ens,X)` also returns scores for all classes.  
`[labels,...] = predict(ens,X,Name,Value)` predicts classifications with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A classification ensemble created by `fitensemble`, or a compact classification ensemble created by `compact`.

### **X**

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `ens`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners `predict` uses for computation of responses, a numeric vector.

**Default:** 1:T, where T is the number of weak learners in ens

## 'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When UseObsForLearner(i, j) is true, learner j is used in predicting the class of row i of X.

**Default:** true(N,T)

## Output Arguments

### labels

Vector of classification labels. labels has the same data type as the labels used in training ens.

### score

A matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. predict averages these scores over all trees in the ensemble.

## Definitions

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

# CompactClassificationEnsemble.predict

---

## Examples

Train a boosting ensemble for the ionosphere data, and predict the classification of the mean of the data:

```
load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
Xbar = mean(X);
[ypredict score] = predict(ada,Xbar)
```

```
ypredict =
    'g'
```

```
score =
    -2.9460    2.9460
```

## See Also

[margin](#) | [edge](#) | [loss](#)

## Purpose

Predict classification

## Syntax

```
label = predict(tree,X)
[label,score] = predict(tree,X)
[label,score,node] = predict(tree,X)
[label,score,node,cnum] = predict(tree,X)
[label,...] = predict(tree,X,Name,Value)
```

## Description

`label = predict(tree,X)` returns a vector of predicted class labels for a matrix `X`, based on `tree`, a trained full or compact classification tree.

`[label,score] = predict(tree,X)` returns a matrix of scores, indicating the likelihood that a label comes from a particular class.

`[label,score,node] = predict(tree,X)` returns a vector of predicted node numbers for the classification, based on `tree`.

`[label,score,node,cnum] = predict(tree,X)` returns a vector of predicted class number for the classification, based on `tree`.

`[label,...] = predict(tree,X,Name,Value)` returns labels with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

A classification tree created by `ClassificationTree.fit`, or a compact classification tree created by `compact`.

### **X**

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `tree`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

# CompactClassificationTree.predict

---

specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## 'subtrees'

Numeric vector of pruning levels, with 0 representing the full, unpruned tree. To use the `subtrees` name-value pair, `tree` must include a pruning sequence as created by the `ClassificationTree.fit` or `prune` methods. If `subtrees` has `T` elements, and `X` has `N` rows, then `labels` is an `N-by-T` matrix. The `i`th column of `labels` contains the fitted values produced by the `subtrees(I)` subtree. Similarly, `score` is an `N-by-K-by-T` array, and `node` and `cnum` are `N-by-T` matrices. `subtrees` must be sorted in ascending order. (To compute fitted values for a tree that is not part of the optimal pruning sequence, first use `prune` to prune the tree.)

**Default:** 0

## Output Arguments

### label

Vector of class labels of the same type as the response data used in training `tree`. Each entry of `label` corresponds to the class with minimal expected cost for the corresponding row of `X`. See “Predicted Class Label” on page 21-2621.

### score

Numeric matrix of size `N-by-K`, where `N` is the number of observations (rows) in `X`, and `K` is the number of classes (in `tree.ClassNames`). `score(i, j)` is the posterior probability that row `i` of `X` is of class `j`.

### node

Numeric vector of node numbers for the predicted classes. Each entry corresponds to the predicted node in `tree` for the corresponding row of `X`.

### cnum

Numeric vector of class numbers corresponding to the predicted labels. Each entry of `cnum` corresponds to a predicted class number for the corresponding row of `X`.

## Definitions

### Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.
- $\hat{P}(k | x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y | k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

### Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

1

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
```

# CompactClassificationTree.predict

```
Y = (abs(X - .55) > .4);  
tree = ClassificationTree.fit(X,Y);  
view(tree,'mode','graph')
```

2

Prune the tree:

```
tree1 = prune(tree,'level',1);  
view(tree1,'mode','graph')
```

# CompactClassificationTree.predict

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

### 3

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0    1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0    1.0000    0.0975  
    0.9059    0.0941    0.2785
```

# CompactClassificationTree.predict

---

0.9059	0.0941	0.5469
0.9059	0.0941	0.9575
0.9059	0.0941	0.9649

Indeed, every value of  $X$  (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `ClassificationTree.fit` method.  $\text{Cost}(i, j)$  is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default,  $\text{Cost}(i, j)=1$  if  $i \neq j$ , and  $\text{Cost}(i, j)=0$  if  $i=j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have  $N_{\text{obs}}$  observations that you want to classify with a trained classifier. Suppose you have  $K$  classes. You place the observations into a matrix  $X_{\text{new}}$  with one observation per row.

The expected cost matrix  $CE$  has size  $N_{\text{obs}}$ -by- $K$ . Each row of  $CE$  contains the expected (average) cost of classifying the observation into each of the  $K$  classes.  $CE(n, k)$  is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{new}(n))$  is the posterior probability of class  $i$  for observation  $X_{new}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Predictive Measure of Association

The predictive measure of association between the optimal split on variable  $i$  and a surrogate split on variable  $j$  is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- $P_L$  and  $P_R$  are the node probabilities for the optimal split of node  $i$  into Left and Right nodes respectively.
- $P_{L_i L_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Left.
- $P_{R_i R_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Right.

Clearly,  $\lambda_{i,j}$  lies from  $-\infty$  to 1. Variable  $j$  is a worthwhile surrogate split for variable  $i$  if  $\lambda_{i,j} > 0$ .

# CompactClassificationTree.predict

---

## Examples

Examine predictions for a few rows in the Fisher iris data:

```
load fisheriris
tree = ClassificationTree.fit(meas,species);
X = meas(99:102,:); % take four rows
[label score node cnum] = predict(tree,X)
```

```
label =
    'versicolor'
    'versicolor'
    'virginica'
    'virginica'
```

```
score =
    0    1.0000         0
    0    1.0000         0
    0    0.0217    0.9783
    0    0.0217    0.9783
```

```
node =
    8
    8
    5
    5
```

```
cnum =
    2
    2
    3
    3
```

---

Examine predictions from pruned trees for the Fisher iris model:

```
load fisheriris
tree = ClassificationTree.fit(meas,species);
X = meas(99:102,:); % taking four rows
```

# CompactClassificationTree.predict

```
[label score node cnum] = predict(tree,X,'subtrees',[2 3 4])
```

```
label =
```

```
    'versicolor'    'versicolor'    'setosa'  
    'versicolor'    'versicolor'    'setosa'  
    'virginica'     'versicolor'    'setosa'  
    'virginica'     'versicolor'    'setosa'
```

```
score(:, :, 1) =
```

```
    0    0.9074    0.0926  
    0    0.9074    0.0926  
    0    0.0217    0.9783  
    0    0.0217    0.9783
```

```

    3    2    1
```

# CompactClassificationTree.predict

---

## Algorithms

`predict` generates predictions by following the branches of `tree` until it reaches a leaf node or a missing value. If `predict` reaches a leaf node, it returns the classification of that node.

If `predict` reaches a node with a missing value for a predictor, its behavior depends on the setting of the `Surrogate` name-value pair when `ClassificationTree.fit` constructs `tree`.

- **Surrogate = 'off'** (default) — `predict` returns the label with the largest number of training samples that reach the node.
- **Surrogate = 'on'** — `predict` uses the best surrogate split at the node. If all surrogate split variables with positive *predictive measure of association* are missing, `predict` returns the label with the largest number of training samples that reach the node. For a definition, see “Predictive Measure of Association” on page 21-2625.

## See Also

`ClassificationTree.fit` | `compact` | `prune` | `loss` | `edge` | `margin`

**Purpose**

Predict response of ensemble

**Syntax**

```
Yfit = predict(ens,Xdata)
Yfit = predict(ens,Xdata,Name,Value)
```

**Description**

`Yfit = predict(ens,Xdata)` returns predicted responses to the data in `Xdata`, based on the `ens` regression ensemble model.

`Yfit = predict(ens,Xdata,Name,Value)` predicts with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments****ens**

Regression ensemble created by `fitensemble`, or by the compact method.

**Xdata**

Numeric array with the same number of columns as the array used for creating `ens`. Each row of `Xdata` corresponds to one data point, and each column corresponds to one predictor.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'learners'**

Indices of weak learners in the ensemble ranging from 1 to `ens.NTrained`. `oobEdge` uses only these learners for calculating loss.

**Default:** `1:NTrained`

**'UseObsForLearner'**

# CompactRegressionEnsemble.predict

---

A logical matrix of size N-by-NTrained, where N is the number of observations in `ens.X`, and NTrained is the number of weak learners. When `UseObsForLearner(I,J)` is true, `predict` uses learner J in predicting observation I.

**Default:** `true(N,NTrained)`

## Output Arguments

### Yfit

A numeric column vector with the same number of rows as `Xdata`. Each row of `Yfit` gives the predicted response to the corresponding row of `Xdata`, based on the `ens` regression model.

## Examples

Find the predicted mileage for a four-cylinder car, with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs, based on the `carsmall` data:

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSBoost',100,'Tree');
Mileage = predict(rens,[4 200 150 3000])
```

```
Mileage =
    20.4982
```

## See Also

`loss` | `fitensemble`

## Purpose

Predict response of regression tree

## Syntax

```
Yfit = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata,Name,Value)
```

## Description

`Yfit = predict(tree,Xdata)` returns predicted responses to the data in `Xdata`, based on the tree regression tree.

`[Yfit,node] = predict(tree,Xdata)` returns the predicted node numbers of tree in response to `Xdata`.

`[Yfit,node] = predict(tree,Xdata,Name,Value)` predicts response with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

Regression tree created by `RegressionTree.fit`, or by the `compact` method.

### **Xdata**

Numeric array with the same number of columns as the array used for creating `tree`. Each row of `Xdata` corresponds to one data point, and each column corresponds to one predictor.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'subtrees'**

Numeric vector of pruning levels, with 0 representing the full, unpruned tree. To use the `subtrees` name-value pair, `tree` must include a pruning sequence as created by the

# CompactRegressionTree.predict

---

RegressionTree.fit or prune methods. If subtrees has T elements, and X has N rows, then Yfit is an N-by-T matrix. The ith column of Yfit contains the fitted values produced by the subtrees(I) subtree. Similarly, node is an N-by-T matrix. subtrees must be sorted in ascending order. (To compute fitted values for a tree that is not part of the optimal pruning sequence, first use prune to prune the tree.)

**Default:** 0

## Output Arguments

### Yfit

A numeric column vector with the same number of rows as Xdata. Each row of Yfit gives the predicted response to the corresponding row of Xdata, based on the tree regression model.

### node

Numeric vector of node numbers for the predictions. Each entry corresponds to the predicted leaf node in tree for the corresponding row of Xdata.

## Examples

Find the predicted mileage for a car with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs, based on the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = RegressionTree.fit(X,MPG);
Mileage = predict(tree,[200 150 3000])
```

```
Mileage =
    21.9375
```

## See Also

RegressionTree.fit | compact | loss

## Purpose

Predict response

## Syntax

```
YFIT = predict(B,X)
[YFIT,stdevs] = predict(B,X)
[YFIT,scores] = predict(B,X)
[YFIT,scores,stdevs] = predict(B,X)
Y = predict(B,X,'param1',val1,'param2',val2,...)
```

## Description

`YFIT = predict(B,X)` computes the predicted response of the trained ensemble `B` for predictors `X`. By default, `predict` takes a democratic (nonweighted) average vote from all trees in the ensemble. In `X`, rows represent observations and columns represent variables. `YFIT` is a cell array of strings for classification and a numeric array for regression.

For regression, `[YFIT,stdevs] = predict(B,X)` also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, `[YFIT,scores] = predict(B,X)` returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[YFIT,scores,stdevs] = predict(B,X)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

`Y = predict(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

# CompactTreeBagger.predict

---

'trees'	Array of tree indices to use for computation of responses. Default is 'all'.
'treeweights'	Array of NTrees weights for weighting votes from the specified trees.
'useifort'	Logical matrix of size Nobs-by-NTrees indicating which trees to use to make predictions for each observation. By default all trees are used for all observations.

## See Also

[ClassificationTree.predict](#) | [RegressionTree.predict](#) | [TreeBagger.predict](#)

## Purpose

Predict response of generalized linear regression model

## Syntax

```
ypred = predict mdl, Xnew
[ypred, yci] = predict mdl, Xnew
[ypred, yci] = predict mdl, Xnew, Name, Value
```

## Description

`ypred = predict mdl, Xnew` returns the predicted response of the `mdl` generalized linear regression model to the points in `Xnew`.

`[ypred, yci] = predict mdl, Xnew` returns confidence intervals for the true mean responses.

`[ypred, yci] = predict mdl, Xnew, Name, Value` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

## Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from dataset arrays, try `feval`.

## Input Arguments

### `mdl`

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

### `Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding

# GeneralizedLinearModel.predict

---

value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'alpha'

Positive scalar from 0 to 1. Confidence level of  $y_{ci}$  is  $100(1 - \alpha)\%$ .

**Default:** 0.05, meaning a 95% confidence interval.

## 'BinomialSize'

Value of the binomial  $n$  parameter for each row in the training data. BinomialSize can be a vector the same length as  $X_{new}$ , or a scalar that applies to each row. The default value 1 produces  $y_{pred}$  values that are predicted proportions. Use BinomialSize only if `mdl` is fit to a binomial distribution.

**Default:** 1

## 'Offset'

Value of the offset for each row in  $X_{new}$ . Offset can be a vector the same length as  $X_{new}$ , or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at 1. In other words, if  $\mathbf{b}$  is the fitted coefficient vector, and  $\text{link}$  is the link function,

$$\text{link}(y_{\text{pred}}) = \text{Offset} + X_{\text{new}} * \mathbf{b}.$$

**Default:** `zeros(size(Xnew,1))`

## 'Simultaneous'

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the

entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

**Default:** `false`

## Output Arguments

### **ypred**

Vector of predicted mean values at `Xnew`.

### **yci**

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

## Examples

### **Generalized Linear Model Predictions**

Create a generalized linear model, and predict its response to new data.

Generate artificial data for the model using Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create points for prediction.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Xnew = [Xtest1(:),Xtest2(:)];
```

Predict responses at the new points.

# GeneralizedLinearModel.predict

---

```
ypred = predict mdl, Xnew;
```

Plot the predictions.

```
surf(Xtest1, Xtest2, reshape(ypred, 9, 9))
```

Create confidence intervals on the predictions.

```
[ypred yci] = predict(mdl, Xnew);
```

## Alternatives

`feval` gives the same predictions, but uses separate input arrays for each predictor, instead of one input array containing all predictors.

`random` predicts with added noise.

**Concepts**

- “Generalized Linear Models” on page 10-12

# LinearModel.predict

---

**Purpose** Predict response of linear regression model

**Syntax**

```
ypred = predict mdl,Xnew
[ypred,yci] = predict mdl,Xnew
[ypred,yci] = predict mdl,Xnew,Name,Value)
```

**Description** `ypred = predict mdl,Xnew` returns the predicted response of the `mdl` linear regression model to the points in `Xnew`.

`[ypred,yci] = predict mdl,Xnew` returns confidence intervals for the true mean responses.

`[ypred,yci] = predict mdl,Xnew,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For predictions with added noise, use `random`.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **Xnew**

Points at which `mdl` predicts responses.

- If `Xnew` is a dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'alpha'

Positive scalar from 0 to 1. Confidence level of  $y_{ci}$  is  $100(1 - \alpha)\%$ .

**Default:** 0.05, meaning a 95% confidence interval.

## 'Prediction'

String specifying the type of prediction:

- 'curve' — predict predicts confidence bounds for the fitted mean values.
- 'observation' — predict predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

**Default:** 'curve'

## 'Simultaneous'

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

**Default:** `false`

## Output Arguments

### `ypred`

Vector of predicted mean values at `Xnew`.

# LinearModel.predict

---

**yci**

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

## Examples

### Predict Response to Data

Create a model of car mileage as a function of weight, and predict the response.

Create a quadratic model of car mileage as a function of weight from the `carsmall` data.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Create predicted responses to the data.

```
Xnew = X;
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',Xnew,ypred,'x')
legend('Data','Predictions')
```

## Alternatives

`feval` gives the same predictions, but uses multiple input arrays with one component in each input argument. `feval` can be simpler to use with a model created from a dataset array `ds`. `feval` does not give confidence intervals on its predictions.

`random` predicts with added noise.

- “Linear Regression Workflow” on page 9-44

# LinearModel.predict

---

## How To

- “Linear Regression” on page 9-12

**Purpose** Predict response of linear mixed-effects model

**Syntax**

```
ypred = predict(lme)
ypred = predict(lme,dsnew)
ypred = predict(lme,Xnew,Znew)
ypred = predict(lme,Xnew,Znew,Gnew)
ypred = predict(__,Name,Value)
[ypred,ypredCI] = predict(__)
[ypred,ypredCI,DF] = predict(__)
```

**Description** `ypred = predict(lme)` returns a vector of conditional predicted responses `ypred` at the original predictors used to fit the linear mixed-effects model `lme`.

`ypred = predict(lme,dsnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new dataset array `dsnew`. Use a dataset array for `predict` if you use a dataset array for fitting the model `lme`.

If a particular grouping variable in `dsnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.
