Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is `1e5`.

Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Choose `User defined` to enter your own initial codebook values.

Number of levels

Enter the number of codeword vectors, N, in your codebook matrix, where $N \geq 2$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter. The codebook must have the same number of rows as the training set. You must provide at least two codeword vectors.

Distortion measure

When you select `Squared error`, the block finds the nearest codeword by calculating the squared error (unweighted). When you select `Weighted squared error`, the block finds the nearest codeword by calculating the weighted squared error.

Weighting factor

Enter a vector or matrix. The block uses these values to compute the weighted squared error. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The individual weighting factors cannot be negative. The weighting factor vector or matrix cannot contain all zeros.

Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number of iterations at which to stop.

Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

This parameter is available when you choose `Relative threshold` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

This parameter is available when you choose `Maximum iteration` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the maximum number of iterations you want the block to perform.

Tie-breaking rules

When a training vector has the same distortion for two different codeword vectors, select `Lower indexed codeword` to associate the training vector with the lower indexed codeword. Select `Higher indexed codeword` to associate the training vector with the lower indexed codeword.

Codebook update method

When you choose `Mean`, the new codeword vector is calculated by taking the average of all the training vector values that were associated with the original codeword vector. When you choose `Centroid`, the block calculates the new codeword vector by taking the weighted average of all the training vector values that were associated with the original codeword vector Note that if, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

Destination

Choose `Current model` to create a Vector Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type
Select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

Encoder block name
Enter a name for the Vector Quantizer Encoder block.

Decoder block name
Enter a name for the Vector Quantizer Decoder block.

Overwrite target block
When you do not select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Vector Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model
Click this button and VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Design and Plot
Click this button to design a quantizer using the parameters on the left side of the GUI and to update the performance curve and entropy plots on the right side of the GUI.

You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool GUI.

Export Outputs
Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Squared Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

Purpose

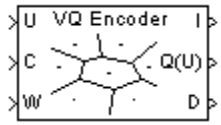
For given input, find index of nearest codeword based on Euclidean or weighted Euclidean distance measure

Library

Quantizers

`dspquant2`

Description



Vector Quantizer Encoder

The Vector Quantizer Encoder block compares each input column vector to the codeword vectors in the codebook matrix. Each column of this codebook matrix is a codeword. The block finds the codeword vector nearest to the input column vector and returns its zero-based index. This block supports real floating-point and fixed-point signals on all input ports.

The block finds the nearest codeword by calculating the distortion. The block uses two methods for calculating distortion: Euclidean squared error (unweighted) and weighted Euclidean squared error. Consider the codebook, $CB = [CW_1 \quad CW_2 \quad ... \quad CW_N]$. This codebook has N codewords; each codeword has k elements. The i-th codeword is defined as a column vector, $CW_i = [a_{1i} \quad a_{2i} \quad ... \quad a_{ki}]$. The multichannel input has M columns and is defined as $U = [U_1 \quad U_2 \quad ... \quad U_M]$, where the p-th input column vector is $U_p = \left[u_{1p} \quad u_{2p} \quad ... \quad u_{kp}\right]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^{k} \left(a_{ji} - u_{jp}\right)^2$$

The weighted squared error is calculated using the equation

$$D = \sum_{j=1}^{k} w_j \left(a_{ji} - u_{jp}\right)^2$$

where the weighting factor is defined as $W = [w_1 \quad w_2 \quad ... \quad w_k]$. The index of the codeword that is associated with the minimum distortion is assigned to the input column vector.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, you can type the codebook values into the block parameters dialog box. Select `Input port` and port C appears on the block. The block uses the input to port C as the **Codebook** parameter.

The **Codebook** parameter is an k-by-N matrix of values, where $k \geq 1$ and $N \geq 1$. Each input column vector is compared to this codebook. Each column of the codebook matrix is a codeword, and each codeword has an index value. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. The codeword vectors must have the same number of rows as the input, U.

For the **Distortion measure** parameter, select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want to use a weighting factor to emphasize or deemphasize certain input values.

For the **Source of weighting factor** parameter, select `Specify via dialog` to enter a weighting factor vector in the dialog box. Choose `Input port` to specify the weighting factor using port W.

Use the **Weighting factor** parameter to emphasize or deemphasize certain input values when calculating the distortion measure. For

example, consider the p-th input column vector, U_p, as previously defined. When you want to neglect the effect of the first element of this vector, enter `[0 1 1 ... 1]` as the **Weighting factor** parameter. This weighting factor is used to calculate the weighted squared error using the equation

$$D = \sum_{j=1}^{k} w_j \left(a_{ji} - u_{jp} \right)^2$$

Because of the weighting factor used in this example, the weighted squared error is not affected by the first element of the input matrix. Therefore, the first element of the input column vector no longer impacts the choice of index value output by the Vector Quantizer Encoder block.

Use the **Index output data type** parameter to specify the data type of the index values output at port I. The data type of the index values can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

When an input vector is equidistant from two codewords, the block uses the **Tie-breaking rule** parameter to determine which index value the block chooses. When you want the input vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Select the **Output codeword** check box to output at port Q(U) the codeword vectors that correspond to each index value. When the input is a matrix, the corresponding codeword vectors are horizontally concatenated into a matrix.

Select the **Output quantization error** check box to output at port D the quantization error that results when the block represents the input column vector by its nearest codeword. When the input is a matrix, the quantization error values are horizontally concatenated.

The Vector Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 1-1841 or “Supported Data Types” on page 1-1848.

Data Type Support

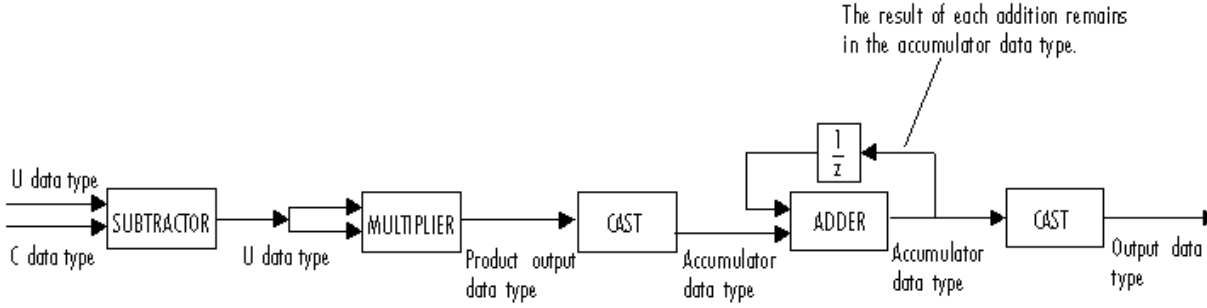
The input data values, codebook values, and weighting factor values are input to the block at ports U, C, and W, respectively. The data type of the input data values, codebook values, and weighting factor values can

be `double`, `single`, or Fixed-point. The input data, codebook values, and weighting factor must be the same data type.

The outputs of the block are the index values, output codewords, and quantization error. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. The data type of the index can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the output codewords and the quantization error can be `double`, `single`, or Fixed-point. The block assigns the data type of the output codewords and the quantization error based on the data type of the input data.

Fixed-Point Data Types

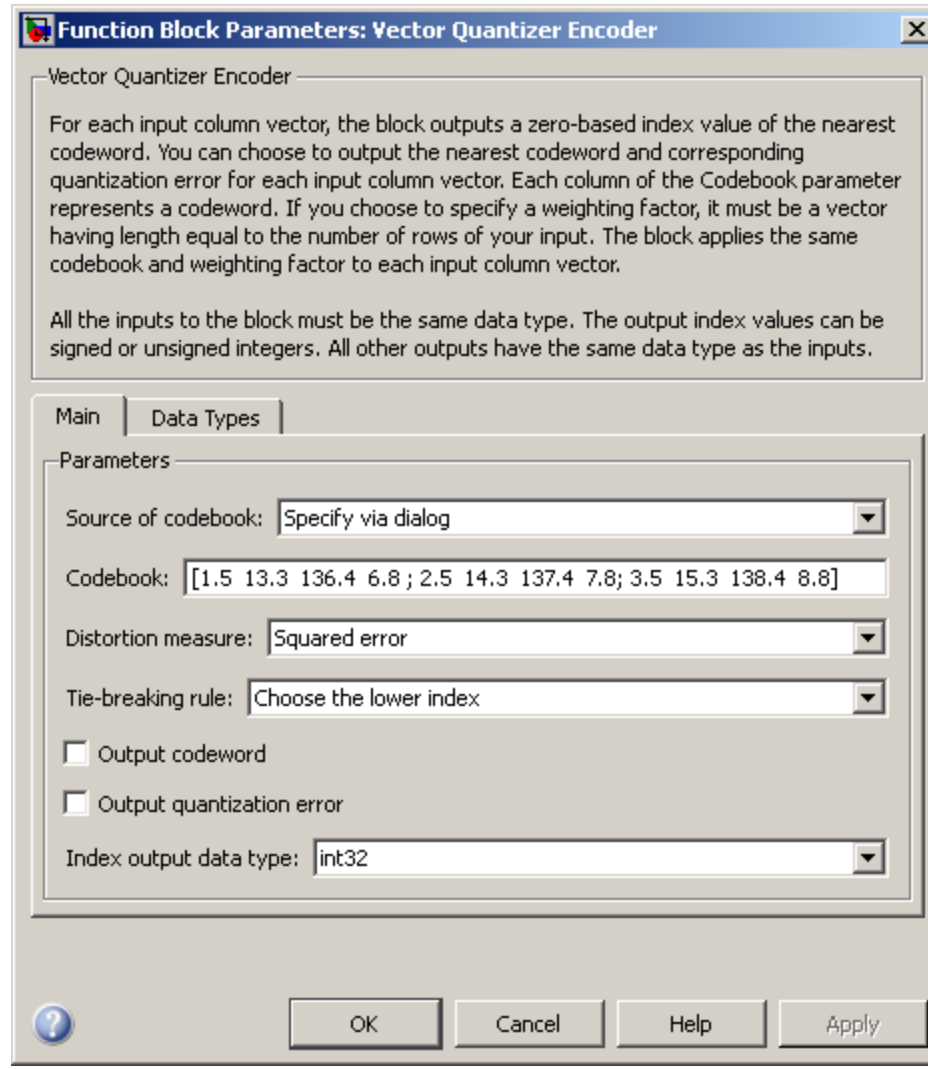
The following diagram shows the data types used within the Vector Quantizer Encoder block for fixed-point signals.



You can set the product output, accumulator, and index output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Vector Quantizer Encoder block dialog appears as follows.



Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, C.

Codebook

Enter a k-by-N matrix of values, where $1 \le k$ and $1 \le N$, to which your input column vector or matrix is compared. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

Distortion measure

Select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want the block to calculate the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values.

Source of weighting factor

Select `Specify via dialog` to enter a value for the weighting factor in the dialog box. Choose `Input port` and specify the weighting factor using port W on the block. This parameter is visible if, for the **Distortion measure** parameter, you select `Weighted squared error`.

Weighting factor

Enter a vector of values. This vector must have length equal to the number of rows of the input, U. This parameter is visible if, for the **Source of weighting factor** parameter, you select `Specify via dialog`.

Tie-breaking rule

Set this parameter to determine the behavior of the block when an input column vector is equidistant from two codewords. When you want the input column vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent

the input column vector by the higher index valued codeword, select `Choose the higher index`.

Output codeword

Select this check box to output the codeword vectors nearest to the input column vectors.

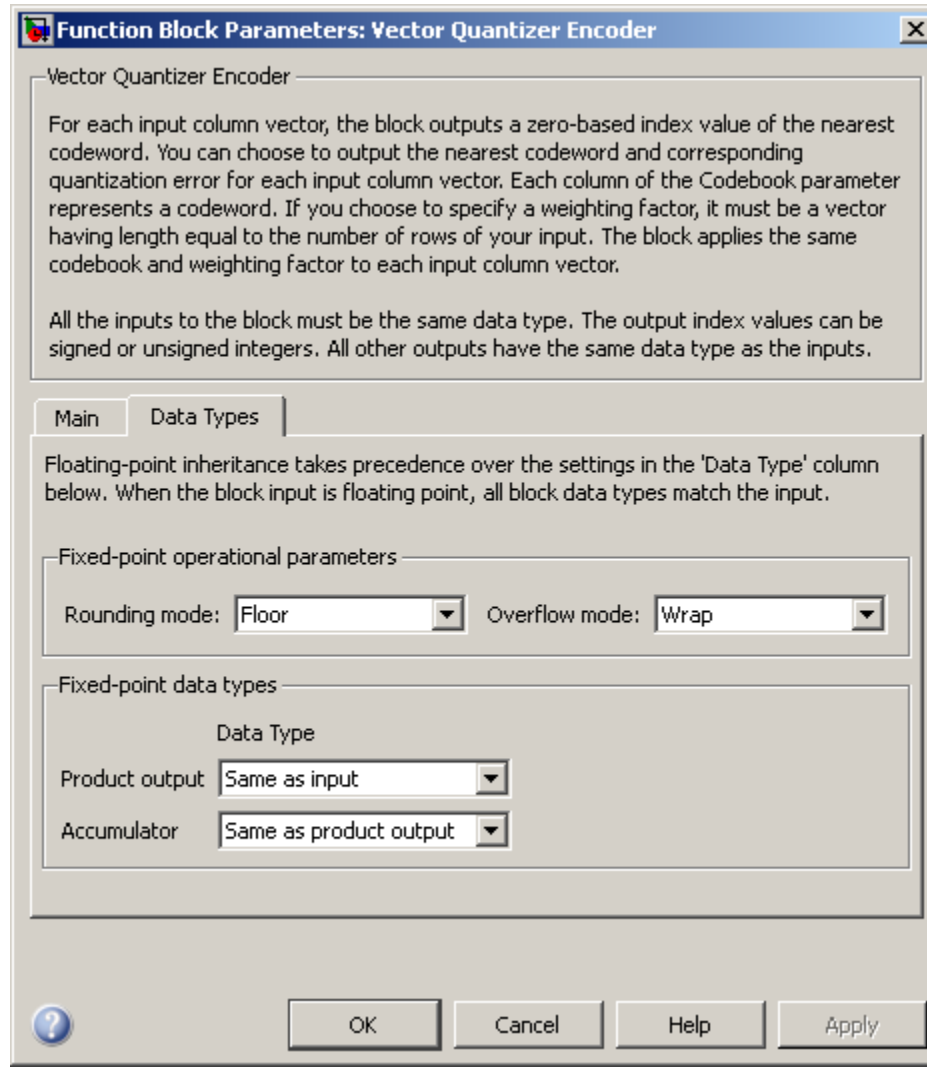
Output quantization error

Select this check box to output the quantization error value that results when the block represents the input column vector by the nearest codeword.

Index output data type

Select `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32` as the data type of the index output at port I.

The **Data Types** pane of the Vector Quantizer Encoder block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

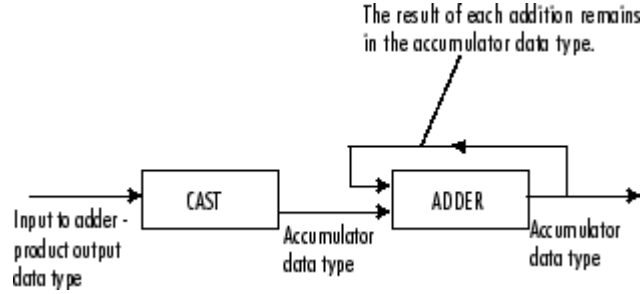
Select the overflow mode to be used when block inputs are fixed point.

Product output

As depicted above, the output of the multiplier is placed into the product output data type and scaling. Use this parameter to specify how you would like to designate this product output word and fraction lengths.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and zero bias.

Accumulator



As depicted above, inputs to the accumulator are cast to the accumulator data type. The output of the adder remains in the

accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and zero bias.

Vector Scope

Purpose

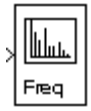
Display vector or matrix of time-domain, frequency-domain, or user-defined data

Library

Sinks

`dspsnks4`

Description



The Vector Scope block is a comprehensive display tool similar to a digital oscilloscope. The block can display time-domain, frequency-domain, or user-defined signals. You can use the Vector Scope block to plot consecutive time samples from a vector, or to plot vectors containing data such as filter coefficients or spectral magnitudes. To compute and plot the periodogram of a signal with a single block, use the Spectrum Analyzer block.

The input to the Vector Scope block can be any real-valued matrix or vector. The block treats each column of an *M*-by-*N* matrix input as an independent channel of data with *M* consecutive samples.

The block plots each sample of each input channel sequentially across the horizontal axis of the plot.

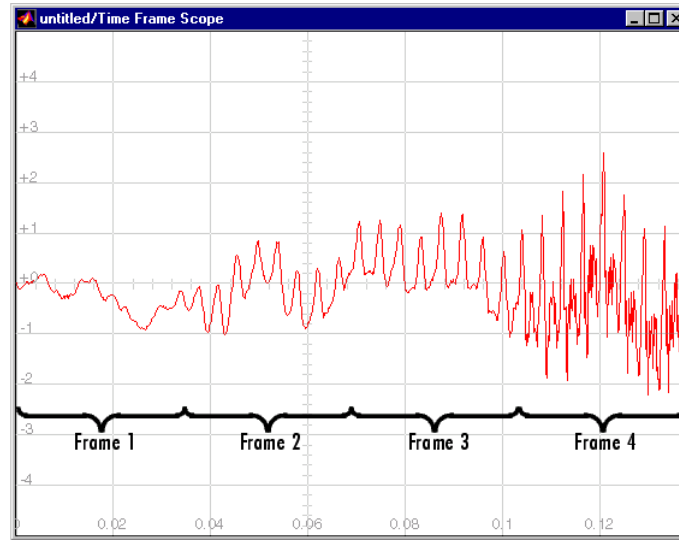
Scope Properties Pane

The **Scope Properties** pane enables you to plot time-domain, frequency-domain, or user-defined data, and adjust the horizontal display span of the plot. The scope displays frames of data, and updates the display for each new input frame.

The **Input domain** parameter specifies the domain of the input data. If you select `Time`, for *M*-by-*N* inputs containing time-domain data, the block treats each of the *N* input frames (columns) as a succession of *M* consecutive samples taken from a time series. That is, each data point in the input frame is assumed to correspond to a unique time value. Also, the **Time display span (number of frames)** parameter appears on the pane. Enter a scalar value greater than or equal to one that corresponds to the number of frames to be displayed across the width of the scope window.

If you select `Frequency` for the **Input domain** parameter, for *M*-by-*N* inputs containing frequency-domain data, the block treats each of the *N* input frames (columns) as a vector of spectral magnitude data corresponding to *M* consecutive ascending frequency indices. That is, when the input is a single column vector, u, each value in the input frame, `u(i)`, is assumed to correspond to a unique frequency value, `f(i)`, where `f(i+1)>f(i)`.

If you select `User-defined` for the **Input domain** parameter, the block does not assume that the input frame data is time-domain or frequency-domain data. You can plot the data in the appropriate manner. Also, the **Horizontal display span (number of frames)** parameter appears on the pane. Enter a scalar value greater than or equal to one that corresponds to the number of frames to be displayed across the width of the scope window.



Display Properties Pane

The **Display Properties** pane enables you to control how the block displays your data.

The **Show grid** parameter toggles the background grid on and off.

If you select the **Persistence** check box, the window maintains successive displays. That is, the scope does not erase the display after each frame (or collection of frames), but overlays successive input frames in the scope display.

If you select the **Frame number** check box, the block displays the number of the current frame in the input sequence on the scope window, and the block increments the count as each new input is received. Counting starts at 1 with the first input frame, and continues until the simulation stops.

If you select the **Channel legend** check box, a legend indicating the line color, style, and marker of each channel's data is added. When the input signal is labeled, that label appears in the channel legend. When the input signal is not labeled, but comes from a Concatenate block or a Mux block with labeled inputs, those labels appear in the channel legend. Otherwise, each channel in the legend is labeled with the channel number (`CH 1`, `CH 2`, etc.). Click and drag the legend to reposition it in the scope window; double-click on the line label to edit the text. If you rerun the simulation, the labels revert to the defaults.

If you select the **Compact display** check box, the scope completely fills the figure window. The scope does not display menus and axis titles, but it does show the numerical axis labels within the axes. If you clear the **Compact display** check box, the scope displays the axis labels and titles in a gray border surrounding the scope axes, and the window's menus and toolbar become visible.

If you select the **Open scope at start of simulation** check box, the scope opens at the start of the simulation. If you clear this parameter, the scope does not open automatically during the simulation. You can use this feature when you have several scope blocks in a model, and you do not want to view all the associated scopes during the simulation.

Note Before running a model that contains a Vector Scope block in Accelerator, Rapid Accelerator, or External mode, you must select the **Open scope at start of simulation** check box. If you do not select this check box before running your model for the first time, the scope will not display your simulation data.

If you want to view a scope window that is not open during simulation, click **Open scope immediately** on the **Display Properties** pane of the desired Scope block.

The **Scope position** parameter specifies a four-element vector of the form

```
[left bottom width height]
```

specifying the position of the scope window on the screen, where (0,0) is the lower-left corner of the display. See the MATLAB `figure` function for more information.

Axis Properties Pane

The parameters that are available on the **Axis Properties** pane depend on the setting of the **Input domain** parameter on the **Scope Properties** pane.

Time Domain Inputs

When **Time display limits** is set to `Auto`, the block scales the horizontal axis of time-domain signals automatically. The range of the time axis is $[0, S * T_{fi}]$, where T_{fi} is the input frame period, and S is the **Time display span (number of frames)** parameter on the **Scope Properties** pane. The spacing between time points is $T_{fi}/(M-1)$, where M is the number of samples in each consecutive input frame.

When **Time display limits** is set to `User-defined`, the **Minimum X-limit (s)** and **Maximum X-limit (s)** parameters set the range of the horizontal axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB axis function.

The **Y-axis label** is the text displayed to the left of the *y*-axis.

Frequency Domain Inputs

The **Frequency units** parameter specifies whether the frequency axis values should be in units of Hertz or rad/sec. When the **Frequency units** parameter is set to `Hertz`, the spacing between frequency points is $1/(M * T_s)$, where T_s is the sample time of the original time-domain signal. When the **Frequency units** parameter is set to `rad/sec`, the spacing between frequency points is $2\pi/(M * T_s)$.

The **Frequency range** parameter specifies the range of frequencies over which the magnitudes in the input should be plotted. The available options are `[0..Fs/2]`, `[-Fs/2..Fs/2]`, and `[0..Fs]`, where `Fs` is the original time-domain signal's sample frequency. The Vector Scope block assumes that the input data spans the range $[0, F_s)$, which is the same as the output from an FFT. To plot over the range `[0..Fs/2]` the scope truncates the input vector, leaving only the first half of the data, then plots these remaining samples over half the frequency range. To plot over the range `[-Fs/2..Fs/2]`, the scope reorders the input vector elements such that the last half of the data becomes the first half, and vice versa; then it relabels the *x*-axis accordingly.

If you select the **Inherit sample time from input** check box for frequency domain inputs, the block scales the frequency axis by reconstructing the frequency data from the frame-period of the frequency-domain input. This is valid when the following conditions hold:

- Each frame of frequency-domain data shares the same length as the frame of time-domain data from which it was generated; for example, when the FFT is computed on the same number of points as are contained in the time-domain input.
- The sample period of the time-domain signal in the simulation is equal to the period with which the physical signal was originally sampled.

- Consecutive frames containing the time-domain signal do not overlap each other; that is, a particular signal sample does not appear in more than one sequential frame.

In cases where not all of these conditions hold, specify the appropriate value for the **Sample time of original time series** parameter.

When **Frequency display limits** is set to `Auto`, the block scales the horizontal axis of frequency-domain signals automatically. To do this, the Vector Scope block needs to know the sample period of the original time-domain sequence represented by the frequency-domain data. Specify this period by entering a value for the **Sample time of original time series** parameter.

When **Frequency display limits** is set to `User-defined`, the **Minimum frequency** and **Maximum frequency** parameters set the range of the horizontal axis.

The **Y-axis scaling** parameter allows you to select `Magnitude` or `dB` scaling along the *y*-axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB axis function.

The **Y-axis label** is the text displayed to the left of the *y*-axis.

User-Defined Inputs

If you select the **Inherit sample increment from input** check box for user-defined input domains, the block scales the horizontal axis by computing the horizontal interval between samples in the input frame from the frame period of the input. For example, when the input frame period is 1, and there are 64 samples per input frame, the interval between samples is computed to be 1/64. Computing the interval this way is usually only valid when the following conditions hold:

- The input is a nonoverlapping time series; the *x*-axis on the scope represents time.

- The input sample period (1/64 in the above example) is equal to the period with which the physical signal was originally sampled.

In cases where not all of these conditions hold, use the **X display offset (samples)** and **Increment per sample in input** parameters.

The **X-axis title** is the text displayed below the *x*-axis.

When **X display limits** is set to `Auto`, the block scales the horizontal axis of user-defined domain signals automatically. To do this, the Vector Scope block needs to know the spacing of the input data. Specify this spacing using the **Increment per sample in input** parameter, I_s. This parameter represents the numerical interval between adjacent *x*-axis points corresponding to the input data. The range of the horizontal axis is $[0, M * I_s * S]$, where M is the number of samples in each consecutive input frame, and S is the **Horizontal display span (number of frames)** parameter that you specify in the **Scope Properties** pane.

When **X display limits** is set to `User-defined`, the **Minimum X-limit (samples)** and **Maximum X-limit (samples)** parameters set the range of the horizontal axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB `axis` function.

The **Y-axis label** is the text displayed to the left of the *y*-axis.

Line Properties Pane

Use the parameters on the **Line Properties** pane to help you distinguish between two or more independent channels of data on the scope.

The **Line visibilities** parameter specifies which channel's data is displayed on the scope, and which is hidden. The syntax specifies the visibilities in list form, where the term `on` or `off` as a list entry specifies the visibility of the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate five distinct plots on the scope. To disable plotting of the third and fifth lines, enter the following visibility specification in the **Line visibilities** parameter.

```
 on | on | off | on | off
ch 1  ch 2  ch 3  ch 4  ch 5
```

Note that the first (leftmost) list item corresponds to the first signal channel (leftmost column of the input matrix).

The **Line styles** parameter specifies the line style with which each channel's data is displayed on the scope. The syntax specifies the channel line styles in list form, with each list entry specifying a style for the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate all five plots with a solid line style. To plot each line with a different style, enter

```
  - | -- | : | -. | -
ch 1  ch 2  ch 3 ch 4  ch 5
```

These settings plot the signal channels with the following styles.

Line Style	Command to Type in Line Style Parameter	Appearance
Solid	-	
Dashed	--	
Dotted	:	
Dash-dot	-.	No line	none	No line appears

Note that the first (leftmost) list item, `'-'`, corresponds to the first signal channel (leftmost column of the input matrix). See the LineStyle property of the MATLAB `line` function for more information about the style syntax.

The **Line markers** parameter specifies the marker style with which each channel's samples are represented on the scope. The syntax specifies the channels' marker styles in list form, with each list entry specifying a marker for the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate all five plots with no marker symbol (that is, the individual sample points are not marked on the scope). To instead plot each line with a different marker style, you could enter

```
  * | . | x | s | d
```

These settings plot the signal channels with the following styles.

Marker Style	Command to Type in Marker Style Parameter	Appearance
Asterisk	*	
Point	.	Cross	x	
Marker Style	Command to Type in Marker Style Parameter	Appearance
Square	s	
Diamond	d	

Note that the leftmost list item, `'*'`, corresponds to the first signal channel or leftmost column of the input matrix. See the LineSpec property of the MATLAB `line` function for more information about the available markers.

To produce a stem plot for the data in a particular channel, type the word `stem` instead of one of the basic marker shapes.

The **Line colors** parameter specifies the color in which each channel's data is displayed on the scope. The syntax specifies the channel colors in list form, with each list entry specifying a color (in one of the MATLAB `ColorSpec` formats) for the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate all five plots in the color black. To instead plot the lines with the color order below, enter

```
[0 0 0] | [0 0 1] | [1 0 0 ] | [0 1 0] | [.7529 0 .7529]
 ch 1       ch 2       ch 3       ch 4           ch 5
```

or

```
 'k' | 'b' | 'r' | 'g' | [.7529 0 .7529]
ch 1   ch 2   ch 3   ch 4         ch 5
```

These settings plot the signal channels in the following colors (8-bit RGB equivalents shown in the center column).

Color	RGB Equivalent	Appearance
Black	(0,0,0)	
Blue	(0,0,255)	
Red	(255,0,0)	
Green	(0,255,0)	
Dark purple	(192,0,192)	

Note that the leftmost list item, `'k'`, corresponds to the first signal channel or leftmost column of the input matrix. See the MATLAB function `ColorSpec` for more information about the color syntax.

Vector Scope Window

The title that appears in the title bar of the scope window is the same as the block title. In addition to the standard MATLAB figure window menus such as **File**, **Window**, and **Help**, the Vector Scope window contains **View**, **Axes**, and **Channels** menus.

The options in the **View** menu allow you to zoom in and out of the scope window:

- To zoom in on the scope window, you must first select **View > Zoom In** or click the corresponding `Zoom In` toolbar button ( ). You can then zoom in by clicking in the center of your area of interest, or by clicking and dragging your cursor to draw a rectangular area of interest inside of the scope window.
- To zoom in on the *x*-axis of the scope window, you must first select **View > Zoom X**, or click the corresponding `Zoom X-Axis` toolbar

button ( ) on the scope window. You can then zoom in on the *x*-axis with a single click inside the scope window or by clicking and dragging the cursor along the *x*-axis over your area of interest.

- To zoom in on the *y*-axis of the scope window, you must first select **View > Zoom Y** or click the corresponding `Zoom Y-Axis` toolbar button ( ). You can then zoom in on the *y*-axis with a single click inside the scope window or by clicking and dragging the cursor along the *y*-axis over your area of interest.
- To return to the original view of the scope window, you have the following options:
  - Select **Full View** from the **View** menu .
  - Click the `Restore default view` toolbar button ( ) on the Vector Scope window.
  - Right-click inside the scope window, and select `Reset to Original View`.

Note To zoom out in smaller increments, you can right-click inside of the scope window and select `Zoom Out`. You can also zoom out by holding down the **Shift** key and clicking the left mouse button inside the scope window.

The parameters that you set using the **Axes** menu apply to all channels. Many of the parameters in this menu are also accessible through the block parameters dialog box. For descriptions of these parameters, see "Display Properties Pane" on page 1-1851. Below are descriptions of other parameters in the **Axes** menu:

- **Refresh** erases all data on the scope display, except for the most recent trace. This command is useful in conjunction with the **Persistence** setting.
- **Autoscale** resizes the *y*-axis to best fit the vertical range of the data.

Note The **Minimum Y-limit** and **Maximum Y-limit** parameters on the **Axis properties** pane of the block dialog are not updated to display the numerical limits selected by the autoscale feature.

- **Save Axes Settings** allows you to save the current axes settings. When you select this option, the **Minimum Y-limit** and **Maximum Y-limit** parameters of the **Axes Properties** pane update with the current *y*-axes limits. The **Time display limits** (or **Frequency display limits**) parameter is set to `User-defined`, and the current *x*-axes limits are saved in the **Minimum X-limit** and **Maximum X-limit** (or **Minimum Frequency** and **Maximum Frequency**) parameters. To save these axes settings for your next MATLAB session, you need to resave your model.
- **Save Scope Position** updates the **Scope position** parameter on the **Display Properties** pane of the block dialog to reflect the scope window's current position and size. To make the scope window open at a particular location on the screen when the simulation runs, drag the window to the desired location, resize it, and select **Save Scope Position** from the **Axes** menu.

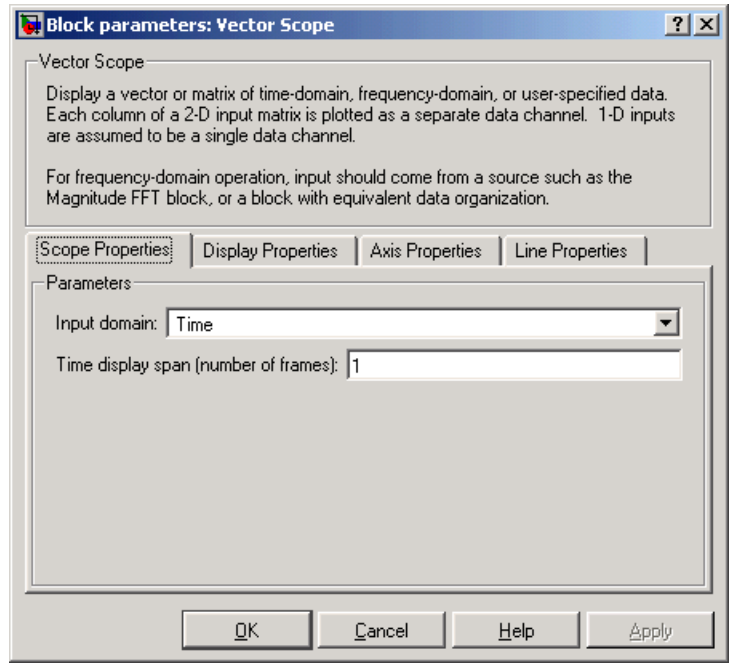
The properties listed in the **Channels** menu apply to a particular channel. All of the parameters in this menu are also accessible through the block parameters dialog box. For descriptions of these parameters, see "Line Properties Pane" on page 1-1857.

Many of these options can also be accessed by right-clicking with the mouse anywhere on the scope display. The menu that is displayed contains a combination of the options available in the **View**, **Axes** and **Channels** menus.

Note When you select **Compact Display** from the **Axes** menu, the scope window menus are no longer visible. Right-click in the Vector Scope window and click **Compact Display** in order to make the menus reappear.

Dialog Box

Scope Properties Pane



Input domain

Select the domain of the input. Your choices are `Time`, `Frequency`, or `User-defined`. Tunable.

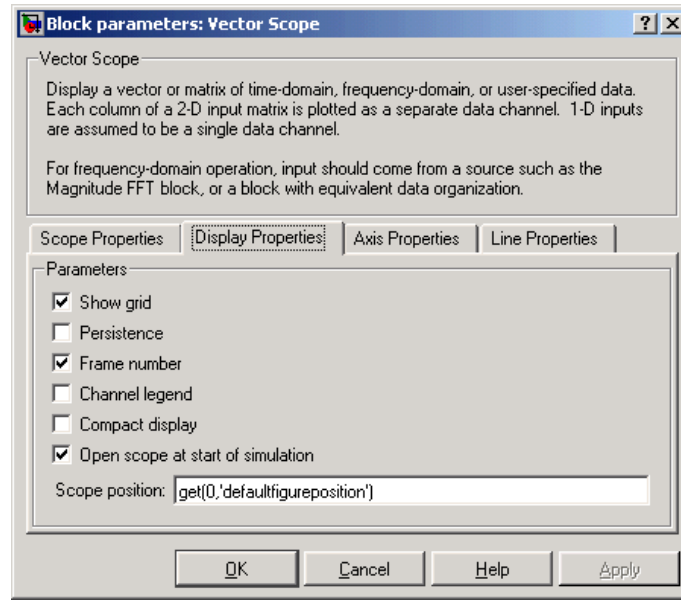
Time display span (number of frames)

The number of consecutive frames to display (horizontally) on the scope at any one time. This parameter is visible when the **Input domain** parameter is set to `Time`.

Horizontal display span (number of frames)

The number of consecutive frames to display (horizontally) on the scope at any one time. This parameter is visible when the **Input domain** parameter is set to `User-defined`.

Display Properties Pane



Show grid

Toggle the scope grid on and off.Tunable.

Persistence

Select this check box to maintain successive displays. That is, the scope does not erase the display after each frame (or collection

of frames), but overlays successive input frames in the scope display. Tunable.

Frame number
If you select this check box, the number of the current frame in the input sequence appears in the Vector Scope window. Tunable.

Channel legend
Toggles the legend on and off. Tunable.

Compact display
Resizes the scope to fill the window. Tunable.

Open scope at start of simulation
Select this check box to open the scope at the start of the simulation. When this parameter is cleared, the scope does not open automatically during the simulation. Tunable.

Note Before running a model that contains a Vector Scope block in Accelerator, Rapid Accelerator, or External mode, you must select the **Open scope at start of simulation** check box. If you do not select this check box before running your model for the first time, the scope will not display your simulation data.

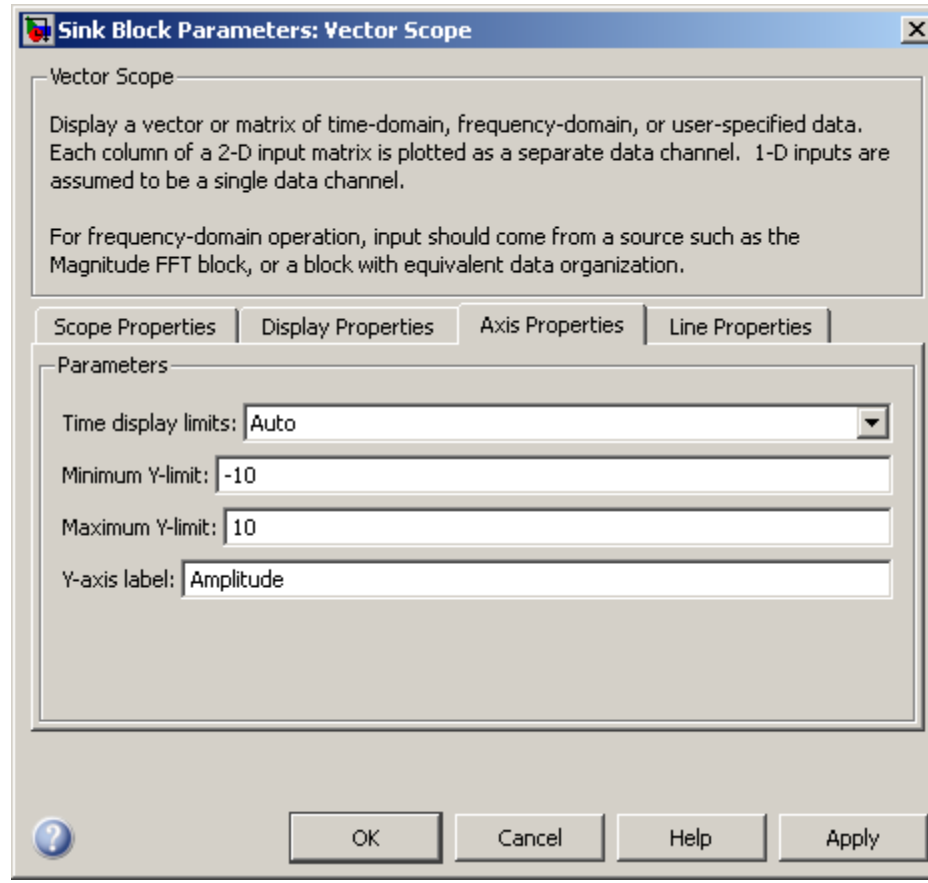
Open scope immediately
If the scope is not open during simulation, select this check box to open it. This parameter is visible only while the simulation is running.

Scope position
A four-element vector of the form `[left bottom width height]` specifying the position of the scope window. `(0,0)` is the lower-left corner of the display. Tunable.

Axis Properties Pane

The parameters that are available on the **Axis Properties** pane depend on the setting of the **Input domain** parameter on the **Scope**

Properties pane. When `Time` is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:



Time display limits

Select `Auto` to have the limits of the *x*-axis set for you automatically, or `User-defined` to set the limits yourself in the **Minimum X-limit (s)** and **Maximum X-limit (s)** parameters.

Minimum X-limit (s)
Specify the minimum value of the *x*-axis in seconds. This parameter is only visible if the **Time display limits** parameter is set to `User-defined`. Tunable.

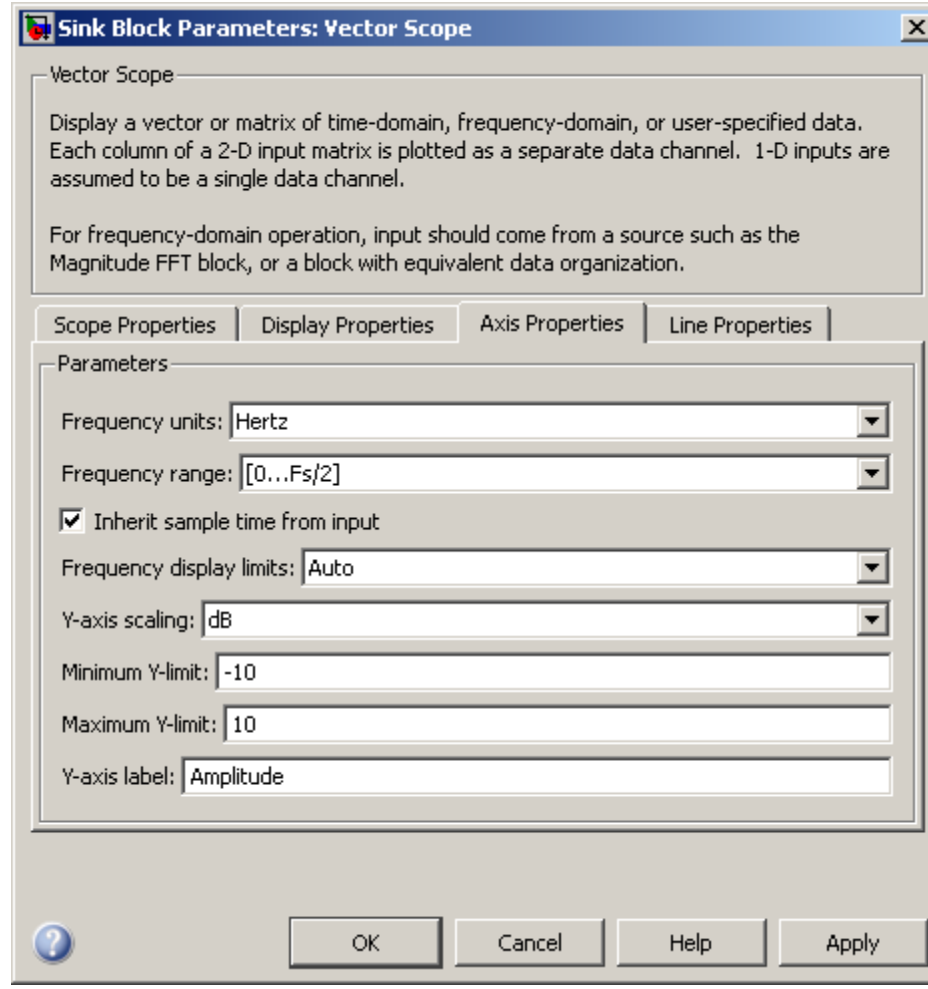
Maximum X-limit (s)
Specify the maximum value of the *x*-axis in seconds. This parameter is only visible if the **Time display limits** parameter is set to `User-defined`. Tunable.

Minimum Y-limit
Specify the minimum value of the *y*-axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable.

Maximum Y-limit
Specify the maximum value of the *y*-axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable.

Y-axis label
Specify text to be displayed to the left of the *y*-axis. Tunable.

When `Frequency` is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:



Frequency units

Choose the frequency units for the *x*-axis, `Hertz` or `rad/sec`. Tunable.

Frequency range
Specify the frequency range over which to plot the data. Tunable.

Inherit sample time from input
If you select this check box, the block computes the time-domain sample period from the frame period and frame size of the frequency-domain input. Use this parameter only when the length of the each frame of frequency-domain data is the same as the length of the frame of time-domain data from which it was generated. Tunable.

Sample time of original time series
Enter the sample period, T_s, of the original time-domain signal. This parameter is only visible when the **Inherit sample time from input** check box is not selected. Tunable.

Increment per sample in input
Enter the numerical interval between adjacent *x*-axis points corresponding to the user-defined input data. This parameter is only visible when the **Inherit sample increment from input** check box is not selected. Tunable.

Frequency display limits
Select `Auto` to have the limits of the *x*-axis set for you automatically, or `User-defined` to set the limits yourself in the **Minimum frequency** and **Maximum frequency** parameters.

Minimum frequency
Specify the minimum frequency value of the *x*-axis in Hertz or rad/sec. This parameter is only visible if the **Frequency display limits** parameter is set to `User-defined`. Tunable.

Maximum frequency
Specify the maximum frequency value of the *x*-axis in Hertz or rad/sec. This parameter is only visible if the **Frequency display limits** parameter is set to `User-defined`. Tunable.

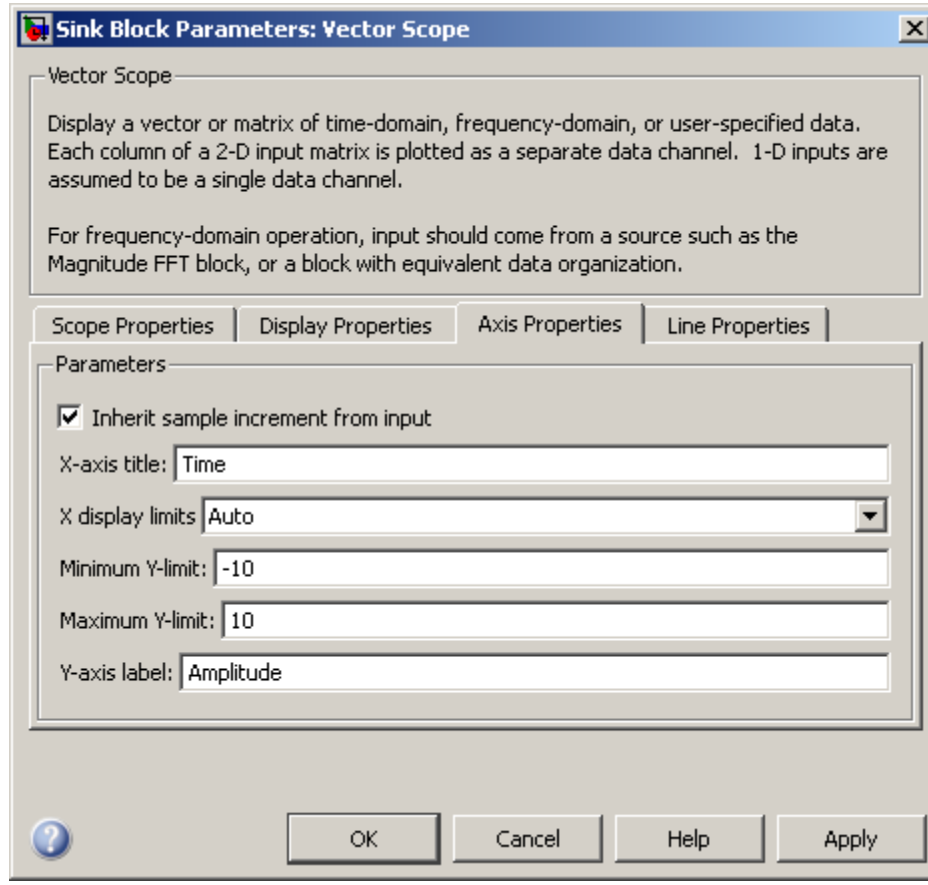
Y-axis scaling
Choose either `dB` (decibel) or `Magnitude` scaling for the *y*-axis. Tunable.

Minimum Y-limit
Specify the minimum value of the *y*-axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable.

Maximum Y-limit
Specify the maximum value of the *y*-axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable.

Y-axis label
Specify text to be displayed to the left of the *y*-axis. Tunable.

When `User-defined` is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:



Inherit sample increment from input

When you select this check box, the block scales the horizontal axis by computing the horizontal interval between samples in the input frame from the frame period of the input. Use this parameter only when the input's sample period is equal to the period with which the physical signal was originally sampled. Tunable.

X display offset (samples)
Specify an offset for the *x*-axis display in samples. This parameter is only visible when the **Inherit sample increment from input** check box is not selected. Tunable.

Increment per sample in input
Enter the numerical interval between adjacent *x*-axis points corresponding to the user-defined input data. This parameter is only visible when the **Inherit sample increment from input** check box is not selected. Tunable.

Sample time of original time series
Enter the sample period, T_s, of the original time-domain signal. This parameter is only visible when the **Inherit sample time from input** check box is not selected. Tunable.

X-axis title
Enter the text to be displayed below the *x*-axis. Tunable.

X display limits
Select `Auto` to have the limits of the *x*-axis set for you automatically, or `User-defined` to set the limits yourself in the **Minimum X-limit (samples)** and **Maximum X-limit (samples)** parameters.

Minimum X-limit (samples)
Specify the minimum value of the *x*-axis in samples. This parameter is only visible if the **X display limits** parameter is set to `User-defined`. Tunable.

Maximum X-limit (samples)
Specify the maximum value of the *x*-axis in samples. This parameter is only visible if the **X display limits** parameter is set to `User-defined`. Tunable.

Minimum Y-limit
Specify the minimum value of the *y*-axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable.

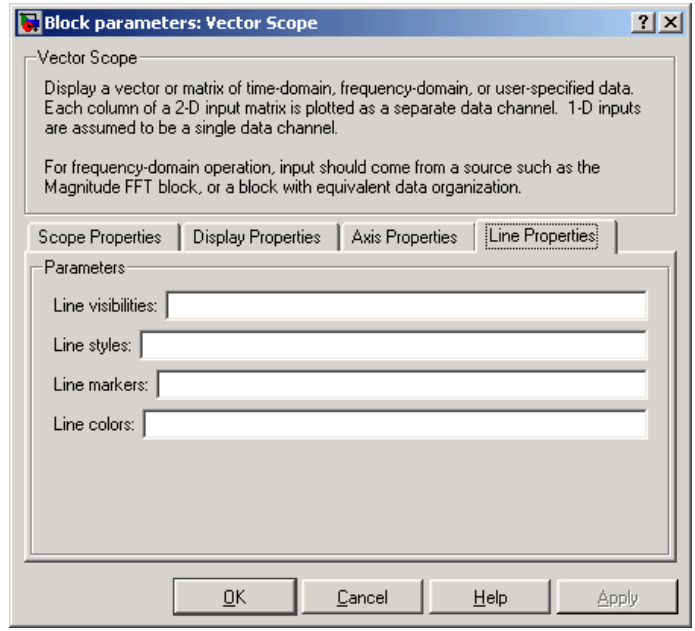
Maximum Y-limit

Specify the maximum value of the *y*-axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable.

Y-axis label

Specify text to be displayed to the left of the *y*-axis. Tunable.

Line Properties Pane



Line visibilities

Enter `on` or `off` to specify the visibility of the various channels' scope traces. Separate your choices for each channel with by a pipe (|) symbol. Tunable.

Line styles
Enter the line styles of the various channels' scope traces. Separate your choices for each channel with by a pipe (|) symbol. Tunable.

Line markers
Enter the line markers of the various channels' scope traces. Separate your choices for each channel with by a pipe (|) symbol.Tunable.

Line colors
Enter the colors of the various channels' scope traces using the `ColorSpec` formats. Separate your choices for each channel with by a pipe (|) symbol.Tunable.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Waterfall

Purpose

View vectors of data over time

Library

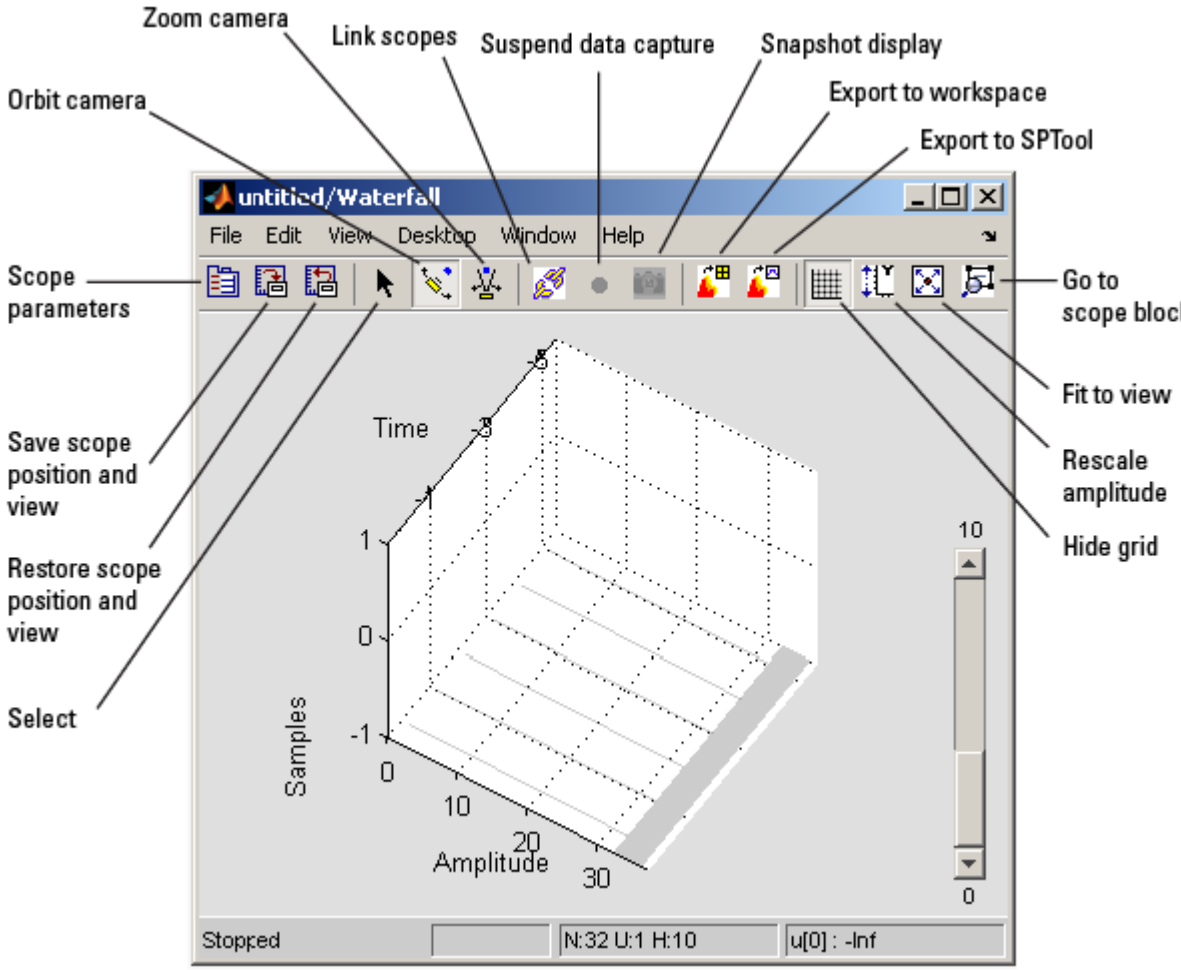
Sinks

`dspsnks4`

Description

The Waterfall block displays multiple vectors of data at one time. These vectors represent the input data at consecutive sample times. The input to the block can be real or complex-valued data vectors of any data type including fixed-point data types. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

The data is displayed in a three-dimensional axis in the Waterfall window. By default, the *x*-axis represents amplitude, the *y*-axis represents samples, and the *z*-axis represents time. You can adjust the number of sample vectors that the block displays, move and resize the Waterfall window, and modify block parameter values during the simulation. The Waterfall window has toolbar buttons that enable you to zoom in on displayed data, suspend data capture, freeze the scope's display, save the scope position, and export data to the workspace. The toolbar buttons are labeled in the following figure, which shows the Waterfall window as it appears when you double-click a Waterfall block.



Sections of This Reference Page

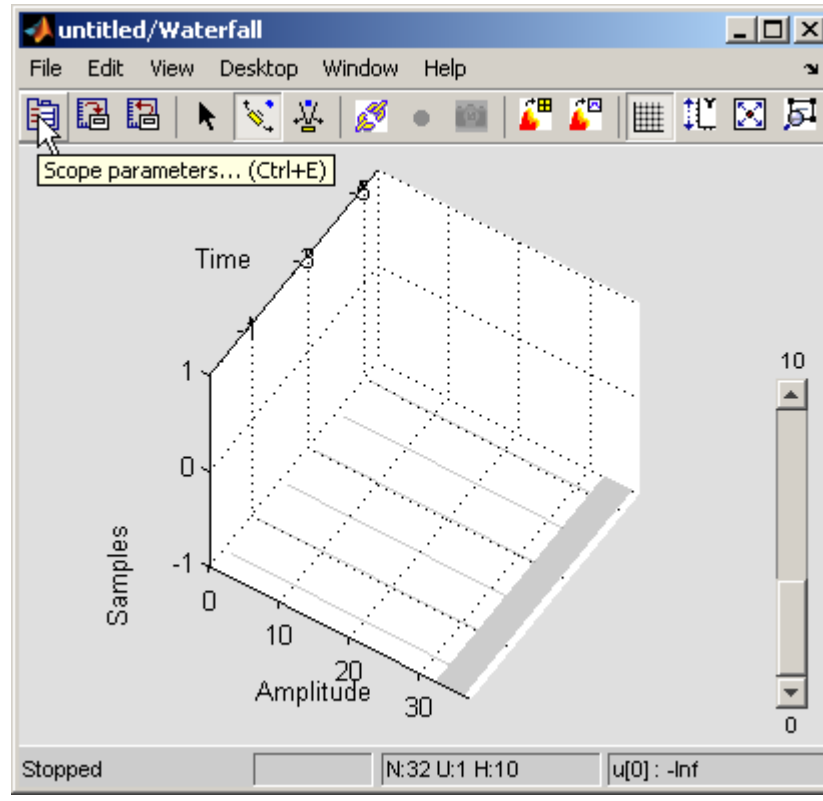
Waterfall Parameters

You can control the display and behavior of the Waterfall window using the Parameters dialog box.

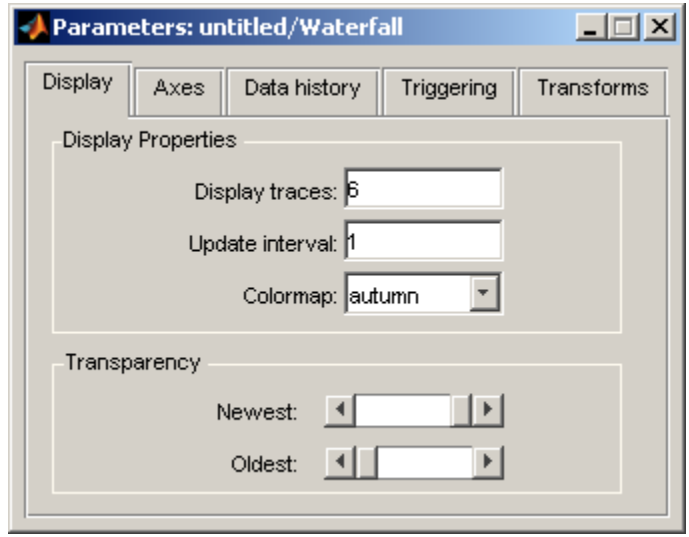
Note You can alter the Waterfall parameters while the simulation is running. However, when you make changes to values in text boxes, you must click **Enter** or click outside the text box before the block accepts your changes.

---

1. To open the Parameters dialog box, click the **Scope parameters** button.



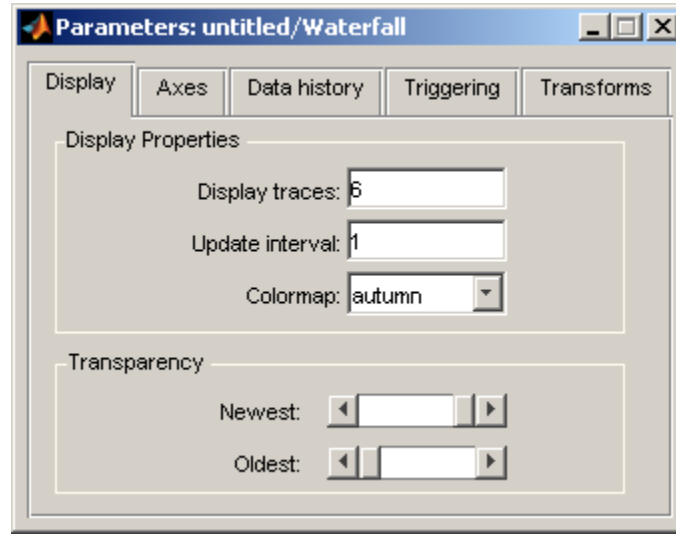
The Parameters dialog box appears.



2 Click on the different panes to enter parameter settings.

Display Parameters

The following parameters control the Waterfall window's display.



Display traces
Enter the number of vectors of data to be displayed in the Waterfall window.

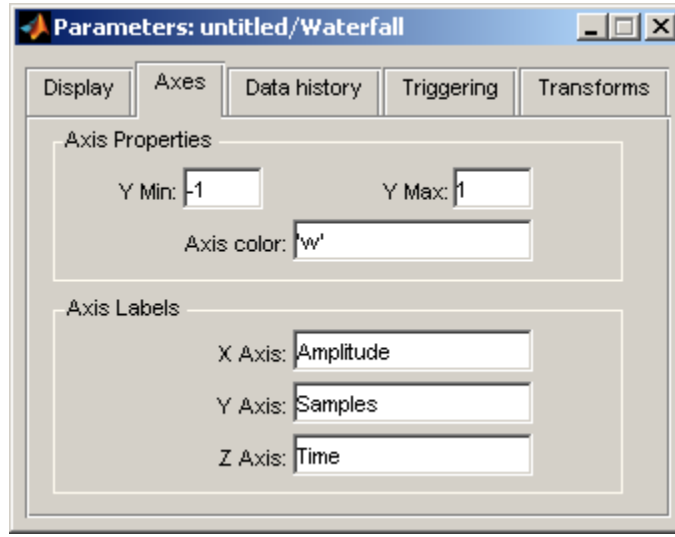
Update interval
Enter the number of vectors the block should store before it displays them to the window.

Colormap
Choose a colormap for the displayed data.

Transparency
Specify the transparency of the newest and oldest data vectors. Placing the slider in the left-most position tells the block to make the data vector transparent. Placing the slider in the right-most position tells the block to make the data vector opaque. The intermediate data vectors transition between the two chosen transparency values.

Axes Parameters

The following parameters control the axes in the Waterfall window.



Y Min
Enter the minimum value of the *y*-axis.

Y Max
Enter the maximum value of the *y*-axis.

Axis color
Enter a background color for the axes. Specify the color using a character string. For example, to specify black, enter `'k'`.

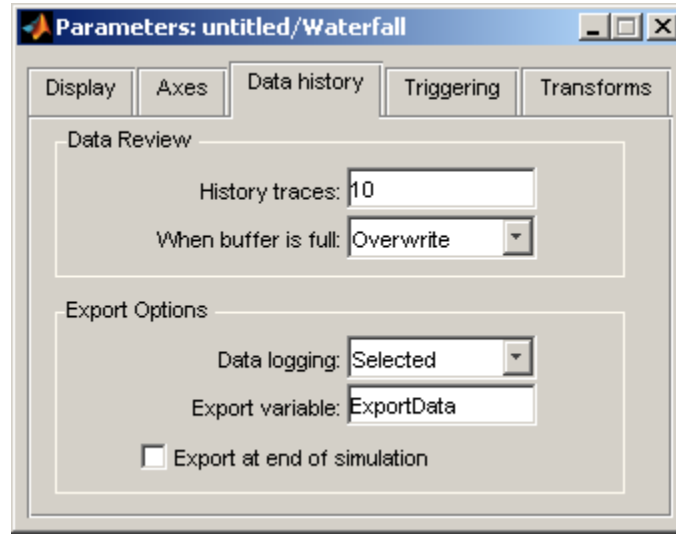
X Axis
Enter the *x*-axis label.

Y Axis
Enter the *y*-axis label.

Z Axis
Enter the *z*-axis label.

Data History Parameters

The following parameters control how many input data vectors the Waterfall block stores. They also control how the data is exported to the MATLAB workspace or SPTool.



History traces

Enter the number of vectors (traces) that you want the block to store.

When the buffer is full

Use this parameter to control the behavior of the block when the buffer is filled:

- `Overwrite` — The old data is replaced with the new data.
- `Suspend` — The block stops storing data in the buffer; however, the simulation continues to run.
- `Extend` — The block extends the buffer so that it can continue to store all the input data.

Data logging

Use this parameter to control which data is exported from the block:

- `Selected` — The selected data vector is exported.
- `All visible` — All of the data vectors displayed in the Waterfall window are exported.
- `All history` — All of the data vectors stored in the block's history buffer are exported.

Export variable

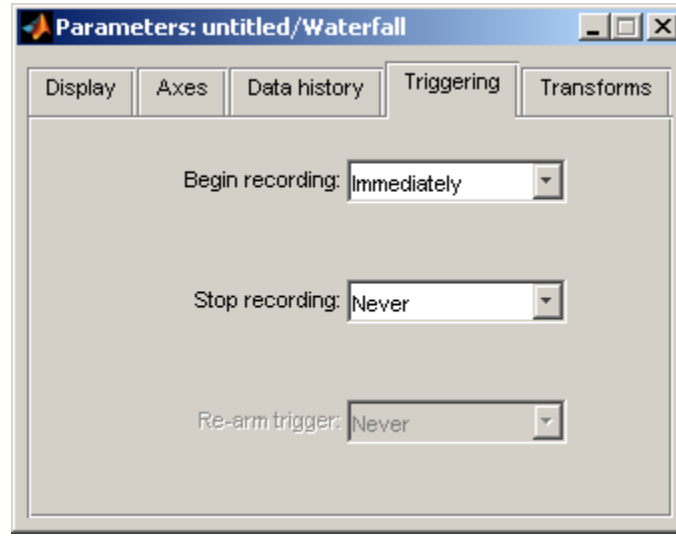
Enter the name of the variable that represents your data in the MATLAB workspace or SPTool. The default variable name is `ExportData`.

Export at end of simulation

Select this check box to automatically export the data to the MATLAB workspace when the simulation stops.

Triggering Parameters

The following parameters control when the Waterfall block starts and stops capturing data.



Begin recording

This parameter controls when the Waterfall block starts capturing data:

- `Immediately` — The Waterfall window captures the input data as soon as the simulation starts.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins capturing data.
- `After N inputs` — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins capturing data.
- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin capturing data. For more information about how you define this function, see “Scope Trigger Function” on page 1-1888.

Stop recording

This parameter controls when the Waterfall block stops capturing data:

- `Never` — The block captures the input data as long as the simulation is running.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it stops capturing data.
- `After N inputs` —The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it stops capturing data.
- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should stop capturing data. For more information about how you define this function, see "Scope Trigger Function" on page 1-1888.

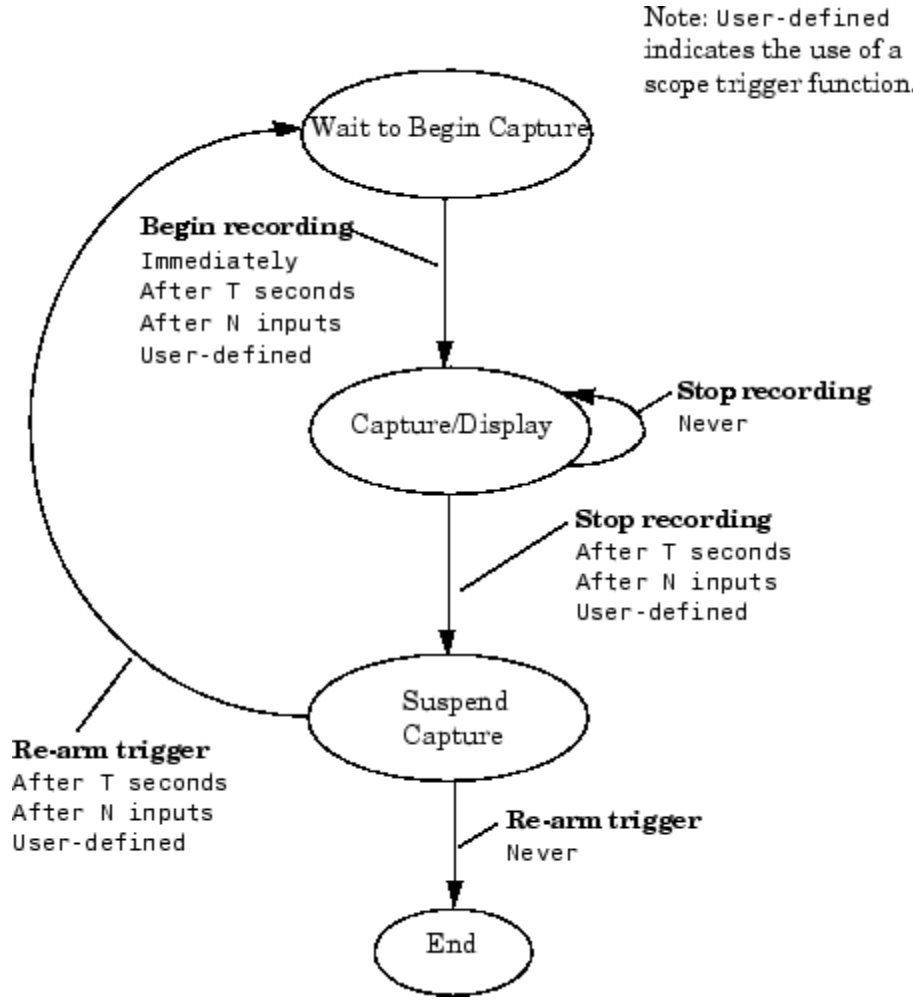
Re-arm trigger

This parameter controls when the Waterfall block begins waiting to capture data. It is available only when you select `After T seconds`, `After N inputs`, or `User-defined` for the **Stop recording** parameter:

- `Never` — The Waterfall Scope block starts and stops capturing data as defined by the **Begin recording** and **Stop recording** parameters.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins waiting to capture data.
- `After N inputs` — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins waiting to capture data.
- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that

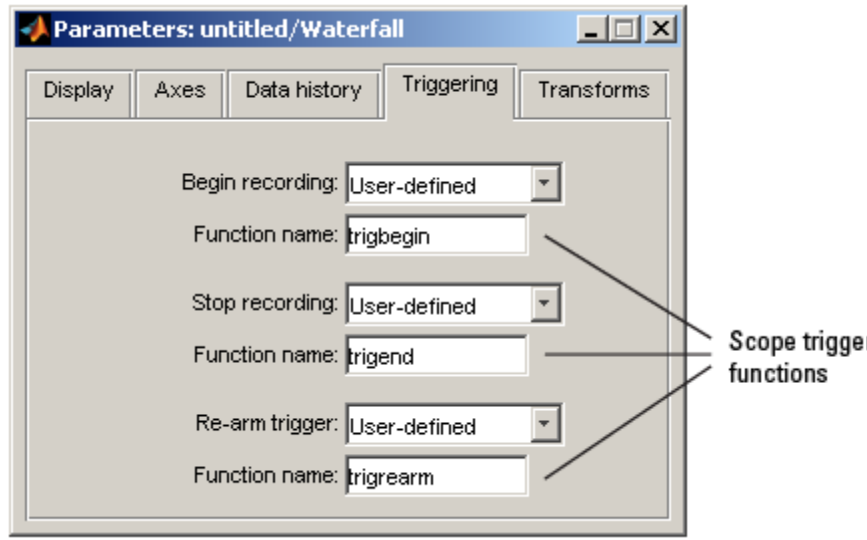
defines when the block should begin waiting to capture data. For more information about how you define this function, see “Scope Trigger Function” on page 1-1888.

The triggering process is illustrated in the state diagram below.



Scope Trigger Function

You can create custom scope trigger functions to control when the scope starts, stops, or begins waiting to capture data.



These functions must be valid MATLAB functions and be located either in the current folder or on the MATLAB path.

Each scope trigger function must have the following form

```
y = functionname(blk,t,u),
```

where `functionname` refers to the name you give your scope trigger function. The variable `blk` is the Simulink block handle. When the scope trigger function is called by the block, Simulink automatically populates this variable with the handle of the Waterfall block. The variable `t` is the current simulation time, represented by a real, double-precision, scalar value. The variable `u` is the vector input to the block. The output of the scope trigger function, `y`, is interpreted as a logical signal. It is either true or false:

- Begin recording scope trigger function
  - When the output of this scope trigger function is true, the Waterfall block starts capturing data.
  - When the output is false, the block remains in its current state.
- Stop recording scope trigger function
  - When the output of this scope trigger function is true, the block stops capturing data.
  - When the output is false, the block remains in its current state.
- Re-arm trigger scope trigger function
  - When the output of this scope trigger function is true, the block waits for a begin recording event.
  - When the output is false, the block remains in its current state.

Note The Waterfall block passes its input data directly to the scope trigger functions. These functions do not use the transformed data defined by the Transform parameters.

The following is an example of a scope trigger function. This function, called `trigPower` detects when the energy in u exceeds a certain threshold.

```
function y = trigPower(blk, t, u)

y = (u'*u > 2300);
```

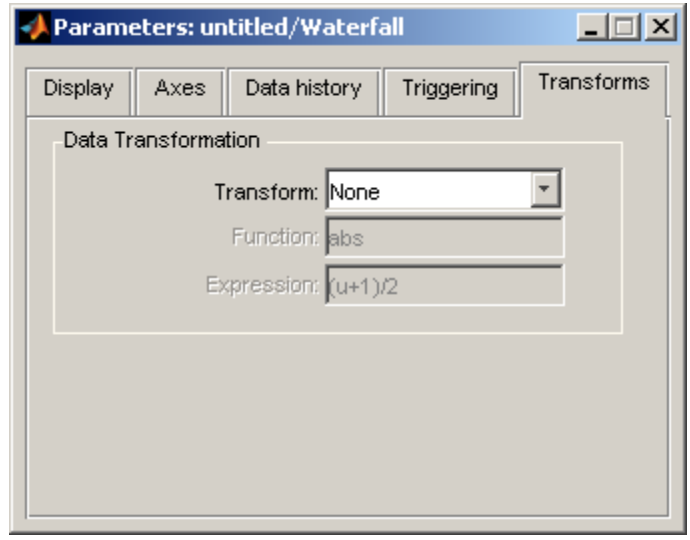
The following is another example of a scope trigger function. This function, called `count3`, triggers the scope once three vectors with positive means are input to the block. Then, the function resets itself and begins searching for the next three input vectors with positive means. This scope trigger function is valid only when one Waterfall block is present in your model.

```
function y = count3(blk, t, u)

persistent state;
if isempty(state); state = 0; end
if mean(u)>0; state = state+1; end
y = (state>=3);
if y; state = 0; end
```

Transform Parameters

The following parameters transform the input data to the Waterfall block. The result of the transform is displayed in the Waterfall window.



Note The block assumes that the input to the block corresponds to the **Transform** parameter you select. For example, when you choose `Complex-> Angle`, the block assumes that the input is complex. The block does not produce an error when the input is not complex. Therefore, you must verify the format of your input data to guarantee that a meaningful result is displayed in the Waterfall window.

Transform

Choose a transform that you would like to apply to the input of the Waterfall block:

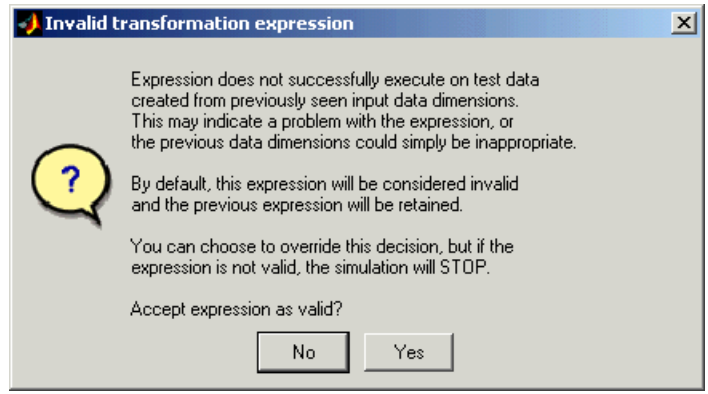
- `None` — The input is displayed as it is received by the block.
- `Amplitude-> dB` — The block converts the input amplitude into decibels.
- `Complex-> Mag Lin` — The block converts the complex input into linear magnitude.
- `Complex-> Mag dB` — The block converts the complex input into magnitude in decibels.
- `Complex-> Angle` — The block converts the complex input into phase.
- `FFT-> Mag Lin Fs/2` — The block takes the linear magnitude of the FFT input and plots it from 0 to the Nyquist frequency.
- `FFT-> Mag dB Fs/2` — The block takes the magnitude of the FFT input, converts it to decibels, and plots it from 0 to the Nyquist frequency.
- `FFT-> Angle Fs/2` — The block converts the FFT input into phase and plots it from 0 to the Nyquist frequency.
- `Power-> dB` — The block converts the input power into decibels.

Function

This parameter is only available when you select `User-defined fcn` for the **Transform** parameter. Enter a function that you would like to apply to the input of the Waterfall block. For more information about how you define this function, see "Scope Transform Function" on page 1-1892.

Expression

This parameter is only available when you select `User-defined expr` for the **Transform** parameter. Enter an expression that you would like to apply to the input of the Waterfall block. The result of this expression must be real-valued. When you write the expression, be sure to include only one unknown variable. The block assumes this unknown variable represents the input to the block. When the block believes your expression is invalid, the following window appears.



When you click **No**, your expression is not applied to the input. When you click **Yes** and your expression is invalid, your simulation stops and Simulink displays an error.

Scope Transform Function

You can create a scope transform function to control how the Waterfall block transforms your input data. This function must have a valid

MATLAB function name and be located either in the current folder or on the MATLAB path.

Your scope transform function must have the following form

```
y = functionname(u),
```

where `functionname` refers to the name you give your function. The variable `u` is the real or complex vector input to the block. The output of the scope transform function, `y`, must be a double-precision, real-valued vector. When it is not, the simulation stops and Simulink displays an error. Note that the output vector does not need to be the same size as the input vector.

Examples

The following examples illustrate some capabilities of the Waterfall block.

Exporting Data

You can use the Waterfall block to export data to the MATLAB workspace or to SPTool:

1. Open and run the `dspanc` example.
2. While the simulation is running, click the **Export to Workspace** button.

3. Type `whos` at the MATLAB command line.

   The variable `ExportData` appears in your MATLAB workspace. `ExportData` is a 40-by-6 matrix. This matrix represents the six data vectors that were present in the Waterfall window at the time you clicked the **Export to Workspace** button. Each column of this matrix contains 40 filter coefficients. The columns of data were captured at six consecutive instants in time.

   You can control what data is exported using the **Data logging** parameter in **Data history** pane of the Parameters dialog box. For more information, see "Data History Parameters" on page 1-1883.

4. While the simulation is running, click the **Export to SPTool** button.

   The SPTool GUI opens and the variable `ExportData` is displayed in the **Signals** list.

For more information about SPTool, see the Signal Processing Toolbox documentation.

Capturing Data

You can use the Waterfall block to interact with your data while it is being captured:

1. Open and run the `dspanc` example.

2. While the simulation is running, click the **Suspend data capture** button.

   The Waterfall block no longer captures or displays the data coming from the Downsample block.

3. To continue capturing data, click the **Resume data capture** button.

4. To freeze the data display while continuing to capture data, click the **Snapshot display** button.

5 To view the Waterfall block that the data is coming from, click the **Go to scope block** button.

In the Simulink model window, the Waterfall block that corresponds to the active Waterfall window flashes. This feature is helpful when you have more than one Waterfall block in a model and you want to clarify which data is being displayed.

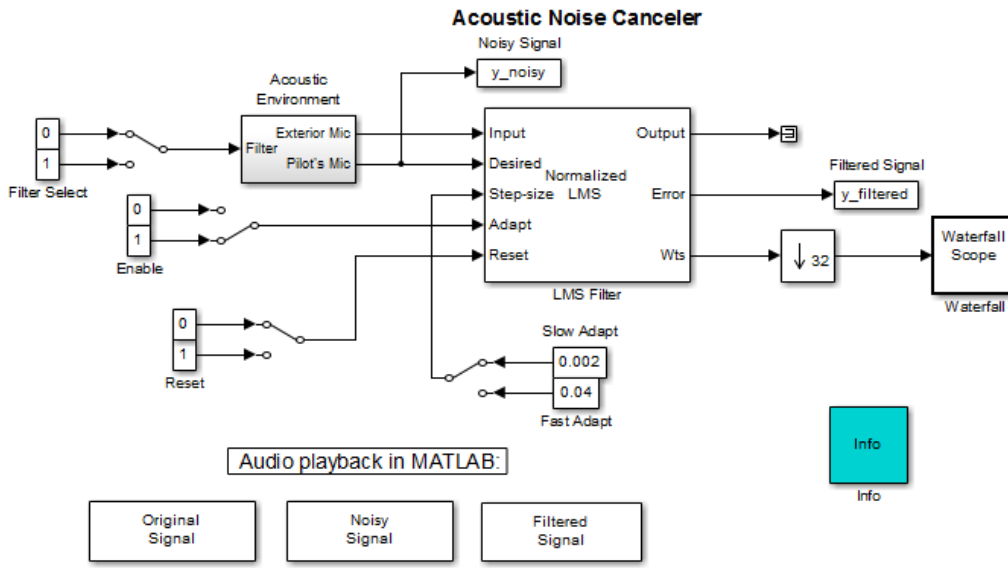
Linking Scopes

You can link several Waterfall blocks together in order to capture the effect of a model event in all of the Waterfall windows in the model:

1 Open the `dspanc` example.

2 Drag a second Waterfall block into the example model.

3 Connect this block to the Output port of the LMS Filter block as shown in the figure below.



4 Run the model and view the model behavior in both Waterfall windows.

5 In the dspanc/Waterfall window, click the **Link scopes** button.

6 In the same window, click the **Suspend data capture** button.

The data capture is suspended in both scope windows.

7 Click the **Resume data capture** button.

The data capture resumes in both scope windows.

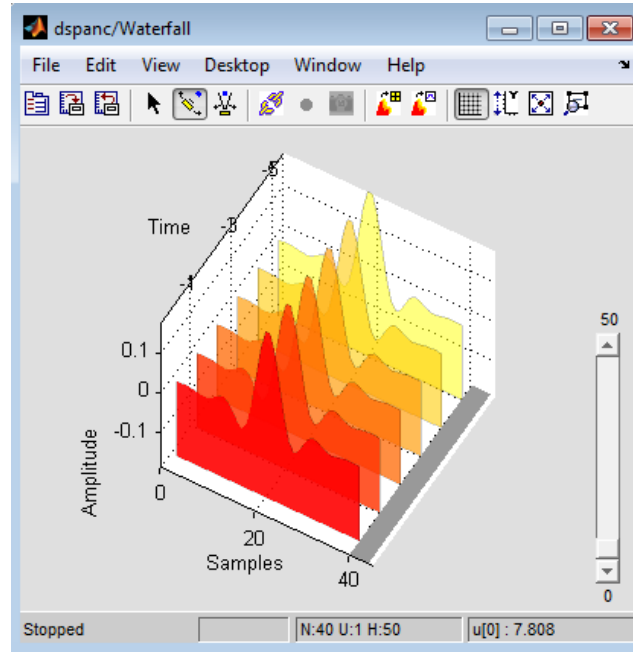
8 In the dspanc/Waterfall window, click the **Snapshot display** button.

In both scope windows, the data display freezes while the block continues to capture data.

9 To continue displaying the captured data, click the **Resume display** button.

Selecting Data

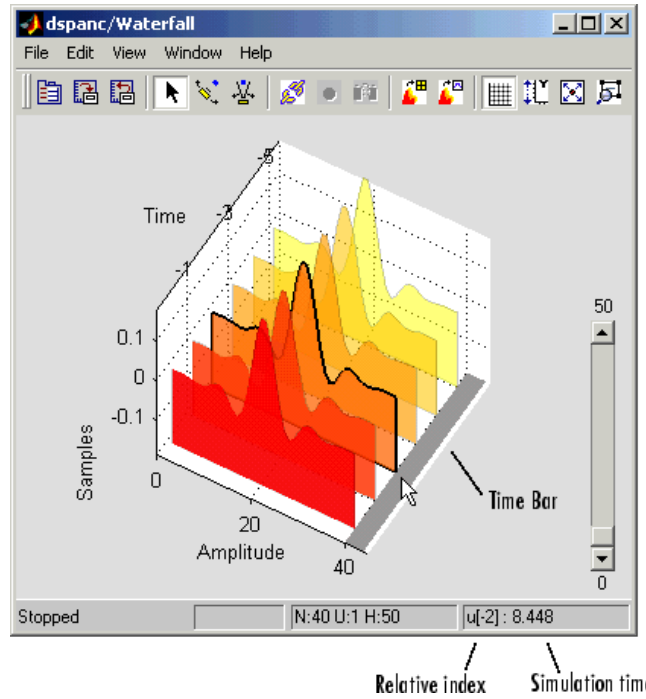
The following figure shows the Waterfall window displaying the output of the `dspanc` example:



1 To select a particular set of data, click the **Select** button.

2 Click on the Time Bar at the bottom right of the axes to select a vector of data.

The Waterfall block highlights the selected trace.



While the simulation is running, in the bottom right corner, the Waterfall window displays the relative index of the selected trace. For example, in the previous figure, the selected vector is two sample times away from the most current data vector. When the simulation is stopped, the Waterfall window displays both the relative index and the simulation time associated with the selected trace.

3 To deselect the data vector, click it again.

4 Click-and-drag along the Time Bar.

Your selection follows the movement of the pointer.

You can use this feature to choose a particular vector to export to the MATLAB workspace or SPTool. For more information, see "Data History Parameters" on page 1-1883.

Zooming

You can use the Waterfall window to zoom in on data:

1. Click the **Zoom camera** button.
2. In the Waterfall window, click and hold down the left mouse button.
3. Move the mouse up and down and side-to-side to move closer and farther away from the axes.
4. To resize the axes to fit the Waterfall window, click the **Fit to view** button.

Rotating the Display

You can rotate the data displayed in the Waterfall window:

1. Click on the **Orbit camera** button.
2. In the Waterfall window, click and hold down the left mouse button.
3. Move the mouse in a circular motion to rotate the axes.
4. To return to the position of the original axes, click the **Restore scope position and view** button.

Scaling the Axes

You can use the Waterfall window to rescale the *y*-axis values:

1. Open and run the `dspanc` example.
2. Click the **Rescale amplitude** button.

   The *y*-axis changes so that its minimum value is zero. The maximum value is scaled to fit the data displayed.

Alternatively, you can scale the *y*-axis using the **Y Min** and **Y Max** parameters in the **Axes** pane of the Parameters dialog box. This is helpful when you want to undo the effects of rescaling the amplitude. For more information, see "Axes Parameters" on page 1-1881.

Saving Scope Settings

The Waterfall block can save the screen position and viewpoint of the Waterfall window:

1. Click the **Save scope position and view** button.
2. Close the Waterfall window.
3. Reopen the Waterfall window.

   It reopens at the same place on your screen. The viewpoint of the axes also remains the same.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

The Waterfall block accepts any of these data types as input. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

Wavelet Analysis (Obsolete)

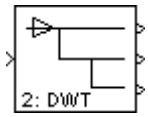
Purpose

Decompose signal into components of logarithmically decreasing frequency intervals and sample rates (requires the Wavelet Toolbox product)

Library

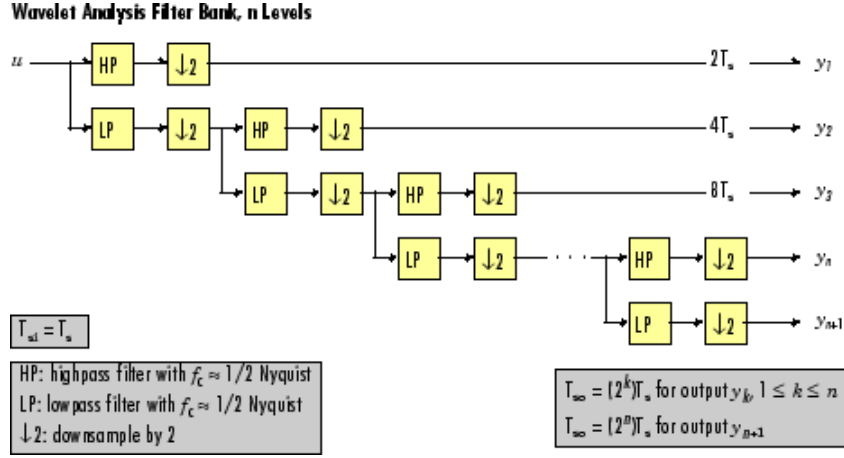
`dspobslib`

Description



Note The Wavelet Analysis block will be removed from the product in a future release. We strongly recommend replacing this block with the DWT block.

The Wavelet Analysis block uses the Wavelet Toolbox `wfilters` function to construct a dyadic analysis filter bank that decomposes a broadband signal into a collection of successively more bandlimited components. An n-level filter bank structure is shown below, where n is specified by the **Number of levels** parameter.



At each level, the low-frequency output of the previous level is decomposed into adjacent high- and low-frequency subbands by a highpass (HP) and lowpass (LP) filter pair. Each of the two output subbands is half the bandwidth of the input to that level. The

bandlimited output of each filter is maximally decimated by a factor of 2 to preserve the bit rate of the original signal.

Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	`wfilters('haar')`
Daubechies	`wfilters('db4')`
Symlets	`wfilters('sym3')`
Coiflets	`wfilters('coif1')`
Biorthogonal	`wfilters('bior3.1')`
Reverse Biorthogonal	`wfilters('rbio3.1')`
Discrete Meyer	`wfilters('dmey')`

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to `6`, the Wavelet Analysis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to `[2 / 6]`, the Wavelet Analysis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the analysis filter bank, use the Dyadic Analysis Filter Bank block.

Tree Structure

The wavelet tree structure has n+1 outputs, where n is the number of levels. The sample rate and bandwidth of the top output are half the input sample rate and bandwidth. The sample rate and bandwidth of each additional output (except the last) are half that of the output from the previous level. In general, for an input with sample period $T_{si} = T_s$, and bandwidth BW, output y_k has sample period $T_{so,k}$ and bandwidth BW_k.

$$T_{so,k} = \begin{cases} \left(2^k\right) T_s & (1 \le k \le n) \\ \left(2^n\right) T_s & (k = n+1) \end{cases}$$

$$BW_k = \begin{cases} \dfrac{BW}{2^k} & (1 \le k \le n) \\ \dfrac{BW}{2^n} & (k = n+1) \end{cases}$$

Note that in frame-based mode, the change in the sample period of output y_k is reflected by its frame size $M_{o,k}$, rather than by its frame rate.

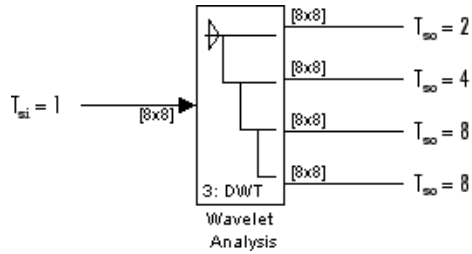
$$M_{o,k} = \begin{cases} \dfrac{M_i}{2^k} & (1 \le k \le n) \\ \dfrac{M_i}{2^n} & (k = n+1) \end{cases}$$

The bottom two outputs (y_n and y_{n+1}) share the same sample period, bandwidth, and frame size because they originate at the same tree level.

Sample-Based Operation

An *M*-by-*N* sample-based matrix input is treated as *M***N* independent channels, and the block filters each channel independently over time. The output at each port is the same size as the input, one output channel for each input channel. As described earlier, each output port has a different sample period.

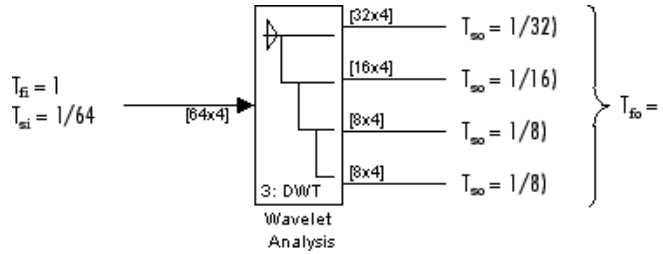
The figure below shows the input and output sample periods for a 64-channel sample-based input to a three-level filter bank. The input has a period of 1, so the fastest output has a period of 2.



Frame-Based Operation

An M_i-by-*N* frame-based matrix input is treated as *N* independent channels, and the block filters each channel independently over time. The input frame size M_i must be a multiple of 2^n, and *n* is the number of filter bank levels. For example, a frame size of 8 would be appropriate for a three-level tree (2^3=8). The number of columns in each output is the same as the number of columns in the input.

Each output port has the same frame period as the input. The reduction in the output sample rates results from the smaller output frame sizes, as shown in the example below for a four-channel input to a three-level filter bank.



Zero Latency

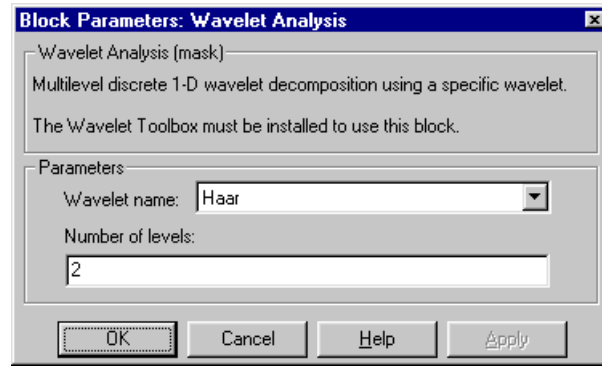
The Wavelet Analysis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore analyzes the first input sample (received at t=0) to produce the first output sample at each port.

Nonzero Latency

For sample-based operation, the Wavelet Analysis block is multirate and has 2^{n-1} samples of latency in both Simulink tasking modes. As a result, the block repeats a zero initial condition in each channel for the first 2^{n-1} output samples, before propagating the first analyzed input sample (computed from the input received at t=0).

Note For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and the topic on models with multiple sample rates in the Simulink Coder documentation.

Dialog Box



The parameters displayed in the dialog box vary for different wavelet types. Only some of the parameters listed below are visible in the dialog box at any one time.

Wavelet name
The wavelet used in the analysis.

Wavelet order
The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

Filter order [synthesis / analysis]
The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, `[2 / 6]` selects a second-order synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

Number of levels
The number of filter bank levels. An n-level structure has n+1 outputs.

Supported Data Types

- Double-precision floating point

See Also

Dyadic Analysis Filter Bank	DSP System Toolbox
Wavelet Synthesis (Obsolete)	DSP System Toolbox
`wfilters`	Wavelet Toolbox

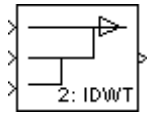
Purpose

Reconstruct signal from its multirate bandlimited components (requires the Wavelet Toolbox product)

Library

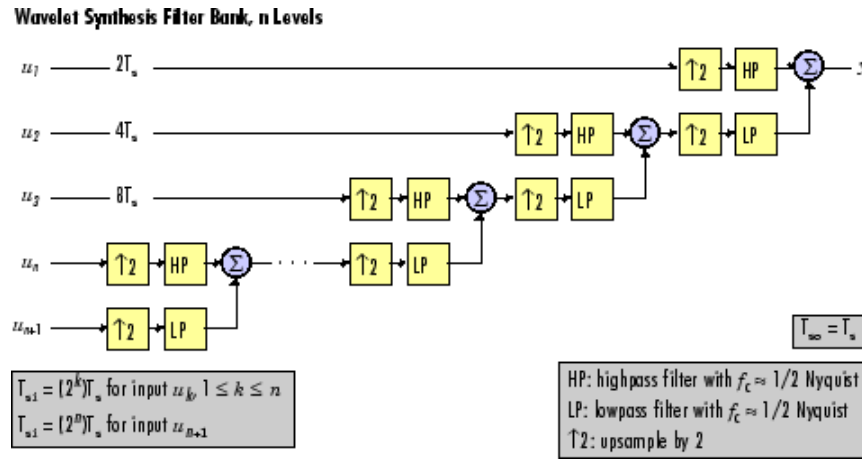
`dspobslib`

Description



Note The Wavelet Synthesis block will be removed from the product in a future release. We strongly recommend replacing this block with the IDWT block.

The Wavelet Synthesis block uses the Wavelet Toolbox `wfilters` function to reconstruct a signal that was decomposed by the Wavelet Analysis (Obsolete) block. The reconstruction or synthesis process is the inverse of the analysis process, and restores the original signal by upsampling, filtering, and summing the bandlimited inputs in stages corresponding to the analysis process. An *n*-level synthesis filter bank structure is shown below, where *n* is specified by the **Number of levels** parameter.



At each level, the two bandlimited inputs (one low-frequency, one high-frequency, both with the same sample rate) are upsampled by

a factor of 2 to match the sample rate of the input to the next stage. They are then filtered by a highpass (HP) and lowpass (LP) filter pair with coefficients calculated to cancel (in the subsequent summation) the aliasing introduced in the corresponding analysis filter stage. The output from each (upsample-filter-sum) level has twice the bandwidth and twice the sample rate of the input to that level.

For perfect reconstruction, the Wavelet Synthesis and Wavelet Analysis blocks must have the same parameter settings.

Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	`wfilters('haar')`
Daubechies	`wfilters('db4')`
Symlets	`wfilters('sym3')`
Coiflets	`wfilters('coif1')`
Biorthogonal	`wfilters('bior3.1')`
Reverse Biorthogonal	`wfilters('rbio3.1')`
Discrete Meyer	`wfilters('dmey')`

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to `6`, the Wavelet Synthesis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows

you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to `[2 / 6]`, the Wavelet Synthesis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the synthesis filter bank, use the Dyadic Synthesis Filter Bank block.

Tree Structure

The wavelet tree structure has n+1 inputs, where n is the number of levels. The sample rate and bandwidth of the output are twice the sample rate and bandwidth of the top input. The sample rate and bandwidth of each additional input (except the last) are half that of the input to the previous level.

$$T_{si,k+1} = 2T_{si,k} \quad 1 \le k < n$$

$$BW_{k+1} = \frac{BW_k}{2} \quad 1 \le k < n$$

The bottom two inputs (u_n and u_{n+1}) should have the same sample rate and bandwidth since they are processed by the same level.

$$T_{si,n+1} = T_{si,n}$$

$$BW_{n+1} = BW_n$$

Note that in frame-based mode, the sample period of input u_k is reflected by its frame size$M_{i,k}$, rather than by its frame rate.

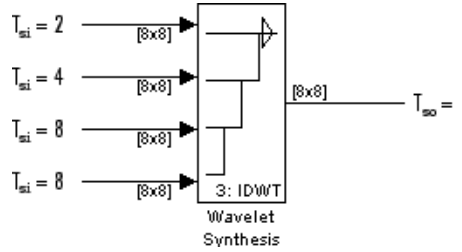
$$M_{i,k+1} = \frac{M_{i,k}}{2} \qquad 1 \le k < n$$

$$M_{i,n+1} = M_{i,n}$$

Sample-Based Operation

An *M*-by-*N* sample-based matrix input is treated as *M***N* independent channels, and the block filters each channel independently over time. The output is the same size as the input at each port, one output channel for each input channel. As described earlier, each input port has a different sample period.

The figure below shows the input and output sample periods for the four 64-channel sample-based inputs to a three-level filter bank. The fastest input has a period of 2, so the output period is 1.



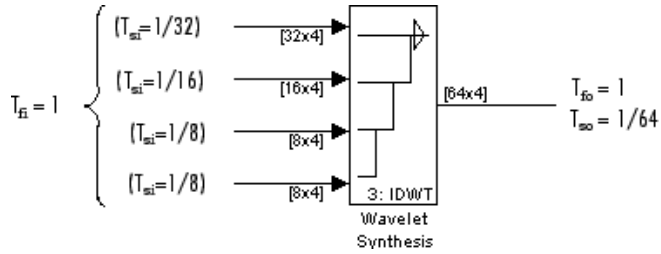
Frame-Based Operation

An M_i-by-*N* frame-based matrix input is treated as *N* independent channels, and the block filters each channel independently over time. The number of columns in the output is the same as the number of columns in the input.

All inputs must have the same frame period, which is also the output frame period. The different input sample rates should be represented by the input frame sizes: If the input to the top port has frame size M_i, the input to the second-from-top port should have frame size $M_i/2$, the input to the third-from-top port should have frame size $M_i/4$, and so on. The input to the bottom port should have the same frame size

as the second-from-bottom port. The increase in the sample rate of the output is also represented by its frame size, which is twice the largest input frame size.

The relationship between sample periods, frame periods, and frame sizes is shown below for a four-channel frame-based input to a 3-level filter bank.



Zero Latency

The Wavelet Synthesis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore uses the first input samples (received at t=0) to synthesize the first output sample.

Nonzero Latency

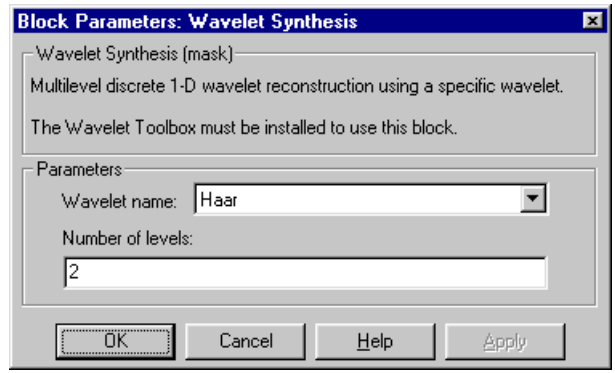
For sample-based operation, the Wavelet Synthesis block is multirate and has the following tasking latencies:

- 2^n-2 samples in Simulink's single-tasking mode
- 2^n samples in Simulink's multitasking mode

In the above cases, the block repeats a zero initial condition in each channel for the first D output samples, where D is the latency shown above. For example, in single-tasking mode the block generates 2^n-2 zero-valued output samples in each channel before propagating the first synthesized output sample (computed from the inputs received at t=0).

Note For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and the topic on models with multiple sample rates in the Simulink Coder documentation.

Dialog Box



The parameters displayed in the dialog box vary for different wavelet types. Only some of the parameters listed below are visible in the dialog box at any one time.

Wavelet name
The wavelet used in the synthesis.

Wavelet order
The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

Filter order [synthesis / analysis]
The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, `[2 / 6]` selects a second-order synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

Number of levels

The number of filter bank levels. An n-level structure has n+1 outputs.

Window Function

Purpose

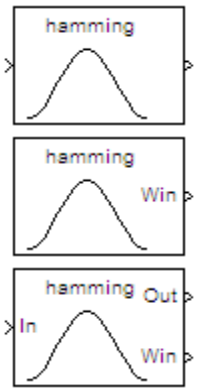
Compute and/or apply window to input signal

Library

Signal Operations

`dspsigops`

Description



The Window Function block computes a window and/or applies a window to an input signal. The input signal can be a matrix or an N-D array.

Operation Modes

The Window Function block has three modes of operation that you can select via the **Operation** parameter. In each mode, the block first creates a window vector w by sampling the window specified in the **Window type** parameter at M discrete points. The operation modes are:

- `Apply window to input`

  In this mode, the block computes an M-by-1 window vector w and applies it to the input. The output y always has the same dimension as the input.

  When the input is an M-by-N matrix u, the window is multiplied element-wise with each of the N channels in the input matrix u. This is equivalent to the following MATLAB code:

  ```
  y = repmat(w,1,N) .* u          % Equivalent MATLAB code
  ```

  The window is always applied to the first dimension:

  $$y(i,j,\ldots,k) = w(i) * u(i,j,\ldots,k) \qquad i = 1,\ldots,M,\ \ j = 1,\ldots,N,\ \ \ldots,\ \ k = 1,\ldots,P$$

  A length-M unoriented vector input is treated as an M-by-1 matrix.

- `Generate window`

In this mode, the block generates an unoriented window vector w with length M specified by the **Window length** parameter. The In port is disabled for this mode.

- `Generate and apply window`

  In this mode, the block generates an M-by-1 window vector w and applies it to the input. The block produces two outputs:

  - At the Out port, the block produces the result of the multiplication y, which has the same dimension as the input.
  - At the Win port, the block produces the M-by-1 window vector w.

  When the input is an M-by-N matrix u, the window is multiplied element-wise with each of the N channels in the input matrix u. This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u        % Equivalent MATLAB code
```

  The window is always applied to the first dimension:

$$y(i,j,...,k) = w(i) * u(i,j,...,k) \qquad i = 1,...,M,\ \ j = 1,...,N,\ \ ...,\ \ k = 1,...,P$$

  A length-M 1-D vector input is treated as an M-by-1 matrix.

Window Type

The following table lists the available window types. For complete information about the window functions, consult the Signal Processing Toolbox documentation.

Window Function

Window Type	Description
Bartlett	Computes a Bartlett window. `w = bartlett(M)`
Blackman	Computes a Blackman window. `w = blackman(M)`
Boxcar	Computes a rectangular window. `w = rectwin(M)`
Chebyshev	Computes a Chebyshev window with stopband ripple `R`. `w = chebwin(M,R)`
Hamming	Computes a Hamming window. `w = hamming(M)`
Hann	Computes a Hann window (also known as a Hanning window). `w = hann(M)`
Hanning	Obsolete. This window type is included only for compatibility with older models. Use the `Hann` **Window type** instead of `Hanning` whenever possible.
Kaiser	Computes a Kaiser window with the Kaiser parameter `beta`. `w = kaiser(M,beta)`

Window Type	Description
Taylor	Computes a Taylor window. `w = taylorwin(M)`
Triang	Computes a triangular window. `w = triang(M)`

User Defined	Computes the user-defined window function specified by the entry in the **Window function name** parameter, `usrwin`.
	
	`w = usrwin(M) % Window takes no extra parameters`
	`w = usrwin(M,`x_1`,...,`x_n`) % Window takes extra parameters {`x_1` ... `x_n`}`

Window Sampling

For the generalized-cosine windows (`Blackman`, `Hamming`, `Hann`, and `Hanning`), the **Sampling** parameter determines whether the window samples are computed in a periodic or a symmetric manner. For example, when **Sampling** is set to `Symmetric`, a Hamming window of length M is computed as

```
w = hamming(M)      % Symmetric (aperiodic) window
```

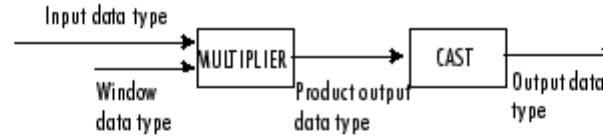
When **Sampling** is set to `Periodic`, the same window is computed as

```
w = hamming(M+1)      % Periodic (asymmetric) window
w = w(1:M)
```

Fixed-Point Data Types

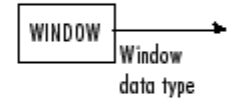
The following diagram shows the data types used within the Window Function block for fixed-point signals for each of the three operating modes.

Apply window to input



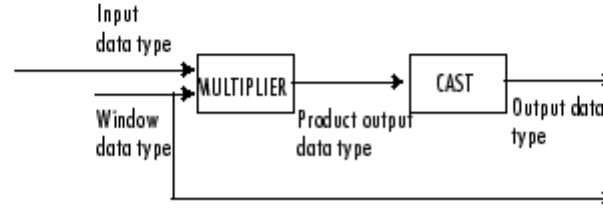
The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is not output from the block.

Generate window



In this mode, the block acts as a source. The window vector is output in the window data type you specify in the block dialog.

Generate and apply window



The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is output from the block.

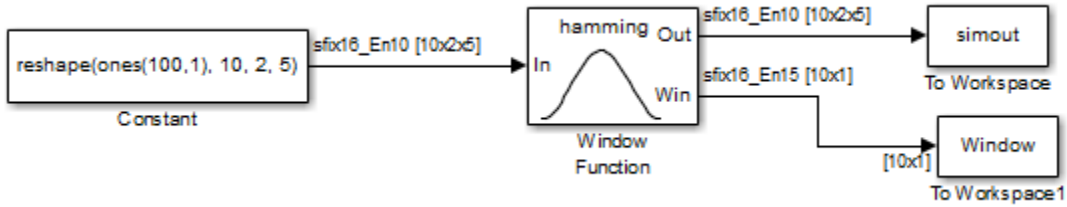
You can set the window, product output, and output data types in the block dialog box. For more information see the “Dialog Box” on page 1-1923 section.

Examples

The following model uses the Window Function block to generate and apply a Hamming window to a 3-dimensional input array.

In this example, set the **Operation** mode of the Window Function block to `Generate and apply window`, so the block provides two outputs: the window vector w at the Win port, and the result of the multiplication y at the Out port.

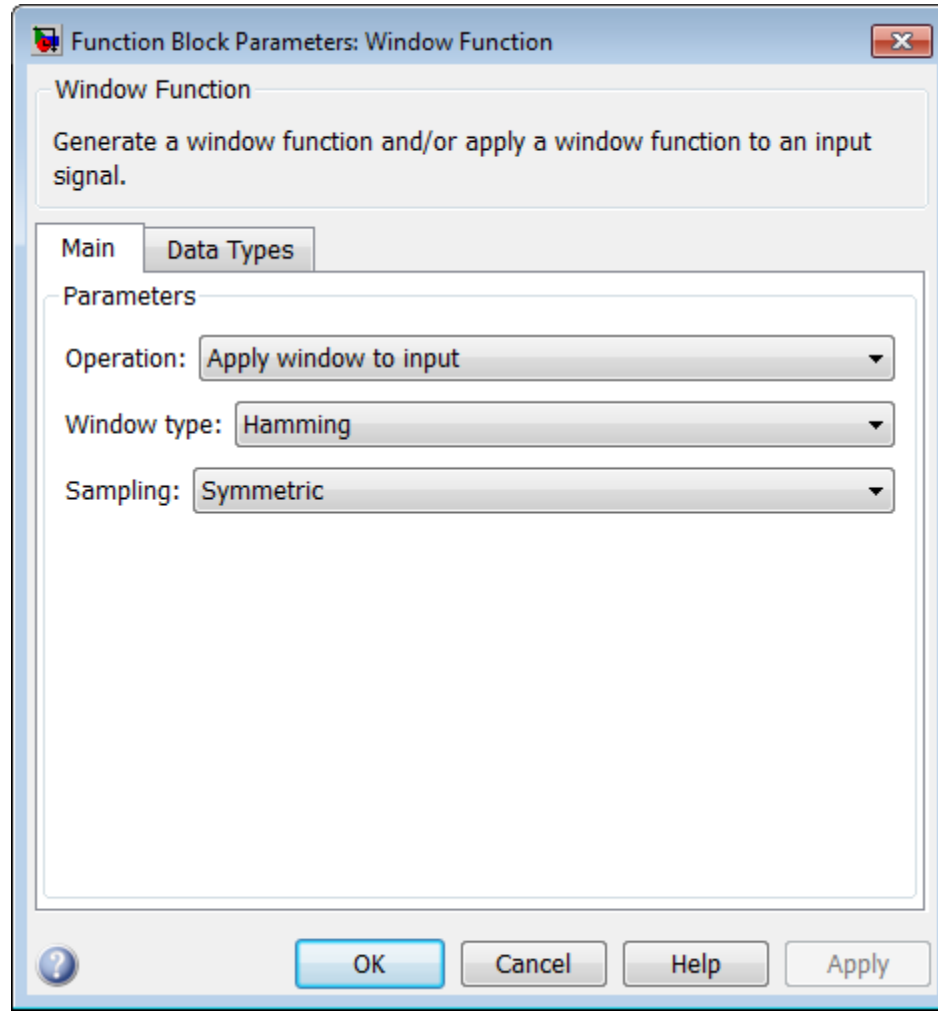
Open the model by typing `ex_windowfunction_ref` at the MATLAB command line, and run it.



- The length of the first dimension of the input array is 10, so the Window Function block generates and outputs a Hamming window vector of length 10. To see the window vector generated by the Window Function block, type `w` at the MATLAB command line.
- To see the result of the multiplication, type `y` at the MATLAB command line.

Dialog Box

The **Main** pane of the Window Function block dialog appears as follows.



Operation

Specify the block's operation, as discussed in "Operation Modes" on page 1-1916. The port configuration of the block is updated to match the setting of this parameter.

Window type

Specify the window type to apply, as listed in "Window Type" on page 1-1917. Tunable in simulation only.

Sampling

Specify the window sampling for generalized-cosine windows. This parameter is only visible when you select `Blackman`, `Hamming`, `Hann`, or `Hanning` for the **Window type** parameter. Tunable in simulation only.

Sample Mode

Specify the sample mode for the block, `Continuous` or `Discrete`, when it is in `Generate Window` mode. In the `Apply window to output` and `Generate and apply window` modes, the block inherits the sample time from its driving block. Therefore, this parameter is only visible when you select `Generate window` for the **Operation** parameter.

Sample time

Specify the sample time for the block when it is in `Generate window` and `Discrete` modes. In `Apply window to output` and `Generate and apply window` modes, the block inherits the sample time from its driving block. This parameter is only visible when you select `Discrete` for the **Sample Mode** parameter.

Window length

Specify the length of the window to apply. This parameter is only visible when you select `Generate window` for the **Operation** parameter. Otherwise, the window vector length is computed to match the length of the first dimension of the input.

Stopband attenuation in dB

Specify the level of stopband attenuation, R_s, in decibels. This parameter is only visible when you select `Chebyshev` for the **Window type** parameter. Tunable in simulation only.

Beta

Specify the `Kaiser` window β parameter. Increasing β widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This parameter is only visible when you select `Kaiser` for the **Window type** parameter. Tunable in simulation only.

Number of sidelobes

Specify the number of sidelobes as a scalar integer value greater than zero. This parameter is only visible when you select `Taylor` for the **Window type** parameter.

Maximum sidelobe level relative to mainlobe (dB)

Specify, in decibels, the maximum sidelobe level relative to the mainlobe. This parameter must be a scalar less than or equal to zero. The default value of –30 produces sidelobes with peaks 30 dB down from the mainlobe peak. This parameter is only visible when you select `Taylor` for the **Window type** parameter.

Window function name

Specify the name of the user-defined window function to be calculated by the block. This parameter is only visible when you select `User defined` for the **Window type** parameter.

Specify additional arguments to the hamming function

Select to enable the **Cell array of additional arguments** parameter, when the user-defined window requires parameters other than the window length. This parameter is only visible when you select `User defined` for the **Window type** parameter.

Cell array of additional arguments

Specify the extra parameters required by the user-defined window function, besides the window length. This parameter is only available when you select the **Specify additional arguments to the hamming function** parameter. The entry must be a cell array.

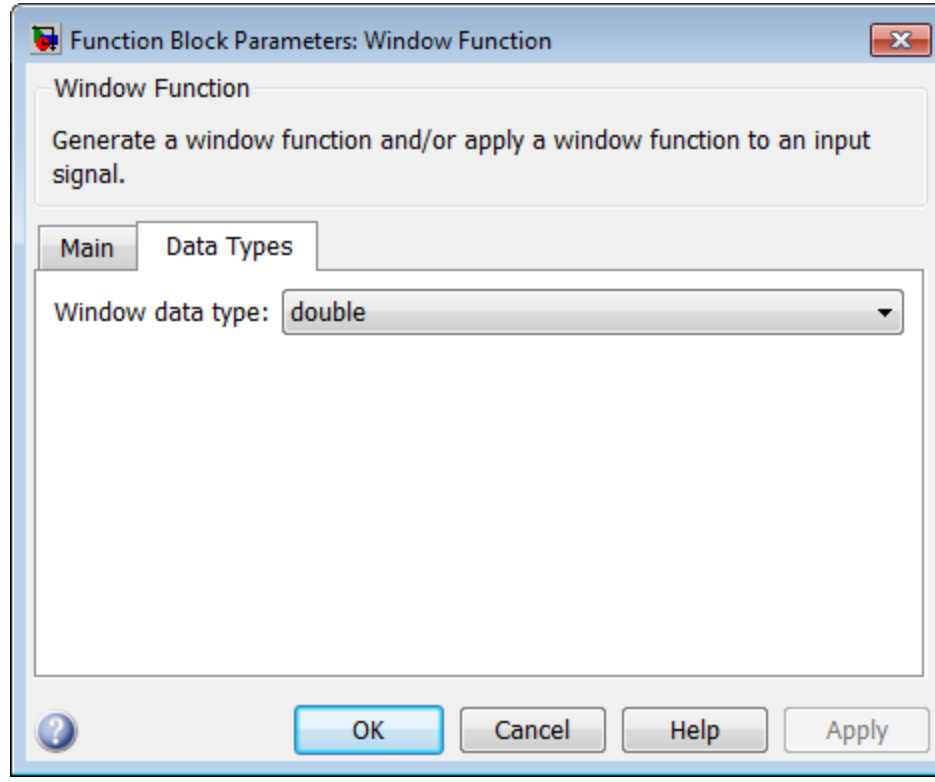
The **Data Types** pane of the Window Function block dialog is discussed in the following sections:

“Parameters for Generate Window Only Mode” on page 1-1926

“Parameters for Apply Window Modes” on page 1-1928

Parameters for Generate Window Only Mode

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to `Generate window`.



Window data type

Specify the window data type in one of the following ways:

- Choose `double` or `single` from the list.

- Choose `Fixed-point` to specify the window data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to,** and **Fraction length** parameters.
- Choose `User-defined` to specify the window data type and scaling in the **User-defined data type**, **Set fraction length in output to,** and **Fraction length** parameters.
- Choose `Inherit via back propagation` to set the window data type and scaling to match the following block.

Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned.

Word length

Specify the word length, in bits, of the fixed-point window data type. This parameter is only visible when you select `Fixed-point` for the **Window data type** parameter.

User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the Fixed-Point Designer functions `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`. This parameter is only visible when you select `User-defined` for the **Window data type** parameter.

Set fraction length in output to

Specify the scaling of the fixed-point window data type by either of the following two methods:

- Choose `Best precision` to have the window data type scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the window data type scaling in the **Fraction length** parameter.

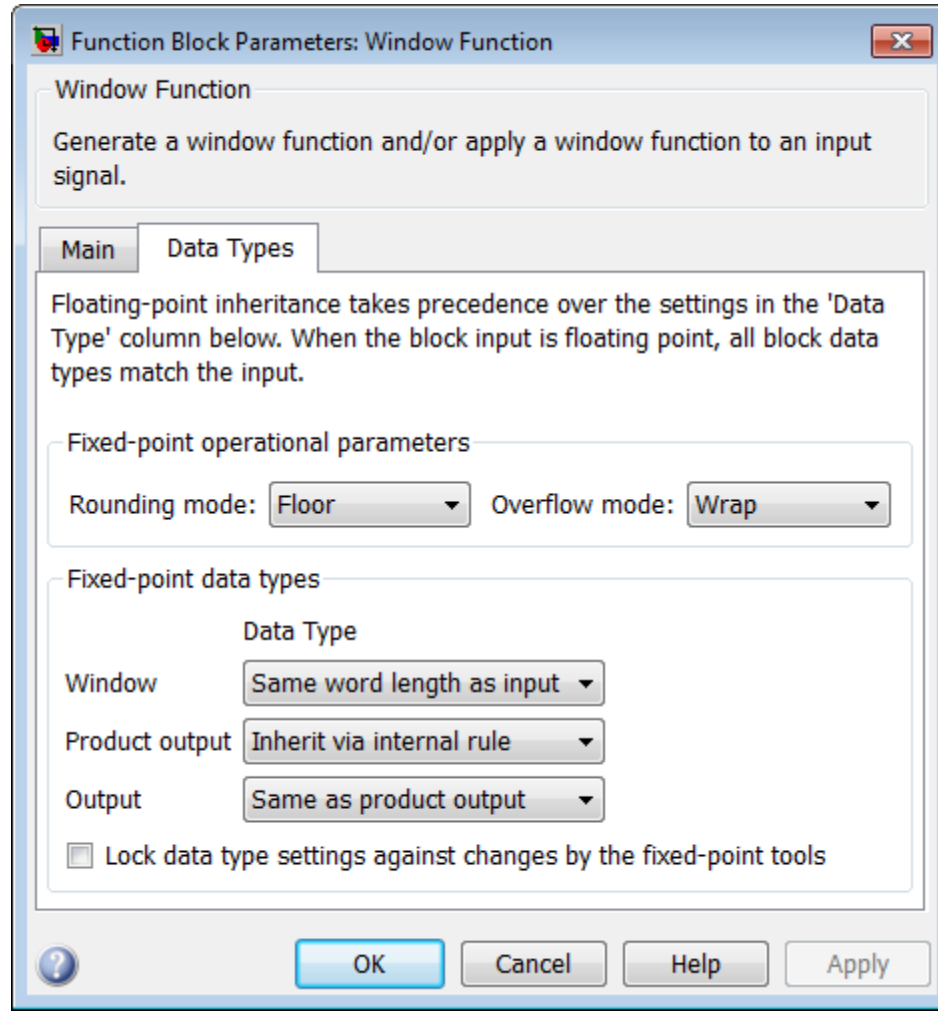
This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Window data type** parameter, and when the specified window data type is a fixed-point data type.

Fraction length

Specify the fraction length, in bits, of the fixed-point window data type. This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Window data type** parameter and `User-defined` for the **Set fraction length in output to** parameter.

Parameters for Apply Window Modes

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to either `Apply window to input` or `Generate and apply window`.



Rounding mode

Select the rounding mode for fixed-point operations.

The window vector w does not obey this parameter; it always rounds to `Nearest`.

Note The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Product output data type** is `Inherit via internal rule`
- **Output data type** is `Same as product output`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the overflow mode for fixed-point operations.

The window vector w does not obey this parameter; it is always saturated.

Window

Choose how you specify the word length and fraction length of the window vector w.

When you select `Same word length as input`, the word length of the window vector elements is the same as the word length of the input. The fraction length is automatically set to the best precision possible.

When you select `Specify word length`, you can enter the word length of the window vector elements in bits. The fraction length is automatically set to the best precision possible.

When you select `Binary point scaling`, you can enter the word length and the fraction length of the window vector elements in bits.

When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the window vector elements. This block requires power-of-two slope and a bias of zero.

The window vector does not obey the **Rounding mode** and **Overflow mode** parameters; it is always saturated and rounded to `Nearest`.

Product output

Use this parameter to specify how you want to designate the product output word and fraction lengths. See "Fixed-Point Data Types" on page 1-1810 for illustrations depicting the use of the product output data type in this block:

- When you select `Inherit via internal rule`, the product output word length and fraction length are calculated automatically. For information about how the product output word and fraction lengths are calculated when an internal rule is used, see "Inherit via Internal Rule".
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the word length and fraction length of the output of the block:

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.

- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools
Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Win	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit integers

Yule-Walker AR Estimator

Purpose

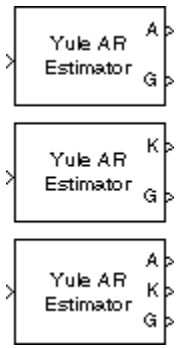
Compute estimate of autoregressive (AR) model parameters using Yule-Walker method

Library

Estimation / Parametric Estimation

`dspparest3`

Description



The Yule-Walker AR Estimator block uses the Yule-Walker AR method, also called the autocorrelation method, to fit an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which are solved by the Levinson-Durbin recursion. Block outputs are always nonsingular.

The Yule-Walker AR Estimator block can output the AR model coefficients as polynomial coefficients, reflection coefficients, or both. Each channel of the input is a sample-based vector (row, column, or 1-D) or frame-based vector (column only) representing a frame of consecutive time samples from a signal that is assumed to be the output of an AR system driven by white noise. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

When you select **Inherit estimation order from input dimensions**, the order p of the all-pole model is one less than the length of each input channel. Otherwise, the order is the value specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be a scalar less than or equal to half the input channel length. The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

When **Output(s)** is set to `A`, port A is enabled. For each channel, port A outputs a column of length p+1 that contains the normalized estimate of the AR model coefficients in descending powers of z

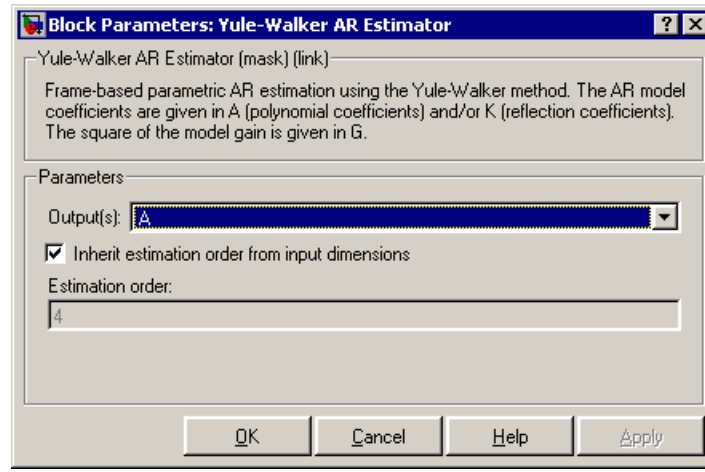
```
[1 a(2) ... a(p+1)]
```

When **Output(s)** is set to `K`, port K is enabled. For each channel, port K outputs a length-p column whose elements are the AR model reflection coefficients. When **Output(s)** is set to `A and K`, both port A and K are enabled, and each port outputs the respective AR model coefficients for each channel.

The square of the model gain, G, is provided at port G. G is a scalar for each channel.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Dialog Box



Output(s)

The type of AR model coefficients output by the block. The block can output polynomial coefficients (`A`), reflection coefficients (`K`), or both (`A and K`).

Inherit estimation order from input dimensions

When selected, sets the estimation order p to one less than the length of each input channel.

Estimation order

The order of the AR model, p. This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

Yule-Walker IIR Filter Design (Obsolete)

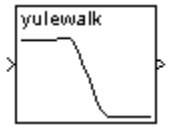
Purpose

Design and apply IIR filter

Library

`dspobslib`

Description



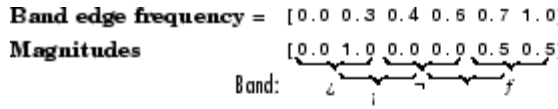
Note The Yule-Walker IIR Filter Design block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Digital Filter block.

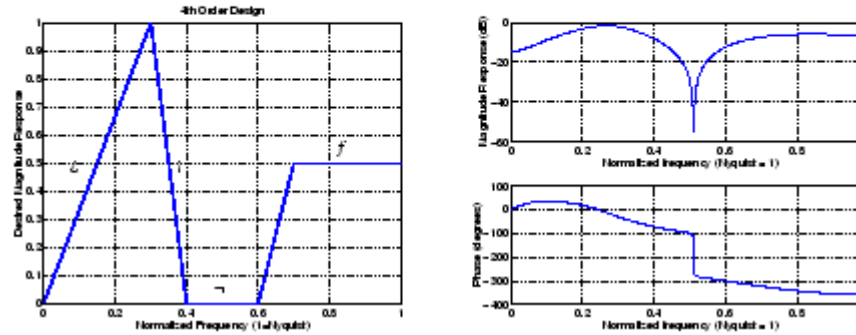
The Yule-Walker IIR Filter Design block designs a recursive (ARMA) digital filter with arbitrary multiband magnitude response, and applies it to a discrete-time input using the Direct-Form II Transpose Filter block. The filter design, which uses the Signal Processing Toolbox `yulewalk` function, performs a least-squares fit to the specified frequency response.

An *M*-by-*N* sample-based matrix input is treated as *M***N* independent channels, and an *M*-by-*N* frame-based matrix input is treated as *N* independent channels. In both cases, the block filters each channel independently over time, and the output has the same size and frame status as the input.

The **Band-edge frequency vector** parameter is a vector of frequency points in the range `0` to `1`, where `1` corresponds to half the sample frequency. The first element of this vector must be `0` and the last element `1`, and intermediate points must appear in ascending order. The **Magnitudes at these frequencies** parameter is a vector containing the desired magnitude response at the points specified in the **Band-edge frequency vector**.

Note that, unlike the Remez FIR Filter Design block, each frequency-magnitude pair specifies the junction of two adjacent frequency bands, so there are no “don’t care” regions.

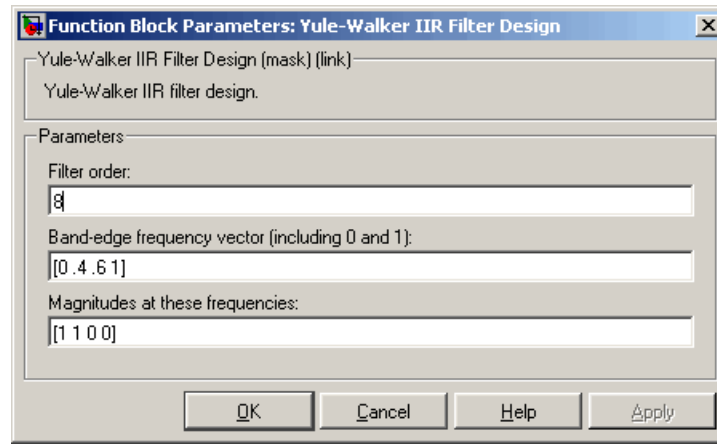




When specifying the **Band-edge frequency vector** and **Magnitudes at these frequencies** vectors, avoid excessively sharp transitions from passband to stopband. You may need to experiment with the slope of the transition region to get the best filter design.

For more details on the Yule-Walker filter design algorithm, see the description of the `yulewalk` function in the Signal Processing Toolbox documentation.

Dialog Box



Filter order

The order of the filter.

Band-edge frequency vector

A vector of frequency points. The value `1` corresponds to half the sample frequency. The first element of this vector must be `0` and the last element `1`. Tunable.

Magnitudes at these frequencies

A vector of frequency response magnitudes corresponding to the points in the **Band-edge frequency vector**. This vector must be the same length as the **Band-edge frequency vector**. Tunable.

Yule-Walker Method

Purpose

Power spectral density estimate using Yule-Walker method

Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Yule-Walker Method block estimates the power spectral density (PSD) of the input using the Yule-Walker AR method. This method, also called the *autocorrelation method*, fits an autoregressive (AR) model to the windowed input data. It does so by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which the Levinson-Durbin recursion solves. Block outputs are always nonsingular.

The input is a sample-based vector (row, column, or 1-D) or frame-based vector (column only). This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

When you select **Inherit estimation order from input dimensions**, the order of the all-pole model is one less that the input frame size. Otherwise, the **Estimation order** parameter value specifies the order. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** check box allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT. The output is always sample based.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

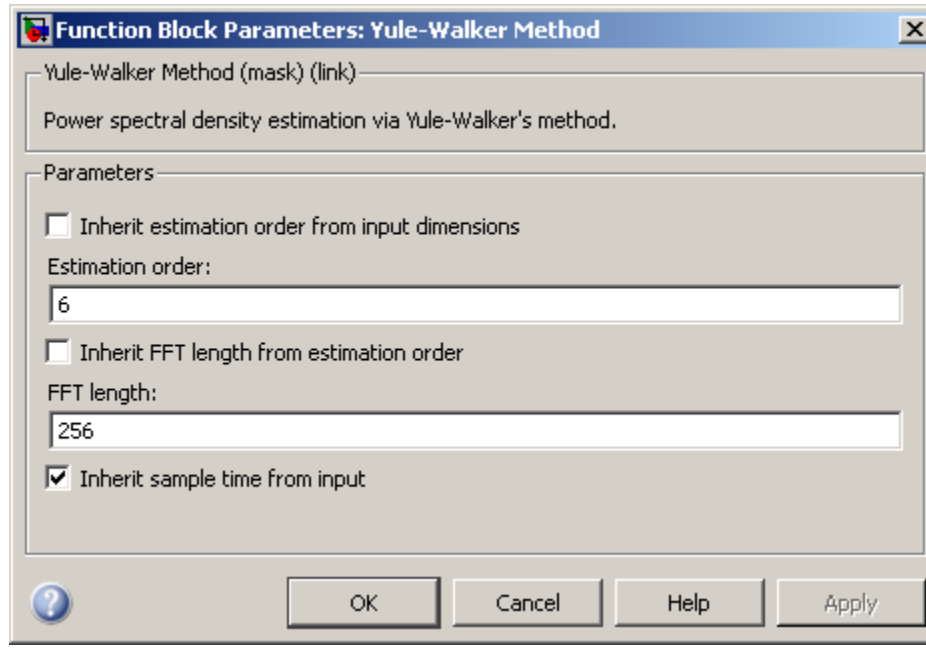
- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker AR Estimator blocks. The Yule-Walker AR Estimator and Burg Method blocks return similar results for large buffer lengths.

Yule-Walker Method

Dialog Box



Inherit estimation order from input dimensions

When you select this option, it sets the estimation order to one less than the length of the input vector.

Estimation order

Specify the order of the AR model. This parameter is only visible when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When you select the **Inherit FFT length from estimation order** check box, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Purpose

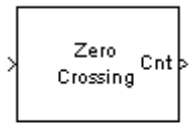
Count number of times signal crosses zero in single time step

Library

Signal Operations

`dspsigops`

Description



Zero Crossing

The Zero Crossing block concludes that a signal in a given channel has passed through zero if it meets any of the following criteria, where x_i is the current signal value, x_{i-1} is the previous signal value, and so on:

- $x_i < 0$ and $x_{i-1} > 0$
- $x_i > 0$ and $x_{i-1} < 0$
- For some positive integer L, $x_i < 0$, $x_{i-l} = 0$, and $x_{i-L-1} > 0$, where $0 \le l \le L$.
- For some positive integer L, $x_i > 0$, $x_{i-l} = 0$, and $x_{i-L-1} < 0$, where $0 \le l \le L$.

For the first input value, x_{i-1} and x_{i-2} are zero. The block outputs the number of times the signal crosses zero in a single time step at the Cnt port.

The input to this block must be a real-valued fixed-point or floating-point signal. If you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input as a time-varying channel. If you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column of the input as an independent channel.

Examples

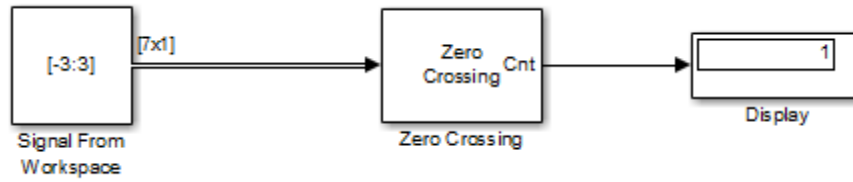
The following example, ex_zero_crossing illustrates the behavior of the Zero Crossing block.

To run the model for one time step, the **Stop time** is set to `0.`

1

Run the model.

Because the signal passes through zero once during the first time step, the Zero Crossing block finds one zero crossing. The number of detected zero crossings in the first time step is shown in the Display block in the following figure.



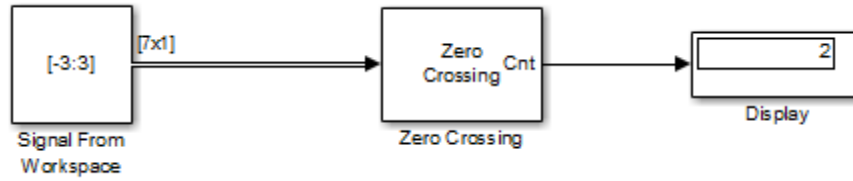
2

To run the model for two time steps, change the simulation **Stop time** to 1. To do so, open the Configuration Parameters dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. In the **Solver** pane, set **Stop time** to 1.

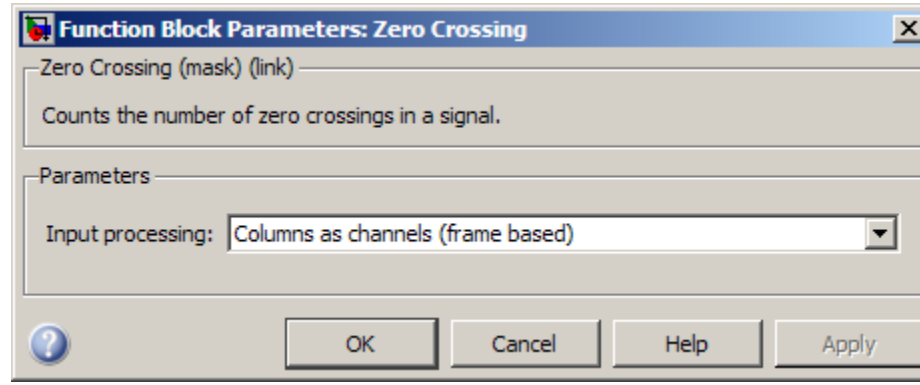
3

Run the model.

The Zero Crossing block remembers that the last value of the last frame was 3. Therefore, the signal passes through zero twice during the second time step. It passes through zero while going from 3 to -3, and it passes through zero again while going from -3 to 3. The Zero Crossing block finds two zero crossings in the second time step as shown in the Display block in the following figure.



Dialog Box



Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating-point • Single-precision floating-point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Cnt	• 32-bit unsigned integers

Analysis Methods for Filter System Objects

Analysis Methods for Filter System Objects

Method	Description
Single-rate and Multirate Analysis	
`fvtool`	Filter visualization tool
`info`	Filter information
`freqz`	Frequency response of a discrete-time filter
`phasez`	Phase response of a discrete-time filter
`zerophase`	Zero-phase response of a discrete-time filter
`grpdelay`	Group delay of a discrete-time filter
`phasedelay`	Phase delay of a discrete-time filter
`impz`	Impulse response of a discrete-time filter
`stepz`	Step response of a discrete-time filter
`zplane`	Pole/Zero plot
`cost`	Cost estimate
`measure`	measure filter response
`order`	Filter order
`firtype`	Determine the type (1–4) of a linear phase FIR filter
`coeffs`	Return filter coefficients
Multirate Analysis	
`polyphase`	Polyphase decomposition of multirate filters
`gain`	Gain of a Cascaded Integrator-Comb (CIC) filter

Method	Description
Second-order Sections	
`scale`	Scale second-order sections
`scalecheck`	Check scale of second-order sections
`scaleopts`	Create options object for sos scaling
`cumsec`	Vector of cumulative second-order section filters
`reorder`	Reorder second-order sections
`sos`	Convert IIR filter to Biquad filter
Code Generation	
`realizemdl`	Filter realization diagram
Fixed-point (supported by FIRFilter, IIRFilter, AllpoleFilter, and BiquadFilter only)	
`noisepsd`	Power spectral density of filter output due to roundoff noise
`noisepsdopts`	Create options object for noisepsd computation
`freqrespest`	Frequency response estimate via filtering
`freqrespopts`	Create options object for frequency response estimate
Other	
`isallpass`	True for allpass discrete-time filter
`islinphase`	True for linear discrete-time filter
`ismaxphase`	True if maximum phase
`isminphase`	True if minimum phase
`isreal`	True for discrete-time filter with real coefficients
`isstable`	True if the filter is stable

Method	Description
`isfir`	True if the filter is FIR
`issos`	True if filter is in second order sections form
`specifyall`	Specify all fixed-point properties

Alphabetical List

dsp.AdaptiveLatticeFilter

Purpose

Adaptive lattice filter

Description

The `dsp.AdaptiveLatticeFilter` computes output, error, and coefficients using a Lattice based FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See "Construction" on page 3-2.
2. Call `step` to implement the filter according to the properties of `dsp.AdaptiveLatticeFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.AdaptiveLatticeFilter` returns a Lattice based FIR adaptive filter System object™, `H`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`H = dsp.AdaptiveLatticeFilter('PropertyName', PropertyValue,...)` returns an `AdaptiveLatticeFilter` System object, `H`, with each specified property set to the specified value.

`H = dsp.AdaptiveLatticeFilter(LEN,'PropertyName',PropertyValue,...)` returns an `AdaptiveLatticeFilter` System object, `H`, with the Length property set to `LEN` and other specified properties set to the specified values.

Properties

Method

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of `'Least-squares Lattice'` | `'QR-decomposition Least-squares Lattice'` | `'Gradient Adaptive Lattice'` . The default value is `'Least-squares Lattice'`. For algorithms used to implement these three different methods, refer to [1] [2]. This property is nontunable.

Length

Length of the filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

ForgettingFactor

Least-squares lattice forgetting factor

Specify the Least-squares lattice forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this value to 1 denotes infinite memory during adaptation. This property applies only if the Method property is set to `'Least-squares Lattice'` or `'QR-decomposition Least-squares Lattice'`. The default value is `1`.

StepSize

Joint process step size of the gradient adaptive filter

Specify the joint process step size of the gradient adaptive lattice filter as a positive numeric scalar less than or equal to 1. This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice'`. The default value is `0.1`.

Offset

Offset for denominator of StepSize normalization term

Specify an offset value for the denominator of the `StepSize` normalization term as a nonnegative numeric scalar. A nonzero offset helps avoid a divide-by-near-zero condition when the input signal amplitude is very small. This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice'`. The default value is `1`.

ReflectionStepSize

Reflection process step size

Specify the reflection process step size of the gradient adaptive lattice filter as a scalar numeric value between 0 and 1, both

inclusive. Use this property only if the `Method` property is set to `'Gradient Adaptive Lattice'`. The default value is the `StepSize` property value.

AveragingFactor

Averaging factor of the energy estimator

Specify the averaging factor as a positive numeric scalar less than 1. Use this property to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice`. The default is the value of `1 - StepSize`.

InitialPredictionErrorPower

Initial prediction error power

Specify the initial values for the prediction error vectors as a scalar positive numeric value.

If the `Method` property is set to `'Least-squares Lattice'` or `'QR-decomposition Least-squares Lattice'`, the default value is `1.0`. If the `Method` property is set to `'Gradient Adaptive Lattice'`, the default value is `0.1`.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property. The default value is `0`.

LockCoefficients

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

This property is applicable only if the `Method` property is set to `'Gradient Adaptive Lattice'`.

Methods

clone	Create Adaptive Lattice filter object with same property values
isLocked	Locked status for input attributes and nontunable properties
msesim	Mean-square error for Adaptive Lattice filter
release	Allow property value and input characteristics changes
reset	Reset filter states for Adaptive Lattice filter
step	Apply Adaptive Lattice filter to input

Examples

QPSK adaptive equalization with FIR filter

Create the QPSK signal and the noise, filter them to obtain the received signal, and delay the received signal to obtain the desired signal:

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr = 1000;
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);
```

Use the Adaptive Lattice Filter to compute the filtered output and the filter error for the input and desired signal:

```
lam = 0.995;
del = 1;
h = dsp.AdaptiveLatticeFilter('Length', 32, ...
    'ForgettingFactor', lam, 'InitialPredictionErrorPower', del);
[y,e] = step(h,x,d);
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals:

```
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
```

Plot the received and equalized signals' scatter plots:

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

dsp.AdaptiveLatticeFilter.msesim

Purpose

Mean-square error for Adaptive Lattice filter

Syntax

```
MSE = msesim(H,X,D)
[MSE,MEANW,W,TRACEK] = msesim(H,X,D)
[...] = msesim(H,X,D,M)
```

Description

`MSE = msesim(H,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(H,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `H`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `H`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(H,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M` > 1, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System identification of an FIR filter

```
ha = fir1(31,0.5);
sa = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
hb = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = step(hb,sign(randn(2000,25)));
n = 0.1*randn(size(x));             % Observation noise signal
d = step(sa,x)+n;                   % Desired signal
```

```
l = 32;                                % Filter length
mu = 0.008;                            % Adaptive Lattice filter Step siz
m  = 5;                                % Decimation factor for analysis
                                       % and simulation results
ha = dsp.AdaptiveLatticeFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Adaptive Lattice filter used in system ident
```

dsp.AdaptiveLatticeFilter.clone

Purpose

Create Adaptive Lattice filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`, with the same property values. The clone method creates a new unlocked object with uninitialized states.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the Adaptive Lattice filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.AdaptiveLatticeFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset filter states for Adaptive Lattice filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the System object,`H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

dsp.AdaptiveLatticeFilter.step

Purpose

Apply Adaptive Lattice filter to input

Syntax

```
[Y, ERR] = step(H, x, D)
Y = step(H,x)
[Y1,...,YN] = step(H,x)
```

Description

`[Y, ERR] = step(H, x, D)` filters the input `x`, using D as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(H,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, H. `[Y1,...,YN] = step(H,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Compute output, error and coefficients using Affine Projection (AP) Algorithm

Description

The `AffineProjectionFilter` object filters each channel of the input using AP filter implementations.

To filter each channel of the input:

1. Define and set up your AP filter. See "Construction" on page 3-15.
2. Call `step` to filter each channel of the input according to the properties of `dsp.AffineProjectionFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.AffineProjectionFilter` returns an adaptive FIR filter System object, `H`. This System object computes the filtered output and the filter error for a given input and desired signal using the Affine Projection (AP) algorithm.

`H = dsp.AffineProjectionFilter('PropertyName',PropertyValue, ...)` returns an AffineProjectionFilter System object, `H`, with each specified property set to the specified value.

`H = dsp.AffineProjectionFilter(LEN, 'PropertyName', PropertyValue, ...)` returns an RLS filter System object, `H`. This System object has the Length property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate the filter coefficients

Specify the method used to calculate filter coefficients as one of `| Direct Matrix Inversion | Recursive Matrix Update | Block Direct Matrix Inversion`. The default value is `Direct Matrix Inversion`. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a scalar positive integer value. The default value is `32`. This property is nontunable.

ProjectionOrder

Projection order of the affine projection algorithm

Specify the projection order of the affine projection algorithm as a scalar positive integer value greater than or equal to 2. This property defines the size of the input signal covariance matrix.. The default value is `2`. This property is nontunable.

StepSize

Affine projection step size

Specify the affine projection step size factor as a scalar non-negative numeric value between 0 and 1, both inclusive. Setting step equal to one provides the fastest convergence during adaptation. The default value is `1`. This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the `Length` property value. The default value is `0`. This property is tunable.

InitialOffsetCovariance

Initial values of the offset input covariance matrix

Specify the initial values for the offset input covariance matrix. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `OffsetCovariance` property is initialized to a diagonal matrix with the diagonal elements equal to that scalar value. If it is a square matrix, the `OffsetCovariance` property is initialized to

the value of that square matrix. This property is applicable only if the Method property is set to `Direct Matrix Inversion` or `Block Direct Matrix Inversion`. The default value is `1`. This property is tunable.

InitialInverseOffsetCovariance

Initial values of the offset input covariance matrix inverse

Specify the initial values for the offset input covariance matrix inverse. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `InverseOffsetCovariance` property is initialized to a diagonal matrix with each diagonal element equal to that scalar value. If it is a square matrix, the `InverseOffsetCovariance` property is initialized to the values of that square matrix. This property is applicable only if the `Method` property is set to `Recursive Matrix Update`. The default value is `20`. This property is tunable.

InitialCorrelationCoefficients

Initial correlation coefficients

Specify the initial values of the correlation coefficients of the FIR filter as a scalar or a vector of length equal to `ProjectionOrder –1`. This property is applicable only if the `Method` property is set to `Recursive Matrix Update`. The default value is `0`. This property is tunable.

LockCoefficients

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients are continuously updated). This property is tunable.

Methods

clone	Create System object with same property values
isLocked	Locked status for input attributes and nontunable properties
msesim	Mean-square error for Affine Projection filter
release	Allow property value and input characteristics changes
reset	Reset the internal states of a System object
step	Process inputs using the affine projection filter algorithm

Examples

QPSK Adaptive Equalization

QPSK Adaptive Equalization Using a 32-Coefficient FIR Filter (1000 Iterations)

```
D = 16;                       % Number of samples of delay
b = exp(j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a = [1 -0.7];                 % Denominator coefficients of channel
ntr = 1000;                   % Number of iterations
s = sign(randn(1,ntr+D)) + j*sign(randn(1,ntr+D)); % Baseband sign

Algorithms

The affine projection algorithm (APA), is an adaptive scheme that estimates an unknown system based on multiple input vectors [1]. It is designed to improve the performance of other adaptive algorithms, mainly those that are LMS-based. The affine projection algorithm reuses old data resulting in fast convergence when the input signal is highly correlated, leading to a family of algorithms that can make trade-offs between computation complexity with convergence speed [2].

The following equations describe the conceptual algorithm used in designing AP filters:

$$\mathbf{U}_{ap}(n) = \begin{pmatrix} u(n) & \cdots & u(n-L) \\ \vdots & \ddots & \vdots \\ u(n-N) & \cdots & u(n-L-N) \end{pmatrix} = \begin{pmatrix} \mathbf{u}(n) & \mathbf{u}(n-1) & \cdots & \mathbf{u}(n-L) \end{pmatrix}$$

$$\mathbf{y}_{ap}(n) = \mathbf{U}^{T}{}_{ap}(n)\mathbf{w}(n) = \begin{pmatrix} y(n) \\ \bullet \\ \bullet \\ \bullet \\ y(n-L) \end{pmatrix}$$

$$\mathbf{d}_{ap}(n) = \begin{pmatrix} d(n) \\ \bullet \\ \bullet \\ \bullet \\ d(n-L) \end{pmatrix}$$

$$\mathbf{e}_{ap}(n) = \mathbf{d}_{ap}(n) - \mathbf{y}_{ap}(n) = \begin{pmatrix} e(n) \\ \bullet \\ \bullet \\ \bullet \\ e(n-L) \end{pmatrix}$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mu \mathbf{U}_{ap}(n)(\mathbf{U}_{ap}{}^{H}(n)\mathbf{U}_{ap}(n) + \mathbf{C})^{-1}\mathbf{e}_{ap}$$

where $\mathbf{C}$ is either $\varepsilon\mathbf{I}$ if the initial offset covariance is a scalar ε, or $\mathbf{R}$ if the initial offset covariance is a matrix $\mathbf{R}$. The variables are as follows:

Variable	Description
n	The current time index
u(n)	The input sample at step n

Variable	Description
$\mathbf{U}_{ap}(n)$	The matrix of the last L+1 input signal vectors
$\mathbf{w}(n)$	The adaptive filter coefficients vector
y(n)	The adaptive filter output
d(n)	The desired signal
e(n)	The error at step n
L	The projection order
N	The filter order (i.e., filter length = N+1)
μ	The step size

dsp.AffineProjectionFilter.msesim

Purpose

Mean-square error for Affine Projection filter

Syntax

```
MSE = msesim(H,X,D)
[MSE,MEANW,W,TRACEK] = msesim(H,X,D)
[...] = msesim(H,X,D,M)
```

Description

`MSE = msesim(H,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(H,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `H`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `H`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(H,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M` > 1, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System identification of an FIR filter

```
ha = fir1(31,0.5);
sa = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
hb = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = step(hb,sign(randn(2000,25)));
n = 0.1*randn(size(x));             % Observation noise signal
d = step(sa,x)+n;                   % Desired signal
```

```
l = 32;                                 % Filter length
mu = 0.008;                             % Affine Projection filter Step si
m  = 5;                                 % Decimation factor for analysis
                                        % and simulation results
ha = dsp.AffineProjectionFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Affine Projection filter used in system iden
```

dsp.AffineProjectionFilter.clone

Purpose

Create System object with same property values

Syntax

```
C = clone(OBJ)
```

Description

`C = clone(OBJ)` creates another instance of the System object, `OBJ`, with the same property values. The `clone` method creates a new unlocked object with uninitialized states.

See Also

`dsp.AffineProjectionFilter.step` | `dsp.AffineProjectionFilter.isLocked` | `dsp.AffineProjectionFilter.reset`

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
L = isLocked(OBJ)
```

Description

`L = isLocked(OBJ)` returns a logical value, `L`, which indicates whether input attributes and nontunable properties are locked for the System object, `OBJ`. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. Once this occurs, the `isLocked` method returns a `true` value.

See Also

`dsp.AffineProjectionFilter.step` | `dsp.AffineProjectionFilter.release`

dsp.AffineProjectionFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(OBJ)
```

Description

`release(OBJ)` releases system resources, such as memory, file handles, and hardware connections of the System object, `OBJ`, and allows all its properties and input characteristics to be changed.

Once you call the `release` method on a System object, subsequent calls to `setup`, `step`, `reset`, or `release` are not supported for code generation.

See Also

`dsp.AffineProjectionFilter.isLocked` | `dsp.AffineProjectionFilter.step`

Purpose

Reset the internal states of a System object

Syntax

```
reset(OBJ)
```

Description

`reset(OBJ)` resets the internal states of the System object, `OBJ`, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

dsp.AffineProjectionFilter.step

Purpose

Process inputs using the affine projection filter algorithm

Syntax

```
Y = step(OBJ,x)
[Y1,...,YN] = step(OBJ,x)
```

Description

`Y = step(OBJ,x)` processes the input data, `x`, to produce the output, `Y`, for the System object, `OBJ`. `[Y1,...,YN] = step(OBJ,x)` produces N outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Purpose

Single section or cascaded allpass filter

Description

The `AllpassFilter` object filters each channel of the input using Allpass filter implementations.

To filter each channel of the input:

1. Define and set up your Allpass filter. See "Construction" on page 3-29.
2. Call `step` to filter each channel of the input according to the properties of `dsp.AllpassFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.AllpassFilter` returns an Allpass filter System object, `H`, that filters each channel of the input signal independently using an allpass filter, with the default structure and coefficients.

`H = dsp.AllpassFilter('PropertyName',PropertyValue, ...)` returns an Allpass filter System object, `H`, with each property set to the specified value.

Properties

Structure

Internal allpass filter structure

You can specify the internal allpass filter implementation structure as one of `| Minimum multiplier | Wave Digital Filter | Lattice`. The default is `Minimum multiplier`. Each structure uses a different set of coefficients, independently stored in the corresponding object property.

AllpassCoefficients

Allpass polynomial coefficients

Specify the real allpass polynomial filter coefficients. This property is applicable only when the Structure property is set to `Minimum multiplier`. The value of this property can be either a row vector (single-section configuration), or a cell array with as many cells as filter sections. The default value of this property is

`[ 0.7071, 0.5000]`. They define a stable second-order allpass filter with poles and zeros located at ±π/3 in the Z plane. This property is tunable.

WDFCoefficients

Wave Digital Filter allpass coefficients

Specify the real allpass coefficients in the Wave Digital Filter form. This property is only applicable when the `Structure` property is set to `Wave Digital Filter`. The value of this property can be either a row vector (single-section configuration) or a cell array with as many cells as there are filter sections. Acceptable section orders are 1, 2 and 4. If the order is 4, then the second and fourth coefficients must be zeros. All elements must have absolute value ≤1. The default value for this property is [0.5, –1.1547]. These are the transformed versions of the default value of AllpassCoefficients, so they define the same stable second-order allpass filter with `Structure` set to `'Wave Digital Filter'`. This property is tunable.

LatticeCoefficients

Lattice allpass coefficients

Specify the real or complex allpass coefficients as lattice reflection coefficients. This property is applicable only if the `Structure` property is set to `Lattice`. The value of this property can be either a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value for this property is [–1.1547, 0.5]. These are the transformed versions of the default value of AllpassCoefficients, so they define the same stable second-order allpass filter when `Structure` is set to `'Lattice'`. This property is tunable.

InitialConditions

Initial values of filter states

Specify the initial values of the internal filter states. The default value of this property is `0`. Acceptable values include numeric

scalar, numeric 1-D or 2-D array, and cell array with as many cells as filter sections. The numeric scalar is used for all filter states, and the numeric 1-D or 2-D array is single-section only. The inner dimensions must match exactly those of the internal filter states.

Methods

clone	Create System object with same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of a System object
step	Process inputs using allpass filter

More “Analysis Methods for Filter System Objects” on page 2-2.

Examples

Using allpass filter to boost frequency component of a random signal

Use a Regalia shelving structure with a first-order allpass filter to boost frequency components of a random signal. This signal is below 10 kHz by 6 dB.

```
Fs = 48000;    % in Hz
wc = 2*pi*10000;
Vo = 2;        % 6 dB
c =  -(2-wc/Fs)/(2+wc/Fs);
hAP = dsp.AllpassFilter('AllpassCoefficients',  c);
hSR = dsp.SignalSource(randn(4096, 1), 128);
hLOG = dsp.SignalSink;
while ~isDone(hSR)
    in = step(hSR);
    shelvedOut = -(1-Vo)/2 * step(hAP, in) + (1+Vo)/2 * in;
```

```
        step(hLOG, [in, shelvedOut]);
    end
    signalTraces = hLOG.Buffer;
    figure
    tfestimate(signalTraces(:,1), signalTraces(:,2),[],[],[],Fs)
```

Algorithms

The transfer function of an allpass filter is defined by:

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + ... + z^{-n}}{1 + c(1)z^{-1} + ... + z^{-n}}$$

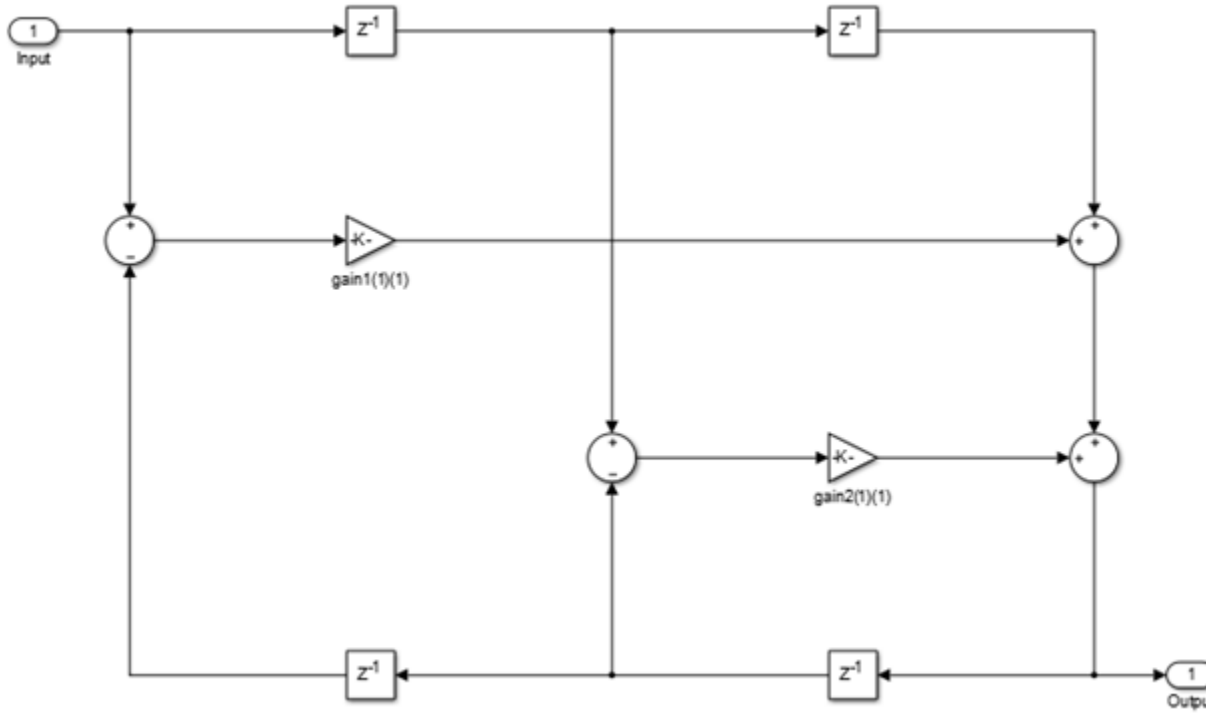
given the nontrivial polynomial coefficients in *c*. The order *n* of the transfer function is given by the length of the vector *c*.

`dsp.AllpassFilter` realizes an allpass filter using three different implementation structures: Minimum multiplier, Wave Digital Filter, and Lattice. These structures differ from generic IIR filters such as df1, df1t, df2, df2t, in that they are computationally more economical and structurally more stable [1]. For all structures, a single instance of `dsp.AllpassFilter` can handle either a single-section or a multiple-section (cascaded) allpass filter. The different sections can have different orders but they are all implemented according to the same structure.

Minimum multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order `n`. It also uses `2n` delay units and `2n` adders. The coefficients used by the multipliers are the same as `AllpassCoefficients`, which are equal to the polynomial vector c in the allpass transfer function. The following code shows an example of a second-order section as a Simulink diagram using basic building blocks. You need a Simulink license to generate the actual diagram using realizemdl.

```
hap = dsp.AllpassFilter('AllpassCoefficients', [0.1, -0.7]);
realizemdl(hap)
```

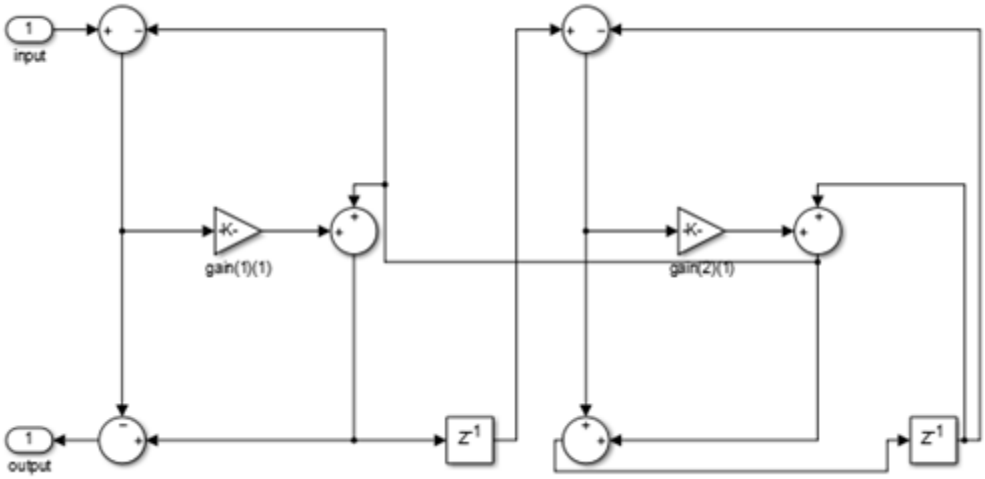


Wave Digital Filter

This structure uses `n` multipliers, but only `n` delay units at the expense of requiring `3n` adders. To use this structure, you must specify the coefficients as `WDFCoefficients` in Wave Digital Filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients such as those in vector `c` in the preceding equation, by using the static method `dsp.AllpassFilter.poly2wdf`. You can also use a similar method, `dsp.AllpassFilter.wdf2poly` to convert given WDF-form coefficients into their equivalent allpass polynomial form. The following code shows an example of a second-order section as a Simulink diagram using basic operation blocks. You need a Simulink license to generate the actual

diagram using realizemdl. Use these coefficients for a functionally equivalent filter to the previous Minimum multiplier example.

```
c = [0.1, -0.7];
w = dsp.AllpassFilter.poly2wdf(c);
hap = dsp.AllpassFilter('Structure', 'Wave Digital Filter', 'WDFCoefficie
realizemdl(hap)
```



The multipliers used in the filter implementation are a transformation of the WDF coefficients previously provided. The implementation structure around each multiplier depends on the actual value of the multiplier and can vary for different filtering stages among five different options. For example notice how in the preceding diagram, the first and the second stages are realized with two different inner structures. For more details refer to [2].

Lattice

This lattice structure uses `2n` multipliers, `n` delay units, and `2n` adders. To use this structure, you must specify the coefficients as `LatticeCoefficients` in Lattice form. Obtain these from the conventional polynomial form of the allpass coefficients by using an

appropriate conversion function, such as `tf2latc`. The following code shows an example of a second-order section as a Simulink diagram using basic operation blocks. You need a Simulink license to generate the actual diagram using realizemdl. Use these coefficients for a functionally equivalent filter to the Minimum multiplier structure.

```
c = [0.1 -0.7];
k = tf2latc([1 c]);
hap = dsp.AllpassFilter('Structure', 'Lattice', 'LatticeCoefficients',
realizemdl(hap)
```

`dsp.BiquadFilter` | `dsp.IIRFilter`

Purpose

Create System object with same property values

Syntax

```
C = clone(OBJ)
```

Description

`C = clone(OBJ)` creates another instance of the System object, `OBJ`, with the same property values. The `clone` method creates a new unlocked object with uninitialized states.

dsp.AllpassFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
L = isLocked(OBJ)
```

Description

`L = isLocked(OBJ)` returns a logical value, `L`, which indicates whether input attributes and nontunable properties are locked for the System object, `OBJ`. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. Once this occurs, the `isLocked` method returns a true value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(OBJ)
```

Description

`release(OBJ)` releases system resources, such as memory, file handles, and hardware connections of the System object, `OBJ`, and allows all its properties and input characteristics to be changed.

Once you call the `release` method on a System object, subsequent calls to `setup`, `step`, `reset`, or `release` are not supported for code generation.

dsp.AllpassFilter.reset

Purpose

Reset internal states of a System object

Syntax

```
reset(OBJ)
```

Description

`reset(OBJ)` resets the internal states of the System object, `OBJ`, to their initial values.

For many System objects, this method is equivalent to no operation being executed. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

Purpose

Process inputs using allpass filter

Syntax

```
Y = step(OBJ,x)
[Y1,...,YN]= step(OBJ,x)
```

Description

`Y = step(OBJ,x)` processes the input data, `x`, to produce the output, `Y`, for the System object, `OBJ`. `[Y1,...,YN]= step(OBJ,x)` produces N outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

dsp.AllpoleFilter

Purpose

IIR Filter with no zeros

Description

The `AllpoleFilter` object filters each channel of the input using Allpole filter implementations.

To filter each channel of the input:

1. Define and set up your Allpole filter. See "Construction" on page 3-42.
2. Call `step` to filter each channel of the input according to the properties of `dsp.AllpoleFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`HAllpole = dsp.AllpoleFilter` returns an Allpole filter System object, `HAllpole`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified Allpole filter implementation, and it supports variable-size input.

`HAllpole = dsp.AllpoleFilter('PropertyName',PropertyValue, ...)` returns an Allpole filter System object, `HAllpole`, with each property set to the specified value.

Properties

Structure

Filter structure

Specify the filter structure.

You can specify the filter structure as one of `| Direct form | Direct form transposed | Lattice AR`. The default is `Direct form`. Analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`. This property is nontunable.

Denominator

Filter denominator coefficients

Specify the denominator coefficients as a real or complex numeric row vector. This property is applicable when the Structure property is set to one of `Direct form` | `Direct form transposed`. The default value of this property is `[1 0.1]`. This property is tunable.

ReflectionCoefficients

Lattice filter coefficients

Specify the lattice filter coefficients as a real or complex numeric row vector. This property is applicable when the Structure property is set to `Lattice AR`. The default value of this property is `[0.2 0.4]`. This property is tunable.

InitialConditions

Initial conditions for the filter states

Specify the initial conditions of the filter states. The default value is `0`.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property is tunable.

FrameBasedProcessing

Process input as frames or as samples

Set this property to `true` to enable frame-based processing. When this property is `true`, the Allpole filter treats each column as an independent channel. Set this property to `false` to enable sample-based processing. When this property is `false`, the Allpole filter treats each element of the input as an individual channel. The default is `true`. This property is nontunable.

CoefficientsDataType

Denominator coefficients word- and fraction-length designations

Specify the denominator coefficients fixed-point data type as one of `Same word length as input | Custom`. The default is `Same word length as input`. This property is nontunable.

ReflectionCoefficientsDataType

Reflection coefficients word- and fraction-length designations

Specify the reflection coefficients fixed-point data type as one of `Same word length as input | Custom`. The default is `Same word length as input`. This property is nontunable.

Fixed-Point Properties

ProductDataType

Product word- and fraction-length designations

Specify the product fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Full precision`. This property is nontunable.

AccumulatorDataType

Accumulator word- and fraction-length designations

Specify the accumulator fixed-point data type to one of `| Full precision | Same as input | Same as product | Custom |`. The default is `Full precision`. This property is nontunable.

OutputDataType

Output word- and fraction-length designations

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as input` | `Custom` |. The default is `Same as input`. This property is nontunable.

StateDataType

State word- and fraction-length designations

Specify the state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom`. The default is `Same as accumulator`. This property is nontunable.

CustomCoefficientsDataType

Custom denominator word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numerictype object. This property is applicable when the `CoefficientsDataType` property is `Custom`. The default value of this property is numerictype ([],16,15). This property is nontunable.

CustomReflectionCoefficientsDataType

Custom reflection coefficients word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numerictype object. This property is applicable when the `ReflectionCoefficientsDataType` property is `Custom`. The default value of this property is numerictype ([],16,15). This property is nontunable.

CustomProductDataType

Custom Product word- and fraction-lengths

Specify the product fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype ([],32,30)`. This property is nontunable.

CustomAccumulatorDataType

Custom accumulator word- and fraction-lengths

Specify the accumulator fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`. This property is nontunable.

CustomStateDataType

Custom state word- and fraction-lengths

Specify the state fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `StateDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

CustomOutputDataType

Custom output word- and fraction-lengths

Specify the output fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

Methods

clone	Create Allpole filter with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response

release	Allow property value and input characteristics changes
reset	Reset internal states of Allpole filter
step	Filter input with Allpole filter object

More “Analysis Methods for Filter System Objects” on page 2-2.

Note In AllpoleFilter, analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`.

Examples

Lowpass filtering a waveform with two frequencies

Use an Allpole filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

```
t = [0:1000]./8e3;
xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t);

hSR = dsp.SignalSource(xin', 4);
hLog = dsp.SignalSink;
hallpole = dsp.AllpoleFilter;
tt = (-25:25)';
xsinc = 0.4*sinc(0.4*tt);
asinc = lpc(xsinc,51);
hallpole.Denominator = asinc;

h = dsp.SpectrumAnalyzer('SampleRate',8e3,...
   'PlotAsTwoSidedSpectrum',false,...
   'OverlapPercent', 80,'PowerUnits','dBW',...
   'YLimits', [-150 50]);
```

```
while ~isDone(hSR)
      input = step(hSR);
      filteredOutput = step(hallpole,input);
      step(hLog,filteredOutput);
      step(h,filteredOutput)
 end

 filteredResult = hLog.Buffer;
 fvtool(hallpole,'Fs',8000)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Allpole Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.BiquadFilter` | `dsp.FIRFilter` | `dsp.IIRFilter`

dsp.AllpoleFilter.clone

Purpose

Create Allpole filter with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a Allpole filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Frequency response

Syntax

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

dsp.AllpoleFilter.fvtool

Purpose

Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description

`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.AllpoleFilter.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description

`[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

dsp.AllpoleFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the Allpole filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Unwrapped phase response

Syntax

```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

dsp.AllpoleFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of Allpole filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the Allpole filter object, `H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the Allpole filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

For example:

```
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
H = dsp.AllpoleFilter;
a = lpc(x,20);
H.Denominator = a;
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

dsp.AllpoleFilter.step

Purpose

Filter input with Allpole filter object

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` filters the real or complex input signal `X` using the Allpole filter, `H`, to produce the output `Y` . When the input data is of a fixed-point type, it must be signed. The Allpole filter object operates on each channel of the input signal independently over successive calls to step method.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Analytic signals of discrete-time inputs

Description

The `AnalyticSignal` object computes analytic signals of discrete-time inputs. The real part of the analytic signal in each channel is a replica of the real input in that channel, and the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component. The object computes the Hilbert transform using an equiripple FIR filter.

To compute the analytic signal of a discrete-time input:

1. Define and set up your analytic signal calculation. See "Construction" on page 3-63.
2. Call `step` to compute the analytic signal according to the properties of `dsp.AnalyticSignal`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.AnalyticSignal` returns an analytic signal object, `H`, that computes the complex analytic signal corresponding to each channel of a real *M*-by-*N* input matrix.

`H = dsp.AnalyticSignal('PropertyName',PropertyValue,...)` returns an analytic signal object, `H`, with each specified property set to the specified value.

`H = dsp.AnalyticSignal(order,'PropertyName',PropertyValue,...)` returns an analytic signal object, `H`, with the `FilterOrder` property set to `order` and other specified properties set to the specified values.

Properties

FilterOrder

Filter order used to compute Hilbert transform

Specify the order of the equiripple FIR filter used in computing the Hilbert transform as an even integer scalar. The default is `100`.

FrameBasedProcessing

Process input as frames or samples

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Methods

clone	Create analytic signal object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of analytic signal object
step	Analytic signal

Examples

Compute the analytic signal of a sinusoidal input.

```
t = (-1:0.01:1)';
x = sin(4*pi*t);
hanlytc = dsp.AnalyticSignal(200);
y = step(hanlytc,x);

subplot(2,1,1), plot(t, x);
title('Original Signal');
subplot(2,1,2), plot(t, [real(y) imag(y)]);
title('Analytic signal of the input')
legend('Real signal','Imaginary signal',...
   'Location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Analytic Signal block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.FFT` | `dsp.IFFT`

dsp.AnalyticSignal.clone

Purpose

Create analytic signal object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `AnalyticSignal` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.AnalyticSignal.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `AnalyticSignal` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.AnalyticSignal.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of analytic signal object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `AnalyticSignal` object `H` to their initial values.

dsp.AnalyticSignal.step

Purpose

Analytic signal

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` computes the analytic signal, `Y`, of the *M*-by-*N* input matrix `X`, according to the equation

$$\mathbf{Y} = \mathbf{X} + jH\{\mathbf{X}\}$$

where j is the imaginary unit and $H\{\mathbf{X}\}$ denotes the Hilbert transform.

When you set the `FrameBasedProcessing` property to `false`, each of the *M*-by-*N* matrix elements is an independent channel. Thus, the method computes the analytic signal for each element of `X`. When you set the `FrameBasedProcessing` property to `true`, each of the *N* columns in `X` contains *M* sequential time samples from an independent channel. The method computes the analytic signal for each channel.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Display vectors or arrays

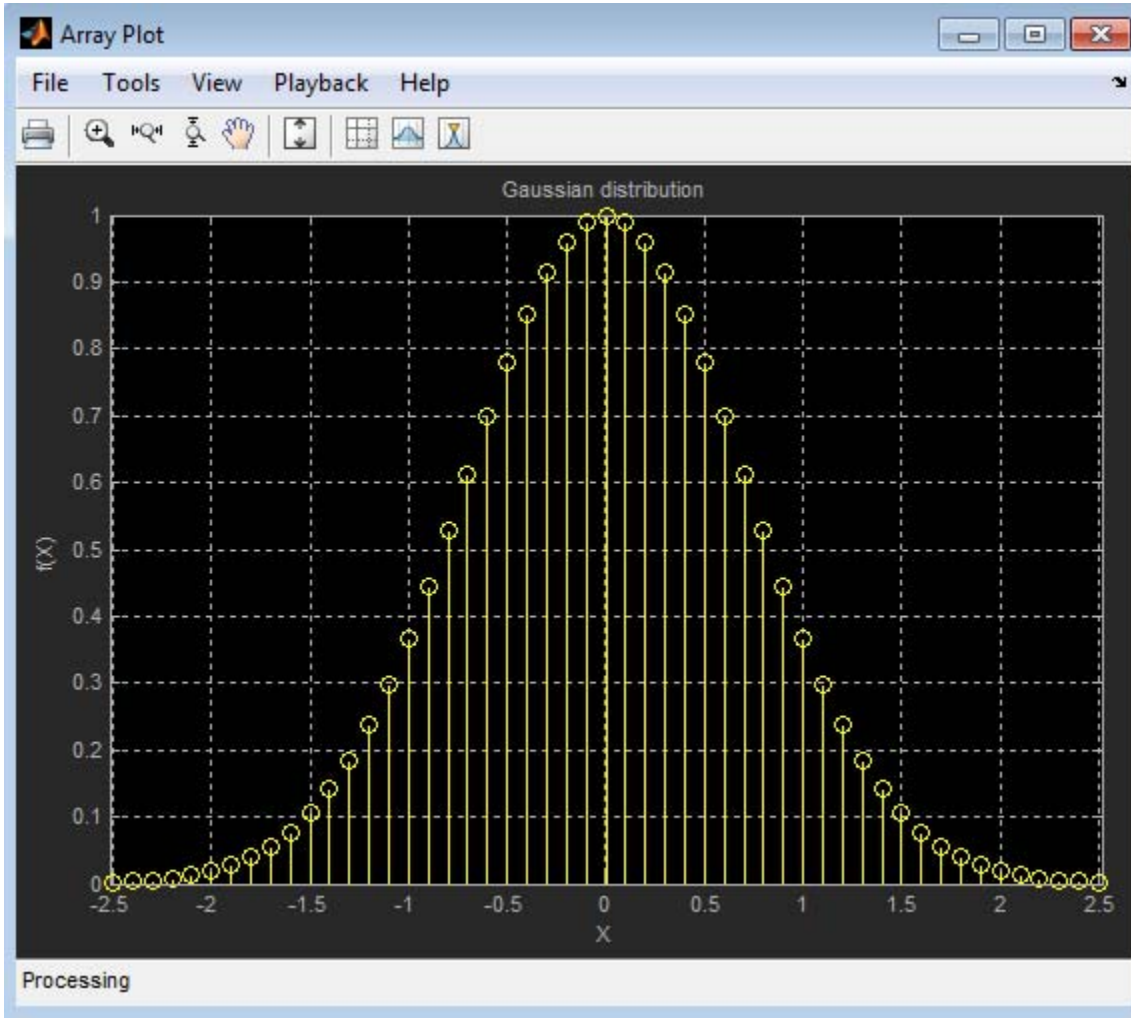
Description

The `ArrayPlot` object displays vectors or arrays.

To display vectors or array in Array Plot:

1. Define and set up your Array Plot. See "Construction" on page 3-75.
2. Call `step` to display the vectors or arrays in the Array Plot figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Array Plot figure window and clear its associated data. Use the `hide` method to hide the ArrayPlot window and the `show` method to make it visible.



See the following sections for more information on the Array Plot Graphical User Interface:

- “Signal Display” on page 3-83

Construction

`H = dsp.ArrayPlot` creates an Array PlotSystem object, `H`. This object displays vectors or arrays.

`H = dsp.ArrayPlot('Name',Value,...)` creates an Array Plot System object, `H`, with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Properties

MaximizeAxes

Maximize axes control

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in the display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized only if the `Title` and `YLabel` properties are empty. If you enter any value for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable.

Default: `'Auto'`

Name

Caption to display on Scope window

Specify as a string the caption to display on the scope window. This property is Tunable.

Default: `'Array Plot'`

NumInputPorts

Number of input signals

Specify the number of input signals to display on the scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

Default: `1`

PlotAsMagnitudePhase

Plot signal as Magnitude-and-Phase

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes. This property is particularly useful for complex-valued input signals. When the input signal is real-valued and you select this check box, the phase will be 0 degrees when the amplitude of the input signal is nonnegative and 180 degrees when the input signal is negative. This property is Tunable.

Default: `false`

PlotType

Option to control the type of plot

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to `'Stem'` , the scope displays the input signal as circles with vertical lines extending down to the *x*-axis at each of the sampled values . This approach is similar to the functionality of the MATLAB `stem` function.
- When you set this property to `'Line'` , the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- When you set this property to `'Stairs'`, the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable.

Default: `'Stem'`

Position

Scope window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable.

Default: The default depends on your screen resolution. By default, the Scope window appears in the center of your screen with a width of `410` pixels and height of `300` pixels.

ReduceUpdates

Reduce updates to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time the `step` method is called. The simulation speed is faster when this property is set to `true`. This property is Tunable.

You can also modify this property from the scope window. Opening the **Playback** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to `false`.

Default: `true`

ShowGrid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable.

Default: `true`

ShowLegend

Source of legend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set this property to `false`, the scope does not display a legend. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. This property is Tunable.

Default: `false`

SampleIncrement

Sample increment of input

Specify the spacing between samples along the *x*-axis as a finite numeric scalar.

Default: `1`

Title

Display title

Specify the display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is Tunable.

Default: `''`

XLabel

The label for the *x*-axis

Specify as a string the text for the scope to display below the *x*-axis. This property is Tunable.

Default: `''`

XOffset

x-axis display offset

Specify the offset to apply to the *x*-axis. This property is a numeric scalar. This property is Tunable.

Default: `0`

YLabel

The label for the *y*-axis

Specify as a string the text for the scope to display to the left of the *y*-axis. Tunable

Default: `'Amplitude'`

YLimits

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is Tunable.

Default: `[-10, 10]`

Methods

clone	Create scope object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
hide	Hide scope window
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of scope object
show	Make scope window visible
step	Display signal in scope figure

Examples

The following examples illustrate how to use the Array Plot object to view a variety of input signals.

Example: Plot a Gaussian Distribution

View a *Gaussian*, or normal, distribution on the Array Plot figure.

Create a new Array Plot object.

```
h=dsp.ArrayPlot;
```

Configure the properties of the Array Plot object for a Gaussian distribution.

```
h.YLimits = [0 1];
h.XOffset = -2.5;
h.SampleIncrement = 0.1;
h.Title = 'Gaussian distribution';
h.XLabel = 'X'
h.YLabel = 'f(X)'
```

Call the `step` method to plot a Gaussian distribution.

```
step(h, exp(-[-2.5:.1:2.5].*[-2.5:.1:2.5])');
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h);
```

Run the MATLAB `clear` function to close the scope window.

```
clear('h');
```

Example: Plot Changing Filter Weights

View Least Mean Squares (LMS) adaptive filter weights on the Array Plot figure. Watch the filter weights change as they adapt to filter a noisy input signal.

Create an LMS adaptive filter System object.

```
hlms = dsp.LMSFilter(40,'Method', 'Normalized LMS', 'StepSize', .002);
```

Create and configure an audio file reader System object to read the input signal from the specified audio file.

```
hsigsource = dsp.AudioFileReader('dspafxf_8000.wav',  ...
    'SamplesPerFrame', 40, ...
    'PlayCount', Inf,...
```

```
    'OutputDataType', 'double');
```

Create and configure a fixed-point Finite Impulse Response (FIR) digital filter System object to filter random white noise, creating colored noise.

```
hfilt = dsp.FIRFilter('Numerator', fir1(39, .25));
```

Create and configure an Array Plot System object to display the adaptive filter weights.

```
harrayplot = dsp.ArrayPlot('XLabel', 'Filter Tap', ...
    'YLabel', 'Filter Weight', ...
    'YLimits', [-.05 .2]');
```

Plot the LMS filter weights as they adapt to a desired signal. Read from the audio file, produce random data, and filter the random data. Call the `step` method to update the filter weights and plot the filter weights after each step.

```
numplays = 0;
while numplays < 3
    [y, eof]    = step(hsigsource);
    noise       = rand(40,1);
    noisefilt   = step(hfilt, noise);
    desired     = y + noisefilt;
    [~, ~, wts] = step(hlms, noise, desired);
    step(harrayplot, wts);
    numplays = numplays + eof;
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(harrayplot);
```

Run the MATLAB `clear` function to close the scope window.

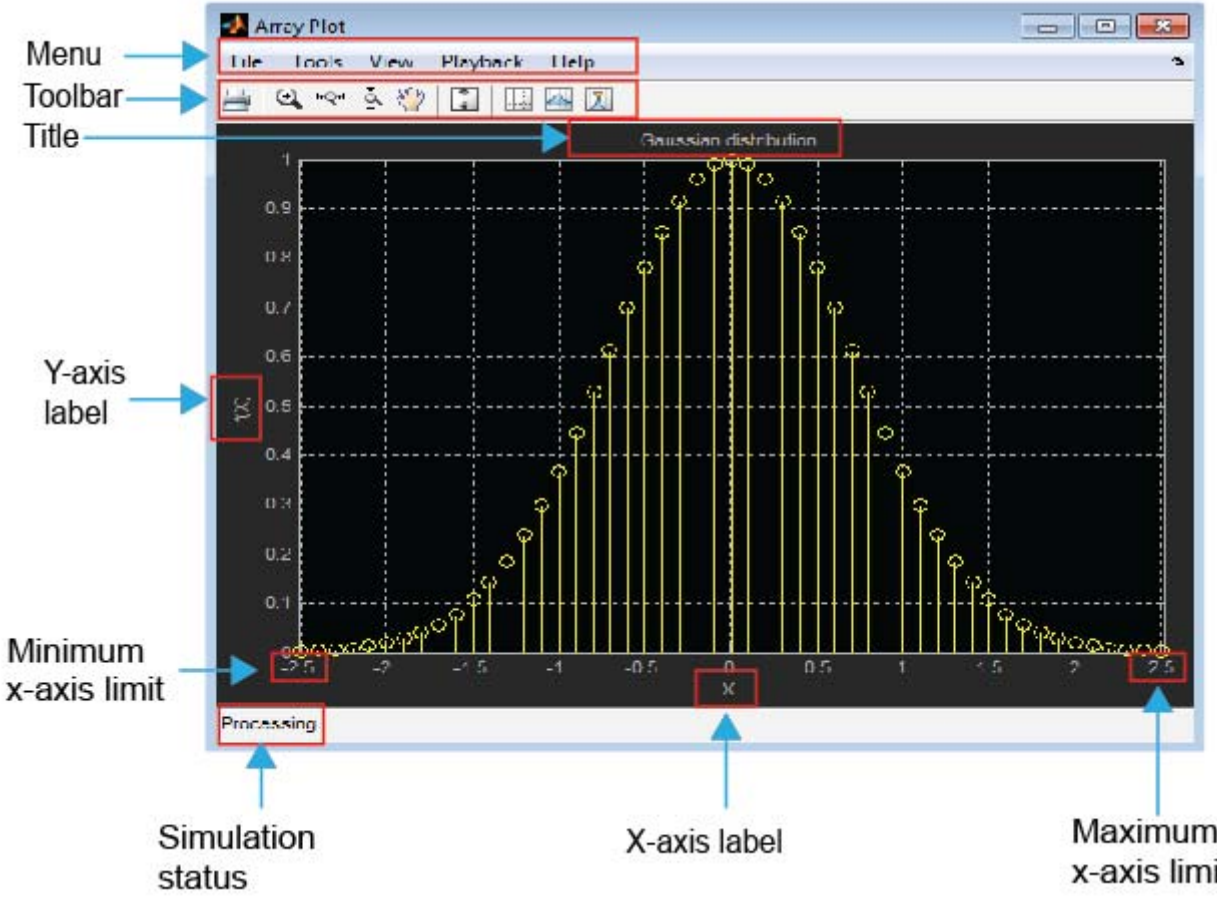
```
clear('harrayplot');
```

Signal Display

Array Plot uses the `XOffset` and `SampleIncrement` properties to determine the time range. To change the **X-offset** setting in the Array Plot figure, select **View > Configuration Properties**. The Visuals — Array Plot Properties dialog box appears. Go to the **Main** tab, and modify the value for the **X-offset**.

The span of the *x*-axis data is related to the `SampleIncrement` property by the equation $x_{span} = \texttt{SampleIncrement} \times (\text{length}(x) - 1)$. Suppose you set `SampleIncrement` to `0.1` and the input signal data has 51 samples. The scope displays values on the *x*-axis from `0` to `5`. If you also set the **X-offset** to `2.5`, the scope displays values on the *x*-axis from `2.5` to `2.5`. The values on the *x*-axis of the scope display remain the same throughout simulation.

The following figure highlights the important aspects of the Array Plot window.



Indicators

- **Minimum *x*-axis limit** — Array Plot sets the minimum *x*-axis limit using the value of the **X-offset** parameter on the **Main** tab of the Visuals—Array Plot Properties dialog box.
- **Maximum *x*-axis limit** — Array Plot sets the maximum *x*-axis limit by summing the value of **X-offset** parameter with the span of *x*-axis

values. The equation $x_{span} = \texttt{SampleIncrement} \times (\text{length}(x) - 1)$ defines the relationship of the span of the x-axis data to the `SampleIncrement` property.

- **Simulation status** — Provides the current status of the model simulation. The status can be either of the following conditions:
  - `Processing` — Occurs after you run the `step` method and before you run the `release` method.
  - `Stopped` — Occurs after you construct the scope object and before you first run the `step` method. This status also occurs after you run the `release` method.

  The **Simulation status** is part of the **Status Bar** in the scope window. You can choose to hide or display the entire **Status Bar**. From the scope menu, select **View > Status Bar**.

Multiple Signal Names and Colors

By default, if the input signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal would have the following default names in the channel legend: `Channel 1`, `Channel 2`. To show the legend, select **View > Configuration Properties**, click the **Display** tab, and select the **Show Legend** check box. If there are a total of 7 input channels, the following legend appears in the display.

By default, the scope has a black axes background and chooses line colors for each channel in a manner similar to the Simulink Scope block.

When the scope axes background is black, it assigns each channel of each input signal a line color in the order shown in the above figure.

If there are more than 7 channels, then the scope repeats this order to assign line colors to the remaining channels. To choose line colors for each channel, change the axes background color to any color except black. To change the axes background color to white, select

View > Style, click the Axes background color button ( ), and select white from the color palette. Run the simulation again. The following legend appears in the display. This is the color order when the background is not black.

Toolbar

The Array Plot toolbar contains the following buttons.

Print, Settings, and Properties Buttons

Button	Menu Location	Shortcut Keys	Description
	**File > Print**	**Ctrl+P**	Print the current scope window. To print the current scope window to a figure rather than sending it to your printer, select **File > Print to figure**.

Zoom and Axes Control Buttons

Button	Menu Location	Shortcut Keys	Description
	**Tools > Zoom In**	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.
	**Tools > Zoom X**	N/A	You access the Zoom X button from the menu under the Zoom In icon. When this tool is active, you can zoom in on the *x*-axis. To do so, click inside the scope window, or click and drag your cursor along the *x*-axis over your area of interest.
	**Tools > Zoom Y**	N/A	You access the Zoom Y button from the menu under the Zoom In icon. When this tool is active, you can zoom in on the *y*-axis. To do so, click inside the scope window, or click and drag your cursor along the *y*-axis over your area of interest.

Button	Menu Location	Shortcut Keys	Description
	**Tools > Pan**	N/A	You access the Pan button from the menu under the Zoom In icon. When this tool is active, you can pan on the scope window. To do so, click in the center of your area of interest and drag your cursor to the left, right, up, or down, to move the position of the display.
	**Tools > Scale Y-Axes Limits**	**Ctrl+A**	Click this button to scale the axes in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Button	Menu Location	Shortcut Keys	Description
	**Tools > Scale X-Axis Limits**	N/A	You access the Scale X-Axis Limits button from the menu under the current Axis Limits icon. Click this button to scale the axes in the X direction in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.
	**Tools > Scale X and Y Axes Limits**	N/A	You access the Scale X and Y Axis Limits button from the menu under the current Axis Limits icon. Click this button to scale the axes in both the X and Y directions in the active scope window. Alternatively, you can enable automatic axes scaling by selecting

Button	Menu Location	Shortcut Keys	Description
			one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Measurements Buttons

	**Tools > Measurements > Cursor Measurements**	N/A	Open or close the **Cursor Measurements** panel. This panel puts screen cursors on the display. See the "Cursor Measurements Panel" on page 3-93 section for more information.
	**Tools > Measurements > Signal Statistics**	N/A	Open or close the **Signal Statistics** panel. This panel displays the maximum, minimum, peak-to-peak difference, mean, median, RMS values of a selected signal, and the times at

			which the maximum and minimum occur. See the "Signal Statistics Panel" on page 3-95 section for more information.
	**Tools > Measurements > Peak Finder**	Y/A	Open or close the **Peak Finder** panel. This panel displays maxima and the frequencies at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. See the "Peak Finder Panel" on page 3-1566 section for more information.

Note The zoom buttons do not change the settings related to span for the scope. These buttons are purely graphical.

You can control whether this toolbar appears in the Array Plot window. From the menu, select **View > Toolbar**.

Measurements Panels

The Measurements panels are the panels that appear to the right side of the Array Plot figure. These panels are labeled **Trace selection**, **Cursor Measurements**, **Signal Statistics**, and **Peak Finder**.

Measurements Panel Buttons

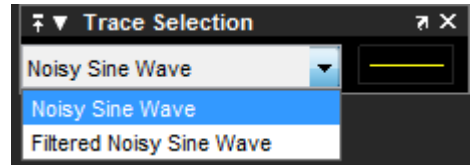
Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

Button	Description
	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button  .
	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button  again.
	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button  in the new window.
	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button  again.
	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button  to show each pane that is hidden in the current panel. Click the pane collapse button  to hide each pane that is shown in the current panel.

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.

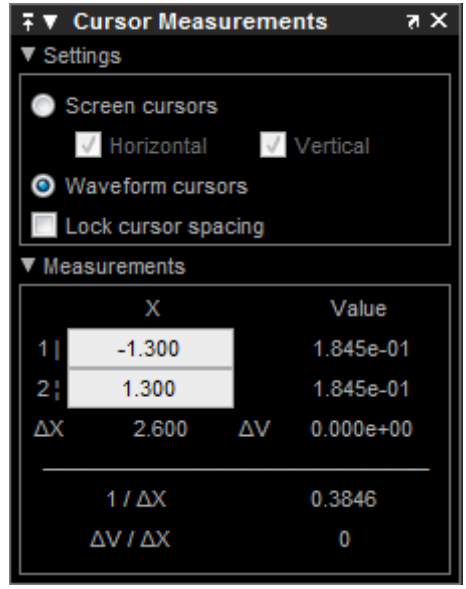


You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. You can choose to hide or display the **Cursor Measurements** panel. In the scope menu, select **Tools > Measurements > Cursor Measurements**.

Alternatively, in the scope toolbar, click the Cursor Measurements  button.



The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used to calculate *x*-axis and *y*-axis value measurements.

- **Screen Cursors**— Shows screen cursors.
- **Horizontal**— Shows horizontal screen cursors.
- **Vertical**— Shows vertical screen cursors.
- **Waveform Cursors**— Shows cursors that attach to the input signals.

- **Lock Cursor Spacing**— Locks the time difference between the two cursors.

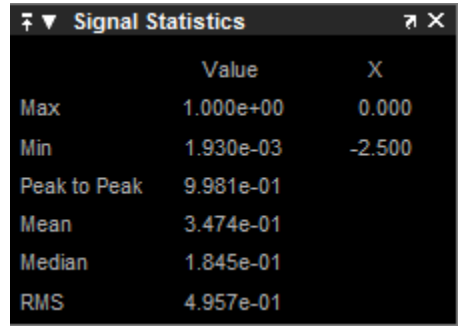
Measurements Pane

The **Measurements** pane shows the time and value measurements.

- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.
- **ΔX**— Shows the absolute value of the difference in the*x*-axis values between cursor number one and cursor number two.
- **ΔV**— Shows the absolute value of the difference in the *y*-axis values, or signal amplitudes, between cursor number one and cursor number two.
- **1/ΔX**— Shows the rate, the reciprocal of the absolute value of the difference in the *x*-axis values between cursor number one and cursor number two.
- **ΔV/ΔX**— Shows the slope, the ratio of the absolute value of the difference in the *y*-axis values between cursors to the absolute value of the difference in the *x*-axis values between cursors.

Signal Statistics Panel

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the *x*-axis indices at which the maximum and minimum values occur. You can choose to hide or display the **Signal Statistics** panel. In the scope menu, select **Tools > Measurements > Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics  button.



Signal Statistics Measurements

The **Signal Statistics** panel shows statistics about the portion of the input signal within the *x*-axis and *y*-axis limits of the active display. The statistics shown are:

- **Max** — Shows the maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.
- **Min** — Shows the minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** — Shows the average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — Shows the median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.

- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

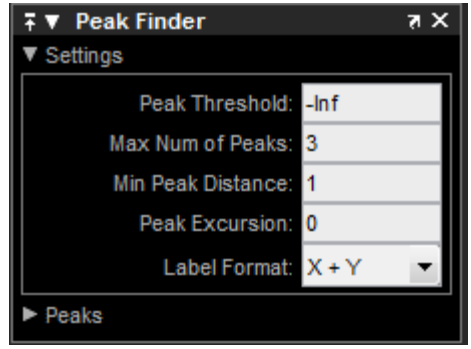
The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts. The SI prefixes are shown in the following table:

Abbreviation	Name	Multiplier
a	atto	10^-18
f	femto	10^-15
p	pico	10^–12
n	nano	10^-9
u	micro	10^-6
m	milli	10^-3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12

Abbreviation	Name	Multiplier
P	peta	10^15
E	exa	10^18

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder button.

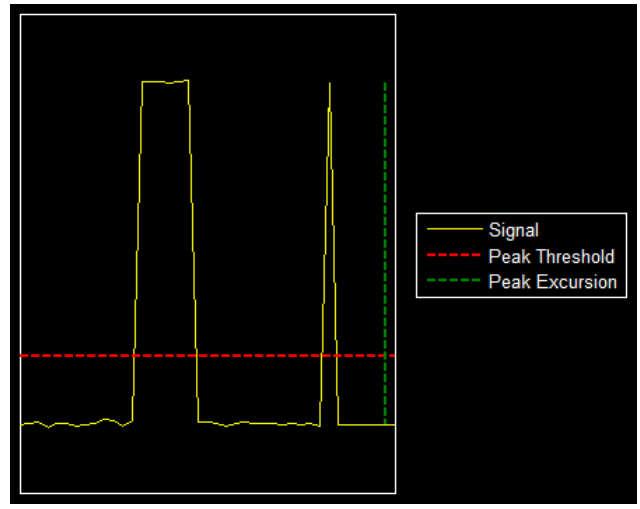


The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer between 1 and 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.



The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than

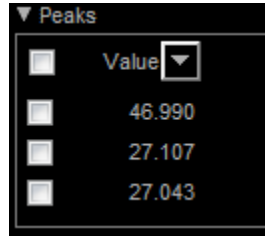
the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are

similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button () to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled (), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Abbreviation	Name	Multiplier
a	atto	10^–18
f	femto	10^–15
p	pico	10^–12

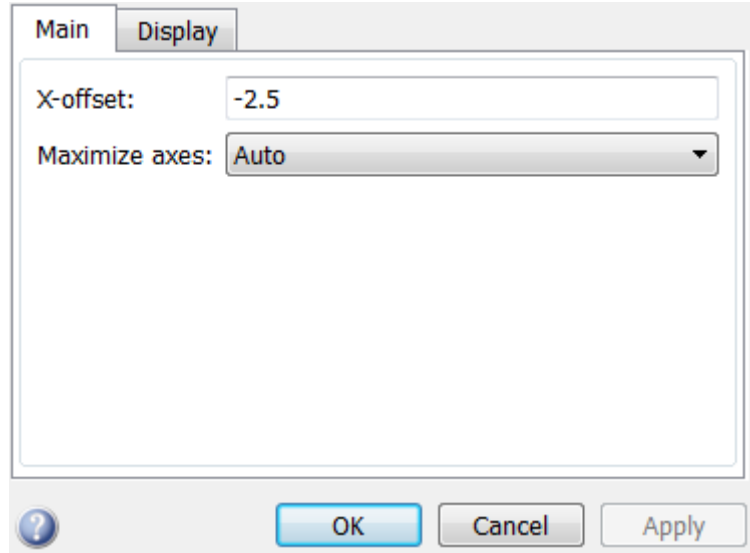
Abbreviation	Name	Multiplier
n	nano	10^–9
u	micro	10^–6
m	milli	10^–3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12
P	peta	10^15
E	exa	10^18

Visuals — Array Plot Properties

The Visuals—Array Plot Properties dialog box controls various properties about the Array Plot display. From the Array Plot menu, select **View > Configuration Properties** to open this dialog box.

Main Pane

The **Main** pane of the Visuals—Array Plot Properties dialog box appears as follows.



X-offset

Specify the offset to apply to the *x*-axis. This property is a numeric scalar. This property is Tunable.

Maximize axes

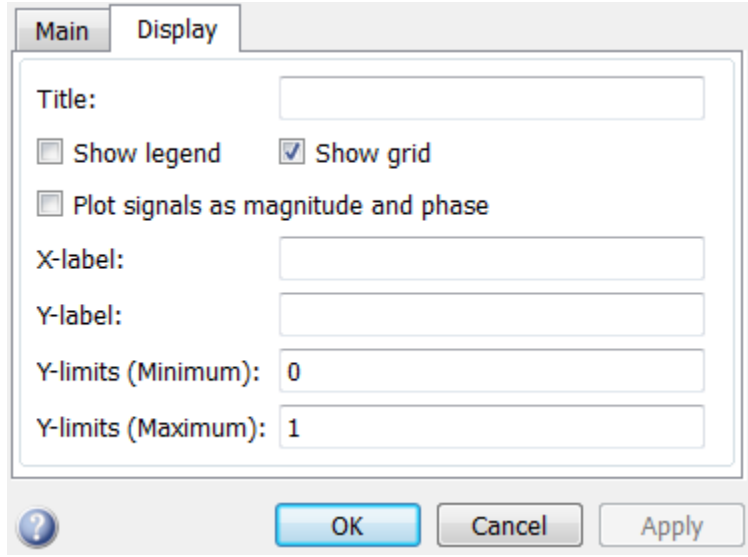
Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in the display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized only if the `Title` and `YLabel` properties are empty. If you enter any value for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable.

Display Pane

The **Display** pane of the Visuals—Array Plot Properties dialog box appears as follows.



Title

Specify the display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is Tunable.

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. Tunable

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, if the signal has multiple channels, the scope uses an index

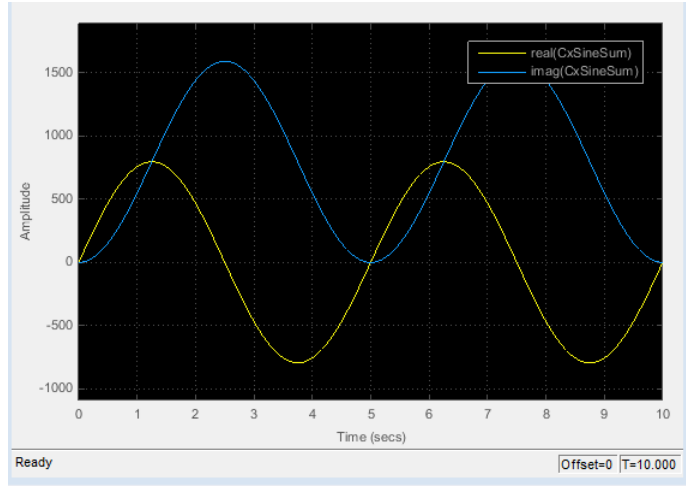
number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View > Style**.

Show grid

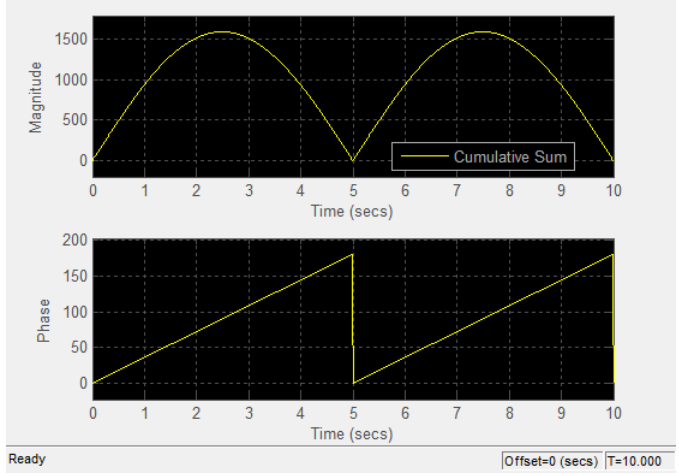
When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable

Plot signals as magnitude and phase

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal is complex valued, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.



Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.



This feature is particularly useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude. The phase is 0 degrees for nonnegative input and 180 degrees for negative input. Tunable

X-label

Specify as a string the text for the scope to display below the *x*-axis. This property is Tunable.

Y-label

Specify as a string the text for the scope to display to the left of the *y*-axis. Tunable

Y-limits (Minimum)

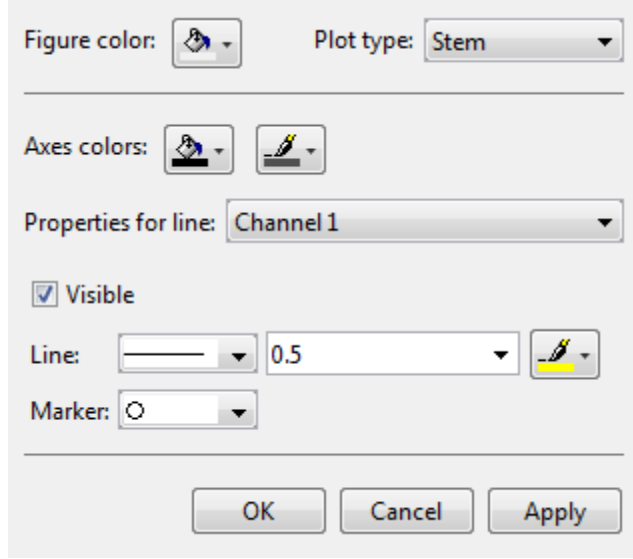
Specify the minimum value of the *y*-axis. Tunable

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. Tunable

Style Dialog Box

In the **Style** dialog box, you can customize the style of displays. You are able to change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. From the scope menu, select **View > Style** to open this dialog box.



Properties

The **Style** dialog box allows you to modify the following properties of the scope figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Plot type

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to `'Stem'` , the scope displays the input signal as circles with vertical lines extending down to the *x*-axis at each of the sampled values . This approach is similar to the functionality of the MATLAB `stem` function.
- When you set this property to `'Line'` , the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.

- When you set this property to `'Stairs'`, the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable.

The default setting is `Stem`.

Axes colors

Specify the color that you want to apply to the background of the axes.

Properties for line

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected channel.

Marker

Specify marks for the selected channel to show at its data points. This parameter is similar to the `Marker` property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

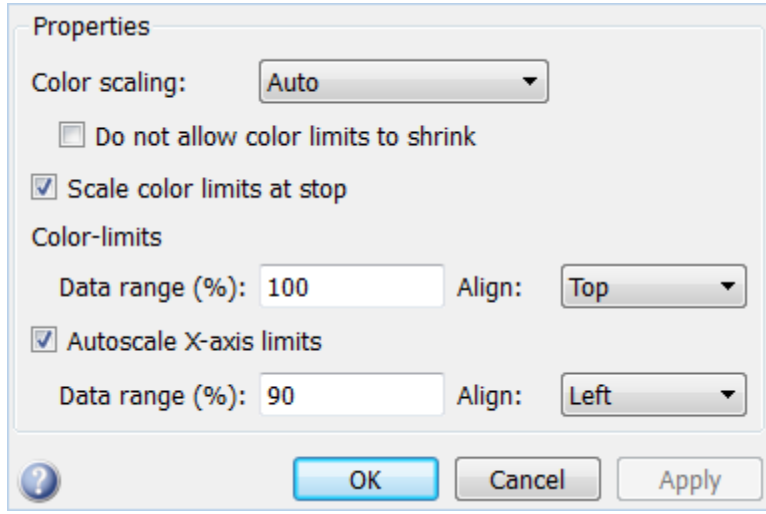
Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
✶	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
✡	Six-pointed star (hexagram)

Tools — Plot Navigation Properties

The Tools—Plot Navigation Properties dialog box allows you to automatically zoom in on and zoom out of your data. You can also scale the axes of the scope. In the scope menu, select **Tools > Axes Scaling Properties** to open this dialog box.

Properties

The Tools—Plot Navigation Properties dialog box appears as follows.



Axes Scaling

Specify when the scope should automatically scale the axes. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools > Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.

- `Auto` — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Selecting this option causes the scope to scale the axes after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to `Auto`. This property is Tunable.

By default, this parameter is set to `Manual`.

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. Tunable.

Number of updates

Specify as a positive integer the number of updates after which to scale the axes, or for the spectrogram, the color. This property appears only when you select `After N Updates` for the **Axes scaling** or **Color scaling** property. Tunable.

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%)

Set the percentage of the *y*-axis that the scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable.

Y-axis Align

Specify where the scope should align your data with respect to the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. Tunable.

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Scale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. Tunable.

X-axis Align

Specify how the Scope should align your data with respect to the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable.

See Also

`dsp.TimeScope` | `dsp.SpectrumAnalyzer` | `dsp.LogicAnalyzer`

Purpose

Create scope object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a scope object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.ArrayPlot.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method. `N` equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method. The scope is a sink object, so `N` equals 0.

dsp.ArrayPlot.hide

Purpose Hide scope window

Syntax `hide(H)`

Description `hide(H)` hides the scope window associated with System object, `H`.

See Also `dsp.ArrayPlot.show`

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the scope object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.ArrayPlot.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the scope figure window. After calling the `release` method, any non-tunable properties can be set once again.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Algorithms

In operation, the `release` method is similar to the `mdlTerminate` function.

See Also

`dsp.ArrayPlot.reset`

Purpose

Reset internal states of scope object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the scope object `H` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

Algorithms

In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

See Also

`dsp.ArrayPlot` | `dsp.ArrayPlot.release`

dsp.ArrayPlot.show

Purpose

Make scope window visible

Syntax

```
show(H)
```

Description

`show(H)` makes the scope window associated with System object, `H`, visible.

See Also

`dsp.ArrayPlot.hide`

Purpose

Display signal in scope figure

Syntax

```
step(H,X)
step(H,X1,X2,...,XN)
```

Description

`step(H,X)` displays the signal, `X`, in the scope figure.

`step(H,X1,X2,...,XN)` displays the signals `X1`, `X2`,...,`XN` in the scope figure when you set the `NumInputPorts` property to `N`. In this case, `X1`, `X2`,...,`XN` can have different data types.

dsp.ArrayVectorAdder

Purpose

Add array to vector along specified dimension

Description

The `ArrayVectorAdder` object adds an N-D array to a vector along a specified dimension. The length of the vector must equal the size of the N-D array along the specified dimension.

To add an N-D array to a vector along a specified dimension:

1. Define and set up your array-vector addition object. See "Construction" on page 3-122.
2. Call `step` to add the N-D array according to the properties of `dsp.ArrayVectorAdder`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.ArrayVectorAdder` returns an array-vector addition object, `H`, that adds a vector to an N-D array along the first dimension.

`H = dsp.ArrayVectorAdder('PropertyName',PropertyValue, ...)` returns an array-vector addition object, `H`, with each property set to the specified value.

Properties

Dimension

Dimension along which to add vector elements to input

Specify the dimension along which to add the input array to the elements of the vector as a positive integer. The length of the vector must match the size of the N-D array along the specified dimension. The default is `1`.

VectorSource

Source of vector

Specify the source of the vector values as `|Input port|Property|`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies only when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `| Full precision | Same as first input | Custom |`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `| Same as accumulator | Same as first input | Custom |`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create array-vector adder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Add vector to N-D array

Examples

Add 2-by-1 vector to 2-by-2 matrix along the first dimension of the array.

```
hava = dsp.ArrayVectorAdder;
a = ones(2);
x = [1 2]';
y = step(hava, a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Add block reference page. The object properties correspond to the block parameters, except:

The array-vector addition object does not have **Minimum** or **Maximum** options for data output.

See Also

`dsp.ArrayVectorMultiplier` | `dsp.ArrayVectorDivider` | `dsp.ArrayVectorSubtractor`

dsp.ArrayVectorAdder.clone

Purpose

Create array-vector adder object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an array-vector adder object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.ArrayVectorAdder.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the array-vector adder.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.ArrayVectorAdder.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Add vector to N-D array

Syntax

```
Y = step(H,A)
Y = step(H,A,V)
```

Description

`Y = step(H,A)` returns `Y` , the result of adding the input array `A` to the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

`Y = step(H,A,V)` returns `Y` , the result of adding the input array `A` to the elements of the input vector `V` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.ArrayVectorDivider

Purpose

Divide array by vector along specified dimension

Description

The `ArrayVectorDivider` object divides an array by a vector along a specified dimension.

To divide an array by a vector along a specified dimension:

1. Define and set up your array-vector division object. See "Construction" on page 3-132.
2. Call `step` to divide the array according to the properties of `dsp.ArrayVectorDivider`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.ArrayVectorDivider` returns an array-vector division object, `H`, that divides an input array by the elements of a vector along the first dimension of the array.

`H = dsp.ArrayVectorDivider('PropertyName',PropertyValue,...)` returns an array-vector division object, `H`, with each property set to the specified value.

Properties

Dimension

Dimension along which to divide input by vector elements

Specify the dimension along which to divide the input array by the elements of a vector as a positive integer. The default is `1`.

VectorSource

Source of vector

Specify the source of the vector values as `| Input port | Property |`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point mode as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `| Same as first input | Custom |`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create array-vector division object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Divide array by vector

Examples

Divide a matrix by a vector.

```
havd = dsp.ArrayVectorDivider;
a = ones(2);
x = [2 3]';
y = step(havd, a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Divide block reference page. The object properties correspond to the block parameters, except:

The array-vector division object does not have **Minimum** or **Maximum** options for data output.

See Also

`dsp.ArrayVectorMultiplier` | `dsp.ArrayVectorAdder` | `dsp.ArrayVectorSubtractor`

dsp.ArrayVectorDivider.clone

Purpose

Create array-vector division object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an array-vector division object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.ArrayVectorDivider.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the array-vector divider.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.ArrayVectorDivider.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Divide array by vector

Syntax

```
Y = step(H,A,V)
Y = step(H,A)
```

Description

`Y = step(H,A,V)` returns `Y` , the result of dividing the input array `A` by the elements of input vector `V` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

`Y = step(H,A)` returns `Y` , the result of dividing the input array `A` by the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.ArrayVectorMultiplier

Purpose

Multiply array by vector along specified dimension

Description

The `ArrayVectorMultiplier` object multiplies an array by a vector along a specified dimension.

To multiply an array by a vector along a specified:

1. Define and set up your array-vector multiplication object. See "Construction" on page 3-142.
2. Call `step` to multiply the array according to the properties of `dsp.ArrayVectorMultiplier`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.ArrayVectorMultiplier` returns an array-vector multiplication object, `H`, that multiplies an input N-D array by the elements of a vector along the second dimension.

`H = dsp.ArrayVectorMultiplier('PropertyName',PropertyValue,...)` returns an array-vector multiplication object, `H`, with each property set to the specified value.

Properties

Dimension

Dimension along which to multiply input by vector elements

Specify the dimension along which to multiply the input array by the elements of vector as a positive integer. The default is `2`.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector to multiply array

Specify the vector by which to multiply the array. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, Simplest', `Zero`. The default is `floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` , `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as product`, `Same as first input`, or `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when

you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create array-vector multiplication object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Multiply array by vector

Examples

Multiply a matrix by a vector:

```
havm = dsp.ArrayVectorMultiplier;
a = ones(2);
x = [2 3]';
y = step(havm, a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Multiply block reference page. The object properties correspond to the block parameters, except:

- The array-vector multiplication object does not have **Minimum** or **Maximum** options for data output.

See Also

`dsp.ArrayVectorAdder` | `dsp.ArrayVectorDivider` | `dsp.ArrayVectorSubtractor`

dsp.ArrayVectorMultiplier.clone

Purpose

Create array-vector multiplication object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an array-vector multiplication object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.ArrayVectorMultiplier.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of output arguments from the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the array-vector multiplication object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.ArrayVectorMultiplier.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Multiply array by vector

Syntax

```
Y = step(H,A,V)
Y = step(H,A)
```

Description

`Y = step(H,A,V)` returns `Y` , the result of multipling the input array `A` by the elements of input vector `V` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

`Y = step(H,A)` returns `Y` , the result of multipling the input array `A` by the elements of vector specified in `Vector` property along the specified dimension when the `VectorSource` property is set to `Property`. The length of the vector specified in `Vector` property must equal the length of the specified dimension of `A`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.ArrayVectorSubtractor

Purpose

Subtract vector from array along specified dimension

Description

The `ArrayVectorSubtractor` object subtracts a vector from an N-D array along a specified dimension.

To subtract a vector from an N-D array along a specified dimension:

1. Define and set up your array-vector subtraction object. See "Construction" on page 3-152.
2. Call `step` to subtract the vector according to the properties of `dsp.ArrayVectorSubtractor`. The behavior of `step` is specified to each object in the toolbox.

Construction

`H = dsp.ArrayVectorSubtractor` returns an array-vector subtraction object, `H`, that subtracts the elements of a vector from an N-D input array along the first dimension.

`H = dsp.ArrayVectorSubtractor('PropertyName',PropertyValue,...)` returns an array-vector subtraction object, `H`, with each property set to the specified value.

Properties

Dimension

Dimension along which to subtract vector elements from input

Specify the dimension along which to subtract the elements of the vector from the input array as an integer-valued scalar greater than `0`. The default is `1`.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` or `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numerictype([],16,15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision` , `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create array-vector subtractor with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Subtract vector from array along specified dimension

Examples

Subtract a vector from a matrix:

```
havs = dsp.ArrayVectorSubtractor;
a = ones(2);
x = [1 2]';
y = step(havs, a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Subtract block reference page. The object properties correspond to the block parameters, except:

The array-vector subtraction object does not have **Minimum** or **Maximum** options for data output.

See Also

`dsp.ArrayVectorMultiplier` | `dsp.ArrayVectorDivider` | `dsp.ArrayVectorAdder`

dsp.ArrayVectorSubtractor.clone

Purpose

Create array-vector subtractor with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an array-vector subtractor object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.ArrayVectorSubtractor.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the array-vector subtractor object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.ArrayVectorSubtractor.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Subtract vector from array along specified dimension

Syntax

```
Y = step(H,A,V)
Y = step(H,A)
```

Description

`Y = step(H,A,V)` returns `Y`. The value of `Y` results from subtracting the elements of input vector `V` from the input array `A` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

`Y = step(H,A)` returns `Y`. The value of `Y` results from subtracting the elements of the vector specified in the `Vector` property from the input array `A` along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.AudioFileReader

Purpose

Read audio samples from audio file

Description

The `AudioFileReader` object reads audio samples from an audio file.

To read audio samples from an audio file:

1. Define and set up your audio file reader object. See "Construction" on page 3-162.
2. Call `step` to read audio samples according to the properties of `dsp.AudioFileReader`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.AudioFileReader` returns an audio file reader System object, `H` that reads audio from an audio file. This audio file can be of the following formats on all platforms:

- MP3
- M4a
- MP4
- WAV
- FLAC
- OGG

`H = dsp.AudioFileReader('PropertyName',PropertyValue,...)` returns an audio file reader System object, `H`, with each specified property set to the specified value.

`H = dsp.AudioFileReader(Filename,'PropertyName',PropertyValue,...)` returns an audio file reader object, `H`, with `Filename` property set to *`FILENAME`* and other specified properties set to the specified values.

Properties

Filename

Name of audio file from which to read

Specify the name of an audio file as a string. Specify the full path for the file only if the file is not on the MATLAB path. The default is `speech_dft.mp3`.

PlayCount

Number of times to play file

Specify a positive integer as the number of times to play the file. The default is `1`.

SampleRate

Sampling rate of the audio file

This read-only property displays the sampling rate, in hertz, of the audio file.

SamplesPerFrame

Number of samples in audio frame

Specify the number of samples in an audio frame as a positive, scalar integer value. The default value is `1024`.

OutputDataType

Data type of output

Set the data type of the audio data output from the audio file reader object. Specify the data type as `|double| single | int16 | uint8|`. The default is `int16`.

Methods

clone	Create audio file reader object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
info	Information about specific audio file

isDone	End-of-file status (logical)
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of audio file reader to read from beginning of file
step	Read audio samples from audio file

Examples

Read and play back an audio file using the standard audio output device.

```
hmfr = dsp.AudioFileReader('speech_dft.mp3');
hap = dsp.AudioPlayer('SampleRate', hmfr.SampleRate);

while ~isDone(hmfr)
   audio = step(hmfr);
   step(hap, audio);
end

release(hmfr); % release the input file
release(hap);  % release the audio output device
```

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`
Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`
Windows	`set PATH = $MATLABROOT\bin\win32;%PATH% set PATH = $MATLABROOT\bin\win64;%PATH%`

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs `EOF` as the last output.
- The object has no corresponding property for the **Multimedia Outputs** parameter because audio is the only supported output.

- The object has no corresponding property for the **Image signal** block parameter.
- The object has no corresponding property for the **Output color format** parameter.
- The object has no corresponding property for the **Video output data type** parameter.

See Also

`dsp.AudioFileWriter`

Purpose

Create audio file reader object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `AudioFileReader` System object, `C`, with the same property values as `H`.

The clone method creates a new unlocked object with uninitialized states.

dsp.AudioFileReader.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.AudioFileReader.info

Purpose

Information about specific audio file

Syntax

```
S = info(H)
```

Description

`S = info(H)` returns a MATLAB structure, `S`, with information about the audio file specified in the `Filename` property. The number of fields in `S` varies depending on the audio content of the file. For possible fields and values for the structure `S`, see the following table.

Field	Value
SampleRate	Audio sampling rate of the audio file in Hz.
NumBits	Number of bits used to encode the audio stream.
NumChannels	Number of audio channels.

Purpose

End-of-file status (logical)

Syntax

```
STATUS = isDone(H)
```

Description

`STATUS = isDone(H)` returns a logical value, `STATUS` , when the file is read `PlayCount` number of times. If you set the `PlayCount` property to a value greater than `1` , `STATUS` is `true` when `EOF` is reached `PlayCount` number of times, and it is `false` otherwise. `STATUS` is the same as the `PlayCount` output value in the `step` method syntax.

dsp.AudioFileReader.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
y = isLocked(H)
```

Description

`y = isLocked(H)` returns the locked state, `Y`, of the `AudioFileReader` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Reset internal states of audio file reader to read from beginning of file

Syntax

```
reset(H)
```

Description

`reset(H)` resets the `AudioFileReader` object to read from the beginning of the file.

dsp.AudioFileReader.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Read audio samples from audio file

Syntax

```
AUDIO = step(H)
[AUDIO,EOF] = step(H)
```

Description

`AUDIO = step(H)` outputs one frame of audio samples, `AUDIO`. You can specify the number of times to play the file using the `PlayCount` property. After playing the file for the number of times you specify, `AUDIO` contains silence.

`[AUDIO,EOF] = step(H)` returns an end-of-file indicator, `EOF`. `EOF` is true each time the output `AUDIO` contains the last audio sample in the file.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.AudioFileWriter

Purpose

Write audio samples to audio file

Description

The `AudioFileWriter` object writes audio samples to an audio file.

To write audio samples to an audio file:

1. Define and set up your audio file writer object. See "Construction" on page 3-176.
2. Call `step` to write audio samples according to the properties of `dsp.AudioFileWriter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.AudioFileWriter` returns an audio file writer System object, `H`. This object writes audio samples to an audio file.

The following platform specific restrictions apply when writing these files:

Windows 7	Mac OS X
• Only sample rates of 44100 and 48000 Hz are supported.	• Only mono or stereo outputs are allowed.
• Only mono or stereo outputs are allowed.	
• The output data is padded on both the front and back of the signal, with extra samples of silence. Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.	• Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.

Windows 7	Mac OS X
• A minimum of 1025 samples must be written to the MPEG-4 AAC file.	

`H = dsp.AudioFileWriter('PropertyName',PropertyValue,...)` returns an audio file writer System object, `H`, with each specified property set to the specified value.

`H = dsp.AudioFileWriter(FILENAME,'PropertyName',PropertyValue,...)` returns an audio file writer System object, `H`. This object has the `Filename` property set to *`FILENAME`* and other specified properties set to the specified values.

Properties

Filename

Name of audio file to which to write

Specify the name of the audio file as a string. The default is `output.wav`.

FileFormat

Audio file format

Specify which audio file format the object writes. On Microsoft platforms, select one of `AVI | WAV | FLAC | OGG | MPEG4 | WMA`. On Linux platforms, select one of `AVI | WAV | FLAC | OGG`. On Mac OS X platforms, select one of `AVI | WAV | FLAC | OGG | MPEG4`. These abbreviations correspond to the following file formats:

- `AVI`: Audio-Video Interleave
- `WAV`: Microsoft WAVE Files
- `WMA`: Windows Media Audio
- `FLAC`: Free Lossless Audio Codec
- `OGG`: Ogg/Vorbis Compressed Audio File

- `MPEG4`: MPEG-4 AAC File — You can use both `.m4a` and `.mp4` extensions

The default is `WAV`.

SampleRate

Sampling rate of audio data stream

Specify the sampling rate of the input audio data as a positive, numeric scalar value. The default is `44100` .

Compressor

Algorithm that compresses audio data

Specify the type of compression algorithm the audio file writer uses to compress the audio data. Compression reduces the size of the audio file. Select `None (uncompressed)` to save uncompressed audio data to the file. The other options available reflect the audio compression algorithms installed on your system. You can use tab completion to query valid `Compressor` options for your computer by typing `H.Compressor = '` and then pressing the tab key. This property applies when writing `WAV` or `AVI` files on Windows platforms.

DataType

Data type of the uncompressed audio

Specify the type of uncompressed audio data written to the file as one of `inherit`, `int16`, `int24`, `single`, or `uint8`. This property only applies when writing uncompressed `WAV` files. The default value of this property is `int16`.

Methods

clone	Create audio file writer object with same property values
getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Write one frame of audio output samples

Examples

Decimate an audio signal, and write it to disk as an WAV file.

```
hmfr = dsp.AudioFileReader('OutputDataType',...
   'double');
hfirdec = dsp.FIRDecimator; % decimate by 2
hmfw = dsp.AudioFileWriter...
   ('speech_dft.wav', ...
   'SampleRate', hmfr.SampleRate/2);

while ~isDone(hmfr)
     audio = step(hmfr);
     audiod = step(hfirdec, audio);
     step(hmfw, audiod);
end

release(hmfr);
release(hmfw);
```

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`
Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`
Windows	`set PATH = $MATLABROOT\bin\win32;%PATH% set PATH = $MATLABROOT\bin\win64;%PATH%`

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object `FileFormat` property does not support video-only file formats.
- The object has no corresponding property for the **Write** parameter. The object writes only audio content to files.
- The object has no corresponding property for the **Video compressor** parameter.

- The object has no corresponding property for the **File color format** parameter.
- The object has no corresponding property for the **Image signal** parameter.

See Also

`dsp.AudioFileReader`

dsp.AudioFileWriter.clone

Purpose

Create audio file writer object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `AudioFileWriter` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, of the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.AudioFileWriter.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, of step method`N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `AudioFileWriter` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.AudioFileWriter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Write one frame of audio output samples

Syntax

```
step(H,AUDIO)
```

Description

`step(H,AUDIO)` writes one frame of audio samples, `AUDIO` , to the output file. `AUDIO` is either a vector or an M-by-N matrix for mono or N-channel audio inputs respectively.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.AudioPlayer

Purpose

Play audio data using computer's audio device

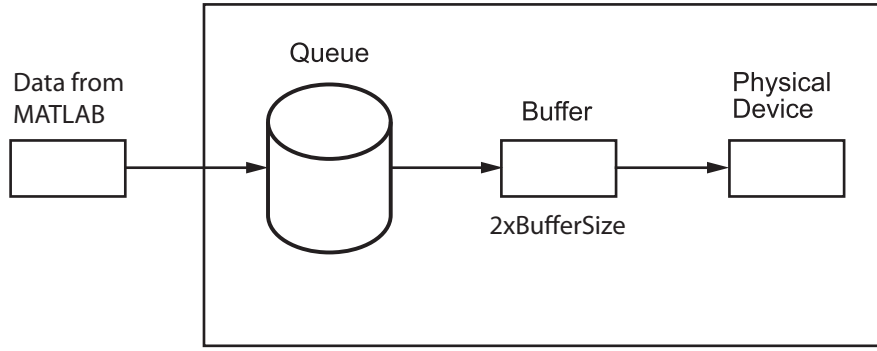
Description

The `AudioPlayer` object plays audio data using the computer's audio device.

To play audio data using the computer's audio device:

1. Define and set up your audio player object. See "Construction" on page 3-188.
2. Call `step` to play audio data according to the properties of `dsp.AudioPlayer`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from the audio device using the process illustrated by the following figure.



Construction

`H = dsp.AudioPlayer` returns an audio player object, `H`, that plays audio samples using an audio output device in real-time.

`H = dsp.AudioPlayer('PropertyName',PropertyValue, ...)` returns an audio player object, `H`, with each property set to the specified value.

```
H =
dsp.AudioPlayer(SAMPLERATE,'PropertyName',PropertyValue,
```

`...)` returns an audio player object, `H`, with the `SampleRate` property set to `SAMPLERATE` and other specified properties set to the specified values. This System object supports variable-size input. If you use variable-size signals with this System object, you may experience sound dropouts when the size of the input frame increases. To avoid this behavior, use a signal of maximum expected size when you first call `step` to start running through this System object.

Properties

DeviceName

Device to which to send audio data

Specify the device to which to send the audio data. The default is `Default`, which is the computer's standard output device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key.

SampleRate

Number of samples per second sent to audio device

Specify the number of samples per second in the signal as an integer. The default is `44100`. This property is tunable.

DeviceDataType

Data type used by device

Specify the data type used by the audio device to acquire audio data as `Determine from input data type` , `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from input data type`.

BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, an appropriate buffer size based on the `SampleRate` gets computed.

BufferSize

Buffer size

Specify the size of the buffer that the audio player object uses to communicate with the audio device as an integer. `BufferSize` is half the size of the sound card buffer. A frame of data cannot be passed to the queue until the device empties the buffer, which introduces *latency*. Latency is the time it takes the device to empty the queue and the buffer. `BufferSize` has to be smaller than the effective queue duration. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun). This property applies when you set the `BufferSizeSource` property to `Property`. The default is `4096`. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to `'Property'`. You can select `BufferSize` in the list of properties.

QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is `1.0`. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:

$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}$. To minimize latency, lower the `QueueDuration` or set it to `0`. However, be aware that data dropouts or loss of system robustness may result. The Queue duration property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer underrun occurs. To correct the underrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer overrun occurs, causing the System object to wait before writing data to the queue. To minimize the chance of dropouts, the System

object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the System object sends a buffer of samples from the top of the queue to the audio device. If the queue does not contain enough data to completely fill the buffer, the System object fills the remaining portion of the buffer with zeros.

ChannelMappingSource

Source of device channel mapping

Specify whether to determine the channel mapping as `'Auto'` or as `'Property'`. If you set the value of `ChannelMappingSource` to `'Auto'`, the `ChannelMapping` field is rendered inactive. If you set this property to `'Property'`, the vector specified in the `ChannelMapping` field is used to route the output.

ChannelMapping

Data-to-device channel mapping

Vector of valid channel indices to represent the mapping between data and device output channels. The term *Channel Mapping* refer to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio data to output a specific channel of audio data. By default, the `ChannelMapping` field is [1:MAXOUTPUTCHANNELS], where MAXOUTPUTCHANNELS depends upon the selected device.

Methods

clone	Create audio player object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Write audio to audio output device

Examples

Read in an AVI audio file, and play the file back using the standard audio output device:

```
hafr = dsp.AudioFileReader;
hap = dsp.AudioPlayer('SampleRate',22050);

while ~isDone(hafr)
   audio = step(hafr);
   step(hap,audio);
end

pause(hap.QueueDuration);  % Wait until audio plays to the end

release(hafr); % close input file, release resources
release(hap);  % close audio output device, release resources
```

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`
Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`
Windows	`set PATH = $MATLABROOT\bin\win32;%PATH%set PATH = $MATLABROOT\bin\win64;%PATH%`

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Audio Device block reference page. The object properties correspond to the block parameters.

How To

- Set the Audio Hardware API

dsp.AudioPlayer.clone

Purpose

Create audio player object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an audio player object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.AudioPlayer.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the audio player object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.AudioPlayer.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Write audio to audio output device

Syntax

```
Y = step(H,AUDIO)
```

Description

`Y = step(H,AUDIO)` writes one frame of `AUDIO` samples to the selected audio output device, `Y`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.AudioRecorder

Purpose

Record audio data using computer's audio device

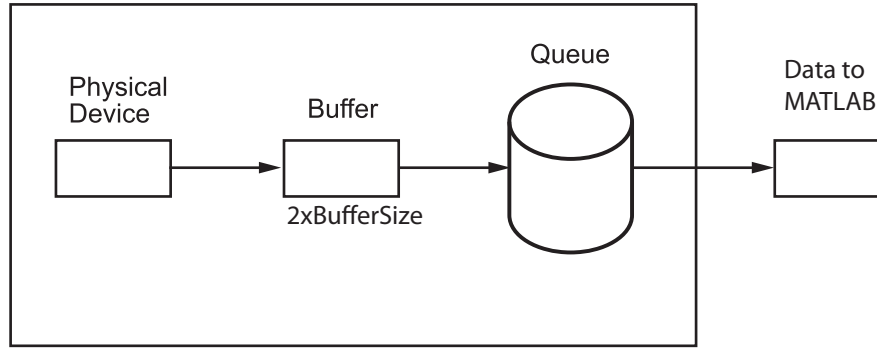
Description

The `AudioRecorder` object records audio data using the computer's audio device.

To record audio data using the computer's audio device:

1. Define and set up your audio recorder object. See "Construction" on page 3-200.
2. Call `step` to record audio data according to the properties of `dsp.AudioRecorder`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from a frame of data using the process illustrated by the following figure.



Construction

`H = dsp.AudioRecorder` returns an audio recorder object, `H`, that records audio samples using an audio input device in real-time.

`H = dsp.AudioRecorder('PropertyName',PropertyValue, ...)` returns an audio recorder object, `H`, with each property set to the specified value.

Properties

DeviceName

Device from which to acquire audio data

Specify the device from which to acquire audio data. The default is `Default`, which is the computer's standard input device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key. The tab completion functionality shows all valid audio device names for your computer.

SampleRate

Number of samples per second read from audio device

Specify the number of samples per second in the signal as an integer. The default is 44100. This property is tunable.

NumChannels

Number of audio channels

Specify the number of audio channels as an integer. The default is 2.

DeviceDataType

Data type used by device

Specify the data type used by the device to acquire audio data as `Determine from output data type` , `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from output data type`.

BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`.

BufferSize

Buffer size

Specify as an integer the size of the buffer that the audio recorder object uses to communicate with the audio device. This property applies when you set the `BufferSizeSource` property to `Property`. The default is `4096`. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun). The instant you receive the buffer from a device, you have samples that are relatively new and samples that are at least as old as the size of the buffer. Therefore, the buffer size introduces *latency*, which is the time required for the device to fill the queue and the buffer. `BufferSize` is half the size of the sound card buffer. The size of the buffer processed in each interrupt from the audio device affects the performance of the system. A frame of data cannot pass through the queue until the buffer is filled by the device, thus introducing latency. `BufferSize` has to be smaller than the effective queue duration. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to 'Property'. You can select `BufferSize` from the list of properties.

QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is `1.0`. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:

$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}$. To minimize latency, lower the `QueueDuration` or set it to 0. However, be aware that data dropouts or loss of system robustness may result. The Queue duration property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer overrun occurs. To correct the overrun, make the queue duration larger than the buffer. If the MATLAB data throughput

rate is higher than the device throughput rate, a buffer underrun occurs, causing the System object to wait for new samples to become available. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the audio device sends a buffer of samples to the top of the queue.

SamplesPerFrame

Number of samples in the output signal

Specify the number of samples in the audio recorder's output as an integer. The default is 1024.

OutputDataType

Data type of the output

Select the output data type as `uint8`, `int16`, `int32` , `single` , or `double`. The default is `double`.

ChannelMappingSource

Source of device channel mapping

Specify whether to determine the channel mapping as `'Auto'` or as `'Property'`. If you set the value of `ChannelMappingSource` to `'Auto'`, the `ChannelMapping` field is rendered inactive. If you set this property to `'Property'`, the vector specified in the ChannelMapping field is used to route the input. Additionally, the `NumChannels` field is rendered inactive, because the channel map contains information about the number of data channels that the user is attempting to read.

ChannelMapping

Device-to-data channel mapping

Vector of valid channel indices to represent the mapping between device input channels and the data. The term *Channel Mapping*

refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. By default, the `ChannelMapping` field is [1:MAXNUMINPUTCHANNELS], where MAXNUMINPUTCHANNELS depends upon the selected device.

Methods

clone	Create audio recorder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Record audio from computer's recording device

Examples

Record ten seconds of speech from a microphone, and send the output to a .wav file:

```
har = dsp.AudioRecorder;
hmfw = dsp.AudioFileWriter('myspeech.wav','FileFormat','WAV');

disp('Speak into microphone now');

tic;
while toc < 10,
     step(hmfw, step(har));
end

release(har);
```

```
release(hmfw);
disp('Recording complete');
```

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`
Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`
Windows	`set PATH = $MATLABROOT\bin\win32;%PATH%set PATH = $MATLABROOT\bin\win64;%PATH%`

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Audio Device block reference page. The object properties correspond to the block parameters.

`dsp.AudioFileReader` | `dsp.AudioPlayer`

How To

- Set the Audio Hardware API

Purpose

Create audio recorder object with same property values

Syntax

```
clone(H)
```

Description

`clone(H)` creates an audio recorder object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.AudioRecorder.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.AudioRecorder.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the audio recorder.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.AudioRecorder.step

Purpose

Record audio from computer's recording device

Syntax

```
AUDIO = step(H)
```

Description

`AUDIO = step(H)` reads one frame of audio samples from the selected audio input device.

Purpose

Autocorrelation sequence

Description

The `Autocorrelator` object returns the autocorrelation sequence for a discrete-time, deterministic input, or the autocorrelation sequence estimate for a discrete-time, wide-sense stationary (WSS) random process at positive lags.

To obtain the autocorrelation sequence:

1. Define and set up your autocorrelator. See "Construction" on page 3-213.
2. Call `step` to compute the autocorrelation sequence according to the properties of `dsp.Autocorrelator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Autocorrelator` returns an autocorrelator, `H`, that computes the autocorrelation along the first dimension of an N-D array. By default, the autocorrelator computes the autocorrelation at lags from zero to $N - 1$, where N is the length of the input vector or the row dimension of the input matrix. Inputting a row vector results in a row of zero-lag autocorrelation sequence values, one for each column of the row vector. The default autocorrelator returns the unscaled autocorrelation and performs the computation in the time domain.

`H = dsp.Autocorrelator('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an autocorrelator, `H`, with each property set to the specified value.

Properties

MaximumLagSource

Source of maximum lag

Specify how to determine the range of lags for the autocorrelation as `Auto` or `Property`. If the value of `MaximumLagSource` is `Auto`, the autocorrelator computes the autocorrelation over all nonnegative lags in the interval `[0, N-1]`, where N is the length of the first dimension of the input. Otherwise, the object computes

the autocorrelation using lags in the range `[0,MaximumLag]`. The default is `Auto`.

MaximumLag

Maximum positive lag

Specify the maximum lag as a positive integer. This property applies only when the `MaximumLagSource` property is `Property`. The `MaximumLag` must be less than the length of the input data. The default is `1`.

Scaling

Autocorrelation function scaling

Specify the scaling to apply to the output as `None`, `Biased`, `Unbiased`, or `Unity at zero-lag`. Set this property to `None` to generate the autocorrelation function without scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The `Biased` option scales the autocorrelation by $1/N$, where N is the length of the input data. Scaling by $1/N$ yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by $1/N$ has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The `Unbiased` option scales the estimate of the autocorrelation by 1/N-1. Scaling by $N - 1$ produces an unbiased estimate of the theoretical autocorrelation. However, using the unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the `Unity at zero-lag` option to normalize the autocorrelation estimate as identically one at lag zero. See

"Definitions" on page 3-217 for more detail on scaling. The default is `None`.

Method

Domain for computing autocorrelations

Specify the domain for computing autocorrelations as `Time Domain` or `Frequency Domain`. You must set this property to `Time Domain` for fixed-point signals. The default is `Time Domain`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. This property applies only when you set the `Method` property to `Time Domain`. The default is `Full precision`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` property is `Time Domain`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and

the `AccumulatorDataType` property to `Custom`. The default is`numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` property is `Time Domain`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` property to `Time Domain` and the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create autocorrelator object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Autocorrelation sequence

Definitions

The autocorrelation of a deterministic discrete-time sequence, *x(n)* is:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0,1,\ldots,N-1$$

where h is the lag and * denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where E{ } is the expectation operator. The `Unity at zero-lag` normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N}\sum_{k=0}^{N-h-1} x^*(n)x(n+h)$$

Examples

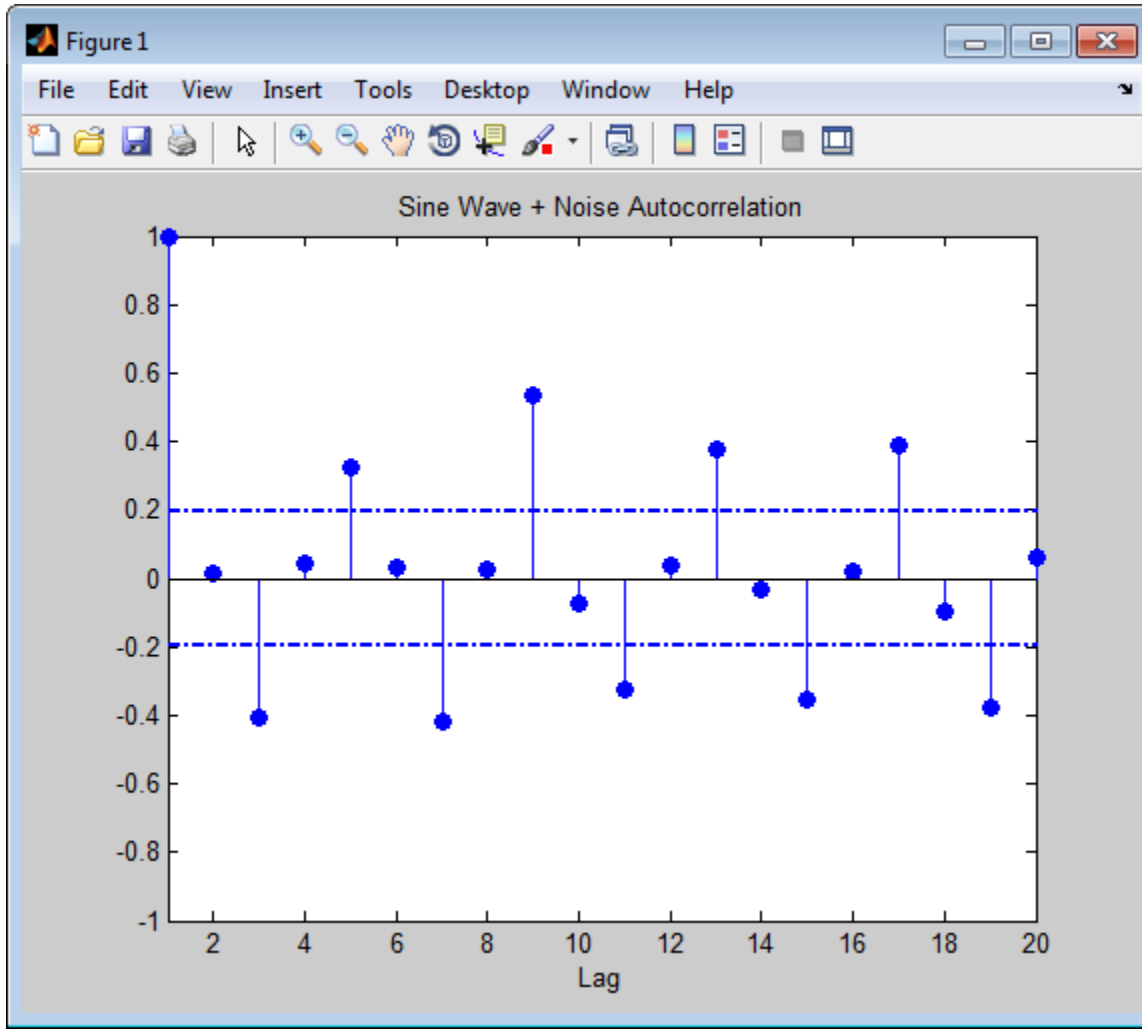
Compute autocorrelation for all positive lags:

```
hac1 = dsp.Autocorrelator;
% x is a column vector
x = [1:100]';
y = step(hac1, x);
```

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits:

```
S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))'+randn(100,1);
```

```
MaxLag = 20;
H = dsp.Autocorrelator('MaximumLagSource',...
'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = step(H,x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
     'linestyle','-.','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
     'linestyle','-.','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```



As this figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Autocorrelation block reference page. The object properties correspond to the block parameters.

See Also

`dsp.Crosscorrelator`

dsp.Autocorrelator.clone

Purpose

Create autocorrelator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an autocorrelator object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Autocorrelator.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the autocorrelator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Autocorrelator.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Autocorrelation sequence

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` computes the autocorrelation sequence `Y` for the columns of the input `X`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.BiquadFilter

Purpose

IIR filter using biquadratic structures

Description

The `BiquadFilter` object implements an IIR filter structure using biquadratic or second–order sections (SOS).

To implement an IIR filter structure using biquadratic or SOS:

1. Define and set up your biquadratic IIR filter. See "Construction" on page 3-228.
2. Call `step` to implement the IIR filter according to the properties of `dsp.BiquadFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.BiquadFilter` returns a default biquadratic IIR filter, `H`, which independently filters each channel of the input over successive calls to the `step` method using the SOS section `[1 0.3 0.4 1 0.1 0.2]` with a direct-form II transposed structure.

`H = dsp.BiquadFilter('PropertyName',PropertyValue, ...)` returns a biquadratic filter object, `H`, with each property set to the specified value.

Properties

Structure

Filter structure

Specify the filter structure as one of `| Direct form I | Direct form I transposed | Direct form II | Direct form II transposed |`. The default is `Direct form II transposed`.

SOSMatrixSource

SOS matrix source

Specify the source of the SOS matrix as one of `| Property | Input port|`. The default is `Property`.

SOSMatrix

SOS matrix

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. The default is `[1 0.3 0.4 1 0.1 0.2]`. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function, *H(z)*, of a biquad filter is:

$$H(z) = \frac{\sum_{k=0}^{2} b_k z^{-k}}{1 - \sum_{l=1}^{2} a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as (b_0, b_1, b_2, 1, $-a_1$, $-a_2$). You can use coefficients of real or complex values. This property applies only when you set the `SOSMatrixSource` property to `Property`. The leading denominator coefficient of the biquad filter, a_0, equals 1 for each filter section, regardless of the specified value.

ScaleValues

Scale values for each biquad section

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be either a scalar or a vector of length `N+1`, where `N` is the number of sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to `1`. If you set this property to a vector of `N+1`values, each value is used for a separate section of the filter.

This property applies only when you set the `SOSMatrixSource` property to `Property`. The default is `1`.

InitialConditions

Initial conditions for direct form II structures

Specify the initial conditions of the filter states when the `Structure` property is one of `| Direct form II | Direct form II transposed |`. The number of states or delay elements (zeros

and poles) in a direct-form II biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all delay elements in the filter to that value. When you specify a vector of length equal to the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is the scalar `0`.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property applies only when you set the `Structure` property to one of `| Direct form I | Direct form I transposed |`. The number of states or delay elements in the numerator of a direct-form I biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the zeros side in the filter to that value. When you specify a vector of length equal to the number of delay elements on the zeros side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of

length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. The default is the scalar `0`.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property only applies when you set the `Structure` property to one of `| Direct form I | Direct form I transposed |`. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay

element on the poles side in the corresponding channel. The default is the scalar `0`.

OptimizeUnityScaleValues

Optimize unity scale values

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy. This property applies only when you set the `SOSMatrixSource` property to `Property`. The default is `true`.

ScaleValuesInputPort

How to specify scale values

Select how to specify scale values. This property applies only when the `SOSMatrixSource` property is `Input port`. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. When this property is `true`, the biquad filter treats each column as an independent channel. Set this property to `false` to enable sample-based processing. When this property is `false`, the biquad filter treats each element of the input as an individual channel. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

MultiplicandDataType

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of | `Same as output` | `Custom` |. This property applies only when you set the `Structure` property to `Direct form I transposed`. The default is `Same as output`.

CustomMultiplicandDataType

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `MultiplicandDataType` property to `Custom`. The default is `numerictype([],32,30)`.

SectionInputDataType

Section input word and fraction lengths

Specify the section input fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomSectionInputDataType

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `SectionInputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

SectionOutputDataType

Section output word and fraction lengths

Specify the section output fixed-point data type as one of | `Same as section input` | `Custom` |. The default is `Same as section input`.

CustomSectionOutputDataType

Custom section output word and fraction lengths

Specify the section output fixed-point type as a signed, scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `SectionOutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

NumeratorCoefficientsDataType

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. This property applies only when you set the `SOSMatrixSource` property to `Property`. Setting this property also sets the `DenominatorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value. The default is `Same word length as input`.

CustomNumeratorCoefficientsDataType

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `SOSMatrixSource` property to `Property` and the `NumeratorCoefficientsDataType` property to `Custom`. The word length of the `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must be the same. The default is `numerictype([],16,15)`.

DenominatorCoefficientsDataType

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the SOSMatrixSource property to Property. Setting this property also sets the NumeratorCoefficientsDataType and ScaleValuesDataType properties to the same value. The default is Same word length as input.

CustomDenominatorCoefficientsDataType

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when you set the SOSMatrixSource property to Property and the DenominatorCoefficientsDataType property to Custom. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths. The default is numerictype([],16,15).

ScaleValuesDataType

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the SOSMatrixSource property to Property. Setting this property also sets the NumeratorCoefficientsDataType and DenominatorCoefficientsDataType properties to the same value. The default is Same word length as input.

CustomScaleValuesDataType

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when you set the SOSMatrixSource property to Property and the ScaleValuesDataType property to Custom. The CustomNumeratorCoefficientsDataType,

`CustomDenominatorCoefficientsDataType`, and `CustomScaleValuesDataType` properties must have the same word lengths. The default is `numerictype([],16,15)`.

NumeratorProductDataType

Numerator product word and fraction lengths

Specify the product fixed-point data type as one of `| Same as input | Custom |`. Setting this property also sets the `DenominatorProductDataType` property to the same value. The default is `Same as input`.

CustomNumeratorProductDataType

Custom numerator product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorProductDataType` property to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

DenominatorProductDataType

Denominator product word and fraction lengths

Specify the product fixed-point data type as one of `| Same as input | Custom |`. Setting this property also sets the `NumeratorProductDataType` property to the same value. The default is `Same as input`.

CustomDenominatorProductDataType

Custom denominator product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorProductDataType` to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

NumeratorAccumulatorDataType

Numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point data type as one of | `Same as input` | `Same as product` | `Custom` |. Setting this property also sets the `DenominatorAccumulatorDataType` property to the same value. The default is `Same as product`.

CustomNumeratorAccumulatorDataType

Custom numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorAccumulatorDataType` property to `Custom`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

DenominatorAccumulatorDataType

Denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point data type as one of | `Same as input` | `Same as product` | `Custom`|. Setting this property also sets the `NumeratorAccumulatorDataType` property to the same value. The default is `Same as product`.

CustomDenominatorAccumulatorDataType

Custom denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorAccumulatorDataType` property to `Custom`. The `CustomNumeratorAccumulatorDataType` and `CustomDenominatorAccumulatorDataType` properties must have the same word lengths. The default is `numerictype([],32,30)`.

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom`|. This property applies when you set the `Structure` property to `Direct form II` or `Direct form II transposed`. The default is `Same as accumulator`.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The default is `numerictype([],16,15)`.

NumeratorStateDataType

Numerator state word and fraction lengths

Specify the numerator state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom` |. Setting this property also sets the `DenominatorStateDataType` property to the same value. This property applies only when you set the `Structure` property to `Direct form I transposed`. The default is `Same as accumulator`.

CustomNumeratorStateDataType

Custom numerator state word and fraction lengths

Specify the numerator state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths. The default is `numerictype([],16,15)`.

DenominatorStateDataType

Denominator state word and fraction lengths

Specify the denominator state fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. Setting this property also sets the `NumeratorStateDataType` property to the same value. This property applies only when you set the `Structure` property to `Direct form I transposed`. The default is `Same as accumulator`.

CustomDenominatorStateDataType

Custom denominator state word and fraction lengths

Specify the denominator state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` property to `Custom`. The `CustomNumeratorStateDataType` and `CustomDenominatorStateDataType` properties must have the same word lengths. The default is `numerictype([],16,15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create biquad filter object with same property values

Examples 1

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a power spectrum using the Spectrum Analyzer:

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t); % Input is 0.3 &
                                         % 3kHz sinusoids
hFromWS = dsp.SignalSource(xin, 100);
hLog = dsp.SignalSink;

[z,p,k] = ellip(4,1,60,.4);    % Set up the filter
[s,g] = zp2sos(z,p,k);
hBqF=dsp.BiquadFilter('Structure','Direct form I', ...
   'SOSMatrix',s,'ScaleValues',g);

h = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
```

```
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-160 -10]);

while ~isDone(hFromWS)
     input = step(hFromWS);
     filteredOutput = step(hBqF,input);
     step(hLog,filteredOutput);
     step(h,filteredOutput)
end

filteredResult = hLog.Buffer;
fvtool(hBqF,'Fs',8000)
```

Algorithm

This object implements the algorithm, inputs, and outputs described on the Biquad Filter block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source** – the biquad filter object does not accept `dfilt` objects as an `SOSMatrixSource`.
- **Action when the a0 values of the SOS matrix are not one** – the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the `Error` or `Warn` options found in the corresponding block.

Both this object and its corresponding block support variable-size input. This means that the step method can handle an input which is changing in size. They also let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.DigitalFilter`

Purpose

Create biquad filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a biquad filter object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.BiquadFilter.freqz

Purpose

Frequency response

Syntax

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

Purpose

Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description

`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

dsp.BiquadFilter.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.BiquadFilter.impz

Purpose

Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description

`[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the biquad filter object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.BiquadFilter.phasez

Purpose

Unwrapped phase response

Syntax

```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.BiquadFilter.reset

Purpose

Reset states of biquad filter object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the biquad filter object,`H`, to the specified initial conditions. After the `step` method applies the biquad filter object to nonzero input data, the states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Example of resetting filter states:

```
n =0:20;
x = cos(pi/4*n)+sin(pi/2*n);
H = dsp.BiquadFilter;
y = step(H,x');
% Apply step method without invoking reset
y1 = step(H,x');
isequal(y,y1) % Returns a 0
% Reset filter states to zero
reset(H)
% Now invoke step method
y2 = step(H,x');
isequal(y,y2) % Returns a 1
```

Purpose

Filter input with biquad filter object

Syntax

```
Y = step(H,X)
Y = step(H,X,NUM,DEN)
Y = step(H,X,NUM,DEN,G)
```

Description

`Y = step(H,X)` filters the real or complex input signal `X` , and outputs the filtered values, `Y`. The biquad filter object filters each channel of the input signal over successive calls to the `step` method.

`Y = step(H,X,NUM,DEN)` filters the input using `NUM` as the numerator coefficients, and `DEN` as the denominator coefficients of the biquad filter. `NUM` must be a 3-by-N numeric matrix and `DEN` must be a 2-by-N numeric matrix, where N is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1. This configuration applies when the `SOSMatrixSource` property is `Input port` and the `ScaleValuesInputPort` property is `false`.

`Y = step(H,X,NUM,DEN,G)` specifies the scale values, `G`, of the biquad filter. `G` must be a 1-by-(N +1) numeric vector, where `N` is the number of biquad filter sections. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is true.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.BlockLMSFilter

Purpose

Output, error, and weights using Block LMS adaptive algorithm

Description

The `BlockLMSFilter` object computes output, error, and weights using the Block LMS adaptive algorithm.

To compute the output, error, and weights:

1. Define and set up your adaptive FIR filter. See "Construction" on page 3-258.
2. Call `step` to compute the output, error, and weights according to the properties of `dsp.BlockLMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H=dsp.BlockLMSFilter` returns an adaptive FIR filter, `H`, that filters the input signal and computes filter weights based on the Block Least Mean Squares (LMS) algorithm.

`H=dsp.BlockLMSFilter('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an adaptive FIR filter, `H`, with each specified property set to the specified value.

`H=dsp.BlockLMSFilter(length,blocksize,'`*`PropertyName`*`',...` *`PropertyValue`*`,...)` returns an adaptive FIR filter, `H`, with the `Length` property set to `length`, the `BlockSize` property set to `blocksize`, and other specified properties set to the specified values.

Properties

Length

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer scalar. The default is `32`.

BlockSize

Number of samples acquired before weight adaptation

Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size. The default is `32`.

StepSizeSource

Source of adaptation step size

Choose to specify the adaptation step size factor as `Property` or `Input port`. The default is `Property`.

StepSize

Adaptation step size

Specify the adaptation step size factor as a scalar, nonnegative numeric value. The default is `0.1`. This property applies only when you set the `StepSizeSource` property to `'Property'`. This property is tunable.

LeakageFactor

Leakage factor used in Leaky LMS algorithm

Specify the leakage factor used in Leaky LMS algorithm as a scalar numeric value between `0` and `1`, both inclusive. When the value is less than `1`, the System object implements a leaky LMS algorithm. The default is `1`, providing no leakage in the adapting algorithm. This property is tunable.

InitialWeights

Initial values of filter weights

Specify the initial values of the filter weights as a scalar or a vector of length equal to the `Length` property value. The default is `0`.

AdaptInputPort

Additional input to enable adaptation of filter weights.

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the `step` method. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort

Additional input to enable weights reset

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the `step` method.

WeightsResetCondition

Condition that triggers the resetting of filter weights

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset input to the `step` method. This property applies only when you set the `WeightsResetInputPort` property to `true`. The default is `Non-zero`.

WeightsOutputPort

Output filter weights

Set this property to `true` to output the adapted filter weights. The default is `true`.

Methods

clone	Create adaptive block LMS filter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

msepred	Predicted mean-square error for Block LMS filter
msesim	Mean-square error for Block LMS filter
release	Allow property value and input characteristics changes
reset	Reset internal states of adaptive FIR filter object
step	Filter inputs using Block LMS algorithm

Examples

Remove noise using the Block LMS adaptive algorithm:

```
hblms = dsp.BlockLMSFilter(10, 5);
hblms.StepSize = 0.01;
hblms.WeightsOutputPort = false;
hfilt = dsp.DigitalFilter;
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, [.5, .75]);
x = randn(1000,1); % Noise
d = step(hfilt, x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = step(hblms, x, d);
subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Block LMS Filter block reference page. The object properties correspond to the block parameters.

See Also

`dsp.LMSFilter` | `dsp.DigitalFilter`

dsp.BlockLMSFilter.msepred

Purpose

Predicted mean-square error for Block LMS filter

Syntax

```
[MMSE,EMSE] = msepred(H,X,D)
[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(H,X,D)
[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(H,X,D,M)
```

Description

`[MMSE,EMSE] = msepred(H,X,D)` predicts the steady-state values at convergence of the minimum mean-squared error (`MMSE`) and the excess mean-squared error (`EMSE`) given the input and desired response signal sequences in `X` and `D` and the quantities in the adaptive filter `H`.

`[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(H,X,D)` calculates three sequences corresponding to the analytical behavior of the adaptive filter defined by `H`. `MEANW` is the sequence of coefficient vector means. The columns of this matrix contain predictions of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `MSE` is the sequence of mean-square errors. This column vector contains predictions of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains predictions of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(H,X,D,M)` specifies an optional decimation factor for computing `MEANW`, `MSE`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is one.

Purpose

Mean-square error for Block LMS filter

Syntax

```
MSE = msesim(H,X,D)
[MSE,MEANW,W,TRACEK] = msesim(H,X,D)
[...] = msesim(H,X,D,M)
```

Description

`MSE = msesim(H,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(H,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `H`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `H`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(H,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System identification of an FIR filter

```
ha = fir1(31,0.5);
sa = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
hb = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = step(hb,sign(randn(2000,25)));
n = 0.1*randn(size(x));             % Observation noise signal
d = step(sa,x)+n;                   % Desired signal
```

```
l = 32;                                 % Filter length
mu = 0.008;                             % Block LMS Step size.
m  = 32;                                % Decimation factor for analysis
                                        % and simulation results
ha = dsp.BlockLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Block LMS filter used in system identification'
```

Purpose

Create adaptive block LMS filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `BlockLMSFilter` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.BlockLMSFilter.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.BlockLMSFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `BlockLMSFilter` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.BlockLMSFilter.reset

Purpose

Reset internal states of adaptive FIR filter object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `BlockLMSFilter` object `H` to their initial values.

Purpose

Filter inputs using Block LMS algorithm

Syntax

```
[Y,ERR,WTS] = step(H,X,D)
[Y,ERR] = step(H,X,D)
[...] = step(H,X,D,MU)
[...] = step(H,X,D,A)
[...] = step(H,X,D,R)
[Y,ERR,WTS] = step(H,X,D,MU,A,R)
```

Description

`[Y,ERR,WTS] = step(H,X,D)` filters the input `X`, using `D` as the desired signal, and returns the filtered output in `Y`. The filter error is in `ERR`, and the estimated filter weights is in `WTS`. The filter weights update once for every block of data that the object processes.

`[Y,ERR] = step(H,X,D)` returns only the filtered output in `Y` and the filter error in `ERR`, when the `WeightsOutputPort` property is `false`.

`[...] = step(H,X,D,MU)` uses `MU` as the step size, when you set the `StepSizeSource` property to `Input port`.

`[...] = step(H,X,D,A)` uses `A` as the adaptation control, when you set the `AdaptInputPort` property to `true`. When `A` is nonzero, the filter continuously updates the filter weights. When `A` is zero, the filter weights remain constant.

`[...] = step(H,X,D,R)` uses `R` as a reset signal, when you set the `WeightsResetInputPort` property to `true`. Use the `WeightsResetCondition` property to set the reset trigger condition. If a reset event occurs, the filter resets the filter weights to their initial values.

`[Y,ERR,WTS] = step(H,X,D,MU,A,R)` filters input `X`, using `D` as the desired signal, `MU` as the step size, `A` as the adaptation control, and `R` as the reset signal. The objects returns the filtered output in `Y`, the filter error in `ERR`, and the adapted filter weights in `WTS`. Set the properties appropriately to provide all possible inputs.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Buffer input signal

Description

The `Buffer` object buffers an input signal. The number of samples per channel in the input must equal the difference between the output buffer size and buffer overlap (i.e., `Length - OverlapLength`). When you set `FrameBasedProcessing` to `true`, the number of samples per channel equals the number of rows in the input. If you set `FrameBasedProcessing` to false, the number of samples per channel equals `1`.

To buffer an input signal:

1. Define and set up your buffer System object. See "Construction" on page 3-273.
2. Call `step` to buffer the input according to the properties of `dsp.Buffer`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H=dsp.Buffer` returns a buffer System object, `HBUFF`, used to buffer input signals with overlap.

`H=dsp.Buffer('PropertyName',PropertyValue,...)` returns a buffer object, `H`, with each specified property set to the specified value.

`H=dsp.Buffer(LEN,OVRLAP,ICS,'PropertyName',... PropertyValue,...)` returns a buffer object, `H`, with `Length` property set to `LEN`, `OverlapLength` property set to `OVRLAP`, `InitialConditions` property set to `ICS` and other specified properties set to the specified values.

Properties

Length

Number of samples to buffer

Specify the number of consecutive samples from each input channel to buffer. You can set this property to any scalar integer greater than `0` of MATLAB built-in numeric data type. The default is `64`.

OverlapLength

Amount of overlap between outputs

Specify the number of samples by which consecutive output frames overlap. You can set this property to any scalar integer greater than or equal to `0` of MATLAB built-in numeric data type. The default is `0`.

InitialConditions

Initial output

Specify the value of the object's initial output for cases of nonzero latency as a scalar, vector, or matrix. The default is `0`.

FrameBasedProcessing

Enable frame-based processing

If this property is set to `true`, each column of the input is treated as a separate channel for buffering. If the value of this property is `false`, each element of the input is treated as a separate channel. The default is `true`.

Methods

clone	Create instance of an object with the same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes

reset	Reset the internal states of a System object
step	Buffer input signal based on past values

Examples

Create a buffer of 256 samples with 128 sample overlap:

```
hreader=dsp.SignalSource(randn(1024,1),128);
hbuff=dsp.Buffer(256,128);

for i=1:8
     y=step(hbuff,step(hreader));
     % y is of length 256 with 128 samples
     %   from previous input
 end
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Buffer block reference page. The object properties correspond to the block properties, except as noted.

This object processes inputs as frames or as samples by setting the `FrameBasedProcessing` property. The corresponding block has a temporary **Treat Mx1 and unoriented sample-based signals as** parameter with `One channel` option for frame behavior and `M channels` option for sample behavior. See the Buffer block reference page and "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.DelayLine` | `dsp.Delay`

dsp.Buffer.clone

Purpose

Create instance of an object with the same property values

Syntax

```
C=clone(H)
```

Description

`C=clone(H)` creates a `Buffer` System object `C`, with the same property values as `H`.

The `clone` method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Buffer.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `Buffer` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Buffer.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset the internal states of a System object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of buffer to their initial values.

For many System objects, this method is a no-op. Objects that have internal states will describe in their help what the reset method does for that object.

The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

dsp.Buffer.step

Purpose

Buffer input signal based on past values

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` creates output `Y` based on current input and stored past values of `X` . Output length equals the `Length` property.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Estimate of autoregressive (AR) model parameters using Burg method

Description

The `BurgAREstimator` object computes the estimate of the autoregressive (AR) model parameters using the Burg method.

To compute the estimate of the AR model parameters:

1. Define and set up your System object. See "Construction" on page 3-283.
2. Call `step` to compute the estimate according to the properties of `dsp.BurgAREstimator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.BurgAREstimator` returns a Burg `BurgAREstimator` System object, `H`, that performs parametric `AR` estimation using the Burg maximum entropy method.

`H = dsp.BurgAREstimator('PropertyName',PropertyValue,...)` returns a Burg `AR` estimator object, `H`, with each specified property set to the specified value.

Properties

AOutputPort

Enable output of polynomial coefficients

Set this property to `true` to output the polynomial coefficients, `A`, of the AR model the object computes. The default is `true`. Either the `AOutputPort` property, the `KOutputPort` property, or both must be `true`.

KOutputPort

Enable output of reflection coefficients

Set this property to `true` to output the reflection coefficients, `K`, for the AR model that the object computes. The default is `false`. Either the `AOutputPort` property, the `KOutputPort` property, or both must be `true`.

EstimationOrderSource

Source of estimation order

Specify how to determine estimator order as `Auto` or `Property`. When you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. When you set this property to `Property`, the value in EstimationOrder is used. The default is `Auto`.

EstimationOrder

Order of AR model

Set the AR model estimation order to a real positive integer. This property applies when you set the `EstimationOrderSource` to `Property`. The default is `4`.

Methods

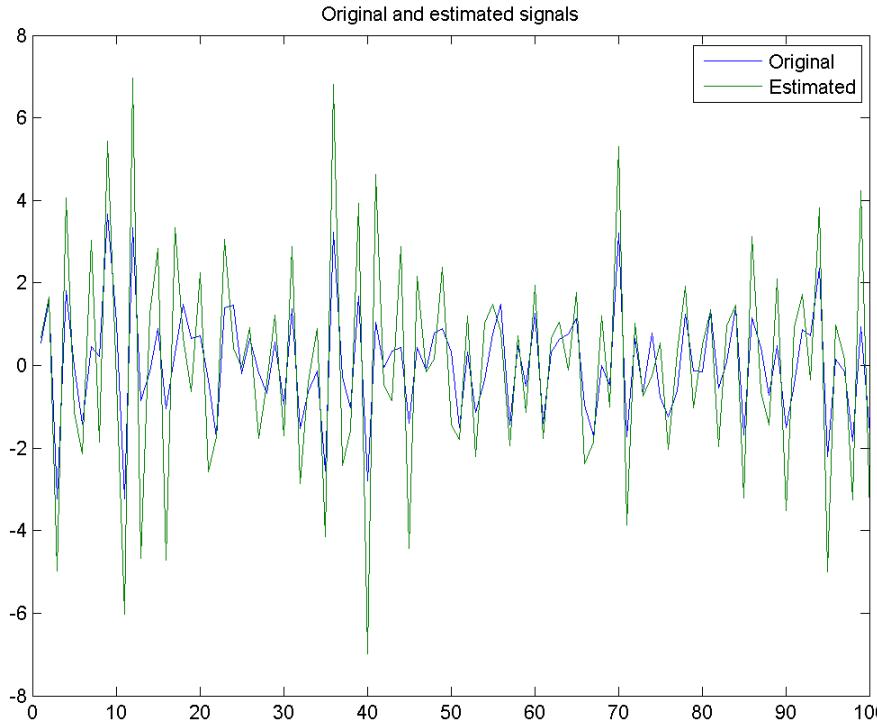
clone	Create Burg AR Estimator object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Normalized estimate of AR model parameter

Examples

Use the Burg AR Estimator System object to estimate the parameters of an AR model:

```
rng default; % Use default random number generator and seed
noise = randn(100,1); % Normalized white Gaussian noise
x = filter(1,[1 1/2 1/3 1/4 1/5],noise);
hburgarest = dsp.BurgAREstimator(...
```

```
'EstimationOrderSource', 'Property', ...
'EstimationOrder', 4);
[a, g] = step(hburgarest, x);
x_est = filter(g, a, x);
plot(1:100,[x x_est]);
title('Original and estimated signals');
legend('Original', 'Estimated');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg AR Estimator block reference page. The object properties correspond to the block parameters, except:

Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

See Also

`dsp.LevinsonSolver`

Purpose

Create Burg AR Estimator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `BurgAREstimator` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.BurgAREstimator.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.BurgAREstimator.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `BurgAREstimator` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.BurgAREstimator.step

Purpose

Normalized estimate of AR model parameter

Syntax

```
[A,G] = step(H,X)
[K,G] = step(H,X)
[A,K,G] = step(H,X)
```

Description

`[A,G] = step(H,X)` computes the normalized estimate of the `AR` model parameters to fit the input, `X`, in the least square sense. The input `X` must be a column vector. Output `A` is a column vector that contains the normalized estimate of the `AR` model polynomial coefficients in descending powers of z. The scalar `G` is the `AR` model gain.

`[K,G] = step(H,X)` returns `K`, a column vector containing the `AR` model reflection coefficients when you set the `KOutputPort` property to `true` and the `AOutputPort` property to `false`.

`[A,K,G] = step(H,X)` returns the `AR` model polynomial coefficients `A`, reflection coefficients `K`, and the scalar gain `G` when the `AOutputPort` and `KOutputPort` properties are both `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Parametric spectral estimate using Burg method

Description

The `BurgSpectrumEstimator` object computes a parametric spectral estimate of the input using the Burg method. The object fits an autoregressive (AR) model to the signal by minimizing the forward and backward prediction errors (via least-squares). The AR parameters are constrained to satisfy the Levinson-Durbin recursion.

To compute the parametric spectral estimate of the input:

1. Define and set up your System object. See "Construction" on page 3-293.
2. Call `step` to compute the estimate according to the properties of `dsp.BurgSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.BurgSpectrumEstimator` returns an object, `H`, that estimates the power spectral density (PSD) of the input frame using the Burg method.

`H = dsp.BurgSpectrumEstimator('PropertyName',PropertyValue,...)` returns a spectrum estimator, `H`, with each specified property set to the specified value.

Properties

EstimationOrderSource

Source of estimation order

Specify the source of the estimation order as `Auto` or `Property`. If you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. The default value is `Property`.

EstimationOrder

Order of AR model

Specify the order of AR model as a real positive integer. This property applies only when you set the `EstimationOrderSource` property to `Property`. The default value is `6`.

FFTLengthSource

Source of FFT length

Specify the source of the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the objects assumes the FFT length is one more than the estimation order. When you set this property to `Property`, the `FFTLength` property value must be an integer power of two.

FFTLength

FFT length as power-of-two integer value

Specify the FFT length as a power-of-two numeric scalar. This property applies when you set the `FFTLengthSource` property to `Property`. The default value is `256`.

SampleRate

Sample rate of input time series

Specify the sampling rate of the original input time series as a positive numeric scalar in hertz. The default value is `1`.

Methods

clone	Create estimator object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Estimate of power spectral density

Examples

Estimate PSD using the Burg method:

```
x = randn(100,1);
h = dsp.BurgSpectrumEstimator('EstimationOrder', 4);
y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Fourth order AR filter
p = step(h,y); % Uses default FFT length of 256

plot([0:255]/256, p);
title('Burg Method Spectral Density Estimate');
xlabel('Normalized frequency'); ylabel('Power/frequency');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg Method block reference page. The object properties correspond to the block properties.

See Also

`dsp.BurgAREstimator` | `dsp.LevinsonSolver`

dsp.BurgSpectrumEstimator.clone

Purpose

Create estimator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `BurgSpectrumEstimator` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.BurgSpectrumEstimator.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `BurgSpectrumEstimator` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.BurgSpectrumEstimator.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Estimate of power spectral density

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` outputs `Y`, a spectral estimate of input `X`, using the Burg method.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.CepstralToLPC

Purpose

Convert cepstral coefficients to linear prediction coefficients

Description

The `CepstralToLPC` object converts cepstral coefficients to linear prediction coefficients (LPC).

To convert cepstral coefficients to LPC:

1. Define and set up your System object. See "Construction" on page 3-302.
2. Call `step` to convert the coefficients according to the properties of `dsp.CepstralToLPC`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H=dsp.CepstralToLPC` returns a System object, `H`, that converts the cepstral coefficients(CCs) to linear prediction coefficients (LPCs).

`H=dsp.CepstralToLPC('PropertyName',PropertyValue,...)` returns a `Cepstral to LPC` object, `H`, with each specified property set to the specified value.

Properties

PredictionErrorOutputPort

Enable prediction error power output

Set this property to `true` to output the prediction error power. The prediction error power is the power of the error output of an FIR analysis filter represented by the LPCs for a given input signal. The default is `false`.

Methods

clone	Create cepstral to LPC object with same property values
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	LPC coefficients from column of cepstral coefficients

Examples

Convert cepstral coefficients to linear prediction coefficients (LPC):

```
cc=[0 0.9920 0.4919 0.3252 0.2418 , ...
0.1917 0.1583 0.1344 0.1165 0.0956]';
hcc2lpc=dsp.CepstralToLPC;
a=step(hcc2lpc,cc);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from Cepstral Coefficients block reference page. The object properties correspond to the block parameters.

See Also

`dsp.LPCToCepstral` | `dsp.LSFToLPC` | `dsp.RCToLPC`

dsp.CepstralToLPC.clone

Purpose

Create cepstral to LPC object with same property values

Syntax

```
C=clone(H)
```

Description

`C=clone(H)` creates a `CepstralToLPC` System object `C`, with the same property values as `H`.

The `clone` method creates a new unlocked object.

Purpose

Number of expected inputs to the `step` method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.CepstralToLPC.getNumOutputs

Purpose

Number of outputs of the `step` method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `CepstralToLPC` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.CepstralToLPC.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

LPC coefficients from column of cepstral coefficients

Syntax

```
A=step(H,CC)
[A,P]=step(H,CC)
```

Description

`A=step(H,CC)` computes the linear prediction coefficients (LPC) coefficients, `A` , from the columns of cepstral coefficients, `CC`.

`[A,P]=step(H,CC)` converts the columns of the cepstral coefficients `CC` to the LPCs and returns the prediction error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Chirp

Purpose

Generate swept-frequency cosine (chirp) signal

Description

The `Chirp` object generates a swept-frequency cosine (chirp) signal.

To generate the chirp signal:

1. Define and set up your chirp signal. See "Construction" on page 3-310.
2. Call `step` to generate the signal according to the properties of `dsp.Chirp`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Chirp` returns a chirp signal, `H`, with unity amplitude.

`H = dsp.Chirp('PropertyName',PropertyValue,...)` returns a chirp signal, `H`, with each specified property set to the specified value.

Properties

Type

Frequency sweep type

Specify the frequency sweep type as `Swept cosine`, `Linear`, `Logarithmic`, or `Quadratic`. This property specifies how the output instantaneous frequency sweep varies over time. The default value is `Linear`.

SweepDirection

Sweep direction

Specify the sweep direction as either `Unidirectional` or `Bidirectional`. The default value is `Unidirectional`.

InitialFrequency

Initial frequency (hertz)

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the `Type` property to `Logarithmic`, the value of this property is one

less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` property. This property is tunable. The default value is `1000`.

TargetFrequency

Target frequency (hertz)

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time. When you set the `Type` property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` property. This property is tunable. The default value is `4000`.

TargetTime

Target time

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` property to `Swept cosine`, this property specifies the time at which the sweep reaches $2f_{tgt} - f_{init}$ Hz, where f_{tgt} is the `TargetFrequency` and f_{init} is the `InitialFrequency`. The target time should not be greater than the sweep time, specified by the `SweepTime` property. This property is tunable. The default value is `1`.

SweepTime

Sweep time

When you set the `SweepDirection` property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` property to `Bidirectional`, the sweep time is half the period of the output

frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime`. This property must be a positive numeric scalar and is tunable. The default value is `1`.

InitialPhase

Initial phase

Specify initial phase of the output in radians at time $t = 0$. This property is tunable. The default value is `0`.

SampleRate

Sample rate

Specify the sampling rate of the output in hertz as a positive numeric scalar. The default value is `8000`.

SamplesPerFrame

Samples per output frame

Specify the number of samples to buffer into each output as a positive integer. The default value is `1`.

OutputDataType

Output data type

Specify the output data type as `double` or `single`. The default value is `double`.

Methods

clone	Create chirp object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset internal states of chirp object
step	Generate chirp signal

Examples

Generate a bidirectional swept chirp signal:

```
hchirp = dsp.Chirp(...
'SweepDirection', 'Bidirectional', ...
'TargetFrequency', 25, ...
'InitialFrequency', 0,...
'TargetTime', 1, ...
'SweepTime', 1, ...
'SamplesPerFrame', 400, ...
'SampleRate', 400);
plot(step(hchirp));
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Chirp block reference page. The object properties correspond to the block parameters.

See Also

`dsp.SineWave`

dsp.Chirp.clone

Purpose

Create chirp object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `Chirp` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Chirp.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `Chirp` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Chirp.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of chirp object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `Chirp` object `H` to their initial values. After you reset `H`, the frequency sweep restarts from the beginning.

dsp.Chirp.step

Purpose

Generate chirp signal

Syntax

```
Y = step(H)
```

Description

`Y = step(H)` returns a swept-frequency cosine output, `Y`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Decimate input using Cascaded Integrator-Comb filter

Description

The `CICDecimator` object decimates inputs using a Cascaded Integrator-Comb filter. Inputs and outputs to the object have signed fixed-point data types. You must have a Fixed-Point Designer license to use the `CICDecimator` System object.

To decimate inputs using a CIC filter:

1. Define and set up your System object. See "Construction" on page 3-321.
2. Call `step` to decimate the input according to the properties of `dsp.CICDecimator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.CICDecimator` returns a `CICDecimator` System object, `H`, that you can use to decimate the input with a cascaded integrator-comb (CIC) decimation filter.

`H = dsp.CICDecimator('PropertyName',PropertyValue,...)` returns a `CICDecimator` object, `H`, with each specified property set to the value you specify.

`H = dsp.CICDecimator(R,M,N,'PropertyName', PropertyValue, ...)` returns a `CICDecimator` object, `H`, with the `DecimationFactor` property set to *`R`*, the `DifferentialDelay` property set to *`M`*, the `NumSections` property set to *`N`*, and any other specified properties set to the values you specify.

Properties

DecimationFactor

Decimation factor of filter

Specify a positive integer amount by which the object decimates the input. The default is `2`.

DifferentialDelay

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is `1`.

NumSections

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is `2`.

FixedPointDataType

Fixed-point property setting

Specify the fixed-point data type as one of `| Full precision | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths |`. The default is `Full precision`. When you set this property to:

- `Full precision` – the `CICDecimator` object automatically determines the word and fraction lengths of the filter sections and output.
- `Minimum section word length` – the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the `OutputWordLength`.
- `Specify word lengths` – the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the `OutputWordLength` and the `SectionWordLengths` properties.
- `Specify word and fraction lengths`, – the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the `OutputFractionLength`, `OutputWordLength`, `SectionFractionLengths`, and `SectionWordLengths` properties.

SectionWordLengths

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length `2*NumSections`. This property applies only when you set the `FixedPointDataType` property to either `Specify word lengths` or `Specify word and fraction lengths`. The default is `[16 16 16 16]`.

SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length `2*NumSections`. This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is `0`.

OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the `FixedPointDataType` property to `Minimum section word lengths`, `Specify word lengths`, or`Specify word and fraction lengths`. The default is `32`.

OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is `0`.

Methods

clone	Create CIC Decimator object with same property values
freqz	Frequency response

fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset filter states of CIC decimator object
step	Decimate input using Cascaded Integrator-Comb filter

More “Analysis Methods for Filter System Objects” on page 2-2.

Examples

Decimate signal by a factor of 4 (i.e., downsample the signal from 44.1 kHz to 11.025 kHz):

```
hcicdec = dsp.CICDecimator(4);
%    DecimationFactor = 4
%    default NumSections = 2 and DifferentialDelay = 1
hcicdec.FixedPointDataType = 'Minimum section word lengths';
hcicdec.OutputWordLength = 16;

% Create fixed-point sinusoidal input signal
Fs = 44.1e3;              % Original sampling frequency
n = (0:1023)';            % 1024 samples, 0.0232 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);

% Create SignalSource System object
```

```
hsr = dsp.SignalSource(x, 64);

% Decimate output with 16 samples per frame
y = zeros(16,16);
for ii=1:16
     y(ii,:) = step(hcicdec, step( hsr ));
end

% Plot first frame of original and decimated signals.
% Output latency is 2 samples.
gainCIC = ...
   (hcicdec.DecimationFactor*hcicdec.DifferentialDelay)^hcicdec.NumSec
stem(n(1:56)/Fs, double(x(4:59))); hold on;
stem(n(1:14)/(Fs/hcicdec.DecimationFactor),double(y(1,3:end))/gainCIC,
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Decimated signal', 'location', 'north');
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CIC Decimation block reference page. The object properties correspond to the block properties, except:

- The **Rate options** block parameter is not supported by the `dsp.CICDecimator` object.

See Also

`dsp.CICInterpolator` | `dsp.FIRDecimator`

dsp.CICDecimator.clone

Purpose

Create CIC Decimator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `CICDecimator` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with un-initialized states.

Purpose

Frequency response

Syntax

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

dsp.CICDecimator.fvtool

Purpose

Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description

`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.CICDecimator.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description

`[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

dsp.CICDecimator.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `CICDecimator` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Unwrapped phase response

Syntax

```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

dsp.CICDecimator.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset filter states of CIC decimator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the `CICDecimator` System object `H` to zero.

dsp.CICDecimator.step

Purpose

Decimate input using Cascaded Integrator-Comb filter

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` decimates the fixed-point input `X` to produce a fixed-point output `Y` using the `CICDecimator` System object `H`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Interpolate signal using Cascaded Integrator-Comb filter

Description

The `CICInterpolator` object interpolates inputs using a Cascaded Integrator-Comb (CIC) filter. Inputs and outputs to the object have signed fixed-point data types. You must have a Fixed-Point Designer license to use the `CICInterpolator` System object.

To interpolate inputs using a CIC filter:

1. Define and set up your System object. See "Construction" on page 3-337.
2. Call `step` to interpolate the input according to the properties of `dsp.CICInterpolator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.CICInterpolator` returns a System object, `H`, that you can use to interpolate the input with a cascaded integrator-comb (CIC) interpolation filter.

`H = dsp.CICInterpolator('PropertyName',PropertyValue,...)` returns a `CIC` interpolation object, `H`, with each specified property set to the value you specify.

`H = dsp.CICInterpolator(R,M,N,'PropertyName',PropertyValue,...)` returns a `CICInterpolator` object, `H`, with the `InterpolationFactor` property set to *`R`*, the `DifferentialDelay` property set to *`M`*, the `NumSections` property set to *`N`*, and other specified properties set to the values you specify.

Properties

InterpolationFactor

Interpolation factor of filter

Specify a positive integer amount by which the object interpolates the input signal. The default is `2`.

DifferentialDelay

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is `1`.

NumSections

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is `2`.

FixedPointDataType

Fixed-point property setting

Specify the fixed-point data type as one of `| Full precision | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths |`. The default is `Full precision`. When you set this property to:

- `Full precision` – the `CICInterpolator` object automatically determines the word and fraction lengths of the filter sections and output.
- `Minimum section word length` – the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the `OutputWordLength`.
- `Specify word lengths` – the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the `OutputWordLength` and the `SectionWordLengths` properties.
- `Specify word and fraction lengths` – the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the `OutputFractionLength`, `OutputWordLength`, `SectionFractionLengths`, and `SectionWordLengths` properties.

SectionWordLengths

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length `2*NumSections`. This property applies only when you set the `FixedPointDataType` property to `Specify word lengths` or `Specify word and fraction lengths`. The default is `[16 16 16 16]`.

SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length `2*NumSections`. This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is `0`.

OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the `FixedPointDataType` property to `Minimum section word lengths`, `Specify word lengths`, or`Specify word and fraction lengths`. The default is `32`.

OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the `FixedPointDataType` property to `Specify word and fraction lengths`. The default is `0`.

Methods

clone	Create CIC Interpolator object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset internal states of CIC Interpolator object
step	Interpolate signal using Cascaded Integrator-Comb filter

More “Analysis Methods for Filter System Objects” on page 2-2.

Examples

Interpolate signal by a factor of 2 (upsample the signal from 22.05 kHz to 44.1 kHz):

```
hcicint = dsp.CICInterpolator(2);
%    default NumSections = 2, DifferentialDelay = 1

% Create fixed-point sinusoidal input signal
Fs = 22.05e3;      % Original sampling frequency
n = (0:511)';      % 512 samples, 0.0113 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

```
% Create SignalSource System object
hsr = dsp.SignalSource(x, 32);

% Interpolate output with 64 samples per frame
y = zeros(16,64);
for ii=1:16
     y(ii,:) = step(hcicint,step( hsr ));
end

% Plot first frame of original and interpolated signals.
% Output latency is 2 samples.
gainCIC = ...
   (hcicint.InterpolationFactor*hcicint.DifferentialDelay)...
   ^hcicint.NumSections/hcicint.InterpolationFactor;
stem(n(1:31)/Fs, double(x(1:31)),'r','filled'); hold on;
stem(n(1:61)/(Fs*hcicint.InterpolationFactor), ...
   double(y(1,4:end))/gainCIC,'b');
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Interpolated signal',...
   'location', 'north');
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the CIC Interpolation block reference page. The object properties correspond to the block properties, except:

- The **Framing** block parameter is not supported by the `dsp.CICInterpolation` object. The object always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the `dsp.CICInterpolation` object.
- The **Input processing** block parameter is not supported by the `dsp.CICInterpolation` object.

- The object does not have a property that allows you to specify the source of the coefficients. The object cannot import coefficients from an `mfilt` object.

See Also

`dsp.CICDecimator` | `dsp.FIRInterpolator`

Purpose

Create CIC Interpolator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `CICInterpolator` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with un-initialized states.

dsp.CICInterpolator.freqz

Purpose

Frequency response

Syntax

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

Purpose

Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description

`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

dsp.CICInterpolator.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the step method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.CICInterpolator.impz

Purpose

Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description

`[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `CICInterpolator` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.CICInterpolator.phasez

Purpose

Unwrapped phase response

Syntax

```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.CICInterpolator.reset

Purpose

Reset internal states of CIC Interpolator object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the `CICInterpolator` System object `H` to zero.

Purpose

Interpolate signal using Cascaded Integrator-Comb filter

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` interpolates the fixed-point input `X` to produce a fixed-point output `Y` using the `CICInterpolator` System object `H`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ColoredNoise

Purpose

Colored noise generator

Description

The `ColoredNoise` object generates pink noise and other colored noise signals. The form of the PSD is $1/|f|^{\alpha}$ with the exponent, α, a real number in the interval [-2,2].

To generate a colored noise signal:

1. Define and set up your colored noise generator. See "Construction" on page 3-354.
2. Call `step` to generate the colored noise signal according to the properties of `dsp.ColoredNoise`. The signal is an array with the number of rows given by the `SamplesPerFrame` property. The number of columns is given by the `NumChannels` property.

Construction

`H = dsp.ColoredNoise` returns a colored noise generator, `H`, with default settings. Calling `step` with the default property settings generates a pink noise signal.

`H = dsp.ColoredNoise('PropertyName',PropertyValue, ...)` returns a colored noise generator, `H`, with each specified property set to the specified value.

`H = dsp.ColoredNoise(POW,SAMP,CHAN,'PropertyName',PropertyValue)` returns a colored noise generator, `H`, with `InverseFrequencyPower` equal to `POW`, `SamplesPerFrame` equal to `SAMP`, and `NumChannels` equal to `CHAN`. Other specified properties are set to the specified values.

Properties

InverseFrequencyPower

Inverse PSD exponent

Specify the inverse PSD exponent, α, as a real number in the interval [-2,2]. The inverse exponent defines the PSD of the random process by $1/|f|^{\alpha}$. The default value of this property is 1. Values of `InverseFrequencyPower` greater than 0 generate lowpass noise with a singularity (pole) at f=0. These processes

exhibit long memory. Values of `InverseFrequencyPower` less than 0 generate highpass noise with increments that are negatively correlated. These processes are referred to as anti-persistent. Special cases include:

- An `InverseFrequencyPower` value of 1 generates a pink noise. This is the default value.
- An `InverseFrequencyPower` value of 2 generates a Brownian process.
- An `InverseFrequencyPower` value of 0 generates a white noise process with a flat PSD.
- An `InverseFrequencyPower` value of -2 generates a violet (purple) noise process.

In a log-log plot of power as a function of frequency, processes generated by `dsp.ColoredNoise` exhibit an approximate linear relationship with slope equal to -α.

NumChannels

Number of output channels

Specify the number of output channels as a positive integer. This determines the number of columns of the signal. The default value of this property is 1.

SamplesPerFrame

Samples per frame

Specify the number of samples per frame as a positive integer. This determines the number of rows of the signal. The default value of this property is 1024.

RandomStream

Source of random number stream

Specify the source of the random number stream as `'Global Stream'` or `'mt19937ar with seed'`. If you set `RandomStream` to

'Global Stream', the current random number generator settings are used. The current settings of the random number generator are returned by rng. The default value of this property is 'Global Stream'.

Seed

Initial seed

Specify the initial seed of the mt19937ar random number generator as a nonnegative integer. This property only applies when RandomStream is 'mt19937ar with seed'. The default value of this property is 67.

OutputDataType

Output data type

Specify the output data type as 'double' or 'single'. The default value of this property is 'double'.

Methods

clone	Create colored noise generator with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset random number generator seed
step	Generate colored noise signal

Definitions

Colored Noise Processes

Many phenomena in diverse fields such as hydrology and finance produce time series with power spectral density (PSD) functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^{\alpha}}$$

where α is a real number in the interval [-2,2] and $L(f)$ is a positive slowly-varying or constant function. Plotting the power spectral density of such processes on a log-log plot displays an approximate linear relationship between the log frequency and log PSD with slope equal to -α

$$\ln S(f) = -\alpha \ln |f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as function of the log frequency to base 2 in order to characterize the slope in dB/octave. Rewriting the preceding equation, you obtain

$$10 \log S(f) = -10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)} + 10\frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)}$$

If α>0, *S(f)* goes to infinity as the frequency, *f*, approaches 0. Stochastic processes with power spectral densities of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If α<0, the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of $\frac{1}{|f|^{\alpha}}$ processes include:

- α=0 — white noise where *L(f)* is a constant proportional to the process variance.
- α=1 — pink, or flicker noise. Pink noise has equal energy per octave. See "Measure Pink Noise Power in Octave Bands" on page 3-358 for a demonstration. Accordingly, the power spectral density of pink noise decreases 3 dB per octave.
- α=2 — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still define a generalized power spectrum, which behaves like $\frac{1}{|f|^2}$. Accordingly, power in a brown noise decreases 6 dB per octave.
- α= -1 — blue noise. The power spectral density of blue noise increases 3 dB per octave.
- α= -2 — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

Examples

Measure Pink Noise Power in Octave Bands

This example shows how pink noise has approximately equal power in octave bands.

Generate a single-channel signal of pink noise that is 44100 samples in length. Set the random number generator to the default settings for reproducible results.

```
hpink = dsp.ColoredNoise(1,44.1e3,1);
rng default;
x = step(hpink);
```

Assume the sampling frequency is 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)
```

```
ans =

    freqinterval       Pwr
    ____________    _______

     100      200    0.19436
     200      400    0.18472
     400      800    0.20873
     800     1600     0.2177
    1600     3200    0.21887
    3200     6400    0.23617
    6400    12800    0.23526
```

The pink noise has roughly equal power in octave bands. Repeat the preceding example with `'InverseFrequencyPower'` equal to 0, which generates a white noise signal. A white noise signal has a flat power

spectral density, or equal power per unit frequency. Set the random number generator to the default settings for reproducible results.

```
hwhite = dsp.ColoredNoise(0,44.1e3,1);
rng default;
x = step(hwhite);
```

Assume the sampling frequency is 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)
```

```
ans =

    freqinterval        Pwr

    1600     3200     0.071139
    3200     6400      0.15183
    6400    12800      0.28611
```

White noise has approximately equal power per unit frequency. Therefore, you expect octave bands to have an unequal distribution of power. Because the width of an octave band increases with increasing frequency, the power per octave band increases for a white noise.

PSD of Pink Noise Realization

Generate a pink noise signal 2048 samples in length. Assume a sampling rate of 1 Hz. Obtain an estimate of the power spectral density using Welch's overlapped segment averaging.

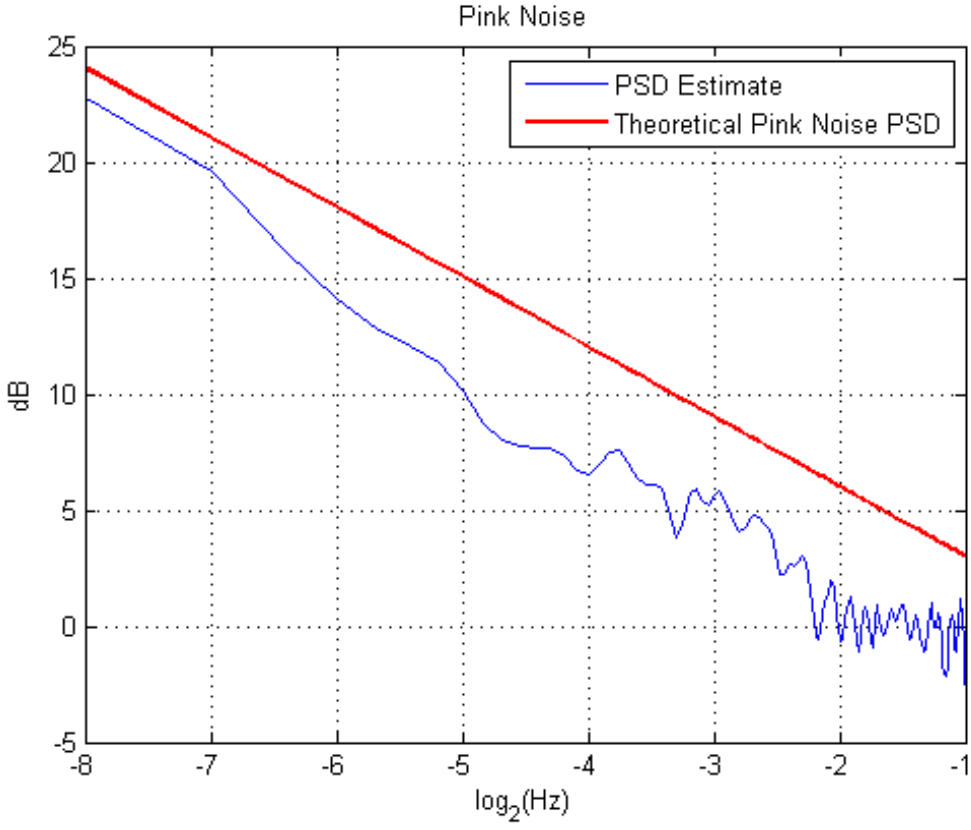
```
hcn = dsp.ColoredNoise('InverseFrequencyPower',1,'SamplesPerFrame',204
x = step(hcn);
Fs = 1;
[Pxx,F] = pwelch(x,hamming(128),[],[],Fs,'psd');
```

Construct the theoretical PSD of the pink noise process.

```
PSDPink = 1./F(2:end);
```

Display the Welch PSD estimate of the noise along with the theoretical PSD on a log-log plot. Plot the frequency axis as the logarithm to the base 2 to clearly show the octaves. Plot the PSD estimate in dB, $10\log_{10}$.

```
plot(log2(F(2:end)),10*log10(Pxx(2:end)));
hold on;
plot(log2(F(2:end)),10*log10(PSDPink),'r','linewidth',2)
xlabel('log_2(Hz)'); ylabel('dB');
title('Pink Noise');
grid on;
legend('PSD Estimate','Theoretical Pink Noise PSD');
```

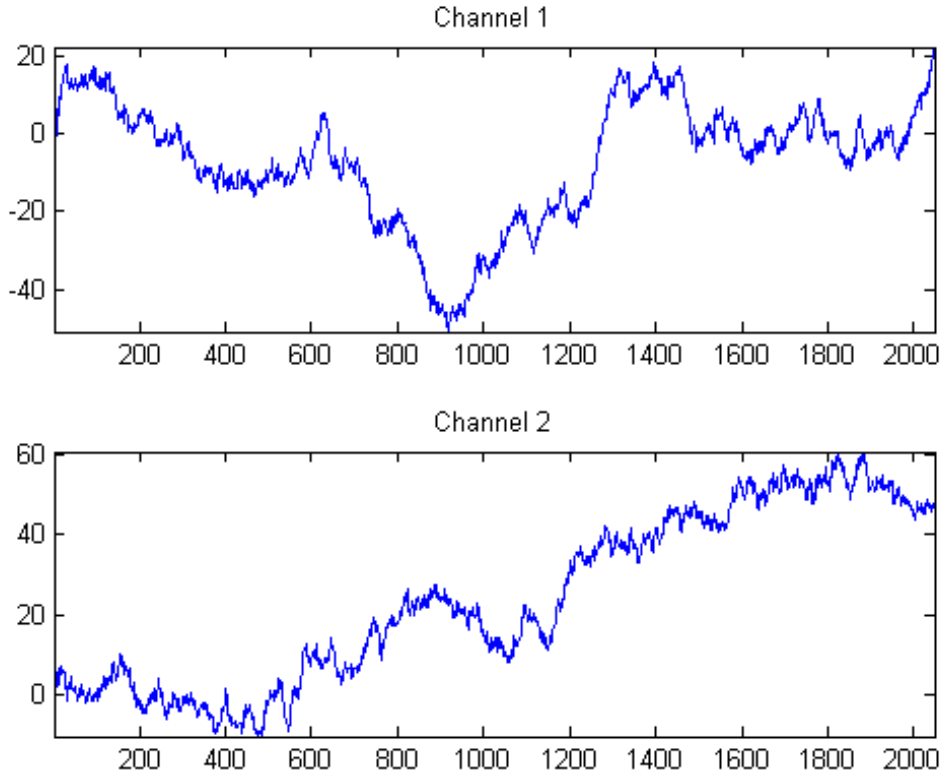


Two-Channel Brownian Noise

Generate two channels of Brownian noise by setting `alpha` and `'NumChannels'` equal to 2. Set the random number generator to its default settings for reproducible results.

```
hcn = dsp.ColoredNoise('InverseFrequencyPower',2,'SamplesPerFrame',2048,.
    'NumChannels',2);
rng default;
x = step(hcn);
```

```
subplot(2,1,1)
plot(x(:,1)); title('Channel 1'); axis tight;
subplot(2,1,2)
plot(x(:,2)); title('Channel 2'); axis tight;
```



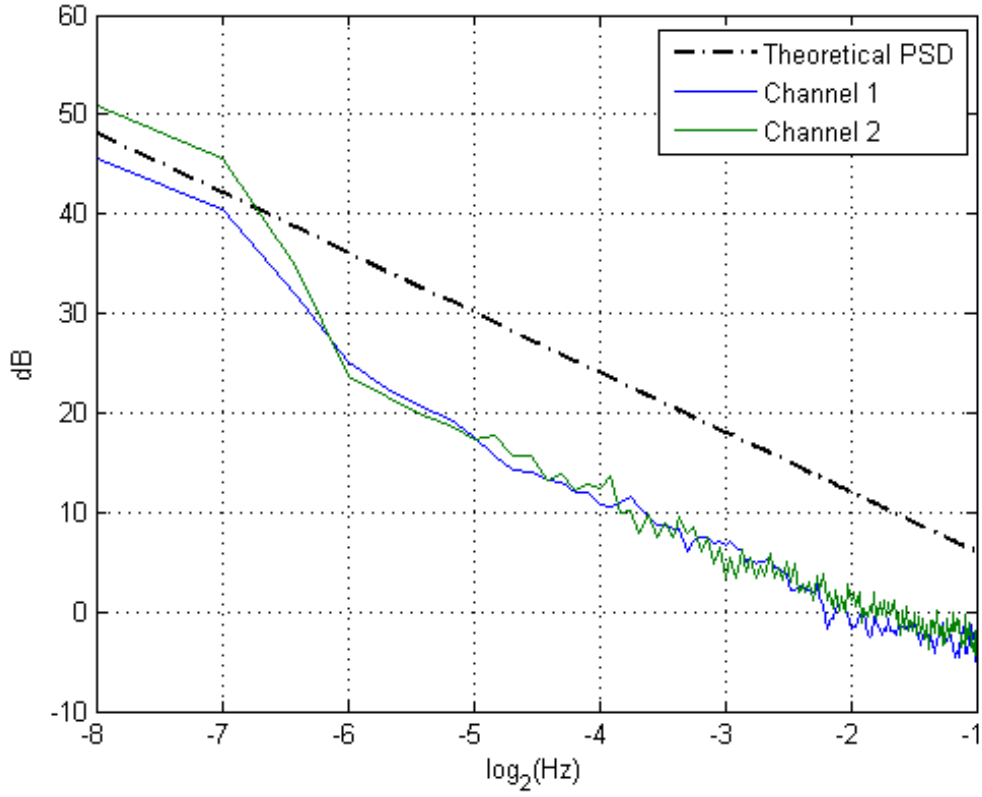
Assume a sampling frequency of 1 Hz. Obtain Welch PSD estimates for both channels.

```
Fs = 1;
for nn = 1:size(x,2)
```

```
[Pxx(:,nn),F] = pwelch(x(:,nn),hamming(128),[],[],Fs,'psd');
end
```

Construct the theoretical PSD of a Brownian process. Plot the theoretical PSD along with both realizations on a log-log plot. Use the logarithm to the base 2 for the frequency axis and plot the power spectral densities in dB.

```
PSDBrownian = 1./F(2:end).^2;
figure;
plot(log2(F(2:end)),10*log10(PSDBrownian),'k-.','linewidth',2);
hold on;
plot(log2(F(2:end)),10*log10(Pxx(2:end,:)));
xlabel('log_2(Hz)'); ylabel('dB');
grid on;
legend('Theoretical PSD','Channel 1', 'Channel 2');
```



Add Pink Noise at 0 dB SNR

This example shows how to stream in an audio file and add pink noise at a 0 dB SNR. The example reads in frames of an audio file 1024 samples in length, measures the RMS value of the audio frame, and adds pink noise with the same RMS value as the audio frame.

Set up the System objects. Set the number of `'SamplesPerFrame'` for both the file reader and the colored noise generator to 1024 samples.

Set 'InverseFrequency' to 1 to generate pink noise with a $1/|f|$ power spectral density.

```
N = 1024;
hafr = dsp.AudioFileReader('Filename','speech_dft.mp3','SamplesPerFrame',
hap = dsp.AudioPlayer('SampleRate',hafr.SampleRate);
hcn = dsp.ColoredNoise('InverseFrequencyPower',1,'SamplesPerFrame',N);
hrms = dsp.RMS;
```

Test whether the default sound output device is ready. A 1 indicates that the device is ready.

```
~isempty(dspAudioDeviceInfo('defaultOutput'))
```

```
ans =

     1
```

Stream the audio file in 1024 samples at a time. Measure the signal RMS value for each frame, generate a frame of pink noise equal in length, and scale the RMS value of the pink noise to match the signal. Add the scaled noise to the signal and play the output.

```
while ~isDone(hafr)
    audio = step(hafr);
    speechRMS = step(hrms,audio);
    noise = step(hcn);
    noiseRMS = step(hrms,noise);
    noise = noise*(speechRMS/noiseRMS);
    sigPlusNoise = audio+noise;
    step(hap,sigPlusNoise);
end

pause(hap.QueueDuration);
release(hafr);
```

```
release(hap);
```

Averaged Power Spectrum of Pink Noise

The example shows how to generate two-channels of pink noise and compute the power spectrum based on a running average of 50 PSD estimates.

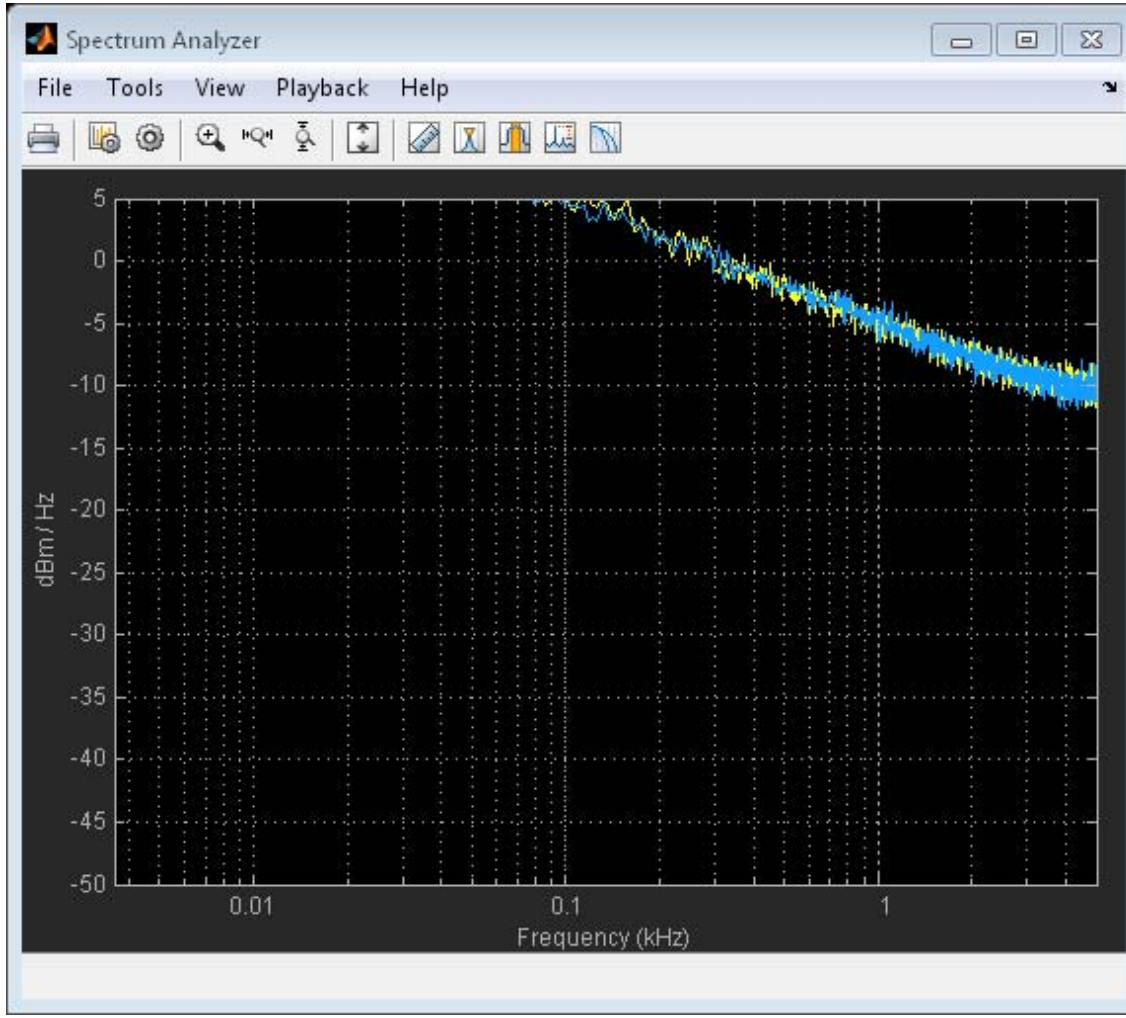
Set up the colored noise generator to generate two-channels of pink noise with 1024 samples. Set up the spectrum analyzer to compute modified periodograms using a Hamming window and 50% overlap. Obtain a running average of the PSD using 50 spectral averages.

```
Hpink = dsp.ColoredNoise(1, 1024, 2);
Hsa   = dsp.SpectrumAnalyzer('SpectrumType', 'Power density',...
                             'PlotAsTwoSidedSpectrum', false,...
                             'FrequencyScale', 'Log',...
                             'OverlapPercent', 50,...
                             'Window', 'Hamming',...
                             'YLimits', [-50,5],...
                             'SpectralAverages',50);
```

Run the simulation for 30 seconds.

```
tic,
while toc < 30

    pink = step(Hpink);
    step(Hsa, pink);
end
```



Algorithms

AR Generation Method

`dsp.ColoredNoise` generates colored noise using a white noise input in an autoregressive model (AR) of order 63.

$$\sum_{k=0}^{63} a_k y(n-k) = w(n)$$

where a_0=1 and w(n) is a zero-mean white noise process.

The AR coefficients for k≥1 are generated according to the following recursive formula with α the inverse PSD exponent

$$a_k = (k - 1 - \tfrac{\alpha}{2})\frac{a_{k-1}}{k} \quad k = 1, 2, \ldots$$

The AR method used in `dsp.ColoredNoise` is detailed on pp. 820–822 in [2].

See Also

`randn`

dsp.ColoredNoise.clone

Purpose

Create colored noise generator with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a colored noise generator, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, N, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.ColoredNoise.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the colored noise generator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.ColoredNoise.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset random number generator seed

Syntax

```
reset(H)
```

Description

`reset(H)` resets the random number generator stream if the `RandomStream` property is set to `'mt19937ar with seed'`. The seed of the random number generator is the value of the `Seed` property.

dsp.ColoredNoise.step

Purpose

Generate colored noise signal

Syntax

```
x = step(H)
```

Description

`x = step(H)` generates a colored noise signal for the number of channels specified by the `NumChannels` property. If the value of `NumChannels` is 1, `x` is a column vector. If the value of `NumChannels` is $M > 1$, `x` is a matrix with M columns. The number of samples (rows) in `x` is equal to the value of `SamplesPerFrame` .

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Two Channels of Pink Noise

Generate two channels of pink noise 1000 samples in length.

```
NumChannels = 2;
NumSamples = 1000;
hcn = dsp.ColoredNoise('InverseFrequencyPower',1,'NumChannels',2,...
    'SamplesPerFrame',NumSamples);
x = step(hcn);
subplot(2,1,1)
plot(x(:,1)); title('Channel 1');
subplot(2,1,2)
plot(x(:,2)); title('Channel 2');

dsp.Convolver

Purpose

Convolution of two inputs

Description

The `Convolver` computes the convolution of two inputs.

To compute the convolution of two inputs:

1. Define and set up your convolver. See "Construction" on page 3-378.
2. Call `step` to compute the convolution according to the properties of `dsp.Convolver`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Convolver` returns a convolver object, `H`, that convolves two inputs. For N-D arrays, the convolver computes the convolution column-wise. For arrays, the inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the convolver computes the convolution of the vector with each column of the N-D array. Convolving inputs of length N and M results in a sequence of length $N+M-1$. Convolving matrices of size M-by-N and P-by-N results in a matrix of size $(M+P-1)$-by-N.

`H = dsp.Convolver('PropertyName',PropertyValue, ...)` returns a convolver object, `H`, with each property set to the specified value.

Properties

Method

Domain for computing convolutions

Specify the domain in which the convolver performs the convolutions as `Time Domain`, `Frequency Domain`, or `Fastest`. Computing convolutions in the time domain minimizes memory use. Computing convolutions in the frequency domain may require fewer computations depending on the input length. If the value of this property is `Fastest`, the object computes convolutions in the domain which minimizes the number of computations. The default is `Time Domain`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create convolver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convolution of inputs

Examples

Convolution of two rectangular sequences:

```
hconv = dsp.Convolver;
x = ones(10,1);
y = step(hconv, x, x);
% Result is a triangular sequence
plot(y);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Convolution block reference page. The object properties correspond to the block parameters.

See Also

`dsp.Autocorrelator` | `dsp.Crosscorrelator`

dsp.Convolver.clone

Purpose

Create convolver object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a convolver object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Convolver.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the convolver object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Convolver.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Convolution of inputs

Syntax

```
Y = step(H,A,B)
```

Description

`Y = step(H,A,B)` convolves the inputs `A` and `B`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.DCBlocker

Purpose

Remove DC component

Description

The `DCBlocker` object filters or blocks the DC component of an incoming signal.

To filter the DC component of a signal:

1. Define and set up your DC blocker object. See "Construction" on page 3-388.
2. Call `step` to filter the DC component of a signal according to the properties of `dsp.DCBlocker`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.DCBlocker` creates a DC blocker System object, `H`, that removes the DC component of each channel, i.e., column, of an input signal.

`H = dsp.DCBlocker(Name,Value)` creates a DC blocker object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

Algorithm

DC offset algorithm type

Specify the DC offset estimating algorithm as one of `IIR | FIR | Subtract mean`. You can visualize the IIR and FIR responses using the fvtool method. The default is `IIR`.

- `IIR` uses a recursive estimate based on a narrow, low-pass elliptic filter. You specify the filter order using the `Order` property and you set the bandwidth using the `NormalizedBandwidth` property. This algorithm typically uses less memory than FIR and is more efficient.
- `FIR` uses a non-recursive, moving-average estimate based on a finite number of past input samples that is set using the

`Length` property. This algorithm typically uses more memory than IIR and is less efficient.

- `Subtract mean` computes the means of the columns of the input matrix and subtracts the means from the input. This method does not retain state between inputs.

NormalizedBandwidth

Normalized bandwidth of the low-pass, IIR, elliptic filter

Specify the normalized bandwidth of the IIR filter used to estimate the DC component of the input signal as a real scalar greater than 0 and less than 1. This property applies when the `Algorithm` property is set to `IIR`. The default value is `0.001`.

Order

Order of the low-pass, IIR, elliptic filter

Specify the order of the IIR elliptic filter used to estimate the DC level. This property applies when the `Algorithm` property is set to `IIR`. Use an integer greater than 3. The default value is `6`.

Length

Number of past input samples for the FIR algorithm

Specify the number of past inputs used to estimate the running mean. This property applies when the `Algorithm` property is set to `FIR`. Use a positive integer. The default value is `50`.

Methods

clone	Create DC blocker object with same property values
fvtool	Show the frequency response of the filter used by the System object
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset states of the System object
step	Blocks DC components of input signal

Examples

Remove DC Component and Display Results

The step method is used in conjunction with the `DCBlocker` to remove the input signal's DC component using all three estimation algorithms.

Create a signal that is a sum of a 15 Hz tone, a 25 Hz tone, and a DC bias.

```
t = (0:0.001:100)';
x = sin(30*pi*t) + 0.33*cos(50*pi*t) + 1;
```

Create three DC blocker objects, one for each estimation technique.

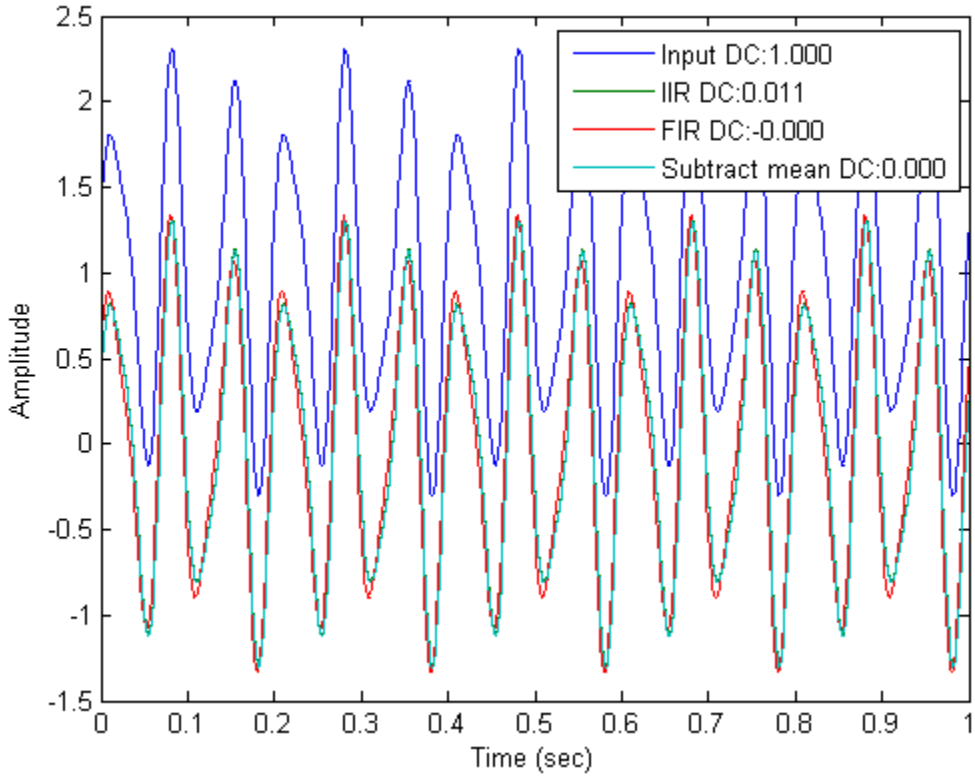
```
hDC1 = dsp.DCBlocker('Order', 6);
hDC2 = dsp.DCBlocker('Algorithm', 'FIR', 'Length', 100);
hDC3 = dsp.DCBlocker('Algorithm', 'Subtract mean');
```

For each second of time, use the step method to apply the DC blockers to the input signal. By implementing the DC blockers in 1-second increments, you can see the convergence differences among the techniques.

```
for idx = 1 : 100
    range = (1:1000) + 1000*(idx-1);
    y1 = step(hDC1, x(range));          % IIR estimate
    y2 = step(hDC2, x(range));          % FIR estimate
    y3 = step(hDC3, x(range));          % Subtract mean
end
```

Plot the input and output data for the three DC blockers for the first second of time and show the mean value for each signal. You can see that the `FIR` and `Subtract mean` algorithms converge more quickly.

```
plot(t(1:1000),x(1:1000),...
    t(1:1000),y1, ...
    t(1:1000),y2, ...
    t(1:1000),y3);
xlabel('Time (sec)')
ylabel('Amplitude')
legend(sprintf('Input DC:%.3f',    mean(x)), ...
    sprintf('IIR DC:%.3f',           mean(y1)), ...
    sprintf('FIR DC:%.3f',           mean(y2)), ...
    sprintf('Subtract mean DC:%.3f', mean(y3)));
```



Frequency Response Before and After DC Blocker

Compare the frequency response of the DC blocker using the `FIR` algorithm to the frequency response of the biased input signal.

Create an input signal composed of three tones with a DC bias of 1. Set the sampling frequency to 1 kHz and the signal duration to 100 seconds.

```
fs = 1000;
t = (0:1/fs:100)';
x = sin(30*pi*t) + 0.67*sin(40*pi*t) + 0.33*sin(50*pi*t) + 1;
```

Create a DC blocker object with the `Algorithm` property set to `FIR`.

```
hDCBlock = dsp.DCBlocker('Algorithm', 'FIR', 'Length', 100);
```

Create a `SpectrumAnalyzer` System object with power units set to `dBW` and a frequency range of [-30, 30] to display the frequency response of the input signal. Using the clone method, create a second spectrum analyzer to display the response of the output. Then, use the `Name` property to label the two objects.

```
hsa = dsp.SpectrumAnalyzer('SampleRate', fs, ...
    'PowerUnits','dBW','FrequencySpan','Start and stop frequencies',...
    'StartFrequency',-30,'StopFrequency',30);
hsa.Name = 'Signal Spectrum';

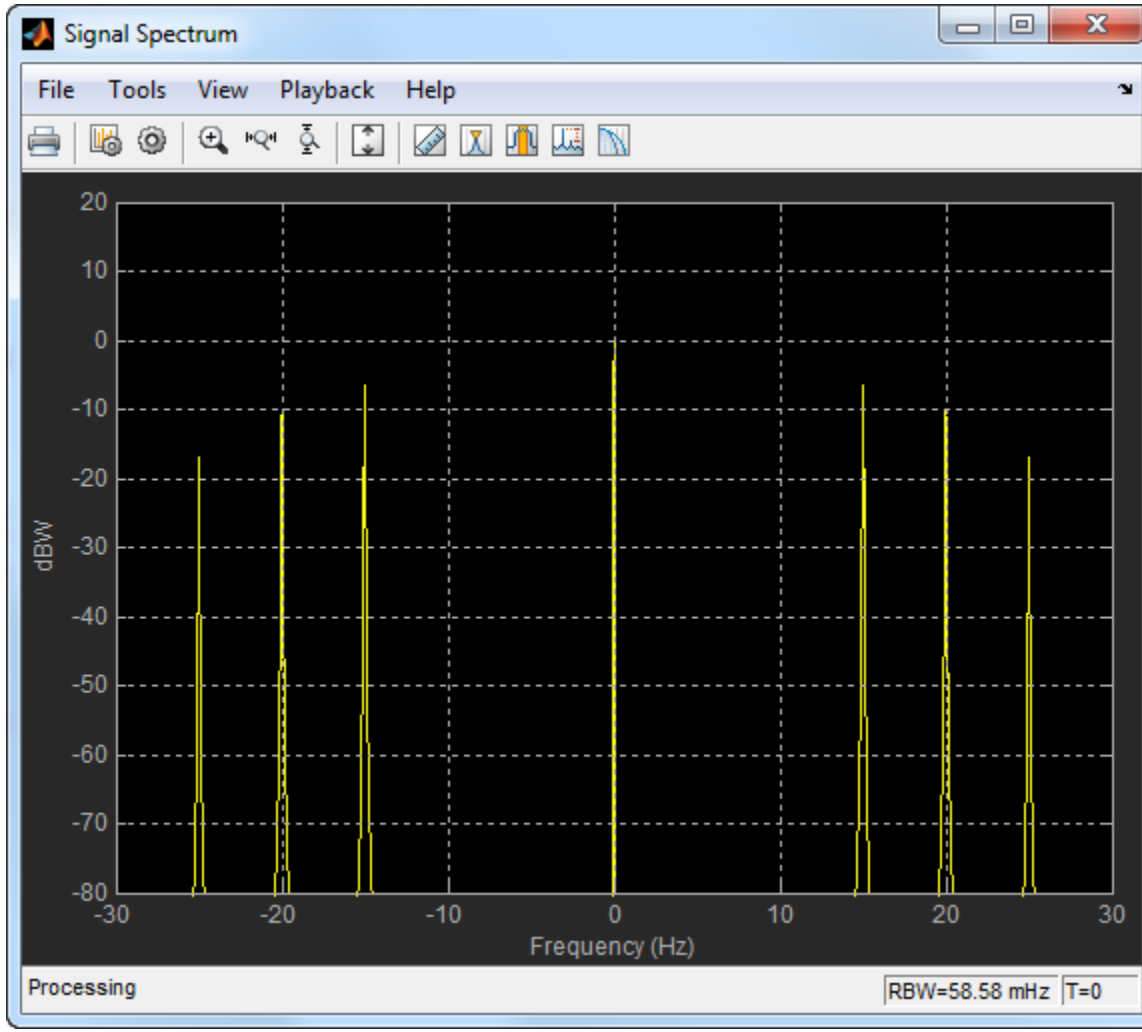
hsb = clone(hsa);
hsb.Name = 'Signal Spectrum after DC Blocker';
```

Use the step method to apply the DC blocker to the input signal, `x`, to generate the output signal, `y`.

```
y = step(hDCBlock, x);
```

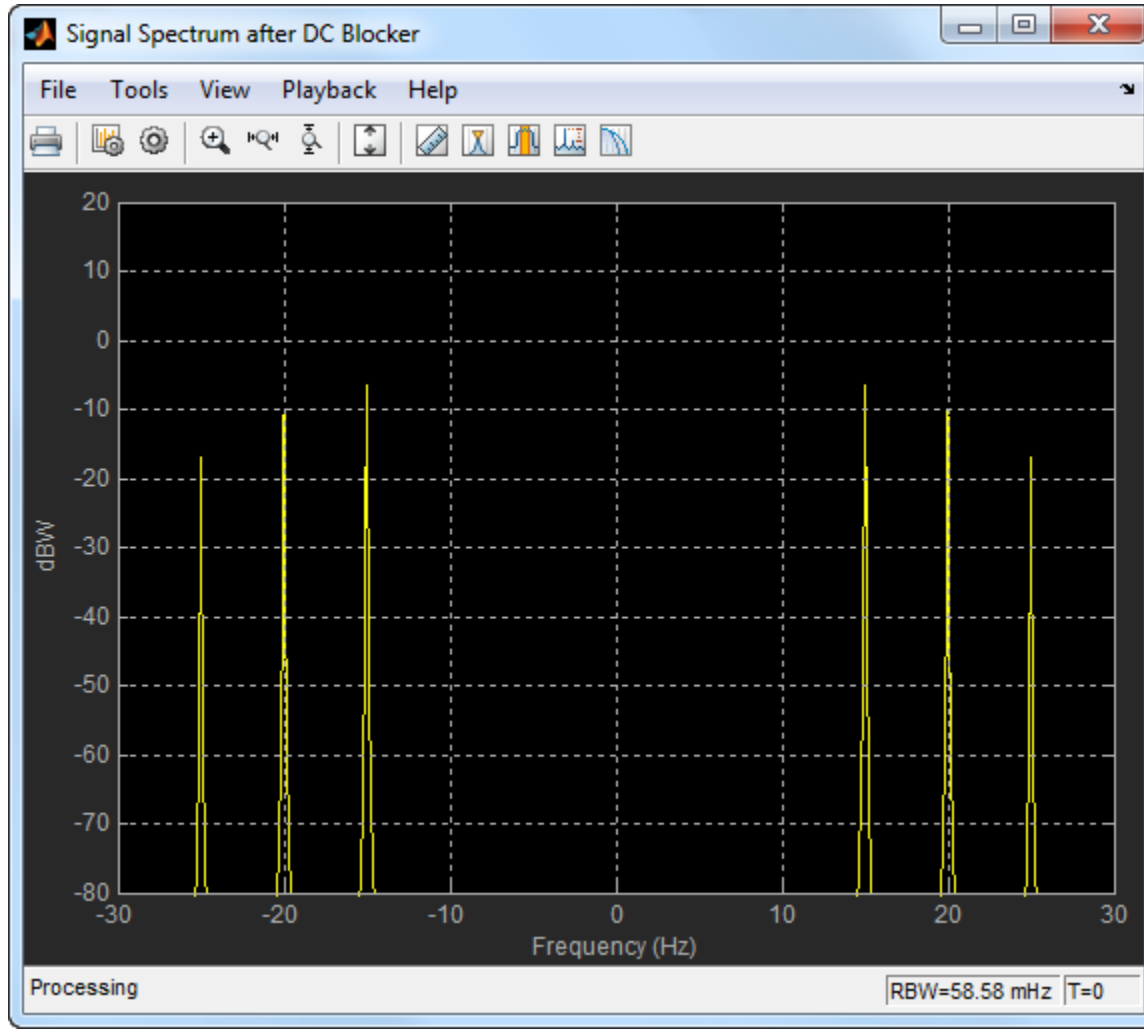
Use the step method of the `hsa` object to display the frequency characteristics of the input signal. Note the tones at 15 Hz, 20 Hz, and 25 Hz as well as the DC component.

```
step(hsa, x)
```



Use the step method of the `hsb` object to display the frequency characteristics of the output signal. The DC component has been removed.

```
step(hsb, y)
```



Algorithms

The `DCBlocker` System object subtracts the DC component from the input signal. The DC component is estimated by one of the following:

- Passing the input signal through an IIR, low-pass, elliptical filter
- Passing the input signal through an FIR filter that uses a non-recursive, moving average from a finite number of past input samples
- Computing the mean value of the input signal

The elliptical IIR filter has a pass-band ripple of 0.1 dB and a stop-band attenuation of 60 dB. You specify the normalized bandwidth and filter order. The FIR filter coefficients are given as `ones(1,Length)/Length`, where you specify the `Length` parameter. The FIR filter structure is a direct form 1 transposed.

See Also

`dsp.BiquadFilter` | `dsp.FIRFilter`

Purpose

Create DC blocker object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `DCBlocker` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.DCBlocker.fvtool

Purpose

Show the frequency response of the filter used by the `DCBlocker` System object

Syntax

```
fvtool(H)
```

Description

`fvtool(H)` shows the frequency response of the filter used by the `DCBlocker` System object. The fvtool method allows the user to visualize the lowpass filter response used to estimate the DC component. The magnitude response, phase response, group delay, impulse response, or pole-zero plot can be displayed.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
TF = isLocked(H)
```

Description

`TF = isLocked(H)` returns the locked status, `TF` of the `DCBlocker` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.DCBlocker.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources (such as memory, file handles or hardware connections) and allows all properties and input characteristics to be changed.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset states of the `DCBlocker` System object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the `DCBlocker` object, `H`.

dsp.DCBlocker.step

Purpose

Blocks DC components of input signal

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` removes the DC component from the input signal, `X`, and returns the output, `Y`. The input signal is a numeric, signed matrix, with time samples recorded in rows and independent channels of data recorded in columns.

Purpose

Count up or down through specified range of numbers

Description

The `Counter` object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

1. Define and set up your counter. See "Construction" on page 3-403.
2. Call `step` to count up or down according to the properties of `dsp.Counter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Counter` returns a counter System object, `H`, that counts up when the input is nonzero.

`H = dsp.Counter('PropertyName',PropertyValue,...)` returns a counter System object, `H`, with each specified property set to the specified value.

Properties

Direction

Count up or down

Specify the counter direction as `Up` or `Down`. The default is `Up`. This property is tunable.

CountEventInputPort

Add input to specify a count event

Set this property to `true` to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the `CountEventCondition` property. When you set this property to `false`, the internal counter is free running, that is, the counter increments or decrements on every call to the `step` method. The default is `true`.

CountEventCondition

Condition that increments, decrements, or resets internal counter

Specify the event at the count event input that increments or decrements the counter as `Rising edge`, `Falling edge`, `Either edge` or `Non-zero`.

If you set the `ResetInputPort` and `CountEventInputPort` properties to `true`, the counter is reset when the event you specify for the `CountEventCondition` occurs. This property applies only when you set the `CountEventInputPort` property to `true`.

CounterSizeSource

Source of counter size data type

Specify the source of the counter size data type as `Property` or `Input port`. The default is `Property`.

CounterSize

Range of integer values to count through

Specify the range of integer values to count through before recycling to zero as `8 bits`, `16 bits`, `32 bits` or `Maximum`. The default is `Maximum`.

MaximumCount

Counter's maximum value

Specify the counter's maximum value as a numeric scalar value. This property applies only when you set the `CounterSizeSource` property to `Property` and the `CounterSize` property to `Maximum`. The default is `255`. This property is tunable.

InitialCount

Counter initial value

Specify the initial value for the counter. The default is `0`. This property is tunable.

CountOutputPort

Output count

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

HitOutputPort

Output hit events

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time. The default is `true`.

HitValues

Values whose occurrence in count produce a true hit output

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit. This property applies only when you set the `HitOutputPort` property to `true`.

ResetInputPort

Add input to enable internal counter reset

When you set this property to `true`, specify a reset input to the `step` method. When the reset input receives the event you specify for the `CountEventCondition` property, the counter resets. If you set the `CountEventInputPort` property to `false`, the counter resets whenever the reset input is not zero.

SamplesPerFrame

Number of samples in each output frame

Specify the number of samples in each output frame. This property applies only when you set the `CountEventInputPort` property to `false`, indicating a free-running counter. The default is `1`.

CountOutputDataType

Data type of count output

Specify the data type of the count output, CNT, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`. This property applies when you set the `CountOutputPort` property to `true`. The default is `double`.

Methods

clone	Create counter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of Counter object
step	Increment or decrement the internal counter

Examples

Use Counter System object for counting from 0 to 5:

```
hcounter = dsp.Counter('MaximumCount', 5, ...
'CountOutputPort', true, ...
'HitOutputPort', false, ...
'ResetInputPort', false);
 sgnl = [0 1 0 1 0 1 0 1 0 1 0 1 ];
   for ii = 1:length(sgnl)
 %count at every rising edge of the input signal.
 cnt(ii) = step(hcounter, sgnl(ii));
   end
   cnt
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Counter block reference page. The object properties correspond to the block parameters.

- The `CountEventCondition` object property does not have a free-running option. Set the `CountEventInputPort` property to `false` to obtain the free-running option.
- The `CounterSizeSource` and `CounterSize` object properties correspond to the **Counter size** block parameter.
- The `CountOutputPort` and `HitOutputPort` correspond to the **Output** block parameter.
- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

dsp.Counter.clone

Purpose

Create counter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `Counter` object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Counter.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, from the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `Counter` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Counter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of Counter object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the counter object `H` to their initial values.

dsp.Counter.step

Purpose

Increment or decrement the internal counter

Syntax

```
[CNT,HIT] = step(H,EVENT,RESET)
CNT = step(H,EVENT,RESET)
HIT = step(H,EVENT,RESET)
[...] = step(H)
[...] = step(H,EVENT)
```

Description

`[CNT,HIT] = step(H,EVENT,RESET)` increments, decrements, or resets the internal counter as specified by the values of the `EVENT` and `RESET` inputs. The output argument `CNT` denotes the present value of the counter. A trigger event at the `EVENT` input causes the counter to increment or decrement. A trigger event at the `RESET` input resets the counter to its initial state.

`CNT = step(H,EVENT,RESET)` returns the current value of the count when you set the `CountOutputPort` property to `true`, and the `HitOutputPort` property to `false`.

`HIT = step(H,EVENT,RESET)` returns a Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. This condition applies when you set the `HitOutputPort` property to `true` and the `CountOutputPort` property to `false`.

`[...] = step(H)` increments or decrements the free-running internal counter when you set the `CountEventInputPort` property to `false` and the `ResetInputPort` property to `false`.

`[...] = step(H,EVENT)` increments or decrements the internal counter when the `EVENT` input matches the event you specify for the `CountEventCondition` property and you set the `ResetInputPort` property to `false`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CoupledAllpassFilter

Purpose

Coupled allpass IIR filter

Description

The `CoupledAllpassFilter` object implements a coupled allpass filter structure composed of two allpass filters connected in parallel. Each allpass branch can contain multiple sections. The overall filter output is computed by adding the output of the two respective branches. An optional second output can also be returned, which is power complementary to the to the first. For example, from the frequency domain perspective, if the first output implements a lowpass filter, the second output implements the power complementary highpass filter. For real signals, the power complementary output is computed by subtracting the output of the second branch from the first. `CoupledAllpassFilter` supports double- and single-precision floating point and allows you to choose between different realization structures. This System object also supports complex coefficients, multichannel variable length input, and tunable filter coefficient values.

To filter each channel of the input:

1. Define and set up your Coupled Allpass Filter. See "Construction" on page 3-416.
2. Call `step` to filter each channel of the input according to the properties of `dsp.CoupledAllpassFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.CoupledAllpassFilter` returns a coupled allpass filter System object, H, that filters each channel of the input signal independently. The coupled allpass filter uses the default inner structures and coefficients.

`H = dsp.CoupledAllpassFilter('PropertyName',PropertyValue, ...)` returns a Coupled allpass filter System object, `H`, with each property set to the specified value.

`H = CoupledAllpassFilter(AllpassCoefficients1,AllpassCoefficients2)` returns a coupled allpass filter System object, H, with `Structure` set to

'Minimum multiplier'. The allpass coefficients for each of the two branches are set to their two corresponding specified values.

H = CoupledAllpassFilter(Structure,AllpassCoefficients1, AllpassCoefficients2) returns a coupled allpass filter System object, H, with Structure set to a specified value. This value can be 'Minimum multiplier' | 'Wave Digital Filter' | 'Lattice'. The coefficients relevant to the specified structure are set to the values provided.

Properties

Structure

Internal structure of allpass branches

Specify the internal structure of allpass branches as one of 'Minimum multiplier' | 'Wave Digital Filter' | 'Lattice'. Each structure uses a different pair of coefficient values, independently stored in the relevant object property.

AllpassCoefficients1

Allpass polynomial coefficients of branch 1

Specify the polynomial filter coefficients for the first allpass branch. This property is applicable only if you set the Structure property to 'Minimum multiplier'. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is [0 0.5]. This property is tunable.

WDFCoefficients1

Wave Digital Filter coefficients of branch 1

Specify the Wave Digital Filter coefficients for the first allpass branch. This property is applicable only if you set the Structure property to 'Wave Digital Filter'. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is [0.5 0]. This property is tunable.

LatticeCoefficients1

Lattice coefficients of branch 1

Specify the allpass lattice coefficients for the first allpass branch. This property is applicable only if you set the `Structure` property to `'Lattice'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[0.5 0]`. This property is tunable.

Delay

length in samples for branch 1

`Delay` is the integer number of the delay taps in the top branch. This property is applicable only if you set the `PureDelayBranch` property to `true`. This property is a scalar positive integer, and is tunable.

Gain1

Independent Branch 1 Phase Gain

`Gain1` is the individual branch phase gain. This property can accept only values equal to `'1'`, `' 1'`, `'0+i'`, or `'0 i'`. The default value is `1`. This property is nontunable.

AllpassCoefficients2

Allpass polynomial coefficients of branch 2

Specify the polynomial filter coefficients for the second allpass branch. This property is applicable only if you set the `Structure` property to `'Minimum Multiplier'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is [ ]. This property is tunable.

WDFCoefficients2

Wave Digital Filter coefficients of branch 2

This property is applicable only if you set the `Structure` property to `'Wave Digital Filter'`. This property can accept values

either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is [ ]. This property is tunable.

LatticeCoefficients2

Lattice coefficients of branch 2

Specify the allpass lattice coefficients for the second allpass branch. This property is applicable only if you set the `Structure` property to `'Lattice'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is [ ]. This property is tunable.

Gain2

Independent Branch 2 Phase Gain

Specify the value of the independent phase gain applied to branch 2. This property can accept only values equal to `'1'`, `' 1'`, `'0+1i'` or `'0 1i'`. The default value is `1`. This property is nontunable.

Beta

Coupled phase gain

Specify the value of the phasor gain in complex conjugate form, in each of the two branches, and in complex coefficient configuration. This property is applicable only when the selected `Structure` property supports complex coefficients. The absolute value of this property should be `1` and its default value is `1`. This property is tunable.

PureDelayBranch

Replace allpass filter in first branch with pure delay

If you set `PureDelayBranch` to true, the property holding the coefficients for the first allpass branch is disabled and Delay becomes enabled. You can use this property to improve

performance, when one of the two allpass branches is known to be a pure delay (e.g. for halfband filter designs)

ComplexConjugateCoefficients

Allow inferring coefficients of second allpass branch as complex conjugate of first

When the input signal is real, this property triggers the use of an optimized structural realization. This property is only enabled if the currently selected structure supports complex coefficients. Use it only if the filter coefficients are actually complex.

Methods

clone	Create Coupled Allpass Filter System object with same property values
getBranches	Return internal allpass branches
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of Coupled Allpass filter
step	Filter input with CoupledAllpas filter object

Examples

Allpass Realization of a Butterworth Lowpass Filter — Manual Design

Realize a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```
Fs = 48000;
Fc = 12000;
[b, a] = butter(3, 2*Fc/Fs);
```

```
[c1, c2] = tf2ca(b, a);
Hca = dsp.CoupledAllpassFilter(c1(2:end), c2(2:end));
Hsr = dsp.SignalSource(randn(4096, 1), 128);
Hlog = dsp.SignalSink;
```

After creating the filter, generate a random signal, and set up a log of the output signal, step through the System objects.

```
while ~isDone(Hsr)
   in = step(Hsr);
   out = step(Hca, in);
   step(Hlog, [in, out]);
end
signalTraces = Hlog.Buffer;
tfestimate(signalTraces(:,1), signalTraces(:,2))
hold on
[A, w] = freqz(Hca);
plot(w/pi, db(A), 'r')
ylim([-80, 10])
hold off
```

Allpass Realization of an Elliptic Highpass Filter — Automated Design

Remove a low-frequency sinusoid using an elliptic highpass filter design implemented through a coupled allpass structure.

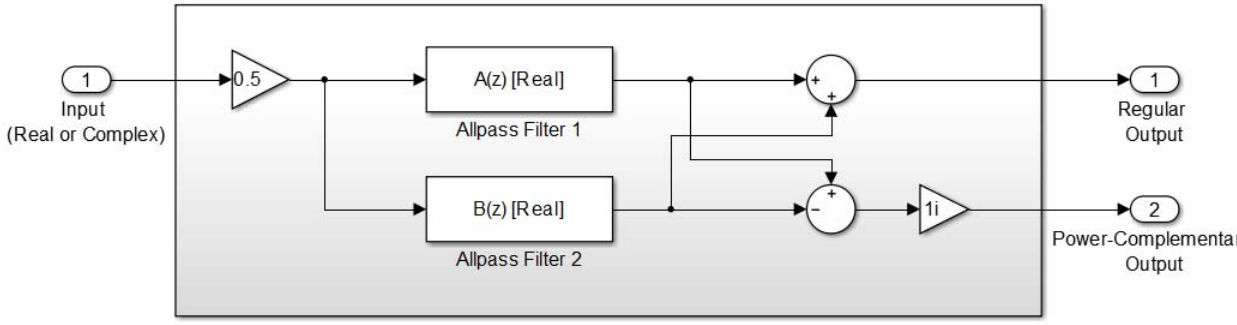
```
% Initialize
Fs = 1000;
f1 = 50; f2 = 100;
Fpass = 70; Apass = 1;
Fstop = 60; Astop = 80;
filtSpecs = fdesign.highpass(Fstop,Fpass,Astop,Apass,Fs);
hHP = design(filtSpecs,'ellip','FilterStructure','cascadeallpass',...
    'SystemObject',true);
frameLength = 1000;
nFrames = 100;
hSR   = dsp.SineWave('Frequency',[f1,f2],'SampleRate',Fs,...
```

```
  'SamplesPerFrame',frameLength); % Input composed of two sinusoids.
hplot = dsp.SpectrumAnalyzer('SampleRate',Fs,'YLimits',[-150 30],...
  'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,...
  'FrequencyResolutionMethod', 'WindowLength','WindowLength',1000,...
  'FFTLengthSource', 'Property','FFTLength', 1000,...
  'Title','Original (Channel 1) Filtered (Channel 2)');
% Simulate
for k = 1:nFrames
  original = sum(step(hSR),2); % Add the two sinusoids together
  filtered = step(hHP,original);
  step(hplot,[original,filtered]);
end
```

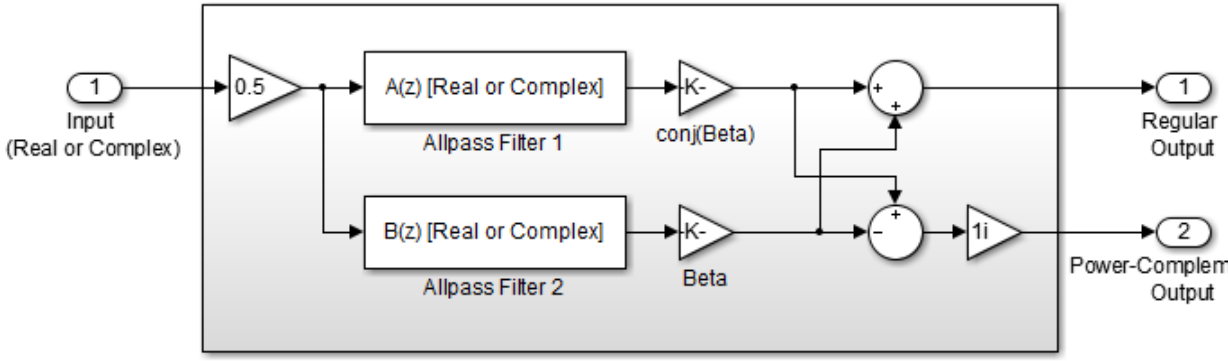
Algorithms

The following three figures summarize the main structures supported by `dsp.CoupledAllpassFilter`.

- Minimum Multiplier and WDF



- Lattice



- Lattice with Complex Conjugate Coefficients

See Also

`dsp.AllpassFilter` | `dsp.BiquadFilter` | `dsp.IIRFilter`

Purpose

Create Coupled Allpass Filter System object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`,with the same property values. The `clone` method creates a new unlocked object with uninitialized states.

dsp.CoupledAllpassFilter.getBranches

Purpose

Return internal allpass branches

Syntax

```
getBranches(H)
```

Description

`getBranches(H)` returns copies of the internal allpass branches, as a two-field structure. Each branch is an instance of `dsp.AllpassFilter`.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the CoupledAllpass filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.CoupledAllpassFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of Coupled Allpass filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the Coupled Allpass filter object, `H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

dsp.CoupledAllpassFilter.step

Purpose

Filter input with CoupledAllpas filter object

Syntax

```
Y = step(H,X)
[Y1,...,YN] = step(H,X)
```

Description

`Y = step(H,X)` processes the input data, `X` to produce the output, `Y`, for System object, `H`.

`[Y1,...,YN] = step(H,X)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs (but not for this object).

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Estimate cross-spectral density

Description

The `dsp.CrossSpectrumEstimator` computes the cross- spectrum density of a signal, using the Welch algorithm and the Periodogram method.

To implement the cross-spectrum estimation object:

1. Define and set up your cross-spectrum estimator object. See "Construction" on page 3-431.
2. Call `step` to implement the estimator according to the properties of `dsp.CrossSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.CrossSpectrumEstimator` returns a System object, H, that computes the cross-power spectrum of real or complex signals using the periodogram method and Welch's averaged, modified periodogram method.

`H = dsp.CrossSpectrumEstimator('`*`PropertyName`*`', `*`PropertyValue`*`,...)` returns a `Cross-Spectrum Estimator` System object, H, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SampleRate

Sample rate of input

Specify the sample rate of the input, in hertz, as a finite numeric scalar. The default value is `1 Hz`. The sample rate is the rate at which the signal is sampled in time.

SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Cross-Spectrum Estimator computes the current

cross-spectral estimate by averaging the last `N` estimates. `N` is the number of spectral averages defined in the `SpectralAverages` property. The default is `8`.

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto' | 'Property'`. The default is `'Auto'`. If you set this property to `'Auto'`, the Cross-Spectrum Estimator sets the FFT length to the input frame size. If you set this property to `'Property'`, then you specify the number of FFT points using the `FFTLength` property.

FFTLength

FFT Length

Specify the length of the FFT that the Cross-Spectrum Estimator uses to compute cross-spectral estimates as a positive, integer scalar. This property applies when you set the `FFTLengthSource` property to `'Property'`. The default value is `128`.

Window

Window function

Specify a window function for the cross-spectral estimator as one of `'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'`. The default value is `'Hann'`.

SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The default is `60 dB`.

FrequencyRange

Frequency range of the cross-spectrum estimate

Specify the frequency range of the cross-spectrum estimator as one of `'twosided' | 'onesided' | 'centered'`.

If you set the `FrequencyRange` to `'onesided'`, the cross-spectrum estimator computes the onesided spectrum of real input signals, `x` and `y`. If the FFT length, NFFT, is even, the length of the cross-spectrum estimate is `NFFT/2+1` and is computed over the interval `[0,SampleRate/2]`. If NFFT is odd, the length of the cross-spectrum estimate is equal to `(NFFT+1)/2` and the interval is `[0,SampleRate/2)`.

If you set the `FrequencyRange` to `'twosided'`, the cross-spectrum estimator computes the two-sided spectrum of complex or real input signals, `x` and `y`. The length of the cross-spectrum estimate is equal to NFFT. This value is computed over `[0, SampleRate)`.

If you set the `FrequencyRange` to `'centered'`, the cross-spectrum estimator computes the centered twosided spectrum of complex or real input signals, `x` and `y`. The length of the cross-spectrum estimate is equal to NFFT and it is computed between `(-SampleRate/2, SampleRate/2]` and `(-SampleRate/2, SampleRate/2)` for even and odd lengths, respectively. The default value is `'Twosided'`.

Methods

clone	Create cross-spectrum estimator object with same property values
getFrequencyVector	Get the vector of frequencies at which the cross-spectrum is estimated
getRBW	Get the resolution bandwidth of the cross-spectrum
isLocked	Locked status for input attributes and nontunable properties

reset	Reset the internal states of the cross-spectrum estimator
step	Estimate the cross-spectrum of a signal

Examples

Compute the cross-power spectrum of two noisy sine waves

Generate two sine waves:

```
hsin1 = dsp.SineWave('Frequency',200, 'SampleRate', 1000);
hsin1.SamplesPerFrame = 1000;
hsin2 = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
hsin2.SamplesPerFrame =  1000;
```

Use the Cross-Spectrum Estimator to compute the cross-spectrum of the signals. Also, use the Array Plot to display the spectra:

```
hs = dsp.CrossSpectrumEstimator('SampleRate', hsin1.SampleRate,...
     'FrequencyRange','centered');
hplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
        [-150 -60],'YLabel','Power Spectrum Density (Watts/Hz)',...
        'XLabel','Frequency (Hz)',...
        'Title','Cross Power Spectrum of Two Signals');
```

Add random noise to the sine waves. Step through the System objects to obtain the data streams, and plot the cross-power spectrum of the two signals:

```
for ii = 1:10
x = step(hsin1) + 0.05*randn(1000,1);
y = step(hsin2) + 0.05*randn(1000,1);
Pxy = step(hs, x, y);
step(hplot,20*log10(abs(Pxy)));
end
```

Algorithms

Given two signals `x` and `y` as inputs. We first window the two inputs, and scale them by the window power. We then take FFT of the signals,

calling them `X` and `Y`. This is followed by taking the cross correlation of the FFT, i.e., `Z = X*conj(Y)`. We average the last N number of `Z`'s, and scale the answer by the sample rate.

For further information refer to the "Algorithms" on page 3-1416 section in Spectrum Analyzer, which uses the same algorithm.

`dsp.SpectrumAnalyzer` | `dsp.TransferFunctionEstimator` | `dsp.SpectrumEstimator`

dsp.CrossSpectrumEstimator.clone

Purpose

Create cross-spectrum estimator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`, with the same property values. The clone method creates a new unlocked object with uninitialized states.

Purpose

Get the vector of frequencies at which the cross-spectrum is estimated

Syntax

```
getFrequencyVector(H)
```

Description

`getFrequencyVector(H)` returns the vector of frequencies at which the cross-spectrum is estimated.

If you set the `FrequencyRange` to `'onesided'` and the FFT length, `NFFT`, is even, the frequency vector is of length `NFFT/2+1`, and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'onesided'` and `NFFT` is odd, the frequency vector is of length `(NFFT+1)/2` and covers the interval `[0,SampleRate/2)`. If you set the `FrequencyRange` to `'twosided'`, the frequency vector is of length `NFFT` and covers the interval `[0, SampleRate)`. If you set the `FrequencyRange` to `'centered'`, the frequency vector is of length `NFFT` and covers the range `(-SampleRate/2, SampleRate/2]` and `(-SampleRate/2, SampleRate/2)` for even and odd length `NFFT`, respectively.

dsp.CrossSpectrumEstimator.getRBW

Purpose

Get the resolution bandwidth of the cross-spectrum

Syntax

```
getRBW(H)
```

Description

`getRBW(H)` returns the resolution bandwidth of the cross-spectrum.

The resolution bandwidth, `RBW`, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to `ENBW*SampleRate/ L`, where `L` is the input length, and `ENBW` is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`, `RBW=enbw(hann(1024))*100/1024`.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
L = isLocked(H)
```

Description

`L = isLocked(H)` returns a logical value, `L`, which indicates whether input attributes and nontunable properties are locked for the System object. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. Once this occurs, the `isLocked` method returns a `true` value.

dsp.CrossSpectrumEstimator.release

Purpose

Allow property value and input characteristics to change

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset the internal states of the cross-spectrum estimator

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the System object,`H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

dsp.CrossSpectrumEstimator.step

Purpose

Estimate the cross-spectrum of a signal

Syntax

```
Y = step(H,x)
[Y1,...,YN] = step(H,x)
```

Description

`Y = step(H,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, H. `[Y1,...,YN] = step(H,x)` produces `N` outputs.

The columns of `x` are treated as independent channels.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Cross-correlation of two inputs

Description

The `Crosscorrelator` returns the cross-correlation sequence for two discrete-time deterministic inputs. This object can also return the cross-correlation sequence estimate for two discrete-time, jointly wide-sense stationary (WSS), random processes.

To obtain the cross-correlation for two discrete-time deterministic inputs:

1. Define and set up your cross-correlator. See "Construction" on page 3-443.
2. Call `step` to compute the cross-correlation according to the properties of `dsp.Crosscorrelator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Crosscorrelator` returns a cross-correlator object, `H`, that computes the cross-correlation of two inputs. For N-D arrays, the cross-correlator computes the correlation column-wise. The inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the cross-correlator computes the cross-correlation of the vector with each column of the N-D array. Cross correlating inputs of length N and M results in a cross-correlation sequence of length $N+M-1$. Cross correlating matrices of size M-by-N and P-by-N results in a matrix of cross-correlation sequences of size $M+P-1$-by-N.

`H = dsp.Crosscorrelator('PropertyName',PropertyValue, ...)` returns a cross-correlator, `H`, with each property set to the specified value.

Properties

Method

Domain for computing correlations

Specify the domain for computing correlation as `Time Domain`, `Frequency Domain`, or `Fastest`. Computing correlations in the time domain minimizes memory use. Computing correlations

in the frequency domain may require fewer computations than computing in the time domain depending on the input length. If the value of this property is `Fastest`, the cross-correlator operates in the domain which minimizes the number of computations. The default is `Time Domain`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full Precision`, `Same as first input`, or `Custom`. The default is `Full Precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full Precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full Precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Same as accumulator`, `Same as product`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create cross-correlator object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Cross-correlation sequence

Definitions

The cross-correlation of two length N deterministic inputs, or realizations of jointly WSS random processes, x and y, is:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \le h \le N-1 \\ r_{yx}^*(h) & -(N-1) \le h \le 0 \end{cases}$$

where h is the lag and * denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where E{ } is the expectation operator.

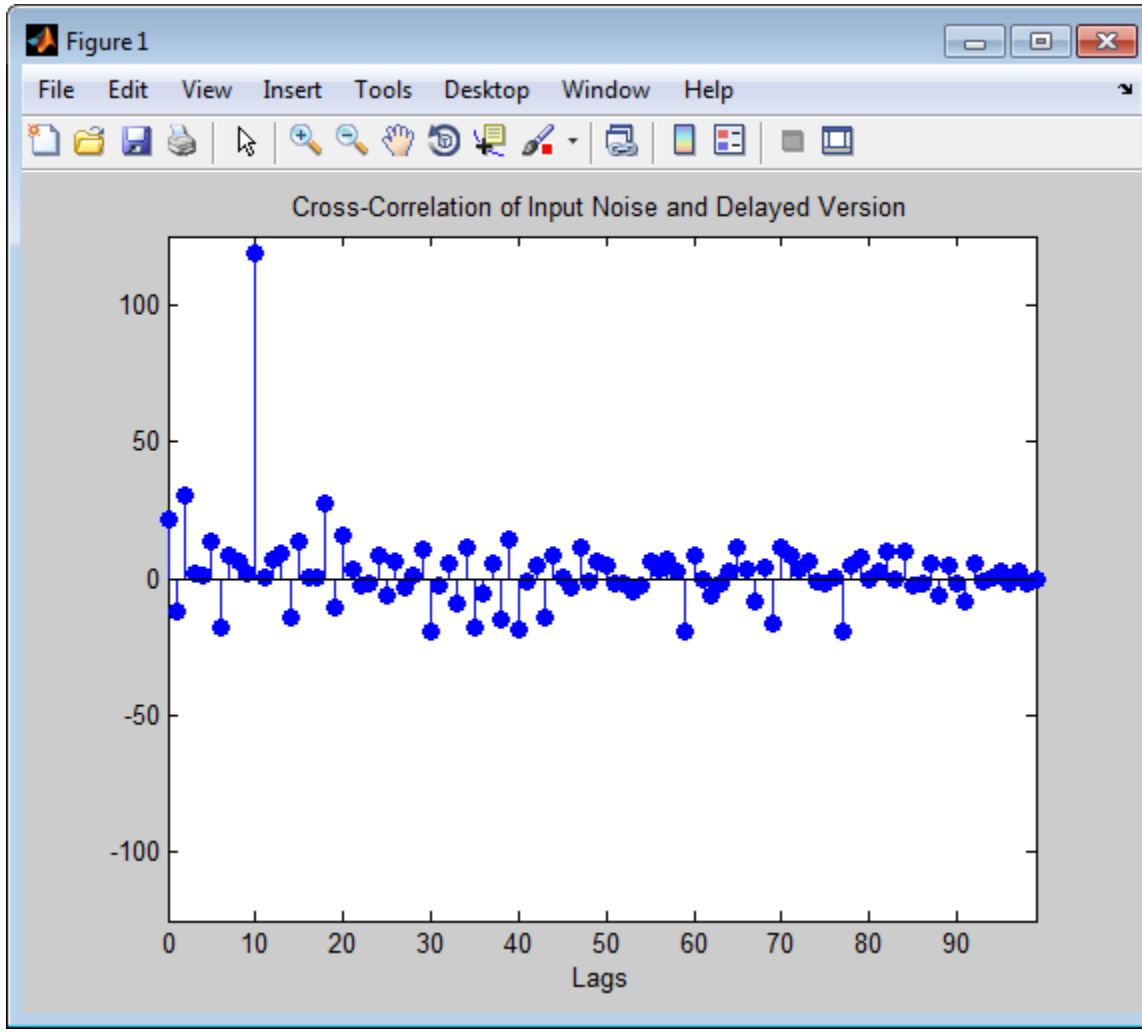
Examples

Compute correlation between two signals:

```
hcorr = dsp.Crosscorrelator;
t=[0:0.001:1];
x1=sin(2*pi*2*t)+0.05*sin(2*pi*50*t);
x2=sin(2*pi*2*t);
y=step(hcorr,x1,x2); %computes cross-correlation of x1 and x2
figure,plot(t,x1,'b',t, x2, 'g');
legend('Input signal 1',' Input signal 2')
figure, plot(y); title('Correlated output')
```

Use cross-correlation to detect delay in jointly stationary white Gaussian noise inputs:

```
S = rng('default');
% white Gaussian noise input
x = randn(100,1);
% Create copy delayed by 10 samples
% x1[n]=x[n-10]
Hdelay = dsp.Delay(10);
x1= step(Hdelay,x);
Hxcorr = dsp.Crosscorrelator;
y = step(Hxcorr,x1,x);
lags = 0:99; %Positive lags
stem(lags,y(100:end),'markerfacecolor',[0 0 1]);
axis([0 99 -125 125]);
xlabel('Lags');
title('Cross-Correlation of Input Noise and Delayed Version');
```



The theoretical cross-correlation sequence is identically zero except at lag 10. Note this is not true in the sample cross-correlation sequence, but the estimate demonstrates a peak at the correct lag.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Correlation block reference page. The object properties correspond to the block parameters.

See Also

`dsp.Autocorrelator` | `dsp.Convolver`

dsp.Crosscorrelator.clone

Purpose

Create cross-correlator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a cross-correlator object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Crosscorrelator.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the cross–correlator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Crosscorrelator.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Cross-correlation sequence

Syntax

```
Y = step(H,A,B)
```

Description

`Y = step(H,A,B)` computes the cross–correlation of `A` and `B` and returns the result in `Y`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.CumulativeProduct

Purpose

Cumulative product of channel, column, or row elements

Description

The `CumulativeProduct` object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

1. Define and set up your cumulative product object. See "Construction" on page 3-456.
2. Call `step` to compute the cumulative product according to the properties of `dsp.CumulativeProduct`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.CumulativeProduct` returns a cumulative product object, `H`, that computes the cumulative product of input matrix or input vector elements along the default Dimension.

`H = dsp.CumulativeProduct('PropertyName',PropertyValue,...)` returns a cumulative product object, `H`, with each specified property set to the specified value.

Properties

Dimension

Computation dimension for cumulative product

Specify the computation dimension as one of `| Channels (running product) | Rows | Columns |`. The default is `Channels (running product)`.

ResetInputPort

Enable resetting cumulative product via input port

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the `step` method to reset the cumulative product. You can access this property when the `Dimension` property is set to `Channels (running product)`. The default is `false`.

ResetCondition

Reset condition for cumulative product

Specify the event on the reset input port that causes resetting the cumulative product to one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies when you set the `ResetInputPort` property to `true` and the `Dimension` property to `Channels (running product)`. The default is `Rising edge`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. You can access this property when the `Dimension` property is set to `Channels (running product)`. The default is `false`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest`, | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numerictype([], 16, 15)`.

ProductDataType

Product output word and fraction lengths

Specify the product output fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

CustomProductDataType

Custom product output word and fraction lengths

Specify the product output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Same as product output | Same as input | Custom |`. The default is `Same as input`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as product output` | `Same as input` | `Custom` |. The default is `Same as input`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([], 16, 15)`.

Methods

clone	Create cumulative product object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset running cumulative product
step	Cumulative product of input along specified dimension for input

Examples

Compute the cumulative product of a matrix:

```
hcprod = dsp.CumulativeProduct;
x = magic(2);
y = step(hcprod,x);
y = step(hcprod,x)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except:

The **Reset port** block parameter corresponds to both the `ResetCondition` and `ResetInputPort` object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.CumulativeSum`

Purpose

Create cumulative product object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `CumulativeProduct` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.CumulativeProduct.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.CumulativeProduct.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `CumulativeProduct` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.CumulativeProduct.reset

Purpose

Reset running cumulative product

Syntax

```
reset(H)
```

Description

`reset(H)` resets the running cumulative product for object `H` to zero.

Purpose

Cumulative product of input along specified dimension for input

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

`Y = step(H,X)` computes the cumulative product along the specified dimension for the input `X`.

`Y = step(H,X,R)` resets the cumulative product object's state based on the `ResetCondition` property value and the value of the reset signal, `R` when the `ResetInputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.CumulativeSum

Purpose

Cumulative sum of channel, column, or row elements

Description

The `CumulativeSum` object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

1. Define and set up your cumulative sum object. See "Construction" on page 3-468.
2. Call `step` to compute the cumulative sum according to the properties of `dsp.CumulativeSum`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.CumulativeSum` returns a cumulative sum System object, `H`, which computes the running cumulative sum for each channel in the input.

`H = dsp.CumulativeSum('PropertyName',PropertyValue,...)` returns a cumulative sum object, `H`, with each specified property set to the specified value.

Properties

Dimension

Computation dimension for cumulative sum

Specify the computation dimension as one of `| Channels (running sum) | Rows | Columns |`. The default is `Channels (running sum)`.

ResetInputPort

Enable resetting cumulative sum via input port.

Set this property to `true` to enable resetting the cumulative sum. When you set this property to `true`, you also specify a reset input to the `step` method to reset the cumulative sum. The default is `false`.

ResetCondition

Reset condition for cumulative sum

Specify the event on the reset input port that resets the cumulative sum as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies when you set the `ResetInputPort` property to `true`. The default is `Rising edge`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. You can access this property when the `Dimension` property is `Channels (running sum)`. The default is `false`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor`, `Nearest`, `Round`, `Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of one of `| Same as accumulator | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([], 16, 15)`.

Methods

clone	Create cumulative sum object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of cumulative sum object to zero
step	Cumulative sum along specified dimension for input

Examples

Use a cumulative sum object to compute the cumulative sum of a matrix:

```
hcsum = dsp.CumulativeSum;
x = magic(2);
y = step(hcsum,x);
y = step(hcsum,x)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Sum block reference page. The object properties correspond to the block properties, except:

The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.CumulativeProduct`

dsp.CumulativeSum.clone

Purpose

Create cumulative sum object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `CumulativeSum` object `C`, with same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.CumulativeSum.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `CumulativeSum` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.CumulativeSum.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of cumulative sum object to zero

Syntax

```
reset(H)
```

Description

`reset(H)` sets the states for the running cumulative sum object, `H`, to zero when the `Dimension` property is set to `Channels (running sum)`.

dsp.CumulativeSum.step

Purpose

Cumulative sum along specified dimension for input

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

`Y = step(H,X)` computes the cumulative sum along the specified dimension for the input `X`.

`Y = step(H,X,R)` resets the System object state based on the `ResetCondition` property value and the value of the reset signal, `R`. You can only reset the state if the `ResetInputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Discrete cosine transform (DCT)

Description

The `DCT` object computes the discrete cosine transform (DCT) of input.

To compute the DCT of input:

1. Define and set up your DCT object. See "Construction" on page 3-479.
2. Call `step` to compute the DCT according to the properties of `dsp.DCT`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.DCT` returns a discrete cosine transform (DCT) object, `H`, used to compute the DCT of a real or complex input signal.

`H = dsp.DCT('PropertyName',PropertyValue, ...)` returns a DCT object, `H`, with each property set to the specified value.

Properties

SineComputation

Method to compute sines and cosines

Specify how the DCT object computes the trigonometric values as `Trigonometric function` or `Table lookup`. This property must be set to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` property to `Table lookup`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision` , `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create discrete cosine transform object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Discrete cosine transform (DCT) of input

Examples

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
hdct = dsp.DCT;
X = step(hdct, x);
% Set the DCT coefficients which represent less
% than 0.1% of the total energy to 0 and
% reconstruct the sequence using IDCT.
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
ii = ii+1;
end
disp(['Number of DCT coefficients that represent 99.9%',...
'of the total energy in the sequence: ',num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
hidct = dsp.IDCT;
xt = step(hidct, XXt);
plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
 'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DCT block reference page. The object properties correspond to the block parameters.

See Also

`dsp.IDCT` | `dsp.FFT` | `dsp.IFFT`

Purpose

Create discrete cosine transform object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an instance of the current discrete cosine transform object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.DCT.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.DCT.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the DCT object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.DCT.step

Purpose

Discrete cosine transform (DCT) of input

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` computes the `DCT` of the input `X`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Delay input by specified number of samples or frames

Description

The `Delay` object delays an input by a specified number of samples or frames.

To delay an input by a specified number of samples or frames:

1. Define and set up your delay object. See "Construction" on page 3-489.
2. Call `step` to delay the input according to the properties of `dsp.Delay`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Delay` returns a delay object, `H`, to delay the input by one sample.

`H = dsp.Delay('PropertyName', PropertyValue, ...)` returns a delay object, `H`, with each property set to the specified value.

`H = dsp.Delay(LEN,'PropertyName',PropertyValue, ...)` returns a delay object, `H`, with the `Length` property set to `LEN` and other specified properties set to the specified values.

Properties

Units

Delay units as samples or frames

Specify the delay units as one of `| Samples | Frames |`. This property applies when you set the `FrameBasedProcessing` property to `true`. The default is `Samples`.

Length

Amount of delay

Specify amount of delay to apply to the input signal. You can set this property to a scalar, a vector, or an array containing nonnegative integers depending on the value of the `FrameBasedProcessing` property.

If the `FrameBasedProcessing` property is `false`, the value can be a scalar by which to delay all input channels equally, or an N-D array of the same dimensions as the input whose values specify the number of sample intervals to delay each channel of the input.

If the `FrameBasedProcessing` property is `true`, the value can be an integer by which to equally delay all channels or a vector whose length equals the number of input columns (channels).

The default is 1.

InitialConditionsPerChannel

Enable different initial conditions per channel

Set this property to `true` to specify different initial conditions per channel. The default value is `false`.

InitialConditionsPerSample

Enable different initial conditions per sample

Set this property to `true` to specify different initial conditions per sample. The default value is `false`.

InitialConditions

Initial output of delay object

Specify the initial output(s) of the delay object. You can set this property to a scalar, vector, matrix, or a cell array depending on the values of the `FrameBasedProcessing`, `InitialConditionsPerChannel`, `InitialConditionsPerSample`, and `Units` properties. The default is `0`.

If the `FrameBasedProcessing` property is `false`, and the input is an N-D array, the dimensions of this property value have the following requirements:

- If the `InitialConditionsPerChannel` and `InitialConditionsPerSample` properties are both `false`, the property value must be a scalar. If the `InitialConditionsPerChannel` property is `true` and the

`InitialConditionsPerSample` property is `false`, the value must have the same dimensions as the input. If the `InitialConditionsPerChannel` property is `false` and the `InitialConditionsPerSample` property is `true`, the value must be a vector of length equal to the `Length` property value.

- If the `InitialConditionsPerChannel` and `InitialConditionsPerSample` properties are both `true`, the property value must be a cell array of the same size as the input signal. Each cell of the cell array contains the delay values for one channel, and must be a vector of length equal to the `Length` property value.

If the `FrameBasedProcessing` property is `true`, and the input is an *M*-by-*N* matrix, the dimensions of this property value must be as follows:

- If the `InitialConditionsPerChannel` and `InitialConditionsPerSample` properties are both `false`, the property value must be a scalar.
- If the `InitialConditionsPerChannel` property is `true` and the `InitialConditionsPerSample` property is `false`, the value must be a vector of length *N*.
- If the `InitialConditionsPerChannel` property is `false`, the `InitialConditionsPerSample` property is `true`, and the `Units` property is `Frames`, the value must be a vector of length equal to the product of *M* and the `Length` property value.
- If the `InitialConditionsPerChannel` property is `false`, the `InitialConditionsPerSample` property is `true`, and the `Units` property is `Samples`, the value must be a vector of length equal to the `Length` property value.
- If the `InitialConditionsPerChannel` and `InitialConditionsPerChannel` properties are both `true`, the property value must be a cell array of size *N*. Each cell of the cell array contains the delay values for one channel.

- If the `Units` property is `Frames`, each cell must be a vector of length equal to the product of *M* and the `Length` property value.
- If the `Units` property is `Samples`, each cell must be a vector of length equal to the `Length` property value.

ResetInputPort

Enable resetting delay states

Specify when the delay object should reset the delay states. By default, the value of this property is `false`, and the object does not reset the delay states. When this property is set to `true`, a reset control input is provided to the `step` method, and the `ResetCondition` property applies. The object resets the delay states based on the values of the `ResetCondition` property and the reset input to the `step` method.

ResetCondition

Reset trigger setting for delay

Specify the event to reset the delay as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. The delay object resets the delay based on the values of this property and the reset input to the `step` method. This property applies when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Methods

clone	Create delay object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset delay states
step	Apply delay to input

Examples

Delay input by five samples:

```
hdelay1 = dsp.Delay(5);
% Output is [0 0 0 0 0 1 2 3 4 5]'
y = step(hdelay1, (1:10)');
```

Delay input by one frame:

```
hdelay2 = dsp.Delay;
hdelay2.Units = 'Frames';
hdelay2.Length = 1;

% Output is zeros(10,1)
y1 = step(hdelay2, (1:10)');

% Output is (1:10)'
y2 = step(hdelay2, (11:20)');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.VariableIntegerDelay` | `dsp.VariableFractionalDelay`.

Purpose

Create delay object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a delay object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.Delay.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.Delay.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the delay object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Delay.reset

Purpose

Reset delay states

Syntax

```
reset(H)
```

Description

`reset(H)` resets the states of the delay object `H` to the values specified in the `InitialConditions` property.

After you invoke the `step` method for a nonzero input, the delay object states may change and invoking the `step` method again without invoking the `reset` method may produce different outputs for identical inputs.

For example:

```
H = dsp.Delay(5);
% Delay input by 5 samples
y = step(H, (1:10)');
% Output is [0 0 0 0 0 1 2 3 4 5]'
% Invoke step without reset
y1 = step(H,(1:10)');
% Output is [6 7 8 9 10 1 2 3 4 5]'
% Reset states
reset(H);
y2 = step(H,(1:10)');
% Output is [0 0 0 0 0 1 2 3 4 5]'
```

Purpose

Apply delay to input

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

`Y = step(H,X)` adds delay to input `X` to return output `Y`.

`Y = step(H,X,R)` adds delay to `X` , and selectively resets the delay object's state based on the value of reset input `R` and the value of the `ResetCondition` property. You can use this option only when you set the `ResetInputPort` property to `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.DelayLine

Purpose

Rebuffer sequence of inputs with one-sample shift

Description

The `DelayLine` object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

1. Define and set up your delay line object. See "Construction" on page 3-502.
2. Call `step` to rebuffer the sequence of inputs according to the properties of `dsp.DelayLine`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.DelayLine` returns a delay line System object, `H`, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

`H = dsp.DelayLine('PropertyName',PropertyValue,...)` returns a delay line System object, `H`, with each specified property set to the specified value.

`H = dsp.DelayLine(DELAYSIZE,INITIAL,'PropertyName',PropertyValue,...)` returns a delay line System object, `H`, with the `Length` property set to `DELAYSIZE`, `InitialConditions` property set to `INITIAL` and other specified properties set to the specified values.

Properties

Length

Number of rows in output matrix

Specify the number of rows in the output matrix as a scalar positive integer. The default is `64`.

InitialConditions

Initial delay line output

Set the value of the object's initial output as one of `| scalar | vector | matrix |`.

For vector outputs, the following selections apply for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, the following selections apply for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

The default is `0`.

DirectFeedthrough

Enable passing input data to output without extra frame delay

When you set this property to `true`, there is no input data delay by an extra frame before it is available at the output buffer. Instead, the input data is available immediately at the output. When you set this property to `false`, there is one frame delay on the output. The default is `false`.

EnableOutputInputPort

Enable selective output linearization

The object internally uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If Boolean the input value is `1`, the object's output is linearized and thus valid. If Boolean the input value is `0`, the output is not linearized and is invalid. This allows the object to be

more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid. The default is `false`.

HoldPreviousValue

Hold previous valid value for invalid output

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data. This property applies only when you set the `EnableOutputInputPort` property to `true`. The default is `false`.

Methods

clone	Create delay line object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of delay line object
step	Delayed version of input

Examples

Use a delay line object with a delay line size of 4 samples:

```
hdelayline = dsp.DelayLine( ...
   'Length', 4, ...
   'DirectFeedthrough', true, ...
   'InitialConditions', -2, ...
   'EnableOutputInputPort', true, ...
   'HoldPreviousValue', true);
```

```
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
     y(:,ii) = step(hdelayline, ii, en(ii));
end
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay Line block reference page. The object properties correspond to the block properties, except as noted.

This object processes inputs as separate channels (frames). The corresponding block has a temporary **Treat Mx1 and unoriented sample-based signals as** parameter with a `One channel` option for frame-based behavior and an `M channels` option for sample-based behavior. See the Delay Line block reference page and "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.Delay`

dsp.DelayLine.clone

Purpose

Create delay line object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `DelayLine` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.DelayLine.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, from the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `DelayLine` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.DelayLine.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of delay line object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal delay buffers of the `DelayLine` object `H` to their initial conditions.

dsp.DelayLine.step

Purpose

Delayed version of input

Syntax

```
Y = step(H,X)
Y = step(H,X,EN)
```

Description

`Y = step(H,X)` returns the delayed version of input `X`. `Y` is an output matrix with the same number of rows as the delay line size. Each column of `X` is treated as a separate channel.

The System object rebuffers a sequence of *Mi*-by-*N* matrix inputs into a sequence of *Mo*-by-*N* matrix outputs, where *Mo* is the output frame size specified by the `Length` property. Depending on whether *Mo* is greater than, less than, or equal to the input frame size, *Mi*, the output frames can be underlapped or overlapped. Each of the *N* input channels is rebuffered independently:

- When*Mo* > *Mi*, the output frame overlap is the difference between the output and input frame size, *Mo*–*Mi*.
- When *Mo* < *Mi*, the output is underlapped; the object discards the first *Mi*–*Mo* samples of each input frame so that only the last *Mo* samples are buffered into the corresponding output frame.
- When *Mo* = *Mi*, the output data is identical to the input data, but is delayed by the latency of the object.

`Y = step(H,X,EN)` selectively outputs the delayed version of input `X` depending on the Boolean input `EN`. This occurs only when you set the `EnableOutputInputPort` property to `true`. If `EN` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.DigitalDownConverter

Purpose

Digitally downconvert input signal

Description

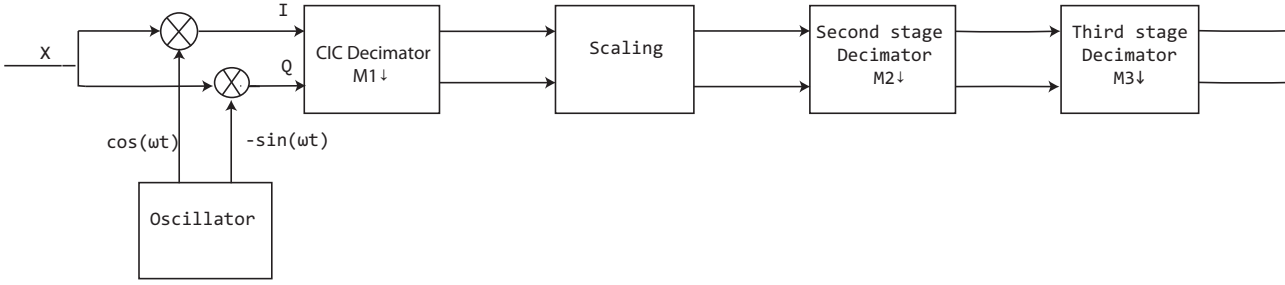
The `DigitalDownConverter` object digitally downconverts the input signal.

To digitally downconvert the input signal:

1. Define and set up your digital down converter. See "Construction" on page 3-514.
2. Call `step` to downconvert the input according to the properties of `dsp.DigitalDownConverter`. The behavior of `step` is specific to each object in the toolbox.

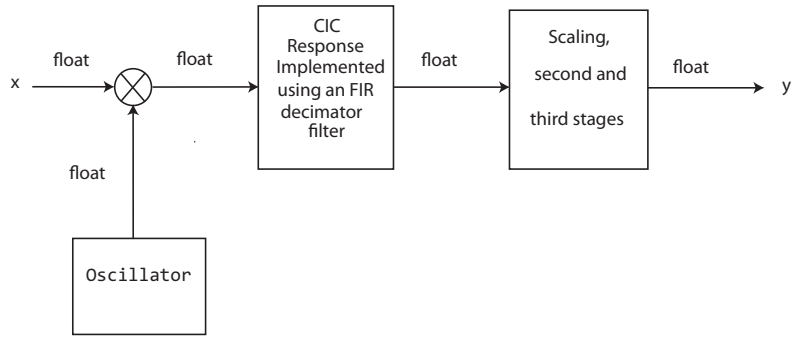
Construction

`h = dsp.DigitalDownConverter` returns a digital down-converter (DDC) System object, `h`. The object downconverts the input signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. The object downsamples the frequency down-converted signal using a cascade of three decimation filters. When you set the `FilterSpecification` property to `Design parameters`, the DDC object designs the decimation filters according to the filter parameters that you set in the filter-related object properties. In this case the filter cascade consists of a CIC decimator, a CIC compensator and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

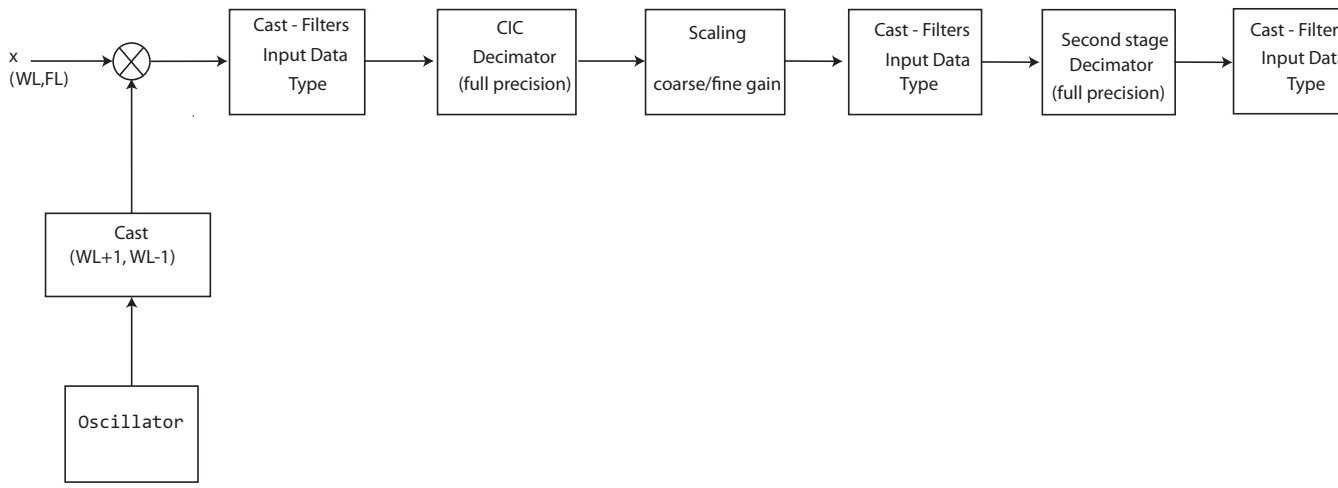


The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. When you set the **Oscillator** property to `InputPort`, the normalization factor does not include the oscillator power factor. Depending on the setting of the **DecimationFactor** property, you may be able to bypass the third filter stage. When the arithmetic is double or single precision, the CIC interpolator is implemented as a simple FIR interpolator with a boxcar response. A true CIC interpolator can only operate with fixed-point signals. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

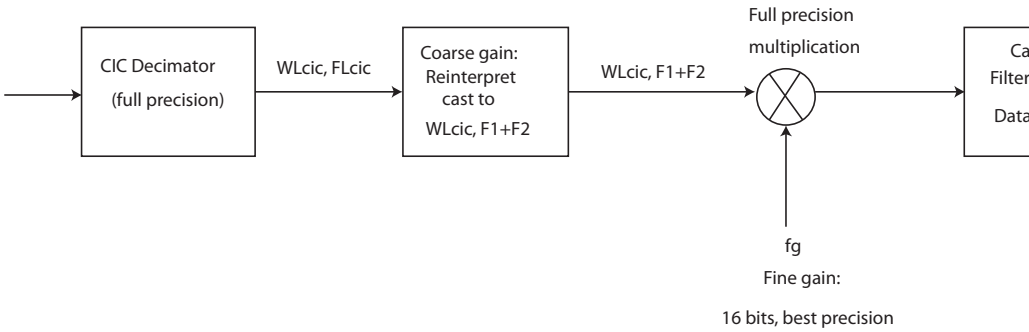


The following block diagram represents the DDC arithmetic with signed fixed-point inputs.



- `WL` is the word length of the input, and `FL` is the fraction length of the input.
- The input of each filter is cast to the data type specified in the **FiltersInputDataType** and **CustomFiltersInputDataType** properties.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.



If the normalization gain is G, (where $0<G\leqq1$), then:

- `WLcic` is the word length of the CIC decimator output and `FLcic` is the fraction length of the CIC decimator output
- `F1 = abs(nextpow2(G))` , indicating the part of G achieved using bit shifts (coarse gain)

- `F2` = fraction length specified by the **FiltersInputDataType** and **CustomFiltersInputDataType** properties
- `fg = fi((2^F1)*G, true, 16)` , indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`h = dsp.DigitalDownConverter(Name,Value)` returns a DDC object, `h`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

SampleRate

Sample rate of input signal

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property. The default is 30 Megahertz.

DecimationFactor

Decimation factor

Set this property to a positive, integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the decimation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. When you set the `FilterSpecification` property to `Design parameters`, both elements of the `DecimationFactor` vector must be greater than one. When you set the `FilterSpecification` property to `Coefficients`, the first element of the `DecimationFactor` vector must be greater than 1.

When you set this property to a 1-by-3 vector, the i^{th} element of the vector specifies the decimation factor for the i^{th} filtering stage. When you set the `FilterSpecification` property to `Design parameters`, the first and second elements of the `DecimationFactor` vector must be greater than one and the third element must be 1 or 2. When you set the `FilterSpecification` property to `Coefficients`, the first element of the `DecimationFactor` vector must be greater than 1. When you set the `FilterSpecification` property to `Coefficients`, you must set the `DecimationFactor` property to a 1-by-3 or 1-by-2 vector. The default is 100.

FilterSpecification

Filter specification

Set the filter specification as one of `Design parameters | Coefficients`. The default is `Design parameters`. The DDC object performs decimation using a cascade of three decimation filters. The first filter stage is always a CIC decimator. When you set the `FilterSpecification` property to `Design parameters`, the object designs the cascade of decimation filters internally, according to a set of parameters that you specify using the filter-related object properties. In this case, the second and third stages of the cascade consist of a CIC compensator, and a halfband or lowpass FIR decimator respectively. When you set the `FilterSpecification` property to `Coefficients`, you specify an arbitrary set of filter coefficients for the second and third filter stages using the `SecondFilterCoefficients`, and `ThirdFilterCoefficients` properties respectively. You specify the number of CIC sections using the `NumCICSections` property. In all cases, the third filter stage can be bypassed by setting the `DecimationFactor` property appropriately.

When the input data type is double or single the object implements an *N*-section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed point type.

MinimumOrderDesign

Minimum order filter design

When you set this property to true the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. When you set this property to false, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the Bandwidth, `StopbandFrequencySource`, and `StopbandFrequency` properties. This property applies when you set the `FilterSpecification` property to `Design parameters`. The default is true.

NumCICSections

Number of sections of CIC decimator

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false, or when you set the `FilterSpecification` property to `Coefficients`. The default is `3`.

SecondFilterCoefficients

Coefficients of second filter stage

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. Usually, the response of this filter should be that of a CIC compensator since a CIC decimation filter precedes the second filter stage. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is `1`.

ThirdFilterCoefficients

Coefficients of third filter stage

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the value of the `ThirdFilterCoefficients` property because the third filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is `1`.

SecondFilterOrder

Order of CIC compensation filter stage

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false. The default is `12`.

ThirdFilterOrder

Order of third filter stage

Set this property to a positive, integer, even scalar. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the `ThirdFilterOrder` property because the third filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false. The default is `10`.

Bandwidth

Two sided bandwidth of input signal in Hertz

Set this property to a positive, integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. This property applies when you set the `FilterSpecification` property to `Design parameters`. The default is 200 kilohertz.

StopbandFrequencySource

Source of stopband frequency

Specify the source of the stopband frequency as one of `Auto | Property`. The default is `Auto`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately F_c = `SampleRate`/M/2 Hertz, where M is the total decimation factor that you specify in the `DecimationFactor` property. The object computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response computed as $2*(F_c-F_p)$, and the passband frequency, F_p, equals `Bandwidth`/2. This property applies when you set the `FilterSpecification` property to `Design parameters`.

StopbandFrequency

Stopband frequency in Hertz

Set this property to a double precision positive scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `StopbandFrequencySource` property to `Property`. The default is 150 kilohertz.

PassbandRipple

Passband ripple of cascade response in decibels.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to true. The default is `0.1` decibels.

StopbandAttenuation

Stopband attenuation of cascade response in decibels

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the

`StopbandAttenuation` property. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to true. The default is `60` decibels.

Oscillator

Type of oscillator

Specify the oscillator as one of `Sine wave | NCO | Input port`. The default is `Sine wave`. When you set this property to `Sine wave`, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO` the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to `Input port`, the object performs frequency down conversion using the complex signal that you set as an input to the step method.

CenterFrequency

Center frequency of input signal in Hertz

Specify this property as a double precision positive scalar that is less than or equal to half the value of the `SampleRate` property. The object down converts the input signal from the passband center frequency you specify in the `CenterFrequency` property, to `0` Hertz. This property applies when you set the `Oscillator` property to `Sine wave` or `NCO`. The default is 14 Megahertz.

NumAccumulatorBits

Number of NCO accumulator bits

Specify this property as an integer scalar in the range `[1 128]`. This property applies when you set the `Oscillator` property to `NCO`. The default is `16`.

NumQuantizedAccumulatorBits

Number of NCO quantized accumulator bits

Specify this property as an integer scalar in the range `[1 128]`. The value you specify in this property must be less than the value you specify in the `NumAccumulatorBits` property. This property applies when you set the Oscillator property to `NCO`. The default is `12`.

Dither

Dither control for NCO

When you set this property to true, a number of dither bits specified in the `NumDitherBits` property will be used to apply dither to the NCO signal. This property applies when you set the `Oscillator` property to `NCO`. The default is true.

NumDitherBits

Number of NCO dither bits

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO` and the Dither property to true. The default is `4`.

Fixed-Point Properties

SecondFilterCoefficientsDataType

Data type of second filter coefficients

Specify the second filter coefficients data type as `Same as input |Custom`. The default is `Same as input`. This property applies when you set the `FilterSpecification` property to `Coefficients`.

CustomSecondFilterCoefficientsDataType

Fixed-point data type of second filter coefficients

Specify the second filter coefficients fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property

applies when you set the `SecondFilterCoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ThirdFilterCoefficientsDataType

Data type of third filter coefficients

Specify the third filter coefficients data type as `Same as input` | `Custom`. The default is `Same as input`. This property applies when you set the `FilterSpecification` property to `Coefficients`.

CustomThirdFilterCoefficientsDataType

Fixed-point data type of third filter coefficients

Specify the third filter coefficients fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `ThirdFilterCoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

FiltersInputDataType

Data type of input of each filter stage

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of `Same as input` | `Custom`. The default is `Same as input`. The object casts the data at the input of each filter stage according to the value you set in this property.

CustomFiltersInputDataType

Fixed-point data type of input of each filter stage

Specify the filters input fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `FiltersInputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Data type of output

Specify the data type of output as `Same as input | Custom`. The default is `Same as input`.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create digital down converter object with same property values
fvtool	Visualize response of filter cascade
getDecimationFactors	Get decimation factors of each filter stage
getFilterOrders	Get orders of decimation filters
getFilters	Get handles to decimation filter objects
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
groupDelay	Group delay of filter cascade
isLocked	Locked status for input attributes and non-tunable properties
release	Allow property value and input characteristics changes
step	Digitally down convert input signal
visualizeFilterStages	Display response of filter stages

Examples

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

```
% Create a sine wave generator to obtain the 1 KHz
% sinusoidal signal with a sample rate of 6 KHz.
Fs = 6e3; % Sample rate
hSig = dsp.SineWave('Frequency',1000,'SampleRate',...
Fs,'SamplesPerFrame',1024);
x = step(hSig); % generate signal

% Create a DUC object. Use minimum order filter designs and set
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB.
% Set the double sided signal bandwidth to 2 KHz.
hDUC = dsp.DigitalUpConverter(...
 'InterpolationFactor', 20,...
 'SampleRate', Fs,...
 'Bandwidth', 2e3,...
 'StopbandAttenuation', 55,...
 'PassbandRipple',0.2,...
 'CenterFrequency',50e3);

% Create a DDC object. Use minimum order filter designs and set the
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB.
hDDC = dsp.DigitalDownConverter(...
  'DecimationFactor',20,...
  'SampleRate', Fs*20,...
  'Bandwidth', 3e3,...
  'StopbandAttenuation', 55,...
  'PassbandRipple',0.2,...
  'CenterFrequency',50e3);

% Create a spectrum estimator to visualize the signal spectrum before
% up converting, after up converting, and after down converting.
window = hamming(floor(length(x)/10));
figure; pwelch(x,window,[],[],Fs,'centered')
```

```
title('Spectrum of baseband signal x')

% Up convert the signal and visualize the spectrum
xUp = step(hDUC,x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered');
title('Spectrum of up converted signal xUp')

% Down convert the signal and visualize the spectrum
xDown = step(hDDC,xUp); % down convert
window = hamming(floor(length(xDown)/10));
figure; pwelch(xDown,window,[],[],Fs,'centered')
title('Spectrum of down converted signal xDown')

% Visualize the response of the decimation filters
visualizeFilterStages(hDDC)
```

For additional examples using this System object, see the following demos:

- "Digital Up and Down Conversion for Family Radio Service"
- "Design and Analysis of a Digital Down Converter"

See Also

`dsp.DigitalUpConverter`

Purpose

Create digital down converter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `DigitalDownConverter` System object, `C`, with the same property values as `H`.

The clone method creates a new unlocked object with uninitialized states.

dsp.DigitalDownConverter.fvtool

Purpose

Visualize response of filter cascade

Syntax

```
fvtool(H)
fvtool(H,..,'Arithmetic',ARITH,...)
fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2,...)
```

Description

`fvtool(H)` plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the `FilterSpecification` property to `Design parameters` the method plots a mask based on the filter specifications.

`fvtool(H,..,'Arithmetic',ARITH,...)` specifies the arithmetic of the filter cascade. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state you must specify the arithmetic. When object `H` is in a locked state the arithmetic input is ignored.

`fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2,...)` launches FVTool and sets the specified FVTool properties to the specified values.

Purpose

Get decimation factors of each filter stage

Syntax

```
M = getDecimationFactors(H)
```

Description

`M = getDecimationFactors(H)`) returns a vector, `M`, with the decimation factors of each filter stage. If the third filter stage is bypassed, then `M` is a 1-by-2 vector containing the decimation factors of the first and second filter stages in the first and second elements respectively. If the third filter stage is not bypassed then `M` is a 1-by-3 vector containing the decimation factors of the first, second and third filter stages.

dsp.DigitalDownConverter.getFilters

Purpose

Get handles to decimation filter objects

Syntax

```
S = getFilters(H)
getFilters(H,'Arithmetic',ARITH)
```

Description

`S = getFilters(H)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the decimation filter cascade. The `ThirdFilterStage` structure field is empty if the third filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(H,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You can set `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state, you must specify the arithmetic input. When object `H` is in a locked state, the arithmetic input is ignored.

When `H` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalDownConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `H` is in a locked state, and the input to the step method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point properties of these System objects are set to the exact values that the `dsp.DigitalDownConverter` System object uses to process the data.

Purpose

Get orders of decimation filters

Syntax

```
S = getFilterOrders(H)
```

Description

`S = getFilterOrders(H)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `ThirdFilterOrder` structure field will be empty if the third filter stage has been bypassed.

dsp.DigitalDownConverter.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.DigitalDownConverter.groupDelay

Purpose

Group delay of filter cascade

Syntax

```
D = groupDelay(H,N)
[D,F] = groupDelay(H,N)
```

Description

`D = groupDelay(H,N)` returns a vector of group delays, `D`, evaluated at `N` frequency points equally spaced around the upper half of the unit circle. If you don't specify `N`, it defaults to `8192`.

`[D,F] = groupDelay(H,N)` returns a vector of frequencies, `F`, at which the group delay has been computed.

Purpose

Locked status for input attributes and non-tunable properties

Syntax

```
Y = isLocked(H)
```

Description

`Y = isLocked(H)` returns the locked state, `Y`, of the `DigitalUpConverter` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.DigitalDownConverter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Purpose

Digitally down convert input signal

Syntax

```
Y = step(H,X)
Y = step(H,X,Z)
```

Description

`Y = step(H,X)` takes a real or complex input column vector `X` and outputs a frequency down converted and down sampled signal `Y`. The length of input `X` must be a multiple of the decimation factor. `X` can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of Y is equal to the length of `X` divided by the `DecimationFactor`. When the data type of `X` is double or single precision, the data type of `Y` is the same as that of `X`. When the data type of `X` is of a fixed point type, the data type of `Y` is defined by the `OutputDataType` property.

`Y = step(H,X,Z)` uses the complex input, `Z`, as the oscillator signal used to frequency down convert input `X`, when you set the `Oscillator` property to `Input port`. The length of `Z` must be equal to the length of `X`. `Z` can be of data type double, single, signed integer, or signed fixed point (fi objects).

dsp.DigitalDownConverter.visualizeFilterStages

Purpose

Display response of filter stages

Syntax

```
visualizeFilterStages(H)
visualizeFilterStages(H,'Arithmetic',ARITH)
hfvt = visualizeFilterStages(H)
```

Description

`visualizeFilterStages(H)` plots the magnitude response of the filter stages and of the cascade response. When you set the `FilterSpecification` property to `Design parameters` the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(H,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state you must specify the arithmetic. When object `H` is in a locked state the arithmetic input is ignored.

`hfvt = visualizeFilterStages(H)` returns the handle to the FVTool object.

Purpose

Static or time-varying digital filter

Description

The `DigitalFilter` object filters each channel of the input using static or time-varying digital filter implementations.

To filter each channel of the input using digital filter implementation:

1. Define and set up your IIR digital filter. See "Construction" on page 3-541.
2. Call `step` to filter each channel according to the properties of `dsp.DigitalFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.DigitalFilter` returns a default IIR digital filter object, `H`, which independently filters each channel of the input over successive calls to the `step` method, using a specified digital filter implementation. The default numerator coefficients are `[1 2]` and denominator coefficients are `[1 0.1]`.

`H = dsp.DigitalFilter('PropertyName',PropertyValue, ...)` returns a digital filter object, `H`, with each property set to the specified value.

Properties

TransferFunction

Type of filter transfer function

Specify the type of digital filter transfer function as one of `| IIR (poles & zeros) | IIR (all poles) | FIR (all zeros) |`. The default is `IIR (poles & zeros)`.

Structure

Filter structure

Specify the filter structure.

When you set the `TransferFunction` property to `FIR (all zeros)`, you can specify the filter structure as one of `|`

`Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed` | `Lattice MA` |. The default is `Direct form`.

When you set the `TransferFunction` property to `IIR (all poles)`, you can specify the filter structure as `Direct form`, `Direct form transposed`, or `Lattice AR`. The default is `Direct form`.

When you set the `TransferFunction` to `IIR (poles & zeros)`, you can specify the filter structure as `Direct form I`, `Direct form I transposed`, `Direct form II`, `Direct form II transposed`, `Biquad direct form I (SOS)`, `Biquad direct form I transposed (SOS)`, `Biquad direct form II (SOS)`, or `Biquad direct form II transposed (SOS)`. The biquad filter structure does not apply when you set the `CoefficientsSource` property to `Input port`. The default is `Direct form II transposed`.

CoefficientsSource

Source of filter coefficients

Specify the source of the filter coefficients as one of | `Property` | `Input port` |. The default is `Property`. When you specify `Input port`, the digital filter object updates the time-varying filter once every frame, when the `FrameBasedProcessing` property is `true`. When the `FrameBasedProcessing` property is `false`, it updates once every sample.

Numerator

Numerator coefficients

Specify the filter numerator coefficients as a real or complex numeric vector. This property applies when you set the `TransferFunction` property to `FIR (all zeros)`, the `CoefficientsSource` property to `Property`, and the `Structure` property is not set to `Lattice MA`. This property also applies when you set the `TransferFunction` property to `IIR (poles & zeros)`, the `CoefficientsSource` to `Property`, and the

`TransferFunction` property to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `[1 2]`. This property is tunable.

Denominator

Denominator coefficients

Specify the filter denominator coefficients as a real or complex numeric vector. This property applies when you set the `TransferFunction` property to `IIR (all poles)`, the `CoefficientsSource` property to `Property` and the `Structure` property is not set to `Lattice AR`. This property also applies when you set the `TransferFunction` property to `IIR (poles & zeros)`, the `CoefficientsSource` to `Property`, and the `TransferFunction` property to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. When the `TransferFunction` property is `IIR (poles & zeros)`, the numerator and denominator must have the same complexity. The default is `[1 0.1]`. This property is tunable.

ReflectionCoefficients

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric vector. This property applies when you set the `TransferFunction` property to `FIR (all zeros)`, the `Structure` property to `Lattice MA`, and the `CoefficientsSource` property to `Property`. This property also applies when you set the `TransferFunction` property to `IIR (all poles)`, the `Structure` property to `Lattice AR`, and the `CoefficientsSource` property to `Property`. The default is `[0.2 0.4]`. This property is tunable.

SOSMatrix

SOS matrix of biquad filter structure

Specify the second-order section (SOS) matrix of a biquad filter as an *M*-by-6 matrix, where *M* is the number of sections in the

filter. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding filter section. The first three elements of each row are the numerator coefficients and the last three elements are the denominator coefficients. You can use real or complex coefficients. This property applies when you set the `TransferFunction` property to `IIR (poles and zeros)`, the `CoefficientsSource` property to `Property`, and the `Structure` property to `Biquad direct form I (SOS)`, `Biquad direct form I transposed (SOS)`, `Biquad direct form II (SOS)`, or `Biquad direct form II transposed (SOS)`. The default is `[1 0.3 0.4 1 0.1 0.2]`. This property is tunable.

ScaleValues

Scale values of biquad filter structure

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be a scalar or a vector of length *M*+1, where*M* is the number of sections. If you specify a scalar value, that value is used as the gain value before the first section of the second-order filter and the rest of the gain values are set to 1. If you specify a vector of *M*+1 values, each value is used for a separate section of the filter. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)`, the `CoefficientsSource` property to `Property`, and the `Structure` property to `Biquad direct form I (SOS)`, `Biquad direct form I transposed (SOS)`, `Biquad direct form II (SOS)`, or `Biquad direct form II transposed (SOS)`. The default is `1`. This property is tunable.

IgnoreFirstDenominatorCoefficient

Assume first denominator coefficient is 1

Setting this Boolean property to `true` reduces the number of computations to produce the digital filter output by omitting the first denominator term, *a0*, (poles side) in the filter structure. The object output is invalid when you set this property to `true` when the first denominator coefficient is not always 1 for your time-varying filter. The object ignores this property for

fixed-point inputs, because this object does not support nonunity *a0* coefficients for fixed-point inputs.

This property applies when you set the `CoefficientsSource` property to `Input port`, the `TransferFunction` property to `IIR (all poles)`, and the `Structure` property is not set to `Lattice AR`. This property also applies when you set the `CoefficientsSource` property to `Input port`, the `TransferFunction` property to `IIR (poles & zeros)`, and the `Structure` property to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `true`.

InitialConditions

Initial conditions for all poles or all zeros filter

Specify the initial conditions of the filter states. When the `TransferFunction` property is `FIR (all zeros)` or `IIR (all poles)`, the number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures. When the `TransferFunction` property is `IIR (poles & zeros)`, the number of states for direct form II and direct form II transposed structures equals the `max(N,M)`–1, where `N` and `M` are the number of poles and zeros, respectively.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the digital filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property applies when you do not set the `Structure` property to `Direct Form I`, `Direct Form I transposed`, `Biquad direct form I (SOS)`, or `Biquad direct form I transposed (SOS)`. The default is 0.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)` and the `Structure` property is `Direct form I`, `Direct form I transposed`, `Biquad direct form I (SOS)`, or `Biquad direct form I transposed (SOS)`. The default is `0`. See the `InitialConditions` property for information on setting initial conditions.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the direct form I (noncanonic) filter structure with the poles. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)` and the `Structure` property to `Direct form I`, `Direct form I transposed`, `Biquad direct form I (SOS)`, or `Biquad direct form I transposed (SOS)`. The default is 0. See the `InitialConditions` property for information on setting initial conditions.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`.

TapSumDataType

Tap sum word and fraction lengths

Specify the tap sum fixed-point data type as one of `| Same as input | Custom |`. This property applies when you set the `TransferFunction` property to `FIR (all zeros)` and the `Structure` property to either `Direct form symmetric` or `Direct form antisymmetric`. The default is `Same as input`.

CustomTapSumDataType

Custom tap sum word and fraction lengths

Specify the tap sum fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `TapSumDataType` property to `Custom`. The default is `numerictype([],32,30)`.

MultiplicandDataType

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of | `Same as output` | `Custom` |. This property applies when you set the `Structure` property to either `Direct form I transposed` or `Biquad direct form I transposed (SOS)`. The default is `Same as output`.

CustomMultiplicandDataType

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `MultiplicandDataType` property to `Custom`. The default to `numerictype([],32,30)`.

SectionInputDataType

Section input word and fraction lengths

Specify the section input fixed-point data type as one of | `Same as input` | `Custom` |. Setting this property also sets the `SectionOutputDataType` property to the same value. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)` and the `Structure` property to one of the biquad filter structures. The default is `Same as input`.

CustomSectionInputDataType

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SectionInputDataType` property to `Custom`. The `CustomSectionInputDataType` and `CustomSectionOutputDataType` property values must have equal word lengths. The default is `numerictype([],16,15)`.

SectionOutputDataType

Section output word and fraction lengths

Specify the section output fixed-point data type as one of | `Same as input` | `Custom` |. Setting this property also sets

the `SectionInputDataType` property to the same value. This property applies when you set the `TransferFunction` property to `IIR (poles & zeros)` and the `Structure` property to one of the biquad filter structures. The default is `Same as input`.

CustomSectionOutputDataType

Custom section output word and fraction lengths

Specify the section output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SectionOutputDataType` property to `Custom`. The `CustomSectionInputDataType` and `CustomSectionOutputDataType` property values must have equal word lengths. The default is `numerictype([],16,15)`.

NumeratorCoefficientsDataType

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of `| Same word length as input | Custom |`. Setting this property also sets the `DenominatorCoefficientsDataType` and the `ScaleValuesDataType` properties, if applicable, to the same value. This property applies when you set the `CoefficientsSource` property to `Property` and the `TransferFunction` property is not set to `IIR (all poles)`. The default is `Same word length as input`.

CustomNumeratorCoefficientsDataType

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `NumeratorCoefficientsDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType` and `ScaleValuesDataType` properties, if applicable, must have equal word lengths. The default is `numerictype([],16,15)`.

DenominatorCoefficientsDataType

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. Setting this property also sets the `NumeratorCoefficientsDataType` and `ScaleValuesDataType` properties, if applicable, to the same value. This property applies when you set the `CoefficientsSource` property to `Property` and the `TransferFunction` property is not set to `FIR (all zeros)`. The default is `Same word length as input`.

CustomDenominatorCoefficientsDataType

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `DenominatorCoefficientsDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType` and `CustomScaleValuesDataType` properties, if they apply, must have equal word lengths. The default is `numerictype([],16,15)`.

ScaleValuesDataType

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of | `Same word length as input` | `Custom` |. Setting this property also sets the `NumeratorCoefficientsDataType` and the `DenominatorCoefficientsDataType` properties, if they apply, to the same value. This property applies when you set the `CoefficientsSource` property to `Property`, the `TransferFunction` property to `IIR (poles & zeros)`, and the `Structure` property to one of the biquad filter structures. The default is `Same word length as input`.

CustomScaleValuesDataType

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsSource` property to `Property` and the `ScaleValuesDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType`, `CustomDenominatorCoefficientsDataType`, and the `CustomScaleValuesDataType` properties, if applicable, must have equal word lengths. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of `| Same as input | Same as product | Custom |`. The default is `Same as product`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom` |. This property does not apply to any of the direct form or direct form I filter structures. The default is `Same as accumulator`.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `StateDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create static or time-varying digital filter with same property values
getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of digital filter
step	Filter input with digital filter object

Examples

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components:

```
t = [0:63]./32e3;
xin = (sin(2*pi*4e3*t)+sin(2*pi*12e3*t)) / 2;

hSR = dsp.SignalSource(xin', 4);
hLog = dsp.SignalSink;
hFilt = dsp.DigitalFilter;
hFilt.TransferFunction = 'FIR (all zeros)';
hFilt.Numerator = fir1(10,0.5);

while ~isDone(hSR)
     input = step(hSR);
     filteredOutput = step(hFilt,input);
     step(hLog,filteredOutput);
end

filteredResult = hLog.Buffer;
periodogram(filteredResult,[],[],32e3)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Digital Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.BiquadFilter`

Purpose

Create static or time-varying digital filter with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a digital filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.DigitalFilter.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.DigitalFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the digital filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.DigitalFilter.reset

Purpose

Reset internal states of digital filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the digital filter object,`H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the digital filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

For example:

```
H = dsp.DigitalFilter;
H.TransferFunction = 'FIR (all zeros)';
H.Numerator = fir1(20,0.25);
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

Purpose

Filter input with digital filter object

Syntax

```
Y = step(HFILT,X)
Y = step(HFILT,X,COEFF)
Y = step(HFILT,X,NUM,DEN)
```

Description

`Y = step(HFILT,X)` filters the real or complex input signal `X` using the digital filter, `H`, to produce the output `Y` . The digital filter object operates on each channel of the input signal independently over successive calls to step method.

`Y = step(HFILT,X,COEFF)` uses the time-varying numerator or denominator coefficients, `COEFF` , to filter the input signal `X` and produce the output `Y` . You can use this option when you set the `TransferFunction` property to either `FIR (all zeros)` or `IIR (all poles)` and the `CoefficientsSource` property to `Input port`.

`Y = step(HFILT,X,NUM,DEN)` uses the time-varying numerator coefficients `NUM` and the time-varying denominator coefficients `DEN` to filter the input signal `X` and produce the output `Y` . You can use this option when you set the `TransferFunction` property to `IIR (poles and zeros)` and the `CoefficientsSource` property to `Input port`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.DigitalUpConverter

Purpose

Digitally upconvert input signal

Description

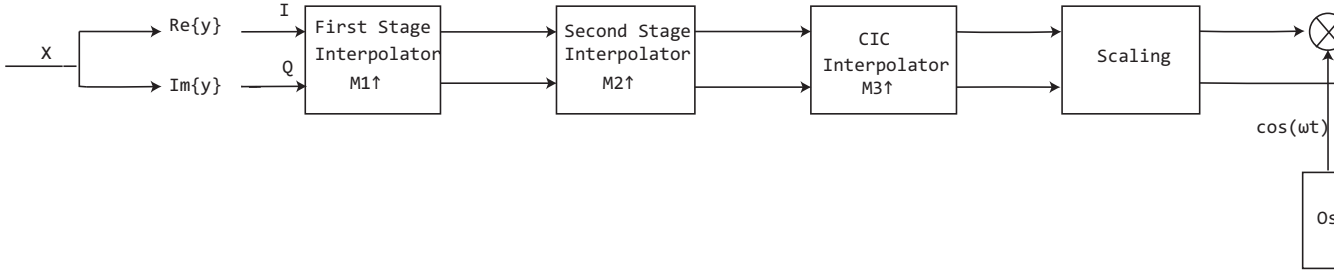
The `DigitalUpConverter` object digitally upconverts the input signal.

To digitally up convert the input signal:

1. Define and set up your digital up converter. See "Construction" on page 3-562.
2. Call `step` to upconvert the input according to the properties of `dsp.DigitalUpConverter`. The behavior of `step` is specific to each object in the toolbox.

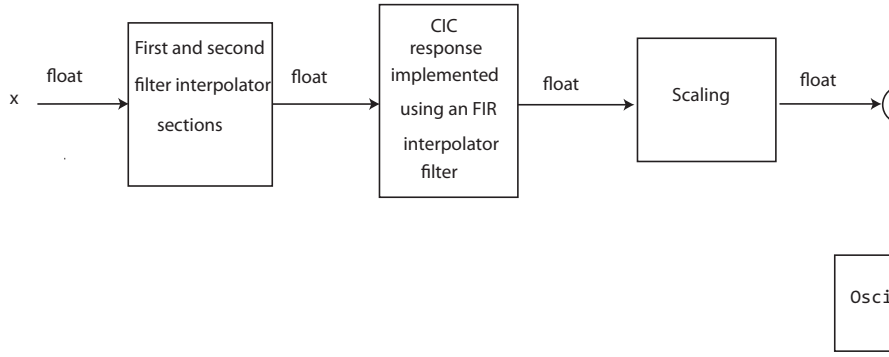
Construction

`h = dsp.DigitalUpConverter` returns a digital up-converter (DDC) System object, `h`. The object up samples the input signal using a cascade of three interpolation filters. This object frequency upconverts the up sampled signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. When you set the `FilterSpecification` property to 'Design parameters', the DUC object designs the interpolation filters according to the filter specifications that you set in the filter-related object properties. In this case the filter cascade consists of a first FIR interpolation stage, a CIC compensator, and a CIC interpolator. The following block diagram shows the architecture of the digital up converter.

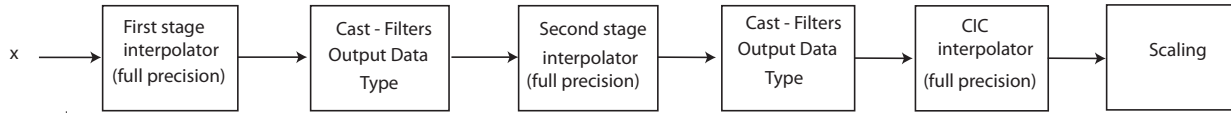


The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. Depending on the setting of the **InterpolationFactor** property, you may be able to bypass the first filter stage. When the arithmetic is double or single precision, the CIC interpolator is implemented as a simple FIR interpolator with a boxcar response. A true CIC interpolator can only operate with fixed-point signals. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following diagram represents the DUC arithmetic with single or double-precision, floating-point inputs.

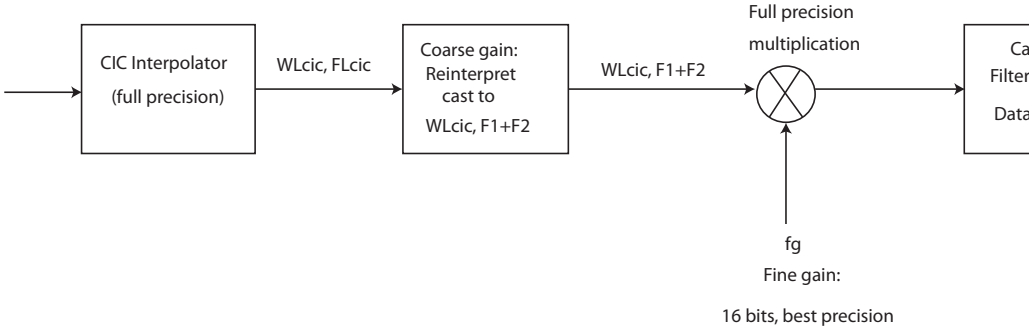


The following block diagram represents the DUC arithmetic with signed fixed-point inputs.



- `WL` is the word length of the input, and `FL` is the fraction length of the input.
- The output of each filter is cast to the data type specified in the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties. The casting of the CIC output occurs after the scaling factor is applied.
- The oscillator output is cast to a word length equal to the **FiltersOutputDataType** word length plus one. The fraction length is equal to the **FiltersOutputDataType** word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.



If the normalization gain is G, (where $0<G\leqq1$), then:

- `WLcic` is the word length of the CIC interpolator output and `FLcic` is the fraction length of the CIC interpolator output
- `F1 = abs(nextpow2(G))` , indicating the part of G achieved using bit shifts (coarse gain)
- `F2` = fraction length specified by the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties
- `fg = fi((2^F1)*G, true, 16)` , indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`h = dsp.DigitalUpConverter('PropertyName','PropertyValue')` returns a DUC object, `h`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

SampleRate

Sample rate of input signal

Set this property to a positive scalar. The value of this property multiplied by the total interpolation factor must be greater than

or equal to twice the value of the `CenterFrequency` property. The default is 30e6.

InterpolationFactor

Set this property to a positive, integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers. When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages. When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements respectively. When you set the `FilterSpecification` property to `Design parameters`, both elements of the `InterpolationFactor` vector must be greater than one. When you set the `FilterSpecification` property to `Coefficients`, `InterpolationFactor` vector must be greater than `1`. When you set this property to a 1-by-3 vector, the i^{th} element of the vector specifies the interpolation factor for the i^{th} filtering stage. When you set the `FilterSpecification` property to `Design parameters`, the second and third elements of the `InterpolationFactor` vector must be greater than one and the first element must be `1` or `2`. When you set the `FilterSpecification` property to `Coefficients`, the third element of the `InterpolationFactor` vector must be greater than `1`. When you set the `InterpolationFactor` property to `Coefficients`, you must set the `InterpolationFactor` property to a 1-by-3 or 1-by-2 vector . The default is `100`.

FilterSpecification

Set the filter specification as one of `Design parameters |Coefficients`. The default is `Design parameters`. The DUC object performs interpolation using a cascade of three interpolation filters. The third filter stage is always a CIC interpolator. When you set this property to `Design parameters`, the object designs the cascade of interpolation filters internally, according to a set of parameters that you specify using the filter-related object properties. In this case, the first and second

stages of the cascade consist of a halfband or lowpass FIR interpolator, and a CIC compensator respectively. When you set this property to `Coefficients`, you specify an arbitrary set of filter coefficients for the first and second stages using the `FirstFilterCoefficients`, and `SecondFilterCoefficients` properties respectively. You specify the number of CIC sections using the `NumCICSections` property. In all cases, the first filter stage can be bypassed by setting the `InterpolationFactor` property appropriately.

When the input data type is double or single the object implements an N-section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed point type.

MinimumOrderDesign

Minimum order filter design.

When you set this property to true the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. When you set this property to false, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. This property applies when you set the `FilterSpecification` property to `Design parameters`. The default is true.

FirstFilterCoefficients

Coefficients of first filter stage.

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. When you set

the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the value of the `FirstFilterCoefficients` property because the first filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is `1`.

SecondFilterOrder

Order of CIC compensation filter stage

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false. The default is `12`.

SecondFilterCoefficients

Coefficients of second filter stage.

Set this property to a double precision row vector of real coefficients that correspond to an FIR filter. Usually, the response of this filter should be that of a CIC compensator since a CIC interpolation filter follows the second filter stage. This property applies when you set the `FilterSpecification` property to `Coefficients`. The default is `1`.

FirstFilterOrder

Order of first filter stage

Set this property to a positive, integer, even scalar. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property because the first filter stage is bypassed. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to false. The default is `10`.

NumCICSections

Number of sections of CIC interpolator

Set this property to a positive, integer scalar. This property applies when you set the `FilterSpecification` property to

`Design parameters` and the `MinimumOrderDesign` property to false, or when you set the `FilterSpecification` property to `Coefficients`. The default is `3`.

Bandwidth

Two sided bandwidth of input signal in Hertz .

Set this property to a positive, integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. This property applies when you set the `FilterSpecification` property to `Design parameters`. The default is 200e3 Hertz.

StopbandFrequencySource

Source of stopband frequency.

Specify the source of the stopband frequency as one of `Auto | Property`. The default is `Auto`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately F_c = `SampleRate`/2 Hertz, and computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response, computed as $2*(F_c-F_p)$, and the passband frequency, F_p, equals Bandwidth/2. This property applies when you set the `FilterSpecification` property to `Design parameters`.

StopbandFrequency

Stopband frequency in Hertz

Set this property to a double precision positive scalar. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `StopbandFrequencySource` property to `Property`. The default is 150e3 Hertz.

PassbandRipple

Passband ripple of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs

the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to true. The default is `0.1` dB.

StopbandAttenuation

Stopband attenuation of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the `MinimumOrderDesign` property to true, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property. This property applies when you set the `FilterSpecification` property to `Design parameters` and the `MinimumOrderDesign` property to true. The default is 60 dB.

Oscillator

Type of oscillator.

Specify the oscillator as one of `Sine wave | NCO`. The default is `Sine wave`. When you set this property to `Sine wave`, the object frequency up converts the output of the interpolation filter cascade using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO` the object performs frequency up conversion with a complex exponential obtained using a numerically controlled oscillator (NCO).

CenterFrequency

Center frequency of output signal in Hertz .

Specify this property as a double precision, positive scalar. The value of this property must be less than or equal to half the product of the `SampleRate` property times the total interpolation factor. The object up converts the input signal so that the

output spectrum centers at the frequency you specify in the `CenterFrequency` property. The default is 14e6 Hertz.

NumAccumulatorBits

Number of NCO accumulator bits

Specify this property as an integer scalar in the range `[1 128]`. This property applies when you set the `Oscillator` property to `NCO`. The default is `16`.

See also `dsp.NCO`.

NumQuantizedAccumulatorBits

Number of NCO quantized accumulator bits.

Specify this property as an integer scalar in the range`[1 128]`. The value you specify for this property must be less than the value you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO`. The default is `12`.

See also `dsp.NCO`.

Dither

Dither control for NCO .

When you set this property to true, the object uses the number of dither bits specified in the `NumDitherBits` property when applying dither to the NCO signal. This property applies when you set the `Oscillator` property to `NCO`. The default is true.

See also `dsp.NCO`.

NumDitherBits

Number of NCO dither bits.

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO` and the Dither property to true. The default is `4`.

See also `dsp.NCO`.

Fixed-Point Properties

FirstFilterCoefficientsDataType

Data type of first filter coefficients

Specify first filter coefficients data type as `Same as input|Custom`. The default is `Same as input`. This property applies when you set the `FilterSpecification` property to `Coefficients`.

CustomFirstFilterCoefficientsDataType

Fixed-point data type of first filter coefficients

Specify the first filter coefficients fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `FirstFilterCoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

SecondFilterCoefficientsDataType

Data type of second filter coefficients

Specify the second filter coefficients data type as `Same as input |Custom`. The default is `Same as input`. This property applies when you set the `FilterSpecification` property to `Coefficients`.

CustomSecondFilterCoefficientsDataType

Fixed-point data type of second filter coefficients

Specify the second filter coefficients fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `SecondFilterCoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

FiltersOutputDataType

Data type of output of each filter stage

Specify the data type at the output of the first (if it has not been bypassed), second, and third filter stages as one of `Same as input | Custom`. The default is `Same as input`. The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal has been scaled by the normalization factor.

CustomFiltersOutputDataType

Fixed-point data type of output of each filter stage

Specify the filters output fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `FiltersOutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Data type of output

Specify the data type of output as `Same as input | Custom`. The default is `Same as input`.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create digital up converter object with same property values
fvtool	Visualize response of filter cascade
getFilterOrders	Get orders of interpolation filters

getFilters	Get handles to interpolation filter objects
getInterpolationFactors	Get interpolation factors of each filter stage
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
groupDelay	Group delay of filter cascade
isLocked	Locked status for input attributes and non-tunable properties
release	Allow property value and input characteristics changes
step	Process inputs using the digital up converter
visualizeFilterStages	Display response of filter stages

Examples

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz.

```
% Create a sine wave generator to obtain the 1 KHz sinusoidal signal
% with a sample rate of 6 KHz.
Fs = 6e3; % Sample rate
hSig = dsp.SineWave('Frequency',1000,'SampleRate', Fs,'SamplesPerFram
x = step(hSig); % generate signal

% Create a DUC object. Use minimum order filter designs and set the
% passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Se
% the double sided signal bandwidth to 2 KHz.
hDUC = dsp.DigitalUpConverter(...
 'InterpolationFactor', 20,...
 'SampleRate', Fs,...
 'Bandwidth', 2e3,...
 'StopbandAttenuation', 55,...
```

```
 'PassbandRipple',0.2,...
 'CenterFrequency',5Oe3);

% Create a spectrum estimator to visualize the signal spectrum bef
% and after up converting.
window = hamming(floor(length(x)/10));
figure; pwelch(x,window,[],[],Fs,'centered')
title('Spectrum of baseband signal x')

% Up convert the signal and visualize the spectrum
xUp = step(hDUC,x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],2O*Fs,'centered')
title('Spectrum of up converted signal xUp')

% Visualize the response of the interpolation filters
visualizeFilterStages(hDUC)
```

For additional examples using this System object, see the following demos:

- "Digital Up and Down Conversion for Family Radio Service"
- "Design and Analysis of a Digital Down Converter"

See Also

`dsp.DigitalDownConverter`

dsp.DigitalUpConverter.clone

Purpose

Create digital up converter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `DigitalUpConverter` System object, `C`, with the same property values as `H`.

The clone method creates a new unlocked object with uninitialized states.

Purpose

Visualize response of filter cascade

Syntax

```
fvtool(H)
fvtool(H,..,'Arithmetic',ARITH,...)
fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2)
```

Description

`fvtool(H)` plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the `FilterSpecification` property to `Design parameters` the method plots a mask based on the filter specifications.

`fvtool(H,..,'Arithmetic',ARITH,...)` specifies the arithmetic of the filter cascade. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state you must specify the arithmetic. When object `H` is in a locked state the arithmetic input is ignored.

`fvtool(H,..., PROP1, VALUE1,PROP2,VALUE2)` launches FVTool and sets the specified FVTool properties to the specified values.

dsp.DigitalUpConverter.getFilters

Purpose

Get handles to interpolation filter objects

Syntax

```
S = getFilters(H)
getFilters(H,'Arithmetic',ARITH)
```

Description

`S = getFilters(H)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the interpolation filter cascade. The `FirstFilterStage` structure field is empty if the first filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(H,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You set `ARITH` to `double`, `single`, or `fixed-point`. When object `H` is in an unlocked state, you must specify the arithmetic input. When object `H` is in a locked state, the arithmetic input is ignored.

When `H` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalUpConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `H` is in a locked state, and the input to the step method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point properties of these System objects are set to the exact values that the `dsp.DigitalUpConverter` System object uses to process the data.

Purpose

Get orders of interpolation filters

Syntax

```
S = getFilterOrders(H)
```

Description

`S = getFilterOrders(H)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `FirstFilterOrder` structure field will be empty if the first filter stage has been bypassed.

dsp.DigitalUpConverter.getInterpolationFactors

Purpose

Get interpolation factors of each filter stage

Syntax

```
M = getInterpolationFactors(H)
```

Description

`M = getInterpolationFactors(H)` returns a vector, `M`, with the interpolation factors of each filter stage. If the first filter stage is bypassed, then `M` is a 1-by-2 vector containing the interpolation factors of the second and third stages in the first and second elements respectively. If the first filter stage is not bypassed then `M` is a 1-by-3 vector containing the interpolation factors of the first, second and third filter stages.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.DigitalUpConverter.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Group delay of filter cascade

Syntax

```
D = groupDelay(H,N)
[D,F] = groupDelay(H,N)
```

Description

`D = groupDelay(H,N)` returns a vector of group delays, `D`, evaluated at `N` frequency points equally spaced around the upper half of the unit circle. If you don't specify `N`, it defaults to `8192`.

`[D,F] = groupDelay(H,N)` returns a vector, `F`, of frequencies at which the group delay has been computed.

dsp.DigitalUpConverter.isLocked

Purpose

Locked status for input attributes and non-tunable properties

Syntax

```
Y = isLocked(H)
```

Description

`Y = isLocked(H)` returns the locked state, `Y`, of the `DigitalUpConverter` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.DigitalUpConverter.step

Purpose

Process inputs using the digital up converter

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` takes a real or complex input column vector `X` and outputs an up sampled and frequency up converted signal `Y`. `X` can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of `Y` is equal to the length of `X` multiplied by the `InterpolationFactor`. When the data type of `X` is double or single precision, the data type of `Y` is the same as that of `X`. When the data type of `X` is of a fixed point type, the data type of Y is defined by the `OutputDataType` property.

Purpose

Display response of filter stages

Syntax

```
visualizeFilterStages(H)
visualizeFilterStages(H,'Arithmetic',ARITH)
hfvt = visualizeFilterStages(H)
```

Description

`visualizeFilterStages(H)` plots the magnitude response of the filter stages and of the cascade response. When the `FilterSpecification` property is set to `Design parameters` the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(H,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You set input ARITH to 'double', 'single', or 'fixed-point'. When object `H` is in an unlocked state you must specify the arithmetic. When object `H` is in a locked state the arithmetic input is ignored.

`hfvt = visualizeFilterStages(H)` returns the handle to the FVTool object.

dsp.DyadicAnalysisFilterBank

Purpose

Dyadic analysis filter bank

Description

The `DyadicAnalysisFilterBank` object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

1. Define and set up your dyadic analysis filter bank. See "Construction" on page 3-588.
2. Call `step` to get the octave half band frequency decompositions of the input according to the properties of `dsp.DyadicAnalysisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `H`, that computes the level-two discrete wavelet transform (DWT) of a column vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

`H = dsp.DyadicAnalysisFilterBank('PropertyName',PropertyValue, ...)` returns a dyadic analysis filter bank object, `H`, with each property set to the specified value.

Properties

Filter

Type of filter used in subband decomposition

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as `Custom` , `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse`

`Biorthogonal`, or `Discrete Meyer`. All property values except `Custom` require Wavelet Toolbox software. If the value of this property is `Custom`, the filter coefficients are specified by the values of the `CustomLowpassFilter` and `CustomHighpassFilter` properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function `wfilters` to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

Filter	Example Setting	Syntax for Analysis Filters
Haar	N/A	`[Lo_D,Hi_D]=wfilters('haar');`
Daubechies extremal phase	`WaveletOrder=3;`	`[Lo_D,Hi_D]=wfilters('db3');`
Symlets (Daubechies least-asymmetric)	`WaveletOrder=4;`	`[Lo_D,Hi_D]=wfilters('sym4');`
Coiflets	`WaveletOrder=1;`	`[Lo_D,Hi_D]=wfilters('coif1');`
Biorthogonal	`FilterOrder='[3/1]';`	`[Lo_D,Hi_D,Lo_R,Hi_R]=...` `wfilters('bior3.1');`
Reverse biorthogonal	`FilterOrder='[3/1]';`	`[Lo_D,Hi_D,Lo_R,Hi_R]=...` `wfilters('rbior3.1');`
Discrete Meyer	N/A	`[Lo_D,Hi_D]=wfilters('dmey');`

CustomLowpassFilter

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in powers of z^{-1}. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomHighpassFilter` property. This property applies when you set the `Filter` property to `Custom`. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

CustomHighpassFilter

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in powers of z^{-1}. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. This property applies when you set the `Filter` property to `Custom`. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

WaveletOrder

Order for orthogonal wavelets

Specify the order of the wavelet selected in the `Filter` property. This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`. The default is `2`.

FilterOrder

Analysis and synthesis filter orders for biorthogonal filters

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as `1 / 1`, `1 / 3`, `1 / 5`, `2 / 2`, `2 / 4`, `2 / 6`, `2 / 8`, `3 / 1`, `3 / 3`, `3 / 5`, `3 / 7`, `3 / 9`, `4 / 4`, or `5 / 5`, `6 / 8`. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter. This property applies when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`. The default is `1 / 1`.

NumLevels

Number of filter bank levels used in analysis (decomposition)

Specify the number of filter bank analysis levels a positive integer. A level-N asymmetric structure produces N+1 output subbands. A level-N symmetric structure produces 2^N output subbands. The

default is 2. The size of the input along the first dimension must be a multiple of 2^N, where N is the number of levels.

TreeStructure

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension and N is the value of the `NumLevels` property. When this property is `Asymmetric`, the output has $N+1$ subbands. The following equation gives the length of the output in the kth subband in the asymmetric case:

$$M_k = \begin{cases} \dfrac{M}{2^k} & 1 \le k \le N \\ \dfrac{M}{2^N} & k = N+1 \end{cases}$$

The default is `Asymmetric`.

Methods

clone	Create dyadic analysis filter bank object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset filter states
step	Decompose input with dyadic filter bank

Examples

Denoise square wave input using dyadic analysis and synthesis filter banks:

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
hdydanl = dsp.DyadicAnalysisFilterBank;

% The filter coefficients correspond to a 'haar' wavelet.
hdydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
hdydsyn = dsp.DyadicSynthesisFilterBank;
hdydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];

C = step(hdydanl, xn);

% Subband outputs
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);

% Set higher frequency coefficients to zero
% to remove the noise.
x_den = step(hdydsyn, [zeros(length(C1),1);...
zeros(length(C2),1);C3]);

subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Analysis Filter Bank block reference page. The object properties correspond to the block parameters, except:

The dyadic analysis filter bank object always concatenates the subbands into a single column vector for a column vector input, or into the columns of a matrix for a matrix input. This behavior corresponds to the block's behavior when you set the **Output** parameter to `Single port`.

See Also

`dsp.DyadicSynthesisFilterBank` | `dsp.SubbandAnalysisFilter`

dsp.DyadicAnalysisFilterBank.clone

Purpose

Create dyadic analysis filter bank object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a dyadic analysis filter bank object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.DyadicAnalysisFilterBank.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the dyadic analysis filter bank object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.DyadicAnalysisFilterBank.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset filter states

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the dyadic analysis filter bank object, `H`, to their initial values of zero. After the `step` method applies the dyadic analysis filter bank to nonzero input data, the filter states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Example of resetting filter states:

```
X = [1 1 7 9 2 8 8 6]';
H = dsp.DyadicAnalysisFilterBank('NumLevels',1);
% Filter states are zero
y = step(H,X);
% Invoke step method again without resetting states
y1 = step(H,X);
isequal(y,y1) % Returns 0
reset(H); % Reset filter states to zero
y2 = step(H,X);
isequal(y,y2) % Returns 1
```

dsp.DyadicAnalysisFilterBank.step

Purpose

Decompose input with dyadic filter bank

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` computes the subband decomposition of the input `X` and outputs the dyadic subband decomposition in `Y` as a single concatenated column vector or matrix of coefficients. Each column of `X` is treated as an independent input, and the number of rows of `X` must be a multiple of 2^N, where N is the value of the `NumLevels` property. The elements of `Y` are ordered with the highest frequency subband first followed by subbands in decreasing frequency

Examples

Subband ordering for level-two asymmetric tree structure:

```
t = 0:.001:1.023;
% Sampling frequency 1 kHz input length 1024
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
% Default asymmetric structure with
% Daubechies order 3 extremal phase wavelet
H = dsp.DyadicAnalysisFilterBank;
Y = step(H,xn);
% Level 2 yields 3 subbands (two detail-one approximation)
% Nyquist frequency is 500 Hz
D1 =Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

Subband ordering for symmetric tree structure:

```
t = 0:.001:1.023;
% Sampling frequency 1 kHz input length 1024
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1); % symmetric structure with
% Daubechies order 3 extremal phase wavelet
```

```
H = dsp.DyadicAnalysisFilterBank('TreeStructure',...
'Symmetric');
Y = step(H,xn);
D1 = Y(1:256); % subband approx. [375,500] Hz
D2 = Y(257:512); % subband approx. [250,375] Hz
D3 = Y(513:768); % subband approx. [125,250] Hz
Approx = Y(769:1024); % subband approx. [0, 125] Hz
```

dsp.DyadicSynthesisFilterBank

Purpose

Reconstruct signals from subbands

Description

The `DyadicSynthesisFilterBank` object reconstructs signals from subbands with smaller bandwidths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

1. Define and set up your synthesis filter bank. See "Construction" on page 3-602.
2. Call `step` to reconstruct the signal according to the properties of `dsp.DyadicSynthesisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `H`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`H = dsp.DyadicSynthesisFilterBank('Propertyname',PropertyValue,...)` returns a synthesis filter bank, `H`, with each specified property set to the specified value.

Properties

Filter

Type of filter used in filter bank

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. If you set this property to `Custom`, the `CustomLowpassFilter` and `CustomHighpassFilter` properties specify the filter coefficients. Otherwise, the object uses the Wavelet Toolbox `wfilters` function to construct the filters. Depending on the filter, the `WaveletOrder` or `FilterOrder`

property might apply. For a list of the supported wavelets, see the following table.

Filter	Sample Setting for Related Filter Specification Properties	Corresponding Wavelet Toolbox Function Syntax
`Haar`	None	`wfilters('haar')`
`Daubechies`	`H.WaveletOrder = 4`	`wfilters('db4')`
`Symlets`	`H.WaveletOrder = 3`	`wfilters('sym3')`
`Coiflets`	`H.WaveletOrder = 1`	`wfilters('coif1')`
`Biorthogonal`	`H.FilterOrder = '[3/1]'`	`wfilters('bior3.1')`
`Reverse Biorthogonal`	`H.FilterOrder = '[3/1]'`	`wfilters('rbior3.1')`
`Discrete Meyer`	None	`wfilters('dmey')`

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the `CustomLowpassFilter` and `CustomHighpassFilter` properties to specify lowpass and highpass FIR filters.

CustomLowpassFilter

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of *z*. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomHighpassFilter` property. This property applies only when you set the `Filter` property to `Custom`. To perfectly reconstruct a signal decomposed by the `DyadicAnalysisFilterBank`, design the filters in the

synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

CustomHighpassFilter

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of *z*. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` property. This property applies only when you set the `Filter` property to `Custom`. To perfectly reconstruct a signal decomposed by the `DyadicAnalysisFilterBank`, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

WaveletOrder

Wavelet order

Specify the order of the wavelet selected in the `Filter` property. This property applies only when you set the `Filter` property to `Daubechies`, `Symlets` or `Coiflets`. The default is `2`.

FilterOrder

Wavelet order for synthesis filter stage

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.

- Fifth order: `'[5/5]'`.
- Sixth order: `'[6/8]'`.

This property applies only when you set the `Filter` property to `Biorthogonal` or `Reverse Biorthogonal`. The default is `'[1/1]'`.

NumLevels

Number of filter bank levels

Specify the number of filter bank levels as a scalar integer. An N-level asymmetric structure has $N + 1$ input subbands, and an N-level symmetric structure has 2^N input subbands. The default is `2`.

rg

TreeStructure

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level. The default is `Asymmetric`.

Methods

clone	Create synthesis filter bank object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of the step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset internal states of dyadic synthesis filter bank object
step	Reconstruct signal from high- and low-frequency subbands

Examples

Remove noise from a signal using filter banks:

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
hdydanl = dsp.DyadicAnalysisFilterBank;

% The filter coefficients correspond to a 'haar' wavelet.
hdydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
hdydsyn = dsp.DyadicSynthesisFilterBank;
hdydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
hdydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];

C = step(hdydanl, xn);

% Subband outputs
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);

% Set high-frequency coefficients to zero to remove noise.
x_den = step(hdydsyn, ...
  [zeros(length(C1),1); ...
   zeros(length(C2),1); ...
   C3]);

subplot(2,1,1), plot(xn); title('Original Noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Synthesis Filter Bank block reference page. The object properties correspond to the block parameters, except:

The object only receives data as a vector or matrix of concatenated subbands, as specified using the `step` method.

See Also

`dsp.DyadicAnalysisFilterBank` | `dsp.SubbandSynthesisFilter`

dsp.DyadicSynthesisFilterBank.clone

Purpose

Create synthesis filter bank object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `DyadicSynthesisFilterBank` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.DyadicSynthesisFilterBank.getNumOutputs

Purpose

Number of outputs of the step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `DyadicSynthesisFilterBank` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.DyadicSynthesisFilterBank.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of dyadic synthesis filter bank object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the dyadic synthesis filter bank object `H` to their initial values.

dsp.DyadicSynthesisFilterBank.step

Purpose

Reconstruct signal from high- and low-frequency subbands

Syntax

```
X = step(H,S)
```

Description

`X = step(H,S)` reconstructs the concatenated subband input `S` to output `X`. Each column of input `S` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of `S` must be a multiple of 2^N, where N is the value of the `NumLevels` property.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Fast Transversal filter

Description

The `dsp.FastTransversalFilter` computes output, error and coefficients using a fast transversal least-squares FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See "Construction" on page 3-615.
2. Call `step` to implement the filter according to the properties of `dsp.FastTransversalFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.FastTransversalFilter` returns a System object, H, which is a fast transversal, least-squares FIR adaptive filter. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`H = dsp.FastTransversalFilter('PropertyName', PropertyValue,...)` returns a `FastTransversalFilter` System object, H, with each specified property set to the specified value.

`H = dsp.FastTransversalFilter(LEN,'PropertyName',PropertyValue,...)` returns a `FastTrasversalFilter` System object, H. In this case, the Length property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of `'Fast transversal least-squares' |'Sliding-window fast transversal least-squares'`. The default value is `` `Fast transversal least-squares' ``. For algorithms used to implement these three different methods, refer to [1]. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

SlidingWindowBlockLength

Width of sliding window

Specify the width of the sliding window as a positive integer value greater than or equal to the `Length` property value. This property applies only if the `Method` property is set to `'Sliding-window fast transversal least-squares'`. The default vale is the value of the `Length` property. This property is nontunable.

ForgettingFactor

Fast transversal filter forgetting factor

Specify the fast transversal filter forgetting factor as a positive numeric value. Setting this value to 1 denotes infinite memory while adaptation. Setting this property value to 1 denotes infinite memory while adapting to find the new filter. For best results, set this property to a value that lies in the range `(1-0.5/L, 1]`, where `L` is the Length property value. This property applies only if the Method property is set to `'Fast transversal least-squares'`. The default value is `1`.

InitialPredictionErrorPower

Initial prediction error power

Specify the initial value of the forward and backward prediction error vectors as a positive numeric scalar. This scalar should be sufficiently large to maintain stability and prevent an excessive number of Kalman gain rescues. The default value is `10`.

InitialConversionFactor

Initial conversion factor (gamma)

Specify the initial value of the conversion factor of the fast transversal filter. If the `Method` property is set to `'Fast transversal least-squares'`, this property must be a positive numeric value less than or equal to `1`. In this case, the default value is `1`. If the `Method` property is set to `'Sliding-window fast transversal least-squares'`, this property must be a 2-element numeric vector. The first element of this vector must lie within the range `(0,1]`, and the second element must be less than or equal to `-1`. In this case, the default value is `[1, -1]`.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property. The default value is `0`.

LockCoefficients

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Methods

clone	Create Fast Transversal filter object with same property values
isLocked	Locked status for input attributes and nontunable properties
msesim	Mean-square error for Fast Transversal filter
release	Allow property value and input characteristics changes

reset	Reset filter states for Fast Transversal filter
step	Apply Fast Transversal filter to input

Examples

System identification of an FIR filter

Use the fast transversal filter and the digital filter to identify an FIR filter.

```
hftf1 = dsp.FastTransversalFilter(11,'ForgettingFactor',0.99);
hfilt = dsp.DigitalFilter;
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10,.25);
x = randn(1000,1);
d = step(hfilt,x) + 0.01*randn(1000,1);
[y,e] = step(hftf1,x,d);
w = hftf1.Coefficients;
subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([hfilt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #'); ylabel('coefficient value');
```

See Also

`dsp.LMSFilter` | `dsp.RLSFilter` | `dsp.AffineProjectionFilter` | `dsp.FrequencyDomainAdaptiveFilter` | `dsp.FilteredXLMSFilter` | `dsp.FIRFilter`

Purpose

Mean-square error for Fast Transversal filter

Syntax

```
MSE = msesim(H,X,D)
[MSE,MEANW,W,TRACEK] = msesim(H,X,D)
[...] = msesim(H,X,D,M)
```

Description

`MSE = msesim(H,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(H,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `H`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `H`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(H,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

dsp.FastTransversalFilter.clone

Purpose

Create Fast Transversal filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`, with the same property values. The clone method creates a new unlocked object with uninitialized states.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the Fast Transversal filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.FastTransversalFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset filter states for Fast Transversal filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the System object,`H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

dsp.FastTransversalFilter.step

Purpose

Apply Fast Transversal filter to input

Syntax

```
[Y, ERR] = step(H, x, D)
Y = step(H,x)
[Y1,...,YN] = step(H,x)
```

Description

`[Y, ERR] = step(H, x, D)` filters the input `x`, using D as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(H,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, H. `[Y1,...,YN] = step(H,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Discrete Fourier transform

Description

The `FFT` object computes the discrete Fourier transform (DFT) of an input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen by FFTW [1], [2]

To compute the DFT of an input:

1. Define and set up your `FFT` object. See "Construction" on page 3-625.
2. Call `step` to compute the DFT of the input according to the properties of `dsp.FFT`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.FFT` returns a `FFT` object, `H`, that computes the DFT of an *N*-D array. For column vectors or multidimensional arrays, the `FFT` object computes the DFT along the first dimension. If the input is a row vector, the `FFT` object computes a row of single-sample DFTs and issues a warning.

`H = dsp.FFT('PropertyName',PropertyValue, ...)` returns a `FFT` object, `H`, with each property set to the specified value.

Properties

FFTImplementation

FFT implementation

Specify the implementation used for the FFT as one of `Auto | Radix-2 | FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

BitReversedOutput

Order of output elements relative to input elements

Designate order of output channel elements relative to order of input elements. Set this property to `true` to output the frequency indices in bit-reversed order. The default is `false`, which corresponds to a linear ordering of frequency indices.

Normalize

Divide butterfly outputs by two

Set this property to `true` if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is `false` with no scaling.

FFTLengthSource

Source of FFT length

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal. The default is `Auto`.

FFTLength

FFT length

Specify the FFT length. This property applies when you set the `FFTLengthSource` property to `Property`. The default is `64`.

This property must be a power of two when the input is a fixed-point data type, or when you set the `BitReversedOutput` property to `true`, or when you set the `FFTImplementation` property to `Radix-2`.

WrapInput

Boolean value of wrapping or truncating input

Wrap input data when FFT length is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is set to false, truncation of the input data to the FFT length occurs before the FFT operation. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

SineTableDataType

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomSineTableDataType

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as one of `Full precision`, `Same as input`, `Custom`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when

you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create FFT object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Discrete Fourier transform of input

Examples

Find frequency components of a signal in additive noise:

```
Fs = 800; L = 1000;
t = (0:L-1)'/Fs;
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);
y = x + .5*randn(size(x)); % noisy signal

hfft = dsp.FFT('FFTLengthSource', 'Property', ...
 'FFTLength', 1024);

 Y = step(hfft, y);

 % Plot the single-sided amplitude spectrum
 plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512)/1024));
 title('Single-sided amplitude spectrum of noisy signal y(t)');
 xlabel('Frequency (Hz)'); ylabel('|Y(f)|');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

`dsp.IFFT` | `dsp.DCT` | `dsp.IDCT`

Purpose

Create FFT object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `FFT` object with the same property values as `H`. The clone method creates a new unlocked object.

dsp.FFT.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.FFT.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the FFT object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.FFT.step

Purpose

Discrete Fourier transform of input

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` computes the FFT, `Y` , of the input `X` along the first dimension of `X`. When the `FFTLengthSource` property is `Auto`, the length of `X` along the first dimension must be a positive integer power of two. This length is also the FFT length . When the `FFTLengthSource` property is `Property`, the `FFTLength` property must be a positive integer power of two.

Purpose

Filtered XLMS filter

Description

The `dsp.FilteredXLMSFilter` computes output, error and coefficients using Filtered-X Least Mean Squares FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See "Construction" on page 3-637.
2. Call `step` to implement the filter according to the properties of `dsp.FilteredXLMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.FilteredXLMSFilter` returns a filtered-x Least Mean Square FIR adaptive filter System object, H. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`H = dsp.FilteredXLMSFilter('PropertyName', PropertyValue,...)` returns a `FilteredXLMSFilter` System object, H, with each specified property set to the specified value.

`H = dsp.FilteredXLMSFilter(LEN,'PropertyName',PropertyValue,...)` returns a `FilteredXLMSFilter` System object, H, with the Length property set to `LEN`, and other specified properties set to the specified values. For the algorithm on how to implement this filter, refer to [1], [2].

Properties

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 10.

StepSize

Adaptation step size

Specify the adaptation step size factor as a positive numeric scalar. The default value is `0.1`. This property is tunable.

LeakageFactor

Adaptation leakage factor

Specify the leakage factor used in a leaky adaptive filter as a numeric value between `0` and `1`, both inclusive. When the value is less than `1`, the System object implements a leaky adaptive algorithm. The default value is `1`, providing no leakage in the adapting method. This property is tunable.

SecondaryPathCoefficients

Coefficients of the secondary path filter model

Specify the coefficients of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value is a vector that represents the coefficients of a 10th-order FIR lowpass filter. This property is tunable.

SecondaryPathEstimate

An estimate of the secondary path filter model

Specify the estimate of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value equals to the `SecondayPathCoefficients` property value. This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property. The default value is `0`.

LockCoefficients

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Methods

clone	Create Filtered-X LMS filter object with same property values
isLocked	Locked status for input attributes and nontunable properties
msesim	Mean-square error for Filtered-X LMS filter
release	Allow property value and input characteristics changes
reset	Reset filter states for Filtered-X LMS filter
step	Apply Filtered-X LMS filter to input

Examples

Active noise control of a random noise signal

Generate noise, create FIR primary path system model, generate observation noise, filter the primary path system model output with added noise, and create FIR secondary path system model:

```
x  = randn(1000,1);
g  = fir1(47,0.4);
n  = 0.1*randn(1000,1);
d  = filter(g,1,x) + n
b  = fir1(31,0.5);
```

Use the Filtered-X LMS Filter to compute the filtered output and the filter error for the input and the signal to be cancelled:

```
mu = 0.008;
ha = dsp.FilteredXLMSFilter(32, 'StepSize', mu, 'LeakageFactor', ...
     1, 'SecondaryPathCoefficients', b);
[y,e] = step(ha,x,d);
```

Plot the results:

```
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

`dsp.LMSFilter` | `dsp.RLSFilter` | `dsp.AffineProjectionFilter` | `dsp.AdaptiveLatticeFilter` | `dsp.FrequencyDomainAdaptiveFilter` | `dsp.FIRFilter`

Purpose

Mean-square error for Filtered-X LMS filter

Syntax

```
MSE = msesim(H,X,D)
[MSE,MEANW,W,TRACEK] = msesim(H,X,D)
[...] = msesim(H,X,D,M)
```

Description

`MSE = msesim(H,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(H,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `H`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `H`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(H,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System identification of an FIR filter

```
ha = fir1(31,0.5);
sa = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
hb = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = step(hb,sign(randn(2000,25)));
n = 0.1*randn(size(x));             % Observation noise signal
d = step(sa,x)+n;                   % Desired signal
```

```
l = 32;                                 % Filter length
mu = 0.008;                             % Filtered-X LMS filter Step size.
m  = 5;                                 % Decimation factor for analysis
                                        % and simulation results
ha = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for Filtered-X LMS filter used in system identifica
```

Purpose

Create Filtered-X LMS filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`, with the same property values. The clone method creates a new unlocked object with uninitialized states.

dsp.FilteredXLMSFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the Filtered-X LMS filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.FilteredXLMSFilter.reset

Purpose

Reset filter states for Filtered-X LMS filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the System object,`H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

Purpose

Apply Filtered-X LMS filter to input

Syntax

```
[Y, ERR] = step(H, x, D)
Y = step(H,x)
[Y1,...,YN] = step(H,x)
```

Description

`[Y, ERR] = step(H, x, D)` filters the input `x`, using D as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(H,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, H. `[Y1,...,YN] = step(H,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.FIRDecimator

Purpose

polyphase FIR decimator

Description

The `FIRDecimator` object resamples vector or matrix inputs along the first dimension. The object reseamples at a rate M times slower than the input sampling rate, where M is the integer-valued downsampling factor. The decimation combines an FIR anti-aliasing filter with downsampling. The FIR decimator object uses a polyphase implementation of the FIR filter.

To resample vector or matrix inputs along the first dimension:

1. Define and set up your FIR decimator. See "Construction" on page 3-648.
2. Call `step` to resample the vector or matrix inputs according to the properties of `dsp.FIRDecimator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.FIRDecimator` returns an FIR decimator, `H`, which applies an FIR filter with a cutoff frequency of `0.4*pi` radians/sample to the input and downsamples the filter output by factor of 2.

`H = dsp.FIRDecimator ('PropertyName',PropertyValue, ...)` returns an FIR decimator, `H`, with each property set to the specified value.

`H = dsp.FIRDecimator(DECIM, NUM, 'PropertyName',PropertyValue, ...)` returns an FIR decimator, `H`, with the integer-valued `DecimationFactor` property set to `DECIM`, the `Numerator` property set to `NUM`, and other specified properties set to the specified values.

Properties

DecimationFactor

Decimation factor

Specify the downsampling factor as a positive integer. The FIR decimator reduces the sampling rate of the input by this factor.

The size of the input along the first dimension must be a multiple of the decimation factor. The default is `2`.

Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR filter in powers of z^{-1}. The following equation defines the system function for a filter of length L:

$$H(z) = \sum_{l=0}^{L-1} b_l z^{-l}$$

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than 1/`DecimationFactor`. You can specify the filter coefficients as a vector in the supported data types. The FIR decimator does not support `dfilt` or `mfilt` objects as sources of the filter coefficients. The default is `fir1(35,0.4)`.

Structure

Filter structure

Specify the implementation of the FIR filter as either `Direct form` or `Direct form transposed`. The default is `Direct form`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are

added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when

you set the `OutputDataType` property to `Custom`. The default is `numerictype([]1,16,15)`.

Methods

clone	Create FIR decimator object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset filter states of FIR decimator
step	Decimate input by integer factor

More “Analysis Methods for Filter System Objects” on page 2-2.

Definitions

Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into M different subfilters, where M is the downsampling, or decimation factor. Let $h(n)$ denote the FIR filter impulse response of length L and $u(n)$ the input signal. Decimating the filter output by a factor of M is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^{L-1} h(l)u(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting *M=2*, the input values *u(0),u(2),u(4), ...* are only combined with the filter coefficients *h(0),h(2),h(4),...*, and the input values *u(1),u(3),u(5), ...* are only combined with the filter coefficients *h(1),h(3),h(5),....* By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output. The following MATLAB code demonstrates how to construct the two polyphase subfilters for the default order 35 filter in the `Numerator` property and the default `DecimationFactor` property value of two:

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
     nzeros = M - rem(FiltLength, M);
     Num = [zeros(nzeros,1); Num];  % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of M , there are M phases and therefore M subfilters.

Examples

Decimate a sum of sine waves with angular frequencies of π/4 and 2π/3 radians/sample by a factor of two. To prevent aliasing, the

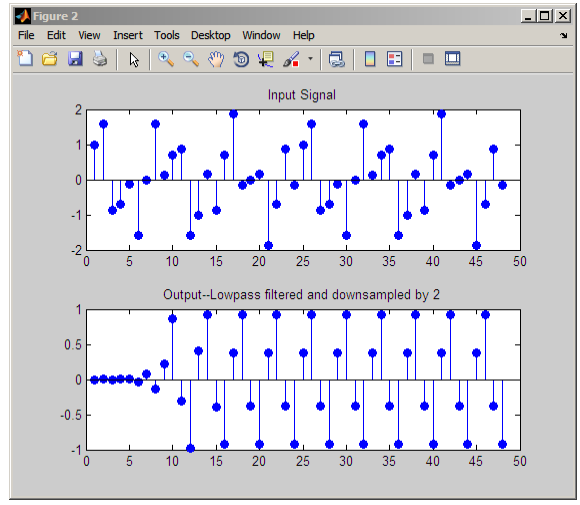
FIR decimator filters out the 2π/3 radians/sample component before downsampling:

```
x = cos(pi/4*[0:95]')+sin(2*pi/3*[0:95]');
H = dsp.FIRDecimator;
y = step(H,x);

% View group delay of default FIR filter
fvtool(fir1(35,0.4),1,'analysis','grpdelay');
% Group delay of the default linear-phase FIR filter
% is 17.5 samples. Downsampling by a factor of
% two expect an approx. 8.75 sample delay in the output
% y with the initial filter states of zero

subplot(211);
stem(x(1:length(x)/2),'b','markerfacecolor',[0 0 1]);
title('Input Signal');
subplot(212);
stem(y,'b','markerfacecolor',[0 0 1]);
title('Output--Lowpass filtered and downsampled by 2');
```

The figure shows that the delay in the decimated output is consistent with the group delay of the filter when the initial filter states are zero.



Reduce the sampling rate of an audio signal by 1/2 and play it:

```
hmfr = dsp.AudioFileReader('OutputDataType',...
  'single');
hap = dsp.AudioPlayer(22050/2);
hfirdec = dsp.FIRDecimator;

while ~isDone(hmfr)
     frame = step(hmfr);
     y = step(hfirdec, frame);
     step(hap, y);
end

release(hmfr);
pause(0.5);
release(hap);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Decimation block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source** – The FIR decimator object does not support `mfilt` objects.
- **Framing** – The FIR decimator object only supports `Maintain input frame rate`
- **Output buffer initial conditions** – The FIR decimator object does not support this parameter.
- **Rate options** – The FIR decimator object does not support this parameter.
- **Input processing** The FIR decimator object does not support this parameter.

See Also

`dsp.FIRInterpolator` | `dsp.FIRRateConverter`

Purpose

Create FIR decimator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an FIR decimator object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.FIRDecimator.freqz

Purpose

Frequency response

Syntax

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

Purpose

Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description

`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

dsp.FIRDecimator.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.FIRDecimator.impz

Purpose

Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description

`[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of `H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points `t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the FIR decimator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.FIRDecimator.phasez

Purpose

Unwrapped phase response

Syntax

```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.FIRDecimator.reset

Purpose

Reset filter states of FIR decimator

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the FIR decimator object,`H`, to the initial values of zero. After the `step` method applies the FIR decimator to nonzero input data, the filter states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Example of resetting filter states:

```
H = dsp.FIRDecimator;
x = cos(pi/8*[0:1023]')+sin(pi/4*[0:1023]');
y = step(H,x);
% Invoke step method again without reset
y1 = step(H,x);
isequal(y,y1) % Returns 0
% Reset filter states
reset(H);
y2 = step(H,x);
isequal(y,y2) % Returns 1
```

Purpose

Decimate input by integer factor

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` outputs the filtered and downsampled values, `Y`, of the input signal, `X`. A *Ki*-by-*N* input matrix is treated as *N* independent channels. The length of each column must be a multiple of the `DecimationFactor` property value. The FIR decimator operates on each channel separately and generates a *Ko*-by-*N* output matrix where $Ko = Ki/M$ with *M* the decimation factor. The object supports real and complex floating-point and fixed-point inputs, except for complex unsigned fixed-point inputs.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.FIRFilter

Purpose

Static or time-varying FIR filter

Description

The `FIRFilter` object filters each channel of the input using static or time-varying FIR filter implementations.

To filter each channel of the input:

1. Define and set up your FIR filter. See "Construction" on page 3-668.
2. Call `step` to filter each channel of the input according to the properties of `dsp.FIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.FIRFilter` returns a default FIR filter object, `H`, which independently filters each channel of the input over successive calls to the `step` method, using a specified FIR filter implementation. This System object supports variable-size input.

`H = dsp.FIRFilter('PropertyName',PropertyValue, ...)` returns an FIR filter system object, `H`, with each property set to the specified value.

Properties

Structure

Filter structure

Specify the filter structure.

You can specify the filter structure as one of `| Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA |`. The default is `Direct form`.

NumeratorSource

Source of filter coefficients

Specify the source of the filter coefficients as one of `| Property | Input port |`. The default is `Property`. When you specify `Input port`, the filter object updates the time-varying filter once

every frame, when the `FrameBasedProcessing` property is `true`. When the `FrameBasedProcessing` property is `false`, it updates once every sample.

This applies when you set the `Structure` to `Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed`.

ReflectionCoefficientsSource

Source of filter coefficients

Specify the source of the Lattice filter coefficients as one of `| Property | Input port |`. The default is `Property`. When you specify `Input port`, the filter object updates the time-varying filter once every frame, when the `FrameBasedProcessing` property is `true`. When the `FrameBasedProcessing` property is `false`, it updates once every sample.

This applies when you set the `Structure` to `Lattice MA` .

Numerator

Numerator coefficients

Specify the filter coefficients as a real or complex numeric row vector. This property applies when you set the `NumeratorSource` property to `Property`, and the `Structure` property is not set to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `[0.5 0.5]`. This property is tunable.

ReflectionCoefficients

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector. This property applies when you set the `Structure` property to `Lattice MA`, and the `ReflectionCoefficientsSource` property to `Property`. The default is `[0.5 0.5]`. This property is tunable.

InitialConditions

Initial conditions for the FIR filter

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is 0.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as one of `| Same word length as input | Custom |`. This property applies when you set the `NumeratorSource` property to `Property`. The default is `Same word length as input`.

CustomCoefficientsDataType

Custom coefficients word and fraction lengths

Specify the coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

ReflectionCoefficientsDataType

Reflection coefficients word and fraction lengths

Specify the reflection coefficients fixed-point data type as one of `| Same word length as input | Custom |`. This property applies when you set the `ReflectionCoefficientsSource` property to `Property`. The default is `Same word length as input`.

CustomReflectionCoefficientsDataType

Custom reflection coefficients word and fraction lengths

Specify the numerator fixed-point type as a signed or unsigned `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ReflectionCoefficientsDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Full precision`.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype(true,32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype(true,32,30)`.

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom` |. This property does not apply to any of the direct form or direct form I filter structures. The default is `Same as accumulator`.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `StateDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

Methods

clone	Create static or time-varying FIR filter with same property values

More “Analysis Methods for Filter System Objects” on page 2-2.

Examples 1

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components:

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);

hSR = dsp.SignalSource;
```

```
hSR.Signal = xin;
hLog = dsp.SignalSink;

hFIR = dsp.FIRFilter;
hFIR.Numerator = fir1(10,0.5);

h = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80, 'PowerUnits','dBW',...
    'YLimits', [-150 -10]);

while ~isDone(hSR)
     input = step(hSR);
     filteredOutput = step(hFIR,input);
     step(hLog,filteredOutput);
     step(h,filteredOutput)
end

filteredResult = hLog.Buffer;
fvtool(hFIR,'Fs',8000)
```

2

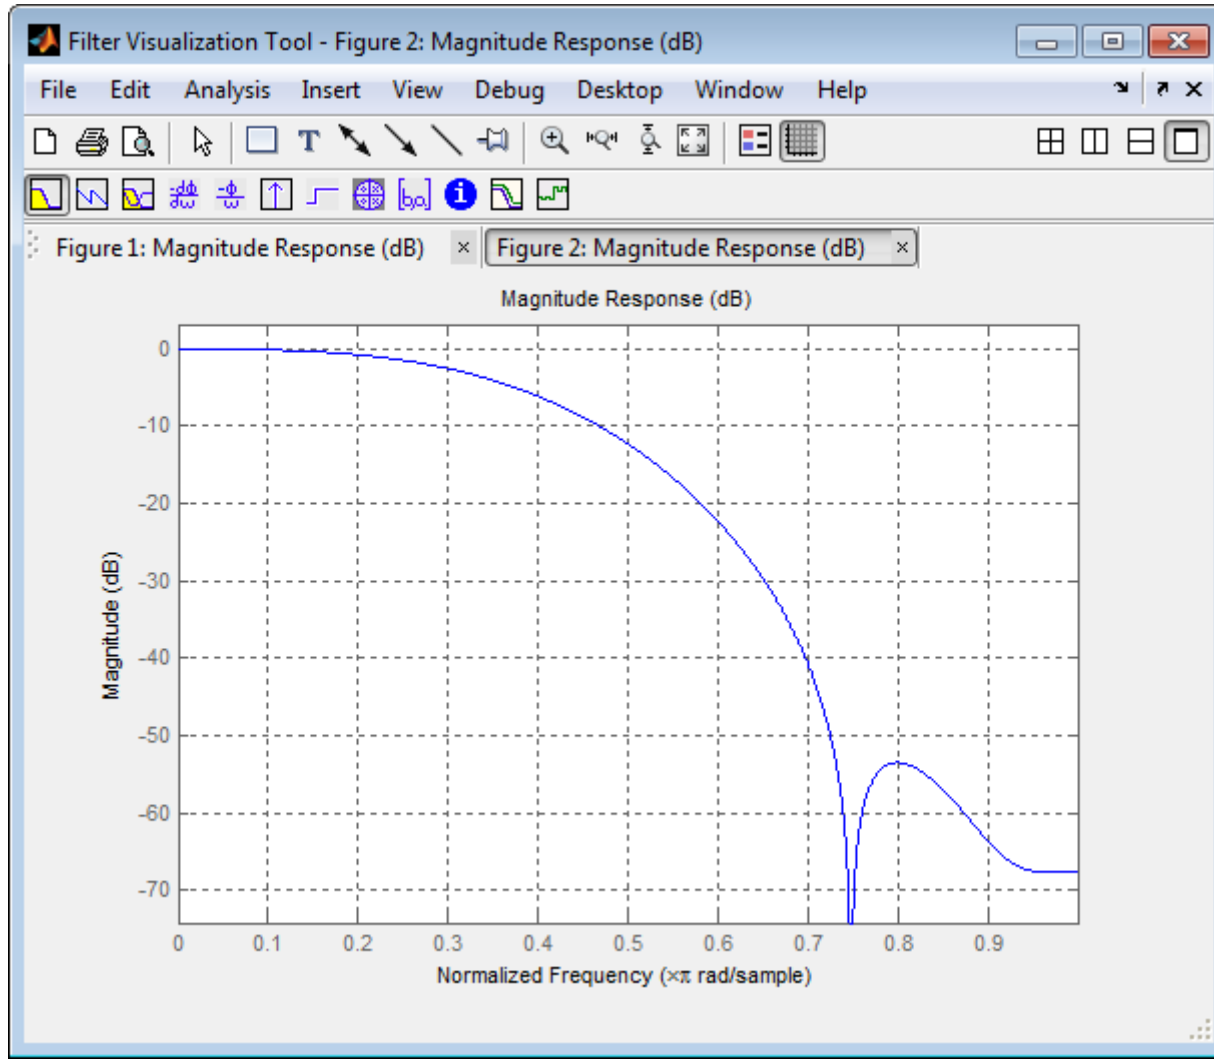
Design an FIR filter as a System object.

```
N = 10;
Fc = 0.4;
B = fir1(N,Fc);
Hf1 = dsp.FIRFilter('Numerator',B);
fvtool(Hf1)
```



This can also be achieved by using `fdesign` as a constructor and `design` to design the filter.

```
N = 10;
Fc = 0.4;
Hf = fdesign.lowpass('N,Fc',N,Fc);
D = design(Hf,'systemobject',true)
fvtool(D);

D =

Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete FIR Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.BiquadFilter`

Purpose

Create static or time-varying FIR filter with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a FIR filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.FIRFilter.freqz

Purpose

Frequency response

Syntax

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

Purpose

Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description

`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

dsp.FIRFilter.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.FIRFilter.impz

Purpose

Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description

`[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the FIR filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.FIRFilter.phasez

Purpose

Unwrapped phase response

Syntax

```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.FIRFilter.reset

Purpose

Reset internal states of FIR filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the FIR filter object,`H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the FIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

For example:

```
H = dsp.FIRFilter;
H.Numerator = fir1(20,0.25);
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

Purpose

Filter input with FIR filter object

Syntax

```
Y = step(HFIR,X)
Y = step(HFIR,X,COEFF)
```

Description

`Y = step(HFIR,X)` filters the real or complex input signal `X` using the FIR filter, `H`, to produce the output `Y` . When the input data is of a fixed-point type, it must be signed when the structure is set to `Direct form symmetric` or `Direct form antisymmetric`. The FIR filter object operates on each channel of the input signal independently over successive calls to step method.

`Y = step(HFIR,X,COEFF)` uses the time-varying coefficients, `COEFF` , to filter the input signal `X` and produce the output `Y` . You can use this option when you set the `NumeratorSource` or `ReflectionCoefficientsSource` property to `Input port`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.FIRInterpolator

Purpose

Polyphase FIR interpolator

Description

The `FIRInterpolator` object upsamples an input by the integer upsampling factor, *L*, followed by an FIR anti-imaging filter. The filter coefficients are scaled by the interpolation factor. A polyphase interpolation structure implements the filter. The resulting discrete-time signal has a sampling rate *L* times the original sampling rate.

To upsample an input:

1. Define and set up your FIR interpolator. See "Construction" on page 3-694.
2. Call `step` to upsample the input according to the properties of `dsp.FIRInterpolator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H= dsp.FIRInterpolator` returns an FIR interpolator, `H`, which upsamples an input signal by a factor of 3 and applies an FIR filter to interpolate the output.

`H = dsp.FIRInterpolator('PropertyName',PropertyValue, ...)` returns an FIR interpolator, `H`, with each property set to the specified value.

`H = dsp.FIRInterpolator(INTERP, NUM,'PropertyName',PropertyValue, ...)` returns an FIR interpolation object, `H`, with the `InterpolationFactor` property set to `INTERP`, the `Numerator` property set to `NUM`, and other properties set to the specified values.

Properties

InterpolationFactor

Interpolation factor

Specify the integer factor, *L*, by which to increase the sampling rate of the input signal. The polyphase implementation uses *L* polyphase subfilters to compute convolutions at the lower sample

rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output. The property value defaults to 3.

Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR anti-imaging filter as the coefficients of a polynomial in z^{-1}. Indexing from zero, the filter coefficients are:

$$H(z) = \sum_{n=0}^{N-1} b(n) z^{-n}$$

To act as an effective anti-imaging filter, the coefficients must correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the `InterpolationFactor`. The filter coefficients are scaled by the value of the `InterpolationFactor` property before filtering the signal. To form the L polyphase subfilters, `Numerator` is appended with zeros if necessary. The default is the output of `fir1(15,0.25)`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients fixed-point data type as one of `| Same word length as input | Custom |`. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `CoefficientsDataType` property is `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Full precision | Same as product | Same as input | Custom |`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `| Same as accumulator | Same as product | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create FIR interpolator object with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset FIR interpolator filter states
step	Upsample and interpolate input

More “Analysis Methods for Filter System Objects” on page 2-2.

Examples

Double the sampling rate of an audio signal from 22.05 kHz to 44.1 kHz, and play the audio:

```
hmfr = dsp.AudioFileReader('OutputDataType',...
   'single');
hap = dsp.AudioPlayer(44100);
hfirint = dsp.FIRInterpolator(2, ...
   firpm(30, [0 0.45 0.55 1], [1 1 0 0]));

while ~isDone(hmfr)
     frame = step(hmfr);
     y = step(hfirint, frame);
```

```
    step(hap, y);
end

pause(1);
release(hmfr);
release(hap);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Interpolation block reference page. The object properties correspond to the block parameters, except:

- The `FIRInterpolator` object does not have a property that corresponds to the **Input processing** parameter of the FIR Interpolation block.
- The **Rate options** block parameter is not supported by the `FIRInterpolator` object.

See Also

`dsp.FIRDecimator` | `dsp.FIRRateConverter`

dsp.FIRInterpolator.clone

Purpose

Create FIR interpolator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an FIR interpolator, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

Purpose

Frequency response

Syntax

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

dsp.FIRInterpolator.fvtool

Purpose

Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description

`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.FIRInterpolator.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of output from the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description

`[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

dsp.FIRInterpolator.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the FIR interpolator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Unwrapped phase response

Syntax

```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

dsp.FIRInterpolator.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset FIR interpolator filter states

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the FIR filter in the interpolator object, `H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the `step` method applies the interpolator to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset filter states to 0 to produce consistent output:

```
H = dsp.FIRInterpolator(2);
x =[1 -1]'; x = repmat(x,8,1);
y = step(H,x); % Filter states are nonzero
% Use reset method to set states to zero
reset(H);
% Apply FIR interpolator to input x
y1 = step(H,x);
isequal(y,y1)
% Returns a 1
```

dsp.FIRInterpolator.step

Purpose

Upsample and interpolate input

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` outputs the upsampled and interpolated values, `Y` , of the input signal `X` . A *K*-by-*N* input matrix is treated as *N* independent channels. The FIR interpolator object interpolates each channel over the first dimension and generates a *M*-by-*N* output matrix, where *M* is the product of *K* and the upsampling factor, *L*.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Sample rate converter

Description

The `FIRRateConverter` performs sampling rate conversion by a rational factor on a vector or matrix input. The FIR rate convertor cascades an interpolator with a decimator. The interpolator upsamples the input by the upsampling factor, L, followed by a lowpass FIR filter. The FIR filter acts both as an anti-imaging filter and an anti-aliasing filter prior to decimation. The decimator downsamples the output of upsampling and FIR filtering by the downsampling factor M. You must use upsampling and downsampling factors that are relatively prime, or coprime. The resulting discrete-time signal has a sampling rate L/M times the original sampling rate.

To perform sampling rate conversion:

1. Define and set up your FIR sample rate converter. See "Construction" on page 3-711.
2. Call `step` to perform sampling rate conversion according to the properties of `dsp.FIRRateConverter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.FIRRateConverter` returns a FIR sample rate converter, `H`, that resamples an input signal at a rate 3/2 times the original sampling rate.

`H = dsp.FIRRateConverter('PropertyName',PropertyValue, ...)` returns an FIR sample rate converter, `H`, with each property set to the specified value.

`H = dsp.FIRRateConverter(L,M,NUM,'PropertyName', PropertyValue, ...)` returns an FIR sample rate converter, `H`, with the `InterpolationFactor` property set to `L`, the `DecimationFactor` property set to `M`, the `Numerator` property set to `NUM`, and other specified properties set to the specified values.

Properties

InterpolationFactor

Interpolation factor

Specify the integer upsampling factor. The default is `3`.

DecimationFactor

Decimation factor

Specify the integer downsampling factor. The default is `2`.

Numerator

FIR filter coefficients

Specify the FIR filter coefficients in powers of z^{-1}. The length of filter coefficients must exceed the interpolation factor. Use a lowpass with normalized cutoff frequency no greater than `min(1/InterpolationFactor, 1/DecimationFactor)`. All initial filter states are zero. The default is `firpm(70,[0 0.28 0.32 1],[1 1 0 0])`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `CoefficientsDataType` property is `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only

when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Full precision | Same as product | Same as input | Custom |`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `| Same as accumulator | Same as product | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create FIR sample rate convertor object with same property values
getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset states of FIR sample rate converter
step	Resample input with FIR rate converter

Examples

Resample a 100 Hz sine wave signal by a factor of 3:2:

```
hsin = dsp.SineWave(1, 100,'SampleRate', 5000,'SamplesPerFrame', 50);

% Create a FIR rate converter filter. The default interpolation
% factor is 3 and decimation factor is 2.
hfirrc = dsp.FIRRateConverter;
input = step(hsin);
output = step(hfirrc, input);

% Plot the original and resampled signals.
ndelay = round(length(hfirrc.Numerator)/2/hfirrc.DecimationFactor);
indx = ndelay+1:length(output);
x = (0:length(indx)-1)/hsin.SampleRate*hfirrc.DecimationFactor/hfirrc.
stem((0:38)/hsin.SampleRate, input(1:39)); hold on;
stem(x, hfirrc.InterpolationFactor*output(indx),'r');
legend('Original','Resampled');
```

Resample and play an audio signal from 48 kHz to 32 kHz (Windows only):

```
    hmfr = dsp.AudioFileReader('audio48kHz.wav', ...
    'OutputDataType', 'single', ...
```

```
'SamplesPerFrame', 300);
hap = dsp.AudioPlayer(32000);

% Create an FIRRateConverter System object with interpolation
% factor = 2, decimation factor = 3. Default FIR filter
% coefficients define a lowpass filter with normalized
% cutoff frequency of 1/3.
hfirrc = dsp.FIRRateConverter(2,3);

while ~isDone(hmfr)
  audio1 = step(hmfr);
  audio2 = step(hfirrc, audio1);
  step(hap, audio2);
end

release(hmfr);
release(hap);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FIR Rate Conversion block reference page. The object properties correspond to the block parameters.

See Also

`dsp.FIRInterpolator` | `dsp.FIRDecimator`

Purpose

Create FIR sample rate convertor object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an FIR sample rate converter object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.FIRRateConverter.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.FIRRateConverter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the FIR sample rate converter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.FIRRateConverter.reset

Purpose

Reset states of FIR sample rate converter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the FIR filter in the sample rate converter, `H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the `step` method applies the FIR rate converter to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset filter states to 0 to produce consistent output:

```
H = dsp.FIRRateConverter(2,4);
x =[1 -1]'; x = repmat(x,8,1);
y = step(H,x); % Filter states are nonzero
% Use reset method to set states to zero
reset(H);
% Apply sampling rate converter to input x
y1 = step(H,x);
isequal(y,y1)
% Returns a 1
```

Purpose

Resample input with FIR rate converter

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` resamples the input `X` and returns the resampled signal `Y` . An *M*-by-*N* matrix input is treated as *N* independent channels.

dsp.FrequencyDomainAdaptiveFilter

Purpose

Frequency Domain Adaptive filter

Description

The `dsp.FrequencyDomainAdaptiveFilter` computes output, error, and coefficients using a frequency domain FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See "Construction" on page 3-724.
2. Call `step` to implement the filter according to the properties of `dsp.FrequencyDomainAdaptiveFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.FrequencyDomainAdaptiveFilter` returns a frequency domain FIR adaptive filter System object, `H`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`H = dsp.FrequencyDomainAdaptiveFilter('PropertyName', PropertyValue, ...)` returns an `FrequencyDomainAdaptiveFilter` System object, `H`, with each specified property set to the specified value.

`H = dsp.FrequencyDomainAdaptiveFilter(LEN,'PropertyName', PropertyValue,...)` returns an `FrequencyDomainAdaptiveFilter` System object, `H`, with the Length property set to `LEN` and other specified properties set to the specified values.

Properties

Method

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of `'Constrained FDAF' |'Unconstrained FDAF'`. The default is `'Constrained FDAF'`. For algorithms on how to implement this filter and its three methods, refer to [1]. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

BlockLength

Block length for coefficient updates

Specify the block length of the coefficients updates as a positive integer value. The length of the input vectors must be divisible by the `BlockLength` property value. For faster execution, the sum of the length property value and the `BlockLength` property value should be a power of two. The default value is the value of `Length`. This property is nontunable.

StepSize

Adaptation step size

Specify the adaptation step size factor as a positive numeric scalar less than or equal to `1`. Setting the `StepSize` property equal to `1` provides the fastest convergence during adaptation. The default is `1`.

LeakageFactor

Adaptation leakage factor

Specify the leakage factor used in leaky adaptive filter as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky adaptive algorithm. The default is `1`, providing no leakage in the adapting method.

AveragingFactor

Averaging factor of energy estimator

Specify the averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates

as a scalar positive numeric value less than or equal to 1. The default value is `1`.

Offset

Offset for normalization terms

Specify the offset for the normalization terms in the coefficient updates as a scalar nonnegative numeric value. Use this property to avoid divide by zero or divide by very small numbers. This situation occurs if any of the FFT input signal powers becomes very small. The default value is `0`.

InitialPower

Initial FFT input signal power

Specify the initial common value of all of the FFT input signal powers as a scalar positive numeric value. The default is `1`.

InitialCoefficients

Time-domain initial coefficients of the filter

Specify the initial time-domain coefficients of the adaptive filter as a scalar or a vector of length equal to the `Length` property value. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients. The default is `0`.

LockCoefficients

Locked status of coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Methods

clone	Create Frequency Domain Adaptive filter object with same property values
isLocked	Locked status for input attributes and nontunable properties
msesim	Mean-square error for Frequency Domain Adaptive filter
release	Allow property value and input characteristics changes
reset	Reset filter states for Frequency Domain Adaptive filter
step	Apply Frequency Domain Adaptive filter to input

Examples

QPSK adaptive equalization with FIR filter

Generate QPSK and noise signals, filter to obtain the received signal, and delay the QPSK signal to obtain the desired signal:

```
D = 16;
b  = exp(1i*pi/4)*[-0.7 1];
a  = [1 -0.7];
ntr= 1024;
s  = sign(randn(1,ntr+D))+1i*sign(randn(1,ntr+D));
n  = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r  = filter(b,a,s) + n;
x  = r(1+D:ntr+D);
d  = s(1:ntr);
```

Use the Frequency Domain Adaptive Filter to compute the filtered output and the filter error for the input and desired signal:

```
mu  = 0.1;
ha = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',mu);
```

```
[y,e] = step(ha,x,d);
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals:

```
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
legend('Desired','Output','Error'); title('In-Phase Components');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
legend('Desired','Output','Error'); title('Quadrature Components');
xlabel('Time Index'); ylabel('signal value');
```

Plot the received and equalized signals' scatter plots:

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

See Also

`dsp.LMSFilter` | `dsp.RLSFilter` | `dsp.AffineProjectionFilter` | `dsp.AdaptiveLatticeFilter` | `dsp.FilteredXLMSFilter` | `dsp.FIRFilter`

Purpose

Mean-square error for Frequency Domain Adaptive filter

Syntax

```
MSE = msesim(H,X,D)
[MSE,MEANW,W,TRACEK] = msesim(H,X,D)
[...] = msesim(H,X,D,M)
```

Description

`MSE = msesim(H,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(H,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `H`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `H`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(H,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

dsp.FrequencyDomainAdaptiveFilter.clone

Purpose

Create Frequency Domain Adaptive filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`, with the same property values. The clone method creates a new unlocked object with uninitialized states.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the Frequency Domain Adaptive filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.FrequencyDomainAdaptiveFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset filter states for Frequency Domain Adaptive filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the System object,`H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

dsp.FrequencyDomainAdaptiveFilter.step

Purpose

Apply Frequency Domain Adaptive filter to input

Syntax

```
[Y, ERR] = step(H, x, D)
Y = step(H,x)
[Y1,...,YN] = step(H,x)
```

Description

`[Y, ERR] = step(H, x, D)` filters the input `x`, using D as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(H,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, H. `[Y1,...,YN] = step(H,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Generate real or complex sinusoidal signals—optimized for HDL code generation

Description

The HDL NCO System object generates real or complex sinusoidal signals. In addition, the HDL NCO System object provides hardware-friendly control signals, optional reset signal, optional phase output signal, and an optional external dither input signal. It uses the same phase accumulation and lookup table technology as implemented in the NCO System object. The lookup table in the generated HDL is mapped to a ROM. You can use the lookup table compression option to significantly reduce the lookup table size with less than one LSB loss in precision.

Construction

`HNCO = dsp.HDLNCO` returns a numerically controlled oscillator (NCO) System object, HNCO, that generates a real or complex sinusoidal signal. The amplitude of the generated signal is always 1.

`HNCO = dsp.HDLNCO(Name,Value)` returns an HDL NCO System object, HNCO, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`

`HNCO = dsp.HDLNCO(Inc, 'PhaseIncrementSource','Property')` returns an HDL NCO System object, HNCO, with the `PhaseIncrement` property set to Inc. Inc is an integer scalar. To use the `PhaseIncrement` property, you must also set the `PhaseIncrementSource` property to `Property`. You can add other `Name,Value` pairs before or after `PhaseIncrementSource`.

Input Arguments

Inc

An integer scalar value for the `PhaseIncrement` property. To use this value, you must set the `PhaseIncrementSource` property to `Property`.

Default: 100

Properties

PhaseIncrementSource

Select which phase increment the object uses. Set `PhaseIncrementSource` to `Property` to use the `PhaseIncrement` property. Set `PhaseIncrementSource` to `Input port` to use an input argument of the step method. The default is `Input port`.

```
hnco = dsp.HDLNCO(..., 'PhaseIncrementSource', 'Property', 'PhaseIncrement', phIncr, ...)
```

PhaseIncrement

Specify the phase increment as an integer scalar. This property is applicable when you set the `PhaseIncrementSource` property to `Property`. The default value of this property is 100.

PhaseOffsetSource

Select which phase offset the object uses. Set `PhaseOffsetSource` property to `Property` to use the `PhaseOffset` property. Set `PhaseOffsetSource` property to `Input port` to use an input argument of the step method. The default is `Property`.

```
hnco = dsp.HDLNCO(...,'PhaseOffsetSource', 'Property', 'PhaseOffset', phOffset,...)
```

PhaseOffset

Specify the phase offset as an integer scalar. This property is applicable when you set the `PhaseOffsetSource` property to `Property`. The default value of `PhaseOffset` is 0.

DitherSource

Select which dither size the object uses. Set `DitherSource` property to `Property` to use the `NumDitherBits` property. Other options are `Input port` to use an input argument of the step method, or `None` to disable dithering. The default is `Property`.

```
hnco = dsp.HDLNCO(...,'DitherSource', 'Property', 'NumDitherBits', ditherBits,...)
```

NumDitherBits

Specify the number of dither bits as a positive integer. This property is applicable when you set the `DitherSource` property to `Property`. The default value of `NumDitherBits` is 4.

PhaseQuantization

Set this property to `true` to enable quantization of the accumulated phase. The default value of `PhaseQuantization` is `true`.

```
hnco = dsp.HDLNCO(...,'PhaseQuantization', true, 'NumQuantizerAccumulatorBits', accumBits,...
```

NumQuantizerAccumulatorBits

Specify the number of quantizer accumulator bits as an integer scalar greater than 1 and less than the accumulator word length. `NumQuantizerAccumulatorBits` determines the number of entries in the lookup table of sine values. This property is applicable when you set `PhaseQuantization` to `true`. The default value of this property is 12.

LUTCompress

Set this property to `true` to enable lookup table compression. The object uses the Sunderland compression method to reduce the size of the lookup table. The default value of this property is `false`.

Waveform

Choose whether the object's output is `Sine`, `Cosine`, `Complex exponential`, or `Sine and cosine` signals. If you select complex exponential, the output is of the form `sine + j*cosine`. If you select `Sine and cosine`, the step method returns an additional output. The default is `Sine`.

PhasePort

Set `PhasePort` to `true` to return the current phase along with the output from the step method. The default value of this property is `false`.

ResetAction

Set `ResetAction` to `true` to enable a reset argument to the step method. The default value of this property is `false`.

OverflowAction

Overflow mode for fixed-point operations. `OverflowAction` is a constant property with value `Wrap`.

RoundingMethod

Rounding mode for fixed-point operations. `RoundingMethod` is a constant property with value `Floor`.

AccumulatorDataType

Accumulator data type description. This property is a constant with value `Binary point scaling`.

AccumulatorSigned

Select signed or unsigned accumulator data format. This property is a constant. All output is signed format.

AccumulatorWL

Accumulator word length. Default is 16 bits.

AccumulatorFL

Accumulator fraction length. This property is a constant with value 0 bits.

OutputDataType

Specify the output signal data type. Options are: `double`, `single`, and `Binary point scaling`. If this property is set to `Binary point scaling`, the output sign, word length, and fraction length are taken from the following three properties. The default is `Binary point scaling`.

OutputSigned

Select signed or unsigned output data. This property is a constant. All output is signed format.

OutputWL

Output data word length. The default is 16 bits.

OutputFL

Output data fraction length. The default is 14 bits.

Methods

clone	Create HDLNCO System object with same property values
isLocked	Locked status (logical)
release	Allow property value and input characteristics change
step	Process inputs using the HDL optimized NCO (Numerically Controlled Oscillator)

Examples

Design an NCO Source

Design an NCO source according to specifications.

Specifications:

```
F0 = 510;     % Output frequency = 510 Hz
df = 0.05;    % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/4000;  % Sample period = 1/8000 sec
dphi = pi/2;  % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the frequency resolution.

```
Nacc = ceil(log2(1/(df*Ts)));
actdf = 1/(Ts*2^Nacc); % Actual frequency resolution achieved
```

Calculate number of quantized accumulator bits required from the SFDR requirement.

```
  Nqacc = ceil((minSFDR-12)/6);
```

Calculate the phase increment.

```
phIncr = round(F0*Ts*2^Nacc);
```

Calculate the phase offset.

```
phOffset = 2^Nacc*dphi/(2*pi);
```

Construct NCO HDL System object.

```
hnco = dsp.HDLNCO('PhaseIncrementSource', 'Property', ...
       'PhaseIncrement', phIncr,...
       'PhaseOffset', phOffset,...
       'NumDitherBits', 4, ...
       'NumQuantizerAccumulatorBits', Nqacc,...
       'AccumulatorWL',Nacc);

for k= 1:1/Ts
   y(k) = step(hnco,true);
end
```

Plot the mean-square spectrum of the 510 Hz sine wave generated by the NCO.

```
 hss = dsp.SpectrumAnalyzer('SampleRate', 1/Ts);
 hss.SpectrumType = 'Power density';
 hss.PlotAsTwoSidedSpectrum = false;
 step(hss,y');
```

Algorithms

Lookup Table Algorithm

When you enable lookup table (LUT) compression, the HDL NCO System object applies the Sunderland compression method. Sunderland

techniques use trigonometric identities to divide each phase of the quarter sine wave into three components and express it as:

$$\sin(A+B+C) = \sin(A+B)\cos C + \cos A\cos B\cos C - \sin A\sin B\sin C$$

If the phase has 12 bits, the components are defined as:

- A , the four most significant bits

  $(0 \le A \le \frac{\pi}{2})$

- B, the following four bits

  $(0 \le B \le \frac{\pi}{2} \times 2^{-4})$

- C, the four least significant bits

  $(0 \le C \le \frac{\pi}{2} \times 2^{-8})$

Because C is small enough that $\sin(C) \cong 1$ and $\cos(C) \cong 0$, the equation is approximated by:

$$\sin(A+B+C) \approx \sin(A+B) + \cos A\sin C$$

The HDL NCO System object implements this equation with one LUT for sin(A+B) and one LUT for cos(A)sin(C). The second term is a fine correction factor and can be truncated to fewer bits without losing precision. With the default accumulator size of 16 bits, and the example phase width of 12 bits, the LUTs use only $2^8 \times 16$ plus $2^8 \times 4$ bits (5kb). A quarter sine lookup table would use $2^{12} \times 16$ bits (65kb). This approximation is accurate within 1 LSB which gives an SNR of at least 60 dB on the output. See L. Cordesses, "Direct Digital Synthesis: A Tool for Periodic Wave Generation (Part 1)", IEEE Signal Processing Magazine, DSP Tips & Tricks column, pp. 50–54, Vol. 21, No. 4 July 2004.

See Also `dsp.NCO`

Purpose

Create HDLNCO System object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the HDLNCO System object, `H`, with the same property values. The clone method creates a new unlocked object with uninitialized states.

Input Arguments

`H`

HDLNCO System object

Output Arguments

`C`

New instance of the HDLNCO System object, `H`, with the same property values. The new unlocked object contains uninitialized states.

dsp.HDLNCO.isLocked

Purpose

Locked status (logical)

Syntax

```
L = isLocked(H)
```

Description

`L = isLocked(H)` returns the locked status, `L`, of the HDLNCO System object, `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Input Arguments

`H`

HDLNCO System object

Output Arguments

`L`

Logical value. Either 1 (true) or 0 (false).

Purpose

Allow property value and input characteristics change

Syntax

```
release(H)
```

Description

`release(H)` releases system resources (such as memory, file handles or hardware connections) of the HDLNCO System object, `H`, and allows all its properties and input characteristics to be changed.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Input Arguments

`H`

Instance of HDLNCO System object

dsp.HDLNCO.step

Purpose

Process inputs using the HDL optimized NCO (Numerically Controlled Oscillator)

Syntax

```
[Y,validOut] = step(HNCO,Inc,validIn)
[Y,validOut] = step(HNCO,validIn)
[Y,validOut] = step(HNCO,Offset,validIn)
[Y,validOut] = step(HNCO,Inc,Offset,validIn)
[Y,validOut] = step(HNCO,Dither,validIn)
[Y,validOut] = step(HNCO,Inc,Offset,Dither,validIn)
[Y,COSINE,validOut] = step(HNCO, ___ )
[Y,PHASE,validOut]= step(HNCO, ___ )
```

Description

`[Y,validOut] = step(HNCO,Inc,validIn)` returns a sinusoidal signal, `Y`, generated by the HDLNCO System object, with the specified phase increment, `INC`. `INC` is added to the accumulator when `validIn` is high. `validOut` indicates the validity of output signal. `INC` must be a built-in integer or an fi object scalar. `validIn`/`validOut` are scalars with data type logical.

`[Y,validOut] = step(HNCO,validIn)` returns a sinusoidal signal, `Y`, when the `PhaseIncrementSource` and `PhaseOffsetSource` properties are both set to `Property`.

`[Y,validOut] = step(HNCO,Offset,validIn)` returns a sinusoidal signal, `Y`, with phase offset, `Offset`, when the `PhaseOffsetSource` property is set to `Input port`. `Offset` must be a built-in integer or an fi object scalar.

`[Y,validOut] = step(HNCO,Inc,Offset,validIn)` returns a sinusoidal signal, `Y`, with phase increment, `Inc`, and phase offset, `Offset`, when the `PhaseIncrementSource` and the `PhaseOffsetSource` properties are both set to `Input port`.

`[Y,validOut] = step(HNCO,Dither,validIn)` returns a sinusoidal signal, `Y`, generated by the HDLNCO, System object with the dither, `Dither`, when the `DitherSource` property is set to `Input port`. `Dither` must be a built-in integer or an fi object scalar.

`[Y,validOut] = step(HNCO,Inc,Offset,Dither,validIn)` returns a sinusoidal signal, `Y`, with phase increment, `Inc`, phase offset, `Offset`, and dither, `Dither`, when the `PhaseIncrementSource`, the `PhaseOffsetSource` , and the `DitherSource` properties are each set to `Input port`.

`[Y,COSINE,validOut] = step(HNCO, ___ )` returns a sinusoidal signal, `S`, and a cosinusoidal signal, `COSINE`, when the `Waveform` property is set to `Sine and cosine`. This syntax can include any of the input arguments in previous syntaxes.

`[Y,PHASE,validOut]= step(HNCO, ___ )` returns a sinusoidal signal, `Y`, and output `Phase`, when the `PhasePort` property is true. This syntax can include any of the input arguments in previous syntaxes.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Histogram

Purpose

Histogram of input or sequence of inputs

Description

The `Histogram` object generates a histogram for an input or a sequence of inputs.

To generate a histogram for an input or a sequence of inputs:

1. Define and set up your histogram object. See "Construction" on page 3-748.
2. Call `step` to generate the histogram for an input according to the properties of `dsp.Histogram`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Histogram` returns a histogram object, `H`, that computes the frequency distribution of the elements in each input matrix.

`H = dsp.Histogram('PropertyName',PropertyValue, ...)` returns a histogram object, `H`, with each specified property set to the specified value.

`H = dsp.Histogram(MIN,MAX,NUMBINS,'PropertyName',PropertyValue,...)` returns a histogram object, `H`, with the `LowerLimit` property set to *`MIN`*, `UpperLimit` property set to *`MAX`*, `NumBins` property set to *`NUMBINS`* and other specified properties set to the specified values.

Properties

LowerLimit

Lower boundary

Specify the lower boundary of the lowest-valued bin as a real-valued scalar. `NaN` and `Inf` are not valid values for this property. The default is `0`. This property is tunable.

UpperLimit

Upper boundary

Specify the upper boundary of the highest-valued bin as a real-valued scalar. `NaN` and `Inf` are not valid values for this property. The default is `10`. This property is tunable.

NumBins

Number of bins in histogram

Specify the number of bins in the histogram. The default is `11`.

Dimension

Specify how the histogram calculation is performed over the data as one of `| All | Column |`. The default is `Column`.

Normalize

Enable output vector normalization

Specify whether the histogram object normalizes the output vector, v, so that $sum(v) = 1$. When you set this property to `true`, the output vector is normalized. When you set it to `false`, the object supports fixed-point operations and does not use this property for normalization. The default is `false`.

RunningHistogram

Enable calculation over successive `step` method calls

Set this property to `true` to enable running histogram calculations for the input elements over successive calls to the `step` method. Set this property to `false` to compute a histogram for the current input. The default is `false`.

ResetInputPort

Enable resetting in running histogram mode

Set this property to `true` to enable resetting the running histogram. When you set the property to `true`, specify a reset input to the `step` method that resets the running histogram. This property applies when you set the `RunningHistogram` property to `true`. When this property is `false`, the histogram object does not reset. The default is `false`.

ResetCondition

Reset condition for running histogram mode

Specify the event that resets the running histogram as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies when you set the `ResetInputPort` property to `true`. The default is `Non-zero`

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Same as product` | `Same as input` | `Custom` |. The default is `Same as input`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

Methods

clone	Create histogram object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset histogram bin values to zero
step	Histogram for input data

Examples

Compute a histogram with four bins, for possible input values 1 through 4:

```
hhist = dsp.Histogram(1,4,4);
y = step(hhist, [1 2 2 3 3 3 4 4 4 4]');
% y equals [1; 2; 3; 4] - one one, two twos, etc.
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Histogram block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.
- The **Find histogram over** block parameter corresponds to the Dimension property of the object.

See Also

`dsp.Maximum` | `dsp.Minimum` | `dsp.Mean`

Purpose

Create histogram object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `Histogram` System object C, with the same property values as H. The clone method creates a new unlocked object with uninitialized states.

dsp.Histogram.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.Histogram.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the Histogram System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Histogram.reset

Purpose

Reset histogram bin values to zero

Syntax

```
reset(H)
```

Description

`reset(H)` sets the `Histogram` object bin values to zero when you set the `RunningHistogram` property to `true`.

Purpose

Histogram for input data

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

`Y = step(H,X)` returns a histogram `Y` for the input data `X` . When the `RunningHistogram` property is `true`, `Y` corresponds to the histogram of the input elements over successive calls to the `step` method.

`Y = step(H,X,R)` resets the histogram state based on the value of `R` and the object's `ResetCondition` property. You can reset the histogram state only when the `RunningHistogram` and the `ResetInputPort` properties are `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.IDCT

Purpose

Inverse discrete cosine transform (IDCT)

Description

The `IDCT` object computes the inverse discrete cosine transform (IDCT) of an input.

To compute the IDCT of an input:

1. Define and set up your IDCT object. See "Construction" on page 3-760.
2. Call `step` to compute the IDCT of an input according to the properties of `dsp.IDCT`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.IDCT` returns a inverse discrete cosine transform (IDCT) object, `H`. This object computes the IDCT of a real or complex input signal using the `Table lookup` method.

`H = dsp.IDCT('PropertyName',PropertyValue,...)` returns an inverse discrete cosine transform (IDCT) object, `H`, with each property set to the specified value.

Properties

SineComputation

Method to compute sines and cosines

Specify how the IDCT object computes the trigonometric function values as `Trigonometric function` or `Table lookup`. You must set this property to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` property to `Table lookup`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as a signed, unscaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numerictype(true,16)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numerictype(true,32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numerictype(true,32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision` , `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` property to `Table lookup` and the `OutputDataType` property to `Custom`. The default is`numerictype(true,16,15)`.

Methods

clone	Create inverse discrete cosine transform object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Inverse discrete cosine transform (IDCT) of input

Examples

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
hdct = dsp.DCT;

X = step(hdct, x);
% Set the DCT coefficients which represent less
% than 0.1% of the total energy to 0 and
% reconstruct the sequence using IDCT.
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;

while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
     ii = ii+1;
end

disp(['Number of DCT coefficients that represent 99.9%',...
'of the total energy in the sequence: ',num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
```

```
hidct = dsp.IDCT;
xt = step(hidct, XXt);

plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the IDCT block reference page. The object properties correspond to the block parameters.

See Also

`dsp.DCT` | `dsp.FFT` | `dsp.IFFT`.

Purpose

Create inverse discrete cosine transform object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a copy of the current IDCT object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.IDCT.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.IDCT.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the IDCT object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.IDCT.step

Purpose

Inverse discrete cosine transform (IDCT) of input

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` computes the inverse discrete cosine transform, `Y` , of input `X`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Inverse discrete Fourier transform (IDFFT)

Description

The `IFFT` object computes the inverse discrete Fourier transform (IDFFT) of the input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen by FFTW [1], [2]

To compute the IFFT of the input:

1. Define and set up your IFFT object. See "Construction" on page 3-771.
2. Call `step` to compute the IFFT of the input according to the properties of `dsp.IFFT`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.IFFT` returns an `IFFT` object, `H`, that computes the IDFT of a column vector or *N*-D array. For column vectors or N-D arrays, the `IFFT` object computes the IDFT along the first dimension of the array. If the input is a row vector, the `IFFT` object computes a row of single-sample IDFTs and issues a warning.

`H = dsp.IFFT('PropertyName',PropertyValue, ...)` returns an `IFFT` object, `H`, with each property set to the specified value.

Properties

FFTImplementation

FFT implementation

Specify the implementation used for the FFT as one of `Auto | Radix-2 | FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

BitReversedInput

Enable bit-reversed order interpretation of input elements

Set this property to`true`if the order of Fourier transformed input elements to the `IFFT` object are in bit-reversed order. This property applies only when the `FFTLengthSource` property is `Auto`. The default is `false`, which denotes linear ordering.

ConjugateSymmetricInput

Enable conjugate symmetric interpretation of input

Set this property to `true` if the input is conjugate symmetric to yield real-valued outputs. The discrete Fourier transform of a real valued sequence is conjugate symmetric, and setting this property to `true` optimizes the IDFT computation method. Setting this property to `false` for conjugate symmetric inputs may result in complex output values with nonzero imaginary parts. This occurs due to rounding errors. Setting this property to `true` for nonconjugate symmetric inputs results in invalid outputs. This property applies only when the`FFTLengthSource` property is `Auto`. The default is `false`.

Normalize

Enable dividing output by FFT length

Specify whether to divide the IFFT output by the FFT length. The default is `true` and each element of the output is divided by the FFT length.

FFTLengthSource

Source of FFT length

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal. This property applies only

when both the `BitReversedInput` and `ConjugateSymmetricInput` properties are `false`. The default is `Auto`.

FFTLength

FFT length

Specify the FFT length as a numeric scalar. This property applies when you set the `BitReversedInput` and `ConjugateSymmetricInput` properties to `false`, and the `FFTLengthSource` property to `Property`. The default is `64`.

This property must be a power of two when the input is a fixed-point data type, or when you set the `FFTImplementation` property to `Radix-2`.

When you set the `FFT implementation` property to `Radix-2`, or when you set the `BitReversedOutput` property to `true`, this value must be a power of two.

WrapInput

Boolean value of wrapping or truncating input

Wrap input data when `FFTLength` is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given `FFTLength` is shorter than the input length. If this property is set to false, truncation of the input data to the `FFTLength` occurs before the FFT operation. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

SineTableDataType

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomSineTableDataType

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create IFFT object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Inverse discrete Fourier transform of input

Examples

Use DFT and IDFT to analyze the energy content in a sequence:

```
Fs = 40; L = 128;
t = (0:L-1)'/Fs;
x = sin(2*pi*10*t) + 0.75*cos(2*pi*15*t);
y = x + .5*randn(size(x)); % noisy signal
hfft = dsp.FFT;
hifft = dsp.IFFT('ConjugateSymmetricInput', true);
X = step(hfft, x);
[XX, ind] = sort(abs(X),1,'descend');
XXn = sqrt(cumsum(XX.^2))/norm(XX);
ii = find(XXn > 0.999, 1);
disp('Number of FFT coefficients that represent 99.9% ')
disp(['of the total energy in the sequence: ', num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
xt = step(hifft, XXt);
% Verify the reconstructed signal matches the original
norm(x-xt)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the IFFT block reference page. The object properties correspond to the block parameters, except:

Output sampling mode parameter is not supported by `dsp.IFFT`.

`dsp.FFT` | `dsp.DCT` | `dsp.IDCT`

Purpose

Create IFFT object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an IFFT object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.IFFT.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.IFFT.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the IFFT object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.IFFT.step

Purpose

Inverse discrete Fourier transform of input

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` computes the inverse discrete Fourier transform (IDFT) , `Y` , of the input `X` along the first dimension of `X`. When the `FFTLengthSource` property is `Auto`, the length of `X` along the first dimension must be a positive integer power of two. When the `FFTLengthSource` property is `'Property'`, the length of `X` along the first dimension can be any positive integer and the `FFTLength` property must be a positive integer power of two.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Infinite Impulse Response (IIR) filter

Description

The `IIRFilter` object filters each channel of the input using IIR filter implementations.

To filter each channel of the input:

1. Define and set up your IIR filter. See "Construction" on page 3-783.
2. Call `step` to filter each channel of the input according to the properties of `dsp.IIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`HIIR = dsp.IIRFilter` returns an IIR filter System object, `HIIR`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified IIR filter implementation.

`HIIR = dsp.IIRFilter('PropertyName',PropertyValue, ...)` returns an IIR filter System object, `HIIR`, with each property set to the specified value.

Properties

Structure

Filter structure

Specify the filter structure.

You can specify the filter structure as one of `| Direct form I | Direct form I transposed | Direct form II | Direct form II transposed`. The default is `Direct form II transposed`. This property is nontunable.

Numerator

Filter numerator coefficients

Specify the numerator coefficients as a real or complex numeric row vector. The default is `[1 1]`. This property is tunable.

Denominator

Filter denominator coefficients

Specify the denominator coefficients as a real or complex numeric row vector. The default value of this property is `[1 0.1]`. This property is tunable.

InitialConditions

Initial conditions for the IIR filter

Specify the initial conditions of the filter states. This property is applicable when the structure is one of `Direct form II | Direct form II transposed`. The default value is `0`. The number of states equals the `max(N,M)-1`, where `N` and `M` are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property is tunable.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property is applicable when the Structure property is one of `Direct form I | Direct form I transposed`. The default value of this property is `0`. The number

of states equals the `max(N,M)-1`, where `N` and `M` are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the IIR filter initializes all delay elements on the zeros side in the filter to that value. You can specify a vector of length equal to the number of delay elements on the zeros side in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

You can also specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. This property is tunable.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property is applicable when the Structure property is one of `Direct form I | Direct form I transposed`. The default value of this property is `0`. The number of states equals the `max(N,M)-1`, where `N` and `M` are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the IIR filter initializes all delay elements on the poles side of the filter to that value. You can specify a vector of length equal to the number of delay elements on the poles side in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

You can also specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal. In this case, each

element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. This property is tunable.

FrameBasedProcessing

Process input as frames or as samples

Set this property to `true` to enable frame-based processing. When this property is `true`, the IIR filter treats each column as an independent channel. Set this property to `false` to enable sample-based processing. When this property is `false`, the IIR filter treats each element of the input as an individual channel. The default is `true`. This property is nontunable.

NumeratorCoefficientsDataType

Numerator coefficients word- and fraction-length designations

Specify the numerator coefficients fixed-point data type as one of `Same word length as input | Custom`. The default is `Same word length as input`. This property is nontunable.

DenominatorCoefficientsDataType

Denominator coefficients word- and fraction-length designations

Specify the denominator coefficients fixed-point data type as one of `Same word length as input | Custom`. The default is `Same word length as input`. This property is nontunable.

Fixed-Point Properties

NumeratorProductDataType

Product word- and fraction-length designations on zeros side

Specify the numerator product fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Full precision`. This property is nontunable.

DenominatorProductDataType

Product word- and fraction-length designations on poles side

Specify the denominator product fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Full precision`. This property is nontunable.

NumeratorAccumulatorDataType

Accumulator word- and fraction-length designations on zeros side

Specify the numerator accumulator fixed-point data type to one of `| Full precision | Same as input | Same as product | Custom |`. The default is `Full precision`. This property is nontunable.

DenominatorAccumulatorDataType

Accumulator word- and fraction-length designations on poles side

Specify the denominator accumulator fixed-point data type to one of `| Full precision | Same as input | Same as product | Custom |`. The default is `Full precision`. This property is nontunable.

OutputDataType

Output word- and fraction-length designations

Specify the output fixed-point data type as one of `| Full precision | Same as input | Custom |`. The default is `Same as input`. This property is nontunable.

StateDataType

State word- and fraction-length designations

Specify the state fixed-point data type as one of `| Same as input | Custom |`. This property does not apply to `Direct form I` filter structure. The default is `Same as input`. This property is nontunable.

MultiplicandDataType

Multiplicand word- and fraction-length designations

Specify the multiplicand fixed-point data type as one of | `Same as input` | `Custom` |. This property is applicable only when the `Structure` property is `Direct form I transposed`. The default is `Same as input`. This property is nontunable.

CustomNumeratorCoefficientsDataType

Numerator coefficients word- and fraction-lengths

Specify the numerator coefficients fixed-point type as an autosigned numerictype object. This property is applicable when the `NumeratorCoefficientsDataType` property is `Custom`. The default value of this property is numerictype ([],16,15). This property is nontunable.

CustomDenominatorCoefficientsDataType

Denominator coefficients word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numerictype object. This property is applicable when the `DenominatorCoefficientsDataType` property is `Custom`. The default value of this property is numerictype([], 16, 15) . This property is nontunable.

CustomNumeratorProductDataType

Custom product word- and fraction-lengths on zeros side

Specify the numerator product fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `NumeratorProductDataType` property to `Custom`. The default is `numerictype ([],32,30)`. This property is nontunable.

CustomDenominatorProductDataType

Custom product word- and fraction-lengths on poles side

Specify the denominator product fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `DenominatorProductDataType` property to `Custom`. The default is `numerictype ([],32,30)`. This property is nontunable.

CustomNumeratorAccumulatorDataType

Custom accumulator word- and fraction-lengths on zeros side

Specify the numerator accumulator fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `NumeratorAccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`. This property is nontunable.

CustomDenominatorAccumulatorDataType

Custom accumulator word- and fraction-lengths on poles side

Specify the denominator accumulator fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `DenominatorAccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`. This property is nontunable.

CustomStateDataType

Custom state word- and fraction-lengths

Specify the state fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `StateDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

CustomOutputDataType

Custom output word- and fraction-lengths

Specify the output fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

CustomMultiplicandDataType

Custom multiplicand word- and fraction-lengths

Specify the multiplicand fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set

the `MultiplicandDataType` property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

Methods

clone	Create IIR filter with same property values
freqz	Frequency response
fvtool	Open filter visualization tool
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
impz	Impulse response
isLocked	Locked status for input attributes and nontunable properties
phasez	Unwrapped phase response
release	Allow property value and input characteristics changes
reset	Reset internal states of IIR filter
step	Filter input with IIR filter object

More “Analysis Methods for Filter System Objects” on page 2-2.

Examples 1

Use fvtool to see the magnitude response of a lowpass IIR filter. Also use the Spectrum Analyzer to display the power spectrum of the output signal.

```
x = randn(2048,1);
x = x-mean(x);
Hsr = dsp.SignalSource;
Hsr.Signal = x;
Hlog = dsp.SignalSink;
```

```
N = 10;
Fc = 0.4;
[b,a] = butter(N,Fc);
H = dsp.IIRFilter('Numerator',b,'Denominator',a);

h = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-220 -10]);

while ~isDone(Hsr)
  input = step(Hsr);
  output = step(H,input);
  step(h,output)
  step(Hlog,output);
end

Result = Hlog.Buffer;
fvtool(H,'Fs',8000)
```

2

Design an IIR filter as a System object.

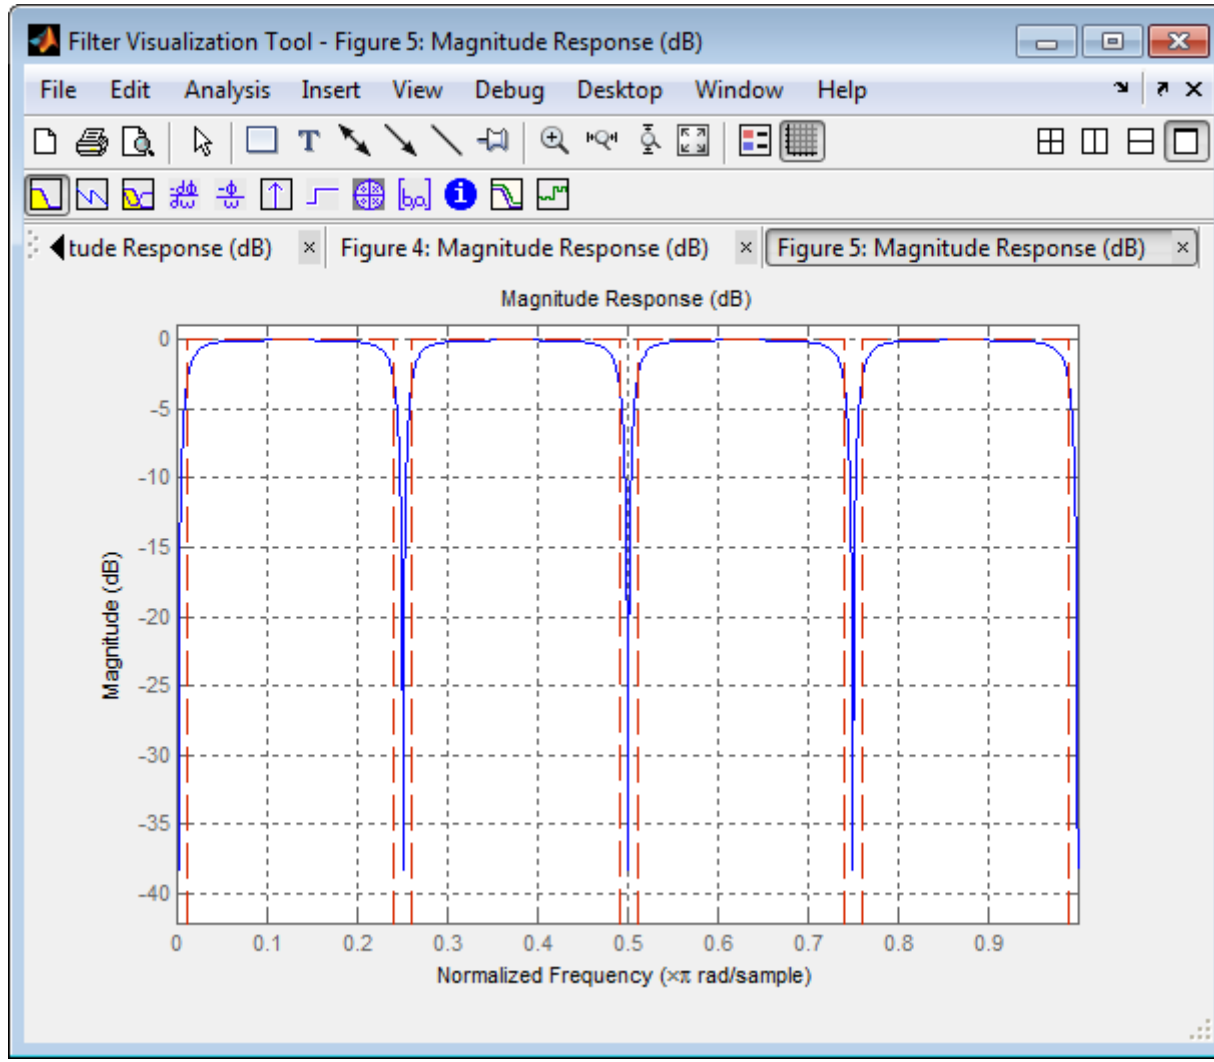
The are two ways, either you first design the constructor and then design the filter as a System object that you can apply:

```
D = fdesign.comb('notch','N,BW',8,0.02);
H = design(D,'systemobject',true)
fvtool(H);

H =

  System: dsp.IIRFilter

  Properties:
              Structure: 'Direct form II'
              Numerator: [0.887839755524806 0 0 0 0 0 0 0 -0.8878397555
            Denominator: [1 0 0 0 0 0 0 0 -0.775679511049613]
       InitialConditions: 0
    FrameBasedProcessing: true
```



or, you have the filter coefficients, and then you use dsp.IIRFilter, to apply it:

```
b = [0.9 zeros(9,1)' -0.9];
a = [1 zeros(9,1)' -0.8];
H = dsp.IIRFilter('Numerator',b,'Denominator',a)
fvtool(H);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete Filter block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.BiquadFilter` | `dsp.FIRFilter` | `dsp.AllpoleFilter`

Purpose

Create IIR filter with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a IIR filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.IIRFilter.freqz

Purpose

Frequency response

Syntax

```
[h,w] = freqz(H)
[h,w] = freqz(H,n)
[h,w] = freqz(H,Name,Value)
freqz(H)
```

Description

`[h,w] = freqz(H)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(H,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(H,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(H)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `H`.

Purpose

Open filter visualization tool

Syntax

```
fvtool(H)
fvtool(H,'Arithmetic',ARITH,...)
```

Description

`fvtool(H)` performs an analysis and computes the magnitude response of the filter System object `H`.

`fvtool(H,'Arithmetic',ARITH,...)` analyzes the filter System object `H`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

dsp.IIRFilter.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the step method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.IIRFilter.impz

Purpose

Impulse response

Syntax

```
[h,t] = impz(H)
[h,t] = impz(H,Name,Value)
impz(H)
```

Description

`[h,t] = impz(H)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`H` is computed.

`[h,t] = impz(H,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(H)` uses FVTool to plot the impulse response of the filter System object `H`.

Note You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the IIR filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.IIRFilter.phasez

Purpose

Unwrapped phase response

Syntax

```
[phi,w] = phasez(H)
[phi,w] = phasez(H,n)
[phi,w] = phasez(H,Name,Value)
phasez(H)
```

Description

`[phi,w] = phasez(H)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(H,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(H,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(H)` uses FVTool to plot the phase response of the filter System object `H`.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.IIRFilter.reset

Purpose

Reset internal states of IIR filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the IIR filter object, `H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the IIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

For example:

```
H = dsp.IIRFilter;
[b,a] = ellip(20, 0.5, 80, 0.25);
H.Numerator = b;
H.Denominator = a;
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

Purpose

Filter input with IIR filter object

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` filters the real or complex input signal `X` using the IIR filter, `H`, to produce the output `Y` . When the input data is of a fixed-point type, it must be signed. The IIR filter object operates on each channel of the input signal independently over successive calls to step method.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Interpolator

Purpose

Linear or FIR interpolation

Description

The `Interpolator` object interpolates real-valued inputs using linear or polyphase FIR interpolation.

To interpolate real-valued inputs:

1. Define and set up your interpolation object. See "Construction" on page 3-810.
2. Call `step` to interpolate the input according to the properties of `dsp.Interpolator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Interpolator` returns a handle to an interpolation object, `H`. The interpolation method defaults to `Linear` and the interpolation points default to a 5×1 vector.

`H = dsp.Interpolator('PropertyName',PropertyValue,...)` returns an interpolation object, `H`, with the specified property name and value pairs.

Properties

InterpolationPointsSource

Source of interpolation points

You can select a value of `Property` or `Input port`. If you set this property to `Input port`, you must provide the interpolation points as an input to the `step` method when you interpolate the input. The default is `Property`.

InterpolationPoints

Interpolation points

This property only applies when you set the `InterpolationPointsSource` property to `Property`. Specify the interpolation points as a column vector or a matrix with the same number of channels as the input.

The valid range of the values in the interpolation vector is from `1` to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is `[2 3.1 -2.1]`, the valid range of interpolation points is from `1` to `3`. If you specify the following vector of interpolation points `[-1 1.5 2 2.5 3 3.5]`, the interpolator object clips `-1` to `1` and `3.5` to `3`. This clipping results in the interpolation points `[1 1.5 2 2.5 3 3]`. The default is `[1.1;4.8;2.67;1.6;3.2]`. This property is tunable.

Method

Interpolation method

Specify the interpolation method as `Linear` or `FIR`. When this property is `Linear`, the interpolator object interpolates data values by assuming that the data varies linearly between adjacent samples. When this property is `FIR`, the interpolator object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. The interpolator object always performs linear interpolation if there are insufficient low-rate samples to perform FIR interpolation as explained in the description of the `FilterHalfLength` property. The default is `Linear`.

FilterHalfLength

Interpolation filter half length

This property applies only when you set the `Method` property to `FIR`. For a filter half length of P, the polyphase FIR subfilters have length $2P$. FIR interpolation always requires $2P$ low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires P low-rate samples below and P low-rate samples above the interpolation point.

- If the interpolation point corresponds to a low-rate sample, the 2*P*-sample requirement includes the low-rate sample.
- If there are less than *2P* neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input `[1 4 1 4 1 4 1 4]`, upsampling by a factor of four results in the equally spaced interpolation points `InterP = 1:0.25:8;`. The points `InterP(9:12)` are `[3.0 3.25 3.5 3.75]`. Assuming a `FilterHalfLength` property equal to 2, interpolating at these points uses the four low-rate samples from the input with indices `(2,3,4,5)`. If you set the `FilterHalfLength` property to 4 in this case, the interpolator object uses linear interpolation because there are not enough low-rate samples to perform FIR interpolation.

The longer the `FilterHalfLength` property, the better the quality of the interpolation. However, the costs are increased computation and requiring more low-rate samples below and above the interpolation point. In general, setting the `FilterHalfLength` property between 4 and 6 provides reasonably accurate interpolation.

InterpolationPointsPerSample

Interpolation points per input sample

This property only applies when you set the `Method` property to `FIR` and indicates the upsampling factor, *L*. An upsampling factor of *L* inserts *L*–1 zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with `InterpolationPointsPerSample` subfilters of length 2*P*, where *P* is the `FilterHalfLength` property. Denoting the low-rate samples in the upsampled input by *nL*, *n=1,2,...*, the interpolator object uses exactly one of the `InterpolationPointsPerSample` subfilters, or filter arms, to interpolate at the points *nL*+*i*/*L*, where *i=0,1,2,...,L-1*.

If you specify interpolation points which do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. For example, you set the `InterpolationPointsPerSample` property to `4` and interpolate at the points `[3 3.2 3.4 3.6 3.8]`. The interpolator object uses the first polyphase subfilter for the points `[3.0 3.2]`, the second subfilter for the point `3.4`, the third subfilter for the point `3.6`, and the fourth subfilter for the point `3.8`.

Bandwidth

Normalized input bandwidth

This property applies only when you set the `Method` property to `FIR`. The normalized bandwidth is a real-valued scalar between 0 and 1, where 1 equals the Nyquist frequency, or 1/2 the sampling frequency (*Fs*). You may know that your input does not have frequency content above some cutoff frequency less than the Nyquist frequency. You can use this information to improve the FIR interpolation filters by relaxing the stopband requirements in frequency regions where the signal has no energy. For example, if the input signal does not have frequency content above *Fs/8*, you can specify a value of `0.25` for the `Bandwidth` property. The default value is `0.5`.

Methods

clone	Create interpolator object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Linear or FIR interpolation

Definitions

A polyphase implementation of an FIR interpolation filter *splits* the lowpass FIR filter impulse response into a number of different subfilters. Let L represent the number of interpolation points per sample, or the upsampling factor, and P the half length of the polyphase subfilters. Indexing from zero, if *h(n)* is the impulse response of the FIR filter, the k-th subfilter is:

$$h_k(n) = h(k + nL) \quad k = 0,1,\ldots,L-1 \quad n = 0,1,\ldots,2P-1$$

The following table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object:

Coefficients	Polyphase Subfilter
h(0),h(3),h(6), ..., h(15)	$h_0(n)$
h(1),h(4),h(7), ..., h(16)	$h_1(n)$
h(2),h(5),h(8), ..., h(17)	$h_2(n)$

The following code shows how to find the polyphase subfilters for the default FIR interpolator object:

```
H = dsp.Interpolator('Method','FIR');
L = H.InterpolationPointsPerSample;
P = H.FilterHalfLength;
FiltCoeffs = intfilt(L,P,H.Bandwidth);
% Returns filter of length 2*P*L-1
FiltLen=length(FiltCoeffs);
FiltCols = ceil(FiltLen/2/L);
```

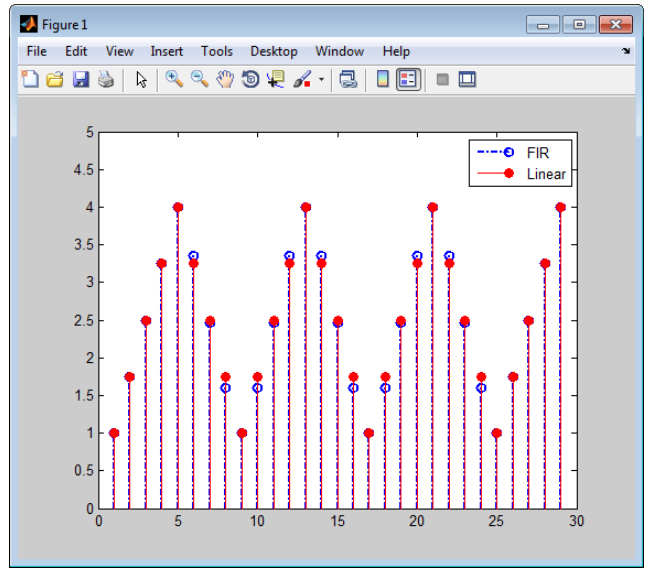
```
% We need 2*P*L coefficients
% Prepending a zero does not affect the filter magnitude
FiltCoeffs = [zeros(FiltCols*2*L-FiltLen,1); FiltCoeffs(:)];

% Each column of PolyPhaseCoeffs is a polyphase subfilter
PolyPhaseCoeffs  = reshape(FiltCoeffs,FiltCols,2*L)';
```

Examples

Compare linear interpolation with FIR interpolation:

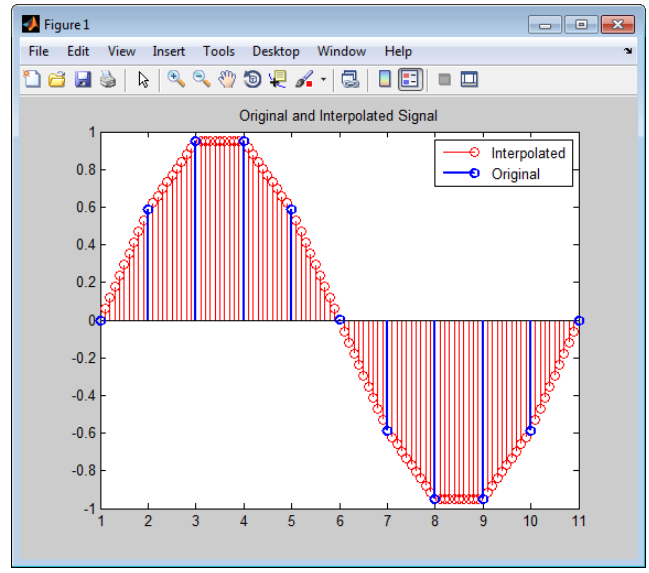
```
x =[1 4];
x = repmat(x,1,4);
x1 = 1:0.25:8;
hFIR =dsp.Interpolator('Method','FIR','FilterHalfLength',2,...
'InterpolationPoints',x1','InterpolationPointsPerSample',4);
hLin =dsp.Interpolator('InterpolationPoints',x1');
OutFIR = step(hFIR,x');
OutLin = step(hLin,x');
stem(OutFIR,'b-.','linewidth',2); hold on;
stem(OutLin,'r','markerfacecolor',[1 0 0]);
axis([0 30 0 5]); legend('FIR','Linear','Location','Northeast');
```



For the indices 1 to 5 and 25 to 29, the interpolator object uses linear interpolation in both cases. The reason for this is that there are not enough low-rate samples surrounding the interpolation points at those indices to use FIR interpolation with the specified filter length.

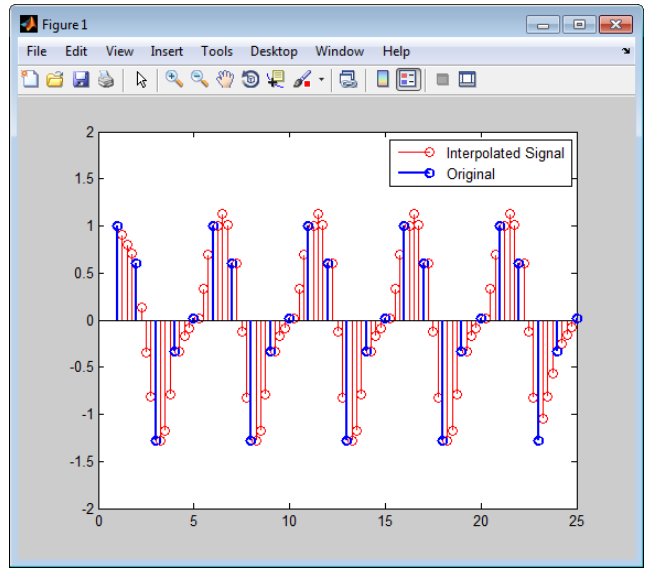
Interpolate a sinusoid with linear interpolation:

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
I = 1:0.1:length(x1);
H = dsp.Interpolator('InterpolationPointsSource',...
'Input port');
y = H.step(x1',I');
stem(I',y, 'r');
title('Original and Interpolated Signal');
hold on; stem(x1, 'Linewidth', 2);
legend('Interpolated','Original');
```



Interpolate a sum of sinusoids with FIR interpolation and `Input Port` as the source of interpolation points:

```
Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
% Decimate without aliasing
H = dsp.Interpolator('Method','FIR',...
'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = H.step(x1',I');
stem(I,y,'r'); hold on;
axis([0 25 -2 2]);
stem(x1,'b','linewidth',2);
legend('Interpolated Signal','Original',...
'Location','Northeast');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Interpolation block reference page. The object properties correspond to the Simulink block parameters, except:

Out of range interpolation points — The interpolator object only has the `Clip` option. The Simulink block has the additional `Clip and warn` and `Error` options.

See Also

`intfilt` | `dsp.FIRInterpolator` | `dsp.VariableFractionalDelay`

Purpose

Create interpolator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an interpolator object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.Interpolator.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.Interpolator.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the interpolator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Interpolator.step

Purpose

Linear or FIR interpolation

Syntax

```
Y = step(H,X)
Y = step(H,X,IPTS)
```

Description

`Y = step(H,X)` outputs the interpolated sequence, `Y`, of the input vector or matrix `X` as specified in the `InterpolationPoints` property.

`Y = step(H,X,IPTS)` outputs the interpolated sequence as specified by the input argument `IPTS` when the `InterpolationPointsSource` property is set to 'Input port'. `IPTS` a column vector or a matrix of interpolation points. If `IPTS` is a matrix, it must have the same number of channels as the input.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Estimate system measurements and states using Kalman filter

Description

The `KalmanFilter` is an estimator used to recursively obtain a solution for linear optimal filtering. This estimation is made without precise knowledge of the underlying dynamic system. The Kalman filter implements the following linear discrete-time process with state, x, at the k^{th} time-step: $x(k) = Ax(k-1) + Bu(k-1) + w(k-1)$ (state equation). This measurement, z, is given as: $z(k) = Hx(k) + v(k)$ (measurement equation).

The Kalman filter algorithm computes the following two steps recursively:

- Prediction: Process parameters x (state) and P (state error covariance) are estimated using the previous state,
- Correction: The state and error covariance are corrected using the current measurement,

To filter each channel of the input:

1. Define and set up your Kalman filter. See "Construction" on page 3-825.
2. Call `step` to filter each channel of the input according to the properties of `dsp.KalmanFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.KalmanFilter` returns the Kalman filter System object, `H`, with default values for the parameters.

`H = dsp.KalmanFilter('PropertyName',PropertyValue, ...)` returns an Kalman filter System object, `H`, with each property set to the specified value.

```
H = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance,
MNCovariance, CIMatrix, 'PropertyName', PropertyValue, ...)
```

returns a Kalman filter System object, H. The `StateTransitionMatrix` property is set to `STMatrix`, and `MeasurementMatrix` property is set to `MMatrix`. In addition, the `ProcessNoiseCovariance` property set to `PNCovariance`, `MeasurementNoiseCovariance` property set to `MNCovariance`, `ControlInputMatrix` property set to `CIMatrix`. Other specified properties are set to the specified values.

Properties

StateTransitionMatrix

Model of state transition

Specify `A` in the state equation that relates the state at the previous time step to the state at current time step. `A` is a square matrix with each dimension equal to the number of states. The default value is `1`.

ControlInputMatrix

Model of relation between control input and states

Specify `B` in the state equation that relates the control input to the state. `B` is a matrix with a number of rows equal to the number of states. This property is activated only when the `ControlInputPort` property value is `true`. The default value is `1`.

MeasurementMatrix

Model of relation between states and measurement output

Specify `H` in the measurement equation that relates the states to the measurements. `H` is a matrix with the number of columns equal to the number of measurements. The default value is `1`.

ProcessNoiseCovariance

Covariance of process noise

Specify `Q` as a square matrix with each dimension equal to the number of states. This matrix, `Q`, is the covariance of the white Gaussian process noise, `w`, in the state equation. The default value is `0.1`.

MeasurementNoiseCovariance

Covariance of measurement noise

Specify `R` as a square matrix with each dimension equal to the number of states. This matrix, `R`, is the covariance of the white Gaussian process noise, `v`, in the measurement equation. The default value is `0.1`.

InitialStateEstimate

Initial value for states

Specify an initial estimate of the states of the model as a column vector with length equal to the number of states. The default value is `0`.

InitialErrorCovarianceEstimate

Initial value for state error covariance

Specify an initial estimate for covariance of the state error, as a square matrix with each dimension equal to the number of states. The default value is `0.1`.

DisableCorrection

Disable port for filters

Specify as a scalar logical value, disabling System object filters from performing the correction step after the prediction step in the Kalman filter algorithm. The default value is `false`.

ControlInputPort

Presence of a control input

Specify if the control input is present, using a scalar logical value. The default value is `true`.

Methods

clone	Create Kalman Filter System object with same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of Kalman filter
step	Filter input with Kalman filter object

Examples

Estimate a changing scalar

Create the System objects for the changing scalar input, the Kalman filter, and the scope (for plotting):

```
numSamples = 4000;
R = 0.02;
hSig = dsp.SignalSource;
hSig.Signal = [ones(numSamples/4,1);   -3*ones(numSamples/4,1);...
               4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
hTScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
          'TimeUnits', 'Seconds', 'YLimits',[-5 5], ...
          'ShowLegend', true); % Create the Time Scope
hKalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
          'MeasurementNoiseCovariance', R,...
          'InitialStateEstimate', 5,...
          'InitialErrorCovarianceEstimate', 1,...
          'ControlInputPort',false); %Create Kalman filter
```

Add noise to the scalar, and pass the result to the Kalman filter. Step through the System objects to obtain the data streams, and plot the filtered signal:

```
while(~isDone(hSig))
   trueVal = step(hSig);
   noisyVal = trueVal + sqrt(R)*randn;
   estVal = step(hKalman, noisyVal);
   step(hTScope,noisyVal,trueVal,estVal);
end
```

Disable the correction step in the Kalman Filter algorithm

Create the signal, Kalman Filter, and Time Scope System objects:

```
numSamples = 4000;
R = 0.02;
hSig = dsp.SignalSource;
hSig.Signal = [  ones(numSamples/4,1);   -3*ones(numSamples/4,1);...
              4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
hTScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ..
          'TimeUnits', 'Seconds', 'YLimits',[-5 5], ...
          'Title', ['True(channel 1), noisy(channel 2) and ',...
          'estimated(channel 3) values'], ...
          'ShowLegend', true);
hKalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
          'MeasurementNoiseCovariance', R,...
          'InitialStateEstimate', 5,...
          'InitialErrorCovarianceEstimate', 1,...
          'ControlInputPort',false);
ctr = 0;
```

Add noise to the signal. Step through the System objects to obtain the data streams, and plot the filtered signal:

```
while(~isDone(hSig))
    trueVal = step(hSig);
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = step(hKalman, noisyVal);
    step(hTScope,trueVal,noisyVal,estVal);

    % Disabling the correction step of second filter for the middle
```

```
    % one-third of the simulation
    if ctr == floor(numSamples/3)
        hKalman.DisableCorrection = true;
    end
    if ctr == floor(2*numSamples/3)
        hKalman.DisableCorrection = false;
    end
    ctr = ctr + 1;
end
```

Use a single System object to track multiple scalar values

Create the signal where the columns are the two scalar values to be tracked. Also create the Kalman Filter, and the Time Scopes:

```
numSamples = 4000;
R = 0.02;
hSig = dsp.SignalSource;
sig1 = [  ones(numSamples/4,1);   -3*ones(numSamples/4,1);...
         4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
sig2 = [-2*ones(numSamples/4,1);   4*ones(numSamples/4,1);...
        -3*ones(numSamples/4,1); 1.5*ones(numSamples/4,1)];

hSig.Signal = [sig1, sig2];

hTScope1 = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
           'TimeUnits', 'Seconds', 'YLimits',[-5 5], ...
           'Title', ['True(channel 1), noisy(channel 2) and ',...
           'estimated(channel 3) values'], ...
           'ShowLegend', true);
hTScope2 = clone(hTScope1);
hKalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance', R,...
    'InitialStateEstimate', -3,...
    'InitialErrorCovarianceEstimate', 1,...
    'ControlInputPort',false);
```

Add noise to the signal. Step through the System objects to obtain the data streams, and plot the filtered signal:

```
while(~isDone(hSig))
    trueVal = step(hSig);
    noisyVal = trueVal + sqrt(R)*randn(1,2);
    estVal = step(hKalman, noisyVal);
           % Plot results of first channel on Time Scope
    step(hTScope1,trueVal(:,1),noisyVal(:,1),estVal(:,1));
           % Plot results of second channel on Time Scope
    step(hTScope2,trueVal(:,2),noisyVal(:,2),estVal(:,2));
end
```

Use a unit step as the control input to track a ramp signal

Create the ramp signal to be tracked, the control input, the Time Scope, and the Kalman Filter:

```
numSamples = 200;
R = 100;
hSig = dsp.SignalSource;
hSig.Signal = (1:numSamples)';
hControl = dsp.SignalSource;
hControl.Signal = ones(numSamples,1);

hTScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ..
          'TimeUnits', 'Seconds', 'YLimits',[-5 205], ...
          'Title', ['True(channel 1), Noisy(channel 2) and ',...
          'estimated(channel 3) values'], ...
          'ShowLegend', true);
hKalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
          'MeasurementNoiseCovariance', R,...
          'InitialStateEstimate', 3,...
          'InitialErrorCovarianceEstimate', 1);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Kalman Filter block reference page. The object properties correspond to the block parameters.

See Also

Kalman Filter

Purpose

Create Kalman Filter System object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`,with the same property values. The `clone` method creates a new unlocked object with uninitialized states.

dsp.KalmanFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the Kalman filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.KalmanFilter.reset

Purpose

Reset internal states of Kalman filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the Kalman filter object, `H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

Purpose

Filter input with Kalman filter object

Syntax

```
Y = step(H,X)
[Y1,...,YN] = step(H,X)
[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = step(H, z, u)
```

Description

`Y = step(H,X)` processes the input data, `X` to produce the output, `Y`, for System object, `H`.

`[Y1,...,YN] = step(H,X)` produces `N` outputs.

`[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = step(H, z, u)` Carries out the iterative Kalman filter algorithm over measurements `z` and control inputs `u`. The columns in `z` and `u` are treated as inputs to separate parallel filters, whose correction (or update) step can be disabled by the `DisableCorrection` property. The values returned are estimated measurements `z_est`, estimated states `x_est`, MSE of estimated states `MSE_Est`, predicted measurements `zPred`, predicted states `xPred` and MSE of predicted states `MSE_Pred`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LDLFactor

Purpose

Factor square Hermitian positive definite matrices into components

Description

The `LDLFactor` object factors square Hermitian positive definite matrices into lower, upper, and diagonal components. The object uses only the lower triangle of S.

To factor these matrices into lower, upper, and diagonal components:

1. Define and set up your LDL factor object. See "Construction" on page 3-838.
2. Call `step` to factor the matrices according to the properties of `dsp.LDLFactor`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LDLFactor` returns an LDL factor System object, `H`, that computes unit lower triangular `L` and diagonal `D` such that `S` = LDL' for square, symmetric/Hermitian, positive definite input matrix `S`.

`H = dsp.LDLFactor('PropertyName',PropertyValue,...)` returns an `LDL` factor System object, `H`, with each specified property set to the specified value.

Properties

Fixed-Point Properties

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you

set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numerictype(true,16,15)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as: `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

Methods

clone	Create an LDL Factor object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs for step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Decompose matrix into components

Examples

Decompose a square Hermitian positive definite matrix using LDL factor:

```
A = gallery('randcorr',5);
hldl = dsp.LDLFactor;
```

```
y = step(hldl, A);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LDL Factorization block reference page. The object properties correspond to the block parameters, except:

No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

See Also

`dsp.LUFactor`

dsp.LDLFactor.clone

Purpose

Create an LDL Factor object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `LDLFactor` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LDLFactor.getNumOutputs

Purpose

Number of outputs for step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LDLFactor` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LDLFactor.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Decompose matrix into components

Syntax

```
Y = step(H,S)
```

Description

`Y = step(H,S)` decomposes the matrix `S` into lower, upper, and diagonal components. The output `Y` is a composite matrix with the `L` as its lower triangular part and `D` as the diagonal and `L'` as its upper triangular part. If `S` is not positive definite the output `Y` is not a valid factorization.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LevinsonSolver

Purpose

Solve linear system of equations using Levinson-Durbin recursion

Description

The `LevinsonSolver` object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

1. Define and set up your System object. See "Construction" on page 3-848.
2. Call `step` to solve the system of equations according to the properties of `dsp.LevinsonSolver`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LevinsonSolver` returns a System object, `H`, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

`H = dsp.LevinsonSolver('PropertyName',PropertyValue,...)` returns a Levinson-Durbin object, `H`, with each specified property set to the specified value.

Properties

AOutputPort

Enable polynomial coefficients output

Set this property to `true` to output the polynomial coefficients *A*. Both `AOutputPort` and `KOutputPort` properties cannot be `false` at the same time. For scalar inputs, set the `AOutputPort` property to `true`. The default is `false`.

KOutputPort

Enable reflection coefficients output

Set this property to `true` to output the reflection coefficients *K*. You cannot set both the `AOutputPort` and `KOutputPort` properties to `false` at the same time. For scalar inputs, you must set the `KOutputPort` property to `false`. The default is `true`.

PredictionErrorOutputPort

Enable prediction error output

Set this property to `true` to output the prediction error. The default is `false`.

ZerothLagZeroAction

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select `Ignore` or `Use zeros`. The default is `Use zeros`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap`, `Saturate`. The default is `Wrap`.

ACoefficientDataType

A coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomACoefficientDataType

A coefficient word and fraction lengths

Specify the *A* coefficient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16,15)`.

KCoefficientDataType

K coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomKCoefficientDataType

K coefficient word and fraction lengths

Specify the *K* coefficient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16,15)`.

PredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomPredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType` property is `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. The default is `Custom`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numerictype([],32,30)`.

Methods

clone	Create Levinson solver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Reflection coefficients corresponding to columns of input

Examples

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients:

```
hlevinson = dsp.LevinsonSolver;
hlevinson.AOutputPort = true;
hlevinson.KOutputPort = false;
x = (1:100)';
hac = dsp.Autocorrelator(...
'MaximumLagSource', 'Property', ...
'MaximumLag', 10);
```

```
a = step(hac, x);
c = step(hlevinson, a); % Compute polynomial coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Levinson-Durbin block reference page. The object properties correspond to the block parameters, except:

Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

See Also

`dsp.Autocorrelator`

Purpose

Create Levinson solver object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `LevinsonSolver` object System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.LevinsonSolver.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.LevinsonSolver.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LevinsonSolver` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.LevinsonSolver.step

Purpose

Reflection coefficients corresponding to columns of input

Syntax

```
K = step(H,X)
A = step(H,X)
[A, K] = step(H,X)
[..., P] = step(H,X)
```

Description

`K = step(H,X)` returns reflection coefficients `K` corresponding to the columns of input `X`. `X` is typically a column or matrix of autocorrelation coefficients with lag `0` as the first element.

`A = step(H,X)` returns polynomial coefficients `A` when the `AOutputPort` property is `true` and the `KOutputPort` property is `false`.

`[A, K] = step(H,X)` returns polynomial coefficients `A` and reflection coefficients `K` when both the `AOutputPort` and `KOutputPort` properties are `true`.

`[..., P] = step(H,X)` also returns the error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

LMS adaptive filter

Description

The `LMSFilter` implements an adaptive FIR filter object that returns the filtered output, the error vector, and filter weights. The LMS filter uses one of five different LMS algorithms.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See "Construction" on page 3-859.
2. Call `step` to implement the filter according to the properties of `dsp.LMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LMSFilter` returns an adaptive FIR filter object, `H`, that computes the filtered output, filter error and the filter weights for a given input and desired signal using the Least Mean Squares (LMS) algorithm.

`H = dsp.LMSFilter('PropertyName', PropertyValue,...)` returns an LMS filter object, `H`, with each property set to the specified value.

`H = dsp.LMSFilter(LEN,'PropertyName',PropertyValue,...)` returns an LMS filter object, `H`, with the `Length` property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate filter weights

Specify the method used to calculate filter weights as `LMS`, `Normalized LMS`, `Sign-Error LMS`, `Sign-Data LMS`, or `Sign-Sign LMS`. The default is `LMS`.

Length

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer. The default is `32`.

StepSizeSource

How to specify adaptation step size

Choose how to specify the adaptation step size factor as `Property` or `Input port`. The default is `Property`.

StepSize

Adaptation step size

Specify the adaptation step size factor as a nonnegative real number. For convergence of the normalized LMS method, set the step size greater than `0` and less than `2`. This property only applies when the `StepSizeSource` property is `Property`. The default is `0.1`. This property is tunable.

LeakageFactor

Leakage factor used in LMS filter

Specify the leakage factor as a real number between `0` and `1` inclusive. A leakage factor of `1` corresponds to no leakage in the adapting method. The default is `1`. This property is tunable.

InitialConditions

Initial conditions of filter weights

Specify the initial values of the FIR filter weights as a scalar or vector of length equal to the `Length` property value. The default is `0`.

AdaptInputPort

Enable weight adaptation

Specify when the LMS filter should adapt the filter weights. By default, the value of this property is `false`, and the object continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the

`step` method. If the value of this input is nonzero, the object continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort

Enable weight reset

Specify when the LMS filter should reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the `reset` input to the `step` method.

WeightsResetCondition

Reset trigger setting for filter weights

Specify the event to reset the filter weights as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The LMS filter resets the filter weights based on the values of this property and the `reset` input to the `step` method. This property only applies when the `WeightsResetInputPort` property is `true`. The default is `Non-zero`.

WeightsOutputPort

Enable returning filter weights

Set this property to `true` to output the adapted filter weights. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

StepSizeDataType

Step size word and fraction lengths

Specify the step size fixed-point data type as `Same word length as first input` or `Custom`. Setting this property also sets the `LeakageFactorDataType` property to the same value. This property only applies when the `StepSizeSource` property is `Property`. The default is `Same word length as first input`.

CustomStepSizeDataType

Step size word and fraction lengths

Specify the step size fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeSource` property is `Property` and the `StepSizeDataType` property is `Custom`. The default is `numerictype([],16,15)`.

LeakageFactorDataType

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point data type as `Same word length as first input` or `Custom`. Setting this property also sets the `StepSizeDataType` property to the same value. This property only applies when the `StepSizeSource` property is `Property`. The default is `Same word length as first input`.

CustomLeakageFactorDataType

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeSource` property is `Property` and the

`LeakageFactorDataType` property is `Custom`. The default is `numerictype([],16,15)`.

WeightsDataType

Weights word and fraction lengths

Specify the filter weights fixed-point data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomWeightsDataType

Weights word and fraction lengths

Specify the filter weights fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `WeightsDataType` property is `Custom`. The default is `numerictype([],16,15)`.

EnergyProductDataType

Energy product word and fraction lengths

Specify the energy product fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionProductDataType`, `StepSizeErrorProductDataType`, `WeightsUpdateProductDataType`, and `QuotientDataType` properties to the same value. The default is `Same as first input`.

CustomEnergyProductDataType

Energy product word and fraction lengths

Specify the energy product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `EnergyProductDataType` property is `Custom`. The default is `numerictype([],32,20)`.

EnergyAccumulatorDataType

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionAccumulatorDataType` property to the same value. The default is `Same as first input`.

CustomEnergyAccumulatorDataType

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `EnergyAccumulatorDataType` property is `Custom`. The default is `numerictype([],32,20)`.

ConvolutionProductDataType

Convolution product word and fraction lengths

Specify the convolution product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `EnergyProductDataType`, `StepSizeErrorProductDataType`, `WeightsUpdateProductDataType` and `QuotientDataType` properties to the same value. The default is `Same as first input`.

CustomConvolutionProductDataType

Convolution product word and fraction lengths

Specify the convolution product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `ConvolutionProductDataType` property is `Custom`. The default is `numerictype([],32,20)`.

ConvolutionAccumulatorDataType

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `EnergyAccumulatorDataType` property to the same value. The default is `Same as first input`.

CustomConvolutionAccumulatorDataType

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `ConvolutionAccumulatorDataType` property is `Custom`. The default is`numerictype([],32,20)`.

StepSizeErrorProductDataType

Step size error product word and fraction lengths

Specify the step size error product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `ConvolutionProductDataType`, `EnergyProductDataType`, `WeightsUpdateProductDataType`, and `QuotientDataType` properties to the same value. The default is `Same as first input`.

CustomStepSizeErrorProductDataType

Step size error product word and fraction lengths

Specify the step size error product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeErrorProductDataType` property is `Custom`. The default is `numerictype([],32,20)`.

WeightsUpdateProductDataType

Weight update product word and fraction lengths

Specify the weight update product fixed-point data type as `Same as first input` or`Custom`. Setting this property also sets the `ConvolutionProductDataType`, `EnergyProductDataType`, `StepSizeErrorProductDataType`, and `QuotientDataType`

properties to the same value. The default is `Same as first input`.

CustomWeightsUpdateProductDataType

Weight update product word and fraction lengths

Specify the weight update product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `WeightsUpdateProductDataType` property is `Custom`. The default is `numerictype([],32,20)`.

QuotientDataType

Quotient word and fraction lengths

Specify the quotient fixed-point data type as `Same as first input`, `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionProductDataType`, `EnergyProductDataType`, `StepSizeErrorProductDataType`, and `WeightsUpdateProductDataType` properties to the same value. The default is `Same as first input`.

CustomQuotientDataType

Quotient word and fraction lengths

Specify the quotient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` property is `Normalized LMS` and the `QuotientDataType` property is `Custom`. The default is `numerictype([],32,20)`.

Methods

clone	Create LMS filter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
maxstep	Maximum step size for LMS adaptive filter convergence
msepred	Predicted mean-square error for LMS filter
msesim	Mean-squared error for LMS filter
release	Allow property value and input characteristics changes
reset	Reset filter states for LMS filter
step	Apply LMS adaptive filter to input

Examples

Determine system identification of an FIR filter:

```
hlms1 = dsp.LMSFilter(11, 'StepSize', 0.01);
hfilt = dsp.DigitalFilter; % System to be identified
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, .25);
x = randn(1000,1); % input signal

d = step(hfilt, x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = step(hlms1, x, d);

subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([hfilt.Numerator.', w]);
legend('Actual','Estimated');
xlabel('coefficient #'); ylabel('coefficient value');
```

Cancel noise in a signal:

```
hlms2 = dsp.LMSFilter('Length', 11, ...
   'Method', 'Normalized LMS',...
   'AdaptInputPort', true, ...
   'StepSizeSource', 'Input port', ...
   'WeightsOutputPort', false);
hfilt2 = dsp.DigitalFilter(...
   'TransferFunction', 'FIR (all zeros)', ...
   'Numerator', fir1(10, [.5, .75]));
x = randn(1000,1); % Noise
d = step(hfilt2, x) + sin(0:.05:49.95)'; % Noise + Signal
a = 1; % adaptation control
mu = 0.05; % step size
[y, err] = step(hlms2, x, d, mu, a);

subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2),plot(err), title('Signal');
```

Algorithms

This filter's algorithm is defined by the following equations.

$$y(n) = \mathbf{w}^T(n-1)\mathbf{u}(n)$$
$$e(n) = d(n) - y(n)$$
$$\mathbf{w}(n) = \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)$$

The various LMS adaptive filter algorithms available in this System object are defined as:

- LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\mathbf{u}^*(n)$$

- Normalized LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

- Sign-Error LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu sign(e(n))\mathbf{u}^*(n)$$

- Sign-Data LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) sign(\mathbf{u}(n))$$

  where **u**(n) is real.

- Sign-Sign LMS:

$$f(\mathbf{u}(n), e(n), \mu) = \mu sign(e(n)) sign(\mathbf{u}(n))$$

  where **u**(n) is real.

The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{u}^*(n)$	The complex conjugate of the vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter weight estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
μ	The adaptation step size
α	The leakage factor ($0 < \alpha \leq 1$)

`dsp.BlockLMSFilter` | `dsp.DigitalFilter`

dsp.LMSFilter.maxstep

Purpose

Maximum step size for LMS adaptive filter convergence

Syntax

```
MUMAX = maxstep(H,X)
[MUMAX,MUMAXMSE] = maxstep(H,X)
```

Description

`MUMAX = maxstep(H,X)` predicts a bound on the step size to provide convergence of the mean values of the adaptive filter coefficients. The columns of the matrix X contain individual input signal sequences. The signal set is assumed to have zero mean or nearly so.

`[MUMAX,MUMAXMSE] = maxstep(H,X)` predicts a bound on the adaptive filter step size to provide convergence of the adaptive filter coefficients in mean square.

Purpose

Predicted mean-square error for LMS filter

Syntax

```
[MMSE,EMSE] = msepred(H,X,D)
[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(H,X,D)
[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(H,X,D,M)
```

Description

`[MMSE,EMSE] = msepred(H,X,D)` predicts the steady-state values at convergence of the minimum mean-squared error (`MMSE`) and the excess mean-squared error (`EMSE`) given the input and desired response signal sequences in `X` and `D` and the quantities in the adaptive filter `H`.

`[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(H,X,D)` calculates three sequences corresponding to the analytical behavior of the adaptive filter defined by `H`. `MEANW` is the sequence of coefficient vector means. The columns of this matrix contain predictions of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `MSE` is the sequence of mean-square errors. This column vector contains predictions of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains predictions of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(H,X,D,M)` specifies an optional decimation factor for computing `MEANW`, `MSE`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is one.

dsp.LMSFilter.msesim

Purpose

Mean-squared error for LMS filter

Syntax

```
MSE = msesim(H,X,D)
[MSE,MEANW,W,TRACEK] = msesim(H,X,D)
[...] = msesim(H,X,D,M)
```

Description

`MSE = msesim(H,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(H,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `H`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `H`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(H,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M` > 1, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System identification of an FIR filter

```
ha = fir1(31,0.5);
sa = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
hb = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = step(hb,sign(randn(2000,25)));
n = 0.1*randn(size(x));             % Observation noise signal
d = step(sa,x)+n;                   % Desired signal
```

```
l = 32;                                 % Filter length
mu = 0.008;                             % LMS Step size.
m  = 5;                                 % Decimation factor for analysis
                                        % and simulation results
ha = dsp.LMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
title('Learning curve for LMS filter used in system identification')
```

dsp.LMSFilter.clone

Purpose

Create LMS filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an LMS filter object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LMSFilter.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the LMS filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LMSFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset filter states for LMS filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the LMS FIR filter,`H`, to their initial values specified in the `InitialConditions` property. The initial filter state values correspond to the initial conditions for difference equation defining the adaptive filter. After the `step` method applies the LMS filter to nonzero input data, the states may be different. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

Example of resetting filter states:

```
hlms1 = dsp.LMSFilter(11, 'StepSize', 0.01);
hfilt = dsp.DigitalFilter; % System to be identified
hfilt.TransferFunction = 'FIR (all zeros)';
hfilt.Numerator = fir1(10, .25);
x = randn(1000,1); % input signal
d = step(hfilt, x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = step(hlms1, x, d);
% Call step method again without resetting filter states
[y1,e1,w1] = step(hlms1,x,d);
isequal(y,y1) % Returns 0
% Now reset the filter states to zero
reset(hlms1)
% invoke step method
[y2,e2,w2] = step(hlms1,x,d);
isequal(y,y2) % Returns 1
```

dsp.LMSFilter.step

Purpose

Apply LMS adaptive filter to input

Syntax

```
[Y,ERR,WTS] = step(H,X,D)
[Y, ERR] = step(H,X,D)
[...] = step(H,X,D,MU)
[...] = step(H,X,D,A)
[...] = step(H,X,D,R)
[Y,ERR,WTS] = step(H,X,D,MU,A,R)
```

Description

`[Y,ERR,WTS] = step(H,X,D)` applies the LMS filter object, `H` to the input `X` , using `D` as the desired signal. This approach returns the filtered output in `Y` , the filter error in `ERR` , and the estimated filter weights in `WTS` . The LMS filter estimates the filter weights needed to minimize the mean square error between the output and the desired signal.

`[Y, ERR] = step(H,X,D)` filters the input `X` , using `D` as the desired signal. This approach returns the filtered output in `Y` and the filter error in `ERR` when the `WeightsOutputPort` property is `false`.

`[...] = step(H,X,D,MU)` uses `MU` as the step size, when the `StepSizeSource` property is `'Input port'`.

`[...] = step(H,X,D,A)` uses `A` as the adaptation control, when the `AdaptInputPort` property is `true`. When `A` is nonzero, the LMS filter continuously updates the filter weights. When `A` is zero, the filter weights remain constant.

`[...] = step(H,X,D,R)` uses `R` as a reset signal when the `WeightsResetInputPort` property is `true`. The `WeightsResetCondition` property can be used to set the reset trigger condition. If a reset event occurs, the LMS filter resets the filter weights to their initial values.

`[Y,ERR,WTS] = step(H,X,D,MU,A,R)` filters the input `X` using `D` as the desired signal, `MU` as the step size, `A` as the adaptation control, and `R` as the reset signal. This approach returns the filtered output in `Y` , the filter error in `ERR` , and the adapted filter weights in `WTS`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Display transitions of signals over time

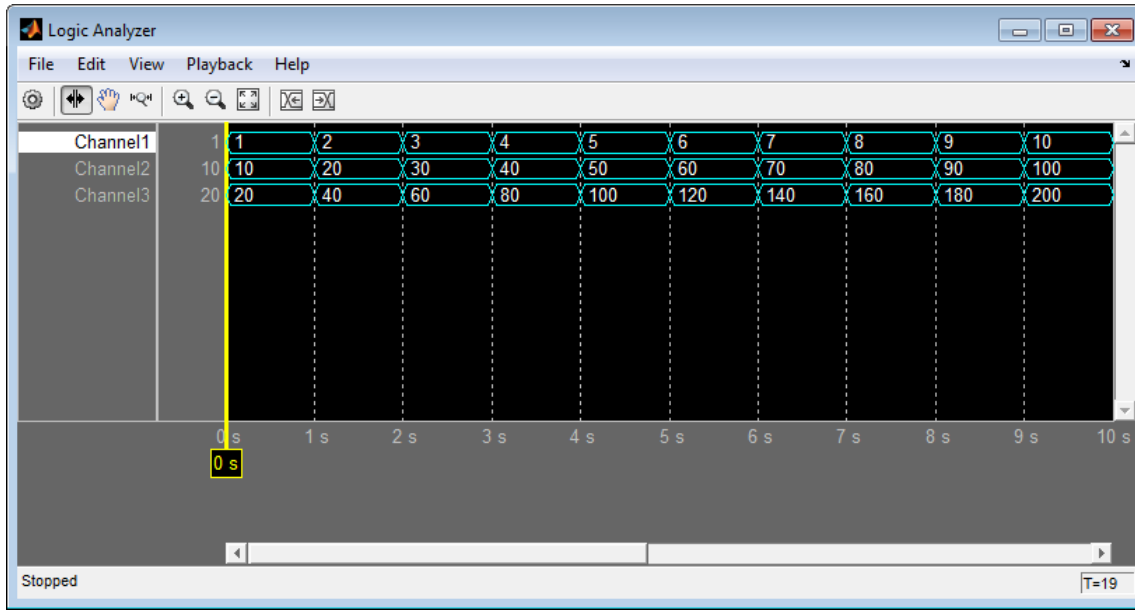
Description

The `LogicAnalyzer` object, hereafter referred to as the scope, displays the transitions in time-domain signals.

To display the transitions of signals in the Logic Analyzer:

1. Define and set up your Logic Analyzer. See "Construction" on page 3-883.
2. Call `step` to display the transitions of the signals in the Logic Analyzer figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Logic Analyzer figure window and clear its associated data. Use the `hide` method to hide the Logic Analyzer window and the `show` method to make it visible.



See the following sections for more information on the Logic Analyzer Graphical User Interface:

- "Signal Display" on page 3-890
- "Toolbar" on page 3-895

Construction

`H = dsp.LogicAnalyzer` creates a Logic Analyzer System object, `H`. This object displays the transitions of signals.

`H = dsp.LogicAnalyzer('Name',Value,...)` creates a Logic Analyzer System object, `H`, with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Properties

BackgroundColor

Background color for display

Specify the background color of the display to be either `'Black'` or `'White'`.

This property is Tunable.

Default: `'Black'`

DisplayChannelColor

Color for channels in the display

Specify the color for channels in the display to be one of the following options:

- `'Black'`
- `'Blue'`
- `'Green'`
- `'Cyan'`
- `'Red'`
- `'Magenta'`

- `'White'`

This property is Tunable.

Default: `'Cyan'`

DisplayChannelFontSize

Font size for channels in the display

Specify as a scalar nonnegative integer the font size in points for values shown in the channels in the display.

This property is Tunable.

Default: `10`

DisplayChannelFormat

Format for channels in the display

Specify as a string the wave format from one of the following options:

- `'Analog'` — Shows values as an analog plot
- `'Digital'` — Shows values as digital transitions

This property is Tunable.

Default: `'Digital'`

DisplayChannelHeight

Height for channels in the display

Specify as a scalar integer the height of the channels in the display in units of 16 pixels.

This property is Tunable.

Default: `1`

DisplayChannelRadix

Base of the enumeration used to display the values

Specify as a string the radix (i.e., base of the numeric system) from one of the following options:

- `'Binary'` — Displays values as 0s and 1s.
- `'Hexadecimal'` — Displays values as symbols from 0 to 9 and A to F
- `'Octal'` — Displays values as numbers from 0 to 7

  `'Signed decimal'` — Displays the signed, stored integer value
- `'Unsigned decimal'` — Displays the stored integer value

This property is applicable only to fixed-point (`fi`) values. This property is Tunable.

Default: `'Hexadecimal'`

DisplayChannelSpacing

Spacing for channels in display

Specify as a positive scalar integer the spacing between channels in the display in units of 4 pixels.

This property is Tunable.

Default: `1`

MaxNumTimeSteps

Maximum number of time steps

Specify as a finite numeric scalar the maximum number of samples for the input ports. The same maximum number of time steps is used for all inputs.

Default: `50000`

Name

Caption to display on scope window

Specify as a string the caption to display on the scope window.

This property is Tunable.

Default: `'Logic Analyzer'`

NumInputPorts

Number of input signals

Specify the number of input signals to the scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

Default: `1`

Position

Scope window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the scope window in a specific position on your screen by modifying the values for this property.

This property is Tunable.

Default: The default depends on your screen resolution. By default, the scope window appears in the center of your screen with a width of `800` pixels and height of `600` pixels.

ReduceUpdates

Reduce updates to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time the `step` method is called. The simulation speed is faster when this property is set to `true`. This property is Tunable.

You can also modify this property from the scope figure. Opening the **Playback** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to `false`.

Default: `true`

SampleTime

Sample time of inputs

Specify as a finite numeric scalar the sampling time of the input ports, in seconds. The same sample time is used for all inputs.

Default: `1`

TimeDisplayOffset

Time display offset

Specify the offset, in seconds, to apply to the *x*-axis (*time*-axis). This property can be either a numeric scalar or a vector of length equal to the number of input channels. If you specify this property as a scalar, then that value is the time display offset for all channels. If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the scope sets the time display offsets for the remaining channels to 0. If a vector has a length greater than the number of input channels, the scope ignores extra vector elements. This property is Tunable.

See `TimeSpan` for information on the *x*-axis limits and time span settings.

Default: `0`

TimeSpan

Specify the time span, in seconds, as a positive, numeric scalar value. The *x*-axis limits are calculated as follows.

Minimum *x*-axis limit = min(`TimeDisplayOffset`)
Maximum *x*-axis limit = max(`TimeDisplayOffset`) + `TimeSpan`

where `TimeDisplayOffset` and `TimeSpan` are the values of their respective properties.

This property is Tunable.

Default: `10`

Methods

addCursor	Add cursor to display
addDivider	Add divider to display
addWave	Add wave corresponding to specified input
clone	Create scope object with same property values
deleteCursor	Delete specified cursor
deleteDisplayChannel	Delete specified display channel
getCursorInfo	Return settings for specified cursor
getCursorTags	Return all cursor tags
getDisplayChannelInfo	Return settings for specified display channel

getDisplayChannelTags	Return all display channel tags
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
hide	Hide scope window
isLocked	Locked status for input attributes and nontunable properties
modifyCursor	Modify properties of specified cursor
modifyDisplayChannel	Modify properties of specified display channel
moveDisplayChannel	Move position of specified display channel
release	Allow property value and input characteristics changes
reset	Reset internal states of scope object
show	Make scope window visible
step	Display signal in scope figure

Examples

The following examples illustrate how to use the Logic Analyzer object to view a variety of input signals in the time domain.

Example: Display Simple Ramp Signals

Construct a `dsp.LogicAnalyzer` object. Run the `step` method to display the signals.

```
hla1 = dsp.LogicAnalyzer('NumInputPorts', 3);
for ii = 1:20
    step(hla1, ii, 10*ii, 20*ii);
end
```

Run the `release` method to let property values and input characteristics change.

```
release(hla1);
```

Run the MATLAB `clear` function to close the scope window.

```
clear('hla1');
```

Example: Display Fixed-Point Signals

Construct a `dsp.LogicAnalyzer` object. Run the `addWave` method to add both floating-point and fixed-point wave channels. Run the `step` method to display the signals.

```
hla2 = dsp.LogicAnalyzer('NumInputPorts', 2); % 2 inputs
hla2.TimeSpan = 12;
addWave(hla2,'InputChannel',1,'Name','Index');
addWave(hla2,'InputChannel',2,'Name','Fi_hex','Radix','Hexadecimal');
addWave(hla2,'InputChannel',2,'Name','Fi_bin','Radix','Binary');
for ii = 1:20
    fival = fi(mod(ii-1, 16), 0, 4, 0);
    step(hla2, ii, fival);
end
```

Run the`release` method to let property values and input characteristics change.

```
release(hla2);
```

Run the MATLAB `clear` function to close the scope window.

```
clear('hla2');
```

Signal Display

Logic Analyzer uses the `Time span` and `Time display offset` properties to determine the time range. To change the signal display settings, modify these properties. For example, if you set the `Time span` to 25 seconds, the scope displays 25 seconds' worth of simulation data at

a time. If you also set the `Time display offset` to `5` seconds, the scope displays values on the *time*-axis from `5` to `30` seconds.

To communicate the simulation time that corresponds to the current display, the scope uses the **Simulation time** indicators on the scope window. The following figure highlights these and other important aspects of the Logic Analyzer window.

Indicators

- **Display Channels** — The scope displays on the *y*-axis a number of display channels. Each display channel may contain either a wave or a divider and is identified by a unique tag. The displayed values are the signal values for the sample period from one transition to another. To get the tags for an existing display channel, call the `getDisplayChannelTags` method. To get information about an existing display channel, call the `getDisplayChannelInfo` method. To modify the properties of an existing display channel, call the `modifyDisplayChannel` method. To move a display channel, call the `moveDisplayChannel` method. To delete a display channel, call the `deleteDisplayChannel` method.

  To select a display channel, click on its name. Use shift-click or control-click (command-click on the Mac OS X platform) to select or deselect multiple display channels. When one or more channels are selected, you can use the **Edit** menu or right-click and use the context menu to cut, copy, and paste channels. The right-click context menu also lets you add a wave or divider, and modify, move, or delete channels.

  - **Wave** — A *wave* is signal data in any format whose name and data are displayed on the *y*-axis. The display of a wave consists of its name, its value at the active cursor, and a visualization of its signal data over the time span. To add a new wave to the display, call the `addWave` method. Each wave uses default values for radix, format, and other wave properties. When one or more wave channels are selected, you can use **Edit** menu to cut, copy, and paste them. To change any of the properties, right-click on a wave name and select **Modify** or set the properties via the `addWave` method for that wave. You can also double-click on a channel name to open the **Logic Analyzer — Modify display channel** dialog box for that channel. If you choose a specific setting for a wave, that setting overrides the default setting.
  - **Divider** — The *divider* is a horizontal line that is intended to separate groups of signal data on the *y*-axis. To add a new divider

to the display, call the `addDivider` method. When one or more divider channels are selected, you can use **Edit** menu to cut, copy, and paste them. To change any of the properties, right-click on a divider name and select **Modify** or set the properties via the `addDivider` method for that divider. You can also double-click on a divider name to open the **Logic Analyzer — Modify display channel** dialog box for that divider. If you choose a specific setting for a divider, that setting overrides the default setting.

- **Cursor** — The scope displays on the *time*-axis a number of cursors. Cursors allow you to compare wave values at the same moment of time. To add a new cursor to the display channel, call the `addCursor` method. To modify the properties of an existing cursor, call the `modifyCursor` method. To delete a display channel, call the `deleteCursor` method or select the channel and use **Edit > Cut**.

  To move the cursor to the previous or next transition, select a display channel and use the **Go to Previous Transition** or **Go to Next Transition** toolbar button, respectively.

- **Simulation status** — Provides the current status of the model simulation. The status can be either of the following conditions:

  - `Processing` — Occurs after you run the `step` method and before you run the `release` method.
  - `Stopped` — Occurs after you construct the scope object and before you first run the `step` method. This status also occurs after you run the `release` method.

  The **Simulation status** is part of the **Status Bar** in the scope window. You can choose to hide or display the entire **Status Bar**. From the scope menu, select **View > Status Bar**.

- **Simulation time** — The amount of time that the Logic Analyzer has spent processing the input. Every time you call the `step` method, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following

formula: $t_{sim} = t_{sim} + \frac{\text{length}(x)}{SampleRate}$. To set the sample rate, modify the `SampleTime` property.

The **Simulation time** is part of the **Status Bar** in the scope window. You can choose to hide or display the entire **Status Bar**. From the scope menu, select **View > Status Bar** .

- **Minimum *time*-axis limit** — The scope sets the minimum *time*-axis limit using the value of the **Time display offset** property.
- **Maximum *time*-axis limit** — The scope sets the maximum *time*-axis limit by summing the value of **Time display offset** parameter with the value of the **Time span** parameter.

Toolbar

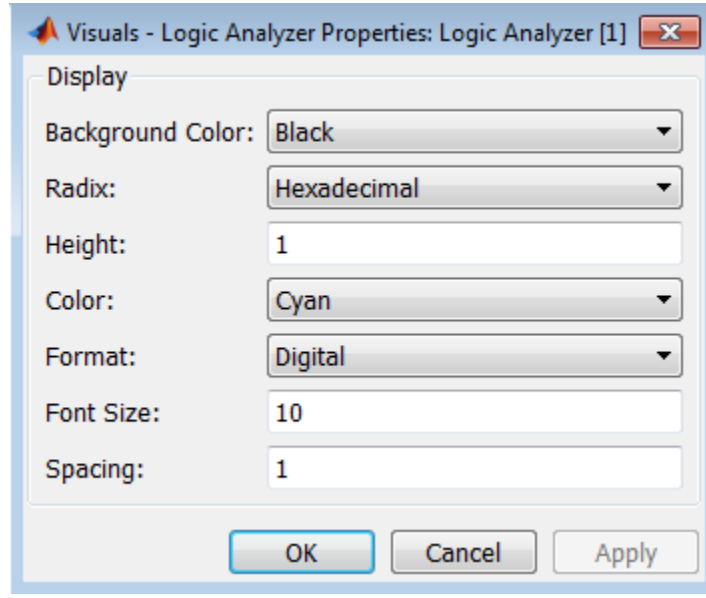
You can control whether the toolbar appears in the Logic Analyzer window. From the Logic Analyzer menu, select **View > Toolbar**. The Logic Analyzer toolbar contains the following buttons.

Button	Shortcut Keys	Description
	n/a	**Configuration Properties** — Click this button to open the Visuals – Logic Analyzer Properties dialog.
	n/a	**Cursor** — When this tool is active, you can place a cursor on the scope window. The cursor shows you the time and allows you to compare the values of the input signals at that time.
	**Left arrow**, **Right arrow**	**Pan** — When this tool is active, you can pan on the scope window. To do so, click in the center of your area of interest, and drag your cursor to the left or right to move the position of the display. Alternatively, you can use the left and right arrows on your keyboard.

Button	Shortcut Keys	Description
	n/a	**Zoom X** — When this tool is active, you can zoom in on the *time*-axis. To do so, click inside the scope window, or click and drag your cursor along the *time*-axis over your area of interest.
	**+**, **i**	**Zoom In** — Click this button to zoom in on the scope window. Use the **Pan** button to center the display on your area of interest before you zoom in.
	**−**, **o**, **_**	**Zoom Out** — Click this button to zoom out on the scope window.
	**f**	**Autoscale** — Click this button to scale the *x*-axis in the active scope window.
	n/a	**Go to Previous Transition** — Click this button to move the cursor in the selected display channel to the previous transition.
	n/a	**Go to Next Transition** — Click this button to move the cursor in the selected display channel to the next transition.

Visuals — Logic Analyzer Properties

The **Visuals — Logic Analyzer Properties** dialog box controls the visual configuration default settings of the Logic Analyzer display. From the Logic Analyzer menu, select **View > Configuration Properties** to open this dialog box. Any changes you make using the **Modify display channel** or **Modify display channels** dialog box affect only the selected channels and these **Visuals — Logic Analyzer Properties** dialog box default settings do no apply.



Background Color

Specify the background color of the display to be either `'Black'` or `'White'`.

Radix

Specify as a string the radix (i.e., base of the numeric system) from one of the following options:

- `'Binary'` — Displays values as 0s and 1s.
- `'Hexadecimal'` — Displays values as symbols from 0 to 9 and A to F
- `'Octal'` — Displays values as numbers from 0 to 7

  `'Signed decimal'` — Displays the signed, stored integer value
- `'Unsigned decimal'` — Displays the stored integer value

Height

Specify as a scalar integer the height of the channels in the display in units of 16 pixels.

Color

Specify the color for channels in the display to be one of the following options:

- `'Black'`
- `'Blue'`
- `'Green'`
- `'Cyan'`
- `'Red'`
- `'Magenta'`
- `'White'`

Format

Specify as a string the wave format from one of the following options:

- `'Analog'` — Shows values as an analog plot
- `'Digital'` — Shows values as digital transitions

Font Size

Specify as a scalar nonnegative integer the font size in points for values shown in the channels in the display.

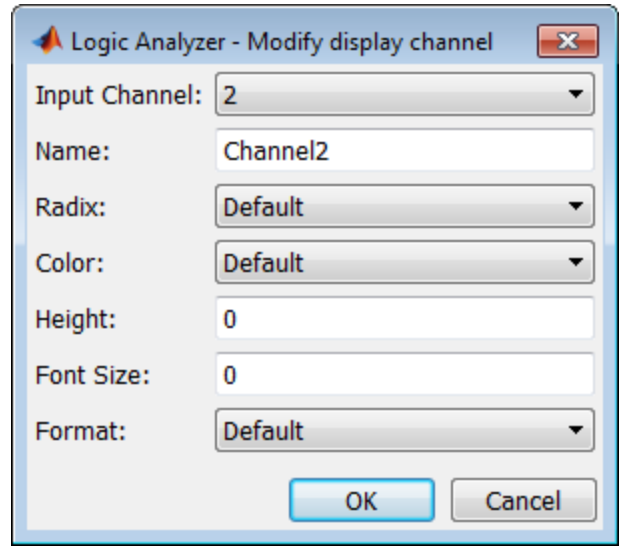
Spacing

Specify as a positive scalar integer the spacing between channels in the display in units of 4 pixels.

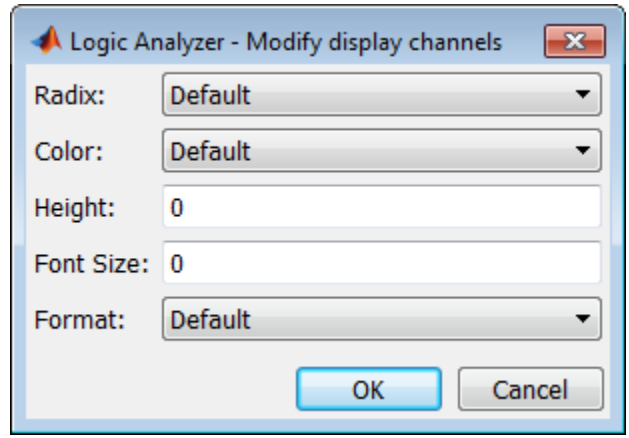
Logic Analyzer — Modify display channel

The **Logic Analyzer — Modify display channel** dialog box controls the visual configuration settings of the selected channel wave or divider. You open this dialog box for a specific wave or divider by double-clicking on the wave or divider name. You can also open this dialog box by selecting a channel wave or divider, right-clicking to open the context menu, and then, selecting **Modify**. To open the dialog box for more than one wave or divider, shift-click or control-click to select the desired waves and dividers and then, select **Modify** from the right-click context menu. Any changes you make using this dialog override the **Visuals — Logic Analyzer Properties** dialog box default settings.

If you select only one channel wave or divider, the dialog box shows these fields.



If you select more than one channel wave or divider, the dialog box shows only these fields.



If you select more than one channel wave or divider with different property values, `No change` is displayed for that property. Selecting a value applies that value to all selected channels.

Input Channel

Select the input data source for the channel. This field is displayed only if you selected a single channel or divider.

Name

Specify the name to display for the selected channel or divider. This field is displayed only if you selected a single channel or divider.

Radix

Select the radix (base of the numeric system) from one of the following options:

- `Default` — Uses the default value specified in the **Visuals — Logic Analyzer Properties** dialog box.
- `Hexadecimal` — Displays values as symbols from 0 to 9 and A to F
- `Octal` — Displays values as numbers from 0 to 7
- `Binary` — Displays values as 0s and 1s.

- `Signed decimal` — Displays the signed, stored integer value
- `Unsigned decimal` — Displays the stored integer value

Color

Select the color for channels in the display to be one of the following options:

- `Default` — Uses the default color specified in the **Visuals — Logic Analyzer Properties** dialog box.
- `Black`
- `Blue`
- `Green`
- `Cyan`
- `Red`
- `Magenta`
- `Yellow`
- `White`

Height

Specify as a scalar integer the height of the selected channel in the display in units of 16 pixels. Setting the height to 0 uses the default value specified in the **Visuals — Logic Analyzer Properties** dialog box. If you have selected more than one channel, specify a scalar integer to apply the same height to all channels or a vector of integer heights to apply different heights to each selected channel.

Font Size

Specify as a scalar integer the font size of the selected channel in the display in units of 16 pixels. Setting the font size to 0 uses the default value specified in the **Visuals — Logic Analyzer Properties** dialog box. If you have selected more than one channel, specify a scalar integer

to apply the same font size to all channels or a vector of font sizes to apply different fone sizes to each selected channel.

Format

Select the wave format from one of the following options:

- `Default` — Uses the default format specified in the **Visuals — Logic Analyzer Properties** dialog box.
- `Digital` — Shows values as digital transitions
- `Analog` — Shows values as an analog plot

`dsp.TimeScope` | `dsp.SpectrumAnalyzer` | `dsp.ArrayPlot`

Purpose

Add cursor to display

Syntax

```
cursorTag = addCursor(H)
cursorTag = addCursor(H,'Name',Value)
```

Description

`cursorTag = addCursor(H)` adds in a cursor to the display. A tag value is returned, which can be used to modify and delete the cursor.

`cursorTag = addCursor(H,'Name',Value)` adds in a cursor to the display with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Input Arguments

H - The Logic Analyzer object to which you want to add a cursor

dsp.LogicAnalyzer object

Example: `'addCursor(H)'` adds a cursor with the default characteristics.

Example: `'H.addCursor()'` adds a cursor with the default characteristics.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Location',2,'Color','Blue'` specifies that a cursor should be moved to the 2-second mark and colored blue.

'Color' - Color of the cursor

string enumeration

Specify as a string the color of the cursor from one of the following options:

- `'Black'`
- `'Blue'`

- 'Cyan'
- 'Green'
- 'Magenta'
- 'Red'
- 'White'
- 'Yellow'

Example: 'Color','Blue'

Data Types
char

Default: 'Yellow'

'Location' - Location of the cursor
numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

Example: 'Location','1.0'

Data Types
double

Default: 0

'Locked' - Locked status of the cursor
logical scalar

Specify as a logical scalar whether the cursor location should be locked.

- If you choose true, then the cursor's location cannot be changed. Logic Analyzer denotes this by assigning a default color of red.

- If you choose `false`, then the cursor's location can be changed. Logic Analyzer denotes this by assigning a default color of yellow.

Example: `'Locked',true`

Data Types
`logical`

Default: `false`

dsp.LogicAnalyzer.addDivider

Purpose

Add divider to display

Syntax

```
dividerTag = addDivider(H)
dividerTag = addDivider(H,'Name',Value)
```

Description

`dividerTag = addDivider(H)` adds in a divider to the display. A tag value is returned, which can be used to modify and delete the divider.

`dividerTag = addDivider(H,'Name',Value)` adds in a divider to the display with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Input Arguments

H - The Logic Analyzer object to which you want to add a divider

dsp.LogicAnalyzer object

Example: `'addDivider(H)'` adds a divider with the default characteristics.

Example: `'H.addDivider()'` adds a divider with the default characteristics.

Divider Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannel',2,'Name','MyDivider'` specifies that a divider should be added to display channel 2 and named “MyDivider”.

'DisplayChannel' - Channel on the display that shows this divider

scalar numeric value in the range (1,`NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types
`double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64`

Default: `NumInputPorts`

'Height' - Height of the divider

scalar integer

Specify as a scalar integer the height of the divider in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types
`double`

Default: `0`

'Name' - The name or label for the divider

string

Specify as a string the name that you would like to set for the new divider.

Example: `'Name','MyDivider'`

Data Types
`char`

Default: `''`

dsp.LogicAnalyzer.addWave

Purpose

Add wave corresponding to specified input

Syntax

```
waveTag = addWave(H)
waveTag = addWave(H,'Name',Value)
```

Description

`waveTag = addWave(H)` adds in a wave corresponding to the specified input channel. A tag value is returned back, which can be used to modify and delete the wave.

`waveTag = addWave(H,'Name',Value)` adds in a wave with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Input Arguments

H - The Logic Analyzer object to which you want to add a wave

dsp.LogicAnalyzer object

Example: `'addWave(H)'` adds a wave with the default characteristics.

Example: `'H.addWave()'` adds a wave with the default characteristics.

Wave Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'InputChannel',2,'Color','Blue'` specifies that a wave should be added to input channel 1 and colored blue.

'Color' - Color of the wave

string enumeration

Specify as a string the color of the display from one of the following options:

- `'Black'`
- `'Blue'`

- 'Cyan'
- 'Default'
- 'Green'
- 'Magenta'
- 'Red'
- 'White'
- 'Yellow'

When you choose 'Default', the value of the DisplayChannelColor property in the Logic Analyzer is used.

Example: 'Color','Blue'

Data Types
char

Default: 'Default'

'DisplayChannel' - Channel on the display that shows this wave

scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

Example: 'DisplayChannel',2

Data Types
double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

Default: NumInputPorts

'FontSize' - Font size for values in the wave

scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the `DisplayChannelFontSize` property in the Logic Analyzer is used.

Example: `'FontSize',8`

Data Types
`double`

Default: `0`

'Format' - Display format for the wave
string enumeration

Specify as a string the wave format from one of the following options:

- `'Analog'`
- `'Default'`
- `'Digital'`

When you choose `'Default'`, the value of the `DisplayChannelFormat` property in the Logic Analyzer is used.

Example: `'Format','Digital'`

Data Types
`char`

Default: `'Default'`

'Height' - Height of the wave
scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types
`double`

Default: `0`

'InputChannel' - Input channel that corresponds to this wave

scalar integer in the range (1,`NumInputPorts`)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

Example: `'InputChannel',2`

Data Types
`double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64`

Default: `1`

'Name' - The name or label for the wave

string

Specify as a string the name that you would like to set for the new wave.

Example: `'Name','MyWave'`

Data Types
`char`

Default: `''`

'Radix' - Radix for the wave

string enumeration

Specify as a string the radix of the display from one of the following options:

- `'Binary'`

- `'Default'`
- `'Hexadecimal'`
- `'Octal'`
- `'Signed decimal'`
- `'Unsigned decimal'`

When the input signals are of class double, single, or logical, you should not set this property. When you choose `'Default'`, the value of the `DisplayChannelRadix` property in the Logic Analyzer is used.

Example: `'Radix','Hexadecimal'`

Data Types
`char`

Default: `'Default'`

Purpose

Create scope object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a scope object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.LogicAnalyzer.deleteCursor

Purpose

Delete specified cursor

Syntax

```
deleteCursor(H,tag)
deleteCursor(H,'CursorTag',tag)
```

Description

`deleteCursor(H,tag)` deletes the cursor specified by the input tag.

`deleteCursor(H,'CursorTag',tag)` deletes the cursor specified by the input tag.

Input Arguments

H - The Logic Analyzer object from which you want to delete a cursor

dsp.LogicAnalyzer object handle

The Logic Analyzer object from which you want to delete a cursor, specified as a handle to the `dsp.LogicAnalyzer` object.

tag - The tag identifying which cursor to delete

string, randomly assigned

The tag identifying which cursor to delete, specified as a randomly assigned string.

Example: `'deleteCursor(H,tag)'` deletes a cursor from Logic Analyzer.

Example: `'H.deleteCursor(tag)'` deletes a cursor from Logic Analyzer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CursorTag','C6'` specifies to delete the divider with tag `'C5'`.

'CursorTag' - The tag identifying which cursor to delete

string, randomly assigned

The tag identifying which cursor to delete, specified as a randomly assigned string.

Example: `'CursorTag','C6'`

Data Types
`char`

dsp.LogicAnalyzer.deleteDisplayChannel

Purpose

Delete specified display channel

Syntax

```
deleteDisplayChannel(H,tag)
deleteDisplayChannel(H,'DisplayChannelTag',tag)
```

Description

`deleteDisplayChannel(H,tag)` deletes the display channel, either a wave or a divider, specified by the input tag.

`deleteDisplayChannel(H,'DisplayChannelTag',tag)` deletes the display channel, either a wave or a divider, specified by the input tag.

Input Arguments

H - The Logic Analyzer object from which you want to delete a display channel

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to delete a display channel, specified as a handle to the `dsp.LogicAnalyzer` object.

tag - The tag identifying which display channel to delete

string

The tag identifying which display channel to delete, specified as a string.

Example: `'deleteDisplayChannel(H,tag)'` deletes a display channel from Logic Analyzer.

Example: `'H.deleteDisplayChannel(tag)'` deletes a display channel from Logic Analyzer.

Data Types
`char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannelTag','C5'` specifies to delete the divider with tag `'C5'`.

'DisplayChannelTag' - The tag identifying which display channel to delete

string

The tag identifying which display channel to delete, specified as a string.

Example: `'DisplayChannelTag','C5'`

Data Types

`char`

dsp.LogicAnalyzer.getCursorInfo

Purpose

Return settings for specified cursor

Syntax

```
getCursorInfo(H,'CursorTag',tag)
```

Description

`getCursorInfo(H,'CursorTag',tag)` returns the settings for the cursor or cursors, specified by the input tag.

Input Arguments

H - The Logic Analyzer object from which you want to return cursor settings

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return cursor settings, specified as a handle to the `dsp.LogicAnalyzer` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CursorTag','C5'` specifies to return settings about the cursor with tag `'C5'`.

'CursorTag' - The tag or tags identifying the cursor or cursors about which to get information

string or cell array of strings

The tag or tags identifying the cursor or cursors about which to get information, specified as a string or cell array of strings.

Example: `'CursorTag','C5'`

Example: `'CursorTag',{'C4','C5'}`

Data Types

`char | cell`

Purpose

Return all cursor tags

Syntax

```
T = getCursorTags(H)
```

Description

`T = getCursorTags(H)` returns all the cursor tags for the Logic Analyzer. You can use these tags to get information about a cursor using the `dsp.LogicAnalyzer.getCursorInfo` method, to modify a cursor using the `dsp.LogicAnalyzer.modifyCursor` method, or to delete a cursor using the `dsp.LogicAnalyzer.deleteCursor` method.

Input Arguments

H - The Logic Analyzer object from which you want to return all cursor tags

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return all cursor tags, specified as a handle to the `dsp.LogicAnalyzer` object.

Output Arguments

T - The cursor tags

cell array of strings

The cursor tags, specified as a cell array of strings.

Example: `{'C1'}`

Example: `{'C1','C2','C3'}`

Data Types

`cell`

dsp.LogicAnalyzer.getDisplayChannelInfo

Purpose

Return settings for specified display channel

Syntax

```
getDisplayChannelInfo(H,'DisplayChannelTag',tag)
```

Description

`getDisplayChannelInfo(H,'DisplayChannelTag',tag)` returns the settings for the display channel or channels, specified by the input tag.

Input Arguments

H - The Logic Analyzer object from which you want to return display channel settings

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return display channel settings, specified as a handle to the `dsp.LogicAnalyzer` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannelTag','W5'` specifies to return display channel settings about the wave with tag `'W5'`.

'DisplayChannelTag' - The tag or tags identifying the display channel or channels about which to get information

string or cell array of strings

The tag or tags identifying the display channel or channels about which to get information, specified as a string or cell array of strings.

Example: `'DisplayChannelTag','W5'`

Example: `'DisplayChannelTag',{'W4','W5'}`

Data Types
`char | cell`

Purpose

Return all display channel tags

Syntax

```
T = getDisplayChannelTags(H)
```

Description

`T = getDisplayChannelTags(H)` returns all the display channel tags for the Logic Analyzer. These tags are particularly useful for getting information about a wave or divider using the `dsp.LogicAnalyzer.getDisplayChannelInfo` method, for modifying a wave or divider using the `dsp.LogicAnalyzer.modifyDisplayChannel` method, or for deleting a wave or divider using the `dsp.LogicAnalyzer.deleteDisplayChannel` method.

Input Arguments

`H` - The Logic Analyzer object from which you want to return all display channel tags

dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return all display channel tags, specified as a handle to the `dsp.LogicAnalyzer` object.

Output Arguments

`T` - The display channel tags

cell array of strings

The display channel tags, specified as a cell array of strings.

Example: `{'W1'}`

Example: `{'W1','W2','W3'}`

Data Types
`cell`

dsp.LogicAnalyzer.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method. `N` equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method. The scope is a sink object, so `N` equals 0.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.LogicAnalyzer.hide

Purpose

Hide scope window

Syntax

```
hide(H)
```

Description

`hide(H)` hides the scope window associated with System object, `H`.

See Also

`dsp.LogicAnalyzer.show`

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the scope object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LogicAnalyzer.modifyCursor

Purpose

Modify properties of specified cursor

Syntax

```
modifyCursor(H,tag)
modifyCursor(H,'CursorTag',tag)
modifyCursor(H,tag,'Name',Value)
modifyCursor(H,'CursorTag',tag,'Name',Value)
```

Description

`modifyCursor(H,tag)` modifies the properties of the cursor specified by the input tag.

`modifyCursor(H,'CursorTag',tag)` modifies the properties of the cursor specified by the input tag.

`modifyCursor(H,tag,'Name',Value)` modifies the properties of the cursor specified by the input tag with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

`modifyCursor(H,'CursorTag',tag,'Name',Value)` modifies the properties of the cursor specified by the input tag with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Input Arguments

H - The Logic Analyzer object for which you want to modify a cursor

dsp.LogicAnalyzer object

The Logic Analyzer object for which you want to modify a cursor specified, as a handle to the `dsp.LogicAnalyzer` object.

tag - The tag identifying which cursor to modify

string, randomly assigned

The tag identifying which cursor to modify specified, as a randomly assigned string.

Example: `'modifyCursor(H,tag)'` modifies a cursor in Logic Analyzer.

Example: `'H.modifyCursor(tag)'` modifies a cursor in Logic Analyzer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Location',2,'Color','Blue'` specifies that a cursor should be moved to the 2-second mark and colored blue.

'Color' - Color of the cursor

string enumeration

Specify as a string the color of the cursor from one of the following options:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Green'`
- `'Magenta'`
- `'Red'`
- `'White'`
- `'Yellow'`

Example: `'Color','Blue'`

Data Types
`char`

Default: `'Yellow'`

'Location' - Location of the cursor

numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

Example: `'Location','1.0'`

Data Types
`double`

Default: `0`

'Locked' - Locked status of the cursor

logical scalar

Specify as a logical scalar whether the cursor location should be locked.

- If you choose `true`, then the cursor's location cannot be changed. Logic Analyzer denotes this by assigning a default color of red.
- If you choose `false`, then the cursor's location can be changed. Logic Analyzer denotes this by assigning a default color of yellow.

Example: `'Locked',true`

Data Types
`logical`

Default: `false`

Purpose

Modify properties of specified display channel

Syntax

```
modifyDisplayChannel(H,tag,'Name',Value)
modifyDisplayChannel(H,'CursorTag',tag,'Name',Value)
```

Description

`modifyDisplayChannel(H,tag,'Name',Value)` modifies the properties of the display channel specified by the input tag with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

`modifyDisplayChannel(H,'CursorTag',tag,'Name',Value)` modifies the properties of the display channel specified by the input tag with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Input Arguments

H - The Logic Analyzer object for which you want to modify a display channel

dsp.LogicAnalyzer object

The Logic Analyzer object for which you want to modify a display channel, specified as a handle to the `dsp.LogicAnalyzer` object.

tag - The tag identifying which display channel to modify

string, randomly assigned

The tag identifying which display channel to modify, specified as a randomly assigned string.

Example: `'modifyDisplayChannel(H,tag)'` modifies a display channel in Logic Analyzer.

Example: `'H.modifyDisplayChannel(tag)'` modifies a display channel in Logic Analyzer.

The first section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a wave. The second section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a divider.

Wave Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'InputChannel',2,'Color','Blue'` specifies that a wave should be added to input channel 1 and colored blue.

'Color' - Color of the wave

string enumeration

Specify as a string the color of the display from one of the following options:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Default'`
- `'Green'`
- `'Magenta'`
- `'Red'`
- `'White'`
- `'Yellow'`

When you choose `'Default'`, the value of the `DisplayChannelColor` property in the Logic Analyzer is used.

Example: `'Color','Blue'`

Data Types
`char`

Default: `'Default'`

'DisplayChannel' - Channel on the display that shows this wave

scalar numeric value in the range (1,`NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types
`double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64`

Default: `NumInputPorts`

'FontSize' - Font size for values in the wave

scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the `DisplayChannelFontSize` property in the Logic Analyzer is used.

Example: `'FontSize',8`

Data Types
`double`

Default: `0`

'Format' - Display format for the wave

string enumeration

Specify as a string the wave format from one of the following options:

- `'Analog'`
- `'Default'`
- `'Digital'`

When you choose `'Default'`, the value of the `DisplayChannelFormat` property in the Logic Analyzer is used.

Example: `'Format','Digital'`

Data Types
`char`

Default: `'Default'`

'Height' - Height of the wave
scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types
`double`

Default: `0`

'InputChannel' - Input channel that corresponds to this wave
scalar integer in the range (1,`NumInputPorts`)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

Example: `'InputChannel',2`

Data Types
`double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64`

Default: `1`

'Name' - The name or label for the wave
string

Specify as a string the name that you would like to set for the new wave.

Example: `'Name','MyWave'`

Data Types
`char`

Default: `''`

'Radix' - Radix for the wave

string enumeration

Specify as a string the radix of the display from one of the following options:

- `'Binary'`
- `'Default'`
- `'Hexadecimal'`
- `'Octal'`
- `'Signed decimal'`
- `'Unsigned decimal'`

When the input signals are of class double, single, or logical, you should not set this property. When you choose `'Default'`, the value of the `DisplayChannelRadix` property in the Logic Analyzer is used.

Example: `'Radix','Hexadecimal'`

Data Types
`char`

Default: `'Default'`

Divider Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannel',2,'Name','MyDivider'` specifies that a divider should be added to display channel 2 and named "MyDivider".

'DisplayChannel' - Channel on the display that shows this divider

scalar numeric value in the range (1,`NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types
`double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64`

Default: `NumInputPorts`

'Height' - Height of the divider

scalar integer

Specify as a scalar integer the height of the divider in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types
`double`

Default: `0`

'Name' - The name or label for the divider

string

Specify as a string the name that you would like to set for the new divider.

Example: `'Name','MyDivider'`

Data Types
`char`

Default: `''`

dsp.LogicAnalyzer.moveDisplayChannel

Purpose

Move position of specified display channel

Syntax

```
moveDisplayChannel(H,'DisplayChannelTag',tag,'DisplayChannel',
   displaychannelvalue)
```

Description

`moveDisplayChannel(H,'DisplayChannelTag',tag,'DisplayChannel', displaychannelvalue)` moves the display channel, either a wave or a divider, specified by the input `tag`, to the new location specified by the input `displaychannelvalue`.

Input Arguments

H - The Logic Analyzer object in which you want to move a display channel

dsp.LogicAnalyzer object

The Logic Analyzer object in which you want to move a display channel, specified as a handle to the `dsp.LogicAnalyzer` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannelTag','W1'` specifies to delete the divider with tag `'C5'`.

'DisplayChannelTag' - The tag identifying which display channel to move

string

The tag identifying which display channel to move, specified as a string.

Example: `'DisplayChannelTag','W1'`

Data Types
`char`

'DisplayChannel' - The location identifying where the display channel should be moved

string

The location identifying where the display channel should be moved, specified as a string.

Example: `'DisplayChannel',2`

Data Types

`double`

dsp.LogicAnalyzer.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the scope figure window. After calling the `release` method, any non-tunable properties can be set once again.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Algorithms

In operation, the `release` method is similar to the `mdlTerminate` function.

See Also

`dsp.LogicAnalyzer.reset`

Purpose

Reset internal states of scope object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the scope object `H` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

Algorithms

In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

See Also

`dsp.LogicAnalyzer` | `dsp.LogicAnalyzer.release`

dsp.LogicAnalyzer.show

Purpose

Make scope window visible

Syntax

```
show(H)
```

Description

`show(H)` makes the scope window associated with System object, `H`, visible.

See Also

`dsp.LogicAnalyzer.hide`

Purpose

Display signal in scope figure

Syntax

```
step(H,X)
step(H,X1,X2,...,XN)
```

Description

`step(H,X)` displays the signal, `X`, in the scope figure.

`step(H,X1,X2,...,XN)` displays the signals `X1`, `X2`,...,`XN` in the scope figure when you set the `NumInputPorts` property to `N`. In this case, `X1`, `X2`,...,`XN` can have different data types and dimensions.

dsp.LowerTriangularSolver

Purpose

Solve lower-triangular matrix equation

Description

The `LowerTriangularSolver` object solves $LX = B$ for X when L is a square, lower-triangular matrix with the same number of rows as B.

To solve $LX = B$ for X:

1. Define and set up your linear system solver. See "Construction" on page 3-942.
2. Call `step` to solve the equation according to the properties of `dsp.LowerTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LowerTriangularSolver` returns a linear system solver, `H`, used to solve the linear system $LX = B$, where L is a lower (or unit-lower) triangular matrix.

`H = dsp.LowerTriangularSolver('PropertyName',PropertyValue,...)` returns a linear system solver, `H`, with each specified property set to the specified value.

Properties

OverwriteDiagonal

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, L, with ones. Set this property to either `true` or `false`. The default is `false`.

RealDiagonalElements

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input, L, are real. This property applies only when you set the `OverwriteDiagonal` property to `false`. Set this property to either `true` or `false`. The default is `false`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create lower triangular solver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Solve matrix equation for specified inputs

Examples

Solve a lower-triangular matrix equation:

```
hlowtriang = dsp.LowerTriangularSolver;
```

```
u = tril(rand(4, 4));
b = rand(4, 1);
% Check that result is the solution to the linear
% equations.
x1 = inv(u)*b
x = step(hlowtriang, u, b)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Forward Substitution block reference page. The object properties correspond to the block parameters.

See Also

`dsp.UpperTriangularSolver`

dsp.LowerTriangularSolver.clone

Purpose

Create lower triangular solver object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `LowerTriangularSolver` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LowerTriangularSolver.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LowerTriangularSolver` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LowerTriangularSolver.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Solve matrix equation for specified inputs

Syntax

```
X = step(H,L,B)
```

Description

`X = step(H,L,B)` computes the solution, X, of the matrix equation $LX = B$, where L is a square, lower-triangular matrix with the same number of rows as the matrix B.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LPCToAutocorrelation

Purpose

Convert linear prediction coefficients to autocorrelation coefficients

Description

The `LPCToAutocorrelation` System object converts linear prediction coefficients to autocorrelation coefficients.

To convert LPC to autocorrelation coefficients:

1. Define and set up your LPC to autocorrelation object. See "Construction" on page 3-952.
2. Call `step` to convert LPC according to the properties of `dsp.LPCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LPCToAutocorrelation` returns an LPC to autocorrelation System object, `H`, that converts linear prediction coefficients (LPC) to autocorrelation coefficients.

`H = dsp.LPCToAutocorrelation('PropertyName',PropertyValue,...)` returns an `LPC` to autocorrelation conversion object, `H`, with each specified property set to the specified value.

Properties

PredictionErrorInputPort

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes that the prediction error power is `1`. The default is `false`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not `1`

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not `1`. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

clone	Create LPC to autocorrelation object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Autocorrelation coefficients from LPC coefficents

Examples

Convert the linear prediction coefficients to autocorrelation coefficients:

```
a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711].';
hlpc2ac = dsp.LPCToAutocorrelation;
ac = step(hlpc2ac, a);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC/RC to Autocorrelation block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to `LPC to autocorrelation`.

See Also

`dsp.LPCToLSF` | `dsp.LPCToRC` | `dsp.LPCToCepstral` | `dsp.RCToAutocorrelation`

dsp.LPCToAutocorrelation.clone

Purpose

Create LPC to autocorrelation object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `LPCToAutocorrelation` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LPCToAutocorrelation.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LPCToAutocorrelation` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LPCToAutocorrelation.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Autocorrelation coefficients from LPC coefficents

Syntax

```
AC = step(H,A)
AC = step(H,A,P)
```

Description

`AC = step(H,A)` converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. The object assumes a prediction error power of `1`.

`AC = step(H,A,P)` when you set the `PredictionErrorInputPort` property to `true`, converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. This conversion uses `P` as the prediction error power. `P` must be a row vector with same number of columns as `A`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LPCToCepstral

Purpose

Convert linear prediction coefficients to cepstral coefficients

Description

The `LPCToCepstral` object converts linear prediction coefficients to cepstral coefficients.

To convert LPC to cepstral coefficients:

1. Define and set up your LPC to cepstral converter. See "Construction" on page 3-960.
2. Call `step` to convert LPC according to the properties of `dsp.LPCToCepstral`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LPCToCepstral` returns an LPC to cepstral converter object, `H`, that converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs).

`H = dsp.LPCToCepstral('PropertyName',PropertyValue,...)` returns an LPC to cepstral converter object, `H`, with each specified property set to the specified value.

Properties

PredictionErrorInputPort

Enable prediction error power input

Choose how to set the prediction error power. When you set this property to `true`, you must specify the prediction error as a second input to the `step` method. When you set this property to `false`, the oajbect assumes the prediction error power is 1. The default is `false`.

CepstrumLengthSource

Source of cepstrum length

Select how to specify the length of cepstral coefficients: `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, the length of each channel of the cepstral coefficients output is the

same as the length of each channel of the input LPC coefficients. The default is `Property`.

CepstrumLength

Number of output cepstral coefficients

Set the length of the output cepstral coefficients vector as a scalar numeric integer. This property applies when you set the `CepstrumLengthSource` property to `Property`. The default is `10`.

NonUnityFirstCoefficientAction

LPC coefficent nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not `1`. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

clone	Create LPC to cepstral object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Cepstral coefficients from columns of input LPC coefficients

Examples

Convert the linear prediction coefficients (LPC) to cepstral coefficients:

```
hlevinson = dsp.LevinsonSolver;
hlevinson.AOutputPort = true; % Output polynomial coefficients
hac = dsp.Autocorrelator;
```

```
hac.MaximumLagSource = 'Property';
hac.MaximumLag = 9; % Compute autocorrelation lags between [0:9]
hlpc2cc = dsp.LPCToCepstral;
x = [1:100]';
a = step(hac, x);
A = step(hlevinson, a); % Compute LPC coefficients
CC = step(hlpc2cc, A); % Convert LPC to CC.
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from Cepstral Coefficients block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to `LPCs to cepstral coefficients`.

See Also

`dsp.CepstralToLPC` | `dsp.LPCToLSF` | `dsp.LPCToRC`

Purpose

Create LPC to cepstral object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `LPCToCepstral` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

dsp.LPCToCepstral.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, from the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.LPCToCepstral.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LPCToCepstral` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.LPCToCepstral.step

Purpose

Cepstral coefficients from columns of input LPC coefficients

Syntax

```
CC = step(H,A)
CC = step(H,A,P)
```

Description

`CC = step(H,A)` computes the cepstral coefficients, `CC`, from the columns of input linear prediction coefficients, `A`. The object assumes the prediction error power is `1`.

`CC = step(H,A,P)` when you set the `PredictionErrorInputPort` property to `true`, computes the cepstral coefficients, `CC`, from the columns of input linear prediction coefficients, `A`. This conversion uses `P` as the prediction error power.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Convert linear prediction coefficients to line spectral frequencies

Description

The `LPCToLSF` object converts linear prediction coefficients to line spectral frequencies.

To convert LPC to LSF:

1. Define and set up your LPC to LSF converter. See "Construction" on page 3-969.
2. Call `step` to convert LPC according to the properties of `dsp.LPCToLSF`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LPCToLSF` returns a System object, `H`, that converts linear prediction coefficients (LPCs) to line spectral frequencies (LSFs).

`H = dsp.LPCToLSF('PropertyName',PropertyValue,...)` returns an `LPC` to `LSF` System object, `H`, with each specified property set to the specified value.

Properties

NumCoarseGridPoints

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, `n`, used for finding line spectral pairs (LSP) values as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (–1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. To compute LSF outputs, the object computes the arc cosine of the LSPs, outputting values ranging from 0 to pi radians. The object divides the interval (–1, 1) into n subintervals and looks for roots in each subinterval. If you set *n* too small in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is `64`. This property is tunable.

NumBisects

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, `k`, used in the Chebyshev polynomial root finding method, where each line spectral pair (LSP) output is within

$$\frac{1}{(n \cdot 2^k)}$$

of the actual LSP value. Here n is the value of the `NumCoarseGridPoints` property, and the object searches a maximum of $k \cdot (n-1)$ points for finding the roots. You must set the `NumBisects` property value k, to a positive scalar integer. The default is `4`. This property is tunable.

ExceptionOutputPort

Produces output with validity status of LSF output

Set this property to `true` to return a second output that indicates whether the computed LSF values are valid. The output is a vector with a length equal to the number of channels. A logical value of `1` indicates valid output. A logical value of `0` indicates invalid output. The LSF outputs are invalid when the object fails to find all the LSF values or when the input LPCs are unstable. The default is `false`.

OverwriteInvalidOutput

Enable overwriting invalid output with previous output

Specify the action that the System object should take for invalid LSF outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object does not take any action on invalid outputs and ignores the outputs.

FirstOutputValuesSource

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies when you

set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When you set this property to `Auto`, the object uses a default value for the first output. The default value corresponds to the LSF representation of an allpass filter.

FirstOutputValues

Value of the first output

Specify a numeric vector of LSF values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, you can set this property to a matrix with the same number of channels as the input, or one vector that is applied to every channel. The default is an empty vector. This property applies when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not `1`

Specify the action the object takes when the first coefficient of each channel of the LPC input is not `1` as `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

clone	Create LPC To LSF object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes

reset	Reset values for overwriting invalid outputs to their initial values
step	Convert LPC coefficients to line spectral frequencies

Examples

Convert to linear prediction coefficients to line spectral frequencies:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
hlpc2lsf = dsp.LPCToLSF;
y = step(hlpc2lsf, a); % Convert to LSF coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Output** block parameter. The object only supports LSF outputs in the range $(0, \prod)$

See Also

`dsp.LSFToLPC` | `dsp.LPCToLSP`

Purpose

Create LPC To LSF object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `LPCToLSF` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.LPCToLSF.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.LPCToLSF.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LPCToLSF` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.LPCToLSF.reset

Purpose

Reset values for overwriting invalid outputs to their initial values

Syntax

```
reset(H)
```

Description

`reset(H)` resets the values for overwriting the invalid outputs to their initial values.

Purpose

Convert LPC coefficients to line spectral frequencies

Syntax

```
LSF = step(H,A)
[..., STATUS] = step(H,A)
```

Description

`LSF = step(H,A)` converts the `LPC` coefficients, `A` , to line spectral frequencies, `LSF`, in the range (0 pi). The System object operates along the columns of the input `A`.

`[..., STATUS] = step(H,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LPCToLSP

Purpose

Convert linear prediction coefficients to line spectral pairs

Description

The `LPCToLSP` object converts linear prediction coefficients to line spectral pairs.

To convert LPC to LSP:

1. Define and set up your LPC to LSP converter. See "Construction" on page 3-980.
2. Call `step` to convert LPC according to the properties of `dsp.LPCToLSP`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LPCToLSP` returns a System object, `H`, that converts linear prediction coefficients (LPCs) to line spectral pairs (LSPs).

`H = dsp.LPCToLSP('PropertyName',PropertyValue,...)` returns an `LPC` to `LSF` System object, `H`, with each specified property set to the specified value.

Properties

NumCoarseGridPoints

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, *n*, used for finding line spectral pairs (LSP) values, as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (–1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. The object divides the interval (–1, 1) into *n* subintervals and looks for roots in each subinterval. If *n* is set to too small a number in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is `64`. This property is tunable.

NumBisects

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, *k*, that the Chebyshev polynomial uses in the root finding method. For each line spectral pair (LSP) the output is within

$$\frac{1}{n \cdot 2^k}$$

of the actual LSP value. Here *n* is the value of the `NumCoarseGridPoints` property and the object searches a maximum of

$$k \cdot (n-1)$$

points for finding the roots. The `NumBisects` property value *k*, must be a positive scalar integer. The default is `4`. This property is tunable.

ExceptionOutputPort

Produces output with validity status of LSP output

Set this property to `true` to return a second output that indicates whether the computed LSP values are valid. The object outputs a vector length equal to the number of channels. A logical value of `1` indicates the output is valid. A logical value of `0` indicates the output is invalid. The LSP outputs are invalid when the object fails to find all the LSP values or when the input LPCs are unstable. The default is `false`.

OverwriteInvalidOutput

Enable overwriting invalid output with previous output

Specify the action that the object takes for invalid LSP outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object takes no action on invalid outputs and ignores the outputs.

FirstOutputValuesSource

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies only when you set the `OverwriteInvalidOutput` property to `true`. The default is `Auto`. When this property is `Auto`, the object uses a default value for the first output. The default value corresponds to the LSP representation of an allpass filter.

FirstOutputValues

Value of first output

Specify a numeric vector of LSP values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, set this property can to a matrix with the same number of channels as the input or one vector that you apply to every channel. The default is an empty vector. This property applies only when you set the `OverwriteInvalidOutput` property to `true` and the `FirstOutputValuesSource` property to `Property`.

NonUnityFirstCoefficientAction

First coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not equal to `1`. Specify as one of `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

clone	Create LPC To LSP object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset values for overwriting invalid outputs to their initial values
step	Convert linear prediction coefficients to line spectral pairs

Examples

Convert the LPC coefficients to LSP coefficients:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
hlpc2lsp = dsp.LPCToLSP;
y = step(hlpc2lsp, a); % Convert to LSP coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to LSF/LSP Conversion block reference page. The object properties correspond to the block parameters, except:

No object property corresponds to the **Output** block parameter. The object only supports LSP outputs.

See Also

`dsp.LSPToLPC` | `dsp.LPCToLSF`

dsp.LPCToLSP.clone

Purpose

Create LPC To LSP object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `LPCToLSP` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LPCToLSP.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LPCToLSP` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LPCToLSP.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset values for overwriting invalid outputs to their initial values

Syntax

```
reset(H)
```

Description

`reset(H)` resets the values for overwriting the invalid outputs to their initial values.

dsp.LPCToLSP.step

Purpose

Convert linear prediction coefficients to line spectral pairs

Syntax

```
LSF = step(H,A)
[..., STATUS] = step(H,A)
```

Description

`LSF = step(H,A)` converts the `LPC` coefficients, `A` , to line spectral pairs normalized in the range (–1 1), `LSP`. The object operates along the columns of the input `A`.

`[..., STATUS] = step(H,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Convert linear prediction coefficients to reflection coefficients

Description

The `LPCToRC` object converts linear prediction coefficients to reflection coefficients.

To convert LPC to reflection coefficients:

1. Define and set up your LPC to RC converter. See "Construction" on page 3-991.
2. Call `step` to convert LPC according to the properties of `dsp.LPCToRC`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LPCToRC` returns an LPC to RC System object, `H`, that converts linear prediction coefficients (LPC) to reflection coefficients (RC).

`H = dsp.LPCToRC('PropertyName',PropertyValue,...)` returns an LPC to RC conversion object, `H`, with each specified property set to the specified value.

Properties

PredictionErrorOutputPort

Enable normalized prediction error power output

Set this property to `true` to return the normalized error power as a vector with one element per input channel. Each element varies between zero and one. The default is `true`.

ExceptionOutputPort

Produces output with stability status of filter represented by LPC coefficients

Set this property to `true` to return the stability status of the filter. A logical value of `1` indicate a stable filter. A logical value of `0` indicate an unstable filter. The default is `false`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

clone	Create LPC to RC object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert columns of linear prediction coefficients to reflection coefficients

Examples

Convert the linear prediction coefficients to reflection coefficients:

```
load mtlb

hlevinson = dsp.LevinsonSolver;
hlevinson.AOutputPort = true;
hlevinson.KOutputPort = false;

hac = dsp.Autocorrelator;
hlpc2rc = dsp.LPCToRC;
hac.MaximumLagSource = 'Property';

% Compute autocorrelation for lags between [0:10]
hac.MaximumLag = 10;
a = step(hac, mtlb);
A = step(hlevinson, a); % Compute LPC coefficients
```

```
[K, P] = step(hlpc2rc, A); % Convert to RC
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from RC block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.
- The `NonUnityFirstCoefficientAction` object property corresponds to the **If first input value is not 1** block parameter. There is neither a `Normalize and warn` nor an `Error` option for the object.

See Also

`dsp.RCToLPC` | `dsp.LPCToAutocorrelation`

dsp.LPCToRC.clone

Purpose

Create LPC to RC object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `LPCToRC` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LPCToRC.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LPCToRC` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LPCToRC.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Convert columns of linear prediction coefficients to reflection coefficients

Syntax

```
[K,P] = step(H,A)
K = step(H,A)
[..., S] = step(H,A)
```

Description

`[K,P] = step(H,A)` converts the columns of linear prediction coefficients, `A`, to reflection coefficients `K` and outputs the normalized prediction error power, `P`.

`K = step(H,A)` when you set the `PredictionErrorOutputPort` property to `false`, converts the columns of linear prediction coefficients, `A`, to reflection coefficients `K`.

`[..., S] = step(H,A)` also outputs the `LPC` filter stability, `S`, when you set the `ExceptionOutputPort` property to `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LSFToLPC

Purpose

Convert line spectral frequencies to linear prediction coefficients

Description

The `LSFToLPC` object converts line spectral frequencies to linear prediction coefficients.

To convert LSF to LPC:

1. Define and set up your LSF to LPC converter. See "Construction" on page 3-1000.
2. Call `step` to convert LSF according to the propeties of `dsp.LSFToLPC`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LSFToLPC` returns an LSF to LPC System object, `H`, which converts line spectral frequencies (LSFs) to linear prediction coefficients (LPCs).

Methods

clone	Create LSF to LPC object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert input line spectral frequencies to linear prediction coefficients

Examples

Convert line spectral frequencies to linear prediction coefficients:

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]'
```

```
hlpc2lsf = dsp.LPCToLSF;
ylsf = step(hlpc2lsf, a);
hlsf2lpc = dsp.LSFToLPC;
ylpc = step(hlsf2lpc, ylsf) % Check values are same as a.
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LSF/LSP to LPC Conversion block reference page. The object properties correspond to the block parameters, except:

The object does not have a property that corresponds to the **Input** block parameter. The object's behavior corresponds to the block's behavior when you set the **Input** parameter to `LSF in range (0 pi)`.

dsp.LSFToLPC.clone

Purpose

Create LSF to LPC object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `LSFToLPC` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LSFToLPC.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LSFToLPC` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LSFToLPC.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Convert input line spectral frequencies to linear prediction coefficients

Syntax

```
A = step(H,LSF)
```

Description

`A = step(H,LSF)` converts the input line spectral frequencies, (LSF), in the range `(0,pi)`, `LSF` , to linear prediction coefficients, `A`. The input can be a vector or a matrix, where each column of the matrix is treated as a separate channel.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LSPToLPC

Purpose

Convert line spectral pairs to linear prediction coefficients

Description

The `LSPToLPC` object converts line spectral pairs to linear prediction coefficients.

To convert LSP to LPC:

1. Define and set up your LSP to LPC converter. See "Construction" on page 3-1008.
2. Call `step` to convert LSP according to the properties of `dsp.LSPToLPC`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LSPToLPC` returns an LSP to LPC System object, `H`, which converts line spectral pairs (LSPs) to linear prediction coefficients (LPCs).

Methods

clone	Create LSP to LPC object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert input line spectral pairs to linear prediction coefficients

Examples

Convert line spectral pairs to linear prediction coefficients:

```
ylsp = [0.7080 0.0103 -0.3021 -0.3218 -0.7093]';
hlsp2lpc = dsp.LSPToLPC;
```

```
ylpc = step(hlsp2lpc, ylsp)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LSF/LSP to LPC Conversion block reference page. The object properties correspond to the block parameters, except:

No object property corresponds to the **Input** block parameter. The object converts LSP in the range (–1, 1) to LPC.

`dsp.LPCToLSP` | `dsp.LSFToLPC`

dsp.LSPToLPC.clone

Purpose

Create LSP to LPC object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `LSPToLPC` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LSPToLPC.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LSPToLPC` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LSPToLPC.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Convert input line spectral pairs to linear prediction coefficients

Syntax

```
A = step(H,LSP)
```

Description

`A = step(H,LSP)` converts the input line spectral pairs in the range (–1,1), `LSP`, to linear prediction coefficients, `A`. The input can be a vector or a matrix, where each column of the matrix is treated as a separate channel.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LUFactor

Purpose

Factor square matrix into lower and upper triangular matrices

Description

The `LUFactor` object factors a square matrix into lower and upper triangular matrices.

To factor a square matrix into lower and upper triangular matrices:

1. Define and set up your System object. See "Construction" on page 3-1016.
2. Call `step` to factor the square matrix according to the properties of `dsp.LUFactor`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.LUFactor` returns an `LUFactor` System object, `H`, which factors a row permutation of a square input matrix `A` as $A_p = L \cdot U$, where `L` is the unit-lower triangular matrix, and `U` is the upper triangular matrix. The row-pivoted matrix A_p contains the rows of A permuted as indicated by the permutation index vector P. The equivalent MATLAB code is `Ap = A(P,:)`.

`H = dsp.LUFactor('PropertyName',PropertyValue,...)` returns an `LUFactor` object, `H`, with each specified property set to the specified value.

Properties

ExceptionOutputPort

Set to `true` to output singularity of input

Set this property to `true` to output the singularity of the input as logical data type values of `true` or `false`. An output of `true` indicates that the current input is singular, and an output of `false` indicates the current input is nonsingular.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `|Ceiling|Convergent|Floor|Nearest |Round | Simplest | Zero|`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create LU Factor object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Decompose matrix into lower and upper triangular matrices

Examples

Decompose a square matrix into the lower and upper components:

```
hlu = dsp.LUFactor;
x = rand(4)
[LU, P] = step(hlu, x);
L = tril(LU,-1)+diag(ones(size(LU,1),1));
U = triu(LU);
y = L*U
```

```
% Check back whether this equals the permuted x
xp = x(P,:)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LU Factorization block reference page. The object properties correspond to the block parameters.

See Also

`dsp.LDLFactor`

dsp.LUFactor.clone

Purpose

Create LU Factor object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `LUFactor` object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, of the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.LUFactor.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `LUFactor` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.LUFactor.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Decompose matrix into lower and upper triangular matrices

Syntax

```
[LU,P] = step(H,A)
[LU,P,S] = step(H,A)
```

Description

`[LU,P] = step(H,A)` decomposes the matrix `A` into lower and uppper triangular matrices. The output `LU` is a composite matrix with lower triangle elements from `L` and upper triangle elements from `U` . The permutation vector `P` is the second output.

`[LU,P,S] = step(H,A)` returns an additional output `S` indicating if the input is singular when the `ExceptionOutputPort` property is set to `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

.

dsp.MatFileReader

Purpose

Read MAT file

Description

The `MatFileReader` object reads V7.3 MAT files.

To read V7.3 MAT files:

1. Define and set up your System object. See "Construction" on page 3-1026.
2. Call `step` to read the MAT file according to the properties of `dsp.MatFileReader`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.MatFileReader` returns a System object, `H`, to read data from a V7.3 MAT file.

`H = dsp.MatFileReader('PropertyName',PropertyValue,...)` returns a MAT file reader System object, `H`, with each specified property set to the specified value.

`H = dsp.MatFileReader(FILENAME,VARIABLENAME'PropertyName', PropertyValue,...)` returns a MAT file reader System object, `H`, with the `Filename` property set to *`FILENAME`*, the `VariableName` property set to *`VARIABLENAME`*, and other specified properties set to the specified values.

Properties

Filename

Name of MAT file from which to read

Specify the name of a MAT file as a string. Specify the full path for the file only if the file is not on the MATLAB path. The default file name is `Untitled.mat`.

VariableName

Name of the variable to read

Name of the variable stored in and read from the MAT file. The default variable name is `x`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

SamplesPerFrame

Number of samples per output frame

Specify the number of elements to read from the MAT file each time the `step` method is called. This property applies when `FrameBaseProcessing` is `true`. The default number of samples per frame is `1`.

Methods

clone	Create MAT file reader object with same property values
isDone	End-of-file status
isLocked	Locked status (logical) for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of multimedia file reader to read from beginning of file
step	Read data from a variable in the MAT file

Examples

Use `dsp.MatFileReader` and `dsp.MatFileWriter` to stream data.

```
filename = [tempname '.mat'];  % Create variable name

originalData = rand(40,2);
```

```
save(filename,'originalData','-v7.3'); % Write to MAT file

H = dsp.MatFileReader(filename,'VariableName',...
   'originalData','SamplesPerFrame', 4);
while ~isDone(H)         % Stream data into MATLAB
    finalData = step(H);
end
```

See Also

dsp.MatFileWriter

Purpose

Create MAT file reader object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `MatFileReader` System object `C`, with the same property values as `H`.

The clone method creates a new unlocked object with uninitialized states.

dsp.MatFileReader.isLocked

Purpose

Locked status (logical) for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `MatFileReader` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

End-of-file status

Syntax

```
STATUS = isDone(H)
```

Description

`STATUS = isDone(H)` returns a logical value, `STATUS`. When the `MatFileReader` object, `H` , reaches the end of the MAT file, `STATUS` is `true`.

dsp.MatFileReader.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of multimedia file reader to read from beginning of file

Syntax

```
reset(H)
```

Description

`reset(H)` resets the `MatFileReader` object to read from the beginning of the file.

dsp.MatFileReader.step

Purpose

Read data from a variable in the MAT file

Syntax

```
X = step(H)
```

Description

`X = step(H)` reads data, `X`, from a variable stored in a MAT-file. The variable is assumed to be *N*-dimensional and a MATLAB built-in datatype. If the `FrameBasedProcessing` property is `true`, the data is read into MATLAB by reading along the first dimension. If `FrameBasedProcessing` is `false`, the data is read into MATLAB along the last dimension.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Write MAT file

Description

The `MatFileWriter` object writes data to a V7.3 MAT file.

To write data to a V7.3 MAT file:

1. Define and set up your System object. See "Construction" on page 3-1035.
2. Call `step` to write data according to the properties of `dsp.MatFileWriter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.MatFileWriter` returns a MAT file writer System object, `H`, that writes data to a V7.3 MAT file.

`H = dsp.MatFileWriter('PropertyName',PropertyValue,...)` returns a MAT file writer System object, `H`, with each specified property set to the specified value.

`H = dsp.MatFileWriter(FILENAME,'PropertyName',PropertyValue,...)` returns a MAT file writer System object, `H`, with `Filename` property set to *`FILENAME`* and other specified properties set to the specified values.

Properties

Filename

Name of MAT file to write

Specify the name of a MAT file as a string. Specify the full path for the file only if the file is not on the MATLAB path. The default file name is `Untitled.mat`.

VariableName

Name of the variable to write

Name of the variable to which to write. This variable is stored in the MAT file. The default variable name is `x`. You cannot overwrite a variable that is already in an existing MAT file.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. In frame-based mode, this System object streams the data to the first dimension. In sample-based mode, a new dimension is appended to the end of the data set. The default is `true`.

Methods

clone	Create MAT file writer object with the same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Write one frame of MAT file data

Examples

Use `dsp.MatFileWriter` and `dsp.MatFileReader` to stream data.

```
% First, create a variable name
      filename = [tempname '.mat'];

% Next, write that variable to a MAT-file.
      hmfw = dsp.MatFileWriter(filename, 'VariableName', 'originalData')
      for i=1:10
          originalData = rand(4,2);
          step(hmfw, originalData);
      end
      release(hmfw); % This will close the MAT file

% Finally, load the variable back into MATLAB.
      data = load(filename, 'originalData');
```

See Also

`dsp.MatFileReader`

Purpose

Create MAT file writer object with the same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `MatFileWriter` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.MatFileWriter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `MatFileWriter` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. `release` also closes the file. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.MatFileWriter.step

Purpose

Write one frame of MAT file data

Syntax

```
step(H,X)
```

Description

`step(H,X)` writes one frame of data, `X` , to the variable stored in the MAT file. The variable is assumed to be N-dimensional and a MATLAB built-in data type. If the `FrameBasedProcessing` property is `true`, the data is written to the file by concatenating along the first dimension. If `FrameBasedProcessing` is `false`, the data is written by appending an additional dimension to the end of the data set.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Find maximum value of input or sequence of inputs

Description

The `Maximum` object finds the maximum values of an input or sequence of inputs.

To compute the maximum value of an input or sequence of inputs:

1. Define and set up your System object. See "Construction" on page 3-1041.
2. Call `step` to find the maximum according to the properties of `dsp.Maximum`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Maximum` returns an object, `H`, that computes the value and index of the maximum elements in an input or a sequence of inputs along the specified `Dimension`.

`H = dsp.Maximum('PropertyName',PropertyValue,...)` returns a maximum-finding object, `H`, with each specified property set to the specified value.

Properties

ValueOutputPort

Output maximum value

Set this property to `true` in order to output the maximum of the input. This property applies only when you set the `RunningMaximum` property to false. The default is `true`.

RunningMaximum

Calculate over single input or multiple inputs

When you set this property to `true`, the object computes the maximum value over successive calls to the `step` method. When you set this property to `false`, the object computes the maximum value over the current input. The default is `false`.

IndexOutputPort

Output index of maximum value

Set this property to `true` to output the index of the maximum value of the input. This property applies only when you set the `RunningMaximum` property to `false`. The default is `true`.

ResetInputPort

Additional input to enable resetting of running maximum

Set this property to `true` to enable resetting the running maximum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running maximum. This property applies only when you set the `RunningMaximum` property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running maximum

Specify the event that resets the running maximum as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

IndexBase

Numbering base for index of maximum value

Specify whether to start the index numbering from `One` or `Zero` when computing the index of the maximum value. This property applies only when you set the `IndexOutputPort` property to `true`. The default is `One`.

Dimension

Dimension to operate along

Specify how the maximum calculation is performed over the data as one of `| All | Row | Column | Custom |`. This property applies when you set the `RunningMaximum` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the maximum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

Enable region-of-interest processing

Set this property to `true` to enable calculation of the maximum value within a particular region of an image. This property applies when you set the `Dimension` property to `All` and the `RunningMaximum` property to `false`. The default is `false`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

ROIForm

Type of region of interest

Specify the type of region of interest as one of `| Rectangles | Lines | Label matrix | Binary mask |`. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as `Rectangles`.

ROIPortion

Calculate over entire ROI or just perimeter

Specify whether to calculate the maximum over the `Entire ROI` or the `ROI perimeter`. This property applies only when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate `Individual statistics for each ROI` or a `Single statistic for all ROIs`. This property applies only when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`.

ValidityOutputPort

Output flag indicating if any part of ROI is outside input image

When you set the `ROIForm` property to one of `| Lines | Rectangles |`, set this property to `true` to return the validity of the specified ROI being completely inside of the image. When you set the `ROIForm` property to `Label Matrix`, set this property to `true` to return the validity of the specified label numbers. The default is `false`.

FrameBasedProcessing

Process input as frames or samples

Set this property to `true` to enable frame-based processing for 2-D inputs. Set this property to `false` to enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than `2`. This property applies when you set the `RunningMaximum` to `true`. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | `Same as product` | `Same as input` | `Custom` |. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

Methods

clone	Create maximum-finding object with same property values
getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset computation of running maximum
step	Maximum value

Examples

Find a maximum value and its index:

```
hmax1 = dsp.Maximum;
x = randn(100,1);
[y, I] = step(hmax1, x);
```

Compute a running maximum:

```
hmax2 = dsp.Maximum;
hmax2.RunningMaximum = true;
x = randn(100,1);
y = step(hmax2, x);
% y(i) is the maximum of all values in the vector x(1:i)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Maximum block reference page. The object properties correspond to the block parameters, except:

Treat sample-based row input as a column block parameter is not supported by the `dsp.Maximum` object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input**

processing parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

See Also

`dsp.Minimum` | `dsp.Mean`

dsp.Maximum.clone

Purpose

Create maximum-finding object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `Maximum` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Maximum.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `Maximum` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Maximum.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset computation of running maximum

Syntax

```
reset(H)
```

Description

`reset(H)` resets the computation of the running maximum for the `Maximum` object `H`.

dsp.Maximum.step

Purpose

Maximum value

Syntax

```
[VAL,IND] = step(H,X)
VAL = step(H,X)
IND = step(H,X)
VAL = step(H,X,R)
[...] = step(H,I,ROI)
[...] = step(H,I,LABEL,LABELNUMBERS)
[...,FLAG] = step(H,I,ROI)
[...,FLAG] = step(H,I,LABEL,LABELNUMBERS)
```

Description

`[VAL,IND] = step(H,X)` returns the maximum value, `VAL`, and the index or position of the maximum value, `IND`, along the specified `Dimension` of `X`.

`VAL = step(H,X)` returns the maximum value, `VAL`, of the input `X`. When the `RunningMaximum` property is `true`, `VAL` corresponds to the maximum value over successive calls to the `step` method.

`IND = step(H,X)` returns the zero- or one-based index `IND` of the maximum value. To enable this type of processing, set the `IndexOutputPort` property to `true` and the `ValueOutputPort` and `RunningMaximum` properties to `false`.

`VAL = step(H,X,R)` resets the state of `H` based on the value of reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMaximum` property to `true` and the `ResetInputPort` property to `true`.

`[...] = step(H,I,ROI)` computes the maximum of an input image, `I`, within the given region of interest, `ROI`. To enable this type of processing, set the `ROIProcessing` property to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[...] = step(H,I,LABEL,LABELNUMBERS)` computes the maximum of an input image, `I`, for a region whose labels are specified in the vector `LABELNUMBERS`. To enable this type of processing, set the `ROIProcessing` property to `true` and the `ROIForm` property to `Label matrix`.

`[...,FLAG] = step(H,I,ROI)` returns `FLAG`, indicating whether the given region of interest is within the image bounds. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[...,FLAG] = step(H,I,LABEL,LABELNUMBERS)` returns `FLAG`, indicating whether the input label numbers are valid. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Label matrix`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Mean

Purpose

Find mean value of input or sequence of inputs

Description

The `Mean` object finds the mean of an input or sequence of inputs.

To compute the mean of an input or sequence of inputs:

1. Define and set up your System object. See "Construction" on page 3-1056.
2. Call `step` to compute the mean according to the properties of `dsp.Mean`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Mean` returns an object, `H`, that computes the mean of an input or a sequence of inputs.

`H = dsp.Mean('PropertyName',PropertyValue,...)` returns a mean-finding object, `H`, with each specified property set to the specified value.

Properties

RunningMean

Calculate over single input or multiple inputs

When you set this property to `true`, the object calculates the mean over successive calls to the `step` method. When you set this property to `false`, the object computes the mean over the current input. The default is `false`.

ResetInputPort

Additional input to enable resetting of running mean

Set this property to `true` to enable resetting of the running mean. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running mean. This property applies only when you set the `RunningMean` property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running mean

Specify the event that resets the running maximum as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

Dimension

Dimension to operate along

Specify how the mean calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMean` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension, indexed from one, of the input signal over which the object calculates the mean. The value cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

Enable region-of-interest processing

Set this property to `true` to enable calculation of the mean within a particular region of an image. This property applies when you set the `Dimension` property to `All` and the `RunningMean` property to `false`. The default is `false`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

ROIForm

Type of region of interest

Specify the type of region of interest as one of `| Rectangles | Lines | Label matrix |`. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as `Rectangles`.

ROIPortion

Calculate over entire ROI or just perimeter

Specify whether to calculate the mean over the `Entire ROI` or the `ROI perimeter`. This property applies only when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate `Individual statistics for each ROI` or a `Single statistic for all ROIs`. This property applies only when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`. The default is `Individual statistics for each ROI`.

ValidityOutputPort

Output flag indicating if any part of ROI is outside input image

When you set the `ROIForm` property to one of `| Lines | Rectangles | Binary mask |`, set this property to `true` to return the validity of the specified ROI being completely inside of the image. When you set the `ROIForm` property to `Label Matrix`, set this property to `true` to return the validity of the specified label numbers. The default is `false`.

FrameBasedProcessing

Process input as frames or samples

Set this property to `true` to enable frame-based processing for 2-D inputs. Set this property to `false` to enable sample-based

processing. The object always performs sample-based processing for N-D inputs where N is greater than 2. This property applies when you set the RunningMean to true. The default is true.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType property to Custom. The default is numerictype([],32,30).

OutputDataType

Data type of output

Specify the output fixed-point data type as one of | Same as accumulator | Same as input | Custom |. The default is Same as accumulator.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],32,30)`.

Methods

clone	Create mean object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of mean-finding object
step	Mean value

Examples

Compute the mean of a signal:

```
hmean1 = dsp.Mean;
x = randn(100,1);
y = step(hmean1, x);
```

Compute the running mean of a signal:

```
hmean2 = dsp.Mean;
hmean2.RunningMean = true;
x = randn(100,1);
```

```
  y = step(hmean2, x);
 % y(i) is the mean of all values in the vector x(1:i)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Mean block reference page. The object properties correspond to the block parameters, except:

Treat sample-based row input as a column block parameter is not supported by the `dsp.Mean` object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.Maximum` | `dsp.Minimum`

dsp.Mean.clone

Purpose

Create mean object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `Mean` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Mean.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `Mean` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Mean.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of mean-finding object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `Mean` object `H` to their initial values.

dsp.Mean.step

Purpose

Mean value

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
Y = step(H,X,ROI)
Y = step(H,X,LABEL,LABELNUMBERS)
[Y,FLAG] = step(H,X,ROI)
[Y,FLAG] = step(H,X,LABEL,LABELNUMBERS)
```

Description

`Y = step(H,X)` computes the mean of `X`. When you set the `RunningMean` property to `true`, `Y` corresponds to the mean successive calls to the `step` method.

`Y = step(H,X,R)` resets the computation of the running mean based on the value of the reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMean` property to `true` and the `ResetInputPort` property to `true`.

`Y = step(H,X,ROI)` computes the mean of input image `X` within the given region of interest `ROI`. To enable this type of processing, set the `ROIProcessing` property to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`Y = step(H,X,LABEL,LABELNUMBERS)` computes the mean of the input image, `X`, for the region whose labels are specified in the vector `LABELNUMBERS`. The regions are defined and labeled in the matrix `LABEL`. To enable this type of processing, set the `ROIProcessing` property to `true` and the `ROIForm` property to `Label matrix`.

`[Y,FLAG] = step(H,X,ROI)` returns `FLAG`, indicating whether the given region of interest `ROI`, is within the image bounds. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[Y,FLAG] = step(H,X,LABEL,LABELNUMBERS)` returns `FLAG` which indicates whether the input label numbers are valid. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Label matrix`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the value of this property as `Rectangles`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Median

Purpose

Median value of input

Description

The `Median` object computes the median value of the input. The object can compute the median along each dimension (row or column) of the input or of the entire input.

To compute the median of the input:

1. Define and set up your median System object. See "Construction" on page 3-1070.
2. Call `step` to compute the median according to the properties of `dsp.Median`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Median` returns a median System object, `H`, that computes the median along the columns of the input using the `Quick sort` sorting method.

`H = dsp.Median('PropertyName',PropertyValue,...)` returns a median System object, `H`, with each property set to the value you specify.

Properties

SortMethod

Sort method

Specify the method the object should use to sort the data before computing the median. You can specify `Quick sort` or `Insertion sort`. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting less than 32 elements. If you are using the `Median` object to generate code, you should use the insertion sort algorithm to prevent recursive function calls in your generated code. The default is `Quick sort`.

Dimension

Dimension to operate along

Specify the dimension along which the object computes the median values. You can specify one of | `All` | `Row` | `Column` | `Custom` |. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the dimension of the input signal (as a one-based value), over which the object computes the median. The cannot exceed the number of dimensions in the input signal. This property applies only when you set the `Dimension` property to `Custom`. The default is `1`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomProductDataType

Product word and fraction lengths

Specify the product data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when

you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as one of `| Same as product | Same as input | Custom |`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as one of `| Same as accumulator | Same as product | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the data type of the output as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create median object with same property values
getNumInputs	Number of expected inputs to step method

getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Median value

Examples

Compute the median value of the input column:

```
h = dsp.Median;
x = [7 -9 0 -1 2 0 3 5 -9]';
y = step(h, x)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Median block reference page. The object properties correspond to the block properties, except:

Treat sample-based row input as a column block parameter is not supported by the `dsp.Median` System object.

See Also

`dsp.Mean` | `dsp.Minimum` | `dsp.Maximum` | `dsp.Variance`

dsp.Median.clone

Purpose

Create median object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a median object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Median.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `Median` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Median.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Median value

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` computes the median value of the input `X` and returns the result in `Y`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Minimum

Purpose

Find minimum values of input or sequence of inputs

Description

The `Minimum` object finds the minimum value of an input or sequence of inputs.

To compute the minimum value of an input or sequence of inputs:

1. Define and set up your System object. See "Construction" on page 3-1080.
2. Call `step` to compute the minimum according to the properties of `dsp.Minimum`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Minimum` returns an object, `H`, that computes the value and/or index of the minimum elements in an input or a sequence of inputs over the specified `Dimension`.

`H = dsp.Minimum('PropertyName',PropertyValue,...)` returns a minimum-finding object, `H`, with each specified property set to the specified value.

Properties

ValueOutputPort

Output minimum value

Set this property to `true` in order to output the minimum value of the input. This property applies only when you set the`RunningMinimum` property to false. The default is `true`.

RunningMinimum

Calculate over single input or multiple inputs

When you set this property to `true`, the object computes the minimum value over successive calls to the `step` method. When you set this property to `false`, the object computes the minimum value over the current input. The default is `false`.

IndexOutputPort

Output index of minimum value

Set this property to `true` to output the index of the minimum value of the input. This property applies only when you set the `RunningMinimum` property to `false`. The default is `true`.

ResetInputPort

Additional input to enable resetting of running minimum

Set this property to `true` to enable resetting of the running minimum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running minimum. This property applies only when you set the `RunningMinimum` property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running minimum

Specify the event that resets the running minimum as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

IndexBase

Numbering base for index of minimum value

Specify the numbering used when computing the index of the minimum value as starting from either `One` or `Zero`. This property applies only when you set the `IndexOutputPort` property to `true`. The default is `One`.

Dimension

Dimension to operate along

Specify how the minimum calculation is performed over the data as one of `| All | Row | Column | Custom |`. This property applies when you set the `RunningMinimum` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the minimum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

Enable region-of-interest processing

Set this property to `true` to enable calculation of the minimum value within a particular region of an image. This property applies when you set the `Dimension` property to `All` and the `RunningMinimum` property to `false`. The default is `false`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you only have the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

ROIForm

Type of region of interest

Specify the type of region of interest as one of `| Rectangles | Lines | Label matrix | Binary mask |`. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the as `Rectangles`.

ROIPortion

Calculate over entire ROI or just perimeter

Specify whether to calculate the minimum over the `Entire ROI` or the `ROI perimeter`. This property applies only when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Calculate statistics for each ROI or one for all ROIs

Specify whether to calculate `Individual statistics for each ROI` or a `Single statistic for all ROIs`. This property applies only when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`.

ValidityOutputPort

Output flag indicating if any part of ROI is outside input image

When you set the `ROIForm` property to `Lines` or `Rectangles`, set this property to `true` to return the validity of the specified ROI being completely inside of the image. When you set the `ROIForm` property to `Label Matrix`, set this property to `true` to return the validity of the specified label numbers. The default is `false`.

FrameBasedProcessing

Process input as frames or samples

Set this property to `true` to enable frame-based processing for 2-D inputs. Set this property to `false` to enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than `2`. This property applies when you set the `RunningMinimum` to `true`. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | `Same as product` | `Same as input` | `Custom` |. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

Methods

clone	Create minimum-finding object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of minimum-finding object
step	Operate on inputs to calculate outputs

Examples

Find a minimum value and its index:

```
hmin1 = dsp.Minimum;
x = randn(100,1);
[y, I] = step(hmin1, x);
```

Compute a running minimum:

```
hmin2 = dsp.Minimum;
hmin2.RunningMinimum = true;
x = randn(100,1);
y = step(hmin2, x);
% y(i) is the minimum of all values in the vector x(1:i)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Minimum block reference page. The object properties correspond to the block parameters, except:

> **Treat sample-based row input as a column** block parameter is not supported by the `dsp.Minimum` object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input**

processing parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

See Also

`dsp.Maximum` | `dsp.Mean`

Purpose

Create minimum-finding object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `Minimum` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.Minimum.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.Minimum.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `Minimum` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Minimum.reset

Purpose

Reset internal states of minimum-finding object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `Minimum` object `H` to their initial values.

Purpose

Operate on inputs to calculate outputs

Syntax

```
[VAL,IND] = step(H,X)
VAL = step(H,X)
IND = step(H,X)
VAL = step(H,X,R)
[...] = step(H,I,ROI)
[...] = step(H,I,LABEL,LABELNUMBERS)
[...,FLAG] = step(H,I,ROI)
[...,FLAG] = step(H,I,LABEL,LABELNUMBERS)
```

Description

`[VAL,IND] = step(H,X)` returns the minimum value, `VAL`, and the index or position of the minimum value, `IND`, along the specified `Dimension` of `X`.

`VAL = step(H,X)` returns the minimum value, `VAL`, of the input `X`. When the `RunningMinimum` property is `true`, `VAL` corresponds to the minimum value over successive calls to the `step` method.

`IND = step(H,X)` returns the zero- or one-based index `IND` of the minimum value when the `IndexOutputPort` property is `true` and the `ValueOutputPort` property is `false`. You must set the `RunningMinimum` property to `false` to use this syntax.

`VAL = step(H,X,R)` resets the state of `H` based on the value of reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMinimum` property to `true` and the `ResetInputPort` property to `true`.

`[...] = step(H,I,ROI)` computes the minimum of an input image, `I`, within the given region of interest, `ROI`. To enable this type of processing, set the `ROIProcessing` property to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[...] = step(H,I,LABEL,LABELNUMBERS)` computes the minimum of an input image, `I`, for a region whose labels are specified in the vector `LABELNUMBERS`. This property applies only when you set the `ROIProcessing` property to `true` and the `ROIForm` property to `Label matrix`.

`[...,FLAG] = step(H,I,ROI)` returns `FLAG`, indicating hether the given region of interest is within the image bounds. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Lines`, `Rectangles` or `Binary mask`.

`[...,FLAG] = step(H,I,LABEL,LABELNUMBERS)` returns `FLAG`, indicating whether the input label numbers are valid. To enable this type of processing, set the `ROIProcessing` and `ValidityOutputPort` properties to `true` and the `ROIForm` property to `Label matrix`.

For full ROI processing support, install the Computer Vision System Toolbox product. If you have only the DSP System Toolbox product installed, you can only specify the value of the `ROIForm` property as `Rectangles`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Read video frames, audio samples, or both from multimedia file

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader`.

Description

The `MultimediaFileReader` object reads video frames, audio samples, or both from a multimedia file.

To read video frames, audio samples, or both from a multimedia file:

1. Define and set up your multimedia file reader. See "Construction" on page 3-1095.
2. Call `step` to read from a multimedia file according to the properties of `signalblks.MultimediaFileReader`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = signalblks.MultimediaFileReader` returns a multimedia file reader System object, `H`, to read video and/or audio from a multimedia file.

`H = signalblks.MultimediaFileReader('PropertyName',PropertyValue,...)` returns a multimedia file reader System object, `H`, with each specified property set to the specified value.

`H = signalblks.MultimediaFileReader(FILENAME,'PropertyName', PropertyValue,...)` returns a multimedia file reader System object, `H`, with `Filename` property set to *`FILENAME`* and other specified properties set to the specified values.

Properties

Filename

Name of multimedia file from which to read

Specify the name of a multimedia file as a string. Specify the full path for the file only if the file is not on the MATLAB path.

On UNIX platforms, the multimedia file reader only supports uncompressed AVI files. The default is `speech_dft.avi`.

PlayCount

Number of times to play file

Specify a positive integer or `inf` to represent the number of times to play the file. The default is `inf`.

AudioOutputPort

Choose to output audio data

Use this property to control the audio output from the multimedia file reader. This property applies only when a multimedia file contains both audio and video streams. The default is `true`.

VideoOutputPort

Choose to output video data

Use this property to control the video output from the multimedia file reader. This property only applies when a multimedia file contains both audio and video streams. The default is `false`.

SamplesPerAudioFrame

Number of samples per audio frame

Specify the number of samples per audio frame as a positive scalar integer value. This property applies when the multimedia file contains only audio data. The default is `1024`.

ImageColorSpace

Choose whether output is RGB, intensity, or YCbCr

Specify whether you want the multimedia file reader to output `RGB`, `Intensity`, or `YCbCr 4:2:2` video frames. This property applies only when the multimedia file contains video. The default is `RGB`.

VideoOutputDataType

Data type of video data output

Set the data type of the video data output from the multimedia file reader. The multimedia file reader supports the following output data types: `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32` or `Inherit`. This property applies if the multimedia file contains video. The default is `single`.

AudioOutputDataType

Data type of audio samples output

Set the data type of the audio data output from the multimedia file reader. The multimedia file reader supports the following output data types: `double`, `single`, `int16`, `uint8`. This property applies only if the multimedia file contains audio. The default is `int16`.

Methods

clone	Create multimedia file reader object with same property values
close	Release resources
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
info	Information about specific multimedia file
isDone	End-of-file status (logical)
isLocked	Locked status for input attributes and nontunable properties
reset	Reset internal states of multimedia file reader to read from beginning of file
step	Output one frame of video frames, audio samples, or both to multimedia signal

Examples

Read an audio file and play the file back using the standard audio output device:

```
hmfr = signalblks.MultimediaFileReader('speech_dft.avi');
hap = dsp.AudioPlayer('SampleRate', 22050);
while ~isDone(hmfr)
audio = step(hmfr);
step(hap, audio);
end
close(hmfr); % close the input file
close(hap); % close the audio output device
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs `EOF` as the last output.
- The **Multimedia outputs** block parameter corresponds to both the `AudioOutputPort` and the `VideoOutputPort` object properties.
- The object has no corresponding property for the **Image signal** block parameter. The object always outputs an *M*-by-*N*-by-*P* color video signal.

See Also

`signalblks.MultimediaFileWriter`

Purpose

Create multimedia file reader object with same property values

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.clone`.

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `MultimediaFileReader` System object `C`, with the same property values as `H`.

The clone method creates a new unlocked object with uninitialized states.

signalblks.MultimediaFileReader.close

Purpose

Release resources

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileWriter.release` .

Syntax

```
close(H)
```

Description

`close(H)` releases system resources (such as memory, file handles or hardware connections).

Purpose

Number of expected inputs to step method

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.getNumInputs`.

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of outputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

signalblks.MultimediaFileReader.getNumOutputs

Purpose

Number of outputs of step method

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.getNumOutputs`.

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Information about specific multimedia file

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.info`.

Syntax

```
S = info(H)
```

Description

`S = info(H)` returns a MATLAB structure, `S`, with information about the multimedia file specified in the `Filename` property. The number of fields for `S` varies depending on the audio or video content of the file. The possible fields and values for the structure `S` are shown in the following table.

Field	Value
Audio	Logical value indicating if the file has audio content.
Video	Logical value indicating if the file has video content.
AudioSampleRate	Audio sampling rate of the multimedia file in hertz. This field is available when the file has audio content.
AudioNumBits	Number of bits used to encode the audio stream. This field is available when the file has audio content.
AudioNumChannels	Number of audio channels. This field is available when the file has audio content.
FrameRate	Frame rate of the video stream in frames per second. The value may vary from the actual frame rate of the recorded video, and considers any synchronization issues between audio and video streams when the file contains both audio and video content. This variation indicates that video frames may be dropped if the audio stream leads the video stream by more than 1/(actual video frames per second). This field is available when the file has video content.

Field	Value
VideoSize	Video size as a two-element numeric vector of the form [VideoWidthInPixels, VideoHeightInPixels]. This field is available when the file has video content.
VideoFormat	Video signal format. This field is available when the file has video content.

Purpose

End-of-file status (logical)

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.isDone`.

Syntax

```
STATUS = isDone(H)
```

Description

`STATUS = isDone(H)` returns a logical value, `STATUS` , when the `MultimediaFileReader` object, `H` , reaches the end of the multimedia file. If you set the `PlayCount` property to a value greater than `1` , `STATUS` is `true` each time the object reaches the end of the file. `STATUS` is the same as the `EOF` output value in the process method syntax.

signalblks.MultimediaFileReader.isLocked

Purpose

Locked status for input attributes and nontunable properties

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.isLocked`.

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `MultimediaFileReader` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Reset internal states of multimedia file reader to read from beginning of file

---

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.reset`.

Syntax

```
reset(H)
```

Description

`reset(H)` resets the `MultimediaFileReader` object to read from the beginning of the file.

signalblks.MultimediaFileReader.step

Purpose

Output one frame of video frames, audio samples, or both to multimedia signal

---

Note `MultimediaFileReader` will be removed in a future release. Use `AudioFileReader` instead. See `dsp.AudioFileReader.step`.

Syntax

```
AUDIO = step(H)
I = step(H)
[I,AUDIO] = step(H)
[...,EOF] = step(H)
[Y,CB,CR] = step(H)
[Y,CB,CR,AUDIO] = step(H)
```

Description

`AUDIO = step(H)` outputs one frame of audio samples, `AUDIO`. This behavior requires the `AudioOutputPort` property to be `true` and an input file that contains audio data. After the object plays the file the number of times `PlayCount` specifies, `AUDIO` contains silence.

`I = step(H)` outputs one frame of multidimensional video signal, `I`. To obtain this behavior, set the `VideoOutputPort` property to `true` and use an input file that contains video data.

`[I,AUDIO] = step(H)` outputs one frame of multidimensional video signal, `I` , and one frame of audio samples, `AUDIO` . This behavior requires the `AudioOutputPort` and `VideoOutputPort` properties to be `true` and an input file that contains audio and video data.

`[...,EOF] = step(H)` gives the end-of-file indicator in `EOF`. `EOF` is true each time the output contains the last audio sample and/or video frame in the file.

`[Y,CB,CR] = step(H)` outputs one frame of `YCbCr 4:2:2` video data in the color components `Y`, `CB`, and `CR`. This behavior applies when you set the `VideoOutputPort` property to `true`, the `ImageColorSpace` property to `YCbCr 4:2:2`, and an input file which contains video data.

`[Y,CB,CR,AUDIO] = step(H)` outputs one frame of `YCbCr 4:2:2` video data in the color components `Y`, `CB`, and `CR`, and one frame of audio samples in AUDIO. This applies when you set the `AudioOutputPort` and `VideoOutputPort` properties to `true`, the `ImageColorSpace` property to `YCbCr 4:2:2`, and an input file which contains audio and video data.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

signalblks.MultimediaFileWriter

Purpose

Write video frames, audio samples, or both to multimedia file

Note `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter`.

Description

The `MultimediaFileWriter` object writes video frames, audio samples, or both to a multimedia file.

To write video frames, audio samples, or both to a multimedia file:

1. Define and set up your multimedia file writer. See "Construction" on page 3-1110.
2. Call `step` to write to a multimedia file according to the properties of `signalblks.MultimediaFileWriter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = signalblks.MultimediaFileWriter` returns a multimedia file writer System object, `H`, that writes video frames, audio samples, or both to a multimedia file (such as an `AVI` file).

`H = signalblks.MultimediaFileWriter('PropertyName',PropertyValue,...)` returns a multimedia file writer System object, `H`, with each specified property set to the specified value.

`H = signalblks.MultimediaFileWriter(FILENAME,'PropertyName', PropertyValue,...)` returns a multimedia file writer System object, `H`, with `Filename` property set to *`FILENAME`* and other specified properties set to the specified values.

Properties

Filename

Name of multimedia file to which to write

Specify the name of the multimedia file as a string. The default is `output.avi`.

FileFormat

Multimedia file format

Specify which multimedia file format the object writes. On Microsoft platforms, select `AVI`, `WAV`, `WMV`, or `WMA`. These abbreviations correspond to the following file formats:

- WAV: Microsoft WAVE Files
- WMV: Windows Media Video
- WMA: Windows Media Audio
- AVI: Audio-Video Interleave

The default setting for this property is AVI.

On all other platforms, the only selection is AVI.

AudioInputPort

Choose to write audio data

Use this property to specify whether the multimedia file writer object writes audio samples to a multimedia file. When you enable both this property and `VideoInputPort`, ensure that the video and audio input signals have the same frame period. Adjust the frame size (or number of rows) of the audio signal so that the frame period of the video signal is the same as the frame period of the audio signal. Calculate frame size by dividing the audio signal frequency by the frame rate of the video signal. The audio signal frequency is in samples per second (specified by `SampleRate`). The video signal frame rate is in frames per second (specified by `FrameRate`). The default selection for this property is `true`.

The multimedia file object takes a column vector as an input. Every column is a separate channel and each row corresponds to a single audio sample.

VideoInputPort

Choose to write video data

Use this property to specify whether the multimedia file writer object writes video frames to a multimedia file. When you enable both this property and the `AudioInputPort` property, ensure that the video and audio input signals have the same frame period. Adjust frame size (or number of rows) for the audio signal so the frame period is equal of both the video signal and the audio signal. Calculate frame size by dividing the audio signal frequency by the frame rate of the video signal. The audio signal frequency is in samples per second (specified by `SampleRate`). The video signal frame rate is in frames per second (specified by `FrameRate`). The default selection for this property is `false`

AudioCompressor

Algorithm that compresses audio data

Specify the type of compression algorithm the multimedia file writer uses to compress the audio data. Compression reduces the size of the multimedia file. Select `None (uncompressed)` to save uncompressed audio data to a multimedia file. The other options available reflect the audio compression algorithms installed on your system. This property is only available when writing WAV or AVI files on Windows platforms.

VideoCompressor

Algorithm that compresses video data

Specify the type of compression algorithm to multimedia file writer uses to compress the video data. This compression reduces the size of the multimedia file. Choose `None (uncompressed)` to save uncompressed video data to a multimedia file. The other options reflect the available video compression algorithms installed on your system. This property is only available when writing AVI files on Windows platforms.

SampleRate

Sampling rate of audio data stream

Specify the sampling rate of the input audio data as a positive numeric scalar. The default is `44100`. This property only applies when you set the `AudioInputPort` property to `true`.

FrameRate

Frame rate of video data stream

Specify the frame rate of the video data in frames per second as a positive numeric scalar. The default is `30`. This property only applies when you set the `VideoInputPort` property to `true`.

AudioDataType

Data type of the uncompressed audio

Specify the type of uncompressed audio data written to the file. This property only applies when writing uncompressed WAV files.

FileColorSpace

Color space to use when creating a file

Specify the color space of AVI files as `RGB` or `YCbCr 4:2:2`. This property only applies on Windows platforms when you set the FileFormat property to `AVI`. The default is `RGB`.

Methods

clone	Create multimedia file writer object with the same property values
close	Release resources
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
step	Write one frame of audio output samples

Examples

Decimate an audio signal, and write signal to disk as an AVI file:

```
hmfr = signalblks.MultimediaFileReader...
   ('AudioOutputDataType','double');
hfirdec = dsp.FIRDecimator; % decimate by 2
hmfw = signalblks.MultimediaFileWriter...
   ('speech_dft_11025.avi', ...
   'SampleRate', 22050/2);

while ~isDone(hmfr)
     audio = step(hmfr);
     audiod = step(hfirdec, audio);
     step(hmfw, audiod);
end

close(hmfr);
close(hmfw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The **Write** block parameter corresponds to both the `AudioOutputPort` and the `VideoOutputPort` object properties.
- The `FrameRate` and `SampleRate` properties are not available on the block. The block inherits these signals from the input line connected to the ports.

See Also

`signalblks.MultimediaFileReader`

signalblks.MultimediaFileWriter.clone

Purpose

Create multimedia file writer object with the same property values

Note `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter.clone`.

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `MultimediaFileWriter` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Release resources

Note `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter.release`.

Syntax

```
close(H)
```

Description

`close(H)` releases system resources (such as memory, file handles or hardware connections).

signalblks.MultimediaFileWriter.getNumInputs

Purpose

Number of expected inputs to step method

Note `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter.getNumInputs`.

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, of the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Note `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter.getNumOutputs`.

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

signalblks.MultimediaFileWriter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Note `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter.isLocked`.

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `MultimediaFileWriter` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Write one frame of audio output samples

Note `MultimediaFileWriter` will be removed in a future release. Use `AudioFileWriter` instead. See `dsp.AudioFileWriter.step`.

Syntax

```
step(H,AUDIO)
step(H,I)
step(H,I,AUDIO)
step(H,Y,Cb,Cr)
step(H,Y,CB,CR)
step(H,Y,CB,CR,AUDIO)
```

Description

`step(H,AUDIO)` writes one frame of audio samples, `AUDIO` , to the output file when you enable the `AudioInputPort` property. `AUDIO` is either a vector or an *M*-by-2 matrix for mono or stereo inputs, respectively.

`step(H,I)` writes one frame of video, `I` , to the output file when you enable the `VideoInputPort` property. `I` is an *M*-by-*N*-by-3 color video signal.

`step(H,I,AUDIO)` writes one frame of video, `I` , and one frame of audio samples, `AUDIO` , to the output file when you enable both the `AudioInputPort` and `VideoInputPort` properties.

`step(H,Y,Cb,Cr)` writes one frame of video with `Y`, `Cb`, `Cr` components to the file. This applies only when you set the `FileColorSpace` property to `YCbCr 4:2:2`

`step(H,Y,CB,CR)` writes one frame of `YCbCr 4:2:2` data in the color components `Y`, `CB`, and `CR`, to the output file when you set the `VideoInputPort` property to `true`. The width of `CB` and `CR` must be half of the width of `Y`, and the value of the `FileColorSpace` property must be set to `YCbCr 4:2:2`.

`step(H,Y,CB,CR,AUDIO)` writes one frame of `YCbCr 4:2:2` data in the color components `Y`, `CB`, and `CR`, and one frame of audio samples, `AUDIO`, to the output file when you set both the `AudioInputPort` and

`VideoInputPort` properties to `true`. The width of `CB` and `CR` must be half of the width of `Y`, and the value of the `FileColorSpace` property must be set to `YCbCr 4:2:2`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Generate real or complex sinusoidal signals

Description

The numerically controlled oscillator, or `NCO`, object generates real or complex sinusoidal signals. The amplitude of the generated signal is always 1.

To generate real or complex sinusoidal signals:

1. Define and set up your NCO System object. See "Construction" on page 3-1123.
2. Call `step` to generate the signals according to the properties of `dsp.NCO`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.NCO` returns an NCO System object, `H`, that generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel.

`H = dsp.NCO('PropertyName',PropertyValue,...)` returns an `NCO` System object, `H`, with each specified property set to the specified value.

Properties

PhaseIncrementSource

Source of phase increment

Indicate how to specify the phase increment: `Property` or `Input port`. The default is `Input port`.

PhaseIncrement

Phase increment

Specify the phase increment as an integer scalar. This property applies only when you set the `PhaseIncrementSource` property to `Property`. The default is `100`.

PhaseOffsetSource

Source of phase offset

Specify the phase offset as `Property` or `Input port`. The default is `Property`.

PhaseOffset

Phase offset

Specify the phase offset as an integer scalar. This property applies only when you set the `PhaseOffsetSource` property to `Property`. The default is `0`.

Dither

Enable adding internal dithering to NCO algorithm

Set this property to `true` to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications System Toolbox product. The default is `true`.

NumDitherBits

Number of dither bits

Specify the number of dither bits as a positive integer. This property applies only when you set the `Dither` property to `true`. The default is `4`.

PhaseQuantization

Enable quantization of accumulated phase

Set this property to `true` to enable quantization of the accumulated phase. The default is `true`.

NumQuantizerAccumulatorBits

Number of quantizer accumulator bits

Specify the number of quantizer accumulator bits as an integer scalar greater than 1 and less than the accumulator word length. This property determines the number of entries in the lookup table of sine values. This property applies only when you set the `PhaseQuantization` property to `true`. The default is `12`.

PhaseQuantizationErrorOutputPort

Enable output of phase quantization error

Set this property to `true` to output the phase quantization error. This property applies only when you set the `PhaseQuantization` property to `true`. The default is `false`.

Waveform

Type of output signal

Specify the type of the output signal: `Sine`, `Cosine`, `Complex exponential` or `Sine and cosine`. The default is `Sine`.

SamplesPerFrame

Number of output samples per frame

Specify the number of samples per frame of the output signal. This property applies only when you set the `PhaseOffsetSource` property to `Property`. The default is `1`. When the `PhaseOffsetSource` property is `Input port`, and the `PhaseIncrementSource` property is `Property`, the number of rows or frame size of the phase offset input determines the number of samples per frame of the output signal. When you set both the `PhaseOffsetSource` and `PhaseIncrementSource` properties to `Input port`, the number of rows in the inputs must be 1, and the samples per frame of the output signal is 1.

OutputDataType

Output data type

Specify the output data type as one of `double`, `single` or `Custom`. The default is `Custom`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

This constant property has a value `Floor`.

OverflowAction

Overflow action for fixed-point operations

This constant property has a value `Wrap`.

AccumulatorDataType

Accumulator word and fraction lengths

This constant property has a value `Custom`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,14)`.

Methods

clone	Create NCO object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
info	Characteristic information about generated signal

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset accumulator of NCO object
step	Generate multichannel real or complex sinusoidal signal using NCO (Numerically Controlled Oscillator)

Examples

Design an NCO source according to given specifications:

```
F0 = 510; % Output frequency = 510 Hz
df = 0.05; % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/8000; % Sample period = 1/8000 sec
dphi = pi/2; % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the given frequency resolution

```
Nacc = ceil(log2(1/(df*Ts)));
% Actual frequency resolution achieved
actdf = 1/(Ts*2^Nacc);
% Calculate number of quantized accumulator bits
% required from the SFDR requirement
Nqacc = ceil((minSFDR-12)/6);
% Calculate the phase increment
phIncr = round(F0*Ts*2^Nacc);
% Calculate the phase offset
phOffset = 2^Nacc*dphi/(2*pi);

hnco = dsp.NCO('PhaseIncrementSource', 'Property', ...
'PhaseIncrement', phIncr,...
'PhaseOffset', phOffset,...
```

```
    'NumDitherBits', 4, ...
    'NumQuantizerAccumulatorBits', Nqacc,...
    'SamplesPerFrame', 1/Ts, ...
    'CustomAccumulatorDataType', numerictype([],Nacc));

    y = step(hnco);
    % Plot the mean-square spectrum of the 510 Hz sinewave
    % generated by the NCO
    periodogram(double(y),hann(length(y),'periodic'),[],1/Ts,'power');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the NCO block reference page. The object properties correspond to the block properties, except:

There is no object property that corresponds to the **Sample time** block parameter. The objects assumes a sample time of one second.

See Also

`dsp.SineWave`

Purpose

Create NCO object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `NCO` system object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states

dsp.NCO.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.NCO.info

Purpose

Characteristic information about generated signal

Syntax

```
S = info(H)
```

Description

`S = info(H)` returns a structure containing characteristic information, `S`, about the signal being generated by the `NCO` System object, `H`. The number of fields of `S`, and their values vary depending on the property value settings of `H`. For description of the possible fields and their values, see the following table.

Field	Value
`NumPointsLUT`	Number of data points for lookup table. The lookup table is implemented as a quarter-wave sine table.
`SineLUTSize`	Quarter-wave sine lookup table size in bytes.
`TheoreticalSFDR`	Theoretical spurious free dynamic range (SFDR) in dBc. This field applies when you set the `PhaseQuantization` property to `true`.
`FrequencyResolution`	Frequency resolution of the `NCO` in Hz. The sample time of the output signal is assumed to be `1` sec.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `NCO` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.NCO.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset accumulator of NCO object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the accumulator of the `NCO` System object, `H`, to zero.

dsp.NCO.step

Purpose

Generate multichannel real or complex sinusoidal signal using NCO (Numerically Controlled Oscillator)

Syntax

```
Y = step(H,INC)
Y = step(H)
Y = step(H,OFFSET)
Y = step(H,INC,OFFSET)
[Y,COSINE] = step(H,___)
[Y,QERR] = step(H,___)
```

Description

`Y = step(H,INC)` returns a sinusoidal signal, `Y` , generated by the `NCO` with the specified phase increment, `INC`. `INC` must be a built-in integer or a fi object comprising either a scalar or a row vector, where each row element corresponds to a separate channel.

`Y = step(H)` when the `PhaseIncrementSource` and `PhaseOffsetSource` properties are both `Property`, returns a sinusoidal signal, `Y`.

`Y = step(H,OFFSET)` returns a sinusoidal signal, `Y`, with phase offset, `OFFSET`, when the `PhaseOffsetSource` property is `Input port`. `OFFSET` must be a built-in integer or a fi object. The number of rows of `OFFSET` determines the number of samples per frame of the output signal. The number of columns of the `OFFSET` determines the number of channels of the output signal.

`Y = step(H,INC,OFFSET)` returns a sinusoidal signal, `Y`, with phase increment, `INC`, and phase offset, `OFFSET`, when the `PhaseIncrementSource` and the `PhaseOffsetSource` properties are both `Input port`. `INC` and `OFFSET` must both be row vectors of the same length, where the length determines the number of channels in the output signal.

`[Y,COSINE] = step(H,___)` returns a sinusoidal signal, `Y`, and a cosinusoidal signal, `COSINE,` when the `Waveform` property is set to `Sine and cosine`. This syntax can include any of the input arguments in previous syntaxes.

`[Y,QERR] = step(H, ___ )` when the `PhaseQuantization` and the `PhaseQuantizationErrorOutputPort` properties are both `true`, returns a sinusoidal signal, `Y`, and output quantization error, `QERR`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Normalizer

Purpose

Vector normalization along specified dimension

Description

The `Normalizer` object performs vector normalization along rows, columns, or specified dimension.

To perform vector normalization:

1. Define and set up your normalization object. See "Construction" on page 3-1138.
2. Call `step` to perform vector normalization according to the properties of `dsp.Normalizer`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Normalizer` returns a normalization object, `H`, that normalizes the input over each column by the squared 2-norm of the column plus a bias term of 1e-10 used to protect against divide-by-zero.

`H = dsp.Normalizer('PropertyName',PropertyValue, ...)` returns a normalization object, `H`, with each property set to the specified value.

Properties

Method

Type of normalization to perform

Specify the type of normalization to perform as `2-norm` or `Squared 2-norm`. The `2-norm` mode supports floating-point signals only. The `Squared 2-norm` supports both fixed-point and floating-point signals. The default is `Squared 2-norm`.

Bias

Real number added in denominator to avoid division by zero

Specify the real number to add in the denominator to avoid division by zero. The default is 1e-10. This property is tunable.

Dimension

Dimension to operate along

Specify whether to normalize along `Column` , `Row`, or `Custom`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` property is `Custom`. The default is 1.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Same as input` or `Custom`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default to `numerictype([],32,32)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Same as accumulator`, `Same as product` , `Same as input`, `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],32,32)`.

Methods

clone	Create normalization object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Normalize input along specified dimension

Examples

Normalize a matrix:

```
hnorm = dsp.Normalizer;
x = magic(3);
y = step(hnorm, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Normalization block reference page. The object properties correspond to the block parameters, except:

- **Treat sample-based row input as column** — The block allows you to input a row vector and normalize the row vector as a column vector. The normalization object always normalizes along the value of the `Dimension` property.
- The normalization object does not support the **Minimum** and **Maximum** options for data output.

See Also

`dsp.ArrayVectorMultiplier`

dsp.Normalizer.clone

Purpose

Create normalization object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a normalizer object, `C`, with the same property values. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Normalizer.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the normalization object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Normalizer.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Normalize input along specified dimension

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` returns a normalized output`Y` . The input `X` must be floating-point for the `2-norm` mode, and either fixed-point and floating-point for the `Squared 2-norm` mode.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.NotchPeakFilter

Purpose

Second-order tunable notching and peaking IIR filter

Description

The `NotchPeakFilter` object filters each channel of the input using IIR filter implementation.

To filter each channel of the input:

1. Define and set up your NotchPeak filter. See "Construction" on page 3-1148.
2. Call `step` to filter each channel of the input according to the properties of `dsp.NotchPeakFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.NotchPeakFilter` returns a second-order notching and peaking IIR filter which independently filters each channel of the input over time, using a specified center frequency and 3 dB bandwidth. Both of these properties are specified in Hz and are tunable. Both of these values must be scalars between `0` and half the sample rate.

`H = dsp.NotchPeakFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a notch filter with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = dsp.NotchPeakFilter('specification', 'Quality factor and center frequency')` specifies the quality factor (Q factor) of the notch or peak filter instead of the `3` dB bandwidth. The Q factor is defined as the center frequency divided by the bandwidth. A higher Q factor corresponds to a narrower notch or peak. The Q factor should be a scalar value greater than 0. The Q factor is tunable.

`H = dsp.NotchPeakFilter('Specification','Coefficients')` specifies the coefficient values that affect bandwidth and center frequency directly, rather than specifying the design parameters in Hz. This removes the trigonometry calculations involved when the properties are tuned. The `CenterFrequencyCoefficients` should be a scalar between `-1` and `1`, with `-1` corresponding to `0` Hz and `1` corresponding to the Nyquist frequency. The `BandwidthCoefficient`

should be a scalar between `-1` and `1`, with `-1` corresponding to the largest `3` dB bandwidth and `1` corresponding to the smallest `3` dB bandwidth. Both coefficient values are tunable.

Properties

Specification

Filter specification

Set the specification as one of `'Bandwidth and center frequency' | 'Quality factor and center frequency' | 'Coefficients'`. The default is `'Bandwidth and center frequency'`.

Bandwidth

3 dB bandwidth

Specify the filter's `3` dB bandwidth as a finite positive numeric scalar in Hertz. This property is applicable only if `specification` is `'Bandwidth and center frequency'`. The default is `2205` Hz. This property is tunable.

CenterFrequency

Notch or Peak center frequency

Specify the filter's center frequency (for both the notch and the peak) as a finite positive numeric scalar in Hertz. This property is applicable only if `specification` is `'Bandwidth and center frequency' | 'Quality factor and center frequency'`. The default is `11025` Hz. This property is tunable.

QualityFactor

Quality factor for notch or peak filter

Specify the quality factor (Q factor) for both the notch and the peak filters. The Q factor is defined as the center frequency divided by the bandwidth. This property is applicable only if `specification` is set to `'Quality factor and center frequency'`. The default value is `5`. This property is tunable.

SampleRate

Sample rate of input

Specify the sample rate of the input in Hertz as a finite numeric scalar. The default is `44100` Hz.

BandwidthCoefficient

Bandwidth coefficient

Specify the value that determines the filter's `3` dB bandwidth as a finite numeric scalar between `0` and `1`. Where `0` corresponds to the maximum `3` dB bandwidth (SampleRate/4), and `1` corresponds to the minimum `3` dB bandwidth (0 Hz, an allpass filter). The default is `0.72654`. This property is only applicable if `specification` is set to `'Coefficients'`. This property is tunable.

CenterFrequencyCoefficient

Center frequency coefficient

Specify the coefficient that determines the filter's center frequency as a finite numeric scalar between `-1` and `1`. Where `-1` corresponds to the minimum center frequency (0 Hz), and 1 corresponds to the maximum center frequency (`SampleRate/2` Hz). This property is only applicable if `specification` is set to `'Coefficients'`. The default is 0 which corresponds to `SampleRate/4` Hz. This property is tunable.

Methods

clone	Create System object with same property values
getBandwidth	Get 3 dB bandwidth
getCenterFrequency	Get center frequency
getOctaveBandwidth	Bandwidth in number of octaves
getQualityFactor	Get quality factor
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset the internal states of notch or peak filter
step	Process input using the notch or peak filter algorithm
tf	Transfer function

Examples

Notch filter

This example shows how to use dsp.NotchPeakFilter as a notch filter with center frequency of 5000 Hz and a 3 dB bandwidth of 500 Hz.

```
h = dsp.NotchPeakFilter('CenterFrequency',5000,'Bandwidth',500);
hscope =  dsp.SpectrumAnalyzer('SampleRate',44100,...
    'PlotAsTwoSidedSpectrum',false,'SpectralAverages',50);
for i=1:5000
    y = step(h,randn(1024,1));
    step(hscope,y);
    if (i==2500)
        % Tune center frequency to 10000
        h.CenterFrequency = 10000;
    end
end
release(h)
release(hscope)
```

Algorithms

The design equations for this filter are:

$$H(z) = (1-b)\frac{1-z^{-2}}{1-2b\cos w_0 z^{-1}+(2b-1)z^{-2}}$$

The previous equation is for peak filter, and the following equation is for notch filter.

$$H(z) = b\frac{1-2\cos w_0 z^{-1}+z^{-2}}{1-2b\cos w_0 z^{-1}+(2b-1)z^{-2}}$$

With

$$b = \frac{1}{1+\tan(\Delta w/2)}$$

where $\omega_0 = 2\pi f_0/f_s$ is the center frequency in radians/sample (f_0 is the center frequency in Hz and f_s is the sampling frequency in Hz). $\Delta\omega = 2\pi\Delta f/f_s$ is the 3 dB bandwidth in radians/sample (Δf is the 3 dB bandwidth in Hz). Note that the two filters are complementary:

$$H_{notch}(z) + H_{peak}(z) = 1$$

they can be written as:

$$H_{peak}(z) = \frac{1}{2}\left[1 - A(z)\right]$$

$$H_{notch}(z) = \frac{1}{2}\left[1 + A(z)\right]$$

where A(z) is a 2^{nd} order allpass filter.

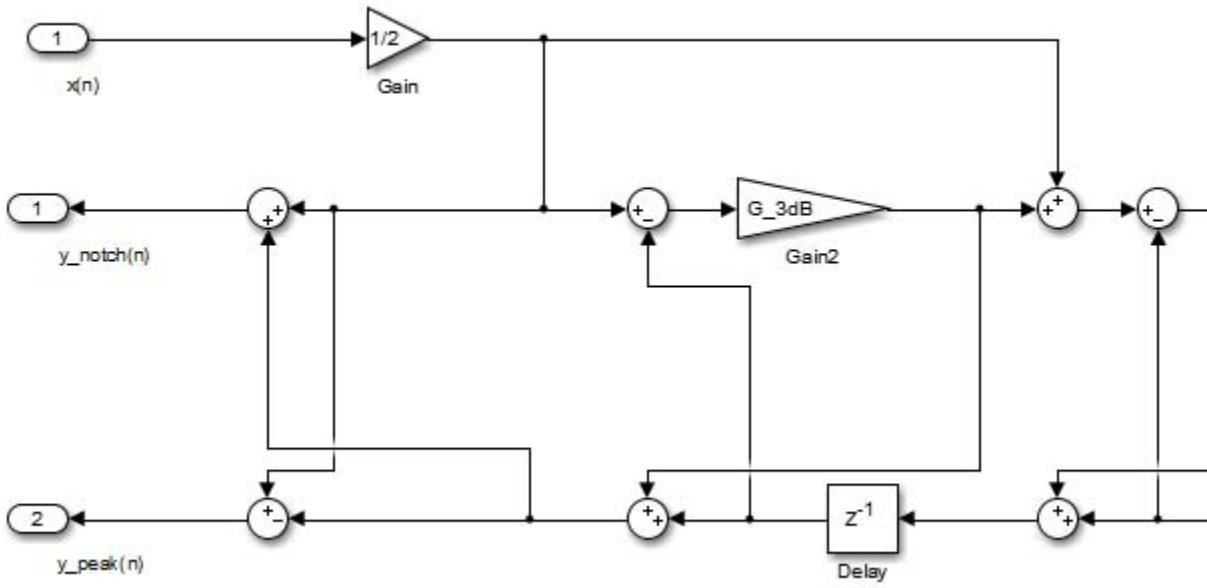
$$A(z) = \frac{a_2 + a_1 z^{-1} + z^{-2}}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

and

$$a_1 = -2b\cos\omega_0$$

$$a_2 = 2b - 1$$

The filter is implemented as follows:



where

$$G_{3dB} = a_2 = 2b - 1$$

$$G_{cf} = \frac{a_1 - a_1 a_2}{1 - {a_2}^2} = -\cos w_0$$

Notice that G_{cf} depends only on the center frequency, and G_{3dB} depends only on the 3 dB bandwidth.

See Also

`dsp.BiquadFilter` | `iirnotch` | `iirpeak`

dsp.NotchPeakFilter.clone

Purpose

Create System object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`, with the same property values. The `clone` method creates a new unlocked object, `C`, with uninitialized states.

Purpose

Get 3 dB bandwidth

Syntax

```
BW= getBandwidth(H)
```

Description

`BW= getBandwidth(H)` returns the 3 dB bandwidth for the notch or peak filter. If the `Specification` is set to `'Quality factor and center frequency'`, the 3 dB bandwidth is determined from the quality factor value. If the `Specification` property is set to `'Coefficients'`, the 3 dB bandwidth is determined from the `BandwidthCoefficient` value and the sample rate.

dsp.NotchPeakFilter.getCenterFrequency

Purpose

Get center frequency

Syntax

```
CF= getCenterFrequency(H)
```

Description

`CF= getCenterFrequency(H)` returns the center frequency of the notch or peak filter. If the `Specification` property is set to `'Coefficients'`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate.

Purpose

Bandwidth in number of octaves

Syntax

```
N = getOctaveBandwidth(H)
```

Description

`N = getOctaveBandwidth(H)` returns the bandwidth of the notch or peak filter, measured in number of octaves rather than Hz.

dsp.NotchPeakFilter.getQualityFactor

Purpose

Get quality factor

Syntax

```
Q = getQualityFactor(H)
```

Description

`Q = getQualityFactor(H)` returns the quality factor (`Q` factor) for both the notch and the peak filters. The `Q` factor is defined as the center frequency divided by the bandwidth.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns a logical value, `L`, which indicates whether input attributes and nontunable properties are locked for the System object, `H`. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After `H` is locked, the `isLocked` method returns a true value.

dsp.NotchPeakFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources of System object, `H`, such as memory, file handles, or hardware connections. It lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset the internal states of notch or peak filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of System object, `H`, to their initial values. System objects without states are unaffected by reset.

dsp.NotchPeakFilter.step

Purpose

Process input using the notch or peak filter algorithm

Syntax

```
Y = step(H,x)
[Y1,...,YN] = step(H,x)
```

Description

`Y = step(H,x)` processes the input data, `x`, to produce the output, `Y`, for System object, `H`.

`[Y1,...,YN] = step(H,x)` produces N outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, nontunable properties or any input characteristics (size, data type and complexity) cannot change without reinitializing (unlocking and relocking) the object.

Purpose

Transfer function

Syntax

```
[B,A] = tf(H)
[B,A,B2,A2] = tf(H)
```

Description

`[B,A] = tf(H)` returns the vector of numerator coefficients, `B`, and the vector of denominators, `A`, for the equivalent transfer function corresponding to the notch filter.

In addition to `B` and `A`, `[B,A,B2,A2] = tf(H)` returns the vector of numerator coefficients, `B2`, and the vector of denominator coefficients, `A2`, for the equivalent transfer function corresponding to the peak filter.

dsp.ParametricEQFilter

Purpose

Tunable second-order parametric equalizer filter

Description

The `ParametricEQFilter` object is a tunable, second-order parametric equalizer filter.

To apply the filter to each channel of the input:

1. Define and set up your equalizer filter. See "Construction" on page 3-1166.
2. Call `step` to filter each channel according to the properties of `dsp.ParametricEQFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.ParametricEQFilter` returns a second-order parametric equalizer filter that independently filters each channel of the input over time, using the default values for `Bandwidth`, `CenterFrequency`, and `PeakGaindB`. The `center frequency` and `bandwidth` are specified in Hz and are tunable. The `peak gain` (dip) is specified in dB and is also tunable. The `bandwidth` is measured at the arithmetic mean between the `peak gain` in absolute power units and one.

`H = dsp.ParametricEQFilter('Specification', 'Quality factor and center frequency')` specifies the quality factor (Q factor) of the filter. The `Q factor` is defined as the center frequency/bandwidth. A higher `Q factor` corresponds to a narrower peak/dip. The Q factor should be a scalar value greater than 0. The Q factor is tunable.

`H = dsp.ParametricEQFilter('Specification', 'Coefficients')` specifies the gain values for the bandwidth and center frequency. This removes the trigonometry calculations involved when the properties are tuned. The `CenterFrequencyCoefficient` should be a scalar between -1 and 1, with -1 corresponding to 0 Hz, and 1 corresponding to the Nyquist frequency. The `BandwidthCoefficient` should be a scalar between -1 and 1, with -1 corresponding to the largest bandwidth, and 1 corresponding to the smallest bandwidth. In this mode, the peak gain is specified in linear units rather than dB.

`H = dsp.ParametricEQFilter('Name', Value, ...)` returns a parametric equalizer filter with each specified property name set to the specified value. You can specify several name-value pair arguments in any order as `('Name1',Value1,...,'NameN',ValueN)`.

Properties

Specification

Design parameters or coefficients that specify the filter

Choose one of the following `Specification` values. Use the corresponding tunable properties to specify the filter:

- `Bandwidth and center frequency` — Use `Bandwidth`, `CenterFrequency`, and `PeakGaindB`.
- `Quality factor and center frequency` — Use `QualityFactor`, `CenterFrequency`, and `PeakGaindB`.
- `Coefficients` — Use `BandwidthCoefficient`, `CenterFrequencyCoefficient`, and `PeakGain`.

The default value is `Bandwidth and center frequency`.

Using `Coefficients` specifies gain values for the bandwidth and center frequency. This approach does not require the trigonometric calculations of the other two approaches where design parameters are specified in Hz.

Bandwidth

bandwidth of filter

Specify the filter's bandwidth as a finite positive numeric scalar, in Hz. This property is applicable if `Specification` is set to `Bandwidth and center frequency`. The default is 2205 Hz. This property is tunable.

BandwidthCoefficient

Coefficient for bandwidth of filter

Specify the value that determines the filter's bandwidth as a finite numeric scalar between 0 and 1:

- 0 corresponds to the maximum bandwidth (`SampleRate`/4).
- 1 corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This property is only applicable if `Specification` is set to `Coefficients`. The default is 0.72654. This property is tunable.

CenterFrequency

Center frequency of filter peak or notch.

Specify the filter's center frequency for both peak and notch, as a finite positive numeric scalar, in Hz. This property is only applicable if `Specification` is set to `Bandwidth and center frequency` or `Quality factor and center frequency`. The default is 11,025 Hz. This property is tunable.

CenterFrequencyCoefficient

Coefficient for center frequency of filter

Specify the value that determines the filter's center frequency as a finite numeric scalar between -1 and 1:

- -1 corresponds to the minimum center frequency (0 Hz).
- 1 corresponds to the maximum center frequency (`SampleRate`/2 Hz).

This property is only applicable if `Specification` is set to `Coefficients`. The default is 0, which corresponds to `SampleRate`/4 Hz.

This property is tunable.

PeakGain

Peak or notch gain of filter in linear units

Specify the filter's peak or notch in linear units. A value greater than one boosts the signal. A value less than one attenuates the signal. The default is 2 (6.0206 dB). This property is tunable.

PeakGaindB

Peak or notch of filter in dB

Specify the filter's peak or notch in dB. A positive value boosts the signal. A negative value attenuates the signal. The default is 6.02036 dB. This property is tunable.

QualityFactor

Q factor of peak or notch filter

Specify the Q factor for the peak or notch filter. The Q factor is defined as the center frequency divided by the bandwidth. A higher Q factor corresponds to a narrower peak or notch. This property is only applicable if `Specification` is set to `Quality factor and center frequency`. The default value is 5. This property is tunable.

SampleRate

Input sample rate

Specify the sample rate of the input as a finite numeric scalar, in Hz. The default is 44,100 Hz.

Methods

clone	Create parametric equalizer filter object with same property values
getBandwidth	Convert quality factor or bandwidth coefficient to bandwidth in Hz

getCenterFrequency	Convert center frequency coefficient to frequency in Hz
getOctaveBandwidth	Measure bandwidth of parametric equalizer filter in octaves
getPeakGain	Convert peak or notch gain from dB to absolute units
getPeakGaindB	Convert peak or notch gain from absolute units to dB
getQualityFactor	Convert bandwidth to quality factor
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset states of `ParametricEQFilter` object
step	Filter input with `ParametricEQFilter` object
tf	Compute transfer function

Examples

Tune Equalizer Filter

Create a `ParametricEQFilter` object where the center frequency and bandwidth of the equalizer filter are 5000 Hz and 500 Hz respectively. The sample rate for the filter is the default, 44,100 Hz.

```
h = dsp.ParametricEQFilter('CenterFrequency',5000,...
       'Bandwidth',500);
```

Create objects to estimate and display the transfer function of the filter.

```
htf = dsp.TransferFunctionEstimator('FrequencyRange','onesided',...
         'SpectralAverages',50);
```

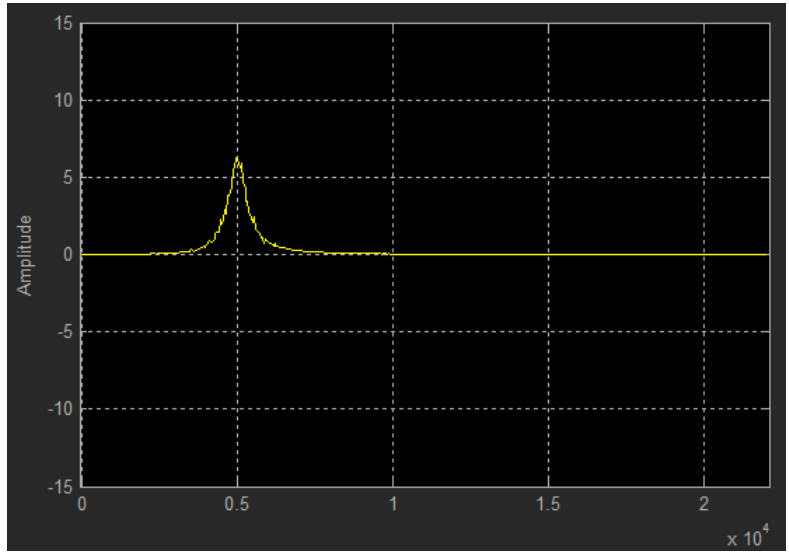
```
hplot = dsp.ArrayPlot('PlotType','Line','YLimits',[-15 15],...
       'SampleIncrement',44100/1024);
```

Generate a random signal and filter the signal.

```
for i=1:1000
   x = randn(1024,1);       % Random signal
   y = step(h,x);           % Filter signal
   H = step(htf,x,y);       % Estimate transfer function
   magdB = 20*log10(abs(H));% Convert to dB
   step(hplot,magdB);       % Display transfer function

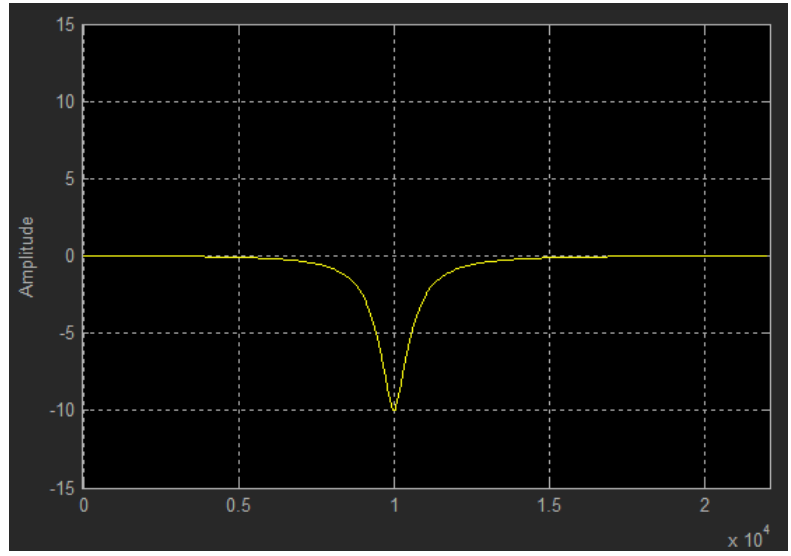
   if (i==1)                % Pause to display initial transfer functi
      pause;
   end
   if (i==500)              % Tune filter
      h.CenterFrequency = 10000;
      h.Bandwidth = 2000;
      h.PeakGaindB = -10;
   end
 end
```

The software displays the initial transfer function estimate.



To continue, press any key.

At `i=500`, the filter is tuned. The center frequency, bandwidth, and peak gain of the filter now have different values. The software displays the new transfer function.

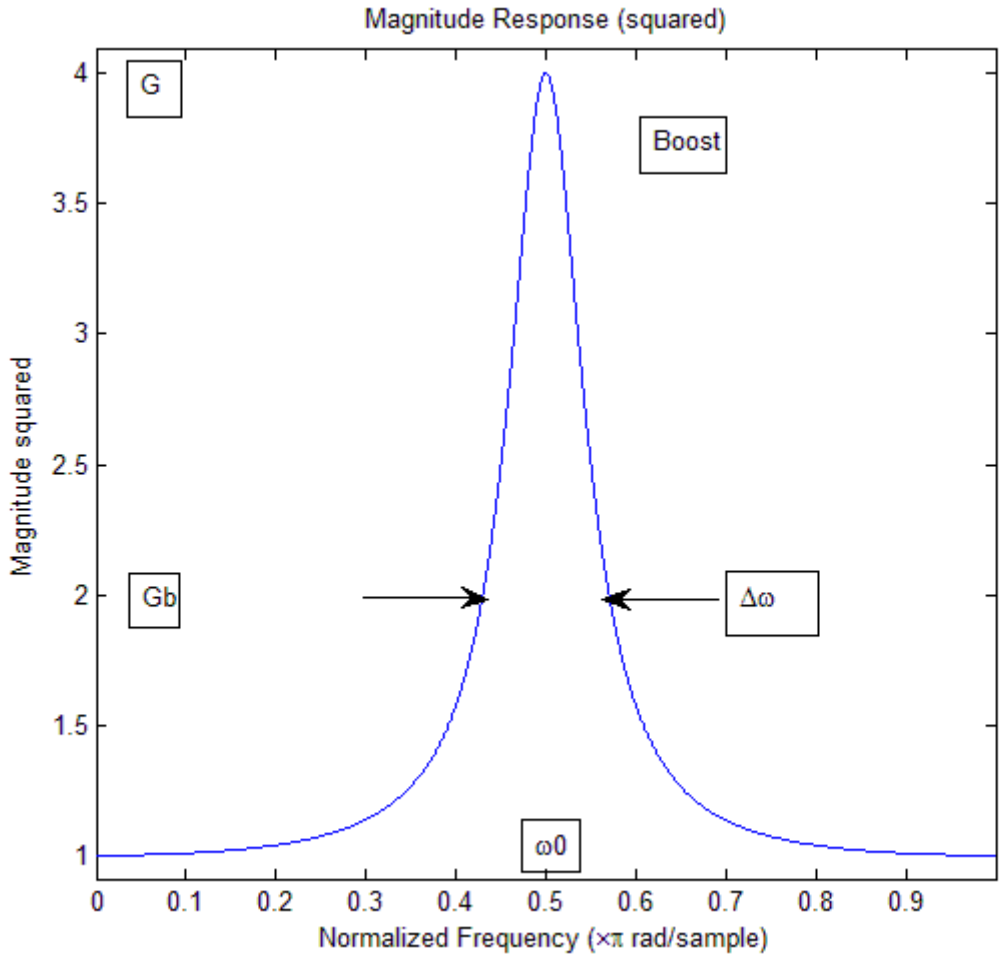


Algorithm

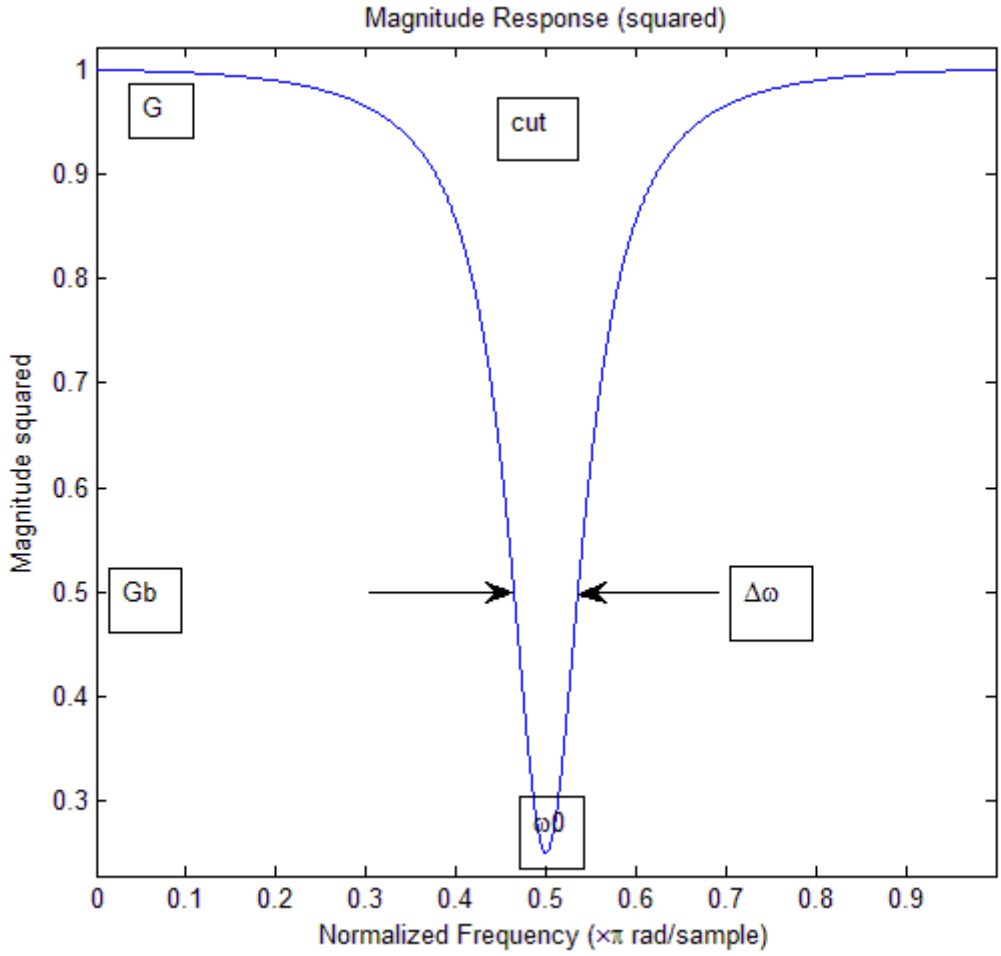
The parametric equalizer is formed by a linear combination of a peak and a notch filter. See the **Algorithm** section of `dsp.NotchPeakFilter` for details.

$$H(z) = H_{notch}(z) + GH_{peak}(z)$$

Here is a graph of the two cases (boost and cut) of the magnitude squared of the transfer functions:



Magnitude Response (squared)
G
Boost
Gb
Δω
ω0
Magnitude squared
Normalized Frequency (×π rad/sample)
4
3.5
3
2.5
2
1.5
1
0
0.1
0.2
0.3
0.4
0.5
0.6
0.7
0.8
0.9



The transfer function can be written as:

$$H(z) = \frac{(\frac{1+G_\gamma}{1+\gamma}) - 2(\frac{\cos\omega_0}{1+\gamma})z^{-1} + (\frac{1-G_\gamma}{1+\gamma})z^{-2}}{1 - 2(\frac{\cos\omega_0}{1+\gamma})z^{-1} + (\frac{1-\gamma}{1+\gamma})z^{-2}}$$

where

$$\gamma = \tan(\frac{\Delta\omega}{2})$$

and

$$G_B{}^2 = \frac{1+G^2}{2}$$

G is the parametric equalizer gain, and G_B is the bandwidth gain, that is, the gain level at which the bandwidth $\Delta\omega$ is measured.

The `dsp.NotchPeakFilter` that does most of the work is implemented in a decoupled way so that the center frequency can be tuned independently from the bandwidth. Note that the Q factor is defined as center frequency/bandwidth.

Related Examples

- Parametric Equalizer Design

Purpose

Create parametric equalizer filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `ParametricEQFilter` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.ParametricEQFilter.getBandwidth

Purpose

Convert quality factor or bandwidth coefficient to bandwidth in Hz

Syntax

```
BW = getBandwidth(H)
```

Description

`BW = getBandwidth(H)` returns the bandwidth of the parametric equalizer filter. The bandwidth is measured halfway between 1 and the peak (or notch) gain of the filter. The gain is specified in absolute power units (filter magnitude squared). If the `Specification` property is set to `Quality factor and center frequency`, the bandwidth is determined from the quality factor of the filter. If the `Specification` property is set to `Coefficients`, the bandwidth is determined from the `BandwidthCoefficient` value and the sample rate of the filter.

Purpose

Convert center frequency coefficient to frequency in Hz

Syntax

```
CF = getCenterFrequency(H)
```

Description

`CF = getCenterFrequency(H)` returns the center frequency of the parametric equalizer filter. If the `Specification` property is set to `Coefficients`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate of the filter.

dsp.ParametricEQFilter.getOctaveBandwidth

Purpose

Measure bandwidth of parametric equalizer filter in octaves

Syntax

```
N = getOctaveBandwidth(H)
```

Description

`N = getOctaveBandwidth(H)` returns the bandwidth of the parametric equalizer filter in octaves instead of Hz.

Purpose

Convert peak or notch gain from dB to absolute units

Syntax

```
G = getPeakGain(H)
```

Description

`G = getPeakGain(H)` returns the peak or notch gain of the parametric equalizer filter in absolute units.

dsp.ParametricEQFilter.getPeakGaindB

Purpose

Convert peak or notch gain from absolute units to dB

Syntax

```
G = getPeakGaindB(H)
```

Description

`G = getPeakGaindB(H)` returns the peak or notch gain of the parametric equalizer filter in dB.

Purpose

Convert bandwidth to quality factor

Syntax

```
Q = getQualityFactor(H)
```

Description

`Q = getQualityFactor(H)` returns the quality factor (Q factor) for the parametric equalizer filter. The Q factor is defined as the center frequency divided by the bandwidth.

dsp.ParametricEQFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `ParametricEQFilter` object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. Through `release(H)`, you can change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

See Also

`dsp.ParametricEQFilter.isLocked` | `dsp.ParametricEQFilter.step`

dsp.ParametricEQFilter.reset

Purpose

Reset states of `ParametricEQFilter` object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the `ParametricEQFilter` object,`H`, to the specified initial conditions. After the `step` method applies the `ParametricEQFilter` object to nonzero input data, the states can change. Invoking the `step` method again without first invoking the `reset` method can produce different outputs for an identical input.

Purpose

Filter input with `ParametricEQFilter` object

Syntax

```
Y = step(H, X)
```

Description

`Y = step(H, X)` filters the real or complex input signal `X` using the specified filter to produce the equalized filter output `Y`. The filter processes each channel of the input signal (each column of `X`) independently over time.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.ParametricEQFilter.tf

Purpose

Compute transfer function

Syntax

```
[B,A] = tf(H)
```

Description

`[B,A] = tf(H)` returns the vector of numerator coefficients `B` and the vector of denominator coefficients `A` for the equivalent transfer function of the parametric equalizer filter.

Purpose

Determine extrema (maxima or minima) in input signal

Description

The `PeakFinder` object determines the extrema (maxima or minima) in the input signal.

To compute the extrema in the input signal:

1. Define and set up your peak finder. See "Construction" on page 3-1189.
2. Call `step` to compute the extrema according to the properties of `dsp.PeakFinder`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.PeakFinder` returns a peak finder System object, `H`, that compares the current signal value to the previous and next values to determine if the current value is an extremum.

`H = dsp.PeakFinder('PropertyName',PropertyValue,...)` returns a peak finder System object, `H`, with each specified property set to the specified value.

Properties

PeakType

Looking for maxima, minima, or both

Specify whether the object is looking for maxima, minima, or both. You can set this property to o`Maxima`, `Minima`, `Maxima and Minima`. The default is `Maxima and Minima`.

PeakIndicesOutputPort

Enable output of extrema indices

Set this property to `true` to output the extrema indices. The default is `false`.

PeakValuesOutputPort

Enable output of extrema values

Set this property to `true` to output the extrema values. The default is `false`.

MaximumPeakCount

Number of extrema to look for in each input signal

The object stops searching the input signal for extrema after the maximum number of extrema has been found. The value of this property must be an integer greater than or equal to one. The default is `10`.

IgnoreSmallPeaks

Enable ignoring peaks below threshold

Set this property to `true` if you want to eliminate the detection of peaks whose amplitudes are within a specified threshold of neighboring values. The default is `false`.

PeakThreshold

Threshold below which peaks are ignored

Specify the noise threshold value. This property defines the current input value as a maximum if:

- The current input value minus the previous input value is greater than the threshold, and
- The current input value minus next input value is greater than the threshold.

This property applies when you set the `IgnoreSmallPeaks` property to `true`. The default is `0`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

The rounding method is a constant property set to `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

Methods

clone	Create peak finder object with same property values
getNumInputs	Number of expected inputs to the step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Number of extrema in input signal

Examples

Determine whether each value of an input signal is local maximum or minimum:

```
hpeaks1 = dsp.PeakFinder;
hpeaks1.PeakIndicesOutputPort = true;
hpeaks1.PeakValuesOutputPort = true;

x1 = [9 6 10 3 4 5 0 12]';
% Find the peaks of each input
% [prev;cur;next]: {[9;6;10],[6;10;3],...}
[cnt1, idx1, val1, pol1] = step(hpeaks1, x1);
```

Determine peak values for a fixed-point input signal:

```
hpeaks2 = dsp.PeakFinder('PeakType', 'Maxima', ...
'PeakValuesOutputPort', true, ...
'MaximumPeakCount', 2, ...
'IgnoreSmallPeaks', true, ...
'PeakThreshold', 0.25, ...
'OverflowAction', 'Saturate');
x2 = fi([-1;0.5;0],true,16,15);
[cnt2, val2] = step(hpeaks2, x2);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Peak Finder block reference page. The object properties correspond to the block parameters.

See Also

`dsp.Maximum` | `dsp.Minimum`

Purpose

Create peak finder object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `PeakFinder` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.PeakFinder.getNumInputs

Purpose

Number of expected inputs to the step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.PeakFinder.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `PeakFinder` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.PeakFinder.step

Purpose

Number of extrema in input signal

Syntax

```
YCNT = step(H,X)
[YCNT,IDX] = step(H,X)
[..., VAL] = step(H,X)
[..., POL] = step(H,X)
```

Description

`YCNT = step(H,X)` returns the number of extrema (minima, maxima, or both) `YCNT` in input signal `X`.

`[YCNT,IDX] = step(H,X)` when the `PeakIndicesOutputPort` property is `true`, returns the number of extrema `YCNT` and peak indices `IDX` in input signal `X`.

`[..., VAL] = step(H,X)` also returns the peak values `VAL` in input signal `X` when the `PeakValuesOutputPort` property is `true`.

`[..., POL] = step(H,X)` also returns the extrema polarity `POL` in input signal `X` when the `PeakType` property is `Maxima and Minima` and the `PeakIndicesOutputPort` property is `true`. The polarity is `1` for maxima and `0` for minima.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Peak-to-peak value

Description

The `PeakToPeak` object computes the peak-to-peak value of an input.

To obtain the peak-to-peak value:

1. Define and set up your peak-to-peak calculation. See "Construction" on page 3-1199.
2. Call `step` to compute the peak-to-peak value for an input vector according to the properties of `dsp.PeakToPeak`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.PeakToPeak` creates a peak-to-peak System object, `H`, that computes the difference between the maximum and minimum value in an input or a sequence of inputs.

`H = dsp.PeakToPeak('PropertyName',PropertyValue,...)` returns an `PeakToPeak` System object, `H`, with each specified property set to the specified value.

Properties

CustomDimension

Dimension to operate along. Specify the dimension as a positive integer along which the peak-to-peak difference is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when the `Dimension` property is `'Custom'`.

Default: `1`

Dimension

Dimension to operate along. Specify the dimension along which to calculate the peak-to-peak ratio as one of `'All'`, `'Row'`, `'Column'`, or `'Custom'`. This property applies when the `RunningPeakToPeak` property is `false`. If you set this property to `'Custom'`, specify the dimension using the `CustomDimension` property.

Default: `'Column'`

FrameBasedProcessing

Process input in frames or as samples. Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies when the `RunningPeakToPeak` property is `true`.

Default: `true`

ResetCondition

Reset condition for running peak-to-peak mode. Specify the event to reset the running peak-to-peak as one of `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies when the `ResetInputPort` property is `true`.

ResetInputPort

Enables resetting in running peak-to-peak mode. Set this property to `true` to enable resetting the running peak-to-peak. When the property is set to `true`, a reset input must be specified to the call of `step` to reset the running peak-to-peak difference. This property applies when the `RunningPeakToPeak` property is `true`.

Default: `false`

RunningPeakToPeak

Calculation over successive calls to `step`. Set this property to `true` to enable the calculation of the peak-to-peak difference over successive calls to the `step`.

Default: `false`

Methods

clone	Clones the current instance of the peak-to-peak object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset the running peak-to-peak object
step	Compute peak-to-peak value

Examples

Peak-to-Peak Value of Vector

Determine the peak-to-peak value for a vector input.

```
in1 = (1:10)';
h1 = dsp.PeakToPeak;
y1 = step(h1, in1);
```

Peak-to-Peak Value of Matrix Input

Determine the peak-to-peak value of a matrix input.

```
in2 = magic(4);
h2 = dsp.PeakToPeak;
h2.Dimension = 'All';
y2 = step(h2, in2)
```

References

See Also

`dsp.Maximum` | `dsp.PeakToRMS`

Purpose

Clones the current instance of the peak-to-peak object

Syntax

```
clone(H)
```

Description

`clone(H)` clones the current instance of the peak-to-peak object, `H`.

dsp.PeakToPeak.getNumInputs

Purpose

Number of expected inputs to the `step` method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the peak-to-peak object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of the `step` method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method for the peak-to-peak object, `H`.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.PeakToPeak.isLocked

Purpose

Locked status (logical) for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the peak-to-peak object `H`.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.PeakToPeak.reset

Purpose Reset the running peak-to-peak object

Syntax `reset(H)`

Description `reset(H)` resets the running peak-to-peak value for the object `H`.

Purpose

Compute peak-to-peak value

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

`Y = step(H,X)` computes the peak-to-peak value, `Y`, of the floating-point input vector `X`. When the `RunningPeakToPeak` property is `true`, `Y` corresponds to the peak-to-peak value of the input elements over successive calls to the `step` method.

`Y = step(H,X,R)` computes the peak-to-peak value of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal, `R`, and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToPeak` and the `ResetInputPort` properties to `true`.

dsp.PeakToRMS

Purpose

Peak-to-root-mean-square value of vector

Description

The `PeakToRMS` object calculates the peak-to-root-mean-square ratio of a vector.

To compute the peak-to-root-mean-square ratio:

1. Define and set up your peak-to-root-mean-square calculation. See "Construction" on page 3-1210.
2. Call `step` to calculate the peak-to-root-mean-square value for an input vector according to the properties of `dsp.PeakToRMS`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.PeakToRMS` creates a peak-to-root-mean-square System object, `H`, that returns the ratio of the maximum magnitude (peak) to the root-mean-square (RMS) value in an input or a sequence of inputs.

`H = dsp.PeakToRMS('PropertyName',PropertyValue,...)` returns an `PeakToRMS` System object, `H`, with each specified property set to the specified value.

Properties

CustomDimension

Numerical dimension to operate along. Specify the dimension as a positive integer along which the peak-to-RMS ratio is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` property is `'Custom'`.

Default: `1`

DecibelScaledOutput

Report output in decibels (dB). Set this property to `true` to enable output in dB. Set this property to `false` to report output as a ratio.

Default: `true`

Dimension

Dimension to operate along. Specify the dimension along which to calculate the peak-to-RMS ratio as one of `'All'`, `'Row'`, `'Column'`, or `'Custom'`. This property applies when the `RunningPeakToRMS` property is `false`. If you set this property to `'Custom'`, specify the dimension using the `CustomDimension` property.

Default: `'Column'`

FrameBasedProcessing

Process input in frames or as samples. Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies when the `RunningPeakToRMS` property is `true`.

Default: `true`

ResetCondition

Reset condition for running peak-to-RMS mode. Specify the event to reset the running peak-to-RMS as one of `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies when the `ResetInputPort` property is `true`.

ResetInputPort

Enables resetting in running peak-to-RMS mode. Set this property to `true` to enable resetting. When the property is set to `true`, a reset input must be specified in the call to `step` to reset the running peak-to-RMS ratio. This property applies when the `RunningPeakToRMS` property is `true`.

Default: `false`

RunningPeakToRMS

Calculation over successive calls to `step`. Set this property to `true` to enable the calculation of the peak-to-RMS ratio over successive calls to the `step`.

Default: `false`

Methods

clone	Clones the current instance of the peak-to-root-mean-square object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset the running peak-to-root-mean-square object
step	Compute peak-to-RMS ratio

Definitions

Peak-magnitude-to-RMS Level

The peak-magnitude-to-RMS level is

$$\frac{||X||_\infty}{\sqrt{\frac{1}{N}\sum_{n=1}^{N}|X_n|^2}}$$

where the l-infinity norm and RMS values are computed along the specified dimension.

Examples

Peak-to-RMS Ratio of Vector Input

Determine the peak-to-RMS ratio of a vector input.

```
in1 = (1:10)';
h1 = dsp.PeakToRMS;
y1 = step(h1,in1);
```

Peak-to-RMS Ratio of Matrix Input

Determine the peak-to-RMS ratio of a matrix input.

```
in2 = magic(4);
h2 = dsp.PeakToRMS;
h2.Dimension = 'All';
y2 = step(h2, in2)
```

References

[1] *IEEE Standard on Transitions, Pulses, and Related Waveforms*, IEEE Standard 181, 2003.

See Also

`dsp.Maximum` | `dsp.PeakToPeak`

dsp.PeakToRMS.clone

Purpose

Clones the current instance of the peak-to-root-mean-square object

Syntax

```
clone(H)
```

Description

`clone(H)` clones the current instance of the peak-to-root-mean-square (RMS) object `H`.

Purpose

Number of expected inputs to the `step` method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the peak-to-root-mean-square object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.PeakToRMS.getNumOutputs

Purpose

Number of outputs of the `step` method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status (logical) for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the peak-to-root-mean-square object `H`.

dsp.PeakToRMS.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset the running peak-to-root-mean-square object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the running peak-to-root-mean-square value for the object `H`.

dsp.PeakToRMS.step

Purpose

Compute peak-to-RMS ratio

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

`Y = step(H,X)` computes the peak-to-RMS ratio, `Y`, of the floating-point input vector `X`. When the `RunningPeakToRMS` property is `true`, `Y` corresponds to the peak-to-RMS ratio of the input elements over successive calls to the `step` method.

`Y = step(H,X,R)` computes the peak-to-RMS ratio of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal, `R`, and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

Purpose

Unwrap signal phase

Description

The `PhaseUnwrapper` object unwraps the signal phase input specified in radians.

To unwrap the signal phase input:

1. Define and set up your System object. See "Construction" on page 3-1221.
2. Call `step` to unwrap the signal phase according to the properties of `dsp.PhaseUnwrapper`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.PhaseUnwrapper` returns a System object, `H`. This System object adds or subtracts appropriate multiples of 2π to each input element to remove phase discontinuities (unwrap).

`H = dsp.PhaseUnwrapper('PropertyName',PropertyValue,...)` returns an unwrapped System object, `H`, with each specified property set to the specified value.

Properties

InterFrameUnwrap

Enable unwrapping of phase discontinuities between successive frames

Set this property to `false` to unwrap phase discontinuities only within the frame. Set this property to `true` to also unwrap phase discontinuities between successive frames. This property applies when you set the `FrameBasedProcessing` to `true`. The default is `true`.

Tolerance

Jump size as true phase discontinuity

Specify the jump size that the phase unwrapper recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features.

To increase the phase wrapper sensitivity, set the `Tolerance` property to a value slightly less than π.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

Methods

clone	Create phase unwrapper object with same property values
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of Phase Unwrapper System object
step	Unwrap input phase signal input

Examples

Unwrap input phase data:

```
hunwrap = dsp.PhaseUnwrapper;
p = [0 2/5 4/5 -4/5 -2/5 0 2/5 4/5 -4/5 -2/5 0 2/5 ...
 4/5 -4/5, -2/5]*pi;
y = step(hunwrap, p');
figure,stem(p); hold
stem(y, 'r');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Unwrap block reference page. The object properties correspond to the Simulink block parameters.

Objects and blocks interpret frames differently. Objects process inputs as frames or as samples by setting the `FrameBasedProcessing` property. Blocks process inputs as frames or as samples by inheriting the frame information from the input ports. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`unwrap`

dsp.PhaseUnwrapper.clone

Purpose Create phase unwrapper object with same property values

Syntax `clone(H)`

Description `clone(H)` clones the current instance of the phase unwrapper object `H`.

Purpose

Number of expected inputs to the `step` method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.PhaseUnwrapper.getNumOutputs

Purpose

Number of outputs of the `step` method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the phase unwrapper object `H`.

dsp.PhaseUnwrapper.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of Phase Unwrapper System object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the 2π multiplier `k` to `0` for the phase unwrapper object `H`. See "Frame-Based Processing" on page 1-1750 for details.

dsp.PhaseUnwrapper.step

Purpose

Unwrap input phase signal input

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` unwraps the input signal `X` in radians for the root mean square (RMS) object `H`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Pulse metrics of bilevel waveforms

Description

The `PulseMetrics` object computes rise times, fall times, pulse widths, and cycle metrics including pulse period, pulse separation, and duty cycle for bilevel waveforms.

To obtain pulse metrics for a bilevel waveform:

1. Define and set up your pulse metrics. See "Construction" on page 3-1231.
2. Call `step` to compute the pulse metrics according to the properties of `dsp.PulseMetrics`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.PulseMetrics` creates a pulse metrics System object, `H`. The object computes the rise time, fall time, and width of a pulse. `dsp.PulseMetrics` also computes cycle metrics such as pulse separations, periods, and duty cycles. Because a pulse contains two transitions, the object contains a superset of the capability defined in `dsp.TransitionMetrics`.

`H = dsp.PulseMetrics('PropertyName',PropertyValue,...)` returns a `PulseMetrics` System object, `H`, with each specified property set to the specified value.

Properties

CycleOutputPort

Enable cycle metrics. If `CycleOutputPort` is `true`, cycle metrics are reported for each pulse period.

Default: `false`

MaximumRecordLength

Maximum samples to preserve between calls to `step`. This property requires a positive integer that specifies the maximum number of samples to save between calls to the step method. When the number of samples to be saved exceeds this length, the

oldest excess samples are discarded. This property applies when the `RunningMetrics` property is `true` and is tunable.

Default: `1000`

PercentReferenceLevels

Lower-, middle-, and upper-percent reference levels. This property contains a three-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the lower and upper states of the waveform when computing the duration of each transition.

Default: `[10 50 90]`

PercentStateLevelTolerance

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Default: `2`

Polarity

Polarity of pulse to extract. This property specifies the type of pulse to extract by the polarity of the leading transition. Valid values for this property are `'positive'` or `'negative'`.

Default: `'positive'`

PostshootOutputPort

Enable posttransition aberration metrics. If this property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins

at the end of each transition and whose duration is the value of `PostshootSeekFactor` times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

Default: `false`

PostshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

Default: `3`

PreshootOutputPort

Enable pretransition aberration metrics. If `PreshootOutputPort` is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

Default: `'false'`

PreshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

Default: `3`

RunningMetrics

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object will defer reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to `step` is made with enough data to compute all enabled metrics for that transition.

Default: `false`

SampleRate

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

Default: `1`

SettlingOutputPort

Enable settling metrics. If the `SettlingOutputPort` property is set to `true`, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last

transition. The metrics are reported for the transition the next time `step` is called if the `RunningMetrics` property is set to `true`.

Default: `false`

SettlingSeekDuration

Duration of time over which to search for settling. This property value is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `PulseMetrics` object will report `NaN` for all settling metrics. This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

Default: `0.02`

StateLevels

Low- and high-state levels. This property is a 2–element numeric row vector that contains the low- and high-state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

Default: `[0 2.3]`

StateLevelsSource

Auto or manual state-level computation. If `StateLevelsSource` is set to `'Auto'`, the first record sent to `step` is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

Default: `'Property'`

TimeInputPort

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

Default: `false`

TransitionOutputPort

Enable transition metrics. If the `TransitionOutputPort` property is set to `true`, transition metrics are reported for the initial and final transitions of each pulse.

Default: `false`

Methods

clone	Clones the current instance of the pulse metrics object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
plot	Plots signal and metrics computed in last call to

reset	Reset the running pulse metrics object
step	Pulse metrics of bilevel waveforms

Examples

Width, Period, and Duty Cycle

Determine the width, period, and duty cycle of a 5 V pulse sampled at 4 MHz.

Load the data and sampling instants.

```
load('pulseex.mat', 'x', 't');
```

Construct your pulse metrics System object. Set the `TimeInputPort` property to `true` to specify the sampling instants as an input to `step`. Set the `CycleOutputPort` property to `true` to obtain metrics for each pulse. Because the input is a 5V pulse, set the `StateLevels` property to `[0 5]`.

```
hpm1 = dsp.PulseMetrics('TimeInputPort',true, ...
                            'CycleOutputPort', true, ...
                            'StateLevels',[0 5])
```

Call `step` to compute the cycle metrics and plot the result.

```
[pulse, cycle] = step(hpm1,x,t);
plot(hpm1)
text(t(2),-0.5,['Duty Cycle: ',num2str(cycle.DutyCycle)]);
```

Slew Rates for 2.3 V Digital Clock

Find the slew rates of the leading and trailing edges of a 2.3 V digital clock sampled at 4 MHz.

Construct your pulse metrics System object. Set the `TransitionOutputPort` property to `true` to report transition metrics for the initial and final transitions. Set the `StateLevelsSource` property to `'Auto'` to estimate the state levels from the data.

```
hpm2 = dsp.PulseMetrics('SampleRate',4e6, ...
                        'TransitionOutputPort', true, ...
                        'StateLevelsSource','Auto');
```

Compute the pulse and transition metrics and plot the result.

```
[pulse, transition] = step(hpm2,x);
plot(hpm2)
```

References

[1] *IEEE Standard on Transitions, Pulses, and Related Waveforms*, IEEE Standard 181, 2003.

See Also

`dsp.StateLevels` | `dsp.TransitionMetrics`

Purpose

Clones the current instance of the pulse metrics object

Syntax

```
clone(H)
```

Description

`clone(H)` clones the current instance of the pulse metrics object `H`.

dsp.PulseMetrics.getNumInputs

Purpose

Number of expected inputs to the `step` method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the pulse metrics object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of the `step` method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.PulseMetrics.isLocked

Purpose

Locked status (logical) for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the pulse metrics object `H`.

Purpose

Plots signal and metrics computed in last call to `step`

Syntax

```
plot(H)
```

Description

`plot(H)` plots the signal and metrics resulting from the last call of the step method.

By default `plot` displays

- the low and high state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When the `TransitionOutputPort` property is set to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true`, the corresponding overshoots and undershoots are plotted as inverted or noninverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the lower and upper state boundaries over the specified seek duration are plotted.

dsp.PulseMetrics.reset

Purpose

Reset the running pulse metrics object

Syntax

```
reset(H)
```

Description

`reset(H)` clears information from previous calls to `step`.

Purpose

Pulse metrics of bilevel waveforms

Syntax

```
PULSE = step(H,X)
[PULSE,CYCLE] = step(H,X)
[PULSE, TRANSITION] = step(H,X)
[PULSE,PRESHOOT] = step(H,X)
[PULSE,POSTSHOOT] = step(H,X)
[PULSE,SETTLING] = step(H,X)
[...] = step(H,X,T)
```

Description

`PULSE = step(H,X)` returns a structure array, `PULSE`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `X`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

`PULSE` fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse
- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse
- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

`[PULSE,CYCLE] = step(H,X)` returns a structure array, `CYCLE`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field

corresponds to the number of complete pulse periods found in the real-valued column vector input, `X`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found in the input `X` does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

`CYCLE` fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse
- `Frequency` — Reciprocal of the period
- `Separation` — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse
- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `PULSE` structure.
- `DutyCycle` — Ratio of the width to the period for each pulse

`[PULSE, TRANSITION] = step(H,X)` returns a structure array, `TRANSITION`, when you set the `TransitionOutputPort` property to `true`. The fields of `TRANSITION` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`TRANSITION` fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels

- `SlewRate` — Ratio of absolute difference between the upper and lower reference levels to the transition duration
- `MiddleCross` — Linearly-interpolated instant in time where the transition first crosses the mid-reference level
- `LowerCross` — Linearly-interpolated instant where the signal crosses the lower-reference level
- `UpperCross` — Linearly-interpolated instant where the signal crosses the upper-reference level

`[PULSE,PRESHOOT] = step(H,X)` returns a structure array, `PRESHOOT`, when you set the `PreshootOutputPort` property to `true`. The fields of `PRESHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `POSTSHOOT` structure array.

`[PULSE,POSTSHOOT] = step(H,X)` returns a structure, `POSTSHOOT`, when you set the `PostshootOutputPort` property to `true`. The fields of `POSTSHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`PRESHOOT` and `POSTSHOOT` fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

`[PULSE,SETTLING] = step(H,X)` returns a structure array, `SETTLING`, when you set the `SettlingOutputPort` property to `true`. The fields of `SETTLING` correspond to the settling metrics for each transition. Each

field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

`SETTLING` fields:

- `Duration` — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified `PercentStateLevelTolerance` of the waveform amplitude over the specified settling seek duration
- `Instant` — Instant in time where the signal enters and remains within the specified tolerance
- `Level` — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

`[PULSE,CYCLE,TRANSITION,PRESHOOT,POSTSHOOT,SETTLING] = step(H,X)` which returns the `PULSE`, `CYCLE`, `TRANSITION`, `PRESHOOT`, `POSTSHOOT`, and `SETTLING` structures when the `CycleOutputPort`, `PreshootOutputPort`, `PostshootPort`, and `SettlingOutputPort` properties are `true`. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

`[...] = step(H,X,T)` performs the above metrics with respect to a sampled signal, whose sample values, `X`, and sample instants, `T`, are real-valued column vectors of the same length. The additional input `T` applies only when you set the `TimeInputPort` property to `true`.

Purpose

Convert reflection coefficients to autocorrelation coefficients

Description

The `RCToAutocorrelation` object converts reflection coefficients to autocorrelation coefficients.

To convert reflection coefficients to autocorrelation coefficients:

1. Define and set up your System object. See "Construction" on page 3-1249.
2. Call `step` to convert reflection coefficients according to the properties of `dsp.RCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.RCToAutocorrelation` returns an `RCToAutocorrelation` System object, `H`. This object converts reflection coefficients to autocorrelation coefficients, assuming an error power of `1`.

`H = dsp.RCToAutocorrelation('PropertyName',PropertyValue,...)` returns an object, `H`, that converts reflection coefficients into autocorrelation coefficients, with each specified property set to the specified value.

Properties

PredictionErrorInputPort

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes a prediction error power of `1`. The default is `false`.

Methods

clone	Create RC to autocorrelation object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert columns of reflection coefficients to autocorrelation coefficients

Examples

Convert reflection coefficients to autocorrelation coefficients:

```
k = [-0.8091 0.2525 -0.5044 0.4295 -0.2804 0.0711].';
hrc2ac = dsp.RCToAutocorrelation;
ac = step(hrc2ac, k);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC/RC to Autocorrelation block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter.
- **PredictionErrorInputPort** is a pop-up menu choice on the block. Setting the `PredictionErrorInputPort` object property to `false` corresponds to selecting `Assume P = 1` in the pop-up menu. Setting `PredictionErrorInputPort` to `true` corresponds to selecting `Via input port` from the pop-up menu.

dsp.LPCToLSF | dsp.LPCToRC | dsp.LPCToCepstral | dsp.LPCToAutocorrelation

dsp.RCToAutocorrelation.clone

Purpose

Create RC to autocorrelation object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `RCToAutocorrelation` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.RCToAutocorrelation.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `RCToAutocorrelation` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.RCToAutocorrelation.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Convert columns of reflection coefficients to autocorrelation coefficients

Syntax

```
AC = step(H,K)
AC = step(H,K,P)
```

Description

`AC = step(H,K)` converts the columns of the reflection coefficients, `K`, to autocorrelation coefficients, `AC`.

`AC = step(H,K,P)` when you set the `PredictionErrorInputPort` property to `true`, converts the columns of the reflection coefficients, `K` , to autocorrelation coefficients, `AC`, using `P` as the prediction error power. `P` must be a row vector with same number of columns as in `K`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.RCToLPC

Purpose

Convert reflection coefficients to linear prediction coefficients

Description

The `RCToLPC` object converts reflection coefficients to linear prediction coefficients.

To convert reflection coefficients to LPC:

1. Define and set up your RC to LPC System object. See "Construction" on page 3-1258.
2. Call `step` to convert RC to LPC according to the properties of `dsp.RCToLPC`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.RCToLPC` returns an RC to LPC System object, `H`, that converts reflection coefficients (RC) to linear prediction coefficients (LPC).

`H = dsp.RCToLPC('PropertyName',PropertyValue,...)` returns an RC to LPC conversion object, `H`, with each specified property set to the specified value.

Properties

PredictionErrorOutputPort

Enable normalized prediction error power output

Set this property to `true` to return the normalized error power as a vector with one element per input channel. Each element varies between `0` and `1`. The default is `true`.

ExceptionOutputPort

Produce output with stability status of filter represented by LPC coefficients

Set this property to `true` to return the stability of the filter. The output is a vector of a length equal to the number of channels. A logical value of `1` indicates a stable filter. A logical value of `0` indicates an unstable filter. The default is `false`.

Methods

clone	Creates instance of object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Convert columns of reflection coefficients to linear prediction coefficients

Examples

Convert reflection coefficients to linear prediction coefficients:

```
hlevinson = dsp.LevinsonSolver;
hac = dsp.Autocorrelator;
hac.MaximumLagSource = 'Property';
hac.MaximumLag = 10; % Compute autocorrelation
                     % lags between [0:10]
hrc2lpc = dsp.RCToLPC;

x = (1:100)';
a = step(hac, x);
k = step(hlevinson, a); % Compute reflection coefficients
[A, P] = step(hrc2lpc, k);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LPC to/from RC block reference page. The object properties correspond to the block parameters, except:

There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.

.

```

Description

`C = clone(H)` creates an `RCToLPC` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.RCToLPC.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.RCToLPC.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `RCToLPC` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.RCToLPC.step

Purpose

Convert columns of reflection coefficients to linear prediction coefficients

Syntax

```
[A,P] = step(H,K)
A = step(H,K)
[..., S] = step(H,K)
```

Description

`[A,P] = step(H,K)` converts the columns of the reflection coefficients, `K`, to linear prediction coefficients, `A`, and outputs the normalized prediction error power, `P`.

`A = step(H,K)` when the `PredictionErrorOutputPort` property is `false`, converts the columns of the reflection coefficients, `K`, to linear prediction coefficients, `A`.

`[..., S] = step(H,K)` also outputs the `LPC` filter stability, `S`, when the `ExceptionOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Compute output, error and coefficients using Recursive Least Squares (RLS) algorithm

Description

The `RLSFilter` object filters each channel of the input using RLS filter implementations.

To filter each channel of the input:

1. Define and set up your RLS filter. See "Construction" on page 3-1267.
2. Call `step` to filter each channel of the input according to the properties of `dsp.RLSFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.RLSFilter` returns an adaptive RLS filter System object, `H`. This System object computes the filtered output, filter error and the filter weights for a given input and desired signal using the RLS algorithm.

`H = dsp.RLSFilter('PropertyName',PropertyValue, ...)` returns an RLS filter System object, `H`, with each specified property set to the specified value.

`H = dsp.RLSFilter(LEN, 'PropertyName', PropertyValue, ...)` returns an RLS filter System object, `H`. This System object has the Length property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate the filter coefficients

You can specify the method used to calculate filter coefficients as one of | `Conventional RLS` [1] [2] | `Householder RLS` [3] [4] | `Sliding-window RLS` [1][2] | `Householder sliding-window RLS` [4] | `QR decomposition` [1] [2]. The default value is `Conventional RLS`. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the RLS filter coefficients vector as a scalar positive integer value. The default value is `32`. This property is nontunable.

SlidingWindowBlockLength

Width of the sliding window

Specify the width of the sliding window as a scalar positive integer value greater than or equal to the Length property value. This property is applicable only when the Method property is set to `Sliding-window RLS` or `Householder sliding-window RLS`. The default value is `48`. This property is nontunable.

ForgettingFactor

RLS forgetting factor

Specify the RLS forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this property value to 1 denotes infinite memory, while adapting to find the new filter. The default value is `1`. This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the `Length` property value. The default value is `0`. This property is tunable.

InitialInverseCovariance

Initial inverse covariance

Specify the initial values of the inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix, with each dimension equal to the `Length` property value. If you set a scalar value, the `InverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the `Method`

property is set to `Conventional RLS` or `Sliding-window RLS`. The default value is `1000`. This property is tunable.

InitialSquareRootInverseCovariance

Initial square root inverse covariance

Specify the initial values of the square root inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootInverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the `Method` property is set to `Householder RLS` or `Householder sliding-window RLS`. The default value is `sqrt(1000)`. This property is tunable.

InitialSquareRootCovariance

Initial square root covariance

Specify the initial values of the square root covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootCovariance` property is initialized to a diagonal matrix with diagonal elements equal to the scalar value. This property applies only when the `Method` property is set to `QR-decomposition RLS`. The default value is `sqrt(1/1000)`. This property is tunable.

LockCoefficients

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients continuously updated). This property is tunable.

Methods

clone	Create System object with same property values
isLocked	Locked status for input attributes and nontunable properties
msesim	Mean-square error for RLS filter
release	Allow property value and input characteristics changes
reset	Reset the internal states of a System object
step	Process inputs using RLS filter

Examples

System Identification of an FIR Filter

Use the RLS filter System object to determine the signal value

```
hrls1 = dsp.RLSFilter(11, 'ForgettingFactor', 0.98);
hfilt = dsp.FIRFilter('Numerator',fir1(10, .25)); % Unknown System
x = randn(1000,1);                        % input signal
d = step(hfilt, x) + 0.01*randn(1000,1); % desired signal
[y,e] = step(hrls1, x, d);
w = hrls1.Coefficients;
subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([hfilt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #'); ylabel('coefficient value');
```

Noise Cancellation

```
hrls2 = dsp.RLSFilter('Length', 11, 'Method', 'Householder RLS');
hfilt2 = dsp.FIRFilter('Numerator',fir1(10, [.5, .75]));
x = randn(1000,1);                            % Noise
```

```
d = step(hfilt2, x) + sin(0:.05:49.95)';     % Noise + Signal
[y, err] = step(hrls2, x, d);
subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');
```

Algorithms

The `dsp.RLSFilter` System object, when `Conventional RLS` is selected, recursively computes the least squares estimate (RLS) of the FIR filter weights. The System object estimates the filter weights or coefficients, needed to convert the input signal into the desired signal. The input signal can be a scalar or a column vector. The desired signal must have the same data type, complexity, and dimensions as the input signal. The corresponding RLS filter is expressed in matrix form as $\mathbf{P}(n)$:

$$\mathbf{k}(n) = \frac{\lambda^{-1}\mathbf{P}(n-1)\mathbf{u}(n)}{1+\lambda^{-1}\mathbf{u}^{H}(n)\mathbf{P}(n-1)\mathbf{u}(n)}$$

$$y(n) = \mathbf{w}^{T}(n-1)\mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}(n)e(n)$$

$$\mathbf{P}(n) = \lambda^{-1}\mathbf{P}(n-1) - \lambda^{-1}\mathbf{k}(n)\mathbf{u}^{H}(n)\mathbf{P}(n-1)$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{P}(n)$	The inverse correlation matrix at step n
$\mathbf{k}(n)$	The gain vector at step n

Variable	Description
$\mathbf{w}(n)$	The vector of filter tap estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The forgetting factor

u, **w**, and **k** are all column vectors.

`dsp.FIRFilter` | `dsp.LMSFilter` | `dsp.AffineProjectionFilter`

Purpose

Mean-square error for RLS filter

Syntax

```
MSE = msesim(H,X,D)
[MSE,MEANW,W,TRACEK] = msesim(H,X,D)
[...] = msesim(H,X,D,M)
```

Description

`MSE = msesim(H,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(H,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `H`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `H`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(H,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

dsp.RLSFilter.clone

Purpose

Create System object with same property values

Syntax

```
C = clone(OBJ)
```

Description

`C = clone(OBJ)` creates another instance of the System object, `OBJ`, with the same property values. The `clone` method creates a new unlocked object with uninitialized states.

See Also

`dsp.RLSFilter.step` | `dsp.RLSFilter.isLocked` | `dsp.RLSFilter.reset`

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
L = isLocked(OBJ)
```

Description

`L = isLocked(OBJ)` returns a logical value, `L`, which indicates whether input attributes and nontunable properties are locked for the System object, `OBJ`. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. Once this occurs, the `isLocked` method returns a `true` value.

See Also

`dsp.RLSFilter.step` | `dsp.RLSFilter.release`

dsp.RLSFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(OBJ)
```

Description

`release(OBJ)` releases system resources, such as memory, file handles, and hardware connections of the System object, `OBJ`, and allows all its properties and input characteristics to be changed.

Once you call the `release` method on a System object, subsequent calls to `setup`, `step`, `reset`, or `release` are not supported for code generation.

See Also

`dsp.RLSFilter.isLocked` | `dsp.RLSFilter.step`

Purpose

Reset the internal states of a System object

Syntax

```
reset(OBJ)
```

Description

`reset(OBJ)` resets the internal states of the System object, `OBJ`, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

dsp.RLSFilter.step

Purpose

Process inputs using RLS filter

Syntax

```
Y = step(OBJ,x)
[Y1,...,YN] = step(OBJ,x)
```

Description

`Y = step(OBJ,x)` processes the input data, `x`, to produce the output, `Y`, for the System object, `OBJ`. `[Y1,...,YN] = step(OBJ,x)` produces N outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Purpose

Root mean square of vector elements

Description

The `RMS` object computes the root mean square (RMS) value.

To compute the RMS value of your input:

1. Define and set up your RMS calculation. See "Construction" on page 3-1279.
2. Call `step` to compute the RMS value for an input according to the properties of `dsp.RMS`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.RMS` returns a System object, `H`, that computes the root mean square (RMS) of an input or a sequence of inputs over the specified `Dimension`.

`H = dsp.RMS('PropertyName',PropertyValue,...)` returns an `RMS` System object, `H`, with each specified property set to the specified value.

Properties

RunningRMS

Enable calculating RMS over time

Set this property to `true` to enable calculating the RMS over successive calls to the `step` method.

Default: `false`

ResetInputPort

Enable resetting in running RMS mode

Set this property to `true` to enable resetting the running RMS. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running RMS. This property applies when you set the `RunningRMS` property to `true`.

Default: `false`

ResetCondition

Reset condition for running RMS mode

Specify the event to reset the running RMS as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. `Non-zero` resets the running RMS each time a nonzero sample is acquired. See "Rising and Falling Edges" on page 3-1281 for definitions of rising and falling edges. This property applies when you set the `ResetInputPort` property to `true`.

Default: `Non-zero`

Dimension

Dimension to compute RMS value along

Specify the dimension along which to calculate the RMS as one of `All`, `Row`, `Column`, or `Custom`. This property applies only when you set the `RunningRMS` property to `false`. Specifying the `Dimension` property as `All` computes the RMS value over the entire input.

Default: `Column`

CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based scalar integer value) of the input signal, along which the RMS is computed. The cannot exceed the number of dimensions in the input signal. This property applies when you set the `Dimension` property to `Custom`.

Default: `1`

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing for 2-dimensional inputs. Set this property to `false` to

enable sample-based processing. The object always performs sample-based processing for N-D inputs where N is greater than `2`. This property applies when you set the `RunningRMS` property to `true`.

Default: `true`

Methods

clone	Clones the current instance of the root mean square object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset the running root mean square object
step	Root mean square of input

Definitions

Root-Mean-Square Level

The root-mean-square level of a vector, X, is

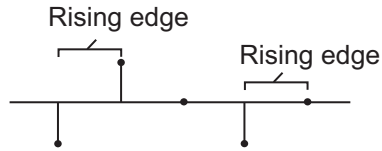
$$X_{\mathrm{RMS}} = \sqrt{\frac{1}{N}\sum_{n=1}^{N}|X_n|^2}$$

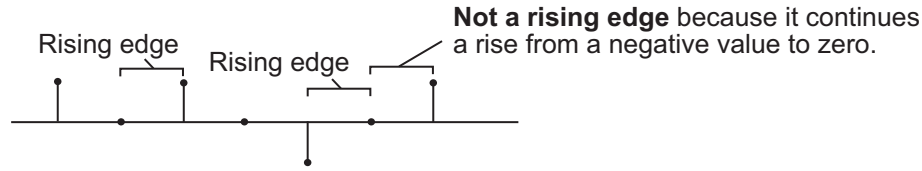
with the summation performed along the specified dimension.

Rising and Falling Edges

A rising edge:

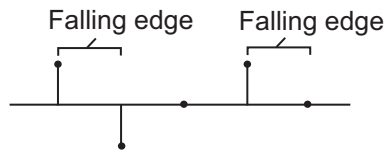
- Rises from a negative value to a positive value or zero.
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

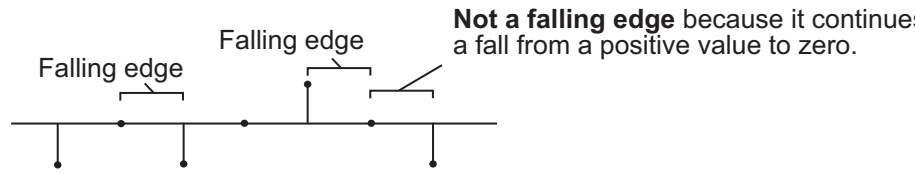




A falling edge:

- Falls from a positive value to a negative value or zero.
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.





Examples

RMS Value of Vector Input

Compute the RMS value of a vector consisting of the integers 1 to 10.

Create a row vector of the integers 1 to 10. Construct the RMS System object with the `Dimension` property set to `'literal'`. Compute the RMS value.

```
x = 1:10;
hrms = dsp.RMS('Dimension','row');
rmsval = step(hrms,x);
```

RMS Value of Matrix Input

Compute the RMS value of a matrix with the `Dimension` property set to `'All'`.

```
in2 = magic(4);
hrms2d = dsp.RMS;
hrms2d.Dimension = 'All';
y_rms2 = step(hrms2d, in2);
```

The output is equivalent to reshaping the 4-by-4 matrix into a 16-by-1, or 1-by-16 vector and computing the RMS value for the vector.

Algorithms

This object implements the algorithm, inputs, and outputs described on the RMS block reference page. The object properties correspond to the Simulink block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the `dsp.RMS` object.
- **Reset Port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.Mean` | `dsp.StandardDeviation` | `dsp.Variance`.

Purpose

Clones the current instance of the root mean square object

Syntax

```
clone(H)
```

Description

`clone(H)` clones the current instance of the root mean square (RMS) object `H`

dsp.RMS.getNumInputs

Purpose

Number of expected inputs to the `step` method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the root mean square (RMS) object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of the `step` method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.RMS.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the root mean square (RMS) object `H`.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.RMS.reset

Purpose Reset the running root mean square object

Syntax `reset(H)`

Description `reset(H)` resets the running root mean square (RMS) for the object `H`.

Purpose

Root mean square of input

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

`Y = step(H,X)` computes the root mean square (RMS) output, `Y` , of input vector `X`. When the `RunningRMS` property is true, `Y` corresponds to the `RMS` of the input elements over successive calls to the `step` method.

`Y = step(H,X,R)` resets the running RMS state based on the value of `R`, the reset signal, and the `ResetCondition` property. This computation is possible when you set both the `RunningRMS` and the `ResetInputPort` properties to `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.ScalarQuantizerDecoder

Purpose

Convert each index value into quantized output value

Description

The `ScalarQuantizerDecoder` object converts each index value into a quantized output value. The specified codebook defines the set of all possible quantized output values or codewords. Input index values less than 0 are set to 0 and index values greater $N-1$ are set to $N-1$. N is the length of the codebook vector.

To convert an index value into a quantized output value:

1. Define and set up your scalar quantizer decoder. See "Construction" on page 3-1292.
2. Call `step` to convert the index value according to the properties of `dsp.ScalarQuantizerDecoder`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.ScalarQuantizerDecoder` returns a scalar quantizer decoder System object, `H`, that transforms zero-based input index values into quantized output values.

`H = dsp.ScalarQuantizerDecoder('PropertyName',PropertyValue,...)` returns a scalar quantizer decoder object, `H`, with each specified property set to the specified value.

Properties

CodebookSource

How to specify codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each index value. The default is `1:10`. This property is tunable.

OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as `Same as input`, `double`, `single` or `Custom`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numerictype` object. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype(true,16)`.

Methods

clone	Create scalar quantizer decoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Decode using scalar quantization

Examples

Given a codebook and index values as inputs, determine the corresponding output quantized values:

```
codebook = single([-2.1655 -1.3238 -0.7365 -0.2249 0.2726, ...
0.7844 1.3610 2.1599]);
```

```
indices = uint8([1 3 5 7 6 4 2 0]);
hsqdec = dsp.ScalarQuantizerDecoder;
hsqdec.CodebookSource = 'Input port';
qout = step(hsqdec, indices, codebook);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than `0` to `0` and any index values greater than or equal to N to $N - 1$.

See Also

`dsp.ScalarQuantizerEncoder` | `dsp.VectorQuantizerDecoder`

Purpose

Create scalar quantizer decoder object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `ScalarQuantizerDecoder` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.ScalarQuantizerDecoder.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.ScalarQuantizerDecoder.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `ScalarQuantizerDecoder` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.ScalarQuantizerDecoder.step

Purpose

Decode using scalar quantization

Syntax

```
Q = step(H, I)
Q = step(H,I,C)
```

Description

`Q = step(H, I)` returns the quantized output values `Q` corresponding to the input indices `I`. The data type of `I` can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type for `Q`.

`Q = step(H,I,C)` uses input `C` as the codebook values when you set the `CodebookSource` property to `Input port`. The data type of `C` can be `double`, `single`, or `fixed-point`. The output `Q` has the same data type as the codebook input `C`.

Purpose

Associate input value with index value of quantization region

Description

The `ScalarQuantizerEncoder` object encodes each input value by associating that value with the index value of the quantization region. Then, the object outputs the index of the associated region.

To encode an input value by associating it with an index value of the quantization region:

1. Define and set up your scalar quantizer encoder. See "Construction" on page 3-1301.
2. Call `step` to encode the input value according to the properties of `dsp.ScalarQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.ScalarQuantizerEncoder` returns a scalar quantizer encoder System object, `H`. This object maps each input value to a quantization region by comparing the input value to the user-specified boundary points.

`H = dsp.ScalarQuantizerEncoder('PropertyName',PropertyValue,...)` returns a scalar quantizer encoder object, `H`, with each specified property set to the specified value.

Properties

BoundaryPointsSource

Source of boundary points

Specify how to determine the boundary points and codebook values as `Property` or `Input port`. The default is `Property`.

Partitioning

Quantizer is bounded or unbounded

Specify the quantizer as `Bounded` or `Unbounded`. The default is `Bounded`.

BoundaryPoints

Boundary points of quantizer regions

Specify the boundary points of quantizer regions as a vector. The vector values must be in ascending order. Let `[p0 p1 p2 p3 ... pN]` denote the boundary points property in the quantizer. If the quantizer is bounded, the object uses this property to specify `[p0 p1 p2 p3 ... pN]`. If the quantizer is unbounded, the object uses this property to specify `[p1 p2 p3 ... p(N-1)]` and sets `p0 = -Inf` and `pN = +Inf`. This property applies when you set the `BoundaryPointsSource` property to `Property`. The default is `1:10`. This property is tunable.

SearchMethod

Find quantizer index by linear or binary search

Specify whether to find the appropriate quantizer index using a linear search or a binary search as one of `Linear` or `Binary`. The computational cost of the linear search method is of the order P and the computational cost of the binary search method is of the order

$$\log_2(\mathrm{P})$$

where P is the number of boundary points. The default is `Linear`.

TiebreakerRule

Behavior when input equals boundary point

Specify whether the input value is assigned to the lower indexed region or higher indexed region when the input value equals boundary point by selecting `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

CodewordOutputPort

Enable output of codeword value

Set this property to `true` to output the codeword values that correspond to each index value. The default is `false`.

QuantizationErrorOutputPort

Enable output of quantization error

Set this property to `true` to output the quantization error for each input value. The quantization error is the difference between the input value and the quantized output value. The default is `false`.

Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each region. If the `Partitioning` property is `Bounded` and the boundary points vector has length N, you must set this property to a vector of length N-1. If the `Partitioning` property is `Unbounded` and the boundary points vector has length N, you must set this property to a vector of length N+1. This property applies when you set the `BoundaryPointsSource` property to `Property` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`. The default is `1.5:9.5`. This property is tunable.

ClippingStatusOutputPort

Enable output of clipping status

Set this property to `true` to output the clipping status. The output is a 1 when an input value is outside the range defined by the `BoundaryPoints` property. When the value is inside the range, the exception output is a 0. This property applies when you set the `Partitioning` property to `Bounded`. The default is `false`.

OutputIndexDataType

Data type of the index output

Specify the data type of the index output from the object as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

Methods

clone	Create an instance of an object with the same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Encode using scalar quantization

Examples

Quantize the varying fractional inputs between zero and five to the closest integers, and then plot the results:

```
hsqe = dsp.ScalarQuantizerEncoder;
hsqe.BoundaryPoints = [-.001 .499 1.499 ...
   2.499 3.499 4.499 5.001];
hsqe.CodewordOutputPort = true;
hsqe.Codebook = [0 1 2 3 4 5];
input = (0:0.02:5)';
[index, quantizedValue] = step(hsqe, input);
plot(1:length(input), [input quantizedValue]);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Scalar Quantizer Encoder block reference page. The object properties correspond to the block parameters.

See Also

`dsp.ScalarQuantizerDecoder` | `dsp.VectorQuantizerEncoder`

dsp.ScalarQuantizerEncoder.clone

Purpose

Create an instance of an object with the same property values

Syntax

Description

`C = clone(H)` creates a `ScalarQuantizerEncoder` object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.ScalarQuantizerEncoder.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `ScalarQuantizerEncoder` object H.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.ScalarQuantizerEncoder.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Encode using scalar quantization

Syntax

```
INDEX= step(HSQE,INPUT)
[...] = step(HSQE,INPUT,BPOINTS)
[...] = step(HSQE,INPUT,BPOINTS,CODEBOOK)
[...,CODEWORD] = step(HSQE, ...)
[..., QERR] = step(HSQE, ...)
[...,CLIPSTATUS] = step(HSQE, ...)
```

Description

`INDEX= step(HSQE,INPUT)` returns the `INDEX` of the quantization region to which the `INPUT` belongs. The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

`[...] = step(HSQE,INPUT,BPOINTS)` when the `BoundaryPointsSource` property is `Input port`, uses input `BPOINTS` as the boundary points .

`[...] = step(HSQE,INPUT,BPOINTS,CODEBOOK)` uses input `BPOINTS` as the boundary points and input `CODEBOOK` as the codebook when the `BoundaryPointsSource` property is `Input port` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`.

`[...,CODEWORD] = step(HSQE, ...)` outputs the `CODEWORD` values that corresponds to each index value when the `CodewordOutputPort` property is `true`.

`[..., QERR] = step(HSQE, ...)` outputs the quantization error `QERR` for each input value when the `QuantizationErrorOutputPort` property is `true`.

`[...,CLIPSTATUS] = step(HSQE, ...)` also returns output `CLIPSTATUS` as the clipping status output port for each input value when the `Partitioning` property is `Bounded` and the `ClippingStatusOutputPort` property is `true`. If an input value is outside the range defined by the `BoundaryPoints` property, `CLIPSTATUS` is `true`. If an input value is inside the range, `CLIPSTATUS` is `false`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Log simulation data in buffer

Description

The `SignalSink` object logs MATLAB simulation data. This object accepts any numeric data type.

To log MATLAB simulation data :

1. Define and set up your signal sink. See "Construction" on page 3-1313.
2. Call `step` to log the simulation data according to the properties of `dsp.SignalSink`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.SignalSink` returns a signal sink, `H`, that logs 2-D input data in the object.

`H = dsp.SignalSink('PropertyName',PropertyValue,...)` returns a signal sink, `H`, with each specified property set to the specified value.

Properties

FrameBasedProcessing

Process input as frames or samples

To enable frame-based processing for 2-D inputs, set this property to `true`. When you set this property to `false`, the object performs sample-based processing on 2-D inputs. The signal sink object always performs sample-based processing for N-D inputs when N is greater than 2. The default is `true`.

BufferLength

Maximum number of input frames or samples to log

Specify the maximum number of frames to log when the object is performing frame-based processing, or the maximum number of samples to log when the object is performing sample-based processing. The object always preserves the most recent data in the buffer. When you specify a buffer length that is greater than the input length, the object pads the end of the logged data with

zeros. To capture all input data without extra padding, set the `BufferLength` property to `inf`. The default is `inf`.

Decimation

Decimation factor

Setting this property to any positive integer d causes the signal sink to write data at every dth sample. The default is `1`.

FrameHandlingMode

Output dimensionality for frame-based inputs

Set the dimension of the output array for frame-based inputs as `2-D array (concatenate)` or `3-D array (separate)`. Concatenation occurs along the first dimension for `2-D array (concatenate)`. This property applies only when you set the `FrameBasedProcessing` property to `true`. The default is `2-D array (concatenate)`.

Buffer

Logged Data (read only)

The signal sink writes simulation data into a buffer. Specify the maximum length of the buffer with the `BufferLength` property.

Methods

clone	Create signal logger object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes

reset	Reset internal states of signal logger object
step	Store signal in buffer

Examples

Log input data.

```
hlog = dsp.SignalSink;
 for i=1:10
     y = sin(i);
     step(hlog,y);
 end
log = hlog.Buffer; % log = sin([1;2;3;4;5;6;7;8;9;10])
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Signal To Workspace block reference page. The object properties correspond to the block properties, except:

The object always generates fixed-point output for fixed-point input.

Objects and blocks interpret frames differently. Objects process inputs as frames or as samples by setting the `FrameBasedProcessing` property. Blocks process inputs as frames or as samples by inheriting the frame information from the input ports. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.SignalSource`

dsp.SignalSink.clone

Purpose

Create signal logger object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `SignalSink` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.SignalSink.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `SignalSink` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.SignalSink.reset

Purpose

Reset internal states of signal logger object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `SignalSink` object `H` to their initial values.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.SignalSink.step

Purpose

Store signal in buffer

Syntax

```
step(H,Y)
```

Description

`step(H,Y)` buffers the signal `Y`. The buffer may be accessed at any time from the `Buffer` property of `H`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Import variable from workspace

Description

The `SignalSource` object imports a variable from the MATLAB workspace.

To import a variable from the MATLAB workspace:

1. Define and set up your signal source. See "Construction" on page 3-1323.
2. Call `step` to import the variable according to the properties of `dsp.SignalSource`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.SignalSource` returns a signal source System object, `H`, that outputs the variable one sample or frame at a time.

`H = dsp.SignalSource('PropertyName',PropertyValue,...)` returns a signal source object, `H`, with each specified property set to the specified value.

`H = dsp.SignalSource(signal,spf,'PropertyName',PropertyValue,...)` returns a signal source object, `H`, with the `Signal` property set to `signal`, the `SamplesPerFrame` property set to `spf`, and other specified properties set to the specified values.

Properties

Signal

Variable or expression containing the signal

Specify the name of the workspace variable from which to import the signal, or a valid expression specifying the signal. The default is `[1:10]`.

SamplesPerFrame

Number of samples per output frame

Specify the number of samples to buffer into each output frame. This property must be `1` when you specify a 3-D array in the `Signal` property. The default is `1`.

SignalEndAction

Action after final signal values are generated

Specify the output after all of the specified signal samples have been generated as one of `Set to zero`, `Hold final value`, or `Cyclic repetition`. The default is `Set to zero`.

Methods

clone	Create signal reader object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isDone	End-of-file status for signal reader object
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of signal reader object
step	Read one sample or frame of signal

Examples

Create a signal source to output one sample at a time:

```
hsr1 = dsp.SignalSource;
hsr1.Signal = randn(1024, 1);
y1 = zeros(1024,1);
idx = 1;
```

```
while(~isDone(hsr1))
  y1(idx) = step(hsr1);
  idx = idx+1;
end
```

Create a signal source to output vectors:

```
hsr2 = dsp.SignalSource(randn(1024, 1), 128);
y2 = step(hsr2); % y2 is a 128-by-1 frame of samples
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Signal From Workspace block reference page. The object properties correspond to the block parameters, except:

The object does not have properties that correspond to the **Sample time** or **Warn when frame size does not evenly divide input length** block parameters.

See Also

`dsp.SignalSink`

dsp.SignalSource.clone

Purpose

Create signal reader object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `SignalSource` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with un-initialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.SignalSource.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

End-of-file status for signal reader object

Syntax

```
isDone(H)
```

Description

`isDone(H)` returns a logical value indicating whether or not the `SignalSource` object, `H`, has reached the end of the imported signal. If the `SignalEndAction` property is set to `Cyclic repetition`, this method will return `true` every time the reader reaches the end.

dsp.SignalSource.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `SignalSource` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Reset internal states of signal reader object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the signal reader object `H`, to start reading from the beginning of the imported signal.

dsp.SignalSource.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Read one sample or frame of signal

Syntax

```
Y = step(H)
```

Description

`Y = step(H)` outputs one sample or frame of data, `Y`, from each column of the imported signal. The imported signal is the variable or expression you specify for the `Signal` property of the `SignalSource` System object `H`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.SineWave

Purpose

Discrete-time sinusoid

Description

The `SineWave` object generates a discrete-time sinusoid. The sine wave object generates a real–valued sinusoid or a complex exponential. A real-valued, discrete-time sinusoid is defined as:

$$y(n) = A\sin(2\pi fn + \phi)$$

where A is the amplitude, f is the frequency in hertz, and φ is the initial phase, or phase offset, in radians. A complex exponential is defined as:

$$y(n) = Ae^{j(2\pi fn+\phi)}$$

For both real and complex sinusoids, the amplitude, frequency, and phase offsets can be scalars or length-N vectors, where N is the desired number of channels in the output. When you specify at least one of these properties as a length-N vector, scalar values specified for the other properties are applied to each of the N channels.

To generate a discrete-time sinusoid:

1. Define and set up your sine wave. See "Construction" on page 3-1334.
2. Call `step` to generate the sinusoid according to the properties of `dsp.SineWave`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.SineWave` returns a sine wave object, `H`, that generates a real-valued sinusoid with an amplitude of 1, a frequency of 100 Hz, and a phase offset of 0. By default, the sine wave object only generates one sample.

`H = dsp.SineWave('PropertyName',PropertyValue, ...)` returns a sine wave object, `H`, with each property set to the specified value.

`H = dsp.SineWave(AMP,FREQ,PHASE, 'PropertyName',PropertyValue, ...)` returns a sine wave object, `H`, with the `Amplitude` property set to `AMP`, the `Frequency` property set to

FREQ, the PhaseOffset property set to PHASE, and the other specified properties set to the specified values.

Properties

Amplitude

Amplitude of the sine wave

Specify the amplitude as a length-*N* vector containing the amplitudes of the sine waves in each of *N* output channels, or a scalar to apply to all *N* channels. The vector length must equal that specified for the Frequency and PhaseOffset properties. The default value is 1. This property is nontunable.

Frequency

Frequency of the sine wave

Specify a length-*N* vector containing frequencies, in hertz, of the sine waves in each of *N* output channels, or a scalar to apply to all *N* channels. The vector length must equal that specified for the Amplitude and PhaseOffset properties. You can specify positive, zero, or negative frequencies. The default is 100. This property is nontunable.

PhaseOffset

Phase offset of the sine wave in radians

A length-*N* vector containing the phase offsets, in radians, of the sine waves in each of *N* output channels, or a scalar to apply to all *N*channels. The vector length must equal that specified for the Amplitude and Frequency properties. The default value is 0. This property is nontunable.

ComplexOutput

Indicates whether the sine wave is complex or real

Set to true to output a complex exponential. The default value is false.

Method

Method used to generate sinusoids

The sinusoids are generated by either the `Trigonometric function` , `Table lookup`, or `Differential` methods . The `trigonometric function` method computes the sinusoid by sampling the continuous-time sinusoid. The `table lookup` method precomputes the unique samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. The `differential` method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time and precomputed update terms. The default value is `Trigonometric function`.

TableOptimization

Optimizes the table of sine values for speed or memory

Optimizes the table of sine values for `Speed` or `Memory`. When optimized for speed, the table contains k elements, and when optimized for memory, the table contains $k/4$ elements, where k is the number of input samples in one full period of the sine wave. This property applies only when the `Method` property is `Table lookup`. The default value is `Speed`.

SampleRate

Sampling rate for the sine wave

Specify the sampling rate of the output, in hertz, as a positive numeric scalar. The default is 1000.

SamplesPerFrame

Number of samples per frame

Specify the number of consecutive samples from each sinusoid to buffer into the output frame. The default is 1.

OutputDataType

Output data type

Specify the output data type as `double`, `single`, or `Custom`. The default value is `double`.

Fixed-Point Properties

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` property is `Custom`. The default value is `numerictype([]1,16)`.

Methods

clone	Create sine wave object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset sine wave to the beginning
step	Discrete-time sine wave

Examples

Generate a sine wave with an amplitude of 2, frequency of 10 Hz, and initial phase of 0:

```
hsin1 = dsp.SineWave(2, 10);
hsin1.SamplesPerFrame = 1000;
y = step(hsin1);
plot(y);
```

Generate two sine waves offset by a phase of π/2 radians:

```
hsin2 = dsp.SineWave;
hsin2.Frequency = 10;
hsin2.PhaseOffset = [0 pi/2];
hsin2.SamplesPerFrame = 1000;
y = step(hsin2);
plot(y);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Sine Wave block reference page. The object properties correspond to the block parameters.

See Also

`dsp.Chirp` | `dsp.NCO`

Purpose

Create sine wave object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a sine wave object, `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.SineWave.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.SineWave.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the sine wave object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.SineWave.reset

Purpose

Reset sine wave to the beginning

Syntax

```
reset(H)
```

Description

`reset(H)` resets the sine wave object to the beginning (*n=0*). If you invoke the `step` method without first invoking the `reset` method, the sine wave object generates additional samples of the original sinusoid. As an example:

```
H = dsp.SineWave('Amplitude',1,'Frequency',1/4,'SamplesPerFrame',7);
% 7 samples of a sine wave with frequency of 1/4 Hz
y = step(H);
% Call step method without reset
y1 = step(H);
stem([y; y1])
% y1 is a continuation of y
% Now reset
reset(H);
y2 = step(H);
% y2 starts at n=0 and equals y
isequal(y,y2)
```

Purpose

Discrete-time sine wave

Syntax

```
Y = step(H)
```

Description

`Y = step(H)` produces the sine wave `Y` using the specifications in the object `H`.

dsp.SpectrumAnalyzer

Purpose

Display frequency spectrum of time-domain signals

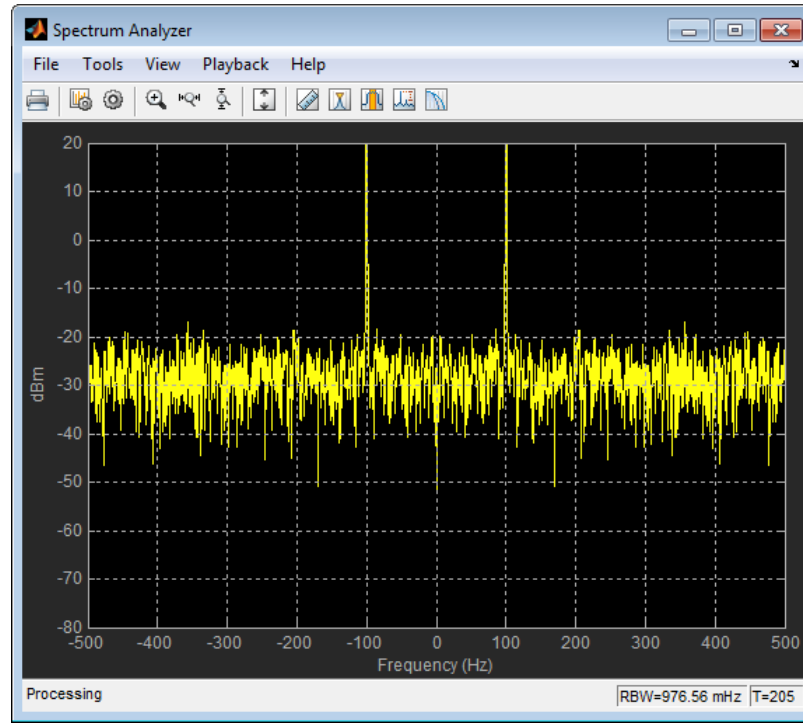
Description

The `SpectrumAnalyzer` object, hereafter referred to as the scope, displays the frequency spectrum of time-domain signals.

To display the spectra of signals in the Spectrum Analyzer:

1. Define and set up your Spectrum Analyzer. See "Construction" on page 3-1348.
2. Call `step` to display the frequency spectrum of the signals in the Spectrum Analyzer figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Spectrum Analyzer figure window and clear its associated data. Use the `hide` method to hide the Spectrum Analyzer window and the `show` method to make it visible.



See the following sections for more information on the Spectrum Analyzer Graphical User Interface:

- “Signal Display” on page 3-1369
- “Toolbar” on page 3-1375
- “Spectrum Settings” on page 3-1379
- “Measurements Panels” on page 3-1388
- “Visuals — Spectrum Properties” on page 3-1408
- “Style Dialog Box” on page 3-1410
- “Tools — Axes Scaling Properties” on page 3-1413

- "Algorithms" on page 3-1416

Note For information about the Spectrum Analyzer block, see Spectrum Analyzer.

Note If you own the MATLAB Coder product, you can generate C or C++ code from MATLAB code in which an instance of this system object is created. When you do so, the scope system object is automatically declared as an *extrinsic* variable. In this manner, you are able to see the scope display in the same way that you would see a figure using the `plot` function, without directly generating code from it. For the full list of system objects supporting code generation, see "DSP System Toolbox" in the MATLAB Coder documentation.

Construction

`H = dsp.SpectrumAnalyzer` creates a Spectrum Analyzer System object, `H`. This object displays the frequency spectrum of real- and complex-valued floating- and fixed-point signals.

`H = dsp.SpectrumAnalyzer('Name',Value,...)` creates a Spectrum Analyzer System object, `H`, with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Properties

CenterFrequency

Frequency over which frequency span is centered

Specify as a real scalar the center frequency, in hertz, of the frequency span over which the Spectrum Analyzer computes and plots the spectrum. This property applies when you set the `FrequencySpan` property to `'Span and center frequency'`. The overall frequency span, defined by the `Span` and `CenterFrequency` properties, must fall within the Nyquist frequency interval. When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval

is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. This property is Tunable.

Default: `0`

FFTLength

FFT length

Specify as a positive, scalar integer the length of the FFT that the Spectrum Analyzer uses to compute spectral estimates. This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'` and the `FFTLengthSource` property to `'Property'`. The `FFTLength` must be greater than or equal to the `WindowLength`. You cannot control the FFT length when the `FrequencyResolutionMethod` property is `'RBW'`. In that case, the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

This property is Tunable.

Default: `128`

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto'` or `'Property'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer sets the FFT length to the window length specified in the `WindowLength` property or to 1024, whichever is larger.
- When you set this property to `'Property'`, specify the number of FFT points using the `FFTLength` property. The `FFTLength` must be greater than the `WindowLength`.

This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'` and the `FFTLengthSource` property to `'Property'`.

This property is Tunable.

Default: `'Auto'`

FrequencyOffset

Frequency offset

Specify as a real, scalar value a frequency offset, in hertz. The *frequency*-axis values are offset by the value specified in this property. The overall span must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. You can control the overall span in different ways based on how you set the `FrequencySpan` property.

Default: `0`

FrequencyResolutionMethod

Frequency resolution method

Specify how to control the frequency resolution of the spectrum analyzer as either `'RBW'` or `'WindowLength'`. When you set this property to `'RBW'`, the `RBWSource` and `RBW` properties control the frequency resolution (in Hz) of the analyzer. When you set this property to `'WindowLength'`, the `WindowLength` property controls the frequency resolution.

In this case, the frequency resolution of the analyzer is defined as $\frac{NENBW * Fs}{N_{window}}$ where *NENBW* is the normalized effective noise bandwidth of the window currently specified in the `Window` property. You can control the number of FFT points only when the `FrequencyResolutionMethod` property is `'WindowLength'`. When the `FrequencyResolutionMethod` property is `'RBW'`, the FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.

This property is Tunable.

Default: `'RBW'`

FrequencyScale

Frequency scale

Specify the frequency scale as either `'Linear'` or `'Log'`. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. When you set the `FrequencyScale` property to `'Log'`, the Spectrum Analyzer displays the frequencies on the *x*-axis on a logarithmic scale. To use the `'Log'` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `false`. When the `PlotAsTwoSidedSpectrum` property is `true`, you must set this property to `'Linear'`.

This property is Tunable.

Default: `'Linear'`

FrequencySpan

Frequency span mode

Specify the frequency span mode as one of `'Full'`, `'Span and center frequency'`, or `'Start and stop frequencies'`.

- When you set this property to `'Full'`, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.
- When you set this property to `'Span and center frequency'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `Span` and `CenterFrequency` properties.
- When you set this property to `'Start and stop frequencies'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `StartFrequency` and `StopFrequency` properties.

This property is Tunable.

Default: `'Full'`

Name

Caption to display on Spectrum Analyzer window

Specify as a string the caption to display on the scope window. This property is Tunable.

Default: `'Spectrum Analyzer'`

OverlapPercent

Overlap percentage

Specify as a real, scalar value, the percentage overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100. This property is Tunable.

Default: `0`

PlotAsTwoSidedSpectrum

Two sided spectrum flag

Set this property to `true` to compute and plot two-sided spectral estimates. Set this property to `false` to compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued. When the input signal is complex valued, you must set this property to `true`.

When this property is `false`, Spectrum Analyzer uses *power folding*. The *y*-axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided PSD contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see the `pwelch` function reference page.

Default: `true`

PlotMaxHoldTrace

Max-hold trace flag

Set this property to `true` to compute and plot the maximum-hold spectrum of each input channel. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations.

This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is Tunable.

See also: `PlotMinHoldTrace` and `PlotNormalTrace`.

Default: `false`

PlotMinHoldTrace

Min-hold trace flag

Set this property to `true` to compute and plot the minimum-hold spectrum of each input channel. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is Tunable.

See also: `PlotMaxHoldTrace` and`PlotNormalTrace`.

Default: `false`

PlotNormalTrace

Normal trace flag

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Note that even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is Tunable.

See also: `PlotMaxHoldTrace` and `PlotMinHoldTrace`.

Default: `true`

Position

Spectrum Analyzer window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable.

Default: The default depends on your screen resolution. By default, the Spectrum Analyzer window appears in the center of your screen with a width of `410` pixels and height of `300` pixels.

PowerUnits

Power units

Specify the units in which the Spectrum Analyzer displays power values as either `'dBm'`, `'dBW'`, or `'Watts'`.

This property is Tunable.

Default: `'dBm'`

RBW

Resolution bandwidth

Specify as a real, positive scalar the resolution bandwidth (RBW), in hertz. RBW controls the spectral resolution of Spectrum Analyzer. This property applies only when you set the `FrequencyResolutionMethod` property to `'RBW'` and the `RBWSource` property to `'Property'`. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to

RBW must be greater than two: $\frac{span}{RBW} > 2$. You can specify

the overall span in different ways based on how you set the `FrequencySpan` property.

This property is Tunable.

See also: `RBWSource`.

Default: `9.76`

RBWSource

Source of resolution bandwidth value

Specify the source of the resolution bandwidth (RBW) as either `'Auto'` or `'Property'`. This property is relevant only when you set the `FrequencyResolutionMethod` property to `'RBW'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer adjusts the spectral estimation resolution to ensures that there are 1024 RBW intervals over the defined frequency span.
- When you set this property to `'Property'`, specify the resolution bandwidth directly using the `RBW` property.

This property is Tunable.

See also: `RBW`.

Default: `'Auto'`

ReducePlotRate

Reduce plot rate to improve performance

When you set this property to `true`, the scope logs data for later use and updates the display at fixed intervals of time. Data occurring between these fixed intervals might not be plotted. When you set this property to `false`, the scope updates every time it computes the power spectrum. Use the `false` setting when you do not want to miss any spectral updates at the expense of

slower simulation speed. The simulation speed is faster when this property is set to `true`. This property is Tunable.

Default: `true`

ReferenceLoad

Reference load

Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values.

This property is Tunable.

Default: `1`

SampleRate

Sample rate of input

Specify the sample rate, in hertz, of the input signals.

The sample rate must be a finite numeric scalar.

Default: `10e3`

ShowGrid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable.

Default: `false`

ShowLegend

Show or hide legend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set

this property to `false`, the scope does not display a legend. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. This property is Tunable.

Default: `false`

SidelobeAttenuation

Sidelobe attenuation of window

Specify as a real, positive scalar the window sidelobe attenuation, in decibels (dB). This property applies only when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The value must be greater than or equal to `45`.

This property is Tunable.

Default: `60`

Span

Frequency span over which spectrum is computed and plotted

Specify as a real, positive scalar the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Span and center frequency'`. The overall span, defined by this property and the `CenterFrequency` property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable.

Default: `10e3`

SpectralAverages

Number of spectral averages

Specify as a positive, scalar integer the number of spectral averages. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*.

This property is Tunable.

Default: `1`

SpectrumType

Spectrum type

Specify the spectrum type as one of `'Power'`, `'Power density'`, or `'Spectrogram'`.

- When you set this property to `'Power'`, the Spectrum Analyzer shows the power spectrum.
- When you set this property to `'Power density'`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.
- When you set this property to `'Spectrogram'`, the Spectrum Analyzer open a spectrogram view, which shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.

This property is Tunable.

Default: `'Power'`

StartFrequency

Start frequency over which spectrum is computed

Specify as a real scalar the start frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Start and stop frequencies'`. The overall span, which is defined by `StopFrequency` and this property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable.

Default: `-5e3`

StopFrequency

Stop frequency over which spectrum is computed

Specify as a real scalar the stop frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Start and stop frequencies'`. The overall span, defined by this property and the `StartFrequency` property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval

is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. This property is Tunable.

Default: `5e3`

TimeResolution

Time resolution

Specify the time resolution of each spectrogram line as a positive scalar, expressed in seconds. This property applies when you set the `SpectrumType` property to `'Spectrogram'`, and the `TimeResolutionSource` property to `'Property'`.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
`'RBW'`	`'Auto'`	`'Auto'`	1/RBW s
`'RBW'`	`'Auto'`	Manually entered	Time Resolution s
`'RBW'`	Manually entered	`'Auto'`	1/RBW s

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
`'RBW'`	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW s. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.
`'Window Length'`	—	`'Auto'`	1/RBW s RBW = *(NENBW**Fs)/Window Length, where *NENBW* is the normalized effective noise bandwidth of the specified window.
`'Window Length'`	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, *(NENBW**Fs)/Window Length. Several spectral estimates are combined into one

Frequency Resolution	RBW Setting	Time Resolution Setting	Time Resolution
			spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW s.

This property is Tunable.

Default: `0.001`

TimeResolutionSource

Source of the time resolution value.

Specify the source for the time resolution of each spectrogram line as either `'Auto'` or `'Property'`. This property applies when you set the `SpectrumType` property to `'Spectrogram'`. See the time resolution table at `TimeResolution`.

This property is Tunable.

Default: `'Auto'`

TimeSpan

Time span

Specify the time span of the spectrogram display as a positive scalar in seconds. This property applies when you set the `SpectrumType` property to `'Spectrogram'` and the `TimeSpanSource` property to `'Property'`. You must set the time span to be at least twice as large as the duration of the number of samples required for a spectral update.

This property is Tunable.

Default: `0.1`

TimeSpanSource

Source of time span value

Specify the source for the time span of the spectrogram as either `'Auto'` or `'Property'`. This property applies when you set the`SpectrumType` property to `'Spectrogram'`. If you set this property to `'Auto'`, the spectrogram displays 100 spectrogram lines at any given time. If you set this property to `'Property'`, the spectrogram uses the time duration you specify in seconds in the `TimeSpan` property.

This property is Tunable.

Default: `'Auto'`

Title

Display title

Specify the display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is Tunable.

Default: `''`

Window

Window function

Specify a window function for the spectral estimator as one of the options in the following table. For information on any window function, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Function in Signal Processing Toolbox
`'Rectangular'`	`rectwin`
`'Chebyshev'`	`chebwin`
`'Flat Top'`	`flattopwin`
`'Hamming'`	`hamming`
`'Hann'`	`hann`
`'Kaiser'`	`kaiser`

This property is Tunable.

Default: `'Hann'`

WindowLength

The window length

Control the frequency resolution by specifying the window length, in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2. This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'`, which controls the frequency resolution based on your window length setting. The resulting resolution bandwidth (RBW) is $\frac{NENBW * Fs}{N_{window}}$ where N_{window} is the `WindowLength` value.

This property is Tunable.

See also: `Window`,

Default: `1024`

YLabel

The label for the *y*-axis

Specify as a string the text for the scope to display to the left of the *y*-axis. Tunable

This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. Regardless of this property, Spectrum Analyzer always displays power units as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, `'Watts/Hz'`.

See also: `PowerUnits` on page 1889.

Default: `''`

YLimits

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is Tunable.

This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. The units directly depend upon the `PowerUnits` property.

Default: `[-80, 20]`

Methods

clone	Create spectrum analyzer object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
hide	Hide Spectrum Analyzer window
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes

reset	Reset internal states of Spectrum Analyzer object
show	Make Spectrum Analyzer window visible
step	Update spectrum in Spectrum Analyzer figure

Examples

View a two-sided power spectrum of a sine wave with noise on the Spectrum Analyzer.

```
hsin = dsp.SineWave('Frequency',100,'SampleRate',1000);
hsin.SamplesPerFrame = 1000;
hsa = dsp.SpectrumAnalyzer('SampleRate',hsin.SampleRate);
for ii = 1:250
  x = step(hsin) + 0.05*randn(1000,1);
  step(hsa, x);
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes. It updates the display one more time if any data is in the internal buffer.

```
release(hsa);
```

Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('hsa');
```

View a one-sided power spectrum made from the sum of five real sine waves with different amplitudes and frequencies.

```
Fs = 100e6;  % Sampling frequency
fSz = 5000;  % Frame size

hsin1 = dsp.SineWave(1e0,   5e6, 0, 'SamplesPerFrame', fSz, 'SampleRat
```

```
hsin2 = dsp.SineWave(1e-1, 15e6, 0, 'SamplesPerFrame', fSz, 'SampleRate',
hsin3 = dsp.SineWave(1e-2, 25e6, 0, 'SamplesPerFrame', fSz, 'SampleRate',
hsin4 = dsp.SineWave(1e-3, 35e6, 0, 'SamplesPerFrame', fSz, 'SampleRate',
hsin5 = dsp.SineWave(1e-4, 45e6, 0, 'SamplesPerFrame', fSz, 'SampleRate',

hsb = dsp.SpectrumAnalyzer;
hsb.SampleRate = Fs;
hsb.SpectralAverages = 1;
hsb.PlotAsTwoSidedSpectrum = false;
hsb.RBWSource = 'Auto';
hsb.PowerUnits = 'dBW';
hsb.Position = [749 227 976 721];
for idx = 1:1e2
     y1 = step(hsin1);
     y2 = step(hsin2);
     y3 = step(hsin3);
     y4 = step(hsin4);
     y5 = step(hsin5);
     step(hsb,y1+y2+y3+y4+y5+0.0001*randn(fSz,1));
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(hsb);
```

Run the MATLAB `clear` function to close the Spectrum Analyzer window.

```
clear('hsb');
```

This example shows the spectrogram for a chirp signal with added random noise.

```
Fs = 233e3;
frameSize = 20e3;
```

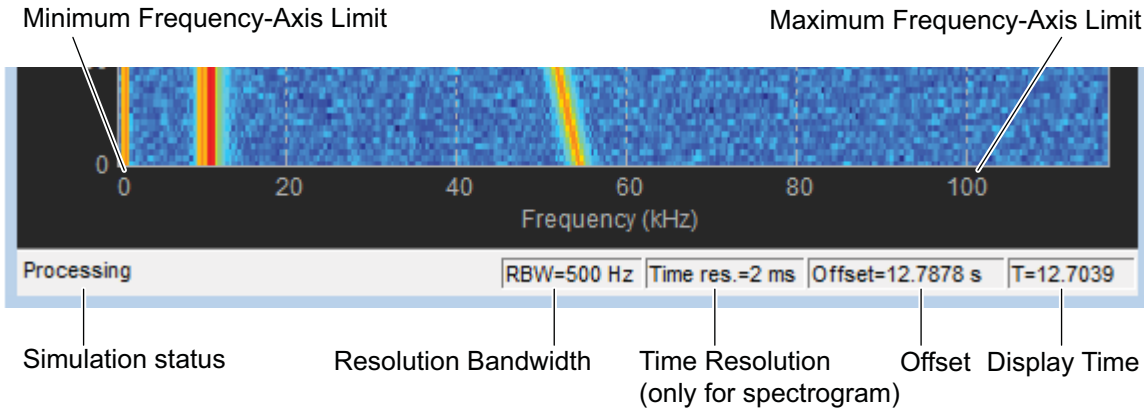
```
hchirp = dsp.Chirp('SampleRate',Fs,...
  'SamplesPerFrame',frameSize,...
  'InitialFrequency',11e3,...
  'TargetFrequency',11e3+55e3);

hss = dsp.SpectrumAnalyzer('SampleRate',Fs);
hss.SpectrumType = 'Spectrogram';
hss.RBWSource = 'Property';
hss.RBW = 500;
hss.TimeSpanSource = 'Property';
hss.TimeSpan = 2;
hss.PlotAsTwoSidedSpectrum = false;

for idx = 1:50
  y = step(hchirp)+ 0.05*randn(frameSize,1);
  step(hss,y);
end
release(hss)
```

Signal Display

The Spectrum Analyzer indicates the spectrum computation settings that are represented in the current display. Check the **RBW**, **Time res.**, and **Offset** indicators in the scope status bar for this information. The values specified by these indicators may be changed by modifying parameters in the **Spectrum Settings** panel. You can also view the object state and the amount of time data that correspond to the current display. Check the **Simulation Status** and **Simulation time** indicators for this information. The following figure highlights these aspects of the Spectrum Analyzer window.



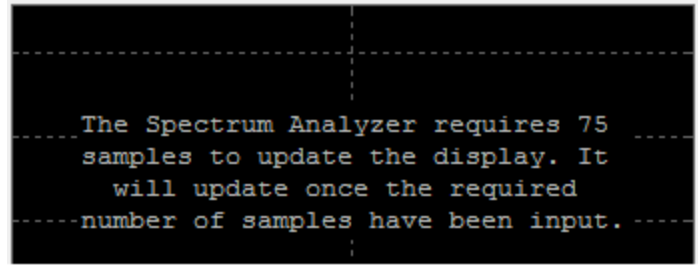
- **Resolution Bandwidth** — The smallest positive frequency or frequency interval that can be resolved.

  ### Details

  Spectrum Analyzer sets the resolution bandwidth based on the `FrequencyResolutionMethod` property setting on the **Main options** pane of the **Spectrum Settings** panel. If `FrequencyResolutionMethod` is `RBW (Hz)` then the specified value of RBW is used. You can also get or set this value from the `RBW` property when `RBWSource` is set to `'Property'`. By default, the `RBW (Hz)` parameter on the **Main options** pane and the related `RBWSource` property are set to `'Auto'`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified **Frequency Span**.

  You can set the resolution bandwidth to whatever value you choose. For this reason, there is a minimum boundary on the number of input samples required to compute a spectral update. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to *RBW* by the following equation:

$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$. Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel. *NENBW* is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane. F_s is the sample rate. In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer shows a warning message on the display.



Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input.

If the `FrequencyResolutionMethod` property setting on the **Main options** pane of the **Spectrum Settings** is `Window length`, you specify the window length and the resulting RBW is $\frac{NENBW * Fs}{N_{window}}$. The **Samples/update** in this case is directly related to N_{window} by the following equation: $N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$

- **Time Resolution** — The time resolution for a spectrogram line.

Details

Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The **Time Resolution** parameter is available only when the spectrum **Type** is `Spectrogram`. The *minimum attainable resolution* is the amount of data time required to compute a single spectral estimate. When the `SpectrumType` property is set to `'Spectrogram'`, you can get or set the minimum attainable resolution value from the `TimeResolution` property. See the time resolution table at `TimeResolution`.

- **Offset** — The constant frequency offset to apply to the entire spectrum.

  ### Details

  Spectrum Analyzer adds this constant offset to the values on the *frequency*-axis using the value of **Offset** on the **Trace options** pane of the **Spectrum Settings** panel. You can also set the offset from the `FrequencyOffset` property. The offset is the current time value at the middle of the interval of the line displayed at 0 seconds. The actual time of a particular spectrogram line is the offset minus the *y*-axis time listing. The offset is displayed on the plot only when the spectrum **Type** is `Spectrogram`.

- **Simulation Status** — Provides the current status of the model simulation.

  ### Details

  The status can be one of the following conditions:

  - `Processing` — Occurs after you construct the `SpectrumAnalyzer` object and before you run the `release` method.
  - `Stopped` — Occurs after you run the `release` method.

  The **Simulation Status** is part of the **Status Bar** in the Spectrum Analyzer window. You can choose to hide or display the entire **Status Bar**. From the Spectrum Analyzer menu, select **View > Status Bar**.

- **Display time** — The amount of time that has progressed since the last update to the Spectrum Analyzer display.

  ### Details

  Every time you call the `step` method, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following formula: $t_{sim} = t_{sim} + \frac{\text{length}(x)}{SampleRate}$. At the beginning of a simulation, you can modify the **SampleRate** parameter on the **Main options** pane of the **Spectrum Settings** panel. You can also set the sample rate using the `SampleRate` property. The display time is updated each time the display is updated. When `ReducePlotRate` is `true`, the simulation time and display time might differ. If at the end of a for loop that includes the Spectrum Analyzer, the times differ, you can call the `release` method to update the display with any data left in the buffer. Note, however, that if the remaining data is not a complete window interval, the display is not updated.

  The **Display time** indicator is a component of the **Status Bar** in the Spectrum Analyzer window. You can choose to hide or display the entire **Status Bar**. From the Spectrum Analyzer menu, select **View > Status Bar** .

- Frequency span — The range of values shown on the *frequency*-axis on the Spectrum Analyzer window.

  ### Details

  Spectrum Analyzer sets the frequency span using the values of parameters on the **Main options** pane of the **Spectrum Settings** panel.

  - `Span(Hz)` and `CF(Hz)` visible — The **Frequency Span** value equals the **Span** parameter in the **Main options** pane. You can also get or set this value from the `Span` property when the `FrequencySpan` property is set to `'Span and Center Frequency'`.

- `FStart(Hz)` and `FStop(Hz)` — The **Frequency Span** value equals the difference of the **FStop** and **FStart** parameters in the **Main options** pane, as given by the formula: $f_{span} = f_{stop} - f_{start}$. You can also get or set these values from the `StartFrequency` and `StopFrequency` properties when the `FrequencySpan` property is set to `'Start and stop frequencies'`.

By default, the **Full Span** check box in the **Main options** pane is enabled, and its equivalent `FrequencySpan` property is set to `'Full'`. In this case, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the **Two-sided spectrum** check box in the **Trace options** pane is enabled, and its equivalent `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

For more information, see “Spectrum Settings” on page 3-1379.

Reduce Plot Rate to Improve Performance

By default, Spectrum Analyzer updates the display at fixed intervals of time at a rate not exceeding 20 hertz. If you want Spectrum Analyzer to plot a spectrum on every simulation time step, you can disable the **Reduce Plot Rate to Improve Performance** option. In the Spectrum Analyzer menu, select **Simulation > Reduce Plot Rate to Improve Performance** to clear the check box. Tunable.

Note When this check box is selected, Spectrum Analyzer may display a misleading spectrum in some situations. For example, if the input signal is wide-band with non-stationary behavior, such as a chirp signal, Spectrum Analyzer might display a stationary spectrum. The reason for this behavior is that Spectrum Analyzer buffers the input signal data and only updates the display periodically at approximately 20 times per second. Therefore, Spectrum Analyzer does not render changes to the spectrum that occur and elapse between updates, which gives the impression of an incorrect spectrum. To ensure that spectral estimates are as accurate as possible, clear the **Reduce Plot Rate to Improve Performance** check box. When you clear this box, Spectrum Analyzer calculates spectra whenever there is enough data, rendering results correctly.

Toolbar

The Spectrum Analyzer toolbar contains the following buttons.

Print, Settings, and Properties Buttons

Button	Menu Location	Shortcut Keys	Description
	**File > Print**	**Ctrl+P**	Print the current Spectrum Analyzer window. To enable printing, run the `release` method. To print the current scope window to a figure rather than sending it to your printer, select **File > Print to figure**.
	**View > Spectrum Settings**	N/A	Open or close the **Spectrum Settings** panel. You can modify the settings in this panel to control the manner in which the spectrum is calculated. See the "Spectrum Settings" on page 3-1379 section for more information.

Button	Menu Location	Shortcut Keys	Description
	**View > Properties**	N/A	Open the **Visuals — Spectrum Options** dialog box. See the "Visuals — Spectrum Properties" on page 3-1408 section for more information.

Axes Control Buttons

	**Tools > Zoom In**	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.
	**Tools > Zoom X**	N/A	When this tool is active, you can zoom in on the *x*-axis. To do so, click inside the scope window, or click and drag your cursor along the *x*-axis over your area of interest.
	**Tools > Zoom Y**	N/A	When this tool is active, you can zoom in on the *y*-axis. To do so, click inside the scope window, or click and drag your cursor along the *y*-axis over your area of interest.
	**Tools > Scaling Properties**	**Ctrl+A**	Click this button to scale the axes in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu:

			• **Automatically Scale Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Note The axes control (zoom) buttons do not change the settings related to frequency span for Spectrum Analyzer. These buttons are purely graphical. Spectrum computations are not affected when you zoom.

Measurements Buttons

	**Tools > Measurements > Cursor Measurements**	N/A	Open or close the **Cursor Measurements** panel. This panel controls the display of vertical and horizontal cursors on the spectrum display.

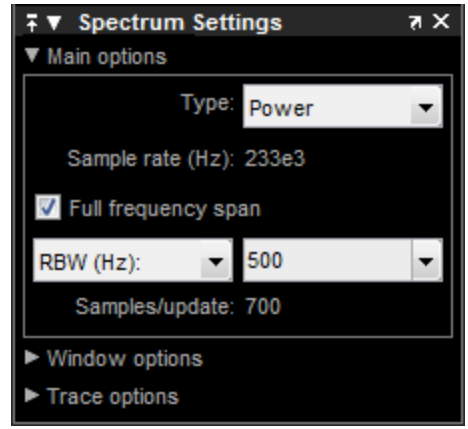
			See the “Cursor Measurements Panel” on page 3-1390 section for more information.
	**Tools > Measurements > Peak Finder**	N/A	Open or close the **Peak Finder** panel. This panel displays maxima and the frequencies at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. See the “Peak Finder Panel” on page 3-1566 section for more information.
	**Tools > Measurements > Channel Measurements**	N/A	Open or close the **Channel Measurements** panel. This panel displays occupied bandwidth and ACPR channel measurements. See the “Channel Measurements Panel” on page 3-1398 section for more information.
	**Tools > Measurements > Distortion Measurements**	N/A	Open or close the **Distortion Measurements** panel. This panel displays harmonic and intermodulation distortion measurements. See the “Distortion Measurements Panel” on page 3-1401 section for more information.
	**Tools > Measurements > CCDF Measurements**	N/A	Open or close the **CCDF Measurements** panel. This panel displays complimentary cumulative distribution function measurements.

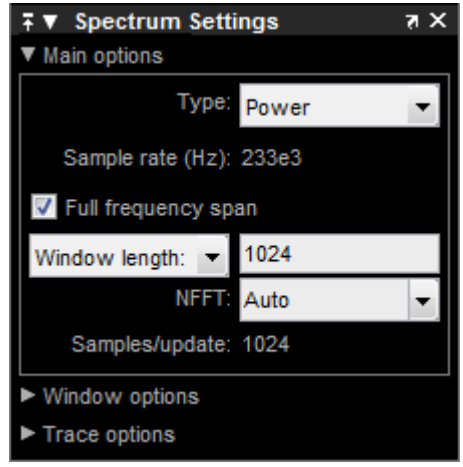
			See the “CCDF Measurements Panel” on page 3-1406 section for more information.

You can control whether this toolbar appears in the Spectrum Analyzer window. From the Spectrum Analyzer menu, select **View > Toolbar**.

Spectrum Settings

The **Spectrum Settings** panel appears at the right side of the Spectrum Analyzer figure. This panel enables you to modify settings to control the manner in which the spectrum is calculated. You can choose to hide or display the **Spectrum Settings** panel. In the Spectrum Analyzer menu, select **View > Spectrum Settings**. Alternatively, in the Spectrum Analyzer toolbar, select the Spectrum Settings button.





The **Spectrum Settings** panel is separated into three panes, labeled **Main Options**, **Window Options**, and **Trace Options**. You can expand each pane to see the available options.

Main Options Pane

The **Main Options** pane enables you to modify or view the main options.

- **Type** — The type of spectrum to display. Available options are `Power`, `Power density`, and `Spectrogram`. When you set this parameter to `Power`, the Spectrum Analyzer shows the power spectrum. When you set this parameter to `Power density`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz. When you set this parameter to `Spectrogram`, the Spectrum Analyzer shows the spectrogram, which displays frequency content over time. This parameter is equivalent to the `SpectrumType` property. Tunable.
- **Channel** — Select the signal channel for which the spectrogram settings apply. This option displays only when the **Type** is `Spectrogram` and only if there is more than one signal channel input.

- **Sample rate (Hz)** — The sample rate, in hertz, of the input signals.
- **Full frequency span** — Enable this check box to have Spectrum Analyzer compute and plot the spectrum over the entire *Nyquist* frequency interval. By default, when the **Two-sided spectrum** check box is also enabled, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right) + FrequencyOffset$ hertz. If you clear the **Two-sided spectrum** check box, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right) + FrequencyOffset$ hertz. Enabling this check box is equivalent to setting the `FrequencySpan` property to `'Full'`. Tunable.
- **Span (Hz)** and **CF (Hz)**, or **FStart (Hz)** and **FStop (Hz)** — When **Span (Hz)** is showing in the **Main Options** pane, you define the range of values shown on the *frequency*-axis on the Spectrum Analyzer window using frequency span and center frequency. From the drop-down list, select **FStart (Hz)** to define the range of *frequency*-axis values using start frequency and stop frequency instead.
  - **Span (Hz)** — The frequency span, in hertz. This parameter defines the range of values shown on the *frequency*-axis on the Spectrum Analyzer window. When this parameter is set to a numeric value, then it is equivalent to the `Span` property when the `FrequencySpan` property is set to `'Span and Center Frequency'`. Tunable.
  - **CF (Hz)** — The center frequency, in hertz. This parameter defines the value shown at the middle point of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the `CenterFrequency` property when the `FrequencySpan` property is set to `'Span and Center Frequency'`. Tunable.
  - **FStart (Hz)** — The start frequency, in hertz. This parameter defines the value shown at the leftmost side of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent

to the `StartFrequency` property when the `FrequencySpan` property is set to `'Start and stop frequencies'`. Tunable.

- **FStop (Hz)** — The stop frequency, in hertz. The parameter defines the value shown at the rightmost side of the *frequency*-axis on the Spectrum Analyzer window. This parameter is equivalent to the `StopFrequency` property when the `FrequencySpan` property is set to `'Start and stop frequencies'`. Tunable.

- **RBW (Hz) / Window length** — The frequency resolution method.

  If set to **RBW (Hz)**, the resolution bandwidth, in hertz. This parameter defines the smallest positive frequency that can be resolved. By default, this parameter is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 *RBW* intervals over the specified **Frequency Span**. This case is equivalent to when you set the `RBWSource` property to `'Auto'`.

  If you set this parameter to a numeric value, then you must specify a value that ensures there are at least two *RBW* intervals over the specified frequency span. In other words, the ratio of the overall

  span to *RBW* must be at least two: $\frac{span}{RBW} > 2$. In this case, this parameter is equivalent to the `RBW` property, when `RBWSource` is set to `'Property'`.

  If set to **Window length**, the length of the window, in samples, to compute the spectral estimates. The window length must be an integer scalar greater than 2.

  . Tunable.

- **NFFT** — The number of Fast Fourier Transform (FFT) points. This parameter is available only when the frequency resolution method is **Window length**. This parameter defines the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are `Auto` or a positive, scalar integer. The **NFFT** (`FFTLength`) value must be greater than or equal to the `WindowLength`. By default, when **NFFT** is set to `Auto`, Spectrum

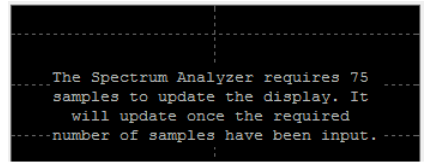
Analyzer sets the number of FFT points to the window length or 1024, whichever is larger. This case is equivalent to when you set the `FFTLengthSource` property to `'Auto'`.

When this parameter is set to a positive integer, this parameter is equivalent to the `n` parameter that you can set when you run the MATLAB `fft` function. In this case, this parameter is also equivalent to `FFTLength` when you set `FFTLengthSource` to `'Property'`. Tunable.

- **Time res. (s)** — The time resolution, in seconds. This parameter is available only in spectrogram mode. *Time resolution* is the amount of data, in seconds, used to compute a spectrogram line. The *minimum attainable resolution* is the amount of time required to compute a single spectral estimate. The tooltip displays the minimum attainable resolution, based on the current settings. When the `SpectrumType` property is set to `'Spectrogram'`, you can get or set the minimum attainable resolution value from the `TimeResolution` property. Tunable.
- **Time span (s)** — The time span over which the Spectrum Analyzer displays the spectrogram, in seconds. This parameter is available only in spectrogram mode. The *time span* is the product of the number of spectral lines you want and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to `Auto`, 100 spectral lines are used. This parameter is equivalent to the `TimeSpan` property when the `SpectrumType` property is set to `'Spectrogram'`. Tunable.
- **Samples/update** — The number of input samples required to compute one spectral update. You cannot modify this parameter; it is shown here for display purposes only. This parameter is directly related to *RBW* by the following equation:

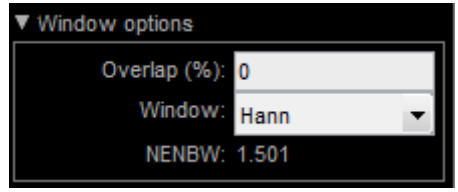
$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$ or to the window length by this

equation: $N_{samples} = \left(1 - \frac{O_p}{100}\right) x\ WindowLength$. $NENBW$ is the normalized effective noise bandwidth, a factor of the windowing method used, which is shown in the **Window Options** pane. F_s is the sample rate. If the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display as shown in the following figure.



Window Options Pane

The **Window Options** pane enables you to modify the window options.



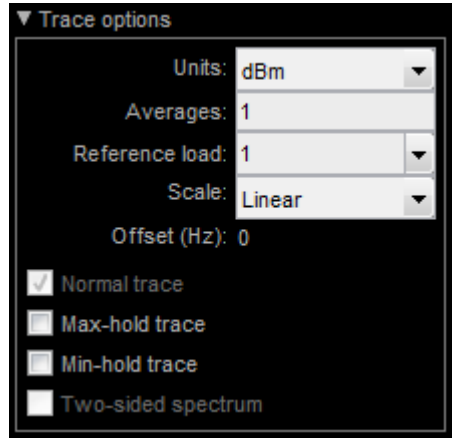
- **Overlap (%)** — The segment overlap percentage. This parameter defines the amount of overlap between the previous and current buffered data segments. The value must be greater than or equal to zero and less than 100. This parameter is equivalent to the `OverlapPercent` property. Tunable.
- **Window** — The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the segment length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see

"Windows" in the Signal Processing Toolbox documentation. This parameter is equivalent to the `Window` property. Tunable.

- **Attenuation (dB)** — The sidelobe attenuation, in decibels (dB). This property applies only when you set the **Window** parameter to `Chebyshev` or `Kaiser`. You must specify a value greater than or equal to `45`. If you use a Chebyshev window and set the sidelobe attenuation to less than 35 dB, the desired resolution bandwidth may not be achieved. This parameter is equivalent to the `SidelobeAttenuation` property. Tunable.
- **NENBW** — Normalized Effective Noise Bandwidth of the window. You cannot modify this parameter; it is a readout shown here for display purposes only. This parameter is a measure of the noise performance of the window. It is the width of a rectangular filter that accumulates the same noise power with the same peak power gain. NENBW can be calculated from the windowing function using the following equation: $NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$. The rectangular window has the smallest NENBW with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

Trace Options Pane

The **Trace Options** pane enables you to modify the trace options.



- **Units** — The units of the spectrum. Available options are `dBm`, `dBW`, and `Watts`. This parameter is equivalent to the `PowerUnits` property. Tunable.
- **Averages** — Specify as a positive, scalar integer the number of spectral averages. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. Spectrum Analyzer computes the current power spectrum estimate by averaging the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*. This parameter is equivalent to the `SpectralAverages` property. Tunable.
- **Reference load** — The reference load, in ohms, used to scale the spectrum. Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values. This parameter is equivalent to the `ReferenceLoad`property. Tunable.
- **Scale** — Linear or logarithmic scale. This parameter applies only when the Spectrum **Type** is `Power` or `Power density` When the frequency span contains negative frequency values, Spectrum Analyzer disables the logarithmic option. This parameter is equivalent to the `FrequencyScale` property. . Tunable.

- **Offset** — The constant frequency offset to apply to the entire spectrum. This constant offset parameter is added to the values on the *frequency*-axis in the Spectrum Analyzer window. It is not used in any spectral computations. You must take this parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within Nyquist limits. The Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz if **Two-sided spectrum** is selected, and $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz otherwise. This parameter is equivalent to the `FrequencyOffset` property.
- **Normal trace** — Normal trace view. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. By default, when this check box is enabled, Spectrum Analyzer calculates and plots the power spectrum or power spectrum density computed by the *Welch* estimator. The Welch estimator performs a smoothing operation by averaging a number of spectral estimates. To clear this check box, you must first select either the **Max hold trace** or the **Min hold trace** check box. This parameter is equivalent to the `PlotNormalTrace` property. Tunable.
- **Max hold trace** — Maximum hold trace view. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained. This parameter is equivalent to the `PlotMaxHoldTrace` property. Tunable.
- **Min hold trace** — Minimum hold trace view. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained. This parameter is equivalent to the `PlotMinHoldTrace` property. Tunable.

- **Two-sided spectrum** — Select this check box to enable two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued. When your signal includes DC input, you should display a two-sided spectrum to resolve low frequency power and DC power. This parameter is equivalent to the property.

Measurements Panels

The Measurements panels are the panels that appear to the right side of the Spectrum Analyzer figure. These panels are labeled **Trace Selection**, **Cursor Measurements**, **Peak Finder**, **Channel Measurements**, **Distortion Measurements**, and **CCDF Measurements**.

Note When `SpectrumType` is `'Spectrogram'`, the Measurements panels are not available.

Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

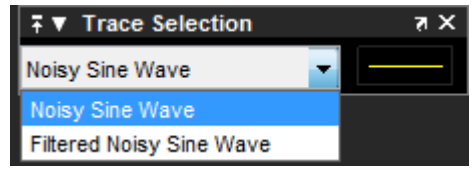
Button	Description
	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button  .

Button	Description
	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button  again.
	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button  in the new window.
	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button  again.
	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button  to show each pane that is hidden in the current panel. Click the pane collapse button  to hide each pane that is shown in the current panel.

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.

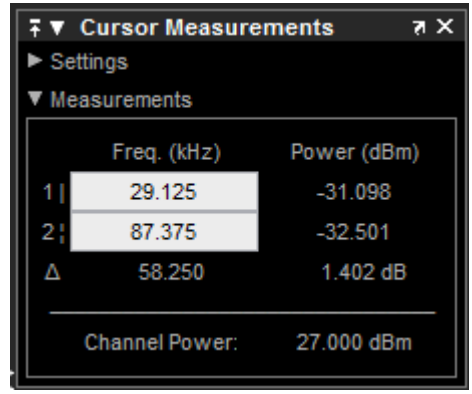


You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

Cursor Measurements Panel

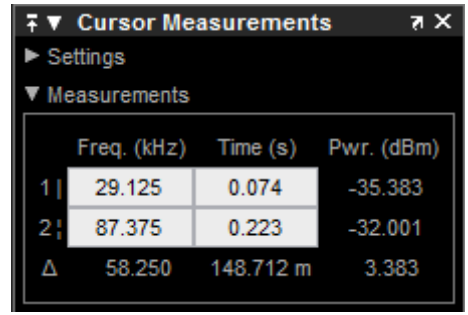
The **Cursor Measurements** panel displays screen cursors. You can choose to hide or display the **Cursor Measurements** panel. In the Scope menu, select **Tools > Measurements > Cursor Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Cursor Measurements** panel appears as follows for power and power density spectra.



The **Cursor Measurements** panel appears as follows for spectrograms.

Note You must pause the spectrogram display before you can use cursors.



The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for power and power density spectra only).
- **Horizontal** — Shows horizontal screen cursors (for power and power density spectra only).
- **Vertical** — Shows vertical screen cursors (for power and power density spectra only).

- **Waveform Cursors** — Shows cursors that attach to the input signals (for power and power density spectra only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

Measurements Pane

The **Measurements** pane displays the frequency (Hz), time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1 |** — Shows or enables you to modify the frequency or time (for spectrograms only), or both, at cursor number one.
- **2 :** — Shows or enables you to modify the frequency or time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

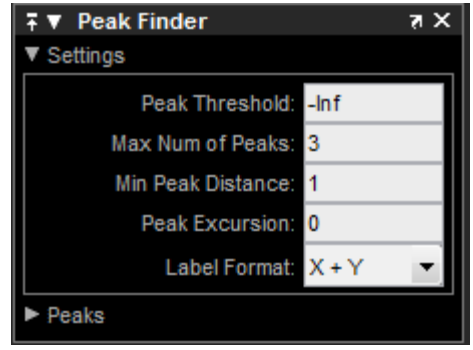
The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*.

Abbreviation	Name	Multiplier
a	atto	10^–18
f	femto	10^–15
p	pico	10^–12
n	nano	10^–9

Abbreviation	Name	Multiplier
u	micro	10^–6
m	milli	10^–3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12
P	peta	10^15
E	exa	10^18

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder button.

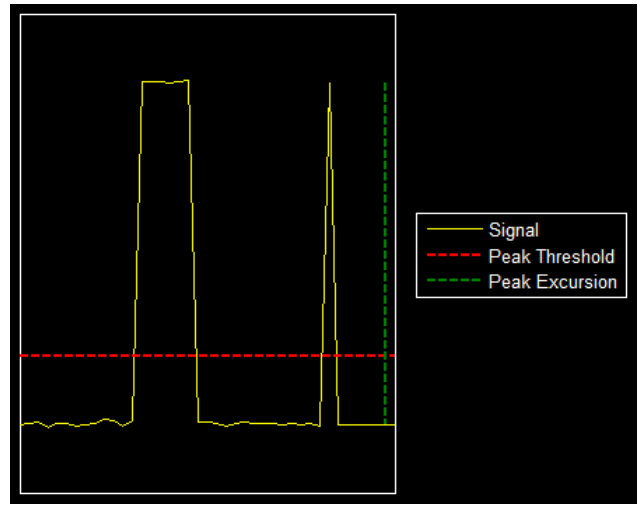


The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer between 1 and 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.



The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

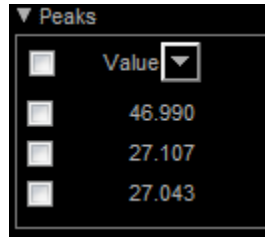
- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.

  - `X+Y` — Display both *x*-axis and *y*-axis values.

- `X` — Display only *x*-axis values.
- `Y` — Display only *y*-axis values.

Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button ( ) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button ( ). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled ( ), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Abbreviation	Name	Multiplier
a	atto	10^–18
f	femto	10^–15
p	pico	10^–12
n	nano	10^–9
u	micro	10^–6
m	milli	10^–3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12
P	peta	10^15
E	exa	10^18

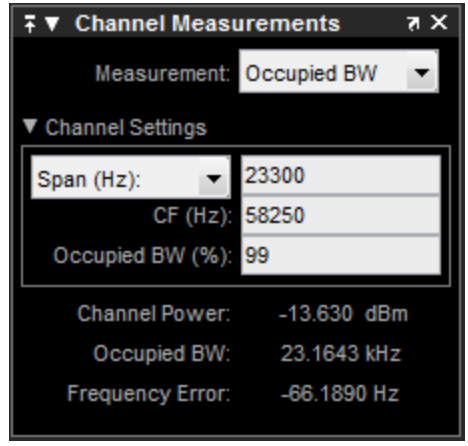
Channel Measurements Panel

The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements. You can choose to hide or display this pane in the Scope menu by selecting **Tools > Measurements > Channel Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are `Occupied BW` or `ACPR`. See "Algorithms" on page 3-1416 for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select `Occupied BW` as the **Measurement**, the following fields appear.



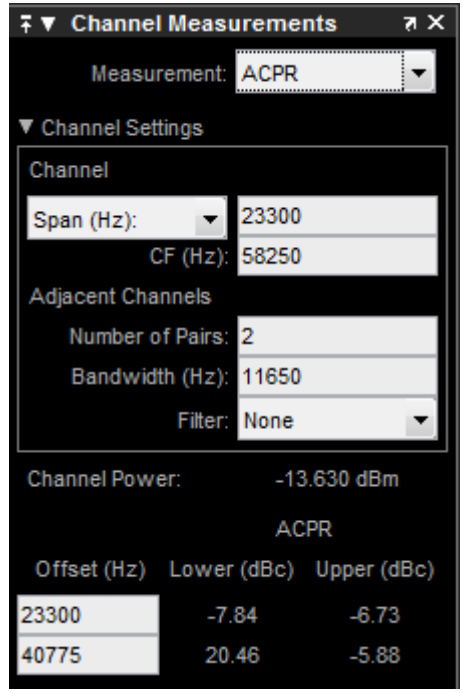
- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

Channel Settings for Occupied BW

- Select the frequency span of the channel, `Span(Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, `FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.

- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select `Occupied BW` as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select `Occupied BW` as the **Measurement** type.

When you select `ACPR` as the **Measurement**, the following fields appear.



- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

  ### Channel Settings for ACPR

  - Select the frequency span of the channel, `Span (Hz)`, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, `FStart(Hz)`, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
  - **CF (Hz)** — The center frequency of the channel.
  - **Number of Pairs** — The number of pairs of adjacent channels.
  - **Bandwidth (Hz)** — The bandwidth of the adjacent channels.

  - **Filter** — The filter to use for both main and adjacent channels. Available filters are `None`, `Gaussian`, and `RRC` (root-raised cosine).
- **Channel Power** — The total power in the channel.
- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select `ACPR` as the **Measurement** type.

Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements. You can choose to hide or display this panel in the Scope menu by selecting **Tools > Measurements > Distortion Measurements**. Alternatively, in the Scope toolbar, click the Distortion Measurements  button.

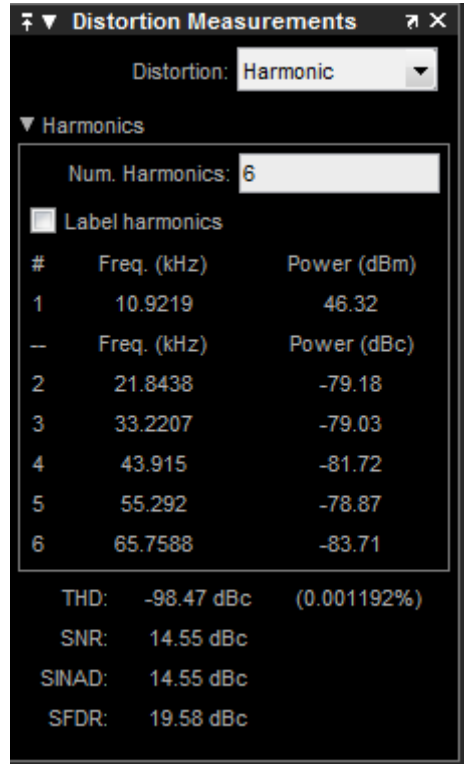
The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

Note For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (`RBW`) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

- **Distortion** — The type of distortion measurements to display. Available options are `Harmonic` or `Intermodulation`. Select `Harmonic` if your system input is a single sinusoid. Select `Intermodulation` if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when when only a small portion of the available bandwidth will be used.

  See "Algorithms" on page 3-1416 for information on how distortion measurements are calculated.

When you select `Harmonic` as the **Distortion**, the following fields appear.



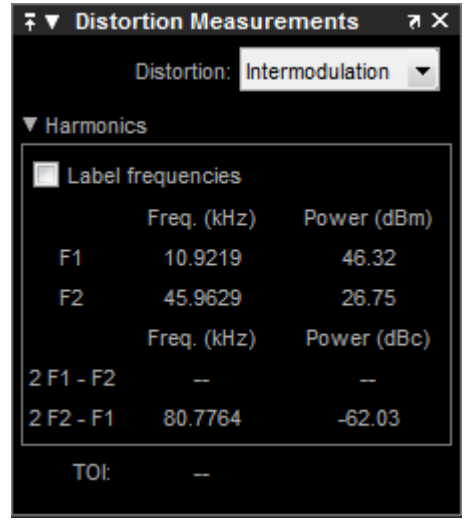
The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

Note To best view the harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Additionally, the noise floor should be visible. Using a Kaiser window with a large sidelobe attenuation may help to reduce the skirts.

- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from `2` to `10`. The default value is `6`.
- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to one milliwatt (dBm).
- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics, D, to the power in the fundamental frequency, S. If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window. $THD = 10\log_{10}(D/S)$.

- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency, *S*, to the power of all nonharmonic content, *N*, including spurious signals, in decibels relative to the carrier (dBc). $SNR = 10\log_{10}(S/N)$. If you see – – as the reported SNR, your signal's total non-harmonic content is less than 30% of the total signal.
- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency, *S* to all other content (including noise, *N*, and harmonic distortion, *D*), in decibels relative to the carrier (dBc). $SINAD = 10\log_{10}(S/(N+D))$.
- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency, *S*, to power of the largest spurious signal, *R*, regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics. $SFDR = 10\log_{10}(S/R)$.

When you select `Intermodulation` as the **Distortion**, the following fields appear.



The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products (2*F1-F2 and 2*F2-F1).

- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency
- **F2** — Upper fundamental first-order frequency
- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different

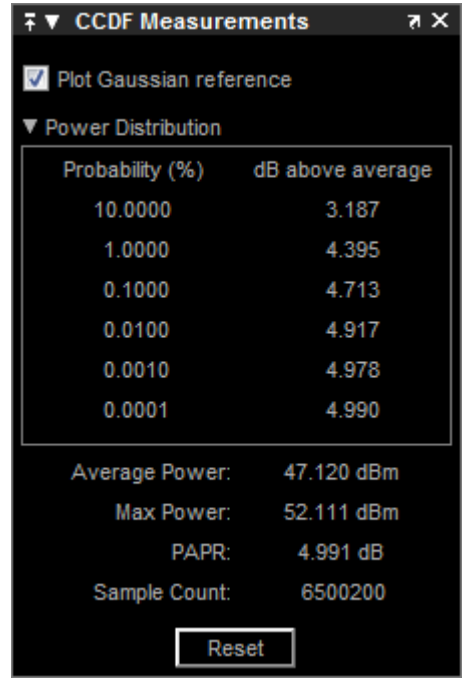
spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of a signal's instantaneous power being a specified level above the signal's average power. These measurements are useful indicators of a signal's dynamic range.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

You can choose to hide or display this panel in the Scope menu by selecting **Tools > Measurements > CCDF Measurements**. Alternatively, in the Scope toolbar, click the Distortion Measurements  button.



- **Plot Gaussian reference** — Select **Plot Gaussian reference** to show the Gaussian white noise reference signal on the plot.
- **Probability (%)** — The percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — The expected minimum power level at the associated **Probability (%)**.
- **Average Power** — The average power level of the signal since the start of simulation or from the last reset.

  Max Power — The maximum power level of the signal since the start of simulation or from the last reset.
- **PAPR** — The ratio of the peak power to the average power of the signal. PAPR should be less that 100 dB to obtain accurate CCDF

measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.

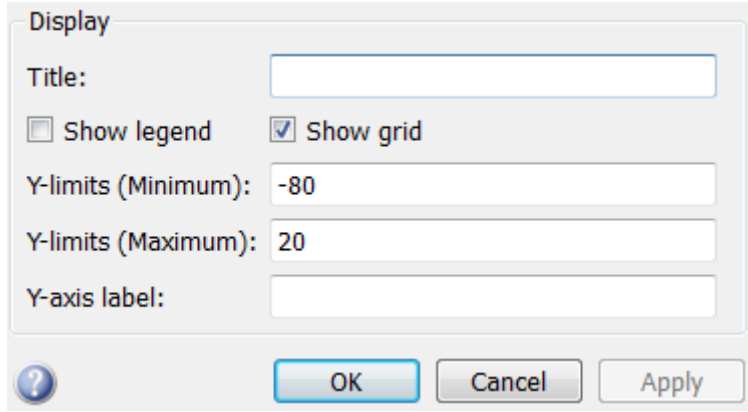
- **Sample Count** — The total number of samples used to compute the CCDF.
- **Reset** — Clear all current CCDF measurements and restart.

Visuals — Spectrum Properties

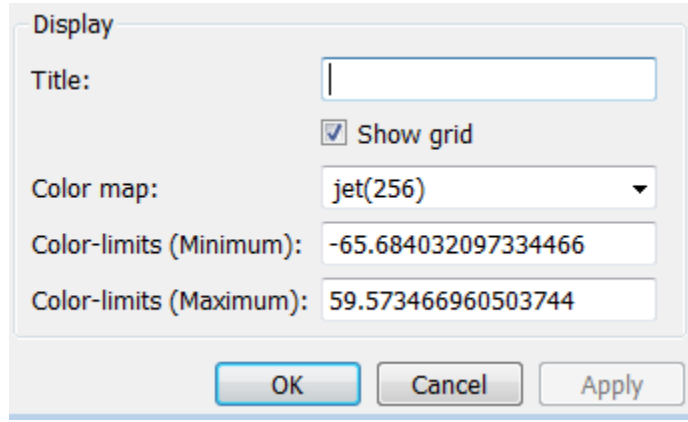
The Visuals—Spectrum Properties dialog box controls the visual configuration settings of the Spectrum Analyzer display. From the Spectrum Analyzer menu, select **View > Configuration Properties** to open this dialog box. Alternatively, in the Spectrum Analyzer toolbar, click the Configuration Properties button.

Display Pane

When the Spectrum **Type** is `Power` or `Power density`, the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



When the Spectrum **Type** is `Spectrogram` the **Display** pane of the Visuals—Spectrum Properties dialog box appears as follows:



Title

Specify the display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is Tunable.

By default, the display has no title.

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. Tunable

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View > Style**.

Show grid

When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable

Y-limits (Minimum)
Specify the minimum value of the *y*-axis. Tunable

Y-limits (Maximum)
Specify the maximum value of the *y*-axis. Tunable

Y-axis label
Specify the text for the scope to display to the left of the *y*-axis. Regardless of this property, Spectrum Analyzer always displays power units after this text as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, or `'Watts/Hz'`. Tunable.

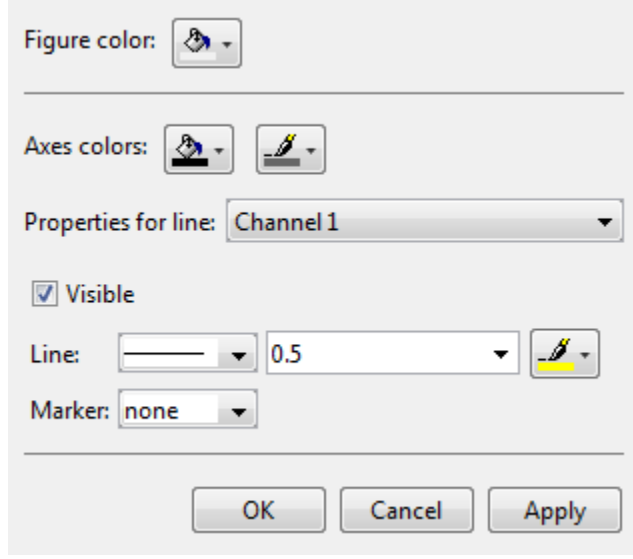
Color map
Select the color map for the spectrogram, or enter a 3-column matrix expression for the color map. See `colormap` for information. Tunable.

Color-limits (Minimum)
Set the signal power for the minimum color value of the spectrogram. Tunable.

Color-limits (Maximum)
Set the signal power for the maximum color value of the spectrogram. Tunable.

Style Dialog Box

In the **Style** dialog box, you can customize the style of power and power density displays. This dialog box is not available in spectrogram view. You are able to change the color of the figure, the background and foreground colors of the axes, and properties of the lines. From the Spectrum Analyzer menu, select **View > Style** to open this dialog box.



Properties

The **Style** dialog box allows you to modify the following properties of the Spectrum Analyzer figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Axes colors

Specify the color that you want to apply to the background of the axes.

Properties for line

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected channel.

Marker

Specify marks for the selected channel to show at its data points. This parameter is similar to the `Marker` property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

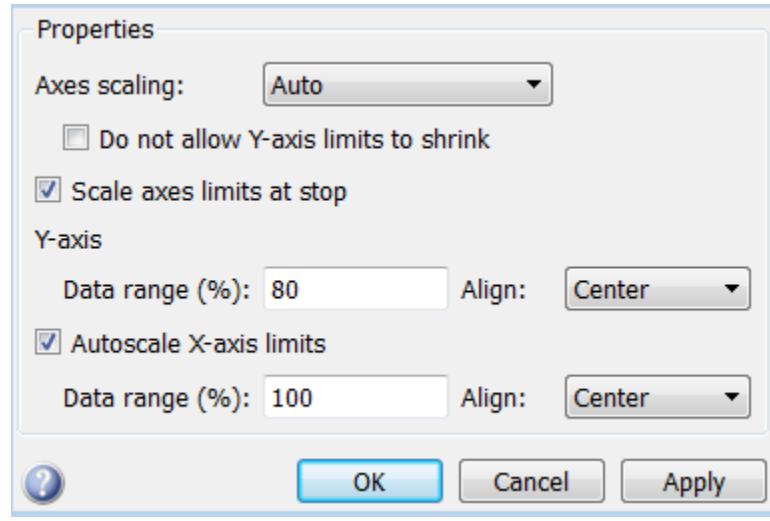
Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
*	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
✡	Six-pointed star (hexagram)

Tools — Axes Scaling Properties

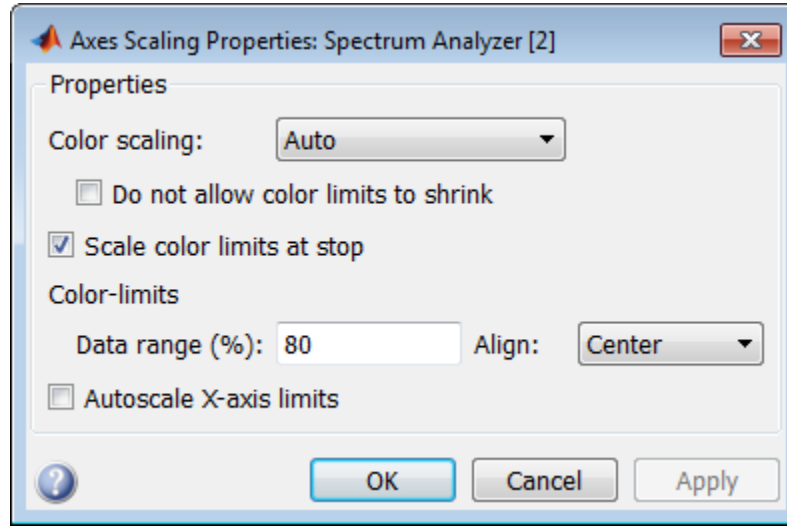
The Tools—Axes Scaling Properties dialog box allows you to automatically zoom in on and zoom out of your data. You can also scale the axes of the Spectrum Analyzer. In the Spectrum Analyzer menu, select **Tools > Scaling Properties** to open this dialog box.

Properties

The Tools—Axes Scaling Properties dialog box appears as follows for power and power density views.



For spectrogram view, the Tools—Axes Scaling Properties dialog box appears as follows.



Axes scaling/Color scaling

Specify when the scope should automatically scale the axes. If the spectrogram is displayed, specify when the scope should automatically scale the color. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
  - Select **Tools > Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink** .

- `After N Updates` — Selecting this option causes the scope to scale the axes or color after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

By default, this parameter is set to `Auto`, and the scope does not shrink the *y*-axis limits when scaling the axes or color. Tunable.

Do not allow Y-axis limits to shrink / Do not allow color limits to shrink

When you select this property, the *y*-axis are only allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this property allows the color limits to only grow during axis scaling. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** or **Color scaling** property. When you set the **Axes scaling** or **Color scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. Tunable.

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. If the spectrogram is displayed, this property specifies the number of updates after which to scale the color. This property appears only when you select `After N Updates` for the **Axes scaling** or **Color scaling** property. Tunable.

Scale axes limits at stop/Scale color limits at stop

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%) / Color-limits Data range

Set the percentage of the *y*-axis that the scope should use to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the color map. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope

increases the *y*-axis range or color such that your data uses only 30% of the *y*-axis range or color. Tunable.

Y-axis Align / Color-limits Align

Specify where the scope should align your data with respect to the *y*-axis when it scales the axes. If the spectrogram is displayed, specify where the scope should align your data with respect to the *y*-axis when it scales the color. You can select `Top`, `Center`, or `Bottom`. Tunable.

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Scale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. Tunable.

X-axis Data range (%)

Set the percentage of the *x*-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the Scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement with respect to the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. Tunable.

X-axis Align

Specify how the Scope should align your data with respect to the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable.

Algorithms

Spectrum Analyzer uses the `RBW` or the `Window Length` setting in the **Spectrum Settings** panel to determine the data window length. The value of the `FrequencyResolutionMethod` property determines whether RBW or window length is used. Then, it partitions the input signal into a number of windowed data segments. Finally, Spectrum Analyzer uses the modified periodogram method to compute spectral updates, averaging the windowed periodograms for each segment.

Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it ignores all adjacent content that decreases monotonically from the peak. After recording the width of the peak, it subsequently clears its content.

1. Spectrum Analyzer requires that a minimum number of samples have been provided before it computes a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, *RBW*, by the following equation or to the window length, by the equation shown in step 1b.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

   The normalized effective noise bandwidth, *NENBW*, is a factor that depends on the windowing method. Spectrum Analyzer shows NENBW in the **Window Options** pane of the **Spectrum Settings** panel. Overlap percentage, O_p, is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** panel. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** panel.

   a. When in RBW mode, the window length required to compute one spectral update, N_{window}, is directly related to the resolution bandwidth and normalized effective noise bandwidth by the following equation.

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

      When in WindowLength mode, the window length is used as specified.

b The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

c The normalized effective noise bandwidth, *NENBW*, is a window parameter determined by the window length, N_{window}, and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then *NENBW* is given by the following equation.

$$NENBW = N_{window} \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n)\right]^2}$$

d When in RBW mode, you can set the resolution bandwidth using the value of the **RBW** parameter on the **Main options** pane of the **Spectrum Settings** panel. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two, as given in the following equation.

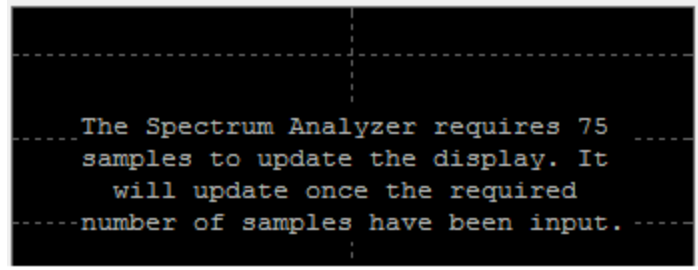
$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to `Auto`. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW** to `Auto`, it is calculated by the following equation. $RBW_{auto} = \frac{span}{1024}$

e When in window length mode, you specify N_{window} and the resulting RBW is

$$\frac{NENBW * Fs}{N_{window}}$$

In some cases, the number of samples provided in the input are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer produces a message on the display, as shown in the following figure.



Spectrum Analyzer removes this message and displays a spectral estimate as soon as enough data has been input. Notice that this behavior differs from the Spectrum Scope block in versions R2012b and earlier. If the **Buffer input** check box was selected, the Spectrum Scope block computed a spectral update using the number of samples given by the **Buffer size** parameter. Otherwise, the

Spectrum Scope block computed a spectral update using the number of samples in each frame.

2 Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, or spectrogram computed by the modified *Periodogram* estimator. For more information about the Periodogram method, see `periodogram` in the Signal Processing Toolbox documentation.

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$PSD(f) = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{(p)}[n]e^{-j2\pi f(n-1)T}\right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{spectrum}(f) = PSD(f) \times RBW = PSD(f) \times \frac{F_s \times NENBW}{N_{window}} = \frac{1}{P}\sum_{p=1}^{P}\frac{\left|\sum_{n=1}^{N_{FFT}} x^{(p)}[n]e^{-j2\pi f(n-1)T}\right|^2}{\left[\sum_{n=1}^{N_{window}} w[n]\right]^2}$$

Spectrogram — Each line of the spectrogram is one periodogram. The time resolution of each line is 1/RBW, which is the minimum

attainable resolution. Achieving the resolution you want may require combining several periodograms may be combined. You then useinterpolation to calculate noninteger values of 1/RBW. In the spectrogram display, time scrolls from bottom to top, so the most recent data is shown at the bottom of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

Note The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values provided that N_{fft} is greater than or equal to N_{window}.

The **Occupied BW** is calculated as follows.

- Calculate the total power in the measured frequency range.
- Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this sum is $\frac{100 - Occupied\ BW\ \%}{2}$ of the total power.
- Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until it reaches $\frac{100 - Occupied\ BW\ \%}{2}$ of the total power.
- The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- The frequency halfway between the lower and upper frequency values is the center frequency.

The **Distortion Measurements** are computed as follows.

1. Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it ignores all adjacent content that decreases monotonically from the peak. After recording the width of the peak, it subsequently clears its content. Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.

2. The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power in the vicinity of the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power associated from the fundamental is removed as in step 1.

3. The power and width of the second, and higher order harmonics (P_2, W_2, P_3, W_3, etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases in a monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.

4. Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{remaining}$) peak value ($P_{maxspur}$), and its median value ($P_{estnoise}$).

5. The sum of all the removed bandwidth is computed as $W_{sum} = W_0+W_1+W_2+...+W_n$.

   The sum of powers of the second and higher order harmonics are computed as $P_{harmonic} = P_2+P_3+P_4+...+P_n$.

6. The sum of the noise power is then estimated as $P_{noise} = (P_{remaining}*\mathrm{dF} + P_{estnoise}*W_{sum})/RBW$, where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.

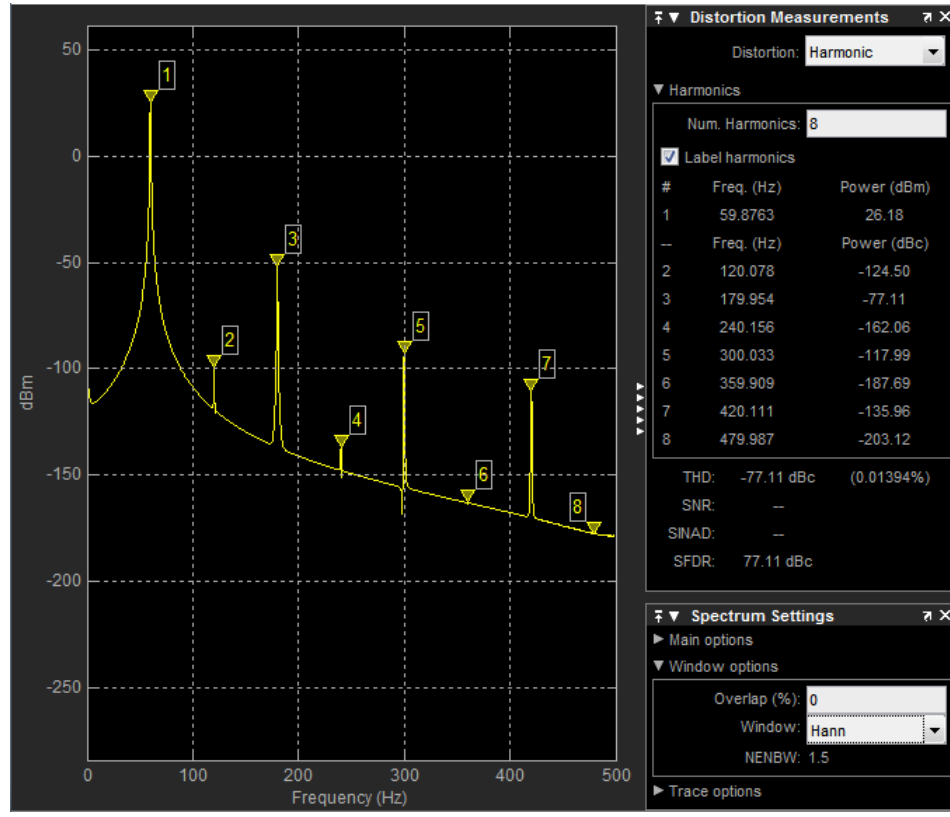
7. The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

   - THD = $10*\log10(P_{harmonic}/P_1)$

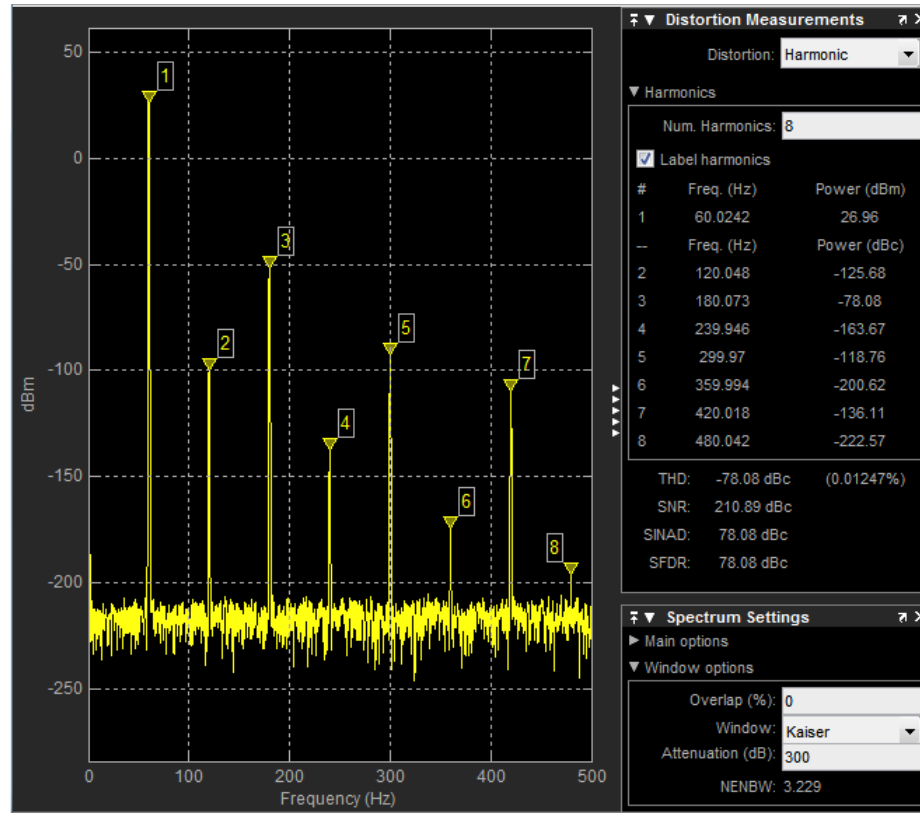
- SINAD = $10*\log_{10}(P_1/(P_{harmonic} + P_{noise})$
- SNR = $10*\log_{10}(P_1/P_{noise})$
- SFDR = $10*\log_{10}(P_1/\max(P_{maxspur}, \max(P_2,P_3,...,P_n))$

The following considerations apply to **Distortion Measurements**.

- The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default `Hann` window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.



The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (–) reported for **SNR** and **SINAD**. Consider using a Kaiser window with a high attenuation (up to 330dB) to minimize spectral leakage if your application can tolerate the increased equivalent noise bandwidth (ENBW) of the Kaiser window.



- The DC component is ignored.
- After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- *N*th order intermodulation products occur at

  *A*F1 + B*F2*

where *F1* and *F2* are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.

- For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to one milliwatt (dBm).:
  - $TOI_{lower} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
  - $TOI_{upper} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
  - $TOI = + (TOI_{lower} + TOI_{upper})/2$

See Also

Spectrum Analyzer | `dsp.TimeScope` | `dsp.ArrayPlot` | `dsp.LogicAnalyzer`

Purpose

Create spectrum analyzer object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `SpectrumAnalyzer` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.SpectrumAnalyzer.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method. `N` equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method. The Spectrum Analyzer is a sink object, so `N` equals 0.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.SpectrumAnalyzer.hide

Purpose

Hide Spectrum Analyzer window

Syntax

```
hide(H)
```

Description

`hide(H)` hides the Spectrum Analyzer window, associated with System object, `H`.

See Also

`dsp.SpectrumAnalyzer` | `dsp.SpectrumAnalyzer.show`

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `SpectrumAnalyzer` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.SpectrumAnalyzer.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the Spectrum Analyzer figure window. After calling the `release` method, any non-tunable properties can be set once again.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Algorithms

In operation, the `release` method is similar to the `mdlTerminate` function.

See Also

`dsp.SpectrumAnalyzer` | `dsp.SpectrumAnalyzer.reset`

Purpose

Reset internal states of Spectrum Analyzer object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `SpectrumAnalyzer` object `H` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the Spectrum Analyzer figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

Algorithms

In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

See Also

`dsp.SpectrumAnalyzer` | `dsp.SpectrumAnalyzer.release`

dsp.SpectrumAnalyzer.show

Purpose

Make Spectrum Analyzer window visible

Syntax

```
show(H)
```

Description

`show(H)` makes the Spectrum Analyzer window, associated with System object, `H`, visible.

See Also

`dsp.SpectrumAnalyzer` | `dsp.SpectrumAnalyzer.hide`

Purpose

Update spectrum in Spectrum Analyzer figure

Syntax

```
step(H,X)
```

Description

`step(H,X)` updates the spectrum of the signal, `X`, in the Spectrum Analyzer figure.

dsp.SpectrumEstimator

Purpose

Estimate power spectrum

Description

The `dsp.SpectrumEstimator` computes the power spectrum of a signal, using the Welch algorithm and the Periodogram method.

To implement the spectrum estimation object:

1. Define and set up your spectrum estimator object. See "Construction" on page 3-1436.
2. Call `step` to implement the estimator according to the properties of `dsp.SpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.SpectrumEstimator` returns a System object, H, that computes the frequency power spectrum of real or complex signals. This System object uses the periodogram method and Welch's averaged, modified periodogram method.

`H = dsp.SpectrumEstimator('PropertyName', PropertyValue,...)` returns a `Spectrum Estimator` System object, H, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SampleRate

Sample rate of input

Specify the sample rate of the input in, hertz, as a finite numeric scalar. The default value is `1 Hz`. The sample rate is the rate at which the signal is sampled in time.

SpectrumType

Spectrum type

Specify the spectrum type as one of `'Power' | 'Power density'`. When the spectrum type is `'Power'`, the power spectral density is

scaled by the equivalent noise bandwidth of the window (in Hz). The default value is `'Power'`. This property is tunable.

SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Spectrum Estimator computes the current power spectrum estimate by averaging the last `N` estimates. `N` is the number of spectral averages defined in the `SpectralAverages` property. The default value is `8`.

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto' | 'Property'`. The default value is `'Auto'`. If you set this property to `'Auto'`, the Spectrum Estimator sets the FFT length to the input frame size. If you set this property to `'Property'`, then you specify the number of FFT points using the `FFTLength` property.

FFTLength

FFT Length

Specify the length of the FFT that the Spectrum Estimator uses to compute spectral estimates as a positive, integer scalar. This property applies when you set the `FFTLengthSource` property to `'Property'`. The default value is `128`.

Window

Window function

Specify a window function for the spectral estimator as one of `'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'`. The default value is `'Hann'`.

SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The default value is `60 dB`.

FrequencyRange

Frequency range of the spectrum estimate

Specify the frequency range of the spectrum estimator as one of `'twosided' | 'onesided' | 'centered'`.

If you set the `FrequencyRange` to `'onesided'`, the spectrum estimator computes the onesided spectrum of real input signals, `x` and `y`. If the FFT length, NFFT, is even, the length of the spectrum estimate is `NFFT/2+1`, and is computed over the interval `[0,SampleRate/2]`. If NFFT is odd, the length of the spectrum estimate is equal to `(NFFT+1)/2` and the interval is `[0,SampleRate/2)`.

If you set the `FrequencyRange` to `'twosided'`, the spectrum estimator computes the twosided spectrum of complex or real input signals, `x` and `y`. The length of the spectrum estimate is equal to NFFT, and is computed over `[0, SampleRate)`.

If you set the `FrequencyRange` to `'centered'`, the spectrum estimator computes the centered twosided spectrum of complex or real input signals, `x` and `y`. The length of the spectrum estimate is equal to NFFT. This value is computed over `(-SampleRate/2, SampleRate/2]` for even lengths, and `(-SampleRate/2, SampleRate/2)` for odd lengths. The default value is `'twosided'`.

Methods

clone	Create spectrum estimator object with same property values
getFrequencyVector	Get the vector of frequencies at which the spectrum is estimated

getRBW	Get the resolution bandwidth of the spectrum
isLocked	Locked status for input attributes and nontunable properties
reset	Reset the internal states of the spectrum estimator
step	Estimate the frequency spectrum of a signal

Examples

Compute the power spectrum of a noisy sine wave

Generate a sine wave:

```
hsin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
hsin.SamplesPerFrame = 1000;
```

Use the Spectrum Estimator to compute the power spectrum of the sine wave. Also, use the Array Plot to display the spectrum:

```
hs = dsp.SpectrumEstimator('SampleRate', hsin.SampleRate,...
     'SpectrumType','Power',...
     'FrequencyRange','centered');
hplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
        [0 .35],'YLabel','Power Spectrum (Watts)',...
        'XLabel','Frequency (Hz)',...
        'Title','Power Spectrum of 100 Hz Sine Wave');
```

Add random noise to the sine wave. Step through the System objects to obtain the data streams, and plot the power spectrum of the signal:

```
for ii = 1:10
x = step(hsin) + 0.05*randn(1000,1);
Pxx = step(hs, x);
step(hplot,Pxx);
end
```

Algorithms

Let `x` be the input frame. We first multiply `x` by the window, and scale it by the window power. We then take FFT of the signal, calling it `Y`. This is followed by taking the square magnitude of the FFT, i.e., `Z = Y*conj(Y)`. We average the last N number of `Z`'s, and scale the answer by the sample rate.

For further information refer to the "Algorithms" on page 3-1416 section in Spectrum Analyzer, which uses the same algorithm.

See Also

`dsp.SpectrumAnalyzer` | `dsp.TransferFunctionEstimator` | `dsp.CrossSpectrumEstimator`

Purpose

Create spectrum estimator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`, with the same property values. The clone method creates a new unlocked object with uninitialized states.

dsp.SpectrumEstimator.getFrequencyVector

Purpose

Get the vector of frequencies at which the spectrum is estimated

Syntax

```
getFrequencyVector(H)
```

Description

`getFrequencyVector(H)` returns the vector of frequencies at which the spectrum is estimated.

If you set the `FrequencyRange` to `'onesided'` and the FFT length, `NFFT`, is even, the frequency vector is of length `NFFT/2+1`, and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'onesided'` and `NFFT` is odd, the frequency vector is of length `(NFFT+1)/2` and covers the interval `[0,SampleRate/2)`. If you set the `FrequencyRange` to `'twosided'`, the frequency vector is of length `NFFT` and covers the interval `[0, SampleRate)`. If you set the `FrequencyRange` to `'centered'`, the frequency vector is of length `NFFT` and covers the range `(-SampleRate/2, SampleRate/2]` and `(-SampleRate/2, SampleRate/2)` for even and odd length `NFFT`, respectively.

Purpose

Get the resolution bandwidth of the spectrum

Syntax

```
getRBW(H)
```

Description

`getRBW(H)` returns the resolution bandwidth of the spectrum.

The resolution bandwidth, `RBW`, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to `ENBW*SampleRate/ L`, where `L` is the input length, and `ENBW` is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`, `RBW=enbw(hann(1024))*100/1024`.

dsp.SpectrumEstimator.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
L = isLocked(H)
```

Description

`L = isLocked(H)` returns a logical value, `L`, which indicates whether input attributes and nontunable properties are locked for the System object. The object performs an internal initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. Once this occurs, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics to change

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.SpectrumEstimator.reset

Purpose

Reset the internal states of the spectrum estimator

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the System object,`H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

Purpose

Estimate the frequency spectrum of a signal

Syntax

```
Y = step(H,x)
[Y1,...,YN] = step(H,x)
```

Description

`Y = step(H,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, H. `[Y1,...,YN] = step(H,x)` produces `N` outputs.

The columns of `x` are treated as independent channels.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.StandardDeviation

Purpose

Standard deviation of input or sequence of inputs

Description

The `StandardDeviation` object computes the standard deviation for an input or sequence of inputs.

To compute the standard deviation for an input or sequence of inputs:

1. Define and set up your standard deviation object. See "Construction" on page 3-1448.
2. Call `step` to compute the standard deviation according to the properties of `dsp.StandardDeviation`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.StandardDeviation` returns a standard deviation System object, `H`, that computes the standard deviation for the columns of input.

`H = dsp.StandardDeviation('PropertyName',PropertyValue,...)` returns a standard deviation System object, `H`, with each specified property set to the specified value.

Properties

RunningStandardDeviation

Enable calculation over successive calls to the `step` method

Set this property to `true` to enable the calculation of standard deviation over successive calls to the `step` method. The default is `false`.

ResetInputPort

Enable resetting in running standard deviation mode

Set this property to `true` to enable resetting for the running standard deviation. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running standard deviation. This property applies only when you set the `RunningStandardDeviation` property to `true`. The default is `false`.

ResetCondition

Reset condition for running standard deviation mode

Specify event to reset the running standard deviation as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the `ResetInputPort` property to `true`. The default is `Non-zero`.

Dimension

Dimension to operate along

Specify how the standard deviation calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies only when you set the `RunningStandardDeviation` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the dimension (one-based value) of the input signal, over which the object computes the standard deviation. The cannot exceed the number of dimensions for the input signal. This property applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

ROIProcessing

Enable region of interest processing

Set this property to `true` to enable calculating the standard deviation within a particular region for each image. This property applies only when you set the `RunningStandardDeviation` property to `false` and the `Dimension` property is `All`. The default is `false`.

Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, `Rectangles` is the only selection that applies for the `ROIForm` property.

ROIForm

Type of region of interest

Specify the type of region of interest as one of `| Rectangles | Lines | Label matrix | Binary mask |`. This property applies only when you set the `ROIProcessing` property to `true`. The default is `Rectangles`.

Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, `Rectangles` is the only selection that applies for the `ROIForm` property.

ROIPortion

Calculate over entire ROI or just perimeter

Specify the region over which to calculate the standard deviation as one of `| Entire ROI | ROI perimeter |`. This property applies if the `ROIForm` property is `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Statistics for each ROI, or one for all ROIs

Specify what statistics to calculate as one of `| Individual statistics for each ROI | Single statistic for all ROIs |`. This property applies when you set the `ROIForm` property to `Rectangles`, `Lines`, or `Label matrix`. The default is `Individual statistics for each ROI`.

ValidityOutputPort

Enable output of validity check of ROI or label numbers

Indicate whether to return the validity of the specified ROI being completely inside image when the `ROIForm` property is `Lines`, `Rectangles` or `Binary mask`. Indicate whether to return the validity of the specified label numbers when the `ROIForm` property is `Label Matrix`. This property applies when you set the `ROIForm` property to anything except `Binary Mask`. The default is `false`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies only when you set the `RunningStandardDeviation` property to `true`. The default is `true`.

Methods

clone	Create standard deviation object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset states for running standard deviation computation
step	Calculate standard deviation of input

Examples

Compute running standard deviation of a signal:

```
hstd2 = dsp.StandardDeviation;
hstd2.RunningStandardDeviation = true;
x = randn(100,1);
y = step(hstd2,x);
% y(i) is the standard deviation of all values
% in the vector x(1:i)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Standard Deviation block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to the `ResetInputPort` and `ResetCondition` object properties.
- **Treat sample-based row input as a column** block parameter is not supported by the `dsp.StandardDeviation` object.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.Variance` | `dsp.Maximum` | `dsp.Minimum` | `dsp.Mean`

Purpose

Create standard deviation object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `StandardDeviation` object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.StandardDeviation.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.StandardDeviation.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `StandardDeviation` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.StandardDeviation.reset

Purpose

Reset states for running standard deviation computation

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `StandardDeviation` object `H` to their initial values when computing the running standard deviation.

Purpose

Calculate standard deviation of input

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
Y = step(H,X,ROI)
Y = step(H,X,LABEL,LABELNUMBERS)
[Y, FLAG] = step(H,X,ROI)
[Y, FLAG] = step(H,X,LABEL,LABELNUMBERS)
```

Description

`Y = step(H,X)` computes the standard deviation,`Y`, of input `X`. The object computes the standard deviation over successive calls to the `step` method when the `RunningStandardDeviation` property is `true`.

`Y = step(H,X,R)` resets its state based on the value of reset signal `R` and the `ResetCondition` property. You can use this option only when the `RunningStandardDeviation` property is `true`.

`Y = step(H,X,ROI)` uses additional input `ROI` as the region of interest when the `ROIProcessing` property is set to `true` and the `ROIForm` property is set to `Lines`, `Rectangles` or `Binary mask`.

`Y = step(H,X,LABEL,LABELNUMBERS)` computes the standard deviation of input image `X` for region labels contained in vector `LABELNUMBERS` , with matrix `LABEL` marking pixels of different regions. This option is available when the `ROIProcessing` property is set to `true` and the `ROIForm` property is set to `Label matrix`.

`[Y, FLAG] = step(H,X,ROI)` returns `FLAG` which indicates whether the given region of interest is within the image bounds when the `ValidityOutputPort` property is `true`.

`[Y, FLAG] = step(H,X,LABEL,LABELNUMBERS)` returns `FLAG` which indicates whether the input label numbers are valid when the `ValidityOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

State-level estimation for bilevel rectangular waveform

Description

The `StateLevels` object estimates the state levels of a bilevel rectangular waveform.

To estimate the state levels of a bilevel waveform:

1. Define and set up your state-level estimation. See "Construction" on page 3-1461.
2. Call `step` to estimate the state levels for an input vector according to the properties of `dsp.StateLevels`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.StateLevels` creates a state-level estimation System object, `H`, that estimates state levels in a bilevel rectangular waveform using the histogram method with 100 bins.

`H = dsp.StateLevels('PropertyName',PropertyValue,...)` returns an `StateLevels` System object, `H`, with each specified property set to the specified value.

Properties

HistogramBounds

Minimum and maximum levels of the histogram. Specify the range of the histogram as a 2-element real–valued row vector. Signal values outside the range defined by this property are ignored. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`, and either `RunningStateLevels` is `true`, or the `HistogramBoundsSource` property is set to `'Property'`.

Default: `[0 5]`

HistogramBoundsSource

Source of histogram bounds. Specify how to determine the histogram bounds as one of `'Auto'` or `'Property'`. When you set this property to `'Auto'`, the histogram bounds are determined by

the minimum and maximum input values. When you set this property to `'Property'`, the histogram bounds are determined by the value of the `HistogramBounds` property. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`, and the `RunningStateLevels` property is `false`.

Default: `'Auto'`

HistogramNumBins

Number of bins in the histogram. Specify the number of bins in the histogram. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`.

Default: `100`

HistogramOutputPort

Enable histogram output. Set this property to `true` to output the histogram used in the computation of the state levels. This property applies when you set the `Method` property to `'Histogram mode'` or `'Histogram mean'`.

Default: `false`

Method

Algorithm used to compute state levels. Specify the method used to compute state levels as one of `'Histogram mean'`, `'Histogram mode'`, or `'Peak to peak'`.

Default: `'Histogram mode'`

RunningStateLevels

Calculation over successive calls to `step`. Set this property to `true` to enable computation of the state levels over successive calls to the `step`. Otherwise, compute the state levels of the current

input. When you set the `RunningStateLevels` property to `false` and you are using a histogram to compute your state levels, you must set the `HistogramBoundsSource` property to `'Property'`.

State

A particular level, which can be associated with an upper and lower state boundary. States are ordered from the most negative to the most positive. In a bilevel waveform, the most negative state is the low state. The most positive state is the high state.

State-Level Tolerances

Each state level can have associated lower- and upper-state boundaries. These state boundaries are defined as the state level plus or minus a scalar multiple of the difference between the high state and low state. To provide a useful tolerance region, the scalar is typically a small number such as 2/100 or 3/100. In general, the α% tolerance region for the low state is defined as

$$S_1 \pm \frac{\alpha}{100}(S_2 - S_1)$$

where S_1 is the low-state level and S_2 is the high-state level. Replace the first term in the equation with S_2 to obtain the α% tolerance region for the high state.

The following figure illustrates lower and upper 2% state boundaries (tolerance regions) for a positive-polarity bilevel waveform. The estimated state levels are indicated by a dashed red line.

Methods

clone	Clones the current instance of the state levels object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
plot	Plot signal, state levels, and histogram
release	Allow property value and input characteristics changes
reset	Reset internal states of state levels object
step	Estimate state levels for bilevel rectangular waveform

Examples

State Levels of 2.3 V Underdamped Noisy Clock

Compute and plot the state levels of a 2.3 V underdamped noisy clock.

Load the clock data in the variable, `x`, and the sampling instants in the variable, `t`.

```
load('clockex.mat', 'x', 't');
```

Estimate the state levels.

```
h = dsp.StateLevels;
levels = step(h, x);
```

Plot the clock data along with the estimated state levels and histograms.

```
plot(h)
```

Algorithms

The `StateLevels` System object uses the histogram method to estimate the states of a bilevel waveform. The histogram method is described in [1]. To summarize the method:

1. Determine the maximum and minimum amplitudes and amplitude range of the data.
2. For the specified number of histogram bins, determine the bin width as the ratio of the amplitude range to the number of bins.
3. Sort the data values into the histogram bins.
4. Identify the lowest-indexed histogram bin, i_{low}, and highest-indexed histogram bin, i_{high}, with nonzero counts.
5. Divide the histogram into two subhistograms. The lower-histogram bins are $i_{low} \le i \le 1/2(i_{high} — i_{low})$.

   The upper-histogram bins are $i_{low} + 1/2(i_{high} - i_{low}) \le i \le i_{high}$.
6. Compute the state levels by determining the mode or mean of the lower and upper histograms.

See Also

`dsp.TransitionMetrics` | `dsp.PulseMetrics`

Purpose

Clones the current instance of the state levels object

Syntax

```
clone(H)
```

Description

`clone(H)` clones the current instance of the state levels object `H`.

dsp.StateLevels.getNumInputs

Purpose

Number of expected inputs to the `step` method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the state levels object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of the `step` method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.StateLevels.isLocked

Purpose

Locked status (logical) for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the state levels object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Plot signal, state levels, and histogram

Syntax

```
plot(H)
```

Description

`plot(H)` plots the signal and state levels computed in the last call to the `step` method. If the `Method` property of the state levels object is set to `'Histogram mode'` or `'Histogram Mean'`, the histogram is plotted in a subplot below the signal.

dsp.StateLevels.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of state levels object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the state levels object, `H`, to clear information accumulated from previous calls to `step`.

dsp.StateLevels.step

Purpose

Estimate state levels for bilevel rectangular waveform

Syntax

```
LEVELS = step(H,X)
[LEVELS,HISTOGRAM] = step(H,X)
```

Description

`LEVELS = step(H,X)` returns a 2-element row vector, `LEVELS`, containing the estimated state levels for `X`. `X` is a real-valued column vector.

`[LEVELS,HISTOGRAM] = step(H,X)` returns a double-precision column vector, `HISTOGRAM`, containing the histogram of the sample values in `X`. You can obtain this output only when you set the `Method` property to either `'Histogram mean'` or `'Histogram mode'`, and you set the `HistogramOutputPort` property to `true`.

Purpose

Decompose signal into high-frequency and low-frequency subbands

Description

The `SubbandAnalysisFilter` object decomposes a signal into high-frequency and low-frequency subbands.

To decompose a signal into high-frequency and low-frequency subbands:

1. Define and set up your two-channel subband analysis filter. See "Construction" on page 3-1475.
2. Call `step` to decompose the signal according to the properties of `dsp.SubbandAnalysisFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.SubbandAnalysisFilter` returns a two-channel subband analysis filter, `H`, that decomposes the input signal into a high-frequency subband and a low-frequency subband, each with half the bandwidth of the input.

`H = dsp.SubbandAnalysisFilter('PropertyName',PropertyValue,...)` returns a two-channel subband analysis filter, `H`, with each specified property set to the specified value.

`H = dsp.SubbandAnalysisFilter(lpc,hpc,'PropertyName',PropertyValue,...)` returns a two-channel subband analysis filter, `H`, with the `LowpassCoefficients` property set to `lpc`, the `HighpassCoefficients` property set to `hpc`, and other specified properties set to the specified values.

Properties

LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of

this property specify a filter based on a third-order Daubechies wavelet.

HighpassCoefficients

Highpass FIR filter coefficient

Specify a vector of highpass FIR filter coefficients, in descending powers of *z*. For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Action to take when integer input is out of range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficients word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Data type of product

Specify the product data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of `Full precision | Same as input | Same as product | Custom |`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as one of `| Same as accumulator | Same as product | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,14)`.

Methods

clone	Create subband analysis filter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset filter states of subband analysis filter object
step	Decompose signal into high- and low-frequency subbands

Examples

Perfectly reconstruct a signal using subband analysis and synthesis filters:

```
load dspwlets; % load the filter coefficients lod, hid, lor and hir
ha = dsp.SubbandAnalysisFilter(lod, hid);
hs = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = step(ha, u); % Two channel analysis
y = step(hs, hi, lo); % Two channel synthesis

% Plot difference between original and reconstructed signals
%  with filter latency compensated
plot(u(1:end-7)-y(8:end));
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Analysis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandAnalysisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Analysis Subband Filter block. The object assumes the input is frame based and always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the `dsp.SubbandAnalysisFilter` object.

See Also

`dsp.SubbandSynthesisFilter` | `dsp.DyadicAnalysisFilterBank`

dsp.SubbandAnalysisFilter.clone

Purpose

Create subband analysis filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` create a `SubbandAnalysisFilter` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.SubbandAnalysisFilter.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outpust from the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `SubbandAnalysisFilter` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.SubbandAnalysisFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset filter states of subband analysis filter object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the filter states of the `SubbandAnalysisFilter` object `H` to `0`.

dsp.SubbandAnalysisFilter.step

Purpose

Decompose signal into high- and low-frequency subbands

Syntax

```
[HI,LO] = step(H,SIG)
```

Description

`[HI,LO] = step(H,SIG)` decomposes the input signal, `SIG`, into a high-frequency subband, `HI`, and a low-frequency subband, `LO`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Reconstruct signal from high-frequency and low-frequency subbands

Description

The `SubbandSynthesisFilter` object reconstructs a signal from high-frequency and low-frequency subbands.

To reconstruct a signal from high-frequency and low-frequency subbands:

1. Define and set up your two-channel subband synthesis filter. See "Construction" on page 3-1487.
2. Call `step` to reconstruct the signal according to the properties of `dsp.SubbandSynthesisFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.SubbandSynthesisFilter` returns a two-channel subband synthesis filter, `H`, that reconstructs a signal from its high-frequency subband and low-frequency subband. Each subband contains half the bandwidth of the original signal.

`H = dsp.SubbandSynthesisFilter('PropertyName',PropertyValue,...)` returns a two-channel subband synthesis filter, `H`, with each specified property set to the specified value.

`H = dsp.SubbandSynthesisFilter(lpc,hpc, 'PropertyName',PropertyValue,...)` returns a two-channel subband synthesis filter, `H`. The object has the `LowpassCoefficients` property set to `lpc`, the `HighpassCoefficients` property set to `hpc`, and other specified properties set to the specified values.

Properties

LowpassCoefficients

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. For the lowpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `HighpassCoefficients` property. The default values of

this property specify a filter based on a third-order Daubechies wavelet.

HighpassCoefficients

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of *z*. For the highpass filter, use a half-band filter that passes the frequency band stopped by the filter specified in the `LowpassCoefficients` property. The default values of this property specify a filter based on a third-order Daubechies wavelet.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Action to take when integer input is out of range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Data type of the coefficients

Specify the FIR filter coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficient word and fraction lengths

Specify the FIR filter coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Data type of product

Specify the product data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,14)`.

Methods

clone	Create subband synthesis filter object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
reset	Reset internal states of subband synthesis filter object
step	Reconstruct signal from high- and low-frequency subbands

Examples

Perfectly reconstruct a signal using subband analysis and synthesis filters:

```
load dspwlets;  % Load filter coefficients lod,
                % hid, lor and hir
ha = dsp.SubbandAnalysisFilter(lod, hid);
hs = dsp.SubbandSynthesisFilter(lor, hir);
u = randn(128,1);

[hi, lo] = step(ha, u); % Two channel analysis
y = step(hs, hi, lo); % Two channel synthesis

% Plot difference between original and reconstructed
%  signals with filter latency compensated
plot(u(1:end-7)-y(8:end));
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Two-Channel Synthesis Subband Filter block reference page. The object properties correspond to the block parameters, except:

- The `SubbandSynthesisFilter` object does not have a property that corresponds to the **Input processing** parameter of the Two-Channel Synthesis Subband Filter block. The object only performs sample-based processing and always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the `SubbandSynthesisFilter` object.

See Also dsp.SubbandAnalysisFilter | dsp.DyadicSynthesisFilterBank

Purpose

Create subband synthesis filter object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `SubbandSynthesisFilter` object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.SubbandSynthesisFilter.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.SubbandSynthesisFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `SubbandSynthesisFilter` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

dsp.SubbandSynthesisFilter.reset

Purpose

Reset internal states of subband synthesis filter object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `SubbandSynthesisFilter` object `H` to their initial values.

Purpose

Reconstruct signal from high- and low-frequency subbands

Syntax

```
Y = step(H,HI,LO)
```

Description

`Y = step(H,HI,LO)` reconstructs a signal from a high-frequency subband, `HI`, and a low-frequency subband, `LO`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.TimeScope

Purpose

Time domain signal display

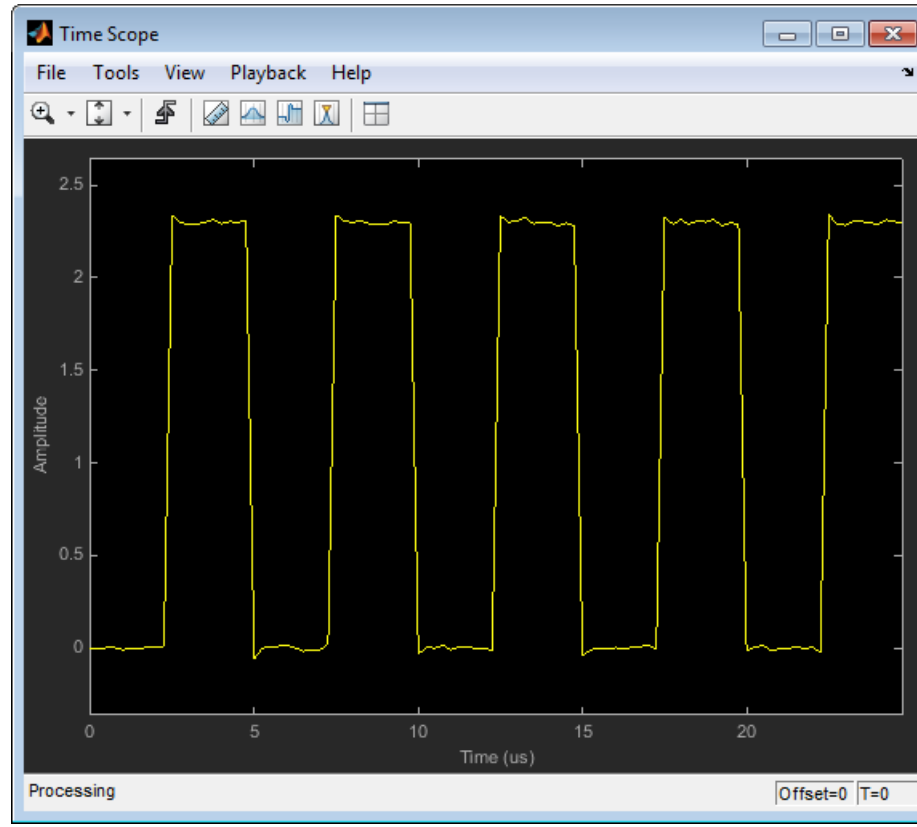
Description

The `TimeScope` object displays time-domain signals.

To display time-domain signals in the Time Scope:

1. Define and set up your Time Scope. See “Construction” on page 3-1502.
2. Call `step` to display the signal in the Time Scope figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Time Scope figure window.



See the following sections for information on the Time Scope System object:

- “Construction” on page 3-1502
- “Properties” on page 3-1503
- “Methods” on page 3-1513

See the following sections for information on the Time Scope Graphical User Interface:

For examples on how to use the Time Scope System object, see "Examples" on page 3-1587.

Note For information about the Time Scope block, see Time Scope.

Note If you own the MATLAB Coder product, you can generate C or C++ code from MATLAB code in which an instance of this system object is created. When you do so, the scope system object is automatically declared as an *extrinsic* variable. In this manner, you are able to see the scope display in the same way that you would see a figure using the `plot` function, without directly generating code from it. For the full list of system objects supporting code generation, see "DSP System Toolbox" in the MATLAB Coder documentation.

Construction

`H = dsp.TimeScope` returns a Time Scope System object, `H`. This object displays real- and complex-valued floating and fixed-point signals in the time domain.

`H = dsp.TimeScope('PropertyName',PropertyValue,...)` creates a Time Scope System object, `H`, with each specified property *`PropertyName`* set to the specified value.

`H = dsp.TimeScope(NUMINPUTS,SAMPLERATE,'PropertyName',PropertyValue, ...)` creates a Time Scope System object, `H`. This object has the `NumInputPorts` property set to *`NUMINPUTS`*, the `SampleRate` property set to *`SAMPLERATE`*, and other specified properties set to the specified values. *`NUMINPUTS`* and *`SAMPLERATE`* are value-only arguments. You can specify *`PropertyName`*–*`PropertyValue`* arguments in any order.

Properties

ActiveDisplay

Active display for display-specific properties

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display should have its axes colors, line properties, marker properties, and visibility changed. Tunable

Setting this property controls which display is used for `ShowGrid`, `ShowLegend`, `Title`, `PlotAsMagnitudePhase`, `YLabel`, and `YLimits`.

Default: `1`

BufferLength

Number of data points in buffer

Specify the size of the buffer that the scope holds in its memory cache. If your signal has *M* rows of data and *N* data points in each row, *M* x *N* is the number of data points per time step. Multiply this result by the number of time steps for your model to obtain the required buffer length. For example, if you have 10 rows of data with each row having 100 data points and your run will be 10 time steps, you should enter 10,000 (which is 10 x 100 x 10) as the buffer length.

Default: `50000`

FrameBasedProcessing

Process input in frames or as samples

When you set this property to `true`, you enable frame-based processing. When you set this property to `false`, you enable sample-based processing.

Default: `true`

LayoutDimensions

Layout grid dimensions

Specify the layout grid dimensions as a 2-element vector: `[numberOfRows, numberOfColumns]`. You can use no more than four rows or four columns. This property is Tunable.

Default: `[1,1]`

MaximizeAxes

Maximize axes control

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable.

Default: `'Auto'`

Name

Caption to display on the Time Scope window

Specify as a string the caption to display on the scope window. This property is Tunable.

Default: `'Time Scope'`

NumInputPorts

Number of input signals

Specify the number of input signals to display on the scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

Default: `1`

PlotAsMagnitudePhase

Plot signal magnitude and phase

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes within the same active display. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes within the same active display. This property is particularly useful for complex-valued input signals. Selecting this check box affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees. This property is Tunable.

When set, `ActiveDisplay` controls which displays are updated. The active display shows the magnitude of the input signal on the top axes and its phase, in degrees, on the bottom axes.

Default: `false`

PlotType

Option to control the type of plot

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to `'Line'` , the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- When you set this property to `'Stairs'`, the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable.

Default: `'Line'`

Position

Time Scope window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the scope window in a specific position

on your screen by modifying the values to this property. This property is Tunable.

Default: The default depends on your screen resolution. By default, the Time Scope window appears in the center of your screen with a width of `410` pixels and height of `300` pixels.

ReduceUpdates

Reduce updates to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time the `step` method is called. The simulation speed is faster when this property is set to `true`. This property is Tunable.

You can also modify this property from the Time Scope GUI. Opening the **Simulation** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to `false`.

Default: `true`

SampleRate

Sample rate of inputs

Specify the sample rate, in hertz, of the input signals.

You can specify a scalar or as a numeric vector with length equal to the value of `NumInputPorts`. The inverse of the sample rate determines the spacing between points on the *time*-axis in the displayed signal. When you set `SampleRate` to a scalar value and `NumInputPorts` is greater than 1, the object uses the same sample rate for all inputs.

Default: `1`

ShowGrid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable.

When set, `ActiveDisplay` controls which display is updated.

Default: `false`

ShowLegend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set this property to `false`, the scope does not display a legend. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. This property is Tunable.

See FrameBasedProcessing for information on input channels.

When set, `ActiveDisplay` controls which display is updated.

Default: `false`

TimeAxisLabels

Time-axis labels

Specify how *time*-axis labels should appear in the scope displays as one of `'All'`, `'Bottom`, or `'None'`.

- When you set this property to `'All'`, *time*-axis labels appear in all displays.
- When you set this property to `'Bottom'`, *time*-axis labels appear in the bottom display of each column.
- When you set this property to `'None'`, there are no labels in any displays.

This property is Tunable.

Default: `'All'`

TimeDisplayOffset

Time display offset

Specify the offset, in seconds, to apply to the *time*-axis. This property can be either a numeric scalar or a vector of length equal to the number of input channels. If you specify this property as a scalar, then that value is the time display offset for all channels. If you specify a vector, each vector element is the time offset for the corresponding channel. For vectors with length less than the number of input channels, the time display offsets for the remaining channels are set to 0. If a vector has a length greater than the number of input channels, the extra vector elements are ignored. This property is Tunable.

See FrameBasedProcessing for information on input channels. See `TimeSpan` and `TimeSpanSource` for information on the *x*-axis limits and time span settings.

Default: `0`

TimeSpan

Time span

Specify the time span, in seconds, as a positive, numeric scalar value. This property applies when `FrameBasedProcessing` is `false`. This property also applies when `FrameBasedProcessing` is `true` and `TimeSpanSource` is `Property`. The *time*-axis limits are calculated as follows.

- Minimum *time*-axis limit = min(`TimeDisplayOffset`)
- Maximum *time*-axis limit = max(`TimeDisplayOffset`) + `TimeSpan`

where `TimeDisplayOffset` and `TimeSpan` are the values of their respective properties. This property is Tunable.

Default: `10`

TimeSpanOverrunAction

Wrap or scroll when the `TimeSpan` value is overrun

Specify how the scope displays new data beyond the visible time span. You can select one of the following options:

- `Wrap` — In this mode, the scope displays new data until the data reaches the maximum *time*-axis limit. When the data reaches the maximum *time*-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum *time*-axis limit.
- `Scroll` — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

This property is Tunable.

Default: `'Wrap'`

TimeSpanSource

Source of time span

Specify the source of the time span for frame-based input signals as one of `'Auto'` or `'Property'`. This property applies when `FrameBasedProcessing` is set to `true`. When you set this property to `'Property'`, the object derives the *x*-axis limits from the `TimeDisplayOffset` and `TimeSpan` properties. When you set this property to `Auto`, the *time*-axis limits are the following:

- Minimum *time*-axis limit = min(`TimeDisplayOffset`)

- Maximum *time*-axis limit = max(`TimeDisplayOffset`) + max(1/`SampleRate`.**FrameSize*)

where `TimeDisplayOffset` and `SampleRate` are the values of their respective properties. *FrameSize* is a vector equal to the number of rows in each input signal. This property is Tunable.

Default: `'Property'`

TimeUnits

Units of the *time*-axis

Specify the units used to describe the *time*-axis. You can select one of the following options:

- `Metric` — In this mode, the scope converts the times on the *time*-axis to the most appropriate measurement units. These can include milliseconds, microseconds, nanoseconds, minutes, days, etc. The scope chooses the appropriate measurement units based on the minimum *time*-axis limit and the maximum *time*-axis limit of the scope window.
- `Seconds` — In this mode, the scope always displays the units on the *time*-axis as seconds.
- `None` — In this mode, the scope does not display any units on the *time*-axis. The scope only shows the word `Time` on the *time*-axis.

This property is Tunable.

Default: `'Metric'`

Title

Display title

Specify the display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is Tunable.

When set, `ActiveDisplay` controls which display is updated.

Default: `''`

YLabel

The label for the *y*-axis

Specify as a string the text for the scope to display to the left of the *y*-axis. Tunable

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two *y*-axis labels are read-only values. The *y*-axis labels are set to `'Magnitude'` and `'Phase'` for the magnitude plot and the phase plot, respectively. When set, `ActiveDisplay` controls which display is updated.

Default: `'Amplitude'` if `PlotAsMagnitudePhase` is `false`

YLimits

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is Tunable.

When `PlotAsMagnitudePhase` is `true`, this property specifies the *y*-axis limits of only the magnitude plot. The *y*-axis limits of the phase plot are always `[-180, 180]`. When set, `ActiveDisplay` controls which display is updated.

Default: `[-10, 10]`, if `PlotAsMagnitudePhase` is `false`, or `[0, 10]`, if `PlotAsMagnitudePhase` is `true`.

Methods

clone	Create time scope object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
hide	Hide time scope window
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of time scope object
show	Make time scope window visible
step	Display signal in time scope figure

Displaying Multiple Signals

Multiple Signal Input

You can configure the Time Scope to show multiple signals within the same display or on separate displays. By default, the signals appear as different-colored lines on the same display. The signals can have different dimensions, sample rates, and data types. Each signal can be either real or complex valued. You can set the number of input ports on the Time Scope in the following ways:

- Set the `NumInputPorts` property. This property is nontunable, so you should set it before you run the `step` method.
- Run the `show` method to open the scope window. In the scope menu, select **File > Number of Input Ports**.

- Run the `show` method to open the scope window. In the scope menu, select **View > Configuration Properties** and set the **Number of input ports** on the **Main** tab.

An input signal may contain multiple channels, depending on its dimensions. Multiple channels of data always appear as different-colored lines on the same display.

Multiple Signal Names and Colors

By default, if the input signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal would have the following default names in the channel legend: `Channel 1`, `Channel 2`. To show the legend, select **View > Configuration Properties**, click the **Display** tab, and select the **Show Legend** check box. If there are a total of 7 input channels, the following legend appears in the display.

By default, the scope has a black axes background and chooses line colors for each channel in a manner similar to the Simulink Scope block. When the scope axes background is black, it assigns each channel of each input signal a line color in the order shown in the above figure.

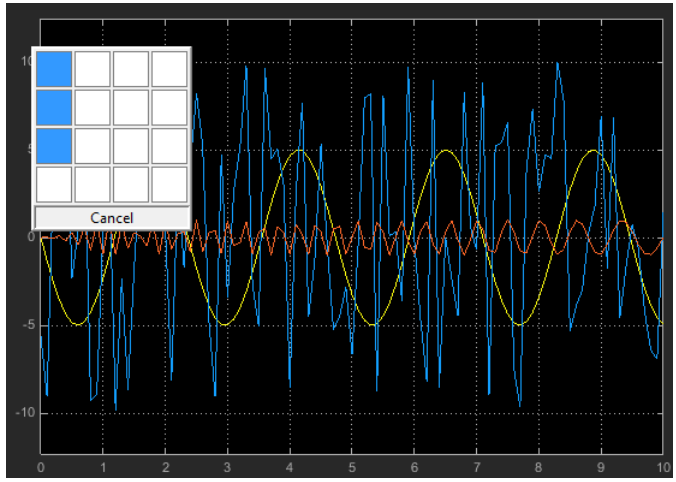
If there are more than 7 channels, then the scope repeats this order to assign line colors to the remaining channels. To choose line colors for each channel, change the axes background color to any color except black. To change the axes background color to white, select **View > Style**, click the Axes background color button (), and select white from the color palette. Run the simulation again. The following legend appears in the display. This is the color order when the background is not black.

Multiple Displays

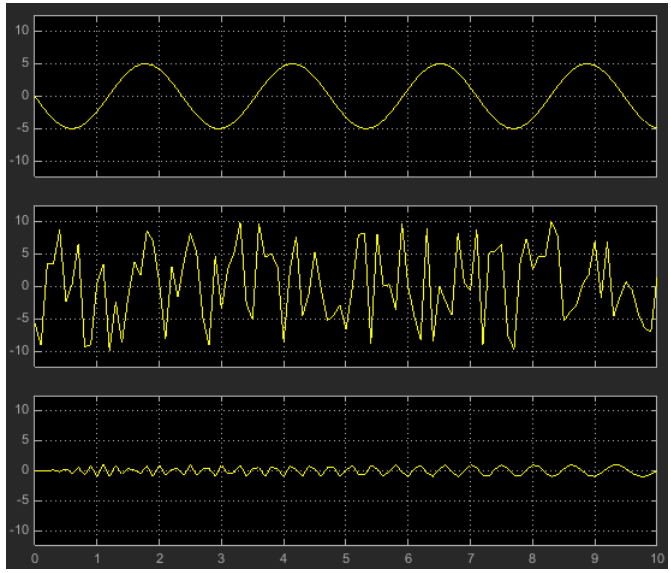
You can display multiple channels of data on different displays in the scope window. In the scope toolbar, select **View > Layout**, or select the Layout button ( ).

Note The **Layout** menu item and button are not available when the scope is in snapshot mode.

This feature allows you to tile the window into a number of separate displays, up to a grid of 4 rows and 4 columns. For example, if there are three inputs to the scope, you can display the signals in separate displays by selecting row 3, column 1, as shown in the following figure.



After you select row 3, column 1, the scope window is partitioned into three separate displays, as shown in the following figure.



When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The scope dialog boxes reference the active display.

Signal Display

Time Scope uses the **Time span** and **Time display offset** parameters in order to determine the time range. To change the signal display settings, select **View > Configuration Properties** to bring up the Visuals—Time Domain Properties dialog box. Then, modify the values for the **Time span** and **Time display offset** parameters on the **Main** tab. For example, if you set the **Time span** to 25 seconds, the scope displays 25 seconds' worth of simulation data at a time. If you also set the **Time display offset** to 5 seconds, the scope displays values on the time axis from 5 to 30 seconds. The values on the *time*-axis of the Time Scope display remain the same throughout simulation.

To communicate the simulation time that corresponds to the current display, the scope uses the **Time units**, **Time offset**, and **Simulation time** indicators on the scope window. The following figure highlights these and other important aspects of the Time Scope window.

Time Indicators

- **Minimum time-axis limit** — The Time Scope sets the minimum *time*-axis limit using the value of the **Time display offset** parameter on the **Main** tab of the Visuals—Time Domain Properties dialog

box. If you specify a vector of values for the **Time display offset** parameter, the scope uses the smallest of those values to set the minimum *time*-axis limit.

- **Maximum time-axis limit** — The Time Scope sets the maximum *time*-axis limit by summing the value of **Time display offset** parameter with the value of the **Time span** parameter. If you specify a vector of values for the **Time display offset** parameter, the scope sets the maximum *time*-axis limit by summing the largest of those values with the value of the **Time span** parameter.
- **Time units** — The units used to describe the *time*-axis. The Time Scope sets the time units using the value of the **Time Units** parameter on the **Time** tab of the Configuration Properties dialog box. By default, this parameter is set to `Metric (based on Time Span)` and displays in metric units such as milliseconds, microseconds, minutes, days, etc. You can change it to `Seconds` to always display the *time*-axis values in units of seconds. You can change it to `None` to not display any units on the *time*-axis. When you set this parameter to `None`, then Time Scope shows only the word `Time` on the *time*-axis.

  To hide both the word `Time` and the values on the *time*-axis, set the **Show time-axis labels** parameter to `None`. To hide both the word `Time` and the values on the *time*-axis in all displays except the bottom ones in each column of displays, set this parameter to `Bottom Displays Only`. This behavior differs from the Simulink Scope block, which always shows the values but never shows a label on the *x*-axis.

For more information, see “Visuals — Time Domain Properties” on page 3-1574.

Simulation Indicators

- **Simulation status** — Provides the current status of the model simulation. The status can be either of the following conditions:
  - `Processing` — Occurs after you run the `step` method and before you run the `release` method.

- `Stopped` — Occurs after you construct the scope object and before you first run the `step` method. This status also occurs after you run the `release` method.

The **Simulation status** is part of the **Status Bar** in the scope window. You can choose to hide or display the entire **Status Bar**. From the scope menu, select **View > Status Bar**.

- **Time offset** — The **Time offset** value helps you determine the simulation times for which the scope is displaying data. The value is always in the range `0`≤ `Time offset`≤ **Simulation time**. Therefore, add the Time offset to the fixed time span values on the *time*-axis to get the overall simulation time.

  For example, if you set the **Time span** to `20` seconds, and you see a **Time offset** of `0 (secs)` on the scope window. This value indicates that the scope is displaying data for the first `0` to `20` seconds of simulation time. If the **Time offset** changes to `20 (secs)`, the scope displays data for simulation times from `20` seconds to `40` seconds. The scope continues to update the **Time offset** value until the simulation is complete.

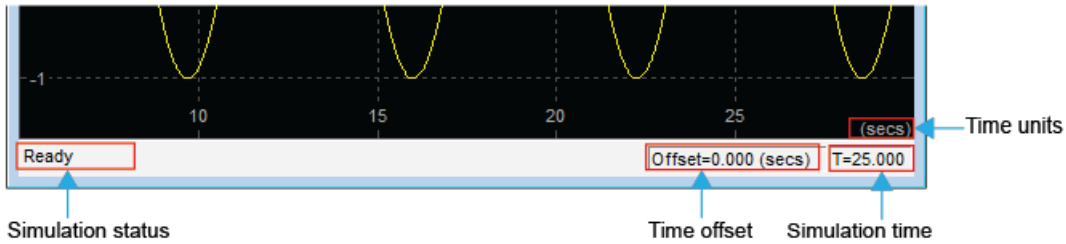
- **Simulation time** — The amount of time that the Time Scope has spent processing the input. Every time you call the `step` method, the simulation time increases by the number of rows in the input signal divided by the sample rate, as given by the following formula:

  $t_{sim} = t_{sim} + \frac{\text{length}(x)}{SampleRate}$. You can set the sample rate using the `SampleRate` property.

  The **Simulation time** is part of the **Status Bar** in the Time Scope window. You can choose to hide or display the entire **Status Bar**. From the Time Scope menu, select **View > Status Bar** .

Axes Maximization

When the scope is in maximized axes mode, the following figure highlights the important indicators on the scope window.



To toggle this mode, in the scope menu, select **View > Configuration Properties**. In the **Main** pane, locate the **Maximize axes** parameter.

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable.

The default setting is `Auto`.

Reduce Updates to Improve Performance

By default, the scope updates the displays periodically at a rate not exceeding 20 hertz. If you would like the scope to update on every simulation time step, you can disable the **Reduce Updates to Improve Performance** option. However, as a recommended practice, leave this option enabled because doing so can significantly improve the speed of the simulation.

In the Time Scope menu, select **Playback > Reduce Updates to Improve Performance** to clear the check box. Alternatively, use the **Ctrl+R** shortcut to toggle this setting. You can also set the `ReduceUpdates` property to `false` to disable this option.

Toolbar

The Time Scope toolbar contains the following buttons.

Print Button

Button	Menu Location	Shortcut Keys	Description
	**File > Print**	**Ctrl+P**	Print the current scope window. Printing is available only when the scope display is not changing. To print the current scope window to a figure rather than sending it to your printer, select **File > Print to figure**.

Zoom and Axes Control Buttons

Button	Menu Location	Shortcut Keys	Description
	**Tools > Zoom In**	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.
	**Tools > Zoom X**	N/A	You access the Zoom X button from the menu under the Zoom In icon. When this tool is active, you can zoom in on the *x*-axis. To do so, click inside the scope window, or click and drag

Button	Menu Location	Shortcut Keys	Description
			your cursor along the *x*-axis over your area of interest.
	**Tools > Zoom Y**	N/A	You access the Zoom Y button from the menu under the Zoom In icon. When this tool is active, you can zoom in on the *y*-axis. To do so, click inside the scope window, or click and drag your cursor along the *y*-axis over your area of interest.
	**Tools > Pan**	N/A	You access the Pan button from the menu under the Zoom In icon. When this tool is active, you can pan on the scope window. To do so, click in the center of your area of interest and drag your cursor to the left, right, up, or down, to move the position of the display.
	**Tools > Scale Y-Axes Limits**	**Ctrl+A**	Click this button to scale the axes in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation.

Button	Menu Location	Shortcut Keys	Description
			• **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.
	**Tools > Scale X-Axis Limits**	N/A	You access the Scale X-Axis Limits button from the menu under the current Axis Limits icon. Click this button to scale the axes in the X direction in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation.

Button	Menu Location	Shortcut Keys	Description
			• **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.
	**Tools > Scale X and Y Axes Limits**	N/A	You access the Scale X and Y Axis Limits button from the menu under the current Axis Limits icon. Click this button to scale the axes in both the X and Y directions in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Measurements Buttons

	**Tools > Triggers**	N/A	Open or close the **Triggers** panel. This panel allows you to pause the display only when certain events occur. You can use the Triggers panel when you want to align or search for interesting events. Triggers can be configured to both select and align specific regions of interest in the display area of the scope. See the "Triggers Panel" on page 3-1528 section for more information.
	**Tools > Measurements > Cursor Measurements**	N/A	Open or close the **Cursor Measurements** panel. This panel puts screen cursors on all the displays. See the "Cursor Measurements Panel" on page 3-1547 section for more information.
	**Tools > Measurements > Signal Statistics**	N/A	You access the Signal Statistics button from the menu under the current Measurements icon. Open or close the **Signal Statistics** panel. This panel displays the maximum, minimum, peak-to-peak difference, mean, median, RMS values of a selected signal, and the times at which the maximum and minimum occur. See the "Signal Statistics Panel" on page 3-1549 section for more information.

	**Tools > Measurements > Bilevel Measurements**	N/A	You access the Bilevel Measurements button from the menu under the current Measurements icon. Open or close the **Bilevel Measurements** panel. This panel displays information about a selected signal's transitions, overshoots or undershoots, and cycles. See the "Bilevel Measurements Panel" on page 3-1552 section for more information.
	**Tools > Measurements > Peak Finder**	N/A	You access the Peak Finder button from the menu under the current Measurements icon. Open or close the **Peak Finder** panel. This panel displays maxima and the times at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. See the "Peak Finder Panel" on page 3-1566 section for more information.

Other Buttons

	**View > Layout**	N/A	Arrange the layout of displays in the Time Scope. This feature allows you to tile your screen into a number of separate displays, up to a grid of 4 rows and 4 columns. You may find multiple displays useful when the Time Scope takes multiple input signals. The default display is 1 row and 1 column. See the "Multiple Displays" on page 3-1515 section for more information.

You can control whether this toolbar appears in the Time Scope window. From the Time Scope menu, select **View > Toolbar**.

Measurements Panels

The Measurements panels are the five panels that appear to the right side of the Time Scope GUI. These panels are labeled **Trace selection**, **Cursor measurements**, **Signal statistics**, **Bilevel measurements**, and **Peak finder**.

Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

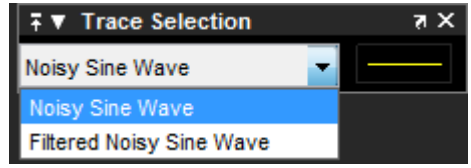
Button	Description
	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button  .
	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button  again.
	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button  in the new window.

Button	Description
	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button  again.
	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button  to show each pane that is hidden in the current panel. Click the pane collapse button  to hide each pane that is shown in the current panel.

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click on any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.

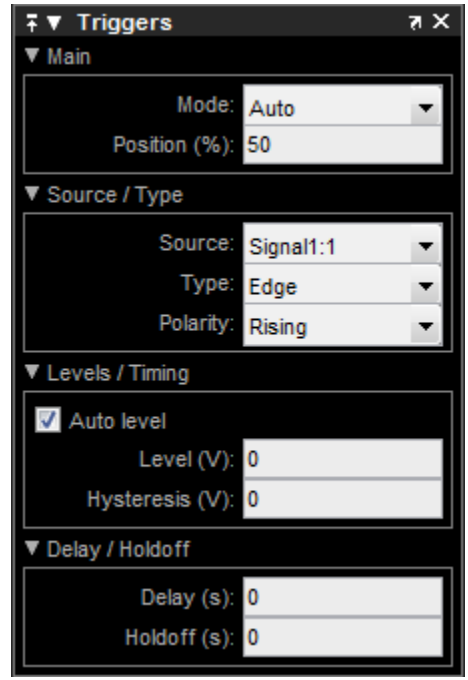


You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools > Measurements > Trace Selection**.

Triggers Panel

The **Triggers** panel allows you to pause the display only when certain events occur. You can use the Triggers panel when you want to align or search for interesting events. You can configure triggers to both select and align specific regions of interest in the display area of the

scope. Triggers work across multiple displays. You can also choose to hide or display the **Triggers** panel. In the scope toolbar, click the Triggers button ( ). Alternatively, in the scope menu, select **Tools > Triggers**.



When the **Triggers** panel is displayed, triangle pointers appear at the top and right side of the axes on each display. These markers indicate the time position ( ) and level ( ) at the event. The color of the markers corresponds to the color of the source signal.

Note The scope does not display an event until at least a full time span is completely viewable inside the display. To prevent data from being shown twice in the display, the scope suppresses the alignment of recurring events until a full time span has elapsed since the previous update.

Main Pane

The **Main** pane lets you choose how often the display updates and in what position the trigger indicator appears.

- **Mode** — Define how often the display should update.
  - **Auto** — The scope aligns and displays data from the latest trigger event. If no event is found after a full time span has elapsed, then the scope displays the last available data. Use this mode to see your data and have it align whenever a trigger event occurs.
  - **Normal** — The scope aligns and displays data only from the latest trigger event. Use this mode to search for infrequently occurring events in your data.
  - **Once** — The scope displays data on the next encountered trigger event and freezes the display. The scope ignores subsequent data until you press the **Rearm** button.
  - **Off** — The scope does not make acquisitions. Triggering is disabled. This setting is equivalent to hiding the **Triggers** panel. You can use panning only if **Mode** is set to **Off**.

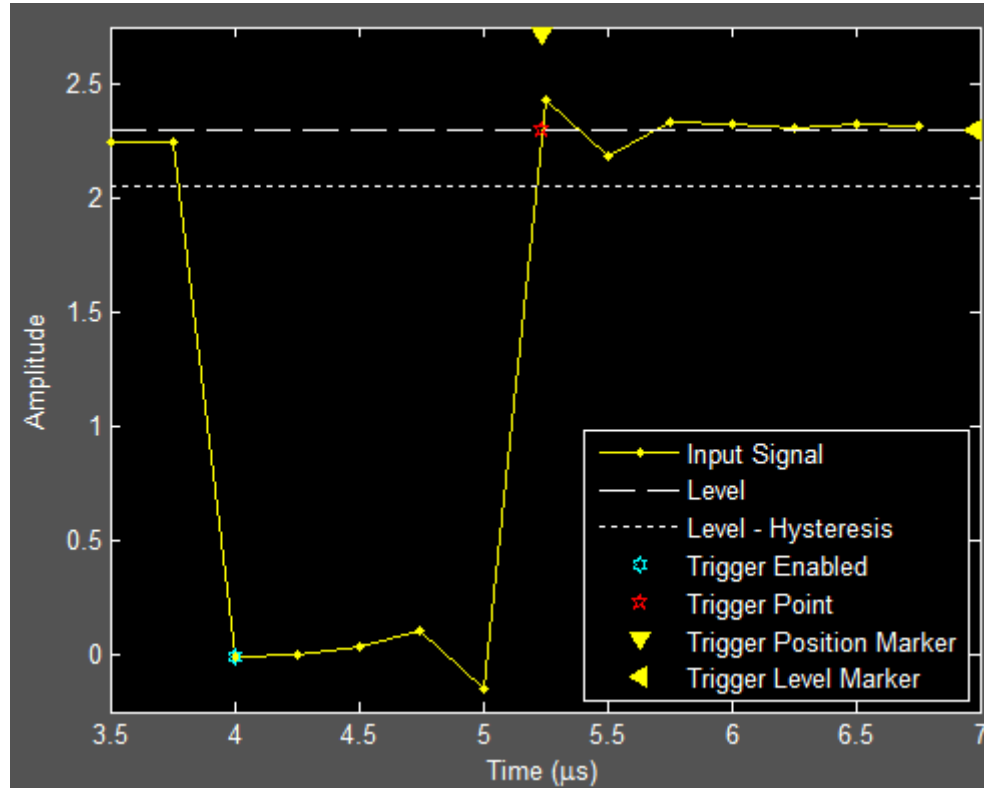
  If mode is set to either **Normal** or **Once** and the Triggers panel does not encounter any event, the display remains blank. Set **Mode** to **Auto** if you want the scope to display signal data regularly, in addition to trigger events.
- **Position (%)** — Specify, as a percentage of the total time span within the active display, the horizontal position in which the trigger indicator appears. A position value of `0` corresponds to the minimum

time-axis value at the far-left side of the display. A position value of 100 corresponds to the maximum *time*-axis value at the far-right side of the display. Drag the trigger position indicator to the left or right to adjust its position.

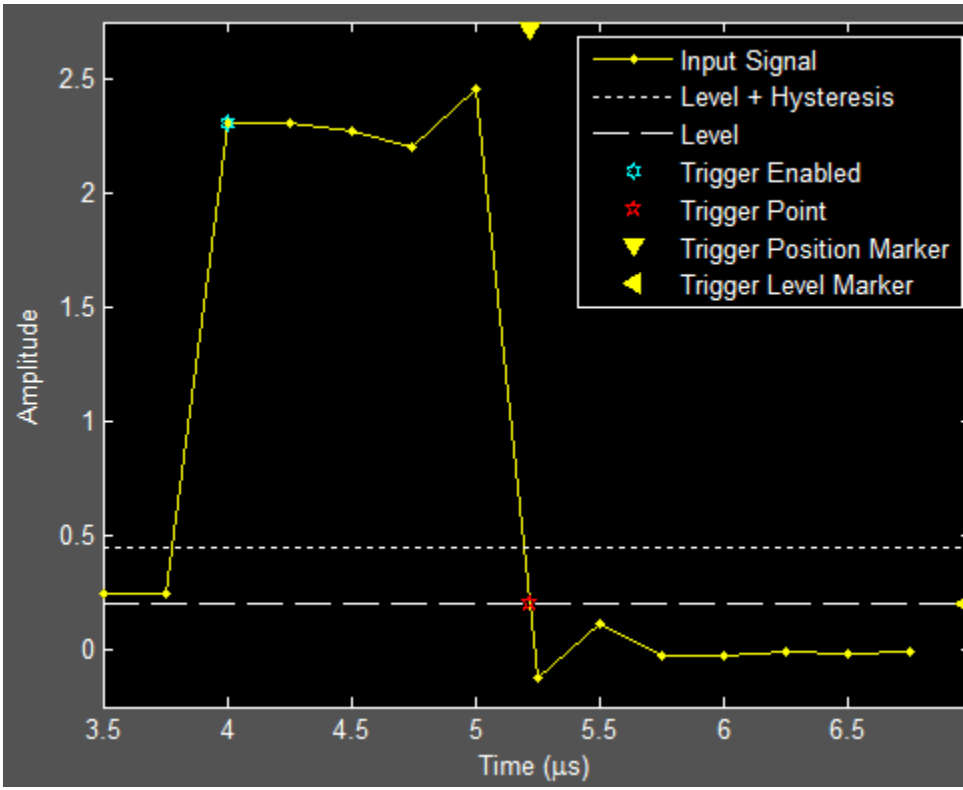
Source / Type Pane

The **Source / Type** pane lets you choose the source of the trigger and the type of events on which to stop.

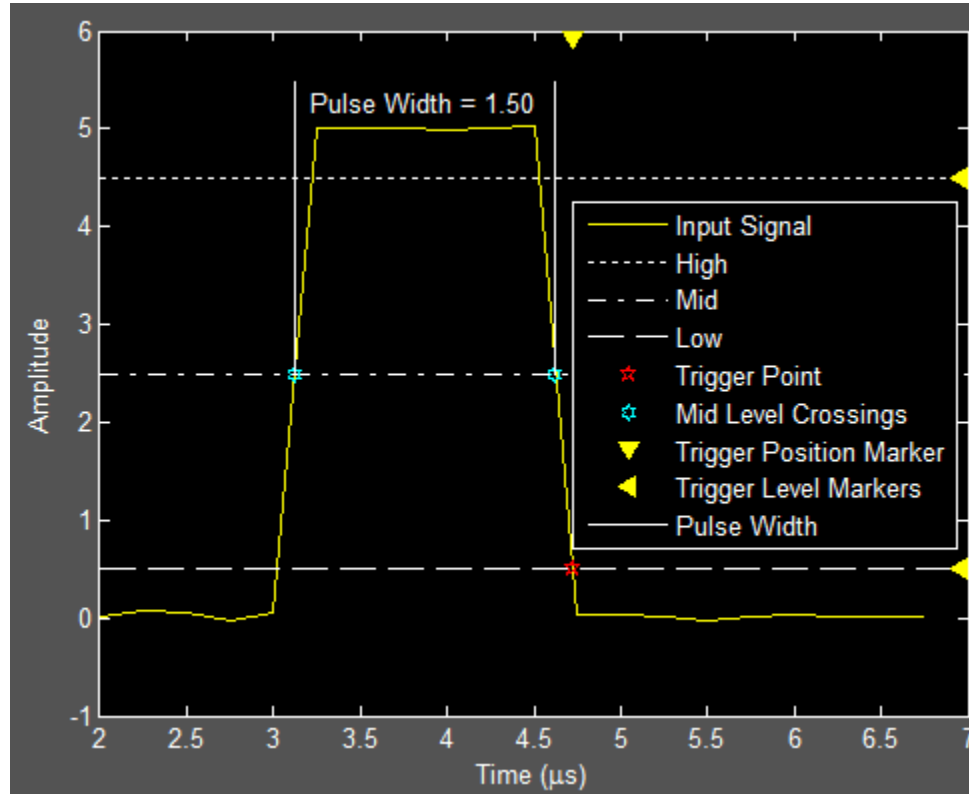
- **Source** — Assign the trigger source to a particular channel. If you are viewing a magnitude/phase plot, you can trigger off the magnitude or the phase. If you are not viewing the magnitude/phase plot, you can trigger off the real or imaginary data. If the input signal has multiple channels, the scope assigns an index number to identify each channel of that signal. For more information, see Multiple Signal Input.
- **Type** — Select the type of trigger to use.
  - **Edge** — Trigger when the scope crosses a level threshold. In the case of a rising edge, the scope enables the trigger event when the signal value becomes less than the level threshold minus hysteresis. The scope disables the trigger event when the signal becomes greater than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold, as shown in the following figure.



In the case of a falling edge, the scope enables the trigger event when the signal value becomes greater than the level threshold plus hysteresis. The scope disables the trigger event when the signal becomes less than the level threshold for the first time. The scope uses linear interpolation to generate a trigger event at the time when the signal crosses the level threshold, as shown in the following figure.



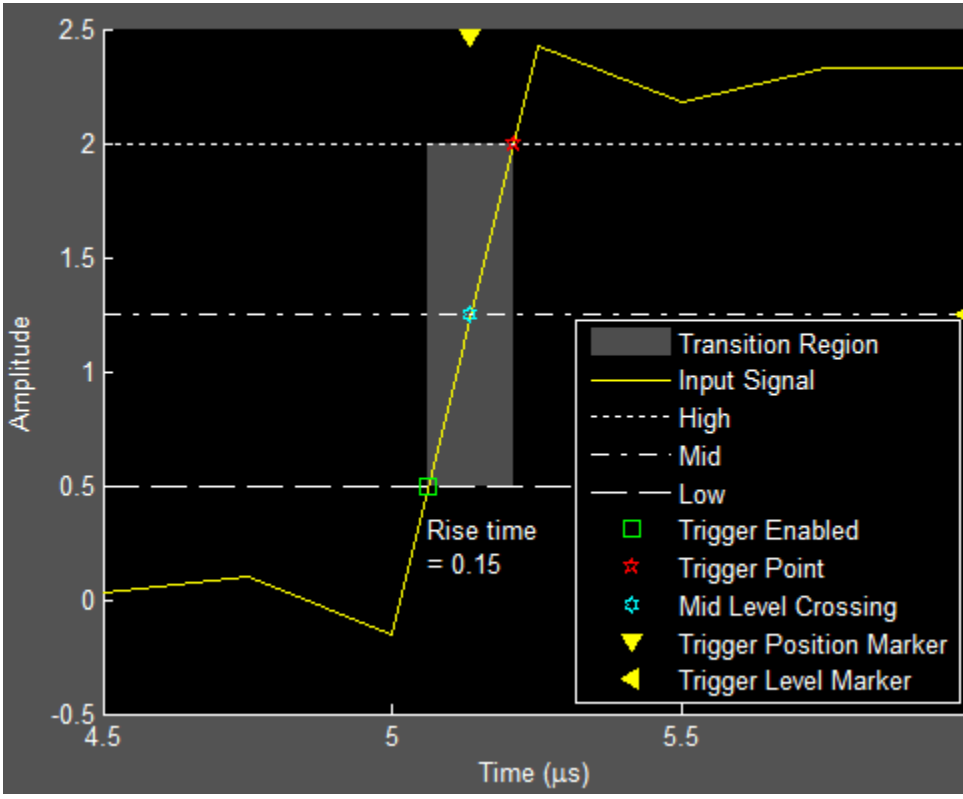
- **Pulse Width** — Trigger when the scope encounters a pulse whose width falls inside or outside specified time limits. You specify the range of valid time limits in the **Levels / Timing** pane. In the case of a positive-polarity pulse, the scope encounters a trigger event when the signal crosses the low threshold for the second time. The scope measures the pulse width as the time between the first and second crossings of the middle threshold, located halfway between the high and low thresholds, as shown in the following figure.



Note A *Glitch*-type trigger looks for a pulse or spike whose duration is less than a specified amount. You can implement a *Glitch* type trigger by using a **Pulse Width** type trigger and manually setting the **Max Width** parameter.

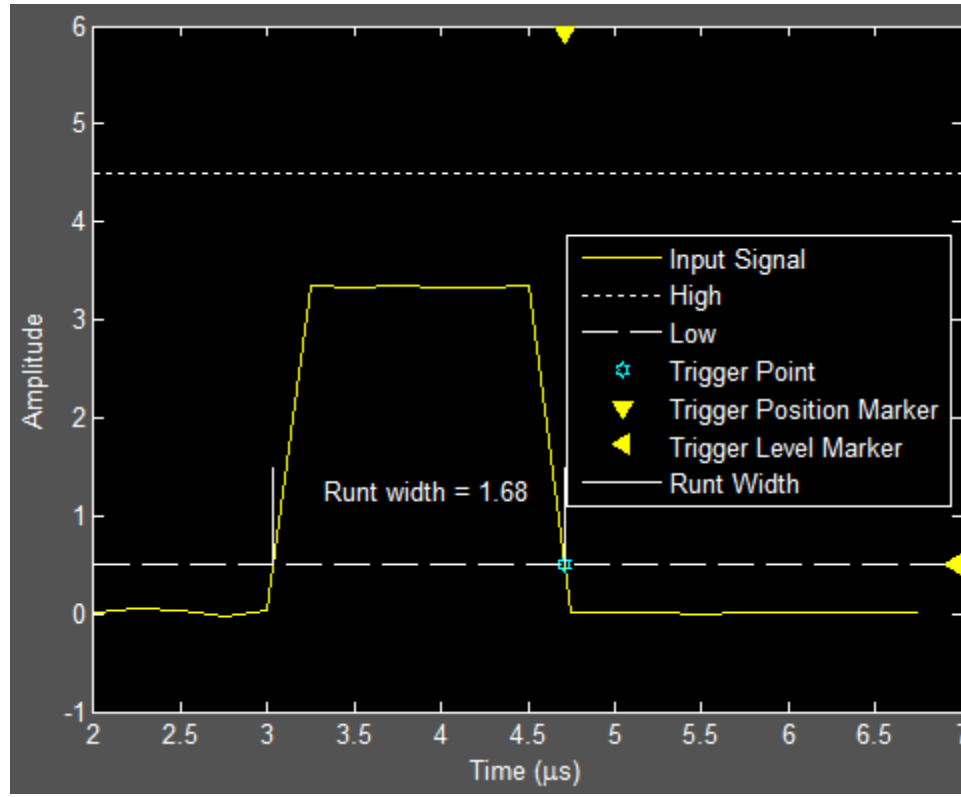
- **Transition** — Trigger on a rising or falling edge that crosses two levels, high and low, inside or outside a specified time interval. You specify the range of valid transition times in the **Levels / Timing** pane. In the case of a rising transition, the

scope encounters the trigger event when the signal crosses the high threshold. The transition time is when the signal crosses the middle threshold, located halfway between the high and low thresholds, as shown in the following figure.



- **Runt** — Trigger on a runt pulse, which crosses one threshold, high or low, but not both. In the case of a positive-polarity runt pulse, the scope encounters a trigger event when the signal crosses the low threshold the second time, without ever crossing the high threshold. The scope measures the runt width as the time between the first and second crossings of the low threshold, as shown in the

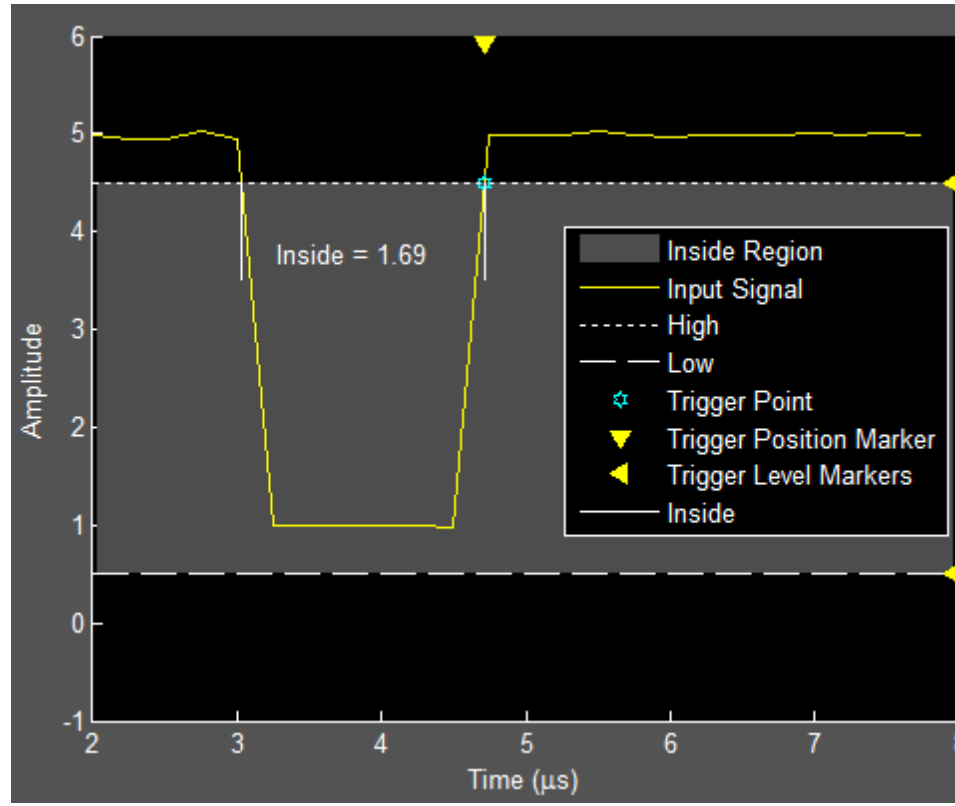
following figure. The runt width is the **Max Width** – **Min Width**. Any runt pulse width that is less than the minimum width or greater than the maximum width will not generate a trigger event.



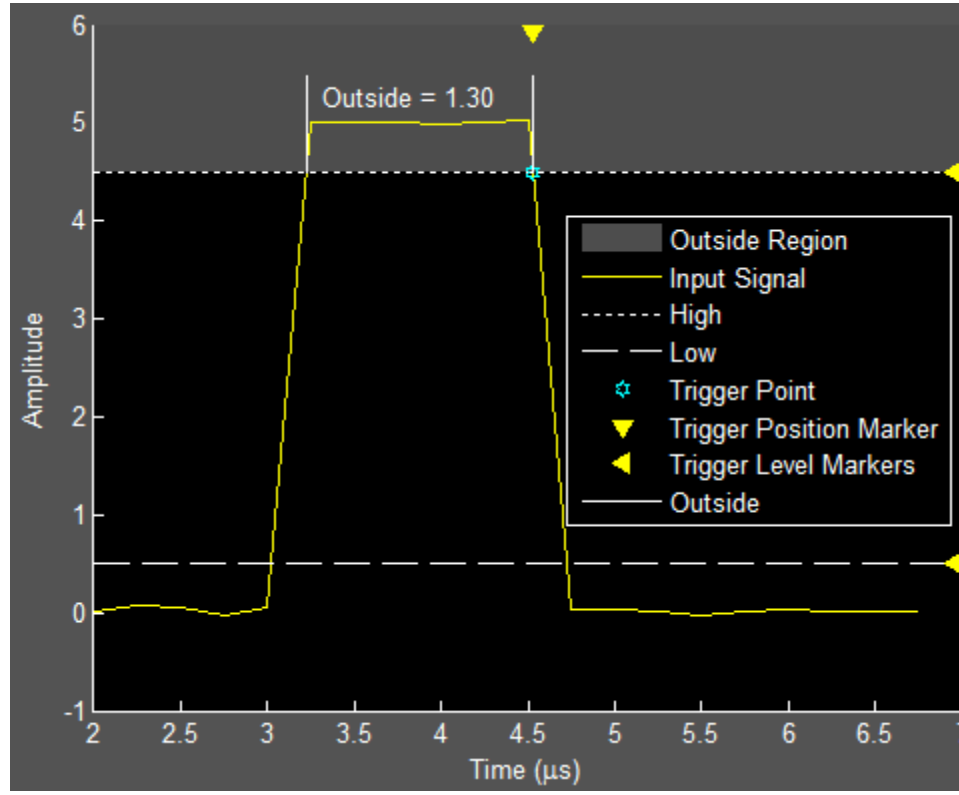
Note You can also replicate a **Runt**-type trigger by using a **Window**-type trigger and setting **Polarity** to **Inside**.

- **Window** — Trigger when the input signal stays within or outside the region defined by the high and low thresholds for a period of

time. In the case of an inside window, the scope encounters a trigger event when the signal enters and exits the inside region, as shown in the following figure.

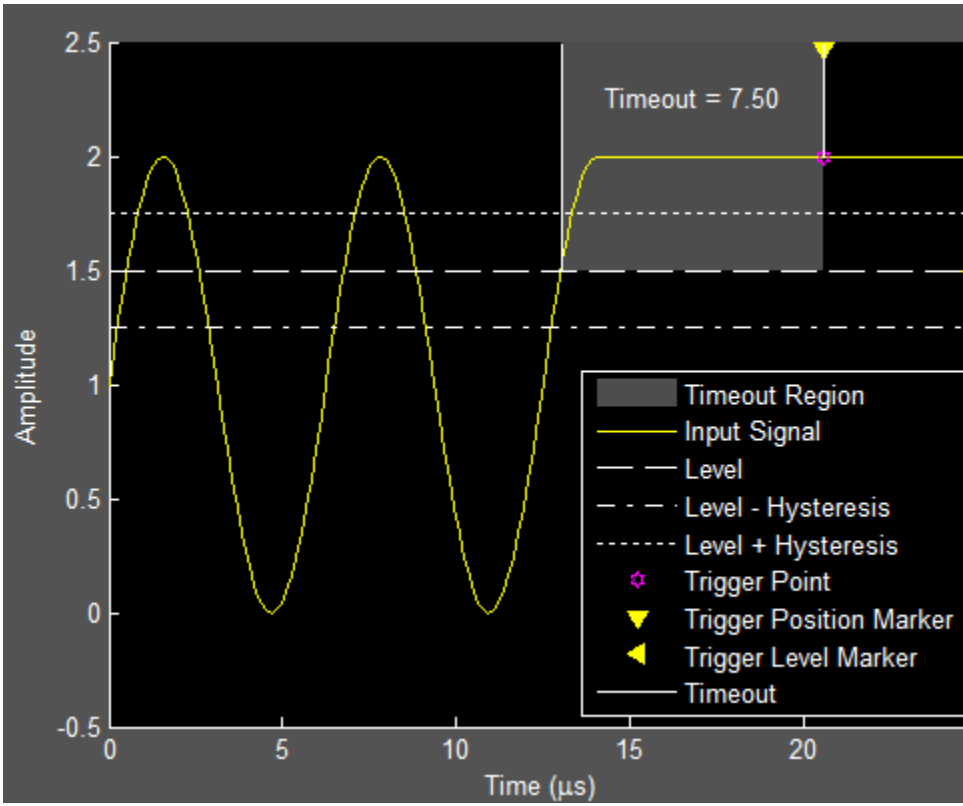


In the case of an outside window, the scope encounters a trigger event when the signal enters and exits the outside region, as shown in the following figure.

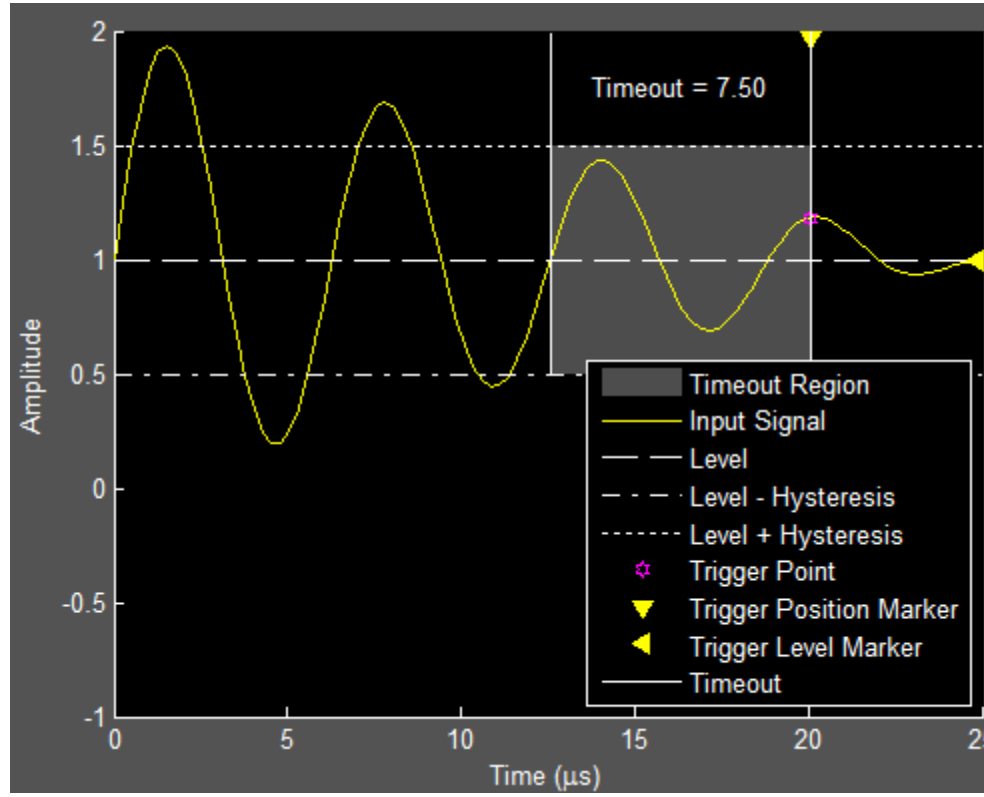


The scope encounters a trigger event when the signal crosses either the high or low threshold the second time.

- **Timeout** — Trigger when the input signal stays above or below a voltage threshold longer than a specified time. In the case of a timeout trigger with polarity set to `Either` and a timeout duration of 7.50 seconds, the scope can encounter the trigger event 7.50 seconds after the signal crosses the level threshold the last time, as shown in the following figure.



Alternatively, the scope can encounter the trigger event when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the level threshold, as shown in the following figure.



- **Polarity** — Select the polarity of the trigger type. The option you choose for **Type** directly affects the options available for **Polarity**, as shown in the following table.

Trigger Type	Polarity Options
Edge	Rising, Falling, Either
Pulse Width	Positive, Negative, Either
Transition	Rise Time, Fall Time, Either
Runt	Positive, Negative, Either

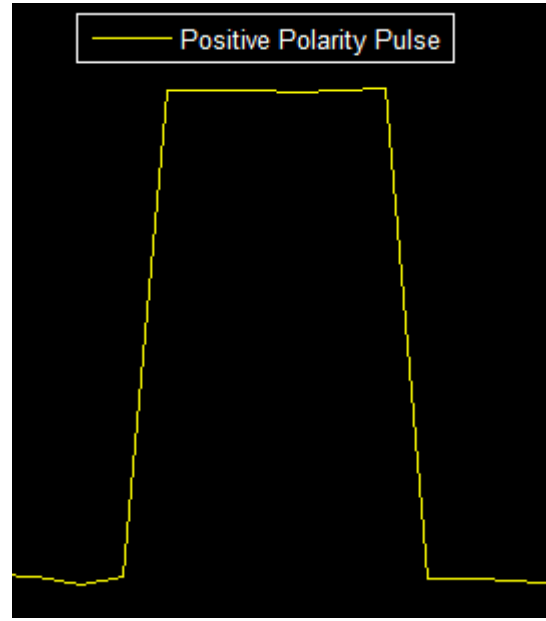
Trigger Type	Polarity Options
Window	Inside, Outside, Either
Timeout	Rising, Falling, Either

When you set **Type** to `Edge`, the polarity options are:

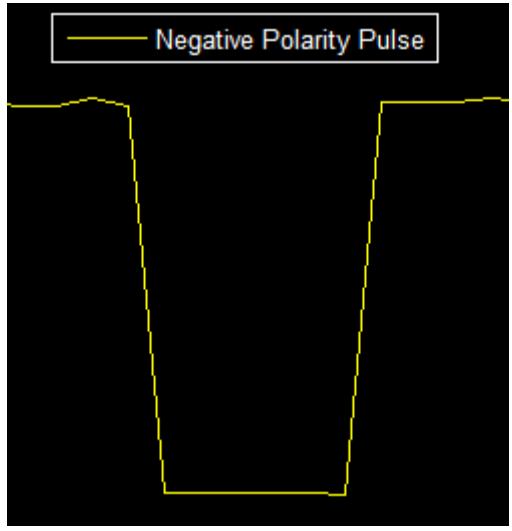
- **Rising** — Trigger on a *rising edge*, a transition from a low-state level to a high-state level.
- **Falling** — Trigger on a *falling edge*, transition from a high-state level to a low-state level.
- **Either** — Trigger on both rising edges and falling edges.

When you set **Type** to `Pulse Width` or `Runt`, the polarity options are:

- **Positive** — Trigger on a positive-polarity pulse, as shown in the following figure.



- **Negative** — Trigger on a negative-polarity pulse, as shown in the following figure.



- **Either** — Trigger on both positive-polarity and negative-polarity pulses.

When you set **Type** to `Transition`, the polarity options are:

- **Rise Time** — Trigger based on how long the signal takes to transition from the low threshold to the high threshold.
- **Fall Time** — Trigger based on how long the signal takes to transition from the high threshold to the low threshold.
- **Either** — Trigger based on how long it takes to make either a rising or falling transition.

When you set **Type** to `Window`, the polarity options are:

- **Inside** — Trigger when the signal stays within the low and high levels for a specified time duration.
- **Outside** — Trigger when the signal stays outside of the low and high levels for a specified time duration.

- **Either** — Trigger on both inside and outside windows.

When you set **Type** to `Timeout`, the polarity options are:

- **Rising** — Trigger when the signal does not cross the reference level from below.
- **Falling** — Trigger when the signal does not cross the reference level from above.
- **Either** — Trigger when the signal does not cross the reference level from either direction.

Levels / Timing Pane

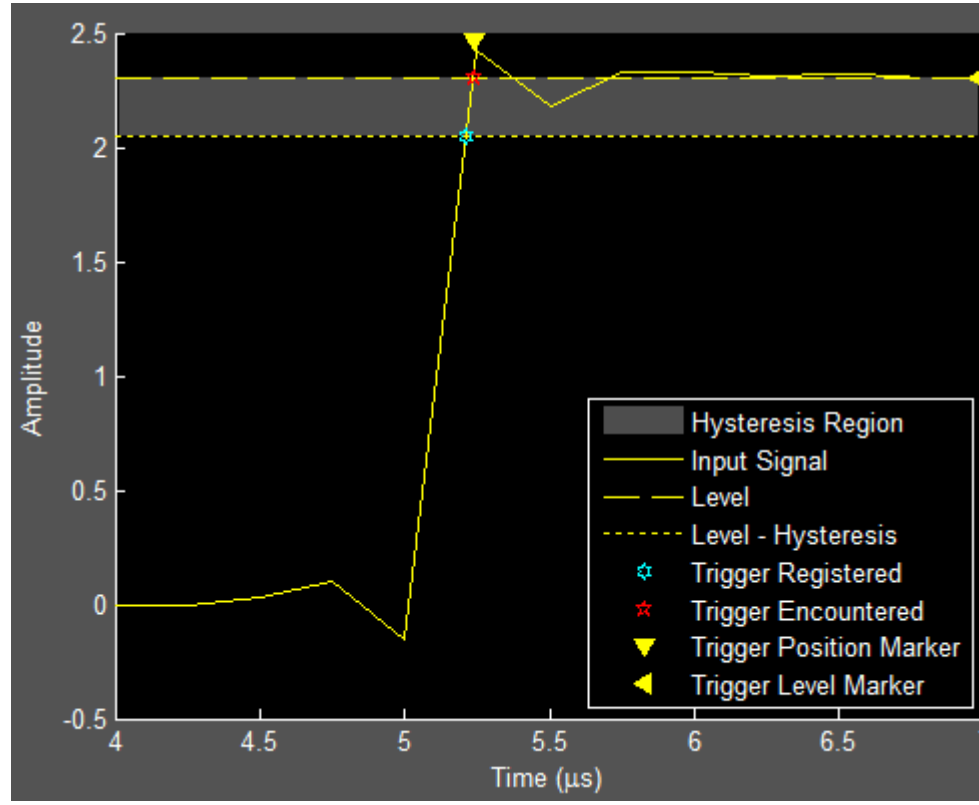
The **Levels / Timing** pane enables you to set the trigger level and hysteresis value. The option you choose for **Type** directly affects which level and timing parameters are available, as shown in the following table.

Trigger Type	Level Parameters	Auto-Level Setting	Timing Parameters
Edge	Level, Hysteresis	Level = 50%	n/a
Pulse Width	High, Low	High = 90%, Low = 10%	Min Width, Max Width
Transition	High, Low	High = 90%, Low = 10%	Min Time, Max Time
Runt	High, Low	High = 90%, Low = 10%	Min Width, Max Width
Window	High, Low	High = 90%, Low = 10%	Min Time, Max Time
Timeout	Level, Hysteresis	n/a	Timeout

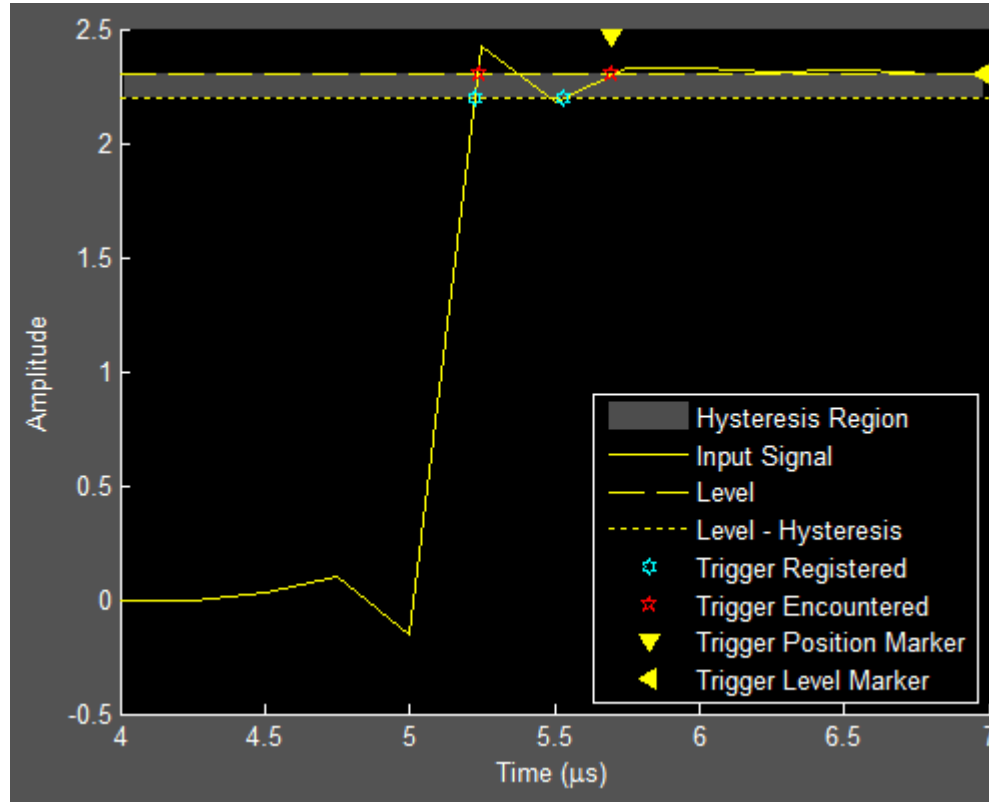
- **Auto level** — Enable the Triggers panel to automatically choose the level parameters. If you set the trigger type to **Edge**, this option sets

the **Level** parameter to 50% of the range of the source signal. If you set the trigger type to **Timeout**, the Triggers panel does not show this option. Setting the trigger type to other menu choices results in **High** and **Low** parameter adjustment. **Auto level** sets the **High** parameter to 90% of the range of the source signal and the **Low** parameter to 10% of the range of the source signal.

- **Level (V)** — Specify, in volts, the trigger level. This parameter is visible when you set **Type** to `Edge` or `Timeout`.
- **Hysteresis (V)** — Specify, in volts, the hysteresis or noise reject value. This parameter is visible when you set **Type** to `Edge` or `Timeout`. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores any times that the signal crosses the trigger level within the hysteresis region, as shown in the following figure.



You can reduce the hysteresis region size by decreasing the hysteresis value. If you set the hysteresis value to 0.07 in this example, then the scope also considers the second rising edge to be a trigger event, as shown in the following figure.



- **High (V)** — Specify, in volts, the value that denotes a positive polarity, or high-state level. This parameter is visible when you set **Type** to `Pulse Width`, `Transition`, `Runt`, or `Window`.
- **Low (V)** — Specify, in volts, the value that denotes a negative polarity, or low-state level. This parameter is visible when you set **Type** to `Pulse Width`, `Transition`, `Runt`, or `Window`.
- **Min Width (s)** — Specify, in seconds, the minimum pulse width. This parameter is visible when you set **Type** to `Pulse Width` or `Runt`.
- **Max Width (s)** — Specify, in seconds, the maximum pulse width. This parameter is visible when you set **Type** to `Pulse Width` or `Runt`.

- **Min Time (s)** — Specify, in seconds, the minimum duration. This parameter is visible when you set **Type** to `Transition` or `Window`.
- **Max Time (s)** — Specify, in seconds, the maximum duration. This parameter is visible when you set **Type** to `Transition` or `Window`.
- **Timeout (s)** — Specify, in seconds, the timeout duration. This parameter is visible when you set **Type** to `Timeout`.

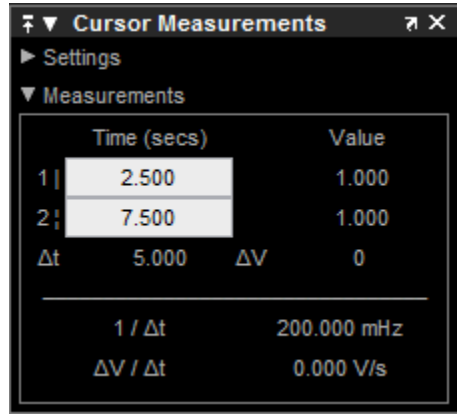
Delay / Holdoff Pane

The **Delay / Holdoff** pane enables you to offset the trigger position by a fixed delay or set the minimum possible time between trigger events.

- **Delay (s)** — Specify, in seconds, the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify, in seconds, the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event is encountered. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the portion of a burst that is of interest.

Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. You can choose to hide or display the **Cursor Measurements** panel. In the Scope menu, select **Tools > Measurements > Cursor Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements  button.



The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for power and power density spectra only).
- **Horizontal** — Shows horizontal screen cursors (for power and power density spectra only).
- **Vertical** — Shows vertical screen cursors (for power and power density spectra only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for power and power density spectra only).

- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

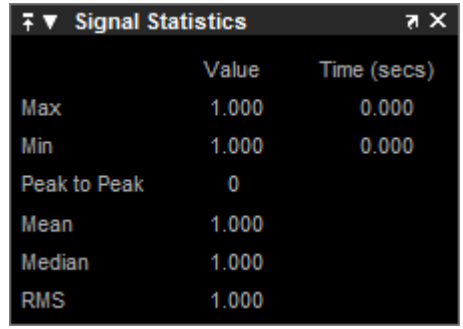
Measurements Pane

The **Measurements** pane shows the time and value measurements.

- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.
- **Δt**— Shows the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV**— Shows the absolute value of the difference in signal amplitudes between cursor number one and cursor number two.
- **1/Δt**— Shows the rate, the reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV/Δt**— Shows the scope, the ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

Signal Statistics Panel

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the *x*-axis indices at which the maximum and minimum values occur. You can choose to hide or display the **Signal Statistics** panel. In the Scope menu, select **Tools > Measurements > Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics  button.



Signal Statistics Measurements

The **Signal Statistics** panel shows statistics about the portion of the input signal within the *x*-axis and *y*-axis limits of the active display. The statistics shown are:

- **Max** — Shows the maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.
- **Min** — Shows the minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** — Shows the average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — Shows the median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.

- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the Scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

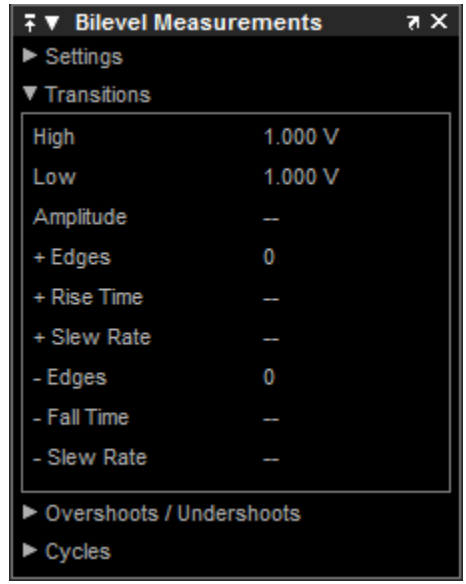
The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts. The SI prefixes are shown in the following table:

Abbreviation	Name	Multiplier
a	atto	10^-18
f	femto	10^-15
p	pico	10^–12
n	nano	10^-9
u	micro	10^-6
m	milli	10^-3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12

Abbreviation	Name	Multiplier
P	peta	10^15
E	exa	10^18

Bilevel Measurements Panel

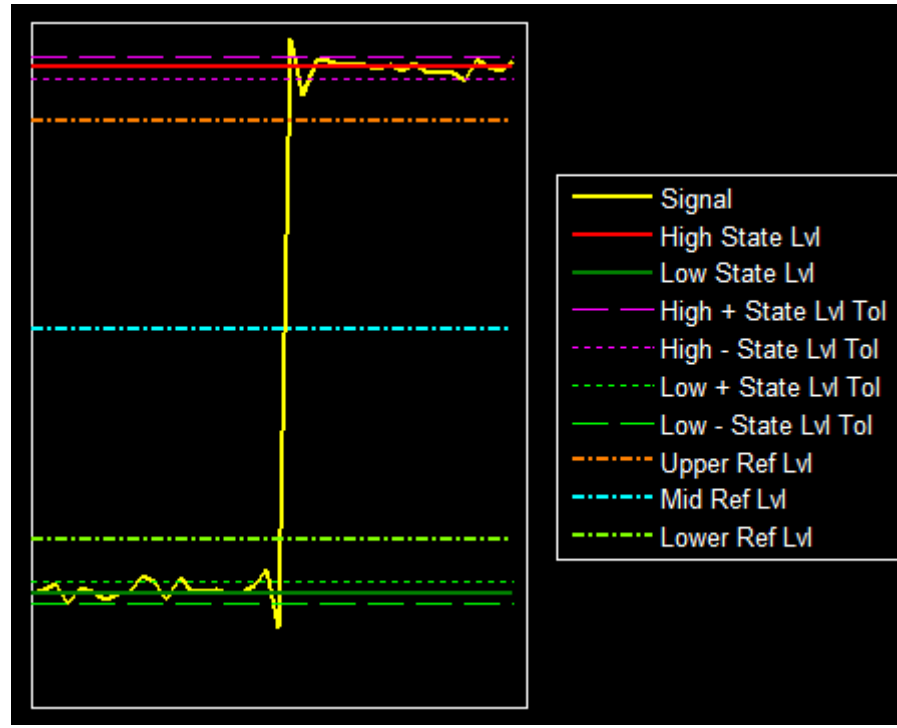
The **Bilevel Measurements** panel shows information about a selected signal's transitions, overshoots or undershoots, and cycles. You can choose to hide or display the **Bilevel Measurements** panel. In the Scope menu, select **Tools > Measurements > Bilevel Measurements**. Alternatively, in the Scope toolbar, you can select the Bilevel Measurements  button.



The **Bilevel Measurements** panel is separated into four panes, labeled **Settings**, **Transitions**, **Overshoots / Undershoots**, and **Cycles**. You can expand each pane to see the available options.

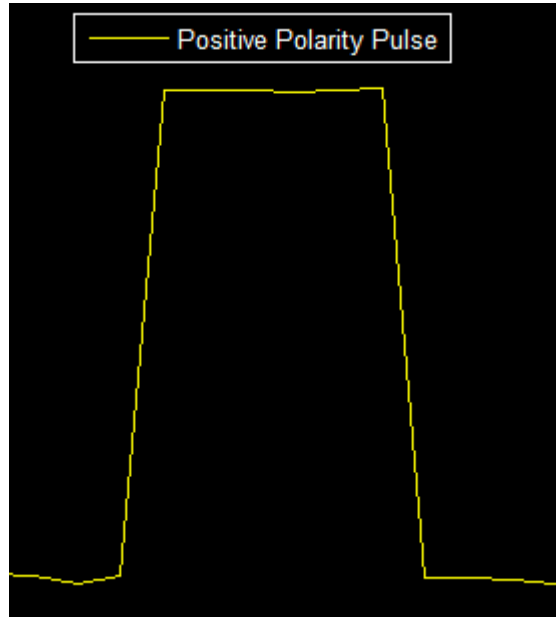
Settings Pane

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level, as shown in the following figure.

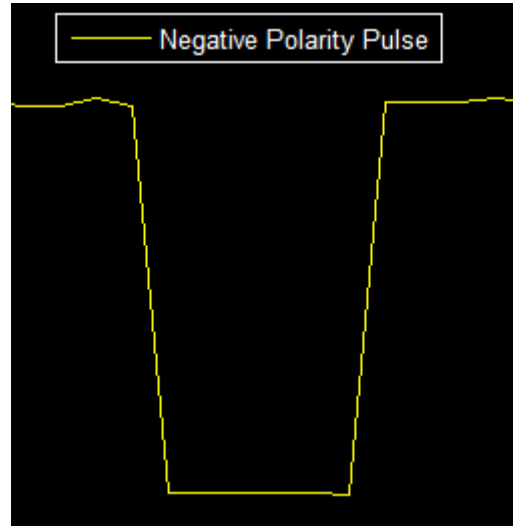


- **Auto State Level** — When this check box is selected, the Bilevel measurements panel autodetects the high- and low- state levels of a bilevel waveform. For more information on the algorithm this option uses, see the Signal Processing Toolbox `statelevels` function reference. When this check box is cleared, you may enter in values for the high- and low- state levels manually.

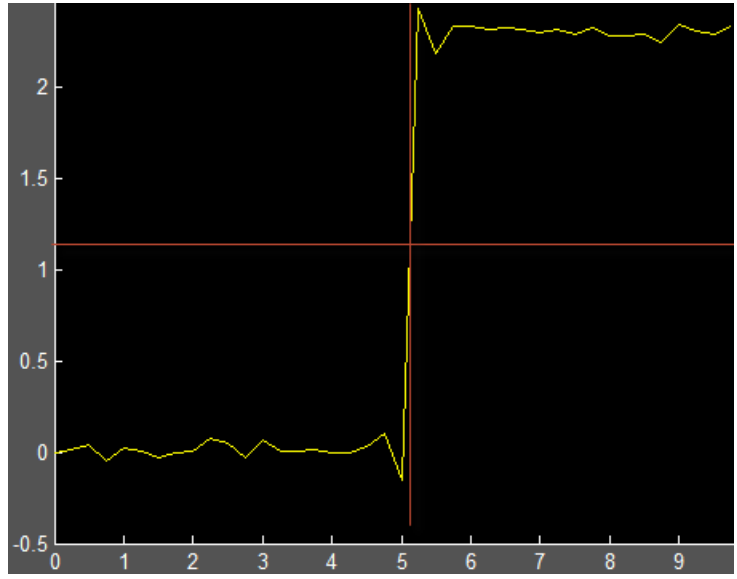
- **High** — Used to manually specify the value that denotes a positive polarity, or high-state level, as shown in the following figure.



- **Low** — Used to manually specify the value that denotes a negative polarity, or low-state level, as shown in the following figure.



- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.



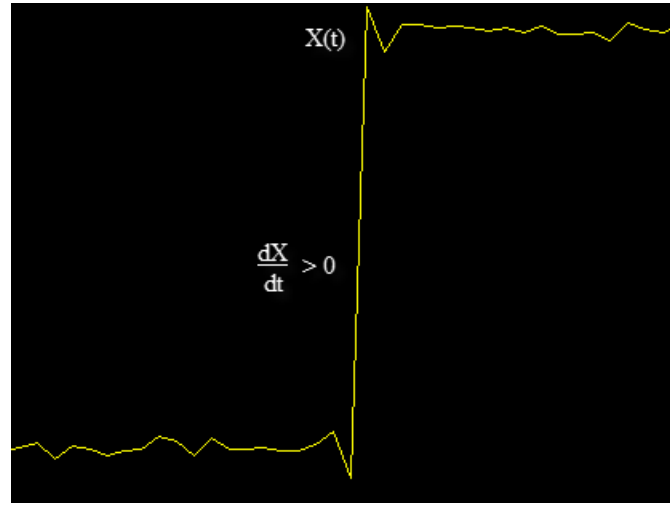
- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, `D`, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

Transitions Pane

The **Transitions** pane displays calculated measurements associated with the input signal changing between its two possible state level values, high and low.

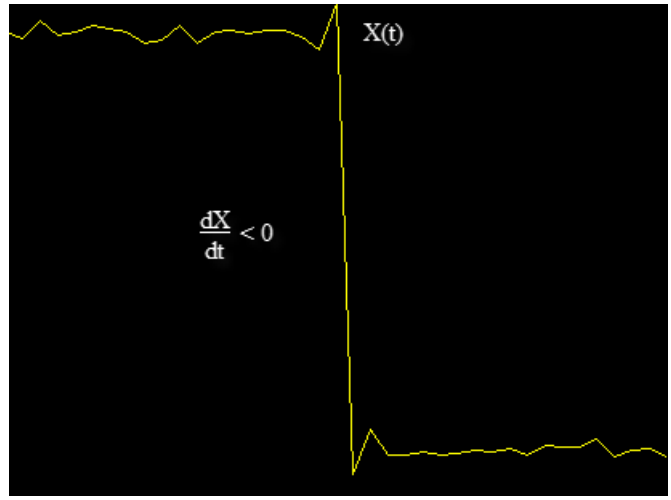
A positive-going transition, or *rising edge*, in a bilevel waveform is a transition from the low-state level to the high-state level. A

positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.



Whenever there is a plus sign (+) next to a text label, this symbol refers to measurement associated with a rising edge, a transition from a low-state level to a high-state level.

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.

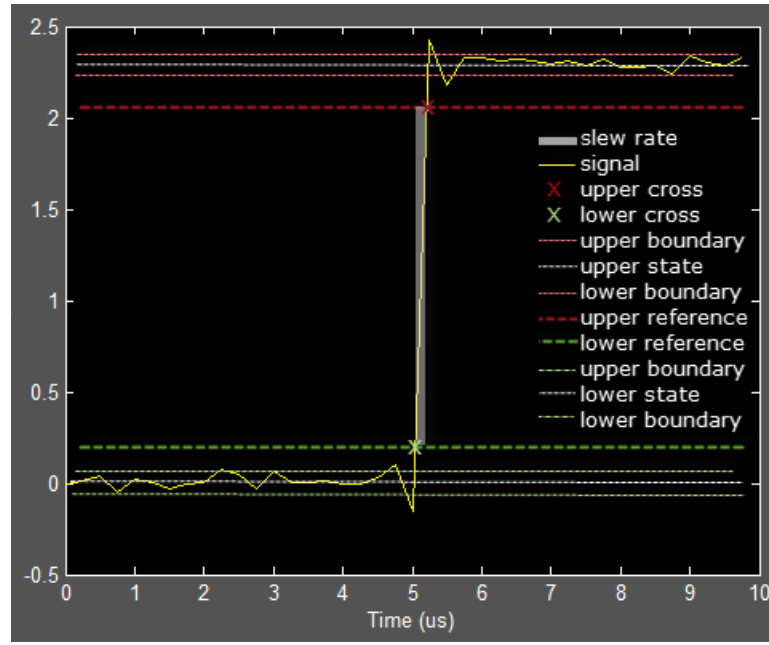


Whenever there is a minus sign (–) next to a text label, this symbol refers to measurement associated with a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. You must convert all input signals to volts for the Transition measurements to be valid.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.

- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `risetime` function reference.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.



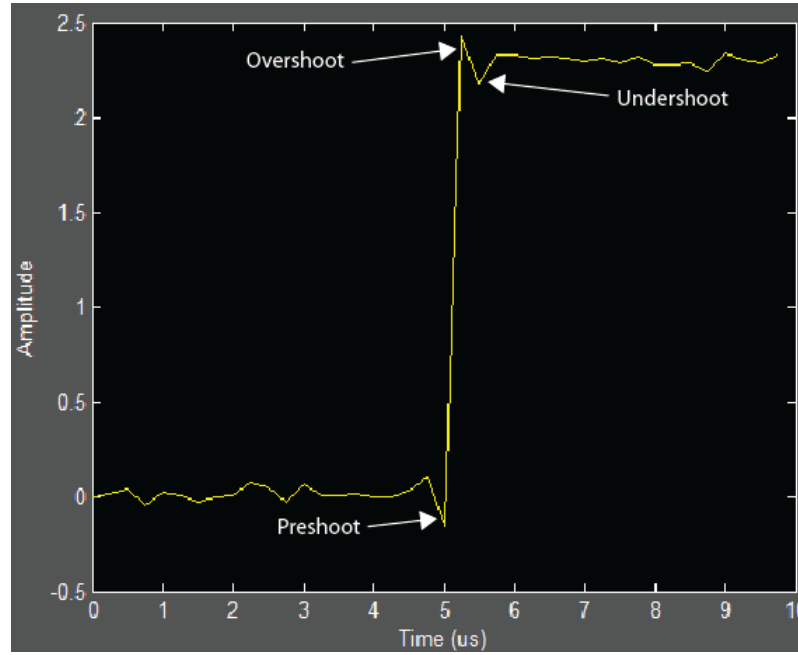
For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.

- **– Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.

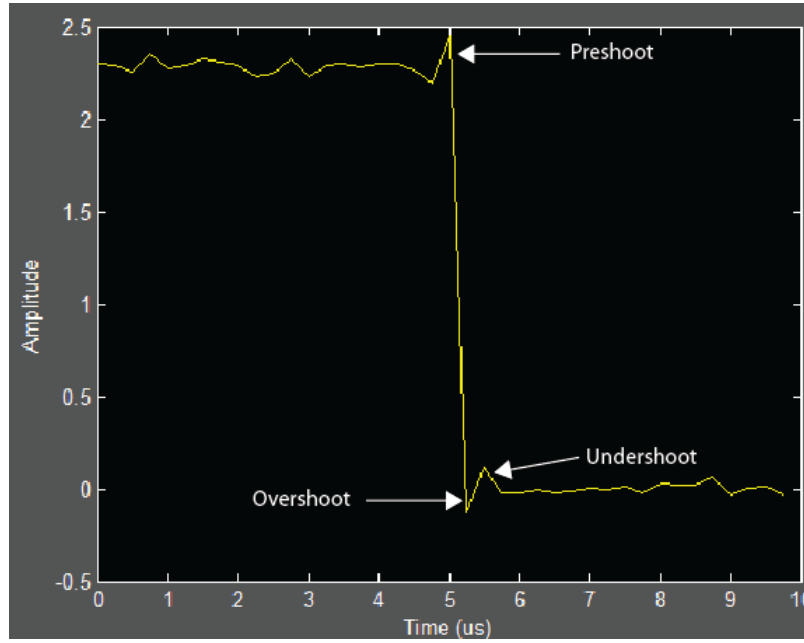
- **– Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `falltime` function reference.
- **– Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.

Overshoots/Undershoots

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. *Overshoot* and *undershoot* refer to the amount that a signal respectively exceeds and falls below its final steady-state value. *Preshoot* refers to the amount prior to a transition that a signal varies from its initial steady-state value. This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

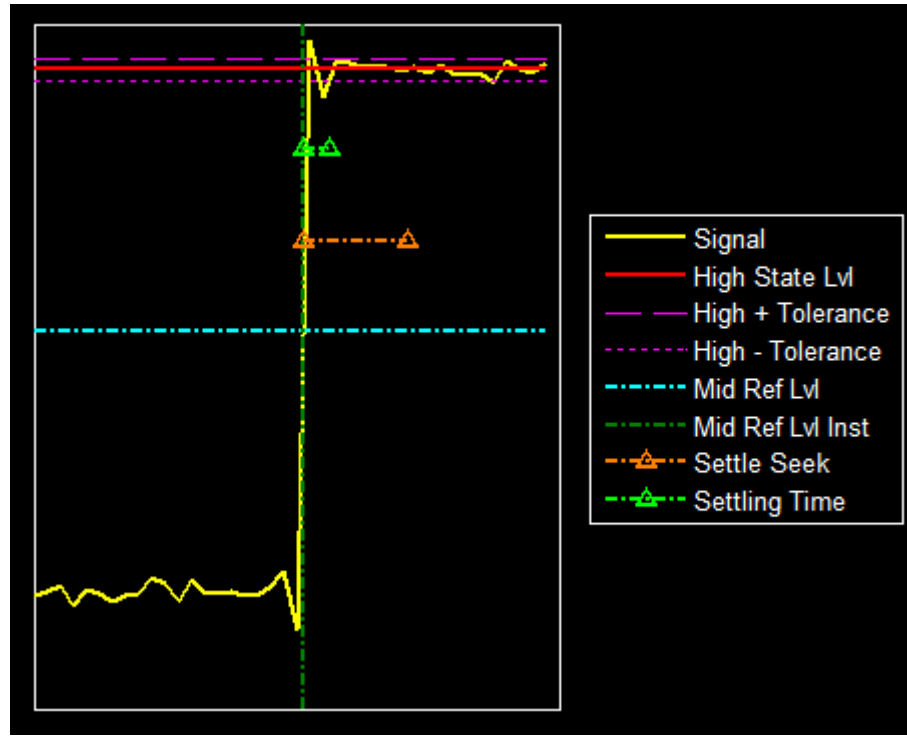


The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.



- **+ Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.
- **+ Overshoot** — Average highest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- **+ Undershoot** — Average lowest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.
- **+ Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and

remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.



You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

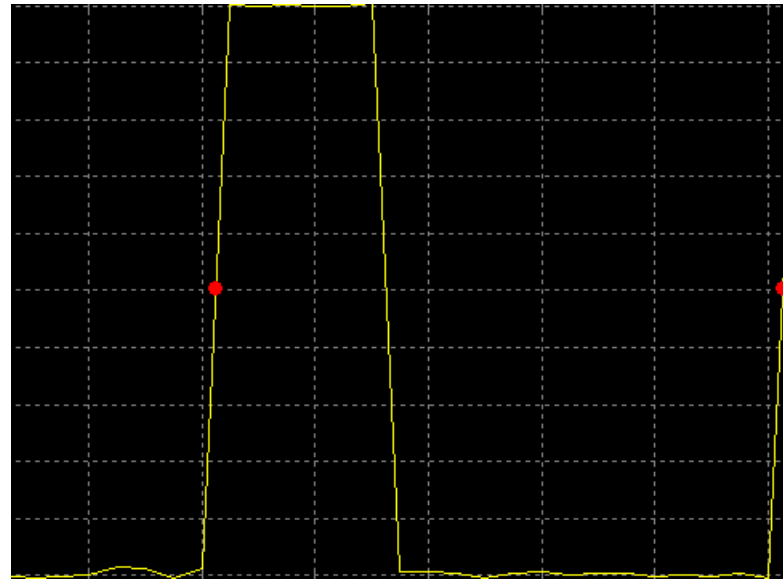
- – **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.
- – **Overshoot** — Average highest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.

- – **Undershoot** — Average lowest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.
- – **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

Cycles

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.



For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulseperiod` function reference.

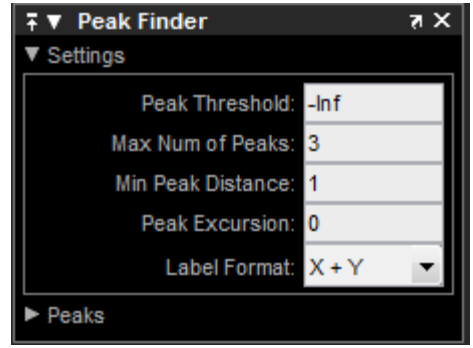
- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.
- **– Pulses** — Number of negative-polarity pulses counted.

- **– Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- **– Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools > Measurements > Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.

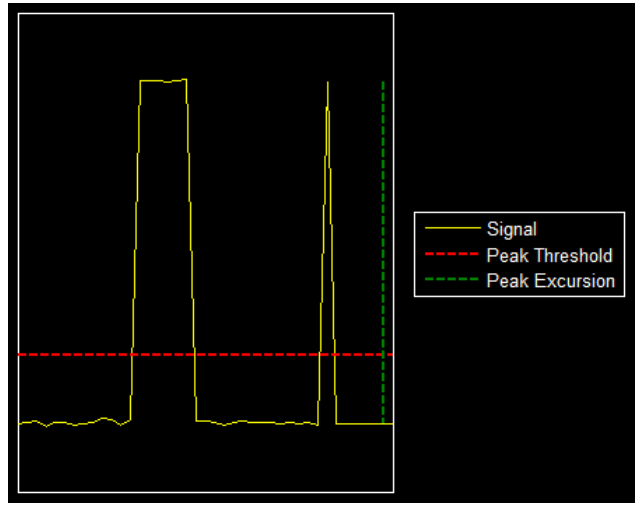


The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer between 1 and 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.



The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

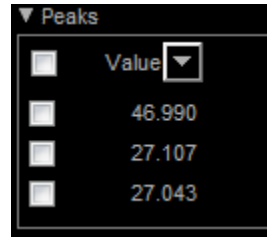
- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.

  - `X+Y` — Display both *x*-axis and *y*-axis values.

- `X` — Display only *x*-axis values.
- `Y` — Display only *y*-axis values.

Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button ( ) to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button ( ). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled ( ), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

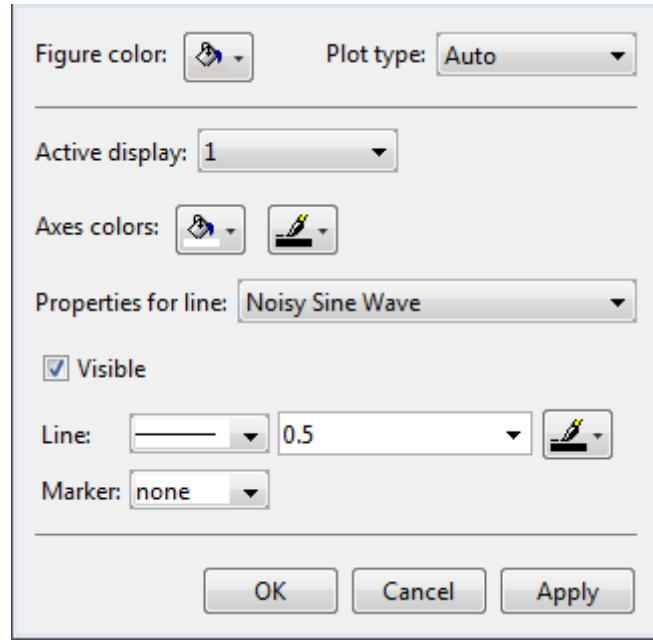
Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Abbreviation	Name	Multiplier
a	atto	10^–18
f	femto	10^–15
p	pico	10^–12
n	nano	10^–9
u	micro	10^–6
m	milli	10^–3
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^12
P	peta	10^15
E	exa	10^18

Style Dialog Box

In the **Style** dialog box, you can customize the style of displays. You can change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. From the scope menu, select **View > Style** or select the Style button ( ) in the dropdown below the Configuration Properties button to open this dialog box.



Properties

The **Style** dialog box allows you to modify the following properties of the scope figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Plot type

Specify the type of plot to use. The default setting is `Line`. Valid values for **Plot type** are:

- `Line` — Displays input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- `Stairs` — Displays input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.
- `Auto` — Displays input signal as a line graph if it is a continuous signal and displays input signal as a stairstep graph if it is a discrete signal.

This property is Tunable.

Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display should have its axes colors, line properties, marker properties, and visibility changed. Tunable

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is `1`.

Axes colors

Specify the color that you want to apply to the background of the axes for the active display.

Properties for line

Specify the signal for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected signal on the active display should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected signal on the active display.

Marker

Specify marks for the selected signal on the active display to show at data points. This property is similar to the `Marker` property for the MATLAB Handle Graphics plot objects. You can choose any of the marker symbols from the following table.

Specifier	Marker Type
none	No marker (default)
○	Circle
□	Square
×	Cross
•	Point
+	Plus sign
✳	Asterisk
◇	Diamond
▽	Downward-pointing triangle
△	Upward-pointing triangle
◁	Left-pointing triangle

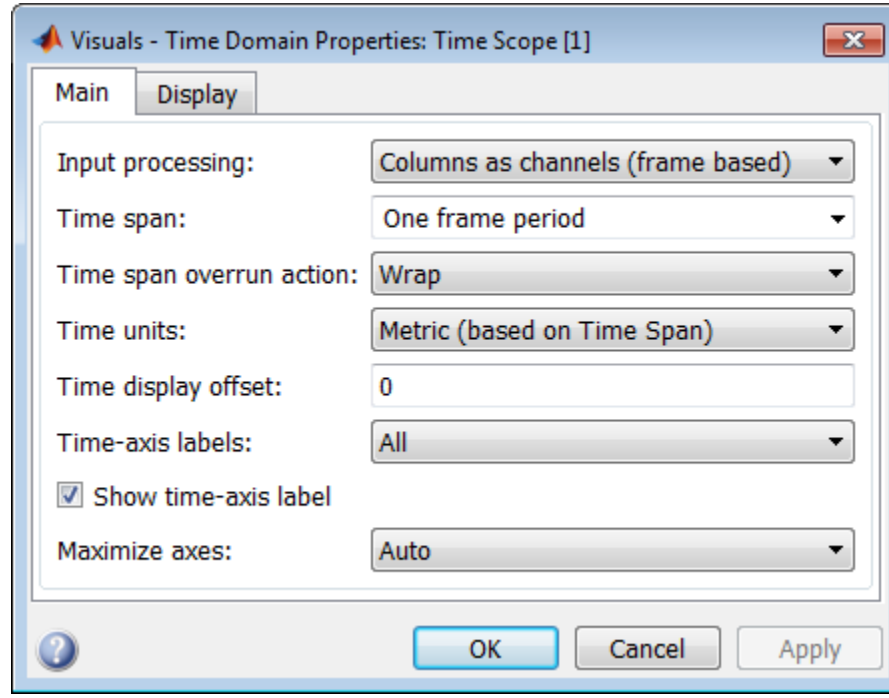
Specifier	Marker Type
▷	Right-pointing triangle
☆	Five-pointed star (pentagram)
✡	Six-pointed star (hexagram)

Visuals — Time Domain Properties

The Visuals — Time Domain Properties dialog box controls the visual configuration settings of the Time Scope displays. From the Time Scope menu, select **View > Configuration Properties** to open this dialog box.

Main Pane

The **Main** pane of the Time Scope Visuals—Time Domain Properties dialog box appears as follows.



Input processing

Specify whether the Time Scope should treat the input signal as `Columns as channels (frame based)` or `Elements as channels (sample based)`.

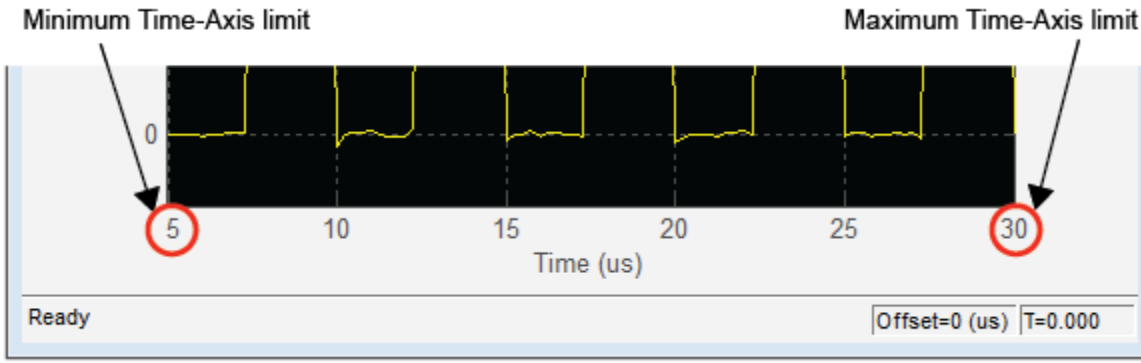
Frame-based processing is only available for discrete input signals. For more information about frame-based input channels, see the "What Is Frame-Based Processing?" section in the DSP System Toolbox documentation. For an example that uses the Time Scope block and frame-based input signals, see the "Display Time-Domain Data" section in the DSP System Toolbox documentation.

Time span

Specify the time span, either by selecting a predefined option or by entering a numeric value in seconds. You can select one of the following options:

- `Auto` — In this mode, the Time Scope automatically calculates the appropriate value for time span from the difference between the simulation "Start time" and "Stop time" properties. This option is available only for the Time Scope block but not for the `dsp.TimeScope` System object.
- `One frame period` — In this mode, the Time Scope uses the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to `Columns as channels (frame based)`. This option is not available when you set the **Input processing** parameter to `Elements as channels (sample based)`.
- `<user defined>` — In this mode, you specify the time span by replacing the text `<user defined>` with a numeric value in seconds.

The scope sets the *time*-axis limits using the value of this property and the value of the **Time display offset** property. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the *time*-axis limits as shown in the following figure.



This property is Tunable.

Time span overrun action

Specify how the scope displays new data beyond the visible time span. You can select one of the following options:

- `Wrap` — In this mode, the scope displays new data until the data reaches the maximum *time*-axis limit. When the data reaches the maximum *time*-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum *time*-axis limit.
- `Scroll` — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

This property is Tunable.

The default setting is `Wrap`.

Time units

Specify the units used to describe the *time*-axis. The default setting is `Metric`. You can select one of the following options:

- `Metric` — In this mode, Time Scope converts the times on the *time*-axis to some metric units such as milliseconds, microseconds, days, etc. Time Scope chooses the appropriate metric units, based on the minimum *time*-axis limit and the maximum *time*-axis limit of the scope window.
- `Seconds` — In this mode, Time Scope always displays the units on the *time*-axis as seconds.
- `None` — In this mode, Time Scope displays no units on the *time*-axis. Time Scope shows only the word `Time` on the *time*-axis.

This property is Tunable.

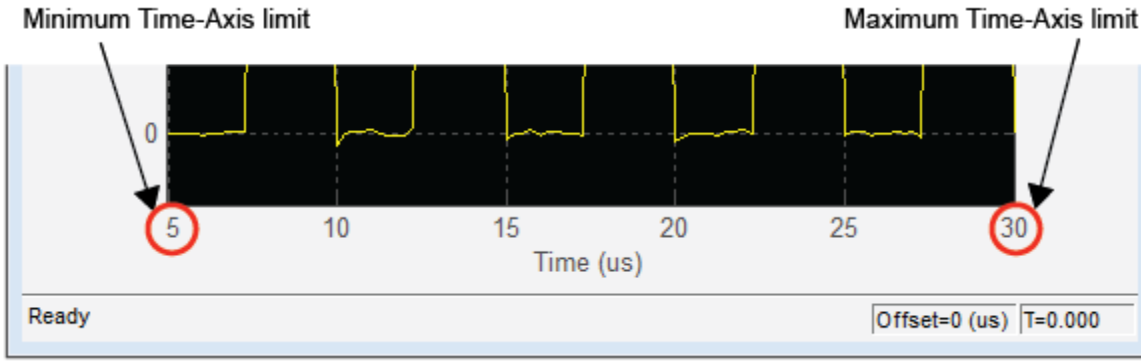
Time display offset

This property allows you to offset the values displayed on the *time*-axis by a specified number of seconds. When you specify a scalar value, the scope offsets all channels equally. When you specify a vector of offset values, the scope offsets each channel independently. Tunable.

When you specify a **Time display offset** vector of length *N*, the scope offsets the input channels as follows:

- When *N* is equal to the number of input channels, the scope offsets each channel according to its corresponding value in the offset vector.
- When *N* is less than the number of input channels, the scope applies the values you specify in the offset vector to the first *N* input channels. The scope does not offset the remaining channels.
- When *N* is greater than the number of input channels, the scope offsets each input channel according to the corresponding value in the offset vector. The scope ignores all values in the offset vector that do not correspond to a channel of the input.

The scope computes the *time*-axis range using the values of the **Time display offset** and **Time span** properties. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the *time*-axis limits as shown in the following figure.



Similarly, when you specify a vector of values, the scope sets the minimum *time*-axis limit using the smallest value in the vector. To set the maximum *time*-axis limit, the scope sums the largest value in the vector with the value of the **Time span** property. For more information, see “Signal Display” on page 3-1517.

Time-axis labels

Specify how to display the time units used to describe the *time*-axis. The default setting is `All`. You can select one of the following options:

- `All` — In this mode, the *time*-axis labels appear in all displays.
- `None` — In this mode, the *time*-axis labels do not appear in the displays.
- `Bottom Displays Only` — In this mode, the *time*-axis labels appear in only the bottom row of the displays.

Tunable.

Show time-axis label

Select to turn on time-axis label display.

Tunable.

Maximize axes

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

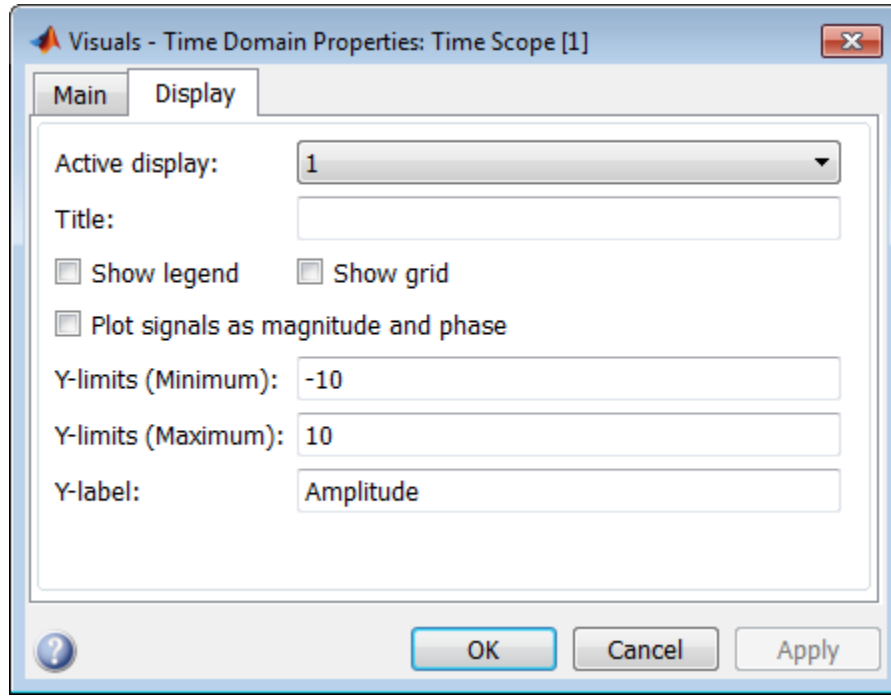
- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable.

The default setting is `Auto`.

Display Pane

The **Display** pane of the Visuals—Time Domain Properties dialog box appears as follows.



Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display should have its axes colors, line properties, marker properties, and visibility changed. Tunable

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is `1`.

Title

Specify the active display title as a string. By default, the active display has no title. Tunable.

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn the legend off, clear the **Show legend** check box. This parameter applies only when the Spectrum **Type** is `Power` or `Power density`. Tunable

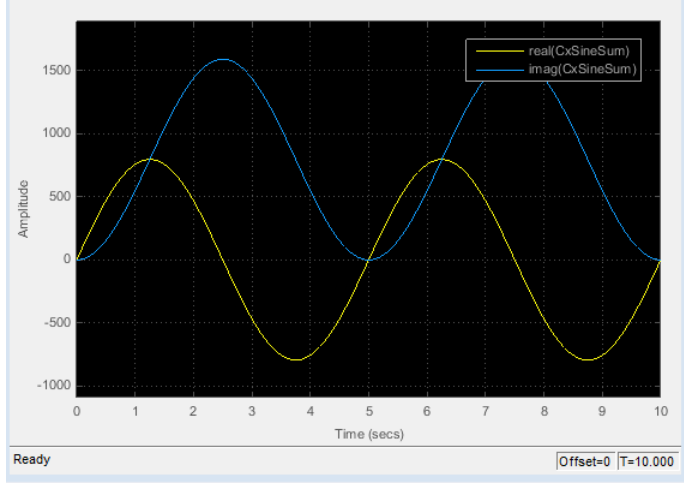
You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, if the signal has multiple channels, the scope uses an index number to identify each channel of that signal. To change the appearance of any channel of any input signal in the scope window, from the scope menu, select **View > Style**.

Show grid

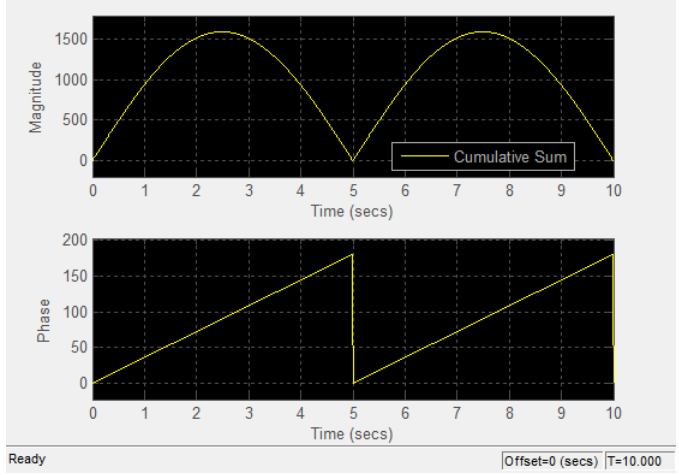
When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable

Plot signals as magnitude and phase

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal is complex valued, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.



Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.



This feature is particularly useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the

absolute value of the signal for the magnitude. The phase is 0 degrees for nonnegative input and 180 degrees for negative input. Tunable

Y-limits (Minimum)

Specify the minimum value of the *y*-axis. Tunable

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a minimum value of -180 degrees.

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. Tunable

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a maximum value of 180 degrees.

Y-label

Specify as a string the text for the scope to display to the left of the *y*-axis. Tunable

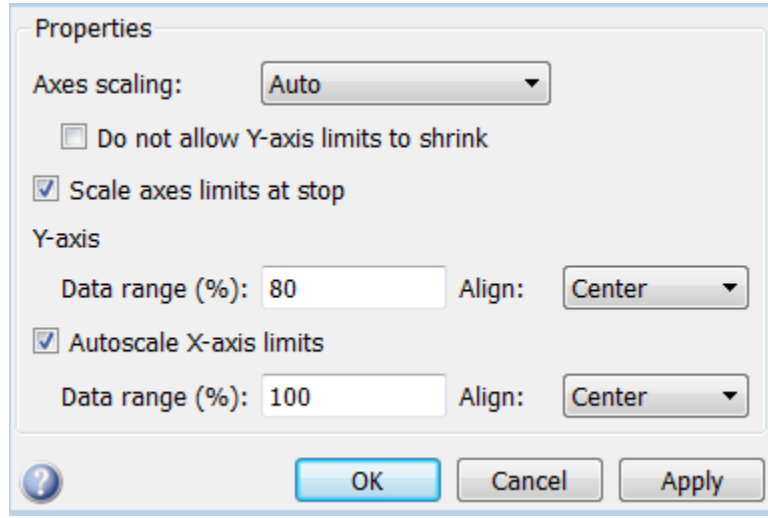
This property becomes invisible when you select the **Plot signal(s) as magnitude and phase** check box. When you enable that property, the *y*-axis label always appears as `Magnitude` on the top axes and `Phase` on the bottom axes.

Tools — Axes Scaling Properties

The Axes Scaling Properties: Time Scope dialog box provides you with the ability to automatically zoom in on and zoom out of your data, and to scale the axes of the Time Scope. In the Time Scope menu, select **Tools > Axes Scaling Options** to open this dialog box.

Properties

The Tools—Axes Scaling Properties dialog box appears as follows.



Axes scaling

Specify when the scope should automatically scale the axes. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools > Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Selecting this option causes the scope to scale the axes after a specified number of updates. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to `Auto`. This property is Tunable.

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. Tunable.

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. This property appears only when you select `After N Updates` for the **Axes scaling** property. Tunable.

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%)

Set the percentage of the *y*-axis that the scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable.

Y-axis Align

Specify where the scope should align your data with respect to the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. Tunable.

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Scale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. Tunable.

X-axis Data range (%)

Set the percentage of the *x*-axis that the Scope should use to display the data when scaling the axes. Valid values are between 1 and 100. For example, if you set this property to `100`, the Scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the Scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement with respect to the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. Tunable.

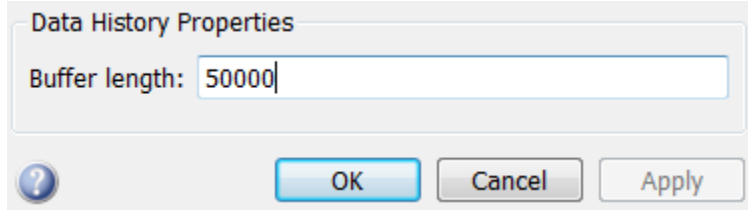
X-axis Align

Specify how the Scope should align your data with respect to the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable.

Sources — Streaming Properties

The Sources – Streaming Properties dialog box lets you control the number of input signal samples that Time Scope holds in memory. In the Time Scope menu, select **View > Data History Properties** to open this dialog box.

Data History Properties



Buffer length

Specify the size of the buffer that the scope holds in its memory cache. If your signal has *M* rows of data and *N* data points in each row, *M* x *N* is the number of data points per time step. Multiply this result by the number of time steps for your model to obtain the required buffer length. For example, if you have 10 rows of data with each row having

100 data points and your run will be 10 time steps, you should enter 10,000 (which is 10 x 100 x 10) as the buffer length.

The default setting is `50000`.

Examples

The first few examples illustrate how to use the Time Scope object to view a variety of input signals in the time domain.

The remaining examples demonstrate how to use the Measurements Panels in the Time Scope GUI to glean information about the input signals.

Example: Display Simple Sine Wave Input Signal

Construct `dsp.SineWave` and `dsp.TimeScope` objects. Run the `step` method to display the signal.

```
hsin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
hsin.SamplesPerFrame = 10;
hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate,'TimeSpan', 0.1);
for ii = 1:10
     x = step(hsin);
     step(hts1, x);
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(hts1)
```

Run the MATLAB `clear` function to close the Time Scope window.

```
clear hts1 hsin x;
```

Example: View Sine Wave Input Signals at Different Sample Rates and Offsets

Construct `dsp.SineWave` and `dsp.FirDecimator` objects. Use the `dsp.FirDecimator` object to create a new signal that equals the original signal, but decimated by a factor of 2. Construct a `dsp.TimeScope` object with 2 input ports. Run the `step` method to display the signal.

```
Fs = 1000;  % Sampling frequency
hsin1 = dsp.SineWave('Frequency',50,...
   'SampleRate',Fs, ...
   'SamplesPerFrame', 100);
% Create FIRDecimator System object to decimate by 2
hfilt = dsp.FIRDecimator;
% Create TimeScope System object with 2 input ports (channels)
hts2 = dsp.TimeScope(2, [Fs Fs/2], ...
   'TimeDisplayOffset', [0 38/Fs], ...
   'TimeSpan', 0.25, ...
   'YLimits',[-1 1], ...
   'ShowLegend', true);
for ii = 1:2
     xsine = step(hsin1);
     xdec = step(hfilt,xsine);
     step(hts2, xsine, xdec);
end
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(hts2)
```

Run the MATLAB `clear` function to close the Time Scope window.

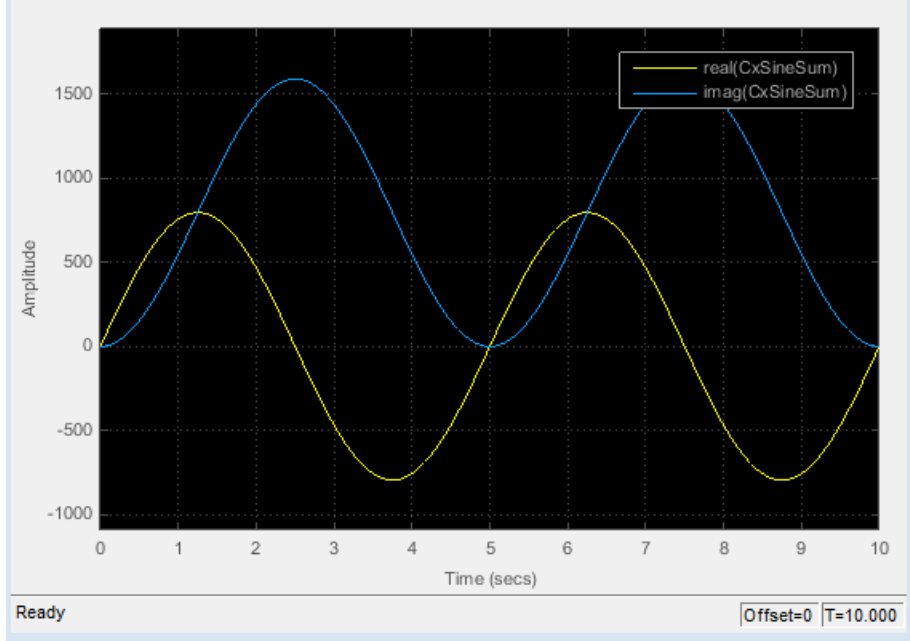
```
clear hts2 Fs hsin1 hfilt ii xsine xdec;
```

Example: Display Complex-valued Input Signal

Create a vector representing a complex-valued sinusoidal signal and construct a `dsp.TimeScope` object. Run the `step` method to display the signal.

```
fs = 1000; t = (0:1/fs:10)';
CxSine = cos(2*pi*0.2*t) + 1i*sin(2*pi*0.2*t);
CxSineSum = cumsum(CxSine);
figure(101); subplot(2,1,1); stairs(t,abs(CxSineSum));  % Plot magnitu
subplot(2,1,2); stairs(t,(180/pi)*angle(CxSineSum));    % Plot phase i
h1 = dsp.TimeScope(1, fs, 'TimeSpanSource', 'Auto');
step(h1,CxSineSum);
```

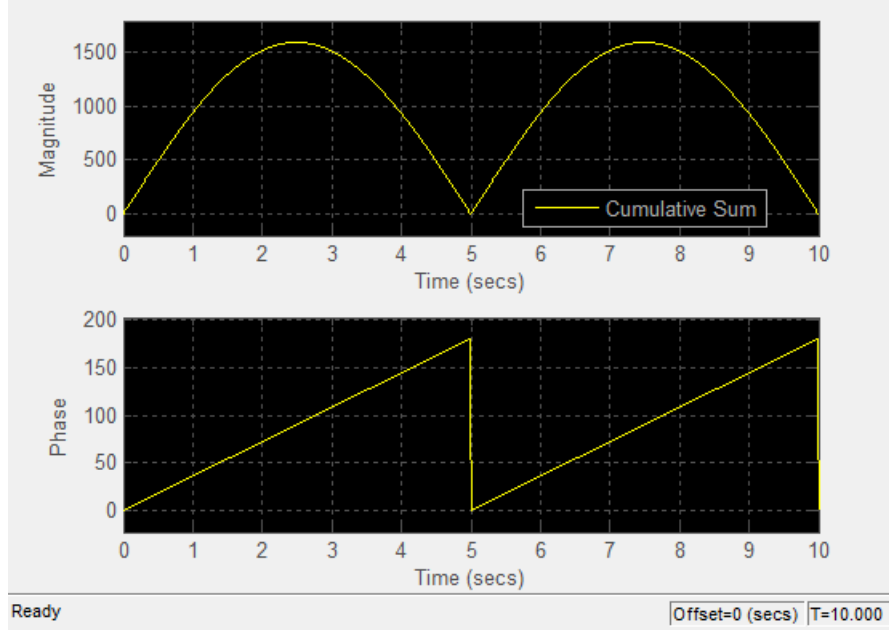
By default, when the input is a complex-valued signal, Time Scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes within the same active display, as shown in the following figure.



Change the `PlotAsMagnitudePhase` property to true.

```
set(h1,'PlotAsMagnitudePhase',true);
```

Time Scope now plots the magnitude and phase of the input signal on two separate axes within the same active display. The active display changes to show the magnitude of the input signal on the top axes and its phase, in degrees, on the bottom axes, as shown in the following figure.



Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h1);
```

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
close(101);
clear h1 fs t CxSine CxSineSum
```

Example: Display Input Signal of Changing Size

Create a vector that represents a two-channel constant signal. Create another vector that represents a three-channel constant signal. Construct a `dsp.TimeScope` object with 2 input ports. Run the `step` method to display the signal.

```
fs = 10;
sigdim2 = [ones(5*fs,1), 1+ones(5*fs,1)];                    % 2-dim 0-5s
sigdim3 = [2+ones(5*fs,1), 3+ones(5*fs,1), 4+ones(5*fs,1)]; % 3-dim 5-10s
h2 = dsp.TimeScope(2, fs, 'TimeSpanSource', 'Property');
set(h2,'PlotType','Stairs');
set(h2,'TimeSpanOverrunAction','Scroll');
set(h2,'TimeDisplayOffset',[0,0,5]);
step(h2,[sigdim2; sigdim3(:,1:2)], sigdim3(:,3));
```

In this example, the size of the input signal to the Time Scope block changes as the simulation progresses. When the simulation time is less than 5 seconds, Time Scope plots only the signal *sigdim2*, which has two channels. After 5 seconds, Time Scope also plots the signal *sigdim3*, which has three channels.

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h2);
```

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h2 fs sigdim2 sigdim3
```

Example: Use Bilevel Measurements Panel with Clock Input Signal

Load the clock data into the variable, *x*. Find the sample time, *ts*.

```
load clockex;
ts = t(2)-t(1);
```

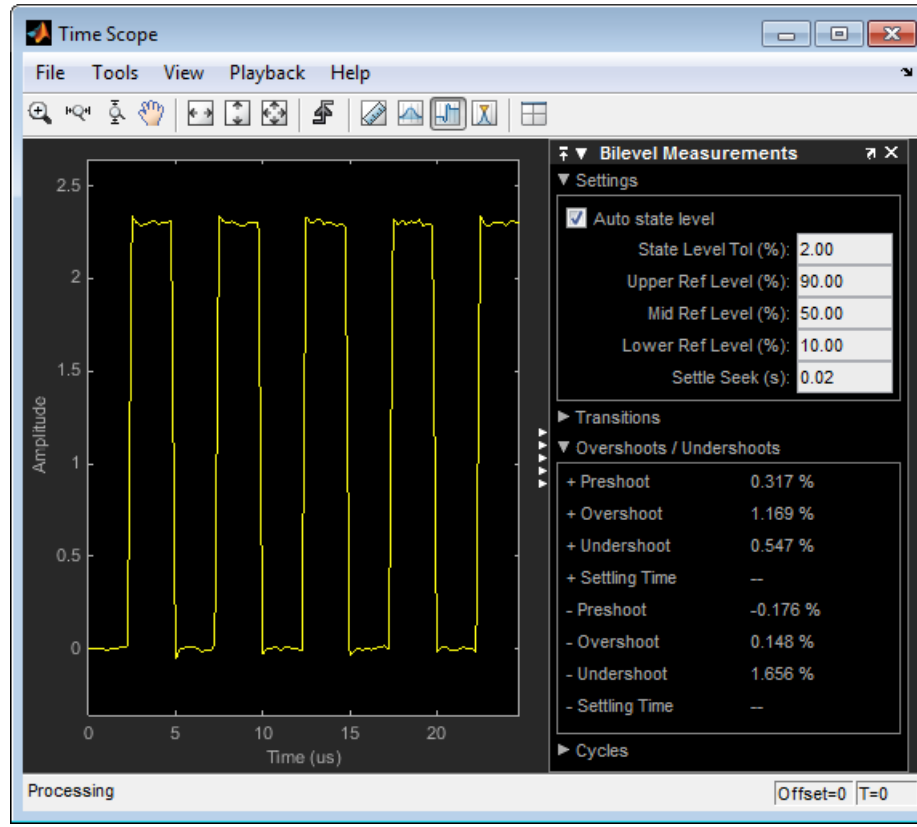
Construct a `dsp.TimeScope` object. Run the `step` method to display the signal.

```
h4 = dsp.TimeScope(1, 1/ts, 'TimeSpanSource','Auto');
step(h4,x);
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h4);
```

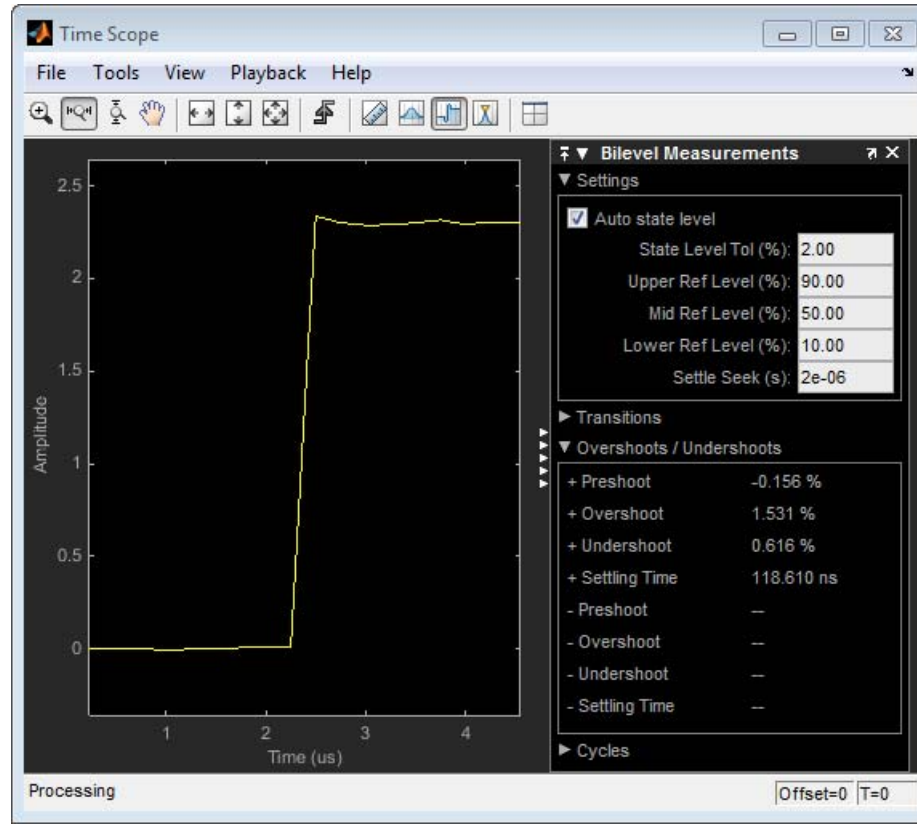
To show the **Bilevel Measurements** panel, in the Time Scope menu, select **Tools > Measurements > Bilevel Measurements**. To collapse the **Transitions** pane, click the pane collapse button (▼) next to that label. To expand the **Settings** pane and the **Overshoots / Undershoots** pane, click the pane expand button (▶) next to each label. The Time Scope figure appears as shown in the following figure.



As you can see in the figure, the value for the rising edge **Settling Time** parameter is initially not displayed. The reason for this is that the default value for the **Settle Seek** parameter is too large for this example. In this case, the settle seek time is longer than the entire simulation duration. Enter a value for settle seek of `2e-6`, and press the **Enter** key. Time Scope now displays a rising edge settling time value of `118.392 ns`.

This settling time value displayed is actually the statistical average of the settling times for all five rising edges. To show the settling time for only one rising edge, you can zoom in on that transition. In the Time

Scope toolbar, click the Zoom X button ( ). Then, click the display near a value of 2 microseconds on the *time*-axis. Drag to the right and release near a value of 4 microseconds on the *time*-axis. Time Scope updates the rising edge **Settling Time** value to reflect the new time window, as shown in the following figure.



Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h4 x t ts
```

Example: Find Heart Rate Using Peak Finder Panel with ECG Input Signal

First, create the electrocardiogram (ECG) signal.

```
x1 = 3.5*ecg(2700).';
y1 = sgolayfilt(kron(ones(1,13),x1),0,21);
n = (1:30000)';
del = round(2700*rand(1));
mhb = y1(n + del);
ts = 0.00025;
```

This example uses the Savitzky-Golay filter in Signal Processing Toolbox. For more information, see the sgolayfilt function reference page or run the `sgolaydemo` example.

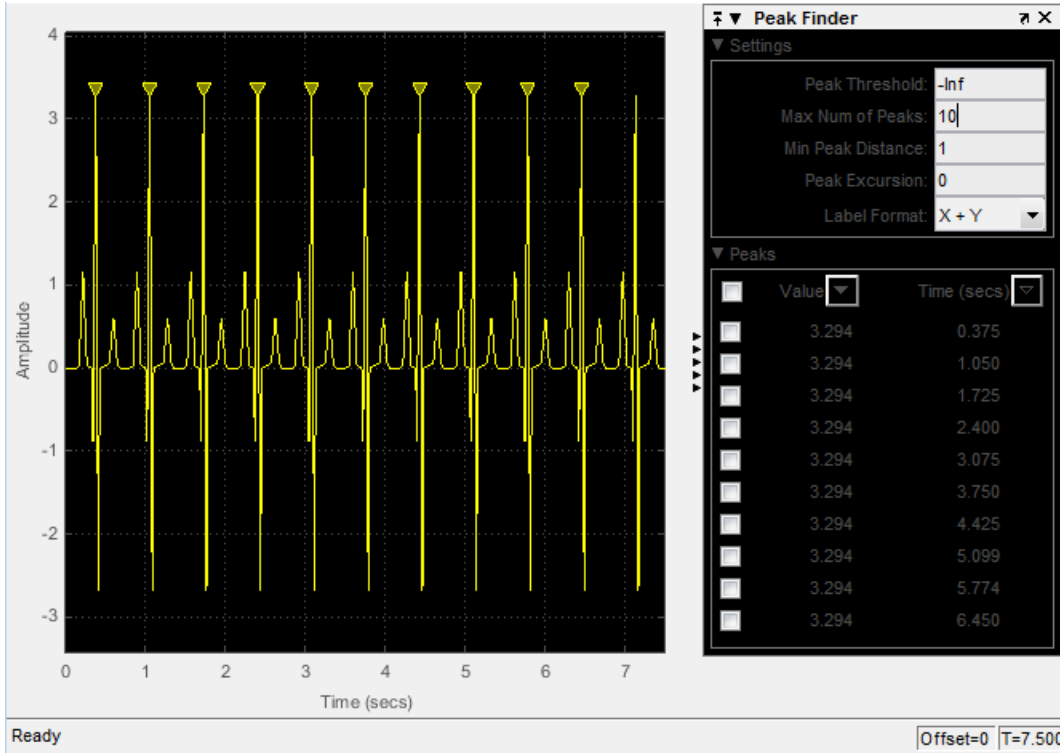
Construct a `dsp.TimeScope` object. Run the `step` method to display the signal.

```
h5 = dsp.TimeScope(1, 1/ts, 'TimeSpanSource','Auto');
step(h5,mhb);
```

Run the `release` method to let property values and input characteristics change. The scope automatically scales the axes.

```
release(h5);
```

To show the **Peak Finder** panel, in the Time Scope menu, select **Tools > Measurements > Peak Finder**. To expand the **Settings** pane, click the pane expand button (▶) next to that label. Enter a value for **Max Num of Peaks** of `10`, and press the **Enter** key. Time Scope now displays in the **Peaks** pane a list of 10 peak amplitude values, and the times at which they occur, as shown in the following figure.



As you can see from the list of peak values, there is a constant time difference of 0.675 seconds between each heartbeat. Therefore, the heart rate of the ECG signal is given by the following equation.

$$\frac{60\,\frac{\text{sec}}{\text{min}}}{0.675\,\frac{\text{sec}}{\text{beat}}} = 88.89\,\frac{\text{beats}}{\text{min}}\,(\text{bpm})$$

Run the MATLAB `clear` function to close the Time Scope window, and remove the variables you created from the workspace.

```
clear h5 x1 y1 n del mhb ts
```

See Also

Time Scope | `dsp.SpectrumAnalyzer` | `sptool`

Purpose

Create time scope object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `TimeScope` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.TimeScope.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method. `N` equals the value of the `NumInputPorts` property.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method. The time scope is a sink object, so `N` equals 0.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.TimeScope.hide

Purpose Hide time scope window

Syntax `hide(H)`

Description `hide(H)` hides the time scope window, associated with System object, `H`.

See Also `dsp.TimeScope.show`

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `TimeScope` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.TimeScope.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

You should call the `release` method after calling the `step` method when there is no new data for the simulation. When you call the `release` method, the axes will automatically scale in the Time Scope figure window. After calling the `release` method, any non-tunable properties can be set once again.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Examples

View a sine wave on the time scope. When you finish the simulation, release system resources. Note that when you run the release method, the axes automatically scale.

```
hsin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
hsin.SamplesPerFrame = 10;

hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate,'TimeSpan', 0.1);
for ii = 1:10
     x = step(hsin);
     step(hts1, x);
end

release(hts1);
```

View two sine waves with different sample rates and time offsets. When you finish the simulation, release system resources. Note that when you run the release method, the axes automatically scale.

```
Fs = 1000;  % Sampling frequency

hsin1 = dsp.SineWave('Frequency',50,...
   'SampleRate',Fs, ...
   'SamplesPerFrame', 100);

% Create FIRDecimator System object to decimate by 2
hfilt = dsp.FIRDecimator;

% Create TimeScope System object with 2 input
% ports (channels)
hts2 = dsp.TimeScope(2, [Fs Fs/2], ...
   'TimeDisplayOffset', [0 38/Fs], ...
   'TimeSpan', 0.25, ...
   'YLimits',[-1 1], ...
   'LegendSource', 'Auto');

for ii = 1:2
     xsine = step(hsin1);
     xdec = step(hfilt,xsine);
     step(hts2, xsine, xdec);
end

release(hts2);
```

Algorithms

In operation, the `release` method is similar to the `mdlTerminate` function.

See Also

`dsp.TimeScope.reset`

dsp.TimeScope.reset

Purpose

Reset internal states of time scope object

Syntax

```
reset(H)
```

Description

`reset(H)` sets the internal states of the `TimeScope` object `H` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the Time Scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

Examples

View a sine wave on the time scope. When you finish the simulation, pause for 5 seconds and then reset the screen. Then, view a different sine wave on the same time scope.

```
hsin = dsp.SineWave('Frequency', 100, 'SampleRate', 1000, 'SamplesPerFram
hsin1 = dsp.SineWave('Frequency', 50, 'SampleRate', 1000, 'SamplesPerFram

hts1 = dsp.TimeScope('SampleRate', hsin.SampleRate,'TimeSpan', 0.1);
for ii = 1:10
     x = step(hsin);
     step(hts1, x);
end

% Pause and then reset internal states
pause(5);
reset(hts1);

for ii = 1:10
     x = step(hsin1);
     step(hts1, x);
end
```

```
release(hts1);
```

Algorithms

In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

See Also

`dsp.TimeScope` | `dsp.TimeScope.release`

dsp.TimeScope.show

Purpose

Make time scope window visible

Syntax

```
show(H)
```

Description

`show(H)` makes the time scope window, associated with System object, `H`, visible.

See Also

`dsp.TimeScope.hide`

Purpose

Display signal in time scope figure

Syntax

```
step(H,X)
step(H,X1,X2,...,XN)
```

Description

`step(H,X)` displays the signal, `X`, in the time scope figure.

`step(H,X1,X2,...,XN)` displays the signals `X1`, `X2`,...,`XN` in the time scope figure when you set the `NumInputPorts` property to `N`. In this case, `X1`, `X2`,...,`XN` can have different data types and dimensions.

dsp.TransferFunctionEstimator

Purpose

Estimate transfer function

Description

The `dsp.TransferFunctionEstimator` computes the transfer function of a system, using the Welch algorithm and the Periodogram method.

To implement the transfer function estimation object:

1. Define and set up your transfer function estimator object. See "Construction" on page 3-1610.
2. Call `step` to implement the estimator according to the properties of `dsp.TransferFunctionEstimator`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.TransferFunctionEstimator` returns a System object, H, that computes the transfer function of real or complex signals. This System object uses the periodogram method and Welch's averaged, modified periodogram method.

`H = dsp.TransferFunctionEstimator('PropertyName', PropertyValue,...)` returns a `Transfer Function Estimator` System object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Transfer Function Estimator computes the current estimate by averaging the last `N` estimates. `N` is the number of spectral averages defined in the `SpectralAverages` property. The default value is `8`.

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto' | 'Property'`. The default value is `'Auto'`. If you set this property to `'Auto'`, the Transfer function Estimator sets the FFT length to the input frame size. If you set this property to `'Property'`, then you specify the number of FFT points using the `FFTLength` property.

FFTLength

FFT Length

Specify the length of the FFT that the Transfer Function Estimator uses to compute spectral estimates as a positive, integer scalar. This property applies when you set the `FFTLengthSource` property to `'Property'`. The default value is `128`.

Window

Window function

Specify a window function for the Transfer Function estimator as one of `'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'`. The default value is `'Hann'`.

SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The default value is `60 dB`.

FrequencyRange

Frequency range of the transfer function estimate

Specify the frequency range of the transfer function estimator as one of `'twosided' | 'onesided' | 'centered'`.

If you set the `FrequencyRange` to `'onesided'`, the transfer function estimator computes the onesided transfer function of real input signals, `x` and `y`. If the FFT length, NFFT, is even,

the length of the transfer function estimate is `NFFT/2+1` and is computed over the interval `[0,SampleRate/2]`. If NFFT is odd, the length of the transfer function estimate is equal to `(NFFT+1)/2` and the interval is `[0,SampleRate/2)`.

If `FrequencyRange` is set to `'twosided'`, the transfer function estimator computes the twosided transfer function of complex or real input signals, `x` and `y`. The length of the transfer function estimate is equal to NFFT and is computed over `[0, SampleRate)`.

If you set the `FrequencyRange` to `'centered'`, the transfer function estimator computes the centered twosided transfer function of complex or real input signals, `x` and `y`. The length of the transfer function estimate is equal to NFFT and it is computed over `(-SampleRate/2, SampleRate/2]` for even lengths, and `(-SampleRate/2, SampleRate/2)` for odd lengths. The default value is `'Twosided'`.

Methods

clone	Create Transfer Function estimator object with same property values
getFrequencyVector	Get vector of frequencies at which transfer function is estimated
getRBW	Get resolution bandwidth of transfer function
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics to change
reset	Reset internal states of transfer function estimator
step	Estimate transfer function of system

Examples

Estimate transfer function of a system represented by an order-64 FIR filter

Generate a sine wave. Use the Transfer Function Estimator to estimate the system transfer function, and use Array Plot to display it.

```
hsin = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
hsin.SamplesPerFrame = 1000;
hs = dsp.TransferFunctionEstimator('SampleRate', hsin.SampleRate,...
     'FrequencyRange','centered');
hplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
        [-120 5],'YLabel','Frequency Response (dB)',...
        'XLabel','Frequency (Hz)',...
        'Title','System Transfer Function');
```

Create an FIR Filter System object of order 64 and (normalized) cutoff frequency of 1/4. Add random noise to the sine wave. Step through the System objects to obtain the data streams, and plot the log of the magnitude of the transfer function.

```
hfilt = dsp.FIRFilter('Numerator',fir1(64,1/4));
for ii = 1:100
x = step(hsin) + 0.05*randn(1000,1);
y = step(hfilt,x);
Txy = step(hs,x,y);
step(hplot,20*log10(abs(Txy)))
end
```

Algorithms

Given two signals `x` and `y` as inputs. We first window the two inputs, and scale them by the window power. We then take FFT of the signals, calling them `X` and `Y`. This is followed by calculating P_{xx} which is the square magnitude of the FFT, `X`, and P_{yx} which is `X` multiplied by the conjugate of `Y`. The transfer function estimate is calculated by dividing P_{yx} by P_{xx}.

For further information refer to the “Algorithms” on page 3-1416 section in Spectrum Analyzer, which uses the same algorithm.

`dsp.SpectrumAnalyzer | dsp.SpectrumEstimator | dsp.CrossSpectrumEstimator`

Purpose

Create Transfer Function estimator object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates another instance of the System object, `H`, with the same property values. The clone method creates a new unlocked object with uninitialized states.

dsp.TransferFunctionEstimator.getFrequencyVector

Purpose

Get vector of frequencies at which transfer function is estimated

Syntax

```
getFrequencyVector(H)
```

Description

`getFrequencyVector(H)` returns the vector of frequencies at which the transfer function is estimated.

If you set the `FrequencyRange` to `'onesided'` and the FFT length, `NFFT`, is even, the frequency vector is of length `NFFT/2+1`, and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'onesided'` and `NFFT` is odd, the frequency vector is of length `(NFFT+1)/2` and covers the interval `[0,SampleRate/2)`. If you set the `FrequencyRange` to `'twosided'`, the frequency vector is of length `NFFT` and covers the interval `[0, SampleRate)`. If you set the `FrequencyRange` to `'centered'`, the frequency vector is of length `NFFT` and covers the range `(-SampleRate/2, SampleRate/2]` and `(-SampleRate/2, SampleRate/2)` for even and odd length `NFFT`, respectively.

Purpose

Get resolution bandwidth of transfer function

Syntax

```
getRBW(H)
```

Description

`getRBW(H)` returns the resolution bandwidth of the transfer function.

The resolution bandwidth, `RBW`, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to `ENBW*SampleRate/ L`, where `L` is the input length, and `ENBW` is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`, `RBW=enbw(hann(1024))*100/1024`.

dsp.TransferFunctionEstimator.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the Transfer Function estimator.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics to change

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.TransferFunctionEstimator.reset

Purpose

Reset internal states of transfer function estimator

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the System object,`H`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

Purpose

Estimate transfer function of system

Syntax

```
Txy = step(H,x,y)
Y = step(H,x)
[Y1,...,YN] = step(H,x)
```

Description

`Txy = step(H,x,y)` computes the transfer function, `Txy`, of the system with input x and output y. This computation uses the Welch's averaged periodogram method. `Txy` is the ratio of the Cross Power Spectral Density of `x` and `y`, and the Power Spectral Density of `x`. The columns of `x` and `y` are treated as independent channels.

`Y = step(H,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, H. `[Y1,...,YN] = step(H,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.TransitionMetrics

Purpose

Transition metrics of bilevel waveforms

Description

The `TransitionMetrics` object extracts information such as duration, slew rate, and reference-level crossings for each transition found in the bilevel waveform. The `TransitionMetrics` object can additionally return preshoot, postshoot and settling metrics for the regions immediately before and after each transition.

To obtain transition metrics for a bilevel waveform:

1. Define and set up your transition metrics. See "Construction" on page 3-1622.
2. Call `step` to calculate the transition metrics according to the properties of `dsp.TransitionMetrics`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.TransitionMetrics` creates a transition metrics System object, `H`. The object computes the rise time, fall time and width of a pulse. `TransitionMetrics` additionally computes cycle metrics such as pulse separations, periods, and duty cycles.

`H = dsp.TransitionMetrics('PropertyName',PropertyValue,...)` returns a `TransitionMetrics` System object, `H`, with each specified property set to the specified value.

Properties

MaximumRecordLength

Maximum samples to preserve between calls to `step`. This property requires a positive integer that specifies the maximum number of samples to save between calls to the `step` method. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded. This property applies when `RunningMetrics` is `true` and is tunable.

Default: `1000`

PercentReferenceLevels

Lower-, middle-, and upper-percent reference levels. This property contains a 3-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the low and high states of the waveform when computing the duration of each transition.

Default: `[10 50 90]`

PercentStateLevelTolerance

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Default: `2`

PostshootOutputPort

Enable posttransition aberration metrics. If this property is set to`true`, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of `PostshootSeekFactor` times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

Default: `false`

PostshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition.

This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

Default: `3`

PreshootOutputPort

Enable pretransition aberration metrics. If the `PreshootOutputPort` property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

Default: `false`

PreshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

Default: `3`

RunningMetrics

Enable metrics over all calls to `step`. If `RunningMetrics` is set to `false`, metrics are computed for each call to `step` independently. If `RunningMetrics` is set to `true`, metrics are computed across subsequent calls to `step`. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object defers reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call

to `step` is made with enough data to compute all enabled metrics for that transition.

Default: `false`

SampleRate

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the `TimeInputPort` property is set to `false`.

Default: `1`

SettlingOutputPort

Enable settling metrics. If `SettlingOutputPort` is set to true, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the `SettlingSeekDuration` has elapsed. If an intervening transition occurs, or the signal has not settled within the `PercentStateLevelTolerance` of the final level, `NaN` is returned for each metric. If there are not enough samples after the last transition to complete the `SettlingSeekDuration`, no metrics are reported for the last transition. The metrics are reported for the transition the next time `step` is called if the `RunningMetrics` property is set to `true`.

Default: `false`

SettlingSeekDuration

Duration of time over which to search for settling. This property is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the `TransitionMetrics` object reports `NaN` for all

settling metrics. This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

Default: `0.02`

StateLevels

Low- and high-state levels. This property is a 2-element numeric row vector that contains the low and high state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

Default: `[0 2.3]`

StateLevelsSource

Auto or manual state level computation. If the `StateLevelsSource` property is set to `'Auto'`, the first record sent to `step` is sent to `dsp.StateLevels` with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

Default: `'Property'`

TimeInputPort

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

Default: `false`

Methods

clone	Clones the current instance of the transition metrics object
getNumInputs	Number of expected inputs to the method
getNumOutputs	Number of outputs of the method
isLocked	Locked status (logical) for input attributes and nontunable properties
plot	Plots signal and metrics computed in last call to
reset	Reset the running transition metrics object
step	Transition metrics of bilevel waveform

Examples

Transition and Preshoot Information of a 2.3 V Step Waveform

Compute transition and preshoot information of a 2.3 V step waveform sampled at 4 MHz

Load the data.

```
load('transitionex.mat', 'x');
```

Construct your transition metrics System object. Set the `SampleRate` property to 4 MHz, set the `StateLevelsSource` property to `'Auto'` to estimate the state levels from the data, set the `PreshootOutputPort` property to `true` to output pretransition aberration metrics when you call `step`.

```
htm1 = dsp.TransitionMetrics('SampleRate',4e6, ...
                                'StateLevelsSource','Auto', ...
                                'PreshootOutputPort',true)
```

Call `step` to compute the transition and preshoot information. Plot the result.

```
[transition, preshoot] = step(htm1, x)
plot(htm1)
```

Transition, Postshoot, and Settling Information of a 2.3 V Step Waveform

Compute transition, postshoot, and settling information of a 2.3 V step waveform sampled at 4 MHz.

Load the data along with the sampling instants.

```
load('transitionex.mat', 'x', 't');
```

Construct your transition metrics object setting the `TimeInputPort` property to `true` and the `StateLevels` property to match waveform state levels. To output the postshoot information and settling information when you call `step`, set the `PostShootOutputPort` and `SettlingOutputPort` properties to `true`. Set the settling seek duration to 2 microseconds.

```
htm2 = dsp.TransitionMetrics('TimeInputPort',true, ...
                             'StateLevels',[0 2.3], ...
                             'PostshootOutputPort',true, ...
                             'SettlingOutputPort',true, ...
                             'SettlingSeekDuration',2e-6)
```

Compute the transition, postshoot, and settling information with `step` and plot the result.

```
[transition, postshoot, settling] = step(htm2,x,t)
plot(htm2)
```

References

[1] *IEEE Standard on Transitions, Pulses, and Related Waveforms*, IEEE Standard 181, 2003.

See Also

`dsp.StateLevels` | `dsp.PulseMetrics`

Purpose

Clones the current instance of the transition metrics object

Syntax

```
clone(H)
```

Description

`clone(H)` clones the current instance of the transition metrics object `H`.

dsp.TransitionMetrics.getNumInputs

Purpose

Number of expected inputs to the `step` method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method for the transition metrics object `H`.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of the `step` method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.TransitionMetrics.isLocked

Purpose

Locked status (logical) for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the transition metrics object `H`.

Purpose

Plots signal and metrics computed in last call to `step`

Syntax

```
plot(H)
```

Description

`plot(H)` plots the signal and metrics resulting from the last call of the step method.

By default `plot` displays

- the low and high state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When you set the `TransitionOutputPort` property to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true`, the corresponding overshoots and undershoots are plotted as inverted or non-inverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the upper- and lower-state boundaries over the specified seek duration are plotted.

dsp.TransitionMetrics.reset

Purpose

Reset the running transition metrics object

Syntax

```
reset(H)
```

Description

`reset(H)` clears information from previous calls to `step`.

Purpose

Transition metrics of bilevel waveform

Syntax

```
PULSE = step(H,X)
[PULSE,CYCLE] = step(H,X)
[PULSE,TRANSITION] = step(H,X)
[PULSE,PRESHOOT] = step(H,X)
[PULSE,POSTSHOOT] = step(H,X)
[PULSE,SETTLING] = step(H,X)
[...] = step(H,X,T)
```

Description

`PULSE = step(H,X)` returns a structure array, `PULSE`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `X`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

`PULSE` fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse
- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse
- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

`[PULSE,CYCLE] = step(H,X)` returns a structure array, `CYCLE`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field

corresponds to the number of complete pulse periods found in the real-valued column vector input, `X`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found the input, `X`, does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

`CYCLE` fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse
- `Frequency` — Reciprocal of the period
- `Separation` — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse
- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `PULSE` structure.
- `DutyCycle` — Ratio of the width to the period for each pulse

`[PULSE,TRANSITION] = step(H,X)` returns a structure array, `TRANSITION`, when you set the `TransitionOutputPort` property to `true`. The fields of `TRANSITION` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`TRANSITION` fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels

- `SlewRate` — Ratio of absolute difference between the upper- and lower-reference levels to the transition duration
- `MiddleCross` — Linearly-interpolated instant where the transition first crosses the mid-reference level
- `LowerCross` — Linearly-interpolated instant where the signal crosses the lower-reference level
- `UpperCross` — Linearly-interpolated instant where the signal crosses the upper-reference level

`[PULSE,PRESHOOT] = step(H,X)` returns a structure array, `PRESHOOT`, when you set the `PreshootOutputPort` property to `true`. The fields of `PRESHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `POSTSHOOT` structure.

`[PULSE,POSTSHOOT] = step(H,X)` returns a structure array, `POSTSHOOT`, when you set the `PostshootOutputPort` property to `true`. The fields of `POSTSHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`PRESHOOT` and `POSTSHOOT` fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

`[PULSE,SETTLING] = step(H,X)` returns a structure, `SETTLING`, when you set the `SettlingOutputPort` property to `true`. The fields of

SETTLING correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

SETTLING fields:

- Duration — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified PercentStateLevelTolerance of the waveform amplitude over the specified settling seek duration
- Instant — Instant in time where the signal enters and remains within the specified tolerance
- Level — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

`[PULSE,CYCLE,TRANSITION,PRESHOOT,POSTSHOOT,SETTLING] = step(H,X)` which returns the PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, and SETTLING structure arrays when the CycleOutputPort, PreshootOutputPort, PostshootPort, and SettlingOutputPort properties are true. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

`[...] = step(H,X,T)` performs the above metrics with respect to a sampled signal, whose sample values, X, and sample instants, T, are real-valued column vectors of the same length. The additional input T applies only when you set the TimeInputPort property to true.

Purpose

Receive UDP packets from network

Description

The `UDPReceiver` object receives UDP packets from the network.

To receive UDP packets from the network:

1. Define and set up your UDP receiver. See "Construction" on page 3-1639.
2. Call `step` to receive the UDP packets according to the properties of `dsp.UDPReceiver`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.UDPReceiver` returns a UDP receiver System object, `H`, that receives UDP packets from a specified port.

`H = dsp.UDPReceiver('PropertyName',PropertyValue, ...)` returns a window object, `H`, with each property set to the specified value.

Properties

LocalIPPort

Local port on which to receive data

Specify the port on which to receive data. The default is `25000`.

RemoteIPAddress

Address from which data was sent

Specify the remote IP address from which to receive data. The default is `'0.0.0.0'`, which indicates that data is accepted from any remote IP address.

ReceiveBufferSize

Maximum size of internal buffer

Specify the size of the buffer that receives UDP packets, in bytes. The default is `8192`.

MaximumMessageLength

Maximum size of output message

Specify the size of the output message. If received packets exceed the specified value, their contents are truncated. The default is `255`.

MessageDataType

Data type of the message

Specify the data type of the message as `| double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | logical |`. The default is `uint8`.

Methods

clone	Create UDP receiver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Multiply input by window

Examples

Send some UDP packets, and calculate the number of successfully transmitted bytes:

```
hudpr = dsp.UDPReceiver;
hudps = dsp.UDPSender;

bytesSent = 0;
bytesReceived = 0;
dataLength = 128;
```

```
for k = 1:20
   dataSent = uint8(255*rand(1,dataLength));
   bytesSent = bytesSent + dataLength;
   step(hudps, dataSent);
   dataReceived = step(hudpr);
   bytesReceived = bytesReceived + length(dataReceived);
end

release(hudps);
release(hudpr);

fprintf('Bytes sent:     %d\n', bytesSent);
fprintf('Bytes received: %d\n', bytesReceived);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the UDP Receive block reference page. The object properties correspond to the block parameters, except:

- The **Output variable-size signal** parameter is not included in the System object.
- The **Sample time** parameter is not included in the System object.

See Also

`dsp.UDPSender`

dsp.UDPReceiver.clone

Purpose

Create UDP receiver object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a UDP receiver object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.UDPReceiver.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
Y = isLocked(H)
```

Description

`Y = isLocked(H)` returns the locked state, `Y`, of the UDP receiver object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.UDPReceiver.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Multiply input by window

Syntax

```
P = step (H)
```

Description

`P = step (H)` receives one UDP packet, `P`, from the network.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

The first time you call the `step` method on a `UDPReceiver` object, the object also allocates resources and begins listening for data. As a result, the first `step` call may not receive data.

dsp.UDPSender

Purpose

Send UDP packets to network

Description

The `UDPSender` object sends UDP packets to the network.

To send UDP packets to the network:

1. Define and set up your UDP sender. See "Construction" on page 3-1648.
2. Call `step` to send the packets according to the properties of `dsp.UDPSender`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.UDPSender` returns a UDP sender object, `H`, that sends UDP packets to a specified port.

`H = dsp.UDPSender('PropertyName',PropertyValue, ...)` returns a UDP sender object, `H`, with each property set to the specified value.

Properties

RemoteIPAddress

Remote address to which to send data

Specify the remote (i.e., host) IP address to which the data is sent. The default is `'127.0.0.1'`, which is the local host.

RemoteIPPort

Remote port to which to send data

Specify the port at the remote IP address to which the data is sent. The default is `25000`.

LocalIPPortSource

Source of the `LocalIPPort` property

Specify how to determine the port on the host as `| Auto | Property |`. If you specify `Auto`, the object selects the port dynamically from the available ports. If you specify `Property`, the object uses the source specified in the `LocalIPPort` property. The default is `Auto`.

LocalIPPort

Local port from which to send data

Specify the port from which to send data. This property applies when you set the `LocalIPPortSource` property to `Auto`. The default is `25000`.

Methods

clone	Create UDP sender object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Send a UDP packet to network

Examples

Send a number of UDP packets, and calculate the number of successfully transmitted bytes:

```
hudpr = dsp.UDPReceiver;
hudps = dsp.UDPSender;

bytesSent = 0;
bytesReceived = 0;
dataLength = 128;

for k = 1:20
   dataSent = uint8(255*rand(1,dataLength));
   bytesSent = bytesSent + dataLength;
   step(hudps, dataSent);
   dataReceived = step(hudpr);
```

```
   bytesReceived = bytesReceived + length(dataReceived);
end

release(hudps);
release(hudpr);

fprintf('Bytes sent:     %d\n', bytesSent);
fprintf('Bytes received: %d\n', bytesReceived);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the UDP Send block reference page. The object properties correspond to the block parameters.

See Also

`dsp.UDPReceiver`

Purpose

Create UDP sender object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a UDP sender object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.UDPSender.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
getNumInputs(H)
```

Description

`getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.UDPSender.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the UDP sender object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
Y = release(H)
```

Description

`Y = release(H)` releases system resources, such as memory, file handles, and hardware connections. This method lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.UDPSender.step

Purpose

Send a UDP packet to network

Syntax

```
Y = step(H,PACKET)
```

Description

`Y = step(H,PACKET)` sends one UDP packet, PACKET, to the network.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Decode integer input into floating-point output

Description

The `UniformDecoder` object decodes integer input into floating-point output. The decoder adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

To decode an integer input into a floating-point output:

1. Define and set up your uniform decoder. See "Construction" on page 3-1657.
2. Call `step` to decode the input according to the properties of `dsp.UniformDecoder`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.UniformDecoder` returns a uniform decoder, `H`, that performs the inverse operation of the `UniformEncoder` object, reconstructing quantized floating-point values from encoded integer input.

`H = dsp.UniformDecoder('PropertyName',PropertyValue,...)` returns a uniform decoder, `H`, with each specified property set to the specified value.

`H = dsp.UniformDecoder(peakvalue,numbits, 'PropertyName',PropertyValue,...)` returns a uniform decoder, `H`, with the `PeakValue` property set to `peakvalue`, the `NumBits` property set to `numbits`, and other specified properties set to the specified values.

Properties

PeakValue

Largest amplitude represented in encoded input

Specify the largest amplitude represented in the encoded input as a nonnegative numeric scalar. To correctly decode values encoded with the `UniformEncoder` object, set the `PeakValue` property in both objects to the same value. For more information on setting this property, see the `PeakValue` property description on the `dsp.UniformEncoder` reference page. The default is `1`.

NumBits

Number of input bits used to encode data

Specify the number of bits used to encode the input data as an integer value between `2` and `32`. The value of this property can be less than the total number of bits supplied by the input data type. To correctly decode values encoded with the `UniformEncoder` object, set the `NumBits` property in both objects to the same value. For more information on setting this property, see the `NumBits` property description on the `dsp.UniformEncoder` reference page. The default is `3`.

OverflowAction

Action to take when integer input is out of range

Specify the behavior of the uniform decoder when the integer input is out of range as `Saturate` or `Wrap`. The value of the `NumBits` property specifies the representable range of the input. The default is `Saturate`.

OutputDataType

Output data type as single or double

Specify the data type of the output as `single` or `double`. The default is `double`.

Methods

clone	Create uniform decoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties

release	Allow property value and input characteristics changes
step	Decode integer input into quantized floating-point output

Examples

Decode an encoded sequence:

```
hue = dsp.UniformEncoder;
hue.PeakValue = 2;
hue.NumBits = 4;
hue.OutputDataType = 'Signed integer';
x = (0:0.25:2)'; % Create an input sequence
hud = dsp.UniformDecoder;
hud.PeakValue = 2;
hud.NumBits = 4;
x_encoded = step(hue, x);
% Check that the last element has been saturated.
x_decoded = step(hud, x_encoded);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Uniform Decoder block reference page. The object properties correspond to the block parameters.

See Also

`dsp.UniformEncoder`

dsp.UniformDecoder.clone

Purpose

Create uniform decoder object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `UniformDecoder` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

The clone method creates an instance of an object. The property values, but not internal states, are copied into the new instance of the object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.UniformDecoder.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `UniformDecoder` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.UniformDecoder.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Decode integer input into quantized floating-point output

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` reconstructs quantized floating-point output `Y` from the encoded integer input `X`. Input `X` can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.UniformEncoder

Purpose

Quantize and encode floating-point input into integer output

Description

The `UniformEncoder` object quantizes floating-point input, using the precision you specify in the `NumBits` property, and encodes the quantized input into integer output. The operations of the uniform encoder adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

To quantize and encode a floating-point input into an integer output:

1. Define and set up your uniform encoder. See "Construction" on page 3-1666.
2. Call `step` to encode the input according to the properties of `dsp.UniformEncoder`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.UniformEncoder` returns a uniform encoder, `H`, that quantizes floating-point input samples and encodes them as integers using $2N$-level quantization, where N is an integer.

`H = dsp.UniformEncoder('PropertyName',PropertyValue,...)` returns an uniform encoder, `H`, with each specified property set to the specified value.

`H = dsp.UniformEncoder(peakvalue,numbits, 'PropertyName',PropertyValue,...)` returns a uniform encoder, `H`, with the `PeakValue` property set to `peakvalue`, the `NumBits` property set to `numbits`, and other specified properties set to the specified values.

Properties

PeakValue

Largest input amplitude to be encoded

Specify the largest input amplitude to be encoded, as a nonnegative numeric scalar. If the real or imaginary input are outside of the interval $[-P,(1-2^{(1-B)})P]$, where P is the peak value and B is the value of the `NumBits` property, the uniform encoder

saturates (independently for complex inputs) at those limits. The default is `1`.

NumBits

Number of bits needed to represent output

Specify the number of bits needed to represent the integer output as an integer value between `2` and `32`. The number of levels at which the uniform encoder quantizes the floating-point input is 2^B, where B is the number of bits. The default is `8`.

OutputDataType

Data type of output

Specify the data type of the output as `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, and signed outputs are `int8`, `int16`, or `int32`. The quantized inputs are linearly (uniformly) mapped to the intermediate integers in the interval $[0,2^{(B-1)}]$ when you set this property to `Unsigned integer`, and in the interval $[-2^{(B-1)},2^{(B-1)}-1]$ when you set this property to `Signed integer`. The variable B in both expressions corresponds to the value of the `NumBits` property.

Methods

clone	Create uniform encoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Quantize and encode input

Examples

Encode a sequence:

```
hue = dsp.UniformEncoder;
hue.PeakValue = 2;
hue.NumBits = 4;
hue.OutputDataType = 'Signed integer';
x = [-1:0.01:1]'; % Create an input sequence
x_encoded = step(hue, x);
plot(x, x_encoded,'.');
xlabel('Input'); ylabel('Encoded Output'); grid
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Uniform Encoder block reference page. The object properties correspond to the block parameters.

See Also

`dsp.UniformDecoder`

Purpose

Create uniform encoder object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `UniformEncoder` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

dsp.UniformEncoder.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.UniformEncoder.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `UniformEncoder` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.UniformEncoder.step

Purpose

Quantize and encode input

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` quantizes and encodes the input `X` to `Y`. Input `X` can be real or complex, double-, or single-precision values. The uniform encoder chooses the output data type according to the following table.

Number of Bits	Unsigned Integer	Signed Integer
2 to 8	`uint8`	`int8`
9 to 16	`uint16`	`int16`
17 to 32	`uint32`	`int32`

The row corresponds to the value of the `NumBits` property, and the column corresponds to the value of the `OutputDataType` property.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Solve upper-triangular matrix equation

Description

The `UpperTriangularSolver` object solves $UX = B$ for X when U is a square, upper-triangular matrix with the same number of rows as B.

To solve $UX = B$:

1. Define and set up your linear system solver. See "Construction" on page 3-1675.
2. Call `step` to solve the equation according to the properties of `dsp.UpperTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.UpperTriangularSolver` returns a linear system solver, `H`, used to solve $UX = B$ where U is an upper (or unit-upper) triangular matrix.

`H = dsp.UpperTriangularSolver('PropertyName',PropertyValue,...)` returns a linear system solver, `H`, with each specified property set to the specified value.

Properties

OverwriteDiagonal

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, U, with ones. Set this property to either `true` or `false`. The default is `false`.

RealDiagonalElements

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input, U, are real. This property applies only when you set the `OverwriteDiagonal` property to `false`. Set this property to either `true` or `false`. The default is `false`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create upper triangular solver object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Solve matrix equation for specified inputs

Examples

Solve an upper-triangular matrix equation:

```
huptriang = dsp.UpperTriangularSolver;
```

```
u = triu(rand(4, 4));
b = rand(4, 1);
% Check that result is the solution to the linear
% equations.
x1 = inv(u)*b
x = step(huptriang, u, b)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Backward Substitution block reference page. The object properties correspond to the block parameters.

See Also

`dsp.LowerTriangularSolver`

Purpose

Create upper triangular solver object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates an `UpperTriangularSolver` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object.

dsp.UpperTriangularSolver.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.UpperTriangularSolver.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `UpperTriangularSolver` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.UpperTriangularSolver.step

Purpose

Solve matrix equation for specified inputs

Syntax

```
X = step(H,U,B)
```

Description

`X = step(H,U,B)` computes the solution, X, of the matrix equation $UX = B$, where U is a square, upper-triangular matrix with the same number of rows as the matrix B.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Variable bandwidth FIR filter

Description

The `VariableBandwidthFIRFilter` object filters each channel of the input using FIR filter implementations. It does so while having the capability of tuning the bandwidth. This filter supports double and single precision inputs.

To filter each channel of the input:

1. Define and set up your variable bandwidth FIR filter. See "Construction" on page 3-1685.
2. Call `step` to filter each channel of the input according to the properties of `dsp.VariableBandwidthFIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`HFIR = dsp.VariableBandwidthFIRFilter` returns a System object, `HFIR`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified FIR filter implementation. The filter's cutoff frequency may be tuned during the filtering operation. The variable bandwidth FIR filter is designed using the window method.

`HFIR = dsp.VariableBandwidthFIRFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a variable bandwidth FIR filter System object, `HFIR`, with each property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1,Value1,...,NameN,ValueN`).

Properties

SampleRate

Input sample rate

Specify the sampling rate of the input in Hertz as a finite numeric scalar. The default is 44.1 kHz. This property is nontunable.

FilterType

Filter type

Specify the type of the filter as one of `'Lowpass' | 'Highpass' | 'Bandpass' | 'Bandstop'`. The default is `'Lowpass'`. This property is nontunable.

FilterOrder

FIR filter order

Specify the order of the FIR filter as a positive integer scalar. The default is 30. This property is nontunable.

Window

Window function

Specify the window function used to design the FIR filter as one of `'Hann' | 'Hamming' | 'Chebyshev' | 'Kaiser'`. The default is `'Hann'`. This property is nontunable.

KaiserWindowParameter

Kaiser window parameter

Specify the Kaiser window parameter as a real scalar. This property applies when you set the window property to `'Kaiser'`. The default is 0.5. This property is nontunable.

CutoffFrequency

Filter cutoff frequency

Specify the filter cutoff frequency in Hz as a real, positive scalar, smaller than the `SampleRate/2`. This property applies if you set the `FilterType` property to `'Lowpass'` or `'Highpass'`. The default is 512 Hz. This property is tunable.

CenterFrequency

Filter center frequency

Specify the filter center frequency in Hz as a real, positive scalar, smaller than `SampleRate/2`. This property applies when you set the `FilterType` property to `'Bandpass'` or `'Bandstop'`. The default is 11025 Hz. This property is tunable.

Bandwidth

Filter bandwidth

Specify the filter bandwidth in Hertz as a real, positive scalar, smaller than `SampleRate/2`. This property applies if you set the `FilterType` property to `'Bandpass'` or `'Bandstop'`. The default is 7680 Hz. This property is tunable.

SidelobeAttenuation

Chebyshev window sidelobe attenuation

Specify the Chebyshev window attenuation as a real, positive scalar in decibels (dB). This property applies if you set the `Window` property to `'Chebyshev'`. The default is 60 dB. This property is nontunable.

Methods

clone	Create variable bandwidth FIR filter with same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of variable bandwidth FIR filter
step	Filter signal using variable bandwidth algorithm

More “Analysis Methods for Filter System Objects” on page 2-2.

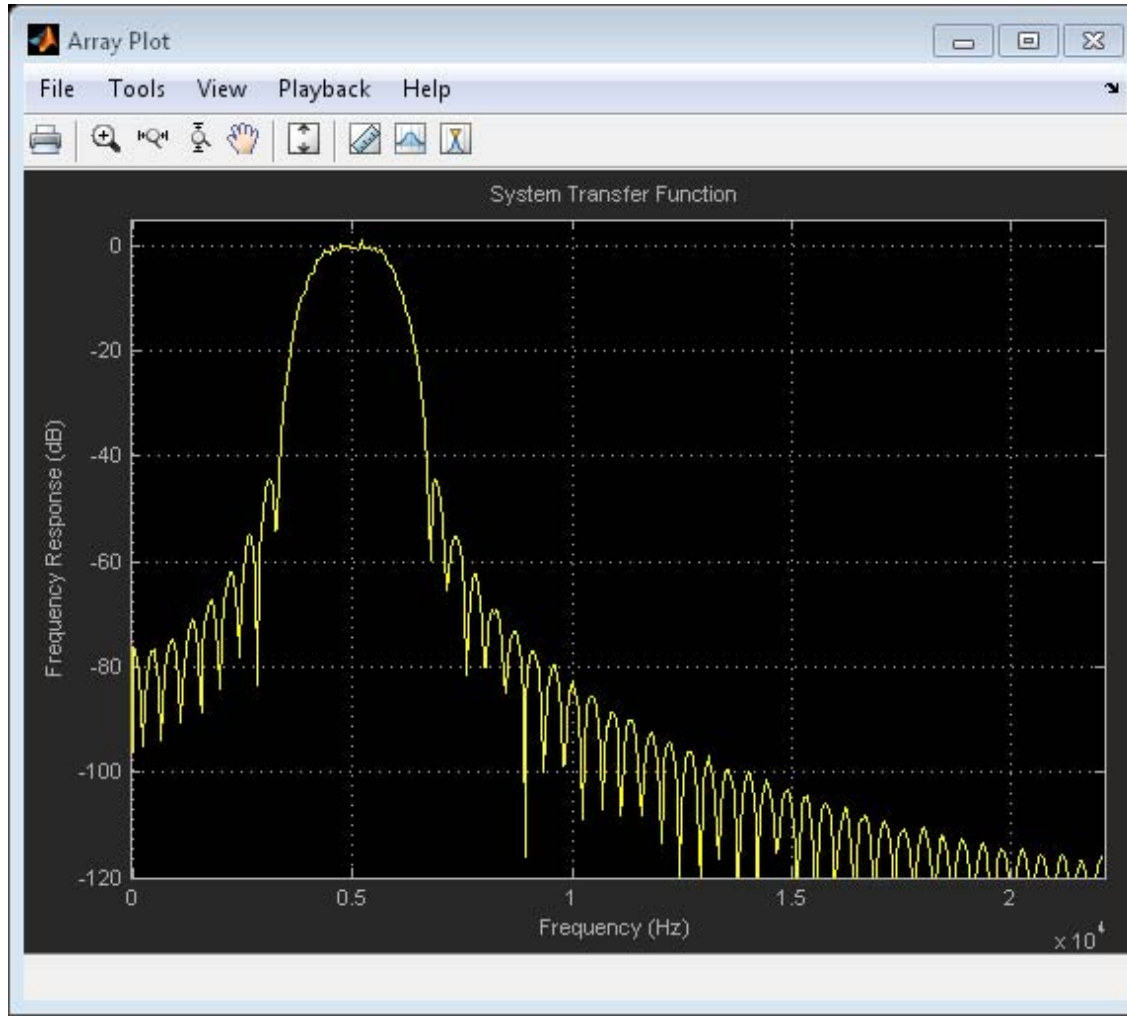
Examples

Filtering through a variable bandwidth bandpass FIR filter

This example shows you how to tune the center frequency and the bandwidth of the FIR filter.

```
Fs = 44100; % Input sample rate
```

```
% Define a bandpass variable bandwidth FIR filter:
hfir = dsp.VariableBandwidthFIRFilter('FilterType','Bandpass',...
                                      'FilterOrder',100,...
                                      'SampleRate',Fs,...
                                      'CenterFrequency',1e4,...
                                      'Bandwidth',4e3);
htfe = dsp.TransferFunctionEstimator('FrequencyRange','onesided');
hplot = dsp.ArrayPlot('PlotType','Line',...
                      'XOffset',0,...
                      'YLimits',[-120 5], ...
                      'SampleIncrement', 44100/1024,...
                      'YLabel','Frequency Response (dB)',...
                      'XLabel','Frequency (Hz)',...
                      'Title','System Transfer Function');
FrameLength = 1024;
hsin = dsp.SineWave('SamplesPerFrame',FrameLength);
for i=1:500
   % Generate input
   x = step(hsin) + randn(FrameLength,1);
   % Pass input through the filter
   y = step(hfir,x);
   % Transfer function estimation
   h = step(htfe,x,y);
   % Plot transfer function
   step(hplot,20*log10(abs(h)))
   % Tune bandwidth and center frequency of the FIR filter
   if (i==250)
      hfir.CenterFrequency = 5000;
      hfir.Bandwidth = 2000;
   end
end
```



Algorithms

FIR Transformations

All transformations assume a lowpass filter of length 2N+1.

Lowpass to Lowpass

Consider an ideal lowpass brickwall filter with normalized cutoff frequency ω_{c1}. By taking the inverse Discrete Fourier Transform of the ideal frequency response, and clipping the resulting sequence to length 2N+1, the impulse response is:

$$\text{for } n = 0$$

$$h_{LP}(n) = \frac{\omega_c}{\pi}.w(0)$$

$$\text{for } 1 \le |n| \le N$$

$$h_{LP}(n) = \frac{\sin(\omega_c n)}{\pi n}.w(n)$$

where w(n) is the window vector. The lowpass filter coefficients are tuned to a new cutoff frequency ω_{c2} as follows:

$$\text{for } n = 0$$

$$h_{LP}(n) = \frac{\omega_{c2}}{\pi}.\omega(0)$$

$$\text{for } 1 \le |n| \le N$$

$$h_{LP}(n) = \frac{\sin(\omega_{c2} n)}{\pi n}.\omega(n)$$

There is no need to recompute the window every time you tune the cutoff frequency.

Lowpass to Highpass

Assuming a lowpass filter with normalized 6–dB cutoff frequency ω_c, a highpass filter with the same cutoff frequency can be obtained by taking the complementary of the lowpass frequency response: $H_{HP}(e^{j\omega}) = 1 — H_{LP}(e^{j\omega})$

Taking the inverse discrete Fourier transform of the above response, we get the following highpass filter coefficients:

$$for\ n = 0$$
$$h_{hp}(n) = 1 - h_{LP}(n)$$
$$for\ 1 \le |n| \le N$$
$$h_{hp}(n) = -h_{LP}(n)$$

Lowpass to Bandpass

A bandpass filtered centered at frequency ω_0 can be obtained by shifting the lowpass response:

$$H_{BP}(e^{j\omega}) = H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega-\omega_0)})$$

The bandwidth of the resulting bandpass filter is $2\omega_c$, as measured between the two cutoff frequencies of the bandpass filter. The equivalent bandpass filter coefficients are then:

$$h_{BP}(n) = (e^{j\omega_0 n} + e^{-j\omega_0 n})h_{LP}(n)$$

which can be written as:

$$h_{BP}(n) = 2\cos(\omega_0 n)h_{LP}(n)$$

Lowpass to Bandstop

We can transform a lowpass filter to a bandstop filter by combining the highpass and bandpass transformations. That is, first make the filter banpass by shifting the lowpass response, and then invert in to get a bandstop response centered at ω_0.

$$H_{BS}(e^{j\omega}) = 1 - (H_{LP}(e^{j(\omega-\omega_0)}) + H_{LP}(e^{j(\omega+\omega_0)}))$$

This yields the following coefficients:

$$for\ n = 0$$
$$h_{BS}(n) = 1 - 2\cos(\omega_0 n)h_{LP}(n)$$
$$for\ 1 \le |n| \le N$$
$$h_{BS}(n) = -2\cos(\omega_0 n)h_{LP}(n)$$

Generalized Transformation

The transformations highlighted above can be combined to transform a lowpass filter to a lowpass, highpass, bandpass or bandstop filter with arbitrary cutoffs.

For example, to transform a lowpass filter with cutoff ω_{c1} to a highpass with cutoff ω_{c2}, you first apply the lowpass-to-lowpass transformation to get a lowpass filter with cutoff ω_{c2}, and then apply the lowpass-to-highpass transformation to get the highpass with cutoff ω_{c2}.

To get a bandpass filter with center frequency ω_0 and bandwidth ß, we first apply the lowpass-to-lowpass transformation to go from a lowpass with cutoff ω_c to a lowpass with cutoff ß/2, and then apply the lowpass-to-bandpass transformation to get the desired bandpass filter. The same approach can be applied to a bandstop filter.

See Also

`dsp.BiquadFilter` | `dsp.IIRFilter` | `dsp.FIRFilter` | `dsp.AllpoleFilter` | `dsp.VariableBandwidthIIRFilter`

Purpose

Create variable bandwidth FIR filter with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a variable bandwidth FIR filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.VariableBandwidthFIRFilter.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the variable bandwidth FIR filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.VariableBandwidthFIRFilter.reset

Purpose

Reset internal states of variable bandwidth FIR filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the variable bandwidth FIR filter object, `H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the variable bandwidth FIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Purpose

Filter signal using variable bandwidth algorithm

Syntax

```
Y = step(H,x)
```

Description

`Y = step(H,x)` filters the real or complex input signal `X` using the variable bandwidth FIR filter, `H`, to produce the output `Y` . The variable bandwidth FIR filter object operates on each channel, which means every column of the input signal independently over successive calls to step method.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.VariableBandwidthIIRFilter

Purpose

Variable bandwidth IIR filter

Description

The `VariableBandwidthIIRFilter` object filters each channel of the input using IIR filter implementations. It does so while having the capability of tuning the bandwidth. This filter supports double and single precision inputs.

To filter each channel of the input:

1. Define and set up your variable bandwidth IIR filter. See "Construction" on page 3-1698.
2. Call `step` to filter each channel of the input according to the properties of `dsp.VariableBandwidthIIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Construction

`HIIR = dsp.VariableBandwidthIIRFilter` returns a System object, `HIIR`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified IIR filter implementation. The filter's passband frequency may be tuned during the filtering operation. The variable bandwidth IIR filter is designed using the elliptical method. The filter is tuned using IIR spectral transformations based on allpass filters.

`HIIR = dsp.VariableBandwidthIIRFilter('PropertyName',PropertyValue, ...)` returns a variable bandwidth IIR filter System object, `HIIR`, with each property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

SampleRate

Input sample rate

Specify the sampling rate of the input in Hertz as a finite numeric scalar. The default is 44.1 kHz. This property is nontunable.

FilterType

Filter type

Specify the type of the filter as one of `'Lowpass' | 'Highpass' | 'Bandpass' | 'Bandstop'`. The default is `'Lowpass'`. This property is nontunable.

FilterOrder

IIR filter order

Specify the order of the IIR filter as a positive integer scalar. The default is 8. This property is nontunable.

PassbandFrequency

Filter passband frequency

Specify the filter passband frequency in Hz as a real, positive scalar, smaller than the `SampleRate/2`. This property applies when you set the `FilterType` property to `'Lowpass'` or `'Highpass'`. The default is 512 Hz. This property is tunable.

CenterFrequency

Filter center frequency

Specify the filter center frequency in Hz as a real, positive scalar, smaller than `SampleRate/2`. This property applies when you set the `FilterType` property to `'Bandpass'` or `'Bandstop'`. The default is 11025 Hz. This property is tunable.

Bandwidth

Filter bandwidth

Specify the filter bandwidth in Hertz as a real, positive scalar, smaller than `SampleRate/2`. This property applies when you set the `FilterType` property to `'Bandpass'` or `'Bandstop'`. The default is 7680 Hz. This property is tunable.

PassbandRipple

Filter passband ripple

Specify the filter passband ripple as a real, positive scalar in decibels (dB). The default is 1 dB. This property is nontunable.

StopbandAttenuation

Filter Stopband attenuation

Specify the filter stopband attenuation as a real, positive scalar in decibels (dB). The default is 60 dB. This property is nontunable.

Methods

clone	Create variable bandwidth IIR filter with same property values
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of variable bandwidth IIR filter
step	Filter signal using variable bandwidth algorithm

More “Analysis Methods for Filter System Objects” on page 2-2.

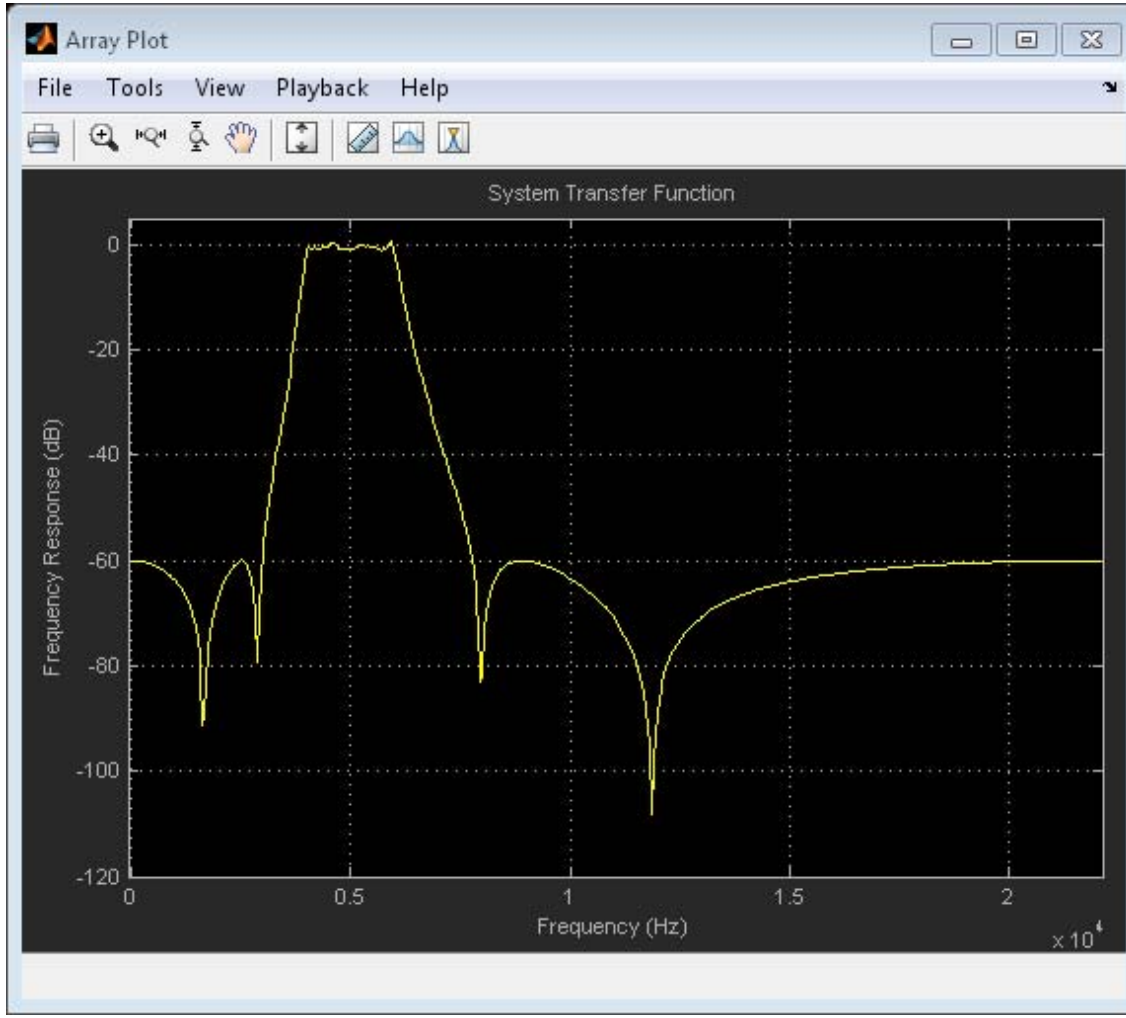
Examples

Filtering Through a Variable Bandwidth Bandpass IIR Filter

This examples shows you how to tune the center frequency and bandwidth of the IIR filter.

```
Fs = 44100; % Input sample rate
% Define a bandpass variable bandwidth IIR filter:
hiir = dsp.VariableBandwidthIIRFilter('FilterType','Bandpass',...
                                      'FilterOrder',8,...
                                      'SampleRate',Fs,...
                                      'CenterFrequency',1e4,...
                                      'Bandwidth',4e3);
htfe = dsp.TransferFunctionEstimator('FrequencyRange','onesided');
```

```
hplot = dsp.ArrayPlot('PlotType','Line',...
                      'XOffset',0,...
                      'YLimits',[-120 5], ...
                      'SampleIncrement', 44100/1024,...
                      'YLabel','Frequency Response (dB)',...
                      'XLabel','Frequency (Hz)',...
                      'Title','System Transfer Function');
FrameLength = 1024;
hsin = dsp.SineWave('SamplesPerFrame',FrameLength);
for i=1:500
   % Generate input
   x = step(hsin) + randn(FrameLength,1);
   % Pass input through the filter
   y = step(hiir,x);
   % Transfer function estimation
   h = step(htfe,x,y);
   % plot transfer function
   step(hplot,20*log10(abs(h)))
   % Tune bandwidth and center frequency of the IIR filter
   if (i==250)
     hiir.CenterFrequency = 5000;
     hiir.Bandwidth = 2000;
   end
end
```



Algorithms

This filter covers frequency transformations. A lowpass IIR prototype is designed, using the elliptical method by specifying its order, passband frequency, passband ripple and stopband attenuation. The passband ripple and stopband attenuation are equal to the values of the

`PassbandRipple` and `StopbandAttenuation` properties. The prototype passband frequency is set to 0.5. If the `FilterType` property is `'Lowpass'` or `'Highpass'`, the prototype's order is equal to the value of `FilterOrder`. If the `FilterType` property is `'Bandpass'` or `'Bandstop'`, the prototype filter order is equal to `FilterOrder/2`. The prototype is a Direct Form II Transposed cascade of second-order sections (Biquad filter). The prototype is transformed into the desired filter using the algorithms used in "Digital Frequency Transformations". Each prototype SOS section is transformed separately. When `FilterType` is `'Lowpass'` or `'Highpass'`, the resulting filter remains a Direct Form II Transposed cascade of second order sections. If the `FilterType` is `'Bandpass'` or `'Bandstop'`, the resulting filter is a cascade of Direct Form II Transposed cascade of fourth order sections.

`dsp.BiquadFilter | dsp.IIRFilter | dsp.FIRFilter | dsp.AllpoleFilter | dsp.VariableBandwidthFIRFilter`

dsp.VariableBandwidthIIRFilter.clone

Purpose

Create variable bandwidth IIR filter with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a variable bandwidth IIR filter object, `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the variable bandwidth IIR filter.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.VariableBandwidthIIRFilter.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of variable bandwidth IIR filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the variable bandwidth IIR filter object, `H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the variable bandwidth IIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

dsp.VariableBandwidthIIRFilter.step

Purpose

Filter signal using variable bandwidth algorithm

Syntax

```
Y = step(H,x)
```

Description

`Y = step(H,x)` filters the real or complex input signal `X` using the variable bandwidth IIR filter, `H`, to produce the output `Y` . The variable bandwidth IIR filter object operates on each channel, which means every column of the input signal independently over successive calls to step method.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Delay input by time-varying fractional number of sample periods

Description

The `VariableFractionalDelay` object delays the input by a time-varying fractional number of sample periods.

To delay the input by a time-varying fractional number of sample periods:

1. Define and set up your variable fractional delay object. See "Construction" on page 3-1709.
2. Call `step` to delay the input according to the properties of `dsp.VariableFractionalDelay`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.VariableFractionalDelay` returns a variable fractional delay System object, `H`, that delays a discrete-time input by a time-varying fractional number of sample periods.

`H = dsp.VariableFractionalDelay('PropertyName',PropertyValue,...)` returns a variable fractional delay System object, `H`, with each property set to the specified value.

Properties

InterpolationMethod

Interpolation method

Specify the method by which the block interpolates between adjacent stored samples to obtain a value for the sample indexed by the input. You can set this property to one of `| Linear | FIR | Farrow |`. When you set this property to `FIR`, the object uses the Signal Processing Toolbox `intfilt` function to compute an FIR filter for interpolation. The default is `Linear`.

FilterHalfLength

FIR interpolation filter half-length

Specify the half-length of the FIR interpolation filter as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `FIR`. For periodic signals, a larger value of this property (that is, a higher order filter) yields a better estimate of the delayed output sample. Setting this property to a value between `4` and `6` (that is, a 7th to 11th order filter) is usually adequate. The default is `4`.

FilterLength

Length of Farrow filter

Specify the length of the FIR filter implemented using the Farrow structure, as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `4`.

InterpolationPointsPerSample

Number of interpolation points per input sample

Specify the number of interpolation points per input sample at which a unique FIR interpolation filter is computed. You must specify the number of interpolation points per input sample as a positive scalar integer. This property applies only when you set the `InterpolationMethod` property to `FIR`. The default is `10`.

Bandwidth

Normalized input bandwidth

Specify the bandwidth to which you want to constrain the interpolated output samples. You must enter the bandwidth as a scalar value between `0` and `1`. You can use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above `Fs/4` (where `Fs` is the sampling frequency), you can specify a value of `0.5` for the `Bandwidth` property. A value of `1` for the `Bandwidth` property corresponds to half the sampling frequency (`Fs`). This property applies only when you set the `InterpolationMethod`property to `FIR`. The default is `1`.

InitialConditions

Initial values in memory

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on the setting of the `FrameBasedProcessing` property, and whether you want fixed or time-varying initial conditions. The default is `0`.

When you set the `FrameBasedProcessing` property to `false`, the object supports N-D input arrays. For an M-by-N-by-P sample-based input array `U`, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the value of the `InterpolationMethod` property:
  - If you set the `InterpolationMethod` property to `Linear`, set the `InitialConditions` property to an array of dimension Mx-by-N-by-P-by-D. The object uses the values in this array to initialize memory samples `U(2:D+1)`, where `D` is the value of the `MaximumDelay` property.
  - If you set the `InterpolationMethod` property to either `FIR` or `Farrow`, set the `InitialConditions` property to an array of dimension M-by-N-by-P-by-(D+L). The object uses the values in this array to initialize memory samples `U(2:D+1)`, where `D` is the value of the `MaximumDelay` property. For FIR interpolation, `L` is the value of the `FilterHalfLength` property. For Farrow interpolation, `L` equals `floor` of half the value of the `FilterLength` property (`floor(FilterLength/2)`).

When you set the `FrameBasedProcessing` property to `true`, the object treats each of the N input columns as a frame containing M sequential time samples from an independent channel.

For an M-by-N frame-based input matrix U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the value of the `InterpolationMethod` property. To specify different time-varying initial conditions for each channel, set the `InitialConditions` property as follows:
  - If you set the `InterpolationMethod` property to `Linear`, set the `InitialConditions` property to an array of size `1`-by-N-by-D, where D is the value of the `MaximumDelay` property.
  - If you set the `InterpolationMethod` property to `FIR` or `Farrow`, set the `InitialConditions` property to an array of size 1-by-N-by-(D+L), where D is the value of the `MaximumDelay` property. For FIR interpolation, `L` is the value of the `FilterHalfLength` property. For Farrow interpolation, `L` equals `floor` of half the value of the `FilterLength` property (`floor(FilterLength/2)`).

MaximumDelay

Maximum delay

Specify the maximum delay the object can produce for any sample. The maximum delay must be a positive scalar integer value. The object clips input delay values greater than the `MaximumDelay` to the `MaximumDelay`. The default is `100`.

DirectFeedthrough

Allow direct feedthrough

When you set this property to `true`, the object allows direct feedthrough. When you set this property to `false`, the object increases the minimum possible delay by one. The default is `true`.

FIRSmallDelayAction

Action for small input delay values in FIR interpolation mode

Specify the action the object should take for small input delay values when using the FIR interpolation method. You can set this property to `Clip to the minimum value necessary for centered kernel`, or `Switch to linear interpolation if kernel cannot be centered`. This property applies only when you set the `InterpolationMethod` property to `FIR`. The default is `Clip to the minimum value necessary for centered kernel`.

FarrowSmallDelayAction

Action for small input delay values in Farrow interpolation mode

Specify the action the object should take for small input delay values when using the Farrow interpolation method. You can set this property to `Clip to the minimum value necessary for centered kernel`, or `Use off-centered kernel`. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Clip to the minimum value necessary for centered kernel`.

FrameBasedProcessing

Treat input as frame based or sample based

Set this property to `true` to enable frame-based processing. When you do so, the object accepts M-by-N input matrices and treats each of the `N` input columns as a frame containing `M` sequential time samples from an independent channel. Set this property to `false` to enable sample-based processing. When you do so, the object supports N-D inputs and treats each element of the input as a separate channel. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent`, | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Zero`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

CoefficientsDataType

Coefficient word and fraction lengths

Specify the coefficients data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Coefficients word length

Specify the coefficients word length as an unscaled `numerictype` object with a `Signedness` of `Auto`. If the `InterpolationMethod` is `Linear`, specify that the `numerictype` object is unsigned; otherwise the object should be signed. This property applies only when you set the `CoefficientsDataType` property to `Custom`. The default is `numerictype([],32)`.

ProductPolynomialValueDataType

Product polynomial values word and fraction lengths

Specify the product polynomial value data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Same as first input`.

CustomProductPolynomialValueDataType

Product polynomial values word and

fraction lengths Specify the product polynomial values fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the `ProductPolynomialValueDataType` property to `Custom`. The default is `numerictype([],32,10)`.

AccumulatorPolynomialValueDataType

Accumulator polynomial value word and fraction lengths

Specify the accumulator polynomial value data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Same as first input`.

CustomAccumulatorPolynomialValueDataType

Accumulator polynomial value word and fraction lengths

Specify the data type of the accumulator polynomial values as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the `AccumulatorPolynomialValueDataType` property to `Custom`. The default is `numerictype([],32,10)`.

MultiplicandPolynomialValueDataType

Multiplicand polynomial value word and fraction lengths

Specify the multiplicand polynomial values data type as one of | `Same as first input` | `Custom` |. This property applies only when you set the `InterpolationMethod` property to `Farrow`. The default is `Same as first input`.

CustomMultiplicandPolynomialValueDataType

Multiplicand polynomial value word and fraction lengths

Specify the fixed-point data type of the multiplicand polynomial values as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `InterpolationMethod` property to `Farrow` and the

`MultiplicandPolynomialValueDataType` property to `Custom`. The default is `numerictype([],32,10)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as one of `| Same as first input | Custom |`. The default is `Same as first input`.

CustomProductDataType

Product word and fraction lengths

Specify the product data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],32,10)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as one of `| Same as product | Same as first input | Custom |`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,10)`.

OutputDataType

Output word and fraction lengths

Specify the output data type as one of `| Same as accumulator | Same as first input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the data type of the output as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],32,10)`.

Methods

clone	Create variable fractional delay object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
info	Characteristic information about valid delay range
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of variable fractional delay object
step	Delay input by time-varying fractional number of sample periods

Examples

Delay a signal by a varying fractional number of sample periods:

```
hsr = dsp.SignalSource;
hvfd = dsp.VariableFractionalDelay;
hLog = dsp.SignalSink;

for ii = 1:10
     delayedsig = step(hvfd, step(hsr), ii/10);
      step(hLog, delayedsig);
```

```
end

sigd = hLog.Buffer;

% The output sigd corresponds to the values of the delayed signal
% that are sampled at fixed-time intervals. For visualization
% purposes, we can instead plot the time instants at which the
% amplitudes of signal samples are constant by treating the
% signals as the sampling instants.

stem(hsr.Signal, 1:10, 'b')
hold on;
stem(sigd.', 1:10, 'r');
legend('Original signal',...
   'Variable fractional delayed signal', ...
   'Location','best')
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Variable Fractional Delay block reference page. The object properties correspond to the block properties, except:

When you set the `DirectFeedthrough` property of the System object to `true`, the object allows direct feedthrough. This behavior is different from the way the block behaves when you select the corresponding **Disable direct feedthrough by increasing minimum possible delay by one** check box on the block dialog. When you enable this block parameter, the block does not allow direct feedthrough.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.VariableIntegerDelay` | `dsp.Delay` | `dsp.DelayLine`

Purpose

Create variable fractional delay object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `VariableFractionalDelay` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.VariableFractionalDelay.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.VariableFractionalDelay.info

Purpose

Characteristic information about valid delay range

Syntax

```
S = info(H)
```

Description

`S = info(H)` returns a structure, `S` , containing characteristic information about the `VariableFractionalDelay` System object, `H` . `S` has one field, `ValidDelayRange` which is a string containing the possible range of delay values based on the current property values of the `VariableFractionalDelay` object. The `ValidDelayRange` is in the format `[MinValidDelay, MaxValidDelay]`. The object clips all input delay values to be within this `ValidDelayRange`.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `VariableFractionalDelay` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.VariableFractionalDelay.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Reset internal states of variable fractional delay object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the `VariableFractionalDelay` System object `H` to their initial values.

dsp.VariableFractionalDelay.step

Purpose

Delay input by time-varying fractional number of sample periods

Syntax

```
Y = step(H,X,D)
```

Description

`Y = step(H,X,D)` delays the input `X` by `D` samples, where `D` should be less than or equal to the value specified in the `MaximumDelay` property.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Delay input by time-varying integer number of sample periods

Description

The `VariableIntegerDelay` object delays input by time-varying integer number of sample periods.

To delay the input by a time-varying integer number of sample periods:

1. Define and set up your variable integer delay object. See "Construction" on page 3-1727.
2. Call `step` to delay the input according to the properties of `dsp.VariableIntegerDelay`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.VariableIntegerDelay` returns a variable integer delay System object, `H`, that delays discrete-time input by a time-varying integer number of sample periods.

`H = dsp.VariableIntegerDelay('PropertyName',PropertyValue,...)` returns a variable integer delay System object, `H`, with each property set to the specified value.

Properties

MaximumDelay

Maximum delay

Specify the maximum delay the object can produce for any sample. The maximum delay must be a positive scalar integer value. The object clips input delay values greater than the `MaximumDelay` to the `MaximumDelay`. The default is `100`.

InitialConditions

Initial values in memory

Specify the values with which the object's memory is initialized. The dimensions of this property can vary depending on the setting of the `FrameBasedProcessing` property, and whether you want fixed or time-varying initial conditions. The default is `0`.

When you set the `FrameBasedProcessing` property to `false`, the object supports N-D input arrays. For an M-by-N-by-P sample-based input array U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- To specify time-varying initial conditions, set the `InitialConditions` property to an array of dimension M-by-N-by-P-by-D. The object uses the values in this array to initialize memory samples `U(2:D+1)`, where `D` is the value of the `MaximumDelay` property.

When you set the `FrameBasedProcessing` property to `true`, the object treats each of the N input columns as a frame containing M sequential time samples from an independent channel. For an M-by-N frame-based input matrix U, you can set the `InitialConditions` property as follows:

- To specify fixed initial conditions, set the `InitialConditions` property to a scalar value. The object initializes every sample of every channel in memory using the value you specify.
- To specify different time-varying initial conditions for each channel, set the `InitialConditions` property to an array of size 1-by-N-by-D, where D is the value of the `MaximumDelay` property.

DirectFeedthrough

Allow direct feedthrough

When you set this property to `true`, the object allows direct feedthrough. When you set this property to `false`, the object increases the minimum possible delay by one. The default is `true`.

FrameBasedProcessing

Treat input as frame based or sample based

Set this property to `true` to enable frame-based processing. When you do so, the object accepts M-by-N input matrices and treats each of the N input columns as a frame containing M sequential time samples from an independent channel. Set this property to `false` to enable sample-based processing. When you do so, the object supports N-D inputs and treats each element of the input as a separate channel. The default is `true`.

Methods

clone	Create variable integer delay object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset internal states of variable integer delay object
step	Delay input by time-varying integer number of sample periods

Examples

Delay a signal by a varying integer number of sample periods:

```
h = dsp.VariableIntegerDelay;
x = 1:100;
ii = 0;
k = 0;
yout = [];

while(ii+10 <= 100)
```

```
    y = step(h, x(ii+1:ii+10)',k*ones(10,1));
    yout = [yout;y];
    ii = ii+10;
    k = k+1;
end

stem(x,'b');
hold on; stem(yout,'r');
legend('Original Signal', 'Variable Integer Delayed Signal')
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Variable Integer Delay block reference page. The object properties correspond to the block properties, except:

- When you set the `DirectFeedthrough` property of the System object to `true`, the object allows direct feedthrough. This behavior is different from the way the block behaves when you select the corresponding **Disable direct feedthrough by increasing minimum possible delay by one** check box on the block dialog. When you enable this block parameter, the block does not allow direct feedthrough.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See "Set the FrameBasedProcessing Property of a System object" for more information.

See Also

`dsp.VariableFractionalDelay` | `dsp.Delay` | `dsp.DelayLine`

Purpose

Create variable integer delay object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `VariableIntegerDelay` System object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

dsp.VariableIntegerDelay.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.VariableIntegerDelay.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `VariableIntegerDelay` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.VariableIntegerDelay.reset

Purpose

Reset internal states of variable integer delay object

Syntax

```
reset(H)
```

Description

`reset(H)` resets the internal states of the `VariableIntegerDelay` System object `H` to their initial values.

Purpose

Delay input by time-varying integer number of sample periods

Syntax

```
Y = step(H,X,D)
```

Description

`Y = step(H,X,D)` delays the input `X` by `D` samples, where `D` should be less than or equal to the value specified in the `MaximumDelay` property and greater than or equal to `0`. The object clips delay values greater than the `MaximumDelay` to the `MaximumDelay`, and clips values less than zero to zero. If you enter a noninteger delay value, the object rounds that value to the nearest integer value.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Variance

Purpose

Variance of input or sequence of inputs

Description

The `Variance` object computes variance for an input or sequence of inputs.

To compute the variance of an input or sequence of inputs:

1. Define and set up your variance System object. See "Construction" on page 3-1738.
2. Call `step` to compute the variance according to the properties of `dsp.Variance`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Variance` returns a variance System object, `H`, that computes the variance of an input or a sequence of inputs over the specified `Dimension`.

`H = dsp.Variance('PropertyName',PropertyValue,...)` returns a variance System object, `H`, with each specified property set to the specified value.

Properties

RunningVariance

Enable calculation over time

Set this property to `true` to enable variance calculation over successive calls to the `step` method. The default is `false`.

ResetInputPort

Enable reset input port

Set this property to `true` to enable reset input port. When you set the property to `true`, specify a reset input for the step method. The running variance resets anytime the variance object achieves the condition you specify for the `ResetCondition` property. This property applies when you set the `RunningVariance` property to `true`. The default is `false`.

ResetCondition

Reset condition for running variance mode

Specify which event resets the running variance as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies when you set the `ResetInputPort` property to `true`.

Dimension

Dimension to operate along

Specify how the object performs the variance calculation over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningVariance` property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the input signal dimension (one-based value) the object uses to compute variance. The cannot exceed the number of dimensions in the input signal. This property applies when you set the `Dimension` property to `Custom`. The default is `1`.

ROIProcessing

Enable region-of-interest processing

Set this property to `true` to enable calculating the variance within a particular region of each image. This property applies when you set the `RunningVariance` property to `false` and the `Dimension` property to `All`. The default is `false`. Full ROI processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, `Rectangles` is the only selection for the `ROIForm` property.

ROIForm

Define the type of region of interest.

Specify the type of region of interest as one of | `Rectangles` | `Lines` | `Label matrix` | `Binary mask` |. This property applies

when you set the `ROIProcessing` property to `true`. The default is `Rectangle`.

ROIPortion

Calculate over entire ROI or just perimeter

Specify the region over which to calculate variance as one of `| Entire ROI | ROI perimeter |`. This property applies when you set the `ROIForm` property to `Rectangles`. The default is `Entire ROI`.

ROIStatistics

Statistics for each ROI or one for all ROIs

Specify if statistics calculations are one of `| Individual statistics for each ROI | Single statistic for all ROIs |`. This property applies when `ROIForm` property is not `Binary mask`. The default is `Individual statistics for each ROI`.

ValidityOutputPort

Enable output of validity check of ROI or label numbers

Indicate whether to return the validity of the specified ROI being completely inside image when the ROIForm property is `Lines` or `Rectangles`. Indicate whether to return the validity of the specified label numbers when the `ROIForm` property is `Label Matrix`. This property applies when you set the `ROIForm` property to anything except `Binary Mask`. The default is `false`.

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. This property applies when you set the `RunningVariance` property to `true`. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

InputSquaredProductDataType

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomInputSquaredProductDataType

Input-squared product word and fraction lengths

Specify the input-squared product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `InputSquaredProductDataType` property to `Custom`. The default is `numerictype([],32,15)`.

InputSumSquaredProductDataType

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point data type as one of | `Same as input-squared product` | `Custom` |. The default is `Same as input-squared product`.

CustomInputSumSquaredProductDataType

Input-sum-squared product word and fraction lengths

Specify the input-sum-squared product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `InputSumSquaredProductDataType` property to `Custom`. The default is `numerictype([],32,23)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Same as input-squared product | Same as input | Custom |`. The default is `Same as input-squared product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numerictype([],32,0)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `| Same as input-squared product | Same as input | Custom |`. The default is `Same as input-squared product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `OutputDataType` property to `Custom`. The default is `numerictype([],16,0)`.

Methods

clone	Create variance object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
reset	Reset variance to zero
step	Variance of input

Examples

Compute the running variance for a signal:

```
hvar = dsp.Variance;
hvar.RunningVariance = true;
x = randn(100,1);
y = step(hvar, x);
% y(i) is the running variance of all values in the vector x(1:i)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Variance block reference page. The object properties correspond to the block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the `dsp.Variance` object.
- **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object

uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

See Also

`dsp.Mean` | `dsp.RMS` | `dsp.StandardDeviation`

Purpose

Create variance object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a `Variance` System object `C`, with the same property values as `H`. The clone method creates a new unlocked object with uninitialized states.

dsp.Variance.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.Variance.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `Variance` System object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.Variance.reset

Purpose

Reset variance to zero

Syntax

```
reset(H)
```

Description

`reset(H)` sets the variance to zero when the `RunningVariance` property is `true`.

Purpose

Variance of input

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
VAR2D = step(H,X,ROI)
VAR2D = step(H,X,LABEL,LABELNUMBERS)
[VAR2D,FLAG] = step(H,X,ROI)
[VAR2D,FLAG] = step(H,X,LABEL,LABELNUMBERS)
```

Description

`Y = step(H,X)` computes the variance, `Y`, of input `X` over successive calls to the `step` method, when the `RunningVariance` property is `true`.

`Y = step(H,X,R)` resets its state based on the value of reset signal `R` , the `ResetInputPort` property and the `ResetCondition` property. This option applies when the `RunningVariance` property is `true` and the `ResetInputPort` property is set to `true`.

`VAR2D = step(H,X,ROI)` computes the variance of input image, `X`, within the given region of interest, `ROI` , when the `ROIProcessing` property is `true` and the `ROIForm` property is `Lines`, `Rectangles` or `Binary mask`. Full `ROI` processing support requires a Computer Vision System Toolbox license. With only the DSP System Toolbox license, the `ROIForm` property only supports `Rectangles`.

`VAR2D = step(H,X,LABEL,LABELNUMBERS)` computes the variance of input image, `X`, for region labels contained in vector `LABELNUMBERS` , with matrix `LABEL` marking pixels of different regions. This option is available when the `ROIProcessing` property is `true` and the `ROIForm` property is `Label matrix`.

`[VAR2D,FLAG] = step(H,X,ROI)` returns `FLAG` which indicates whether the given region of interest is within the image bounds when both the `ROIProcessing` and `ValidityOutputPort` properties are `true` and the `ROIForm` property is set to `Lines`, `Rectangles` or `Binary mask`.

`[VAR2D,FLAG] = step(H,X,LABEL,LABELNUMBERS)` returns `FLAG` which indicates whether the input label numbers are valid when both the `ROIProcessing` and `ValidityOutputPort` properties are `true` and the `ROIForm` property is set to `Label matrix`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Purpose

Vector quantizer codeword for given index value

Description

The `VectorQuantizerDecoder` object returns the vector quantizer codeword for a given index value. Each column of the `Codebook` property is a codeword.

To obtain the vector quantizer codeword for a given index value:

1. Define and set up your vector quantizer decoder. See "Construction" on page 3-1753.
2. Call `step` to get the vector quantizer codeword according to the properties of `dsp.VectorQuantizerDecoder`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.VectorQuantizerDecoder` creates a vector quantizer decoder System object, `H`, that returns a vector quantizer codeword corresponding to a given, zero-based index value.

`H = dsp.VectorQuantizerDecoder('PropertyName',PropertyValue,...)` returns a vector quantizer decoder, `H`, with each specified property set to the specified value.

Properties

CodebookSource

Source of codebook values

Specify the codebook source as `Property` or `Input port`. When you select `Property`, the object reads the codebook from the `codebook` property. When you select `Input port`, the object reads the codebook from the input of the `step` method.

The default is `Property`.

Codebook

codebook

Specify quantized output values as a *k*-by-*N* matrix, where $k \geq 1$ and $N \geq 1$. Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. This property applies when you set the `CodebookSource` property to `Property`. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as: `Same as input`, `double`, `single` or `Custom`. This property applies only when you set `CodebookSource` to `Property`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numerictype` object. This property applies only when you set the `OutputDataType` property to `Custom`. The default is `numerictype(true,16)`.

Methods

clone	Create vector quantizer decoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Perform vector quantization decoding

Examples

Given index values as an input, determine the corresponding vector quantized codewords for a specified codebook:

```
hvqdec = dsp.VectorQuantizerDecoder;
hvqdec.Codebook = [1 10 100;2 20 200;3 30 300];
indices = uint8([1 0 2 0]);
qout = step(hvqdec, indices)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Decoder block reference page. The object properties correspond to the block parameters, except:

There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than `0` to `0` and any index values greater than or equal to *N* to *N*-1.

See Also

`dsp.VectorQuantizerEncoder` | `dsp.ScalarQuantizerDecoder`

dsp.VectorQuantizerDecoder.clone

Purpose

Create vector quantizer decoder object with same property values

Syntax

Description

`C = clone(H)` creates a `VectorQuantizerDecoder` object `C`, with the same property values as `H`. The `clone` method creates a new unlocked object with uninitialized states.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.VectorQuantizerDecoder.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `VectorQuantizerDecoder` object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.VectorQuantizerDecoder.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Perform vector quantization decoding

Syntax

```
Q = step(H,I)
Q = step(H,I,C)
```

Description

`Q = step(H,I)` returns the quantized output values `Q` corresponding to the input indices `I`. The data type of `I` can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type of `Q`.

`Q = step(H,I,C)` uses input `C` as the `codebook` values when the `CodebookSource` property is `Input port`. The data type of `C` can be `double`, `single`, or `fixed-point`. The output `Q` has the same data type as the `codebook` input `C`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.VectorQuantizerEncoder

Purpose

Vector quantization encoding

Description

The `VectorQuantizerEncoder` object performs vector quantization encoding. The object finds the nearest codeword by computing a distortion based on Euclidean or weighted Euclidean distance.

To perform vector quantization encoding:

1. Define and set up your vector quantizer encoder. See "Construction" on page 3-1762.
2. Call `step` to perform the quantization encoding according to the properties of `dsp.VectorQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.VectorQuantizerEncoder` returns a vector quantizer encoder System object, `H`. This object finds a zero-based index of the nearest codeword for each given input column vector.

`H = dsp.VectorQuantizerEncoder('PropertyName',PropertyValue,...)` returns a vector quantizer encoder System object, `H`, with each specified property set to the specified value.

Properties

CodebookSource

Source of codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

Codebook

Codebook

Specify the codebook to which the input column vector or matrix is compared, as a *k*-by-*N* matrix. Each column of the codebook matrix is a codeword, and each codeword corresponds to an index value. The codeword vectors must have the same number of rows as the input. The first codeword vector corresponds to an index

value of `0`, the second codeword vector corresponds to an index value of `1`, and so on. This property applies when you set the `CodebookSource` property to `Property`. The default is:

$$\begin{bmatrix} 1.5 & 13.3 & 136.4 & 6.8 \\ 2.5 & 14.3 & 137.4 & 7.8 \\ 3.5 & 15.3 & 138.4 & 8.8 \end{bmatrix}$$

This property is tunable.

DistortionMeasure

Distortion calculation method

Specify how to calculate the distortion as `Squared error` or `Weighted squared error`. If you set this property to `Squared error`, the object calculates the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. If you set this property to `Weighted squared error`, the object calculates the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values. The default is `Squared error`.

WeightsSource

Source of weighting factor

Specify how to determine weighting factor as `Property` or `Input port`. This property applies when you set the `DistortionMeasure` property to `Weighted squared error`. The default is `Property`.

Weights

Weighting factor

Specify the weighting factor as a vector of length equal to the number of rows of the input. This property applies when you set the `DistortionMeasure` property to `Weighted squared error` and `WeightsSource` property is `Property`. The default is [1 1 1]. This property is tunable.

TiebreakerRule

Behavior when input column vector is equidistant from two codewords.

Specify whether to represent the input column vector by the lower index valued codeword or higher indexed valued codeword when an input column vector is equidistant from two codewords. You can set this property to `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

CodewordOutputPort

Enable output of codeword value

Set this property to `true` to output the codeword vectors nearest to the input column vectors. The default is `false`.

QuantizationErrorOutputPort

Enable output of quantization error

Set this property to `true` to output the quantization error value that results when the object represents the input column vector by the nearest codeword. The default is `false`.

OutputIndexDataType

Data type of index output

Specify the data type of the index output as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Same as input`, or `Custom`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to`Custom`.

Methods

clone	Create vector quantizer encoder object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method

isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Perform vector quantization encoding

Examples

Find the indices of nearest codewords based on Euclidean distances:

```
hvqenc = dsp.VectorQuantizerEncoder(...
'Codebook', [-1 -1 1 1;1 -1 -1 1], ...
'CodewordOutputPort', true, ...
'QuantizationErrorOutputPort', true, ...
'OutputIndexDataType', 'uint8');
% Generate an input signal with some additive noise
x = sign(rand(2,40)-0.5) + 0.1*randn(2,40);
[ind, cw, err] = step(hvqenc, x);
plot(cw(1,:), cw(2,:), 'rO', x(1,:), x(2,:), 'g.');
legend('Quantized', 'Inputs', 'location', 'best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Vector Quantizer Encoder block reference page. The object properties correspond to the block parameters.

See Also

`dsp.VectorQuantizerDecoder` | `dsp.ScalarQuantizerEncoder`

Purpose

Create vector quantizer encoder object with same property values

Syntax

Description

`C = clone(H)` creates a `VectorQuantizerEncoder` object `C`, with the same property values as `H`. The clone method creates a new unlocked object.

dsp.VectorQuantizerEncoder.getNumInputs

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

dsp.VectorQuantizerEncoder.isLocked

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the `VectorQuantizerEncoder` System object `H`.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

---

dsp.VectorQuantizerEncoder.step

Purpose

Perform vector quantization encoding

Syntax

```
INDEX = step(H,INPUT)
INDEX = step(H,...,CODEBOOK)
INDEX = step(H,...,WEIGHTS)
[..., CODEWORD] = step(H, ...)
[..., QERR] = step(H, ...)
```

Description

`INDEX = step(H,INPUT)` returns `INDEX`, a scalar or column vector representing the quantization region(s) to which `INPUT` belongs. `INPUT` can be a column vector of size *k*-by-1 or an *M* multichannel matrix of dimensions *k*-by-*M*, where k is the length of each codeword in the codebook. All inputs to the object can be real floating-point or fixed-point values and must be of the same data type. The output index values can be signed or unsigned integers.

`INDEX = step(H,...,CODEBOOK)` uses the codebook given in input `CODEBOOK`, a *k*-by-*N* matrix with *N* codewords each of length *k*. This option is available when the `CodebookSource` property is `Input port`.

`INDEX = step(H,...,WEIGHTS)` uses the input vector `WEIGHTS` to emphasize or de-emphasize certain input values when calculating the distortion measure. `WEIGHTS` must be a vector of length equal to the number of rows of `INPUT`. This option is available when the `DistortionMeasure` property is `Weighted squared error` and the `WeightsSource` property is `Input port`.

`[..., CODEWORD] = step(H, ...)` outputs the `CODEWORD` values that correspond to each index value when the `CodewordOutputPort` property is `true`.

`[..., QERR] = step(H, ...)` outputs the quantization error `QERR` for each input value when the `QuantizationErrorOutputPort` property is `true`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

.

dsp.Window

Purpose

Window object

Description

The `Window` object applies a window to an input signal.

To apply a window to an input signal:

1. Define and set up your window. See "Construction" on page 3-1774.
2. Call `step` to apply the window according to the properties of `dsp.Window`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.Window` returns a window object, `H`, that applies a Hamming window with symmetric sampling.

`H = dsp.Window('PropertyName',PropertyValue, ...)` returns a window object, `H`, with each property set to the specified value.

`H = dsp.Window(WINDOW,'PropertyName',PropertyValue, ...)` returns a window object, `H`, with the `WindowFunction` property set to `WINDOW` and other properties set to the specified values.

Properties

WindowFunction

Type of window

Specify the type of window to apply as `Bartlett`, `Blackman`, `Boxcar`, `Chebyshev`, `Hamming` , `Hann`, `Hanning`, `Kaiser`, `Taylor`, `Triang`. This property is tunable. The default is `Hamming`.

WeightsOutputPort

Enable the output of window weights

Set this property to `true` to output the window weights. The weights are an *M*-by-1 vector with *M* equal to the first dimension of the input. The default is `false`.

StopbandAttenuation

Level of stopband attenuation in decibels

Specify the level of stopband attenuation in decibels. This property only applies when the `WindowFunction` property is `Chebyshev`. The default is 50. This property is tunable.

Beta

Kaiser window parameter

Specify the Kaiser window parameter as a real number. Increasing the absolute value of `Beta` widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This property only applies when `WindowFunction` property is `Kaiser`. The default is 10. This property is tunable.

NumConstantSidelobes

Number of constant sidelobes

Specify the number of constant sidelobes as an integer greater than zero. This property only applies when `WindowFunction` property is `Taylor`. The default is 4. This property is tunable.

MaximumSidelobeLevel

Maximum sidelobe level relative to mainlobe

Specify, in decibels, the maximum sidelobe level relative to the mainlobe as a real number less than or equal to zero. The default is –30, which produces sidelobes with peaks 30 dB down from the mainlobe peak. This property only applies when `WindowFunction` property is `Taylor`. This property is tunable.

Sampling

Window sampling for generalized-cosine windows

Specify the window sampling for generalized-cosine windows as `Symmetric` or `Periodic`. This property only applies when `WindowFunction` property is `Blackman`, `Hamming`, `Hann`, or `Hanning`. This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

WindowDataType

Window word and fraction lengths

Specify the window fixed-point data type as one of `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomWindowDataType

Window word and fraction lengths

Specify the window fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `WindowDataType` property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Output data type

Specify the output fixed-point data type as one of `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you

set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

clone	Create window object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Multiply input by window

Examples

Apply Hamming window to input signal:

```
 hwin = dsp.Window( ...
'WindowFunction', 'Hamming', ...
'WeightsOutputPort',true);
 x = rand(64,1);
[y, w] = step(hwin, x);
% View the window's time and frequency domain responses
wvtool(w);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Window Function block reference page. The object properties correspond to the block parameters, except:

- **Operation** — The window object does not support the `Generate window` option.
- **Operation** — The `Generate and apply window` option on the block corresponds to the `WeightsOutputPort` property set to `true` on the window object.

- The window object only supports frame-based processing.

dsp.Window.clone

Purpose

Create window object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a window object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.Window.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of the `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the window object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.Window.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Multiply input by window

Syntax

```
Y = step(H,X)
[Y, W] = step(H,X)
```

Description

`Y = step(H,X)` generates the windowed output, `Y` , of the input, `X`, using the specified window.

`[Y, W] = step(H,X)` returns the window values `W` when the `WeightsOutputPort` property is `true`.

dsp.ZeroCrossingDetector

Purpose

Zero crossing detector

Description

The `ZeroCrossingDetector` object counts the number of times the signal crosses zero, or changes sign. The zero crossing detector supports both floating-point and fixed-point data types.

To count the number of times a signal crosses zero or changes sign:

1. Define and set up your zero crossing detector. See "Construction" on page 3-1786.
2. Call `step` to count the number of times according to the properties of `dsp.ZeroCrossingDetector`. The behavior of `step` is specific to each object in the toolbox.

Construction

`H = dsp.ZeroCrossingDetector` returns a zero crossing detector object, `H`, that counts the number of zero crossings in the real-valued,, floating-point, or fixed-point frame-based vector or matrix.

`H = dsp.ZeroCrossingDetector('PropertyName',PropertyValue, ...)` returns a zero crossing detector object, `H`, with each property set to the specified value.

Properties

FrameBasedProcessing

Enable frame-based processing

Set this property to `true` to enable frame-based processing. Set this property to `false` to enable sample-based processing. The default is `true`.

If the `FrameBasedProcessing` property is `true`:

- The zero crossing detector treats a column vector or the columns of a matrix as single, independent channels.
- The zero crossing detector treats a length N row vector as N independent channels.

If the `FrameBasedProcessing` property is `false`:

- The zero crossing detector treats each entry of a vector or matrix as an independent channel.

Methods

clone	Create zero crossing detection object with same property values
getNumInputs	Number of expected inputs to step method
getNumOutputs	Number of outputs of step method
isLocked	Locked status for input attributes and nontunable properties
release	Allow property value and input characteristics changes
step	Count zero crossings in input

Examples

Find number of zero crossings in electrocardiogram data:

```
EcgData = ecg(500)';
Hzerocross = dsp.ZeroCrossingDetector;
NumZeroCross = step(Hzerocross,EcgData);  % Equal to 4
plot(1:500,EcgData,'b',[0 500],[0 0],'r','linewidth',2);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Zero Crossing block reference page. The object properties correspond to the block parameters.

Both this object and its corresponding block let you specify whether to process inputs as individual samples or as frames of data. The object uses the `FrameBasedProcessing` property. The block uses the **Input processing** parameter. See “Set the FrameBasedProcessing Property of a System object” for more information.

dsp.ZeroCrossingDetector.clone

Purpose

Create zero crossing detection object with same property values

Syntax

```
C = clone(H)
```

Description

`C = clone(H)` creates a zero crossing detector object, `C`, with the same property values as `H`. The clone method creates a new unlocked object.

Purpose

Number of expected inputs to step method

Syntax

```
N = getNumInputs(H)
```

Description

`N = getNumInputs(H)` returns the number of expected inputs, `N`, to the `step` method.

The `getNumInputs` method returns a positive integer that is the number of expected inputs (not counting the object itself) to the `step` method. This value will change if you alter any properties that turn inputs on or off. You must call the `step` method with the number of input arguments equal to the result of `getNumInputs(H)`.

dsp.ZeroCrossingDetector.getNumOutputs

Purpose

Number of outputs of step method

Syntax

```
N = getNumOutputs(H)
```

Description

`N = getNumOutputs(H)` returns the number of outputs, `N`, of `step` method.

The `getNumOutputs` method returns a positive integer that is the number of outputs from the `step` method. This value will change if you alter any properties that turn outputs on or off.

Purpose

Locked status for input attributes and nontunable properties

Syntax

```
isLocked(H)
```

Description

`isLocked(H)` returns the locked state of the zero crossing detector object.

The `isLocked` method returns a logical value that indicates whether input attributes and nontunable properties for the object are locked. The object performs an internal initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. After locking, the `isLocked` method returns a `true` value.

dsp.ZeroCrossingDetector.release

Purpose

Allow property value and input characteristics changes

Syntax

```
release(H)
```

Description

`release(H)` releases system resources, such as memory, file handles, and hardware connections, and lets you change any properties or input characteristics.

Note You can use the `release` method on a System object in code generated from MATLAB, but once you release its resources, you cannot use that System object again.

Purpose

Count zero crossings in input

Syntax

```
Y = step(H,X)
```

Description

`Y = step(H,X)` counts the number of zero crossings, `Y`, in the vector or matrix input `X`.

Note The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

matlab.System

Purpose

Base class for System objects

Description

`matlab.System` is the base class for System objects. In your class definition file, you must subclass your object from this base class (or from another class that derives from this base class). Subclassing allows you to use the implementation and service methods provided by this base class to build your object. Type this syntax as the first line of your class definition file to directly inherit from the `matlab.System` base class, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.System
```

Note You must set `Access=protected` for each `matlab.System` method you use in your code.

Methods

cloneImpl	Copy System object
getDiscreteStateImpl	Discrete state property values
getInputNamesImpl	Names of the input ports of the System block
getNumInputsImpl	Number of input arguments passed to step and setup methods
getNumOutputsImpl	Number of outputs returned by method
getOutputNamesImpl	Names of System block output ports
infoImpl	Information about System object
isInactivePropertyImpl	Active or inactive flag for properties
loadObjectImpl	Load saved System object from MAT file

processTunedPropertiesImpl	Action when tunable properties change
releaseImpl	Release resources
resetImpl	Reset System object states
saveObjectImpl	Save System object in MAT file
setProperties	Set property values from name-value pair inputs
setupImpl	Initialize System object
stepImpl	System output and state update equations
validateInputsImpl	Validate inputs to step method
validatePropertiesImpl	Validate property values

Attributes

In addition to the attributes available for MATLAB objects, you can apply the following attributes to any property of a custom System object.

`Nontunable`	After an object is locked (after `step` or `setup` has been called), use `Nontunable` to prevent a user from changing that property value. By default, all properties are tunable. The `Nontunable` attribute is useful to lock a property that has side effects when changed. This attribute is also useful for locking a property value assumed to be constant during processing. You should always specifiy properties that affect the number of input or output ports as `Nontunable`.
`Logical`	Use `Logical` to limit the property value to a logical, scalar value. Any scalar value that can be converted to a logical is also valid, such as 0 or 1.

`PositiveInteger`	Use `PositiveInteger` to limit the property value to a positive integer value.
`DiscreteState`	Use `DiscreteState` to mark a property so it will display its state value when you use the `getDiscreteState` method.

To learn more about attributes, see "Property Attributes" in the MATLAB Object-Oriented Programming documentation.

Examples

Create a Basic System Object

Create a simple System object, `AddOne`, which subclasses from `matlab.System`. You place this code into a MATLAB file, `AddOne.m`.

```
classdef AddOne < matlab.System
%ADDONE Compute an output value that increments the input by one

    methods (Access=protected)
       % stepImpl method is called by the step method.
       function y = stepImpl(~,x)
          y = x + 1;
       end
    end
end
```

Use this object by creating an instance of `AddOne`, providing an input, and using the `step` method.

```
hAdder = AddOne;
x = 1;
y = step(hAdder,x)
```

Assign the `Nontunable` attribute to the `InitialValue` property, which you define in your class definition file.

```
properties (Nontunable)
   InitialValue
```

```
end
```

How To

- "Object-Oriented Programming"
- Class Attributes
- Property Attributes
- "Method Attributes"
- "Define Basic System Objects"
- "Define Property Attributes"

matlab.System.cloneImpl

Purpose

Copy System object

Syntax

```
cloneImpl(obj)
```

Description

`cloneImpl(obj)` copies a System object by using the `saveObjectImpl` and `loadObjectImpl` methods. The default `cloneImpl` copies an object and its current state but does not copy any private or protected properties. If the object you clone is locked and you use the default `cloneImpl`, the new object will also be locked. If you define your own `cloneImpl` and the associated `saveObjectImpl` and `loadObjectImpl`, you can specify whether to clone the object's state and whether to clone the object's private and protected properties.

`cloneImpl` is called by the `clone` method.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle of object to clone.

Examples

Clone a System Object

Use the `cloneImpl` method in your class definition file to copy a System object

```
methods (Access=protected)
   function obj2 = cloneImpl(obj1)
      s = saveObject (obj1);
      obj2 = loadObject(s);
   end
end
```

See Also

`saveObjectImpl` | `loadObjectImpl`

How To

- “Clone System Object”

matlab.System.getDiscreteStateImpl

Purpose

Discrete state property values

Syntax

```
s = getDiscreteStateImpl(obj)
```

Description

`s = getDiscreteStateImpl(obj)` returns a struct `s` of state values. The field names of the struct are the object's `DiscreteState` property names. To restrict or change the values returned by `getDiscreteState` method, you can override this `getDiscreteStateImpl` method.

`getDiscreteStatesImpl` is called by the `getDiscreteState` method, which is called by the `setup` method.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

s

Struct of state values.

Examples

Get Discrete State Values

Use the `getDiscreteStateImpl` method in your class definition file to get the discrete states of the object.

```
methods (Access=protected)
   function s = getDiscreteStateImpl(obj)
   end
end
```

See Also

`setupImpl`

How To

- “Define Property Attributes”

matlab.System.getInputNamesImpl

Purpose

Names of the input ports of the System block

Syntax

```
[name1,name2,...] = getInputNamesImpl(obj)
```

Description

`[name1,name2,...] = getInputNamesImpl(obj)` returns the names of the input ports to System object, `obj` implemented in a MATLAB System block. The number of returned input names matches the number of inputs returned by the `getNumInputs` method. If you change a property value that changes the number of inputs, the names of those inputs also change.

`getInputNamesImpl` is called by the `getInputNames` method by the MATLAB System block.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

Output Arguments

name1,name2,...

Names of the inputs for the specified object.

Default: empty string

Examples

Specify Input Port Name

Specify in your class definition file the names of two input ports as `'upper'` and `'lower'`.

```
methods (Access=protected)
   function varargout = getInputNamesImpl(obj)
      numInputs = getNumInputs(obj);
      varargout = cell(1,numInputs);
      varargout{1} = 'upper';
```

```
        if numInputs > 1
           varargout{2} = 'lower';
        end
     end
end
```

See Also

`getNumInputsImpl` | `getOutputNamesImpl`

How To

- “Validate Property and Input Values”

matlab.System.getNumInputsImpl

Purpose

Number of input arguments passed to step and setup methods

Syntax

```
num = getNumInputsImpl(obj)
```

Description

`num = getNumInputsImpl(obj)` returns the number of inputs `num` (excluding the System object handle) expected by the `step` method.

If your `step` method has a variable number of inputs (uses `varargin`), you should implement the `getNumInputsImpl` method in your class definition file. If the number of inputs expected by the `step` method is fixed (does not use `varargin`), the default `getNumInputsImpl` determines the required number of inputs directly from the `step` method. In this case, you do not need to include `getNumInputsImpl` in your class definition file.

`getNumInputsImpl` is called by the `getNumInputs` method and by the `setup` method if the number of inputs has not been determined already.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

num

Number of inputs expected by the `step` method for the specified object.

Default: 1

Examples

Set Number of Inputs

Specify the number of inputs (2, in this case) expected by the `step` method.

```
methods (Access=protected)
   function num = getNumInputsImpl(obj)
      num = 2;
   end
end
```

Set Number of Inputs to Zero

Specify that the `step` method will not accept any inputs.

```
methods (Access=protected)
   function num = getNumInputsImpl(~)
      num = 0;
   end
end
```

See Also

`setupImpl` | `stepImpl` | `getNumOutputsImpl` | `getNumOutputsImpl`

How To

- "Change Number of Step Inputs or Outputs"

matlab.System.getNumOutputsImpl

Purpose

Number of outputs returned by `step` method

Syntax

```
num = getNumOutputsImpl (obj)
```

Description

`num = getNumOutputsImpl (obj)` returns the number of outputs from the `step` method. The default implementation returns 1 output. To specify a value other than 1, you must use include the `getNumOutputsImpl` method in your class definition file.

`getNumOutputsImpl` is called by the `getNumOutputs` method, if the number of outputs has not been determined already.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

num

Number of outputs to be returned by the `step` method for the specified object.

Examples

Set Number of Outputs

Specify the number of outputs (2, in this case) returned from the `step` method.

```
methods (Access=protected)
   function num = getNumOutputsImpl(obj)
      num = 2;
   end
end
```

Set Number of Outputs to Zero

Specify that the `step` method does not return any outputs.

```
methods (Access=protected)
   function num = getNumOutputsImpl(~)
      num = 0;
   end
end
```

See Also

`stepImpl` | `getNumInputsImpl` | `setupImpl`

How To

- "Change Number of Step Inputs or Outputs"

matlab.System.getOutputNamesImpl

Purpose

Names of System block output ports

Syntax

```
[name1,name2,...] = getOutputNamesImpl(obj)
```

Description

`[name1,name2,...] = getOutputNamesImpl(obj)` returns the names of the output ports from System object, `obj` implemented in a MATLAB System block. The number of returned output names matches the number of outputs returned by the `getNumOutputs` method. If you change a property value that affects the number of outputs, the names of those outputs also change.

`getOutputNamesImpl` is called by the `getOutputNames` method and by the MATLAB System block.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

Output Arguments

name1,name2,...

Names of the outputs for the specified object.

Default: empty string

Examples

Specify Output Port Name

Specify the name of an output port as `'count'`.

```
methods (Access=protected)
   function outputName = getOutputNamesImpl(~)
      outputName = 'count';
   end
end
```

See Also

`getNumOutputsImpl` | `getInputNamesImpl`

How To

- "Validate Property and Input Values"

matlab.System.infoImpl

Purpose

Information about System object

Syntax

```
s = infoImpl(obj,varargin)
```

Description

`s = infoImpl(obj,varargin)` lets you set up information to return about the current configuration of a System object `obj`. This information is returned in a struct from the `info` method. The `varargin` argument is optional. The default `infoImpl` method, which is used if you do not include `infoImpl` in your class definition file, returns an empty struct.

`infoImpl` is called by the `info` method.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

varargin

Allows variable number of inputs

Examples

Define info for System object

Define the `infoImpl` method to return current count information for `info(obj)`.

```
methods (Access=protected)
   function s = infoImpl(obj)
      s = struct('Count',obj.pCount);
   end
end
```

How To

- "Define System Object Information"

Purpose

Active or inactive flag for properties

Syntax

```
flag = isInactivePropertyImpl(obj,prop)
```

Description

`flag = isInactivePropertyImpl(obj,prop)` specifies whether a public, non-state property is inactive for the current object configuration. An *inactive property* is a property that is not relevant to the object, given the values of other properties. Inactive properties are not shown if you use the `disp` method to display object properties. If you attempt to use public access to directly access or use `get` or `set` on an inactive property, a warning occurs.

`isInactiveProperty` is called by the `disp` method and by the `get` and `set` methods.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

prop

Public, non-state property name

Output Arguments

flag

Logical scalar value indicating whether the input property `prop` is inactive for the current object configuration.

Examples

Set Inactive Property

Display the `InitialValue` property only when the `UseRandomInitialValue` property value is `false`.

```
methods (Access=protected)
  function flag = isInactivePropertyImpl(obj,propertyName)
```

```
    if strcmp(propertyName,'InitialValue')
      flag = obj.UseRandomInitialValue;
    else
      flag = false;
    end
  end
end
```

See Also

`setProperties`

How To

- “Hide Inactive Properties”

Purpose

Load saved System object from MAT file

Syntax

```
loadObjectImpl(obj)
```

Description

`loadObjectImpl(obj)` loads a saved System object, `obj`, from a MAT file. Your `loadObjectImpl` method should correspond to your `saveObjectImpl` method to ensure that all saved properties and data are loaded.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

Examples

Load System Object

Load a saved System object. In this case, the object contains a child object, protected and private properties, and a discrete state.

```
methods(Access=protected)
   function loadObjectImpl(obj, s, wasLocked)
      % Load child System objects
      obj.child = matlab.System.loadObject(s.child);

      % Save protected & private properties
      obj.protected = s.protected;
      obj.pdependentprop = s.pdependentprop;

      % Save state only if locked when saved
      if wasLocked
        obj.state = s.state;
      end

      % Call base class method
```

```
        loadObjectImpl@matlab.System(obj,s,wasLocked);
    end
  end
```

See Also

`saveObjectImpl`

How To

- “Load System Object”
- “Save System Object”

Purpose

Action when tunable properties change

Syntax

```
processTunedPropertiesImpl(obj)
```

Description

`processTunedPropertiesImpl(obj)` specifies the actions to perform when one or more tunable property values change. This method is called as part of the next call to the `step` method after a tunable property value changes. A property is tunable only if its `Nontunable` attribute is `false`, which is the default.

`processTunedPropertiesImpl` is called by the `step` method.

Note You must set `Access=protected` for this method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Tips

Use this method when a tunable property affects a different property value. For example, two property values determine when to calculate a lookup table. You want to perform that calculation when either property changes. You also want the calculation to be done only once if both properties change before the next call to the `step` method.

Input Arguments

obj

System object handle

Examples

Specify Action When Tunable Property Changes

Use `processTunedPropertiesIempl` to recalculate the lookup table if the value of either the `NumNotes` or `MiddleC` property changes.

```
methods (Access=protected)
   function processTunedPropertiesImpl(obj)
      % Generate a lookup table of note frequencies
      obj.pLookupTable = obj.MiddleC * (1+log(1:obj.NumNotes)/log(12))
```

```
    end
end
```

See Also

`validatePropertiesImpl` | `setProperties`

How To

- “Validate Property and Input Values”
- “Define Property Attributes”

Purpose

Release resources

Syntax

```
releaseImpl(obj)
```

Description

`releaseImpl(obj)` releases any resources used by the System object, such as file handles. This method also performs any necessary cleanup tasks. To release resources for a System object, you must use `releaseImpl` instead of a destructor.

`releaseImpl` is called by the `release` method. `releaseImpl` is also called when the object is deleted or cleared from memory, or when all references to the object have gone out of scope.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

Examples

Close a File and Release Its Resources

Use the `releaseImpl` method to close a file.

```
methods (Access=protected)
   function releaseImpl(obj)
     fclose(obj.pFileID);
   end
end
```

See Also

`resetImpl`

How To

- "Release System Object Resources"

matlab.System.resetImpl

Purpose

Reset System object states

Syntax

```
resetImpl(obj)
```

Description

`resetImpl(obj)` defines the state reset equations for the System object. Typically you reset the states to a set of initial values. This is useful for initialization at the start of simulation.

`resetImpl` is called by the `reset` method. It is also called by the `setup` method, after the `setupImpl` method.

Note You must set `Access=protected` for this method.

Do not use `resetImpl` to initialize or reset properties. For properties, use the `setupImpl` method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Input Arguments

obj

System object handle

Examples

Reset Property Value

Use the `reset` method to reset the counter `pCount` property to zero.

```
methods (Access=protected)
   function resetImpl(obj)
      obj.pCount = 0;
   end
end
```

See Also

`releaseImpl`

How To

- "Reset Algorithm State"

Purpose

Save System object in MAT file

Syntax

```
saveObjectImpl(obj)
```

Description

`saveObjectImpl(obj)` defines what System object `obj` property and state values are saved in a MAT file when a user calls `save` on that object. `save` calls `saveObject`, which then calls `saveObjectImpl`. If you do not define a `saveObjectImpl` method for your System object class, only public properties and properties with the `DiscreteState` attribute are saved. To save any private or protected properties or state information, you must define a `saveObjectImpl` in your class definition file.

You should save the state of an object only if the object is locked. When the user loads that saved object, it loads in that locked state.

To save child object information, you use the associated `saveObject` method within the `saveObjectImpl` method.

End users can use `load`, which calls `loadObjectImpl` to load a System object into their workspace.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

Examples

Define Property and State Values to Save

Define what is saved for the System object. Call the base class version of `saveObjectImpl` to save public properties. Then, save any child System objects and any protected and private properties. Finally, save the state, if the object is locked.

```
methods(Access=protected)
   function s = saveObjectImpl(obj)
```

```
            s = saveObjectImpl@matlab.System(obj);
            s.child = matlab.System.saveObject(obj.child);
            s.protected = obj.protected;
            s.pdependentprop = obj.pdependentprop;
            if isLocked(obj)
               s.state = obj.state;
            end
         end
      end
```

See Also

`loadObjectImpl`

How To

- "Save System Object"
- "Load System Object"

Purpose

Set property values from name-value pair inputs

Syntax

```
setProperties(obj,numargs,name1,value1,name2,value2,...)
setProperties(obj,numargs,arg1,...,argm,name1,value1,name2,value2,...
   'ValueOnlyPropName1','ValueOnlyPropName2',...,
   'ValueOnlyPropNamem')
```

Description

`setProperties(obj,numargs,name1,value1,name2,value2,...)` provides the name-value pair inputs to the System object constructor. Use this syntax if every input must specify both name and value.

Note To allow standard name-value pair handling at construction, define `setProperties` for your System object.

`setProperties(obj,numargs,arg1,...,argm,name1,value1,name2,value2,...
'ValueOnlyPropName1','ValueOnlyPropName2',...,
'ValueOnlyPropNamem')` provides the value-only inputs, followed by the name-value pair inputs to the System object during object construction. Use this syntax if you want to allow users to specify one or more inputs by their values only.

Input Arguments

obj

System objectSystem object handle

numargs

Number of inputs passed in by the object constructor

name1,name2,...

Name of property

value1,value2,...

Value of the property

arg1,arg2,...

Value of property (for value-only input to the object constructor)

ValueOnlyPropName1,ValueOnlyPropName2,...

Name of the value-only property

Examples

Setup Value-Only Inputs

Set up an object so users can specify value-only inputs for `VProp1`, `VProp2`, and other property values via name-value pairs when constructing the object. In this example, `VProp1` and `VProp2` are the names of value-only properties.

```
methods
   function obj = MyFile(varargin)
      setProperties(obj,nargin,varargin{:},'VProp1','VProp2');
   end
end
```

How To

- "Set Property Values at Construction Time"

Purpose

Initialize System object

Syntax

```
setupImpl(obj)
setupImpl(obj,input1,input2,...)
```

Description

`setupImpl(obj)` sets up a System object and implements one-time tasks that do not depend on any inputs to the `stepImpl` method for this object. To acquire resources for a System object, you must use `setupImpl` instead of a constructor. `setupImpl` executes the first time the `step` method is called on an object after that object has been created. It also executes the next time `step` is called after an object has been released. You typically use `setupImpl` to set private properties so they do not need to be calculated each time `stepImpl` method is called.

`setupImpl(obj,input1,input2,...)` sets up a System object using one or more of the `stepImpl` input specifications. The number and order of inputs must match the number and order of inputs defined in the `stepImpl` method. You pass the inputs into `setupImpl` to use the specifications, such as size and datatypes in the one-time calculations. You do not use the `setupImpl` method to set up input values.

`setupImpl` is called by the `setup` method, which is done automatically as the first subtask of the `step` method on an unlocked System object.

Note You can omit this method from your class definition file if your System object does not require any setup tasks.

You must set `Access=protected` for this method.

Do not use `setupImpl` to initialize or reset states. For states, use the `resetImpl` method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Tips

To validate properties or inputs use the `validatePropertiesImpl`, `validateInputsImpl`, or `setProperties` methods. Do not include validation in `setupImpl`.

Input Arguments

obj

System object handle

input1,input2,...

Inputs to the `stepImpl` method

Examples

Setup a File for Writing

This example shows how to open a file for writing using the `setupImpl` method in your class definition file.

```
methods (Access=protected)
   function setupImpl(obj)
      obj.pFileID = fopen(obj.Filename,'wb');
      if obj.pFileID < 0
         error('Opening the file failed');
       end
    end
end
```

Check input size

This examples shows how to use `setupImpl` to check that the size of a `stepImpl` method input matches the size of a state property.

```
properties (Access = private)
     myState = [1 2];
  end

  methods (Access = protected)
     function setupImpl(obj,u)
        if any(size(obj.myState) ~= size(u))
           error('Size of "myState" does not match size of input "u"');
        end
```

```
    end

    function y = stepImpl(obj,u)
       y = obj.myState;
       obj.myState = u;
    end
  end
end
```

How To

- "Initialize Properties and Setup One-Time Calculations"
- "Set Property Values at Construction Time"

matlab.System.stepImpl

Purpose

System output and state update equations

Syntax

```
[output1,output2,...] = stepImpl(obj,input1,input2,...)
```

Description

`[output1,output2,...] = stepImpl(obj,input1,input2,...)` defines the algorithm to execute when you call the `step` method on the specified object `obj`. The `step` method calculates the outputs and updates the object's state values using the inputs, properties, and state update equations.

`stepImpl` is called by the `step` method.

Note You must set `Access=protected` for this method.

Tips

The number of input arguments and output arguments must match the values returned by the `getNumInputsImpl` and `getNumOutputsImpl` methods, respectively

Input Arguments

obj

System object handle

input1,input2,...

Inputs to the `step` method

Output Arguments

output

Output returned from the `step` method.

Examples

Specify System Object Algorithm

Use the `stepImpl` method to increment two numbers.

```
methods (Access=protected)
   function [y1,y2] = stepImpl(obj,x1,x2)
      y1 = x1 + 1;
```

```
      y2 = x2 + 1;
    end
end
```

See Also

`getNumInputsImpl` | `getNumOutputsImpl` | `validateInputsImpl`

How To

- “Define Basic System Objects”
- “Change Number of Step Inputs or Outputs”

matlab.System.validateInputsImpl

Purpose

Validate inputs to step method

Syntax

```
validateInputsImpl(obj,input1,input2,...)
```

Description

`validateInputsImpl(obj,input1,input2,...)` validates inputs to the `step` method at the beginning of initialization. Validation includes checking data types, complexity, cross-input validation, and validity of inputs controlled by a property value.

`validateInputsImpl` is called by the `setup` method before `setupImpl`. `validateInputsImpl` executes only once.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method. Use the `processTunedPropertiesImpl` method or `setupImpl` method to modify properties.

Input Arguments

obj

System object handle

input1,input2,...

Inputs to the `setup` method

Examples

Validate Input Type

Validate that the input is numeric.

```
methods (Access=protected)
   function validateInputsImpl(~,x)
      if ~isnumeric(x)
         error('Input must be numeric');
      end
   end
end
```

See Also

`validatePropertiesImpl` | `setupImpl`

How To

- "Validate Property and Input Values"

matlab.System.validatePropertiesImpl

Purpose

Validate property values

Syntax

```
validatePropertiesImpl(obj)
```

Description

`validatePropertiesImpl(obj)` validates interdependent or interrelated property values at the beginning of object initialization, such as checking that the dependent or related inputs are the same size.

`validatePropertiesImpl` is the first method called by the `setup` method. `validatePropertiesImpl` also is called before the `processTunablePropertiesImpl` method.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method. Use the `processTunedPropertiesImpl` method or `setupImpl` method to modify properties.

Input Arguments

obj

System object handle

Examples

Validate a Property

Validate that the `useIncrement` property is `true` and that the value of the `increment` property is greater than zero.

```
methods (Access=protected)
   function validatePropertiesImpl(obj)
      if obj.useIncrement && obj.increment < 0
         error('The increment value must be positive');
      end
    end
end
```

`processTunedPropertiesImpl` | `setupImpl` | `validateInputsImpl`

How To

- "Validate Property and Input Values"

matlab.system.display.Header

Purpose

Header for System objects properties

Syntax

```
matlab.system.display.Header(N1,V1,...Nn,Vn)
matlab.system.display.Header(Obj,...)
```

Description

`matlab.system.display.Header(N1,V1,...Nn,Vn)` defines a header for the System object, with the header properties defined in Name-Value (N,V) pairs. You use `matlab.system.display.Header` within the `getHeaderImpl` method. The available header properties are

- `Title` — Header title string. The default value is an empty string.
- `Text` — Header description text string. The default value is an empty string.
- `ShowSourceLink` — Show link to source code for the object.

`matlab.system.display.Header(Obj,...)` creates a header for the specified System object (`Obj`) and sets the following property values:

- `Title` — Set to the `Obj` class name.
- `Text` — Set to help summary for `Obj`.
- `ShowSourceLink` — Set to `true` if `Obj` is MATLAB code. In this case, the **Source Code** link is displayed. If `Obj` is P-coded and the source code is not available, set this property to `false`.

You can use `mfilename('class')` from within this method to get the name of the System object. If you set any Name-Value pairs, those property values override the default settings.

Methods

getHeaderImpl	Header for System object display

Examples

Define System Block Header

Define a header in your class definition file.

```
methods(Static,Access=protected)
   function header = getHeaderImpl
      header = matlab.system.display.Header(mfilename('class'), ...
          'Title','AlternativeTitle',...
          'Text','An alternative class description');
   end
end
```

The resulting output appears as follows. In this case, **Source code** appears because the `ShowSourceLink` property was set to `true`.

`matlab.system.display.Section` | `matlab.system.display.SectionGroup`

How To

- "Object-Oriented Programming"
- Class Attributes
- Property Attributes
- "Add Header to System Block Dialog"

matlab.system.display.Header.getHeaderImpl

Purpose

Header for System object display

Syntax

```
header = getHeaderImpl
```

Description

`header = getHeaderImpl` returns the header to display for the System object. If you do not specify the `getHeaderImpl` method, no title or text appears for the header in the block dialog box.

`getHeaderImpl` is called by the MATLAB System block

Note You must set `Access=protected` and `Static` for this method.

Output Arguments

header

Header text

Examples

Define Header for System Block Dialog Box

Define a header in your class definition file for the `EnhancedCounter` System object.

```
methods(Static,Access=protected)
   function header = getHeaderImpl
      header = matlab.system.display.Header('EnhancedCounter',...
          'Title','Enhanced Counter');
   end
end
```

See Also

`getPropertyGroupsImpl`

How To

- "Add Header to System Block Dialog"

Purpose

Property group section for System objects

Syntax

```
matlab.system.display.Section(N1,V1,...Nn,Vn)
matlab.system.display.Section(Obj,...)
```

Description

`matlab.system.display.Section(N1,V1,...Nn,Vn)` creates a property group section for displaying System object properties, which you define using property Name-Value pairs (`N`,`V`). You use `matlab.system.display.Section` to define property groups using the `getPropertyGroupsImpl` method. The available Section properties are

- `Title` — Section title string. The default value is an empty string.
- `TitleSource` — Source of section title string. Valid values are `'Property'` and `'Auto'`. The default value is `'Property'`, which uses the string from the `Title` property. If the `Obj` name is given, the default value is `Auto`, which uses the `Obj` name.
- `Description` — Section description string. The default value is an empty string.
- `PropertyList` — Section property list as a cell array of property names. The default value is an empty array. If the `Obj` name is given, the default value is all eligible display properties.

Note Certain properties are not eligible for display either in a dialog box or in the System object summary on the command-line. Property types that cannot be displayed are: hidden, abstract, private or protected access, discrete state, and continuous state. Dependent properties do not display in a dialog box, but do display in the command-line summary.

`matlab.system.display.Section(Obj,...)` creates a property group section for the specified System object (`Obj`) and sets the following property values:

- `TitleSource` — Set to `'Auto'`, which uses the `Obj` name.
- `PropertyList` — Set to all publically-available properties in the `Obj`.

You can use `mfilename('class')` from within this method to get the name of the System object. If you set any Name-Value pairs, those property values override the default settings.

Methods

Examples

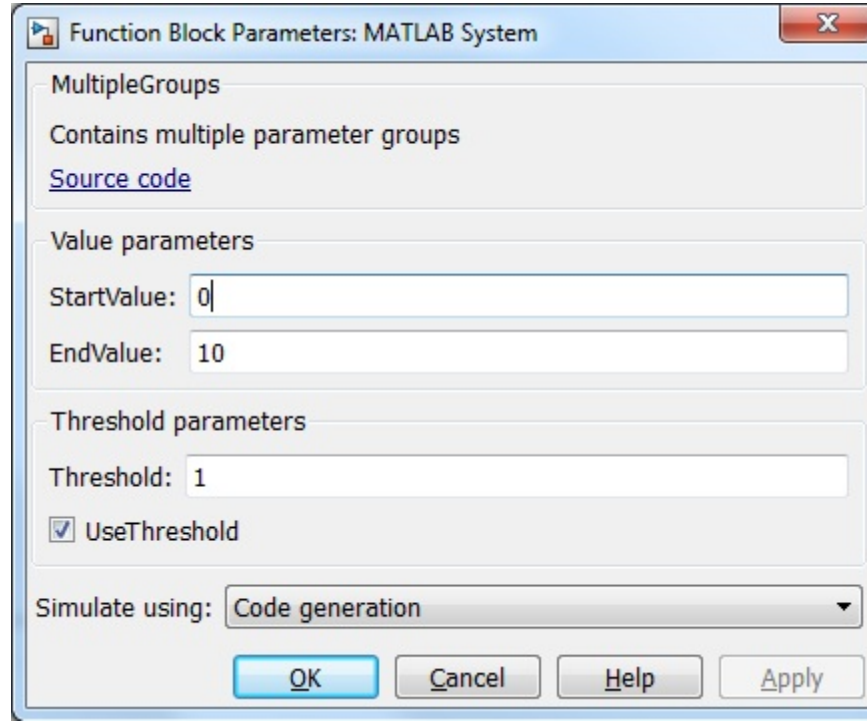
Define Property Groups

Define two property groups in your class definition file by specifying their titles and property lists.

```
methods(Static,Access=protected)
   function groups = getPropertyGroupsImpl
      valueGroup = matlab.system.display.Section(...
           'Title','Value parameters',...
           'PropertyList',{'StartValue','EndValue'});

      thresholdGroup = matlab.system.display.Section(...
           'Title','Threshold parameters',...
           'PropertyList',{'Threshold','UseThreshold'});
      groups = [valueGroup,thresholdGroup];
   end
end
```

When you specify the System object in the MATLAB System block, the resulting dialog box appears as follows.



See Also

`matlab.system.display.Header` | `matlab.system.display.SectionGroup`

How To

- "Object-Oriented Programming"
- Class Attributes
- Property Attributes
- "Add Property Groups to System Object and Block Dialog"

matlab.system.display.Section.getPropertyGroupsImpl

Purpose

Property groups for System object display

Syntax

```
group = getPropertyGroupsImpl
```

Description

`group = getPropertyGroupsImpl` returns the groups of properties to display. You define property sections (`matlab.system.display.Section`) and section groups (`matlab.system.display.SectionGroup`) within this method. Sections arrange properties into groups. Section groups arrange sections and properties into groups. If a System object, included through the MATLAB System block, has a section, but that section is not in a section group, its properties appear above the block dialog tab panels.

If you do not include a `getPropertyGroupsImpl` method in your code, all public properties are included in the dialog box by default. If you include a `getPropertyGroupsImpl` method but do not list a property, that property does not appear in the dialog box.

`getPropertyGroupsImpl` is called by the MATLAB System block and when displaying the object at the command line.

Note You must set `Access=protected` and `Static` for this method.

Output Arguments

group

Property group or groups

Examples

Define Block Dialog Tabs

Define two block dialog tabs, each containing specific properties. For this example, you use the `getPropertyGroupsImpl`, `matlab.system.display.SectionGroup`, and `matlab.system.display.Section` methods in your class definition file.

```
methods(Static, Access=protected)
   function groups = getPropertyGroupsImpl
```

```
        valueGroup = matlab.system.display.Section(...
             'Title','Value parameters',...
             'PropertyList',{'StartValue','EndValue'});

        thresholdGroup = matlab.system.display.Section(...
             'Title','Threshold parameters',...
             'PropertyList',{'Threshold','UseThreshold'});

        mainGroup = matlab.system.display.SectionGroup(...
             'Title','Main', ...
             'Sections',[valueGroup,thresholdGroup]);

        initGroup = matlab.system.display.SectionGroup(...
             'Title','Initial conditions', ...
             'PropertyList',{'IC1','IC2','IC3'});

        groups = [mainGroup,initGroup];
    end
end
```

The resulting dialog box appears as follows.

How To

- "Add Property Groups to System Object and Block Dialog"

matlab.system.display.SectionGroup

Purpose

Section group for System objects

Syntax

```
matlab.system.display.SectionGroup(N1,V1,...Nn,Vn)
matlab.system.display.SectionGroup(Obj,...)
```

Description

`matlab.system.display.SectionGroup(N1,V1,...Nn,Vn)` creates a group for displaying System object properties and display sections created with `matlab.system.display.Section`. You define such sections or properties using property Name-Value pairs (`N`,`V`). A section group can contain both properties and sections. You use `matlab.system.display.SectionGroup` to define section groups using the `getPropertyGroupsImpl` method. Section groups display as separate tabs in the MATLAB System block. The available Section properties are

- `Title` — Group title string. The default value is an empty string.
- `TitleSource` — Source of group title string. Valid values are `'Property'` and `'Auto'`. The default value is `'Property'`, which uses the string from the `Title` property. If the `Obj` name is given, the default value is `Auto`, which uses the `Obj` name.
- `Description` — Group or tab description that appears above any properties or panels. The default value is an empty string.
- `PropertyList` — Group or tab property list as a cell array of property names. The default value is an empty array. If the `Obj` name is given, the default value is all eligible display properties.
- `Sections` — Group sections as an array of section objects. If the `Obj` name is given, the default value is the default section for the `Obj`.

`matlab.system.display.SectionGroup(Obj,...)` creates a section group for the specified System object (`Obj`) and sets the following property values:

- `TitleSource` — Set to `'Auto'`.
- `Sections` — Set to `matlab.system.display.Section` object for `Obj`.

You can use `mfilename('class')` from within this method to get the name of the System object. If you set any Name-Value pairs, those property values override the default settings.

Methods

Examples

Define Block Dialog Tabs

Define in your class definition file two tabs, each containing specific properties. For this example, you use the `matlab.system.display.SectionGroup`, `matlab.system.display.Section`, and `getPropertyGroupsImpl` methods.

```
methods(Static, Access=protected)
   function groups = getPropertyGroupsImpl
      valueGroup = matlab.system.display.Section(...
           'Title','Value parameters',...
           'PropertyList',{'StartValue','EndValue'});

      thresholdGroup = matlab.system.display.Section(...
           'Title','Threshold parameters',...
           'PropertyList',{'Threshold','UseThreshold'});

      mainGroup = matlab.system.display.SectionGroup(...
           'Title','Main', ...
           'Sections',[valueGroup,thresholdGroup]);

      initGroup = matlab.system.display.SectionGroup(...
           'Title','Initial conditions', ...
           'PropertyList',{'IC1','IC2','IC3'});

      groups = [mainGroup,initGroup];
   end
end
```

The resulting dialog appears as follows when you add the object to Simulink with the MATLAB System block.

- “Add Property Groups to System Object and Block Dialog”

matlab.system.mixin.CustomIcon

Purpose

Custom icon mixin class

Description

`matlab.system.mixin.CustomIcon` is a class that defines the `getIcon` method. This method customizes the name of the icon used for the System object implemented through a MATLAB System block.

To use this method, you must subclass from this class in addition to the `matlab.System` base class. Type the following syntax as the first line of your class definition file, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.system &...
    matlab.system.mixin.CustomIcon
```

Methods

getIconImpl	Name to display as block icon

See Also

`matlab.System`

Tutorials

- "Define System Block Icon"

How To

- "Object-Oriented Programming"
- Class Attributes
- Property Attributes

Purpose

Name to display as block icon

Syntax

```
icon = getIconImpl(obj)
```

Description

`icon = getIconImpl(obj)` returns the string or cell array of strings to display on the block icon of the System object implemented through the MATLAB System block. If you do not specify the `getIconImpl` method, the block displays the class name of the System object as the block icon. For example, if you specify `pkg.MyObject` in the MATLAB System block, the default icon is labeled `My Object`

`getIconImpl` is called by the `getIcon` method, which is used by the MATLAB System block during Simulink model compilation.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

Output Arguments

icon

String or cell array of strings to display as the block icon. Each cell is displayed as a separate line.

Examples

Add System Block Icon Name

Specify in your class definition file the name of the block icon as `'Enhanced Counter'` using two lines.

```
methods (Access=protected)
   function icon = getIconImpl(~)
      icon = {'Enhanced','Counter'};
   end
end
```

See Also `matlab.system.mixin.CustomIcon`

How To

- "Define System Block Icon"

Purpose

Finite source mixin class

Description

`matlab.system.mixin.FiniteSource` is a class that defines the `isDone` method, which reports the state of a finite data source, such as an audio file.

To use this method, you must subclass from this class in addition to the `matlab.System` base class. Type the following syntax as the first line of your class definition file, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.System &...
    matlab.system.mixin.FiniteSource
```

Methods

isDoneImpl	End-of-data flag

See Also

`matlab.System`

Tutorials

- "Define Finite Source Objects"

How To

- "Object-Oriented Programming"
- Class Attributes
- Property Attributes

matlab.system.mixin.FiniteSource.isDoneImpl

Purpose

End-of-data flag

Syntax

```
status = isDoneImpl(obj)
```

Description

`status = isDoneImpl(obj)` indicates if an end-of-data condition has occurred. The `isDone` method should return `false` when data from a finite source has been exhausted, typically by having read and output all data from the source. You should also define the result of future reads from an exhausted source in the `isDoneImpl` method.

`isDoneImpl` is called by the `isDone` method.

Note You must set `Access=protected` for this method.

Input Arguments

obj

System object handle

Output Arguments

status

Logical value, `true` or `false`, that indicates if an end-of-data condition has occurred or not, respectively.

Examples

Check for End-of-Data

Set up the `isDoneImpl` method in your class definition file so the `isDone` method checks whether the object has completed eight iterations.

```
methods (Access=protected)
   function bdone = isDoneImpl(obj)
      bdone = obj.NumIters==8;
   end
end
```

How To

- "Define Finite Source Objects"

matlab.system.mixin.Nondirect

Purpose

Nondirect feedthrough mixin class

Description

`matlab.system.mixin.Nondirect` is a class that uses the `output` and `update` methods to process nondirect feedthrough data through a System object.

For System objects that use direct feedthrough, the object's input is needed to generate the output at that time. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends only on the internal states at that time. The inputs are used to update the object states. For these objects, calculating the output with `outputImpl` is separated from updating the state values with `updateImpl`. If you use the `matlab.system.mixin.Nondirect` mixin and include the `stepImpl` method in your class definition file, an error occurs. In this case, you must include the `updateImpl` and `outputImpl` methods instead.

The following cases describe when System objects in Simulink use direct or nondirect feedthrough.

- System object supports code generation and does not inherit from the `Propagates` mixin — Simulink automatically infers the direct feedthrough settings from the System object code.
- System object supports code generation and inherits from the `Propagates` mixin — Simulink does not automatically infer the direct feedthrough settings. Instead, it uses the value returned by the `isInputDirectFeedthroughImpl` method.
- System object does not support code generation — Default `isInputDirectFeedthrough` method returns false, indicating that direct feedthrough is not enabled. To override the default behavior, implement the `isInputDirectFeedthroughImpl` method in your class definition file.

Use the `Nondirect` mixin to allow a System object to be used in a Simulink feedback loop. A delay object is an example of a nondirect feedthrough object.

To use this mixin, you must subclass from this class in addition to subclassing from the `matlab.System` base class. Type the following syntax as the first line of your class definition file, where `ObjectName` is the name of your object:

```
classdef ObjectName < matlab.system &...
    matlab.system.mixin.Nondirect
```

Methods

isInputDirectFeedthroughImpl	Direct feedthrough status of input
outputImpl	Output calculation from input or internal state of System object
updateImpl	Update object states based on inputs

See Also

`matlab.system`

Tutorials

- "Use Update and Output for Nondirect Feedthrough"

How To

- "Object-Oriented Programming"
- Class Attributes
- Property Attributes

matlab.system.mixin.Nondirect.isInputDirectFeedthroughImpl

Purpose

Direct feedthrough status of input

Syntax

```
[flag1,...,flagN] = isInputDirectFeedthroughImpl(obj,u1,u2,...,uN)
```

Description

`[flag1,...,flagN] = isInputDirectFeedthroughImpl(obj,u1,u2,...,uN)` indicates whether each input is a direct feedthrough input. If direct feedthrough is `true`, the output depends on the input at each time instant.

Note You must set `Access=protected` for this method.

You cannot modify any properties or implement or access tunable properties in this method.

If you do not include the `isInputDirectFeedthroughImpl` method in your System object class definition file, all inputs are assumed to be direct feedthrough.

The following cases describe when System objects in Simulink code generation use direct or nondirect feedthrough.

- System object supports code generation and does not inherit from the `Propagates` mixin — Simulink automatically infers the direct feedthrough settings from the System object code.
- System object supports code generation and inherits from the `Propagates` mixin — Simulink does not automatically infer the direct feedthrough settings. Instead, it uses the value returned by the `isInputDirectFeedthroughImpl` method.
- System object does not support code generation — Default `isInputDirectFeedthrough` method returns false, indicating that direct feedthrough is not enabled. To override the default behavior, implement the `isInputDirectFeedthroughImpl` method in your class definition file.

`isInputDirectFeedthroughImpl` is called by the `isInputDirectFeedthrough` method.

Input Arguments

obj

System object handle

u1,u2,...,uN

Specifications of the inputs to the algorithm or `step` method.

Output Arguments

flag1,...,flagN

Logical value or either `true` or `false`. This value indicates whether the corresponding input is direct feedthrough or not, respectively. The number of outputs must match the number of outputs returned by the `getNumOutputs` method.

Examples

Specify Input as Nondirect Feedthrough

Use `isInputDirectFeedthroughImpl` in your class definition file to mark the inputs as nondirect feedthrough.

```
methods (Access=protected)
   function flag = isInputDirectFeedthroughImpl(~,~)
      flag = false;
   end
end
```

See Also

`matlab.system.mixin.Nondirect`

How To

- "Use Update and Output for Nondirect Feedthrough"

matlab.system.mixin.Nondirect.outputImpl

Purpose

Output calculation from input or internal state of System object

Syntax

```
[y1,y2,...,yN] = outputImpl(obj,u1,u2,...,uN)
```

Description

`[y1,y2,...,yN] = outputImpl(obj,u1,u2,...,uN)` implements the output equations for the System object. The output values are calculated from the states and property values. Any inputs that you set to nondirect feedthrough are ignored during output calculation.

`outputImpl` is called by the `output` method. It is also called before the `updateImpl` method in the `step` method. For sink objects, calling `updateImpl` before `outputImpl` locks the object. For all other types of objects, calling `updateImpl` before `outputImpl` causes an error.

Note You must set `Access=protected` for this method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Input Arguments

obj

System object handle

u1,u2,...uN

Inputs from the algorithm or `step` method. The number of inputs must match the number of inputs returned by the `getNumInputs` method. Nondirect feedthrough inputs are ignored during normal execution of the System object. However, for code generation, you must provide these inputs even if they are empty.

Output Arguments

y1,y2,...yN

Outputs calculated from the specified algorithm. The number of outputs must match the number of outputs returned by the `getNumOutputs` method.

Examples

Set Up Output that Does Not Depend on Input

Specify in your class definition file that the output does not directly depend on the current input with the `outputImpl` method. `PreviousInput` is a property of the `obj`.

```
methods (Access=protected)
   function [y] = outputImpl(obj, ~)
      y = obj.PreviousInput(end);
   end
end
```

See Also

`matlab.system.mixin.Nondirect`

How To

- "Use Update and Output for Nondirect Feedthrough"

matlab.system.mixin.Nondirect.updateImpl

Purpose

Update object states based on inputs

Syntax

```
updateImpl(obj,u1,u2,...,uN)
```

Description

`updateImpl(obj,u1,u2,...,uN)` implements the state update equations for the system. You use this method when your algorithm outputs depend only on the object's internal state and internal properties. Do not use this method to update the outputs from the inputs.

`updateImpl` is called by the `update` method and after the `outputImpl` method in the `step` method. For sink objects, calling `updateImpl` before `outputImpl` locks the object. For all other types of objects, calling `updateImpl` before `outputImpl` causes an error.

Note You must set `Access=protected` for this method.

You cannot modify any tunable properties in this method if its System object will be used in the Simulink MATLAB System block.

Input Arguments

obj

System object handle

u1,u2,...uN

Inputs to the algorithm or `step` method. The number of inputs must match the number of inputs returned by the `getNumInputs` method.

Examples

Set Up Output that Does Not Depend on Current Input

Update the object with previous inputs. Use `updateImpl` in your class definition file. This example saves the `u` input and shifts the previous inputs.

```
methods (Access=protected)
```

```
   function updateImpl(obj,u)
      obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
   end
end
```

`matlab.system.mixin.Nondirect`

How To

- "Use Update and Output for Nondirect Feedthrough"

matlab.system.mixin.Propagates

Purpose

Output signal characteristics propagation mixin class

Description

`matlab.system.mixin.Propagates` is a class that defines the System object's output size, data type, and complexity. You implement the methods of this class when the output specifications cannot be inferred directly from the inputs during Simulink model compilation. If you do not include this mixin and the output specifications cannot be inferred, an error occurs. You use this mixin class and its methods when your System object will be used in the MATLAB System block.

To use this mixin, you must subclass from this class in addition to subclassing from the `matlab.System` base class. Type the following syntax as the first line of your class definition file, where `ObjectName` is the name of your System object:

```
classdef ObjectName < matlab.System &...
    matlab.system.mixin.Propagates
```

The `matlab.system.mixin.Propagates` mixin is called by the MATLAB System block during Simulink model compilation.

Methods

getDiscreteStateSpecificationImpl	Discrete state size, data type, and complexity
getOutputDataTypeImpl	Data types of output ports
getOutputSizeImpl	Sizes of output ports
isOutputComplexImpl	Complexity of output ports
isOutputFixedSizeImpl	Fixed- or variable-size output ports
propagatedInputComplexity	Get input complexity during Simulink propagation
propagatedInputDataType	Get input data type during Simulink propagation

propagatedInputFixedSize	Get input fixed status during Simulink propagation
propagatedInputSize	Get input size during Simulink propagation

Note If your System object has exactly one input and one output and no discrete property states, you do not have to implement any of these methods. Default values are used when you subclass from the `matlab.system.mixin.Propagates` mixin.

matlab.system.mixin.Propagates.getDiscreteStateSpecificationI

Purpose

Discrete state size, data type, and complexity

Syntax

```
[sz,dt,cp] = getDiscreteStateSpecificationImpl(obj,name)
```

Description

`[sz,dt,cp] = getDiscreteStateSpecificationImpl(obj,name)` returns the size, data type, and complexity of the property, `name`. This property must be a discrete state property. You must define this method if your System object has discrete state properties and is used in the MATLAB System block. If you define this method for a property that is not discrete state, an error occurs during model compilation.

You always set the `getDiscreteStateSpecificationImpl` method access to `protected` because it is an internal method that users do not directly call or run.

`getDiscreteStateSpecificationImpl` is called by the MATLAB System block during Simulink model compilation.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

name

Name of discrete state property of the System object

Output Arguments

sz

Vector containing the length of each dimension of the property.

Default: `[1 1]`

dt

Data type of the property. For built-in data types, `dt` is a string. For fixed-point data types, `dt` is a numerictype object.

Default: `double`

cp

Complexity of the property as a scalar, logical value, where `true` = complex and `false` = real.

Default: `false`

Examples

Specify Discrete State Property Size, Data Type, and Complexity

Specify in your class definition file the size, data type, and complexity of a discrete state property.

```
methods (Access=protected)
   function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
      sz = [1 1];
      dt = 'double';
      cp = false;
   end
end
```

See Also

`matlab.system.mixin.Propagates`

How To

- "Specify Discrete State Output Specification"

matlab.system.mixin.Propagates.getOutputDataTypeImpl

Purpose

Data types of output ports

Syntax

```
[dt_1,dt_2,...,dt_n] = getOutputDataTypeImpl(obj)
```

Description

`[dt_1,dt_2,...,dt_n] = getOutputDataTypeImpl(obj)` returns the data types of each output port. The number of outputs must match the value returned from the `getNumOutputs` method or the number of output arguments listed in the `step` method.

For System objects with one input and one output and where you want the input and output data types to be the same, you do not need to implement this method. In this case `getOutputDataTypeImpl` assumes the input and output data types are the same and returns the data type of the input.

If your System object has more than one input or output or you need the output and input data types to be different, you must implement the `getOutputDataTypeImpl` method to define the output data type if the output data type differs from the input data type. You also must implement the `propagatedInputDataType` method.

During Simulink model compilation and propagation, the MATLAB System block calls the `getOutputDataType` method, which then calls the `getOutputDataTypeImpl` method to determine the output data type.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

dt_1,dt_2,...

Data type of the property. For built-in data types, `dt` is a string. For fixed-point data types, `dt` is a numerictype object.

Examples

Specify Output Data Type

Specify in your class definition file the data type of a System object with one output.

```
methods (Access=protected)
   function dt_1 = getOutputDataTypeImpl(~)
      dt_1 = 'double';
   end
end
```

See Also

`matlab.system.mixin.Propagates` | `propagatedInputDataType`

How To

- "Set Output Data Type"

matlab.system.mixin.Propagates.getOutputSizeImpl

Purpose

Sizes of output ports

Syntax

```
[sz_1,sz_2,...,sz_n] = getOutputSizeImpl(obj)
```

Description

`[sz_1,sz_2,...,sz_n] = getOutputSizeImpl(obj)` returns the sizes of each output port. The number of outputs must match the value returned from the `getNumOutputs` method or the number of output arguments listed in the `step` method.

For System objects with one input and one output and where you want the input and output sizes to be the same, you do not need to implement this method. In this case `getOutputSizeImpl` assumes the input and output sizes are the same and returns the size of the input. For variable-size inputs, the output size is the maximum input size.

If your System object has more than one input or output or you need the output and input sizes to be different, you must implement the `getOutputSizeImpl` method to define the output size. You also must use the `propagatedInputSize` method if the output size differs from the input size.

During Simulink model compilation and propagation, the MATLAB System block calls the `getOutputSize` method, which then calls the `getOutputSizeImpl` method to determine the output size.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

sz_1,sz_2,...

Vector containing the size of each output port.

Examples

Specify Output Size

Specify in your class definition file the size of a System object output.

```
methods (Access=protected)
   function sz_1 = getOutputSizeImpl(obj)
      sz_1 = [1 1];
   end
end
```

`matlab.system.mixin.Propagates` | `propagatedInputSize`

How To

- "Set Output Size"

matlab.system.mixin.Propagates.isOutputComplexImpl

Purpose

Complexity of output ports

Syntax

```
[cp_1,cp_2,...,cp_n] = isOutputComplexImpl(obj)
```

Description

`[cp_1,cp_2,...,cp_n] = isOutputComplexImpl(obj)` returns whether each output port has complex data. The number of outputs must match the value returned from the `getNumOutputs` method or the number of output arguments listed in the `step` method.

For System objects with one input and one output and where you want the input and output complexities to be the same, you do not need to implement this method. In this case `isOutputComplexImpl` assumes the input and output complexities are the same and returns the complexity of the input.

If your System object has more than one input or output or you need the output and input complexities to be different, you must implement the `isOutputComplexImpl` method to define the output complexity. You also must use the `propagatedInputComplexity` method if the output complexity differs from the input complexity.

During Simulink model compilation and propagation, the MATLAB System block calls the `isOutputComplex` method, which then calls the `isOutputComplexImpl` method to determine the output complexity.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

cp_1,cp_2,...

Logical, scalar value indicating whether the specific output port is complex (`true`) or real (`false`).

Examples

Specify Output as Real-Valued

Specify in your class definition file that the output from a System object is a real value.

```
methods (Access=protected)
   function c1 = isOutputComplexImpl(obj)
       c1 = false;
   end
end
```

See Also

`matlab.system.mixin.Propagates` | `propagatedInputComplexity`

How To

- "Set Output Complexity"

matlab.system.mixin.Propagates.isOutputFixedSizeImpl

Purpose

Fixed- or variable-size output ports

Syntax

```
[flag_1,flag_2,...flag_n] = isOutputFixedSizeImpl(obj)
```

Description

`[flag_1,flag_2,...flag_n] = isOutputFixedSizeImpl(obj)` indicates whether each output port is fixed size. The number of outputs must match the value returned from the `getNumOutputs` method or the number of output arguments listed in the `step` method.

For System objects with one input and one output and where you want the input and output fixed sizes to be the same, you do not need to implement this method. In this case `isOutputFixedSizeImpl` assumes the input and output fixed sizes are the same and returns the fixed size of the input.

If your System object has more than one input or output or you need the output and input fixed sizes to be different, you must implement the `isOutputFixedSizeImpl` method to define the output data type. You also must use the `propagatedInputFixedSize` method if the output fixed size status differs from the input fixed size status.

During Simulink model compilation and propagation, the MATLAB System block calls the `isOutputFixedSize` method, which then calls the `isOutputFixedSizeImpl` method to determine the output fixed size.

Note You must set `Access=protected` for this method.

You cannot modify any properties in this method.

Input Arguments

obj

System object handle

Output Arguments

flag_1,flag2,...

Logical, scalar value indicating whether the specific output port is fixed size (`true`) or variable size (`false`).

Examples

Specify Output as Fixed-Point

Specify in your class definition file that the output from a System object is a fixed-point value.

```
methods (Access=protected)
   function c1 = isOutputFixedSizeImpl(obj)
      c1 = true;
   end
end
```

See Also

`matlab.system.mixin.Propagates` | `propagatedInputFixedSize`

How To

- "Specify Whether Output Is Fixed- or Variable-Size"

matlab.system.mixin.Propagates.propagatedInputComplexity

Purpose

Get input complexity during Simulink propagation

Syntax

```
flag = propagatedInputComplexity(obj,index)
```

Description

`flag = propagatedInputComplexity(obj,index)` returns `true` or `false` to indicate whether the indicated object's input argument is complex. The index specifies the input to the `step` method (excluding the `obj` input) for which to return the complexity. You can only call this method from within the `isOutputComplexImpl` method in your class definition file.

You must use the `isOutputComplexImpl` method if your System object has more than one input or output. Use the `propagatedInputComplexity` method inside `isOutputComplexImpl` when the output complexity is determined using the input complexity. You must also use these two methods for a single input, single output System object if you need the output complexity to be different than the input complexity.

Input Arguments

obj

System object handle

index

Index of the desired `step` method input

Output Arguments

flag

Whether the specified input argument is complex-valued

Examples

Match Input and Output Complexity

This example shows how to use the `propagatedInputComplexity` method in your class definition file. The following code gets the input complexity of the `step` method's second input and returns it as the output complexity. In this case, the `step` method's first input is assumed to have no impact on the output complexity.

```
methods (Access=protected)
   function outcomplx = isOutputComplexImpl(obj)
      outcomplx = propagatedInputComplexity(obj,2);
   end
end
```

See Also

matlab.system.mixin.Propagates | isOutputComplexImpl

How To

- “Set Output Complexity”

matlab.system.mixin.Propagates.propagatedInputDataType

Purpose

Get input data type during Simulink propagation

Syntax

```
dt = propagatedInputDataType(obj,index)
```

Description

`dt = propagatedInputDataType(obj,index)` returns a string (or numerictype for fixed-point inputs) to indicate the data type of the object's input argument. The index specifies the input to the `step` method (excluding the `obj` input) for which to return the data type. You can only call this method from within the `getOutputDataTypeImpl` method in your class definition file.

You must use the `getOutputDataTypeImpl` method if your System object has more than one input or output. Use the `propagatedInputDataType` method inside `getOutputDataTypeImpl` when the output data type is determined using the input data type. You must also use these two methods for a single input, single output System object if you need the output data type to be different than the input data type.

Input Arguments

obj

System object handle

index

Index of the desired `step` method input

Output Arguments

dt

String, or numerictype object for fixed-point inputs, indicating the data type of the object's input argument

Examples

Match Input and Output Data Type

This example shows how to use the `propagatedInputDataType` method in your class definition file. The following code checks the input data type. If the `step` method's second input data type is `double`, then the output data type is `int32`. For all other cases, the output data type matches the second input data type. In this case, the `step` method's first input is assumed to have no impact on the output data type.

```
methods (Access=protected)
   function dt = getOutputDataTypeImpl(obj)
       if strcmpi(propagatedInputDataType(obj,2),'double')
           dt = 'int32';
       else
           dt = propagatedInputDataType(obj,2);
       end
   end
end
```

See Also

`matlab.system.mixin.Propagates` | `getOutputDataTypeImpl` | "Data Type Propagation"

How To

- "Set Output Data Type"

matlab.system.mixin.Propagates.propagatedInputFixedSize

Purpose

Get input fixed status during Simulink propagation

Syntax

```
flag = propagatedInputFixedSize(obj,index)
```

Description

`flag = propagatedInputFixedSize(obj,index)` returns `true` or `false` to indicate whether the indicated object's input argument is a fixed-sized input. The index specifies the input to the `step` method (excluding the `obj` input) for which to return the fixed-size flag. You can only call this method from within the `isOutputFixedSizeImpl` method in your class definition file.

You must use the `isOutputFixedSizeImpl` method if your System object has more than one input or output. Use the `propagatedInputFixedSize` method inside `isOutputFixedSizeImpl` when the output fixed size status is determined using the input fixed size status. You must also use these two methods for a single input, single output System object if you need the output fixed size status to be different than the input fixed size status.

Input Arguments

obj

System object handle

index

Index of the desired `step` method input

Output Arguments

flag

Whether the specified input argument is fixed-size or not

Examples

Determine Fixed-Size Input

This example shows how to use the `propagatedInputFixedSize` method in your class definition file. The following code checks the input fixed size status. Check whether the third input to the `step` method is fixed size and set the output to have the same fixed size status as that third input. In this case, the first and second inputs to the `step` method are assumed to have no impact on the output.

```
methods (Access=protected)
   function outtype = isOutputFixedSizeImpl(obj)
      outtype = propagatedInputFixedSize(obj,3)
   end
end
```

`matlab.system.mixin.Propagates` | `isOutputFixedSizeImpl`

How To

- “Specify Whether Output Is Fixed- or Variable-Size”

matlab.system.mixin.Propagates.propagatedInputSize

Purpose

Get input size during Simulink propagation

Syntax

```
sz = propagatedInputSize(obj,index)
```

Description

`sz = propagatedInputSize(obj,index)` returns, as a vector, the size of the indicated object's input argument. The index specifies the input to the `step` method (excluding the `obj` input) for which to return size information. You can only call this method from within the `getOutputSizeImpl` method in your class definition file.

You must use the `getOutputSizeImpl` method if your System object has more than one input or output. Use the `propagatedInputSize` method inside `getOutputSizeImpl` when the output size is determined using the input size. You must also use these two methods for a single input, single output System object if you need the output size to be different than the input size.

Input Arguments

obj

System object handle

index

Index of the desired `step` method input

Output Arguments

sz

Size of the specified input

Examples

Obtain Input Size

This example shows how to use the `propagatedInputSize` method in your class definition file. The following code checks the input size. If the first dimension of the second input to the `step` method has a size greater than 1, then set the output size to a 1 x 2 vector. For all other cases, the output is a 2 x 1 matrix. In this case, the `step` method's first input is assumed to have no impact on the output size.

```
methods (Access=protected)
```

```
    function outsz = getOutputSizeImpl(obj)
        sz = propagatedInputSize(obj,2);
        if sz(1) == 1
            outsz = [1,2];
        else
            outsz - [2,1];
        end
    end
end
```

How To

- “Set Output Size”

matlab.system.StringSet

Purpose

Set of valid string values

Description

`matlab.system.StringSet` defines a list of valid string values for a property. This class validates the string in the property and enables tab completion for the property value. A *StringSet* allows only predefined or customized strings as values for the property.

A `StringSet` uses two linked properties, which you must define in the same class. One is a public property that contains the current string value. This public property is displayed to the user. The other property is a hidden property that contains the list of all possible string values. This hidden property should also have the transient attribute so its value is not saved to disk when you save the System object.

The following considerations apply when using StringSets:

- The string property that holds the current string can have any name.
- The property that holds the `StringSet` must use the same name as the string property with the suffix "Set" appended to it. The string set property is an instance of the `matlab.system.StringSet` class.
- Valid strings, defined in the `StringSet`, must be declared using a cell array. The cell array cannot be empty nor can it have any empty strings. Valid strings must be unique and are case-insensitive.
- The string property must be set to a valid `StringSet` value.

Examples

Set String Property Values

Set the string property, `Flavor`, and the `StringSet` property, `FlavorSet` in your class definition file.

```
properties
  Flavor='Chocolate';
end

properties (Hidden,Transient)
  FlavorSet = ...
    matlab.system.StringSet({'Vanilla','Chocolate'});
```

```
end
```

spbscopes.SpectrumAnalyzerConfiguration

Purpose

Configure Spectrum Analyzer for programmatic access

Description

The `spbscopes.SpectrumAnalyzerConfiguration` object contains the scope configuration information for the Spectrum Analyzer block.

Construction

Call the `get_param` function, specifying a Spectrum Analyzer block.

`htsc = get_param(gcbh,'ScopeConfiguration')` constructs a new Spectrum Analyzer Configuration object.

Properties

CenterFrequency

Frequency over which frequency span is centered

Specify as a real scalar the center frequency, in hertz, of the frequency span over which the Spectrum Analyzer computes and plots the spectrum. This property applies when you set the `FrequencySpan` property to `'Span and center frequency'`. The overall frequency span, defined by the `Span` and `CenterFrequency` properties, must fall within the Nyquist frequency interval. When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval

is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the

interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. This property is Tunable.

Default: `0`

FFTLength

FFT length

Specify as a positive, scalar integer the length of the FFT that the Spectrum Analyzer uses to compute spectral

estimates. This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'` and the `FFTLengthSource` property to `'Property'`. The `FFTLength` must be greater than or equal to the `WindowLength`. You cannot control the FFT length when the `FrequencyResolutionMethod` property is `'RBW'`. In that case, the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

This property is Tunable.

Default: `128`

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto'` or `'Property'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer sets the FFT length to the window length specified in the `WindowLength` property or to 1024, whichever is larger.
- When you set this property to `'Property'`, specify the number of FFT points using the `FFTLength` property. The `FFTLength` must be greater than the `WindowLength`.

This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'` and the `FFTLengthSource` property to `'Property'`.

This property is Tunable.

Default: `'Auto'`

FrequencyOffset

Frequency offset

Specify as a real, scalar value a frequency offset, in hertz. The *frequency*-axis values are offset by the value specified in this property. The overall span must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. You can control the overall span in different ways based on how you set the `FrequencySpan` property.

Default: `0`

FrequencyResolutionMethod

Frequency resolution method

Specify how to control the frequency resolution of the spectrum analyzer as either `'RBW'` or `'WindowLength'`. When you set this property to `'RBW'`, the `RBWSource` and `RBW` properties control the frequency resolution (in Hz) of the analyzer. When you set this property to `'WindowLength'`, the `WindowLength` property controls the frequency resolution.

In this case, the frequency resolution of the analyzer is defined as $\frac{NENBW * Fs}{N_{window}}$ where *NENBW* is the normalized effective noise bandwidth of the window currently specified in the `Window` property. You can control the number of FFT points only when the `FrequencyResolutionMethod` property is `'WindowLength'`. When the `FrequencyResolutionMethod` property is `'RBW'`, the FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.

This property is Tunable.

Default: `'RBW'`

FrequencyScale

Frequency scale

Specify the frequency scale as either `'Linear'` or `'Log'`. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. When you set the `FrequencyScale` property to `'Log'`, the Spectrum Analyzer displays the frequencies on the *x*-axis on a logarithmic scale. To use the `'Log'` setting, you must also set the `PlotAsTwoSidedSpectrum` property to `false`. When the `PlotAsTwoSidedSpectrum` property is `true`, you must set this property to `'Linear'`.

This property is Tunable.

Default: `'Linear'`

FrequencySpan

Frequency span mode

Specify the frequency span mode as one of `'Full'`, `'Span and center frequency'`, or `'Start and stop frequencies'`.

- When you set this property to `'Full'`, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.
- When you set this property to `'Span and center frequency'`, the Spectrum Analyzer computes and plots the spectrum over

the interval specified by the `Span` and `CenterFrequency` properties.

- When you set this property to `'Start and stop frequencies'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the `StartFrequency` and `StopFrequency` properties.

This property is Tunable.

Default: `'Full'`

Name

Caption to display on Spectrum Analyzer window

Specify as a string the caption to display on the scope window. This property is Tunable.

Default: `'Spectrum Analyzer'`

OpenAtSimulationStart

Open scope when starting simulation

Set this property to `true` to open the scope when the simulation starts. Set this property to `false` to prevent the scope from opening at the start of simulation.

Default: `true`

OverlapPercent

Overlap percentage

Specify as a real, scalar value, the percentage overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100. This property is Tunable.

Default: `0`

PlotAsTwoSidedSpectrum

Two sided spectrum flag

Set this property to `true` to compute and plot two-sided spectral estimates. Set this property to `false` to compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued. When the input signal is complex valued, you must set this property to `true`.

When this property is `false`, Spectrum Analyzer uses *power folding*. The *y*-axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided PSD contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see the `pwelch` function reference page.

Default: `true`

PlotMaxHoldTrace

Max-hold trace flag

Set this property to `true` to compute and plot the maximum-hold spectrum of each input channel. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is Tunable.

See also: `PlotMinHoldTrace` and `PlotNormalTrace`.

Default: `false`

PlotMinHoldTrace

Min-hold trace flag

Set this property to `true` to compute and plot the minimum-hold spectrum of each input channel. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is Tunable.

See also: `PlotMaxHoldTrace` and`PlotNormalTrace`.

Default: `false`

PlotNormalTrace

Normal trace flag

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Note that even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`.

This property is Tunable.

See also: `PlotMaxHoldTrace` and `PlotMinHoldTrace`.

Default: `true`

Position

Spectrum Analyzer window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form, `[left bottom width height]`. You can place the scope window in a specific position

on your screen by modifying the values to this property. This property is Tunable.

Default: The default depends on your screen resolution. By default, the Spectrum Analyzer window appears in the center of your screen with a width of `410` pixels and height of `300` pixels.

PowerUnits

Power units

Specify the units in which the Spectrum Analyzer displays power values as either `'dBm'`, `'dBW'`, or `'Watts'`.

This property is Tunable.

Default: `'dBm'`

RBW

Resolution bandwidth

Specify as a real, positive scalar the resolution bandwidth (RBW), in hertz. RBW controls the spectral resolution of Spectrum Analyzer. This property applies only when you set the `FrequencyResolutionMethod` property to `'RBW'` and the `RBWSource` property to `'Property'`. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to

RBW must be greater than two: $\frac{span}{RBW} > 2$. You can specify the overall span in different ways based on how you set the `FrequencySpan` property.

This property is Tunable.

See also: `RBWSource`.

Default: `9.76`

RBWSource

Source of resolution bandwidth value

Specify the source of the resolution bandwidth (RBW) as either `'Auto'` or `'Property'`. This property is relevant only when you set the `FrequencyResolutionMethod` property to `'RBW'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer adjusts the spectral estimation resolution to ensures that there are 1024 RBW intervals over the defined frequency span.
- When you set this property to `'Property'`, specify the resolution bandwidth directly using the `RBW` property.

This property is Tunable.

See also: `RBW`.

Default: `'Auto'`

ReducePlotRate

Reduce plot rate to improve performance

When you set this property to `true`, the scope logs data for later use and updates the display at fixed intervals of time. Data occurring between these fixed intervals might not be plotted. When you set this property to `false`, the scope updates every time it computes the power spectrum. Use the `false` setting when you do not want to miss any spectral updates at the expense of slower simulation speed. The simulation speed is faster when this property is set to `true`. This property is Tunable.

Default: `true`

ReferenceLoad

Reference load

Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values.

This property is Tunable.

Default: `1`

SampleRate

Sample rate of input

Specify the sample rate, in hertz, of the input signals.

The sample rate must be a finite numeric scalar.

Default: `10e3`

ShowGrid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable.

Default: `false`

ShowLegend

Show or hide legend

When you set this property to `true`, the scope displays a legend with automatic string labels for each input channel. When you set this property to `false`, the scope does not display a legend. This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. This property is Tunable.

Default: `false`

SidelobeAttenuation

Sidelobe attenuation of window

Specify as a real, positive scalar the window sidelobe attenuation, in decibels (dB). This property applies only when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The value must be greater than or equal to `45`.

This property is Tunable.

Default: `60`

Span

Frequency span over which spectrum is computed and plotted

Specify as a real, positive scalar the frequency span, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Span and center frequency'`. The overall span, defined by this property and the `CenterFrequency` property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable.

Default: `10e3`

SpectralAverages

Number of spectral averages

Specify as a positive, scalar integer the number of spectral averages. This property applies only when you set the

`SpectrumType` property to `'Power'` or `'Power density'`. The Spectrum Analyzer computes the current power spectrum estimate by computing a running average of the last *N* power spectrum estimates. This property defines the number of spectral averages, *N*.

This property is Tunable.

Default: `1`

SpectrumType

Spectrum type

Specify the spectrum type as one of `'Power'`, `'Power density'`, or `'Spectrogram'`.

- When you set this property to `'Power'`, the Spectrum Analyzer shows the power spectrum.
- When you set this property to `'Power density'`, the Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude squared of the spectrum normalized to a bandwidth of 1 hertz.
- When you set this property to `'Spectrogram'`, the Spectrum Analyzer open a spectrogram view, which shows frequency content over time. Each line of the spectrogram is one periodogram. Time scrolls from the bottom to the top of the display. The most recent spectrogram update is at the bottom of the display.

This property is Tunable.

Default: `'Power'`

StartFrequency

Start frequency over which spectrum is computed

Specify as a real scalar the start frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Start and stop frequencies'`. The overall span, which is defined by `StopFrequency` and this property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable.

Default: `-5e3`

StopFrequency

Stop frequency over which spectrum is computed

Specify as a real scalar the stop frequency, in hertz, over which the Spectrum Analyzer computes and plots the spectrum. This property applies only when you set the `FrequencySpan` property to `'Start and stop frequencies'`. The overall span, defined by this property and the `StartFrequency` property, must fall within the *Nyquist* frequency interval. When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. This property is Tunable.

Default: `5e3`

Title

Display title

Specify the display title as a string. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is Tunable.

Default: `''`

TreatMby1SignalsAsOneChannel

Treat unoriented sample-based input signal as a column vector

Set this property to `true` to treat *M*-by-1 and unoriented sample-based inputs as a column vector, or one channel. Set this property to `false` to treat *M*-by-1 and unoriented sample-based inputs as a 1-by-*M* row vector.

Default: `true`

Window

Window function

Specify a window function for the spectral estimator as one of the options in the following table. For information on any window function, follow the link to the corresponding function reference in the Signal Processing Toolbox documentation.

Window Option	Corresponding Function in Signal Processing Toolbox
`'Rectangular'`	`rectwin`
`'Chebyshev'`	`chebwin`
`'Flat Top'`	`flattopwin`
`'Hamming'`	`hamming`

Window Option	Corresponding Function in Signal Processing Toolbox
`'Hann'`	`hann`
`'Kaiser'`	`kaiser`

This property is Tunable.

Default: `'Hann'`

WindowLength

The window length

Control the frequency resolution by specifying the window length, in samples used to compute the spectral estimates. The window length must be an integer scalar greater than 2. This property applies only when you set the `FrequencyResolutionMethod` property to `'WindowLength'`, which controls the frequency resolution based on your window length setting. The resulting resolution bandwidth (RBW) is $\frac{NENBW * Fs}{N_{window}}$ where N_{window} is the `WindowLength` value.

This property is Tunable.

See also: `Window`,

Default: `1024`

YLabel

The label for the *y*-axis

Specify as a string the text for the scope to display to the left of the *y*-axis. Tunable

This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. Regardless of this

property, Spectrum Analyzer always displays power units as one of `'dBm'`, `'dBW'`, `'Watts'`, `'dBm/Hz'`, `'dBW/Hz'`, `'Watts/Hz'`.

See also: `PowerUnits` on page 1889.

Default: `''`

YLimits

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is Tunable.

This property applies only when you set the `SpectrumType` property to `'Power'` or `'Power density'`. The units directly depend upon the `PowerUnits` property.

Default: `[-80, 20]`

Examples

Example: Construct a Spectrum Analyzer Configuration Object

Create a new Simulink model with a randomly-generated name.

```
sysname=char(randi(26,1,7)+96);
new_system(sysname);
```

Add a new Spectrum Analyzer block to the model.

```
add_block('built-in/SpectrumAnalyzer',[sysname,'/SpectrumAnalyzer'])
```

Call the `get_param` function to retrieve the default Spectrum Analyzer block configuration properties.

```
hsac = get_param([sysname,'/SpectrumAnalyzer'],'ScopeConfiguration')
```

```
hsac =

  SpectrumAnalyzerConfiguration with properties:
```

```
                    Name: 'SpectrumAnalyzer'
OpenAtSimulationStart: 1
                  Visible: 0
                 Position: [680 390 560 420]
               SampleRate: '10e3'
            SpectrumType: 'Power'
           FrequencySpan: 'Full'
                     Span: '10e3'
          CenterFrequency: '0'
           StartFrequency: '-5e3'
            StopFrequency: '5e3'
FrequencyResolutionMethod: 'RBW'
                RBWSource: 'Auto'
                      RBW: '9.76'
             WindowLength: '1024'
          FFTLengthSource: 'Auto'
                FFTLength: '1024'
           OverlapPercent: '0'
                   Window: 'Hann'
     SidelobeAttenuation: '60'
    TimeResolutionSource: 'Auto'
          TimeResolution: '1e-3'
          TimeSpanSource: 'Auto'
                 TimeSpan: '100e-3'
       SpectralAverages: '1'
             PowerUnits: 'dBm'
          ReferenceLoad: '1'
       PlotMaxHoldTrace: 0
       PlotMinHoldTrace: 0
        PlotNormalTrace: 1
PlotAsTwoSidedSpectrum: 1
        FrequencyScale: 'Linear'
       FrequencyOffset: '0'
                 Title: ''
               YLimits: [-80 20]
                YLabel: ''
```

```
                    ShowLegend: 0
                      ShowGrid: 1

Functions — Alphabetical List

adaptfilt

Purpose

Adaptive filter

Syntax

```
ha = adaptfilt.algorithm('input1',input2,...)
```

Description

`ha = adaptfilt.algorithm('input1',input2,...)` returns the adaptive filter object `ha` that uses the adaptive filtering technique specified by *`algorithm`*. When you construct an adaptive filter object, include an *`algorithm`* specifier to implement a specific adaptive filter. Note that you do not enclose the algorithm option in single quotation marks as you do for most strings. To construct an adaptive filter object you must supply an *`algorithm`* string — there is no default algorithm, although every constructor creates a default adaptive filter when you do not provide input arguments such as `input1` or `input2` in the calling syntax.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Algorithms

For adaptive filter (`adaptfilt`) objects, the *`algorithm`* string determines which adaptive filter algorithm your `adaptfilt` object implements. Each available algorithm entry appears in one of the tables along with a brief description of the algorithm. Click on the algorithm in the first column to get more information about the associated adaptive filter technique.

Least Mean Squares (LMS) Based FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.adjlms`	Use the Adjoint LMS FIR adaptive filter algorithm
`adaptfilt.blms`	Use the Block LMS FIR adaptive filter algorithm
`adaptfilt.blmsfft`	Use the FFT-based Block LMS FIR adaptive filter algorithm
`adaptfilt.dlms`	Use the delayed LMS FIR adaptive filter algorithm
`adaptfilt.filtxlms`	Use the filtered-x LMS FIR adaptive filter algorithm
`adaptfilt.lms`	Use the LMS FIR adaptive filter algorithm
`adaptfilt.nlms`	Use the normalized LMS FIR adaptive filter algorithm
`adaptfilt.sd`	Use the sign-data LMS FIR adaptive filter algorithm
`adaptfilt.se`	Use the sign-error LMS FIR adaptive filter algorithm
`adaptfilt.ss`	Use the sign-sign LMS FIR adaptive filter algorithm

For further information about an adapting algorithm, refer to the reference page for the algorithm.

Recursive Least Squares (RLS) Based FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.ftf`	Use the fast transversal least squares adaptation algorithm
`adaptfilt.qrdrls`	Use the QR-decomposition RLS adaptation algorithm
`adaptfilt.hrls`	Use the householder RLS adaptation algorithm
`adaptfilt.hswrls`	Use the householder SWRLS adaptation algorithm
`adaptfilt.rls`	Use the recursive-least squares (RLS) adaptation algorithm
`adaptfilt.swrls`	Use the sliding window (SW) RLS adaptation algorithm
`adaptfilt.swftf`	Use the sliding window FTF adaptation algorithm

For more complete information about an adapting algorithm, refer to the reference page for the algorithm.

Affine Projection (AP) FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.ap`	Use the affine projection algorithm that uses direct matrix inversion
`adaptfilt.apru`	Use the affine projection algorithm that uses recursive matrix updating
`adaptfilt.bap`	Use the block affine projection adaptation algorithm

To find more information about an adapting algorithm, refer to the reference page for the algorithm.

FIR Adaptive Filters in the Frequency Domain (FD)

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.fdaf`	Use the frequency domain adaptation algorithm
`adaptfilt.pbfdaf`	Use the partition block version of the FDAF algorithm
`adaptfilt.pbufdaf`	Use the partition block unconstrained version of the FDAF algorithm
`adaptfilt.tdafdct`	Use the transform domain adaptation algorithm using DCT
`adaptfilt.tdafdft`	Use the transform domain adaptation algorithm using DFT
`adaptfilt.ufdaf`	Use the unconstrained FDAF algorithm for adaptation

For more information about an adapting algorithm, refer to the reference page for the algorithm.

Lattice Based (L) FIR Adaptive Filters

adaptfilt.algorithm String	Algorithm Used to Generate Filter Coefficients
`adaptfilt.gal`	Use the gradient adaptive lattice filter adaptation algorithm
`adaptfilt.lsl`	Use the least squares lattice adaptation algorithm
`adaptfilt.qrdlsl`	Use the QR decomposition least squares lattice adaptation algorithm

For more information about an adapting algorithm, refer to the reference page for the algorithm.

Properties for All Adaptive Filter Objects

Each reference page for an algorithm and `adaptfilt.algorithm` object specifies which properties apply to the adapting algorithm and how to use them.

Methods for Adaptive Filter Objects

As is true with all objects, methods enable you to perform various operations on `adaptfilt` objects. To use the methods, you apply them to the object handle that you assigned when you constructed the `adaptfilt` object.

Most of the analysis methods that apply to `dfilt` objects also work with `adaptfilt` objects. Methods like `freqz` rely on the filter coefficients in the `adaptfilt` object. Since the coefficients change each time the filter adapts to data, you should view the results of using a method as an analysis of the filter at a moment in time for the object. Use caution when you apply an analysis method to your adaptive filter objects — always check that your result approached your expectation.

In particular, the Filter Visualization Tool (FVTool) supports all of the `adaptfilt` objects. Analyzing and viewing your `adaptfilt` objects is straightforward — use the `fvtool` method with the name of your object

```
fvtool(objectname)
```

to launch FVTool and work with your object.

Some methods share their names with functions in Signal Processing Toolbox software, or even functions in this toolbox. Functions that share names with methods behave in a similar way. Using the same name for more than one function or method is called *overloading* and is common in many toolboxes.

Method	Description
`adaptfilt/coefficients`	Return the instantaneous adaptive filter coefficients
`adaptfilt/filter`	Apply an `adaptfilt` object to your signal
`adaptfilt/freqz`	Plot the instantaneous adaptive filter frequency response
`adaptfilt/grpdelay`	Plot the instantaneous adaptive filter group delay
`adaptfilt/impz`	Plot the instantaneous adaptive filter impulse response.
`adaptfilt/info`	Return the adaptive filter information.
`adaptfilt/isfir`	Test whether an adaptive filter is an finite impulse response (FIR) filters.
`adaptfilt/islinphase`	Test whether an adaptive filter is linear phase
`adaptfilt/ismaxphase`	Test whether an adaptive filter is maximum phase
`adaptfilt/isminphase`	Test whether an adaptive filter is minimum phase
`adaptfilt/isreal`	True whether an adaptive filter has real coefficients
`adaptfilt/isstable`	Test whether an adaptive filter is stable
`adaptfilt/maxstep`	Return the maximum step size for an adaptive filter
`adaptfilt/msepred`	Return the predicted mean square error
`adaptfilt/msesim`	Return the measured mean square error via simulation.

Method	Description
adaptfilt/phasez	Plot the instantaneous adaptive filter phase response
adaptfilt/reset	Reset an adaptive filter to initial conditions
adaptfilt/stepz	Plot the instantaneous adaptive filter step response
adaptfilt/tf	Return the instantaneous adaptive filter transfer function
adaptfilt/zerophase	Plot the instantaneous adaptive filter zerophase response
adaptfilt/zpk	Return a matrix containing the instantaneous adaptive filter zero, pole, and gain values
adaptfilt/zplane	Plot the instantaneous adaptive filter in the Z-plane

Working with Adaptive Filter Objects

The next sections cover viewing and changing the properties of `adaptfilt` objects. Generally, modifying the properties is the same for `adaptfilt`, `dfilt`, and `mfilt` objects and most of the same methods apply to all.

Viewing Object Properties

As with any object, you can use `get` to view a `adaptfilt` object's properties. To see a specific property, use

```
get(ha,'property')
```

To see all properties for an object, use

```
get(ha)
```

Changing Object Properties

To set specific properties, use

```
set(ha,'property1',value1,'property2',value2,...)
```

You must use single quotation marks around the property name so MATLAB treats them as strings.

Copying an Object

To create a copy of an object, use `copy`.

```
ha2 = copy(ha)
```

Note Using the syntax `ha2 = ha` copies only the object handle and does not create a new object — `ha` and `ha2` are not independent. When you change the characteristics of `ha2`, those of `ha` change as well.

Using Filter States

Two properties control your adaptive filter states.

- `States` — stores the current states of the filter. Before the filter is applied, the states correspond to the initial conditions and after the filter is applied, the states correspond to the final conditions.
- `PersistentMemory` — resets the filter before filtering. The default value is `false` which causes the properties that are modified by the filter, such as `coefficients` and `states`, to be reset to the value you specified when you constructed the object, before you use the object to filter data. Setting `PersistentMemory` to `true` allows the object to retain its current properties between filtering operations, rather than resetting the filter to its property values at construction.

Examples

Construct an LMS adaptive filter object and use it to identify an unknown system. For this example, use 500 iteration of the adapting process to determine the unknown filter coefficients. Using the LMS

algorithm represents one of the most straightforward technique for adaptive filters.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 0.008;            % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Purpose

FIR adaptive filter that uses adjoint LMS algorithm

Syntax

```
ha = adaptfilt.adjlms(l,step,leakage,pathcoeffs,pathest,...
errstates,pstates,coeffs,states)
```

Description

`ha = adaptfilt.adjlms(l,step,leakage,pathcoeffs,pathest,...errstates,pstates,coeffs,states)` constructs object `ha`, an FIR adjoint LMS adaptive filter. `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10 when you omit the argument. `step` is the adjoint LMS step size. It must be a nonnegative scalar. When you omit the `step` argument, `step` defaults to 0.1.

`leakage` is the adjoint LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, you implement a leaky version of the `adjlms` algorithm to determine the filter coefficients. `leakage` defaults to 1 specifying no leakage in the algorithm.

`pathcoeffs` is the secondary path filter model. This vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.

`pathest` is the estimate of the secondary path filter model. `pathest` defaults to the values in `pathcoeffs`.

`errstates` is a vector of error states of the adaptive filter. It must have a length equal to the filter order of the secondary path model estimate. `errstates` defaults to a vector of zeros of appropriate length. `pstates` contains the secondary path FIR filter states. It must be a vector of length equal to the filter order of the secondary path model. `pstates` defaults to a vector of zeros of appropriate length. The initial filter coefficients for the secondary path filter compose vector `coeffs`. It must be a length `l` vector. `coeffs` defaults to a length `l` vector of zeros. `states` is a vector containing the initial filter states. It must be a vector of length `l+ne-1`, where `ne` is the length of `errstates`. When you omit `states`, it defaults to an appropriate length vector of zeros.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Specifies the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Length l vector with zeros for all elements	Adjoint LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need `l` entries in `coefficients`. Updated filter coefficients are returned in `coefficients` when you use `s` as an output argument.
`ErrorStates`	[0,...,0]	A vector of the error states for your adaptive filter, with length equal to the order of your secondary path filter.
`FilterLength`	10	The number of coefficients in your adaptive filter.
`Leakage`	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.

Property	Default Value	Description
`SecondaryPathCoeffs`	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor.
`SecondaryPathEstimate`	`pathcoeffs` values	An estimate of the secondary path filter model.
`SecondaryPathStates`	Length of the secondary path filter. All elements are zeros.	The states of the secondary path filter, the unknown system
`States`	l+ne+1, where ne is `length(errstates)`	Contains the initial conditions for your adaptive filter and returns the states of the FIR filter after adaptation. If omitted, it defaults to a zero vector of length equal to l+ne+1. When you use `adaptfilt.adjlms` in a loop structure, use this element to specify the initial filter states for the adapting FIR filter.
`Stepsize`	0.1	Sets the adjoint LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Demonstrate active noise control of a random noise signal that runs for 1000 samples.

```
x  = randn(1,1000);      % Noise source
g  = fir1(47,0.4);       % FIR primary path system model
n  = 0.1*randn(1,1000);  % Observation noise signal
d  = filter(g,1,x)+n;    % Signal to be canceled (desired)
b  = fir1(31,0.5);       % FIR secondary path system model
mu = 0.008;              % Adjoint LMS step size
ha = adaptfilt.adjlms(32,mu,1,b);
[y,e] = filter(ha,x,d);
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

Reviewing the figure shows that the adaptive filter attenuates the original noise signal as you expect.

`adaptfilt.dlms` | `adaptfilt.filtxlms`

Purpose

FIR adaptive filter that uses direct matrix inversion

Syntax

```
ha = adaptfilt.ap(l,step,projectord,offset,coeffs,states,...
errstates,epsstates)
```

Description

`ha = adaptfilt.ap(l,step,projectord,offset,coeffs,states,... errstates,epsstates)` constructs an affine projection FIR adaptive filter `ha` using direct matrix inversion.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ap`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.
`projectord`	Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.
`offset`	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. `offset` should be positive. `offset` defaults to one.

Input Argument	Description
`coeffs`	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`states`	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`errstates`	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`epsstates`	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.

Properties

Since your `adaptfilt.ap` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.ap` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
`ProjectionOrder`	1 to as large as needed.	Projection order of the affine projection algorithm. `ProjectionOrder` defines the size of the input signal covariance matrix and defaults to two.
`OffsetCov`	Matrix of values	Contains the offset covariance matrix
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`ErrorStates`	Vector of elements	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`EpsilonStates`	Vector of elements	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.

Name	Range	Description
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true`.

Examples

Quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. Run the adaptation for 1000 iterations.

```
D  = 16;                    % Number of samples of delay
b  = exp(j*pi/4)*[-0.7 1];  % Numerator coefficients of channel
a  = [1 -0.7];              % Denominator coefficients of channel
ntr= 1000;                  % Number of iterations
s  = sign(randn(1,ntr+D)) + j*sign(randn(1,ntr+D));% Baseband Signal
n  = 0.1*(randn(1,ntr+D) + j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;       % Received signal
x  = r(1+D:ntr+D);    % Input signal (received signal)
d  = s(1:ntr);        % Desired signal (delayed QPSK signal)
mu = 0.1;             % Step size
po = 4;               % Projection order
offset = 0.05;        % Offset for covariance matrix
ha = adaptfilt.ap(32,mu,po,offset);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

The four plots shown reveal the QPSK process at work.

`msesim`

adaptfilt.apru

Purpose

FIR adaptive filter that uses recursive matrix updating

Syntax

```
ha = adaptfilt.apru(l,step,projectord,offset,coeffs,states,
...errstates,epsstates)
```

Description

`ha = adaptfilt.apru(l,step,projectord,offset,coeffs,states, ...errstates,epsstates)` constructs an affine projection FIR adaptive filter `ha` using recursive matrix updating.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.apru`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.
`projectord`	Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.
`offset`	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. `offset` should be positive. `offset` defaults to one.

Input Argument	Description
`coeffs`	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`states`	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`errstates`	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`epsstates`	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.

Properties

Since your `adaptfilt.apru` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.apru` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
`ProjectionOrder`	1 to as large as needed.	Projection order of the affine projection algorithm. `ProjectionOrder` defines the size of the input signal covariance matrix and defaults to two.
`OffsetCov`	Matrix of values	Contains the offset covariance matrix
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`ErrorStates`	Vector of elements	Vector of the adaptive filter error states. `errstates` defaults to a zero vector with length equal to (`projectord` - 1).
`EpsilonStates`	Vector of elements	Vector of the epsilon values of the adaptive filter. `epsstates` defaults to a vector of zeros with (`projectord` - 1) elements.

Name	Range	Description
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true`.

Examples

Demonstrate quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. This example runs the adaptation process for 1000 iterations.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % Baseband
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));  % Noise signal
r  = filter(b,a,s)+n;     % Received signal
x  = r(1+D:ntr+D); % Input signal (received signal)
d  = s(1:ntr);     % Desired signal (delayed QPSK signal)
mu = 0.1;                       % Step size
po = 4;                         % Projection order
offset = 0.05;                     % Offset
ha = adaptfilt.apru(32,mu,po,offset); [y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

In the following component and scatter plots, you see the results of QPSK equalization.

`adaptfilt` | `adaptfilt.ap` | `adaptfilt.bap`

adaptfilt.bap

Purpose

FIR adaptive filter that uses block affine projection

Syntax

```
ha = adaptfilt.bap(l,step,projectord,offset,coeffs,states)
```

Description

`ha = adaptfilt.bap(l,step,projectord,offset,coeffs,states)` constructs a block affine projection FIR adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.bap`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Affine projection step size. This is a scalar that should be a value between zero and one. Setting `step` equal to one provides the fastest convergence during adaptation. `step` defaults to 1.
`projectord`	Projection order of the affine projection algorithm. `projectord` defines the size of the input signal covariance matrix and defaults to two.
`offset`	Offset for the input signal covariance matrix. You should initialize the covariance matrix to a diagonal matrix whose diagonal entries are equal to the offset you specify. `offset` should be positive. `offset` defaults to one.

Input Argument	Description
`coeffs`	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`states`	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Properties

Since your `adaptfilt.bap` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.bap` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ProjectionOrder`	1 to as large as needed.	Projection order of the affine projection algorithm. `ProjectionOrder` defines the size of the input signal covariance matrix and defaults to two.
`OffsetCov`	Matrix of values	Contains the offset covariance matrix

Name	Range	Description
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector, the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `true`.

Examples

Show an example of quadrature phase shift keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                              % delay
```

```
b  = exp(1j*pi/4)*[-0.7 1];             % Numerator coefficients
a  = [1 -0.7];                          % Denominator coefficients
ntr= 1000;                              % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;                         % Received signal
x  = r(1+D:ntr+D);                      % Input signal (received signal)
d  = s(1:ntr);                    % Desired signal (delayed QPSK signal)
mu = 0.5;                         % Step size
po = 4;                           % Projection order
offset = 1.0;                     % Offset for covariance matrix
ha = adaptfilt.bap(32,mu,po,offset);
[y,e] = filter(ha,x,d); subplot(2,2,1);
plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

Using the block affine projection object in QPSK results in the plots shown here.

`adaptfilt` | `adaptfilt.ap` | `adaptfilt.apru`

Purpose

FIR adaptive filter that uses BLMS

Syntax

```
ha = adaptfilt.blms(l,step,leakage,blocklen,coeffs,states)
```

Description

`ha = adaptfilt.blms(l,step,leakage,blocklen,coeffs,states)` constructs an FIR block LMS adaptive filter `ha`, where `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10.

`step` is the block LMS step size. You must set step to a nonnegative scalar. You can use function `maxstep` to determine a reasonable range of step size values for the signals being processed. When unspecified, `step` defaults to 0.

`leakage` is the block LMS leakage factor. It must be a scalar between 0 and 1. If you set leakage to be less than one, you implement the leaky block LMS algorithm. `leakage` defaults to 1 specifying no leakage in the adapting algorithm.

`blocklen` is the block length used. It must be a positive integer and the signal vectors `d` and `x` should be divisible by `blocklen`. Larger block lengths result in faster per-sample execution times but with poor adaptation characteristics. When you choose `blocklen` such that `blocklen + length(coeffs)` is a power of 2, use `adaptfilt.blmsfft`. `blocklen` defaults to `l`.

`coeffs` is a vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector of zeros.

`states` contains a vector of your initial filter states. It must be a length `l` vector and defaults to a length `l` vector of zeros when you do not include it in your calling function.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the

adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l`
`Leakage`		Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
`BlockLength`	Vector of length `l`	Size of the blocks of data processed in each iteration

Property	Default Value	Description
`StepSize`	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use `maxstep` to determine the maximum usable step size.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Use an adaptive filter to identify an unknown 32nd-order FIR filter. In this example 500 input samples result in 500 iterations of the adaptation process. You see in the plot that follows the example code that the adaptive filter has determined the coefficients of the unknown system under test.

```
x  = randn(1,500);        % Input to the filter
b  = fir1(31,0.5);        % FIR system to be identified
no  = 0.1*randn(1,500);   % Observation noise signal
d  = filter(b,1,x)+no;    % Desired signal
mu = 0.008;               % Block LMS step size
n  = 5;                   % Block length
ha = adaptfilt.blms(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
```

```
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');
grid on;
```

Based on looking at the figures here, the adaptive filter correctly identified the unknown system after 500 iterations, or fewer. In the lower plot, you see the comparison between the actual filter coefficients and those determined by the adaptation process.

See Also

`adaptfilt.blmsfft` | `adaptfilt.fdaf` | `adaptfilt.lms`

Purpose

FIR adaptive filter that uses FFT-based BLMS

Syntax

```
ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs,
states)
```

Description

`ha = adaptfilt.blmsfft(l,step,leakage,blocklen,coeffs, states)` constructs an FIR block LMS adaptive filter object `ha` where `l` is the adaptive filter length (the number of coefficients or taps) and must be a positive integer. `l` defaults to 10. `step` is the block LMS step size. It must be a nonnegative scalar. The function `maxstep` may be helpful to determine a reasonable range of step size values for the signals you are processing. `step` defaults to 0.

`leakage` is the block LMS leakage factor. It must also be a scalar between 0 and 1. When `leakage` is less than one, the `adaptfilt.blmsfft` implements a leaky block LMS algorithm. `leakage` defaults to 1 (no leakage). `blocklen` is the block length used. It must be a positive integer such that

```
blocklen + length(coeffs)
```

is a power of two; otherwise, an `adaptfilt.blms` algorithm is used for adapting. Larger block lengths result in faster execution times, with poor adaptation characteristics as the cost of the speed gained. `blocklen` defaults to `l`. Enter your initial filter coefficients in `coeffs`, a vector of length `l`. When omitted, `coeffs` defaults to a length `l` vector of all zeros. `states` contains a vector of initial filter states; it must be a length `l` vector. `states` defaults to a length `l` vector of all zeros when you omit the `states` argument in the calling syntax.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coefficients` defaults to length `l` vector of zeros when you do not provide the argument for input.
`States`	Vector of elements of length `l`	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l`
`Leakage`	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.
`BlockLength`	Vector of length `l`	Size of the blocks of data processed in each iteration

Property	Default Value	Description
`StepSize`	0.1	Sets the block LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution. Use `maxstep` to determine the maximum usable step size.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Examples

Identify an unknown FIR filter with 32 coefficients using 512 iterations of the adapting algorithm.

```
x  = randn(1,512);       % Input to the filter
b  = fir1(31,0.5);       % FIR system to be identified
no  = 0.1*randn(1,512);  % Observation noise signal
d  = filter(b,1,x)+no;   % Desired signal
mu = 0.008;              % Step size
n  = 16;                 % Block length
ha = adaptfilt.blmsfft(32,mu,1,n);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d(1:500);y(1:500);e(1:500)]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error'); xlabel('Time Index');
```

```
ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('actual','estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As a result of running the adaptation process, filter object `ha` now matches the unknown system FIR filter `b`, based on comparing the filter coefficients derived during adaptation.

See Also

`adaptfilt.blms` | `adaptfilt.fdaf` | `adaptfilt.lms` | `filter`

Purpose

FIR adaptive filter that uses delayed LMS

Syntax

```
ha = adaptfilt.dlms(l,step,leakage,delay,errstates,coeffs,
...states)
```

Description

`ha = adaptfilt.dlms(l,step,leakage,delay,errstates,coeffs, ...states)` constructs an FIR delayed LMS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.dlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	LMS step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.
`leakage`	Your LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky LMS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`delay`	Update delay given in time samples. This scalar should be a positive integer — negative delays do not work. `delay` defaults to 1.

Input Argument	Description
`errstates`	Vector of the error states of your adaptive filter. It must have a length equal to the update delay (`delay`) in samples. `errstates` defaults to an appropriate length vector of zeros.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the block LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input. LMS FIR filter coefficients. Should be initialized with the initial coefficients for the FIR filter

Property	Default Value	Description
		prior to adapting. You need `l` entries in `coeffs`.
`Delay`	1	Specifies the update delay for the adaptive algorithm.
`ErrorStates`	Vector of zeros with the number of elements equal to `delay`	A vector comprising the error states for the adaptive filter.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
`Leakage`	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1.

Property	Default Value	Description
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`StepSize`	0.1	Sets the LMS algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Examples

System identification of a 32-coefficient FIR filter. Refer to the figure that follows to see the results of the adapting filter process.

```
x  = randn(1,500);      % Input to the filter
b  = fir1(31,0.5);      % FIR system to be identified
n  = 0.1*randn(1,500);  % Observation noise signal
d  = filter(b,1,x)+n;   % Desired signal
mu = 0.008;             % LMS step size.
```

```
delay = 1;                % Update delay
ha = adaptfilt.dlms(32,mu,1,delay);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using a delayed LMS adaptive filter in the process to identify an unknown filter appears to work as planned, as shown in this figure.

adaptfilt.fdaf

Purpose

FIR adaptive filter that uses frequency-domain with bin step size normalization

Syntax

```
ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen,
offset,...coeffs,states)
```

Description

`ha = adaptfilt.fdaf(l,step,leakage,delta,lambda,blocklen, offset,...coeffs,states)` constructs a frequency-domain FIR adaptive filter `ha` with bin step size normalization. If you omit all the input arguments you create a default object with l = 10 and `step` = 1.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.fdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). l must be a positive integer; it defaults to 10 when you omit the argument.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.
`leakage`	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. `leakage` defaults to 1 — no leakage provided in the algorithm.
`delta`	Initial common value of all of the FFT input signal powers. Its initial value should be positive. `delta` defaults to 1.

Input Argument	Description
`lambda`	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. `lambda` should lie in the range (0,1]. `lambda` defaults to 0.9.
`blocklen`	Block length for the coefficient updates. This must be a positive integer. For faster execution, (`blocklen` + l) should be a power of two. `blocklen` defaults to l.
`offset`	Offset for the normalization terms in the coefficient updates. Use this to avoid divide by zeros or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.
`coeffs`	Initial time-domain coefficients of the adaptive filter. `coeff` should be a length `l` vector. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by the `blocklen`.
`states`	The adaptive filter states. `states` defaults to a zero vector that has length equal to l.

Properties

Since your `adaptfilt.fdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.fdaf` objects. To show you the properties that apply, this table lists and describes each property for the `adaptfilt.fdaf` filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation.
`AvgFactor`	(0, 1]	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. Same as the input argument `lambda`.
`BlockLength`	Any integer	Block length for the coefficient updates. This must be a positive integer. For faster execution, (`blocklen` + l) should be a power of two. `blocklen` defaults to l.
`FFTCoefficients`		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
`FFTStates`		States for the FFT operation.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
`Leakage`		Leakage parameter of the adaptive filter. if this parameter is set to a value between zero and one, you implement a leaky FDAF algorithm. `leakage` defaults to 1 — no leakage provided in the algorithm.

Name	Range	Description
`Offset`	Any positive real value	Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`Power`		A vector of `2*l` elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.
`StepSize`	Any scalar from zero to one, inclusive	Specifies the step size taken between filter coefficient updates

Examples

Quadrature Phase Shift Keying (QPSK) adaptive equalization using 1024 iterations of a 32-coefficient FIR filter. After this example code, a figure demonstrates the equalization results.

```
D = 16;                          % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                   % Denominator coefficients of channel
ntr= 1024;                       % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));  %QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));        % Noise signal
r  = filter(b,a,s)+n;            % Received signal
x  = r(1+D:ntr+D);               % Input signal (received signal)
d  = s(1:ntr);                   % Desired signal (delayed QPSK signal)
del = 1;                         % Initial FFT input powers
mu  = 0.1;                       % Step size
lam = 0.9;                       % Averaging factor
ha = adaptfilt.fdaf(32,mu,1,del,lam);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e])); title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

adaptfilt.filtxlms

Purpose

FIR adaptive filter that uses filtered-x LMS

Syntax

```
ha = adaptfilt.filtxlms(l,step,leakage,pathcoeffs,
pathest,...errstates,pstates,coeffs,states)
```

Description

`ha = adaptfilt.filtxlms(l,step,leakage,pathcoeffs, pathest,...errstates,pstates,coeffs,states)` constructs an filtered-x LMS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.filtxlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Filtered LMS step size. it must be a nonnegative scalar. `step` defaults to 0.1.
`leakage`	is the filtered-x LMS leakage factor. it must be a scalar between 0 and 1. If it is less than one, a leaky version of `adaptfilt.filtxlms` is implemented. `leakage` defaults to 1 (no leakage).
`pathcoeffs`	is the secondary path filter model. this vector should contain the coefficient values of the secondary path from the output actuator to the error sensor.
`pathest`	is the estimate of the secondary path filter model. `pathest` defaults to the values in `pathcoeffs`.

Input Argument	Description
`fstates`	is a vector of filtered input states of the adaptive filter. `fstates` defaults to a zero vector of length equal to (`l` - 1).
`pstates`	are the secondary path FIR filter states. it must be a vector of length equal to the (`length(pathcoeffs)` - 1). `pstates` defaults to a vector of zeros of appropriate length.
`coeffs`	is a vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length l vector of zeros.
`states`	Vector of initial filter states. `states` defaults to a zero vector of length equal to the larger of (`length(pathcoeffs)` - 1) and (`length(pathest)` - 1).

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the adjoint LMS object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not

Property	Default Value	Description
		provide the argument for input.
`FilteredInputStates`	`l-1`	Vector of filtered input states with length equal to `l - 1`.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l + projectord - 2`)
`SecondaryPathCoeffs`	No default	A vector that contains the coefficient values of your secondary path from the output actuator to the error sensor
`SecondaryPathEstimate`	`pathcoeffs` values	An estimate of the secondary path filter model

Property	Default Value	Description
`SecondaryPathStates`	Vector of size (`length (pathcoeffs) -1`) with all elements equal to zero.	The states of the secondary path FIR filter — the unknown system
`StepSize`	0.1	Sets the filtered-x algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Demonstrate active noise control of a random noise signal over 1000 iterations.

As the figure that follows this code demonstrates, the filtered-x LMS filter successfully controls random noise in this context.

```
x  = randn(1,1000);      % Noise source
g  = fir1(47,0.4);       % FIR primary path system model
n  = 0.1*randn(1,1000);  % Observation noise signal
d  = filter(g,1,x)+n;    % Signal to be cancelled
b  = fir1(31,0.5);       % FIR secondary path system model
mu = 0.008;              % Filtered-X LMS step size
ha = adaptfilt.filtxlms(32,mu,1,b);
[y,e] = filter(ha,x,d); plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

Purpose

Fast transversal LMS adaptive filter

Syntax

```
ha = adaptfilt.ftf(l,lambda,delta,gamma,gstates,coeffs,
states)
```

Description

`ha = adaptfilt.ftf(l,lambda,delta,gamma,gstates,coeffs, states)` constructs a fast transversal least squares adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ftf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar that should lie in the range (1-0.5/`l`, 1]. `lambda` defaults to 1.
`delta`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`gamma`	Conversion factor. `gamma` defaults to one specifying soft-constrained initialization.
`gstates`	States of the Kalman gain updates. `gstates` defaults to a zero vector of length `l`.

Input Argument	Description
`coeffs`	Length `l` vector of initial filter coefficients. coeffs defaults to a length `l` vector of zeros.
`states`	Vector of initial filter States. `states` defaults to a zero vector of length (1-1).

Properties

Since your `adaptfilt.ftf` filter is an object, it has properties that define its operating behavior. Note that many of the properties are also input arguments for creating `adaptfilt.ftf` objects. To show you the properties that apply, this table lists and describes each property for the fast transversal least squares filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`BkwdPrediction`		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.

Name	Range	Description
`ConversionFactor`		Conversion factor. Called `gamma` when it is an input argument, it defaults to the matrix [1 -1] that specifies soft-constrained initialization.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`		RLS forgetting factor. This is a scalar that should lie in the range (1-0.5/`l`, 1]. `lambda` defaults to 1.
`FwdPrediction`		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`KalmanGain`		Empty when you construct the object, this gets populated after you run the filter.

Name	Range	Description
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (1 + `projectord` - 2).

Examples

System Identification of a 32-coefficient FIR filter by running the identification process for 500 iterations.

```
x  = randn(1,500);    % Input to the filter
b  = fir1(31,0.5);    % FIR system to be identified
n  = 0.1*randn(1,500);% Observation noise signal
d  = filter(b,1,x)+n; % Desired signal
N  = 31;              % Adaptive filter order
lam = 0.99;           % RLS forgetting factor
del = 0.1;            % Soft-constrained initialization factor
ha = adaptfilt.ftf(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
```

```
xlabel('Time Index'); ylabel('signal value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('coefficient #'); ylabel('Coefficient Value');
```

For this example of identifying an unknown system, the figure shows that the adaptation process identifies the filter coefficients for the unknown FIR filter within the first 150 iterations.

`adaptfilt.swftf` | `adaptfilt.rls` | `adaptfilt.lsl`

Purpose

FIR adaptive filter that uses gradient lattice

Syntax

```
ha = adaptfilt.gal(l,step,leakage,offset,rstep,delta,
lambda,...rcoeffs,coeffs,states)
```

Description

`ha = adaptfilt.gal(l,step,leakage,offset,rstep,delta, lambda,...rcoeffs,coeffs,states)` constructs a gradient adaptive lattice FIR filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.gal`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the reflection coefficients plus one. `l` defaults to 10.
`step`	Joint process step size of the adaptive filter. This scalar should be a value between zero and one. `step` defaults to 0.
`leakage`	Leakage factor of the adaptive filter. It must be a scalar between 0 and 1. Setting leakage less than one implements a leaky algorithm to estimate both the reflection and the joint process coefficients. `leakage` defaults to 1 (no leakage).

Input Argument	Description
`offset`	Specifies an optional offset for the denominator of the step size normalization term. It must be a scalar greater or equal to zero. A non-zero `offset` is useful to avoid divide-by-near-zero conditions when the input signal amplitude becomes very small. `offset` defaults to 1.
`rstep`	Reflection process step size of the adaptive filter. This scalar should be a value between zero and one. `rstep` defaults to `step`.
`delta`	Initial common value of the forward and backward prediction error powers. It should be a positive value. 0.1 is the default value for `delta`.
`lambda`	Specifies the averaging factor used to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. `lambda` should lie in the range (0, 1]. `lambda` defaults to the value (1 - `step`).
`rcoeffs`	Vector of initial reflection coefficients. It should be a length (l-1) vector. `rcoeffs` defaults to a zero vector of length (1-1).
`coeffs`	Vector of initial joint process filter coefficients. It must be a length `l` vector. `coeffs` defaults to a length l vector of zeros.
`states`	Vector of the backward prediction error states of the adaptive filter. `states` defaults to a zero vector of length (1-1).

Properties

Since your `adaptfilt.gal` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.gal` objects. To show you

the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`AvgFactor`		Specifies the averaging factor used to compute the exponentially-windowed forward and backward prediction error powers for the coefficient updates. Same as the input argument `lambda`.
`BkwdPredErrorPower`		Returns the minimum mean-squared prediction error. Refer to [2] in the bibliography for details about linear prediction
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`FwdPredErrorPower`		Returns the minimum mean-squared prediction error in the forward direction. Refer to [2] in the bibliography for details about linear prediction.

Name	Range	Description
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. If this parameter is set to a value between zero and one, you implement a leaky GAL algorithm. `leakage` defaults to 1 — no leakage provided in the algorithm.
`Offset`		Offset for the normalization terms in the coefficient updates. Use this to avoid dividing by zero or by very small numbers when input signal amplitude becomes very small. `offset` defaults to one.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`ReflectionCoeffs`		Coefficients determined for the reflection portion of the filter during adaptation.

Name	Range	Description
`ReflectionCoeffsStep`		Size of the steps used to determine the reflection coefficients.
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`1` + `projectord` - 2).
`StepSize`	0 to 1	Specifies the step size taken between filter coefficient updates

Examples

Perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter over 1000 iterations.

```
D  = 16;                     % Number of delay samples
b  = exp(1j*pi/4)*[-0.7 1];   % Numerator coefficients
a  = [1 -0.7];               % Denominator coefficients
ntr= 1000;                   % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); % QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;        % Received signal
x  = r(1+D:ntr+D);           % Input signal (received signal)
d  = s(1:ntr);               % Desired signal (delayed QPSK signal)
L = 32;                      % filter length
mu = 0.007;                  % Step size
ha = adaptfilt.gal(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
```

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Received Signal Scatter Plot');  axis('square');
xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;
```

To see the results, look at this figure.

Purpose

FIR adaptive filter that uses householder (RLS)

Syntax

```
ha = adaptfilt.hrls(l,lambda,sqrtinvcov,coeffs,states)
```

Description

`ha = adaptfilt.hrls(l,lambda,sqrtinvcov,coeffs,states)` constructs an FIR householder RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.hrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1 meaning the adaptation process retains infinite memory.
`sqrtinvcov`	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to being a length `l` vector of zeros.
`states`	Vector of initial filter states. It must be a length `l`-1 vector. `states` defaults to a length `l`-1 vector of zeros.

Properties

Since your `adaptfilt.hrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.hrls` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. Same as input argument `lambda`. It defaults to 1 meaning the adaptation process retains infinite memory.
`KalmanGain`	Vector of size (`l`,1)	Empty when you construct the object, this gets populated after you run the filter.

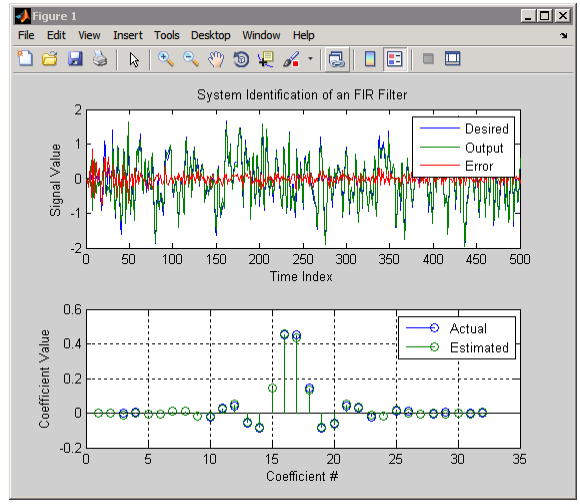
Name	Range	Description
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.
`SqrtInvCov`	Matrix of doubles	Square root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (1 - 1).

Examples

Use 500 iterations of an adaptive filter object to identify a 32-coefficient FIR filter system. Both the example code and the resulting figure show the successful filter identification through adaptive filter processing.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
ha = adaptfilt.hrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
```

```
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
 xlabel('Coefficient #'); ylabel('Coefficient Value');
```



See Also

adaptfilt.hswrls | adaptfilt.qrdrls | adaptfilt.rls

Purpose

FIR adaptive filter that uses householder sliding window RLS

Syntax

```
ha = adaptfilt.hswrls(l,lambda,sqrtinvcov,swblocklen,
dstates,coeffs,states)
```

Description

`ha = adaptfilt.hswrls(l,lambda,sqrtinvcov,swblocklen, dstates,coeffs,states)` constructs an FIR householder sliding window recursive-least-square adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.hswrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	Recursive least square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1 meaning the adaptation process retains infinite memory.
`sqrtinvcov`	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
`swblocklen`	Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklen` defaults to 16.

Input Argument	Description
`dstates`	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to being a length `l` vector of zeros.
`states`	Vector of initial filter states. It must be a length (`l` + `swblocklen` - 2) vector. `states` defaults to a length (`l` + `swblocklen` -2) vector of zeros.

Properties

Since your `adaptfilt.hswrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.hswrls` objects. To show you the properties that apply, this table lists and describes each property for the affine projection filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.

Name	Range	Description
`DesiredSignalStates`	Vector	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	Root-least-square (RLS) forgetting factor. This is a scalar and should lie in the range (0, 1]. Same as input argument `lambda`. It defaults to 1 meaning the adaptation process retains infinite memory.
`KalmanGain`	(1,1) vector	Empty when you construct the object, this gets populated after you run the filter.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.

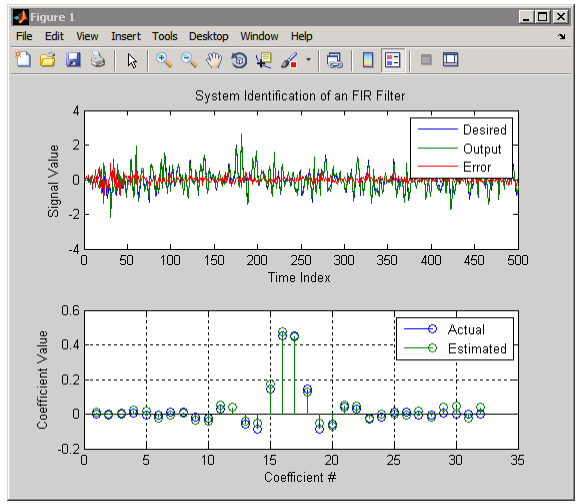
Name	Range	Description
SqrtInvCov	l-by-l Matrix	Square-root of the inverse of the sliding window input signal covariance matrix. This square matrix should be full-ranked.
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (l + projectord - 2).
SwBlockLength	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Examples

System Identification of a 32-coefficient FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
G0 = sqrt(10)*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
N  = 64;               % block length
ha = adaptfilt.hswrls(32,lam,G0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

In the pair of plots shown in the figure you see the comparison of the desired and actual output for the adapting filter and the coefficients of both filters, the unknown and the adapted.



See Also

`adaptfilt.hrls` | `adaptfilt.qrdrls` | `adaptfilt.rls`

Purpose

FIR adaptive filter that uses LMS

Syntax

```
ha = adaptfilt.lms(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.lms(l,step,leakage,coeffs,states)` constructs an FIR LMS adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	LMS step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.1.
`leakage`	Your LMS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky LMS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.

Input Argument	Description
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object created. This table lists the properties for the `adaptfilt.lms` object, their default values, and a brief description of the property.

Property	Range	Property Description
`Algorithm`	None	Reports the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to a length `l` vector of zeros when you do not provide the vector as an input argument.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Property	Range	Property Description
`Leakage`	0 to 1	LMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (1 - 1).
`StepSize`	0 to 1	LMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. `step` defaults to 0.1.

Examples

Use 500 iterations of an adapting filter system to identify and unknown 32nd-order FIR filter.

```
x  = randn(1,500);     % Input to the filter
```

```
b  = fir1(31,0.5);      % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 0.008;            % LMS step size.
ha = adaptfilt.lms(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Using LMS filters in an adaptive filter architecture is a time honored means for identifying an unknown filter. By running the example code provided you can demonstrate one process to identify an unknown FIR filter.

`adaptfilt.blms` | `adaptfilt.blmsfft` | `adaptfilt.dlms` | `adaptfilt.nlms` | `adaptfilt.tdafdft` | `adaptfilt.sd` | `adaptfilt.se` | `adaptfilt.ss`

Purpose

Least squares lattice adaptive filter

Syntax

```
ha = adaptfilt.lsl(l,lambda,delta,coeffs,states)
```

Description

`ha = adaptfilt.lsl(l,lambda,delta,coeffs,states)` constructs a least squares lattice adaptive filter ha.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.lsl`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. L defaults to 10.
`lambda`	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1. `lambda` = 1 denotes infinite memory while adapting to find the new filter.
`delta`	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. `delta` defaults to 1.
`coeffs`	Vector of initial joint process filter coefficients. It must be a length `l` vector. `coeffs` defaults to a length `l` vector of all zeros.
`states`	Vector of the backward prediction error states of the adaptive filter. `states` defaults to a length `l` vector of all zeros, specifying soft-constrained initialization for the algorithm.

Properties

Since your `adaptfilt.lsl` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.lsl` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation.
`BkwdPrediction`		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps.

Name	Range	Description
`ForgettingFactor`		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor = 1` denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`FwdPrediction`		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing.

Name	Range	Description
		States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l`.

Examples

Demonstrate Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter running for 1000 iterations. After you review the example code, the figure shows the results of running the example to use QPSK adaptive equalization with a 32nd-order FIR filter. The error between the in-phase and quadrature components, as shown by the errors plotted in the upper plots, falls to near zero. Also, the equalized signal shows the clear quadrature nature.

```
D  = 16;                      % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];    % Numerator coefficients of channel
a  = [1 -0.7];                % Denominator coefficients of channel
ntr= 1000;                    % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));  % QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;         % Received signal
x  = r(1+D:ntr+D);            % Input signal (received signal)
d  = s(1:ntr);                % Desired signal (delayed QPSK signal)
lam = 0.995;                  % Forgetting factor
del = 1;                      % initialization factor
ha = adaptfilt.lsl(32,lam,del);
[y,e] = filter(ha,x,d);

`adaptfilt.qrdlsl` | `adaptfilt.gal` | `adaptfilt.ftf` | `adaptfilt.rls`

Purpose

Normalized least mean squares adaptive filter

Syntax

```
ha = adaptfilt.nlms(l,step,leakage,offset,coeffs,states)
```

Description

`ha = adaptfilt.nlms(l,step,leakage,offset,coeffs,states)` constructs a normalized least-mean squares (NLMS) FIR adaptive filter object named `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.nlms`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	NLMS step size. It must be a scalar between 0 and 2. Setting this step size value to one provides the fastest convergence. `step` defaults to 1.
`leakage`	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).

Input Argument	Description
`offset`	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, `offset` defaults to zero.
`coeffs`	Vector composed of your initial filter coefficients. Enter a length `l` vector. `coeffs` defaults to a vector of zeros with length equal to the filter order.
`states`	Your initial adaptive filter states appear in the `states` vector. It must be a vector of length `l`-1. `states` defaults to a length `l`-1 vector with zeros for all of the elements.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for normalized LMS objects, their default values, and a brief description of the property.

Property	Range	Property Description
`Algorithm`	None	Reports the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Leakage`	0 to 1	NLMS leakage factor. It must be a scalar between zero and one. When it is less than one, a leaky NLMS algorithm results. `leakage` defaults to 1 (no leakage).
`Offset`	0 or greater	Specifies an optional offset for the denominator of the step size normalization term. You must specify offset to be a scalar greater than or equal to zero. Nonzero offsets can help avoid a divide-by-near-zero condition that causes errors. Use this to avoid dividing by zero (or by very small numbers) when the square of the input data norm becomes very small (when the input signal amplitude becomes very small). When you omit it, `offset` defaults to zero.

Property	Range	Property Description
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` - 1).
`StepSize`	0 to 1	NLMS step size. It must be a scalar between zero and one. Setting this step size value to one provides the fastest convergence. `step` defaults to one.

Examples

To help you compare this algorithm's performance to other LMS-based algorithms, such as BLMS or LMS, this example demonstrates the NLMS adaptive filter in use to identify the coefficients of an unknown FIR filter of order equal to 32 — an example used in other adaptive filter examples.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
mu = 1;                % NLMS step size
offset = 50;           % NLMS offset
```

```
ha = adaptfilt.nlms(32,mu,1,offset);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:500,[d;y;e]);
legend('Desired','Output','Error');
title('System Identification of FIR Filter');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2);
stem([b', ha.coefficients']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

As you see from the figure, the `nlms` variant again closely matches the actual filter coefficients in the unknown FIR filter.

adaptfilt.pbfdaf

Purpose

Partitioned block frequency-domain FIR adaptive filter

Syntax

```
ha = adaptfilt.pbfdaf(l,step,leakage,delta,lambda,blocklen,
offset,coeffs,states)
```

Description

`ha = adaptfilt.pbfdaf(l,step,leakage,delta,lambda,blocklen, offset,coeffs,states)` constructs a partitioned block frequency-domain FIR adaptive filter `ha` that uses bin step size normalization during adaptation.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.pbfdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. L defaults to 10.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. `leakage` defaults to 1— no leakage.
`delta`	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.

Input Argument	Description
`lambda`	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `lambda` should lie in the range (0,1]. `lambda` defaults to 0.9.
`blocklen`	Block length for the coefficient updates. This must be a positive integer such that (`l/blocklen`) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.
`offset`	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. `offset` defaults to zero.
`coeffs`	Initial time-domain coefficients of the adaptive filter. It should be a vector of length `l`. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
`states`	Specifies the filter initial conditions. `states` defaults to a zero vector of length `l`.

Properties

Since your `adaptfilt.pbfdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.pbfdaf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation.
`AvgFactor`		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `AvgFactor` should lie in the range (0,1]. `AvgFactor` defaults to 0.9. Called `lambda` as an input argument.
`BlockLength`		Block length for the coefficient updates. This must be a positive integer such that (`1/blocklen`) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
`FFTCoefficients`		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
`FFTStates`		States for the FFT operation.

Name	Range	Description
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. `leakage` defaults to 1 — no leakage.
`Offset`		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. `offset` defaults to zero.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Name	Range	Description
`Power`		A vector of `2*l` elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.
`StepSize`	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.

Examples

An example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                       % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                 % Denominator coefficients of channel
ntr = 1000;                    % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));     % Noise signal
r  = filter(b,a,s)+n;    % Received signal
x  = r(1+D:ntr+D);             % Input signal (received signal)
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
del = 1;                        % Initial FFT input powers
mu  = 0.1;                      % Step size
lam = 0.9;                      % Averaging factor
N   = 8;                        % Block size
ha = adaptfilt.pbfdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e])); title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
```

```
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
 title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]');  grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');  axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;subplot(2,2,4); plot(y(ntr
title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');  grid on;
```

In the figure shown, the four subplots provide the details of the results of the QPSK process used in the equalization for this example.

Purpose

Partitioned block unconstrained frequency-domain adaptive filter

Syntax

```
ha = adaptfilt.pbufdaf(l,step,leakage,delta,lambda,
blocklen,...offset,coeffs,states)
```

Description

`ha = adaptfilt.pbufdaf(l,step,leakage,delta,lambda, blocklen,...offset,coeffs,states)` constructs a partitioned block unconstrained frequency-domain FIR adaptive filter `ha` with bin step size normalization.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.pbufdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. L defaults to 10.
`step`	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. `leakage` defaults to 1 — no leakage.
`delta`	Initial common value of all of the FFT input signal powers. Its initial value should be positive. delta defaults to 1.

Input Argument	Description
`lambda`	Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `lambda` should lie in the range (0,1]. `lambda` defaults to 0.9.
`blocklen`	Block length for the coefficient updates. This must be a positive integer such that (`l/blocklen`) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.
`offset`	Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small. `offset` defaults to zero.
`coeffs`	Initial time-domain coefficients of the adaptive filter. It should be a vector of length `l`. The PBFDAF algorithm uses these coefficients to compute the initial frequency-domain filter coefficient matrix via FFTs.
`states`	Specifies the filter initial conditions. `states` defaults to a zero vector of length `l`.

Properties

Since your `adaptfilt.pbufdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.pbufdaf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`AvgFactor`		Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates. `AvgFactor` should lie in the range (0,1]. `AvgFactor` defaults to 0.9. Called `lambda` as an input argument.
`BlockLength`		Block length for the coefficient updates. This must be a positive integer such that (`l/blocklen`) is also an integer. For faster execution, `blocklen` should be a power of two. `blocklen` defaults to two.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`FFTCoefficients`		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
`FFTStates`		States for the FFT operation.

Name	Range	Description
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, a leaky version of the PBFDAF algorithm is implemented. `leakage` defaults to 1 — no leakage.
`Offset`		Offset for the normalization terms in the coefficient updates. This can be useful to avoid divide by zeros conditions, or dividing by very small numbers, if any of the FFT input signal powers become very small.`voffset` defaults to zero.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Name	Range	Description
`Power`	2*l element vector	A vector of 2*l elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.
`StepSize`	0 to 1	Step size of the adaptive filter. This is a scalar and should lie in the range (0,1]. `step` defaults to 1.

Examples

Demonstrating Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter. To perform the equalization, this example runs for 1000 iterations.

```
D  = 16;      % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a  = [1 -0.7];             % Denominator coefficients of channel
ntr= 1000;                 % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r  = filter(b,a,s)+n;          % Received signal
x  = r(1+D:ntr+D);             % Input signal (received signal)
d  = s(1:ntr);                 % Desired signal (delayed QPSK signal)
del = 1;                       % Initial FFT input powers
mu  = 0.1;                     % Step size
lam = 0.9;                     % Averaging factor
N   = 8;                       % Block size
ha = adaptfilt.pbufdaf(32,mu,1,del,lam,N);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

You can compare this algorithm to another, such as the `pbfdaf` version. Use the same example of QPSK adaptation. The following figure shows the results.

adaptfilt.qrdlsl

Purpose

QR-decomposition-based least-squares lattice adaptive filter

Syntax

```
ha = adaptfilt.qrdlsl(l,lambda,delta,coeffs,states)
```

Description

`ha = adaptfilt.qrdlsl(l,lambda,delta,coeffs,states)` returns a QR-decomposition-based least squares lattice adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.qrdlsl`.

Input Argument	Description
`l`	Length of the joint process filter coefficients. It must be a positive integer and must be equal to the length of the prediction coefficients plus one. L defaults to 10.
`lambda`	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1. `lambda` = 1 denotes infinite memory while adapting to find the new filter.
`delta`	Soft-constrained initialization factor in the least squares lattice algorithm. It should be positive. `delta` defaults to 1.
`coeffs`	Vector of initial joint process filter coefficients. It must be a length `l` vector. `coeffs` defaults to a length `l` vector of all zeros.
`states`	Vector of the angle normalized backward prediction error states of the adaptive filter

Properties

Since your `adaptfilt.qrdlsl` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.qrdlsl` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`BkwdPrediction`		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`		Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor = 1` denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.

Name	Range	Description
`FwdPrediction`		Returns the predicted samples generated during adaptation in the forward direction. Refer to [2] in the bibliography for details about linear prediction.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to `l -1`

Examples

Implement Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. To see the results of

the equalization process in this example, look at the figure that follows the example code.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D)); % Baseband  QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));   % Noise signal
r  = filter(b,a,s)+n;      % Received signal
x  = r(1+D:ntr+D);         % Input signal (received signal)
d  = s(1:ntr);             % Desired signal (delayed QPSK signal)
lam = 0.995;               % Forgetting factor
del = 1;                   % Soft-constrained initialization factor
ha = adaptfilt.qrdlsl(32,lam,del);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

`adaptfilt.qrdrls` | `adaptfilt.gal` | `adaptfilt.ftf` | `adaptfilt.lsl`

Purpose

FIR adaptive filter that uses QR-decomposition-based RLS

Syntax

```
ha = adaptfilt.qrdrls(l,lambda,sqrtcov,coeffs,states)
```

Description

`ha = adaptfilt.qrdrls(l,lambda,sqrtcov,coeffs,states)` constructs an FIR QR-decomposition-based recursive-least squares (RLS) adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.qrdrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer.`l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. `lambda` defaults to 1.
`sqrtcov`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to length `l` vector whose elements are zeros.
`states`	Vector of initial filter states. It must be a length `l`-1 vector. `states` defaults to a length `l`-1 vector of zeros.

Properties

Since your `adaptfilt.qrdrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.qrdrls` objects. To

show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Vector of length `l`	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor = 1` denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.

Name	Range	Description
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`SqrtCov`	Square matrix with each dimension equal to the filter length `l`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.
`States`	Vector of elements	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

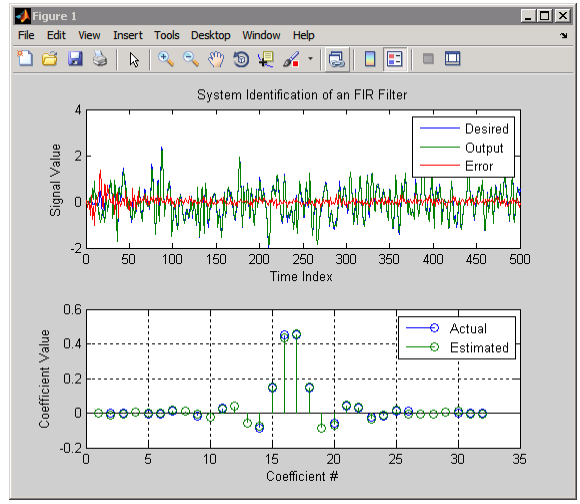
Examples

System Identification of a 32-coefficient FIR filter (500 iterations).

```
x  = randn(1,500);       % Input to the filter
b  = fir1(31,0.5);       % FIR system to be identified
n  = 0.1*randn(1,500);   % Observation noise signal
d  = filter(b,1,x)+n;    % Desired signal
G0 = sqrt(.1)*eye(32);   % Initial sqrt correlation matrix
```

```
lam = 0.99;              % RLS forgetting factor
ha = adaptfilt.qrdrls(32,lam,G0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated'); grid on;
xlabel('Coefficient #'); ylabel('Coefficient Value');
```

Using this variant of the RLS algorithm successfully identifies the unknown FIR filter, as shown here.



See Also

`adaptfilt.rls` | `adaptfilt.hrls` | `adaptfilt.hswrls` | `adaptfilt.swrls`

Purpose

Recursive least-squares FIR adaptive filter

Syntax

```
ha = adaptfilt.rls(l,lambda,invcov,coeffs,states)
```

Description

`ha = adaptfilt.rls(l,lambda,invcov,coeffs,states)` constructs an FIR direct form RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.rls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie in the range (0, 1]. `lambda` defaults to 1.
`invcov`	Inverse of the input signal covariance matrix. For best performance, you should initialize this matrix to be a positive definite matrix.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

Since your `adaptfilt.rls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are

also input arguments for creating `adaptfilt.rls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation.
`Coefficients`	Vector containing `l` elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps. Remember that filter length is filter order + 1.
`ForgettingFactor`	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor` = 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`InvCov`	Matrix of size `l`-by-`l`	Upper-triangular Cholesky (square root) factor of the input covariance matrix. Initialize this matrix with a positive definite upper triangular matrix.

Name	Range	Description
`KalmanGain`	Vector of size (1,1)	Empty when you construct the object, this gets populated after you run the filter.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.
`States`	Double array	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`1` + `projectord` - 2).

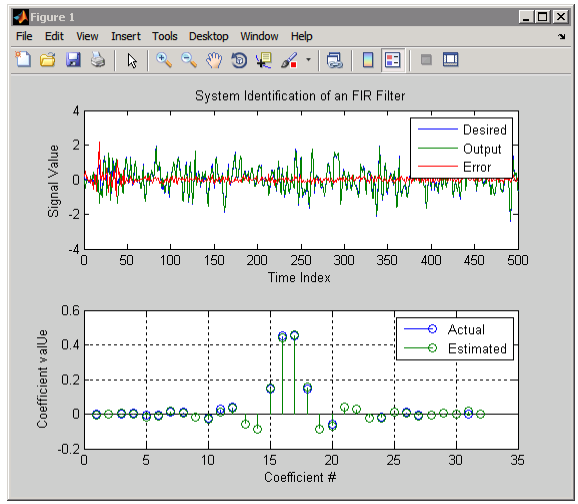
Examples

System Identification of a 32-coefficient FIR filter over 500 adaptation iterations.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
P0 = 10*eye(32); % Initial sqrt correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
ha = adaptfilt.rls(32,lam,P0);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
```

```
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient valUe');  grid on;
```

In this example of adaptive filtering using the RLS algorithm to update the filter coefficients for each iteration, the figure shown reveals the fidelity of the derived filter after adaptation.



See Also

`adaptfilt.hrls` | `adaptfilt.hswrls` | `adaptfilt.qrdrls`

Purpose

Sign-data FIR adaptive filter

Syntax

```
ha = adaptfilt.sd(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.sd(l,step,leakage,coeffs,states)` constructs an FIR sign-data adaptive filter object `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.sd`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SD step size. It must be a nonnegative scalar. `step` defaults to 0.1
`leakage`	Your SD leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.sd` implements a leaky SD algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for sign-data objects, their default values, and a brief description of the property.

Property	Default Value	Description
`Al gorithm`	Sign-data	Defines the adaptive filter algorithm the object uses during adaptation.
`Coefficients`	`zeros`(1,`l`)	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting. You need `l` entries in `coefficients`.
`FilterLength`	10	Reports the length of the filter, the number of coefficients or taps.
`Leakage`	0	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to 0.

Property	Default Value	Description
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	`zeros(1-1,1)`	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (1 - 1).
`StepSize`	0.1	Sets the SD algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Adaptive line enhancement using a 32-coefficient FIR filter to perform the enhancement. This example runs for 5000 iterations, as you see in property `iter`.

```
d  = 1;                         % Number of samples of delay
ntr= 5000;                      % Number of iterations
v  = sin(2*pi*0.05*[1:ntr+d]);  % Sinusoidal signal
n  = randn(1,ntr+d);            % Noise signal
```

```
x  = v(1:ntr)+n(1:ntr);         % Input signal
d  = v(1+d:ntr+d)+n(1+d:ntr+d); % Desired signal
mu = 0.0001;                    % Sign-data step size.
ha = adaptfilt.sd(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of a Noisy Sinusoidal Signal');
legend('Observed','Enhanced','Original');
 xlabel('Time Index'); ylabel('Signal Value');
[pxx,om] = pwelch(x(ntr-1000:ntr));
 pyy = pwelch(y(ntr-1000:ntr));
subplot(2,1,2);
plot(om/pi,10*log10([pxx/max(pxx),pyy/max(pyy)]));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Each of the variants — sign-data, sign-error, and sign-sign — uses the same example. You can compare the results by viewing the figure shown for each adaptive filter method — `adaptfilt.sd`, `adaptfilt.se`, and `adaptfilt.ss`.

See Also

`adaptfilt.lms` | `adaptfilt.se` | `adaptfilt.ss`

Purpose

FIR adaptive filter that uses sign-error algorithm

Syntax

```
ha = adaptfilt.se(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.se(l,step,leakage,coeffs,states)` constructs an FIR sign-error adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.se`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SE step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.1
`leakage`	Your SE leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.se` implements a leaky SE algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.

Input Argument	Description
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l`-1 vector. `states` defaults to a length l-1 vector of zeros.

Properties

In the syntax for creating the `adaptfilt` object, the input options are properties of the object you create. This table lists the properties for the sign-error SD object, their default values, and a brief description of the property.

Property	Default Value	Description
`Algorithm`	Sign-error	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	`zeros`(1,`l`)	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
`FilterLength`	10	Reports the length of the filter, the number of coefficients or taps

Property	Default Value	Description
`Leakage`	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. Defaults to one if omitted.
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	`zeros(l-1,1)`	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l -1`).
`StepSize`	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Use `inspect(ha)` to view or change the object properties graphically using the MATLAB Property Inspector.

Examples

Adaptive line enhancement using a 32-coefficient FIR filter running over 5000 iterations.

```
d = 1;                        % Number of samples of delay
ntr= 5000;                    % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d));    % Sinusoidal signal
n = randn(1,ntr+d);           % Noise signal
x = v(1:ntr)+n(1:ntr);        % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                     % Sign-error step size
ha = adaptfilt.se(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
HWelch = spectrum.welch;
InputPsd = psd(HWelch,x(ntr-1000:ntr));
OutputPsd = psd(HWelch,y(ntr-1000:ntr));
CompPsdEst = [InputPsd.Data/max(InputPsd.Data), OutputPsd.Data/max(OutputPsd.Data)];
subplot(2,1,2); plot(InputPsd.Frequencies/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

Compare the figure shown here to the ones for `adaptfilt.sd` and `adaptfilt.ss` to see how the variants perform on the same example.

Hayes, M, *Statistical Digital Signal Processing and Modeling*, New York, Wiley, 1996.

See Also

`adaptfilt.sd` | `adaptfilt.ss` | `adaptfilt.lms`

Purpose

FIR adaptive filter that uses sign-sign algorithm

Syntax

```
ha = adaptfilt.ss(l,step,leakage,coeffs,states)
```

Description

`ha = adaptfilt.ss(l,step,leakage,coeffs,states)` constructs an FIR sign-error adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ss`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	SS step size. It must be a nonnegative scalar. `step` defaults to 0.1.
`leakage`	Your SS leakage factor. It must be a scalar between 0 and 1. When `leakage` is less than one, `adaptfilt.lms` implements a leaky SS algorithm. When you omit the `leakage` property in the calling syntax, it defaults to 1 providing no leakage in the adapting algorithm.
`coeffs`	Vector of initial filter coefficients. it must be a length `l` vector. `coeffs` defaults to length `l` vector with elements equal to zero.
`states`	Vector of initial filter states for the adaptive filter. It must be a length `l` -1 vector. `states` defaults to a length l-1 vector of zeros.

adaptfilt.ss can be called for a block of data, when x and d are vectors, or in "sample by sample mode" using a For-loop with the method filter:

```
for n = 1:length(x)
ha = adaptfilt.ss(25,0.9);
[y(n),e(n)] = filter(ha,(x(n),d(n),s));
end
```

Properties

In the syntax for creating the adaptfilt object, most of the input options are properties of the object you create. This table lists the properties for sign-sign objects, their default values, and a brief description of the property.

Property	Default Value	Description
Algorithm	Sign-sign	Defines the adaptive filter algorithm the object uses during adaptation
Coefficients	zeros(1,l)	Vector containing the initial filter coefficients. It must be a length l vector where l is the number of filter coefficients. coeffs defaults to length l vector of zeros when you do not provide the argument for input. Should be initialized with the initial coefficients for the FIR filter prior to adapting.
FilterLength	10	Reports the length of the filter, the number of coefficients or taps

Property	Default Value	Description
`Leakage`	1	Specifies the leakage parameter. Allows you to implement a leaky algorithm. Including a leakage factor can improve the results of the algorithm by forcing the algorithm to continue to adapt even after it reaches a minimum value. Ranges between 0 and 1. 1 is the default value.
`PersistentMemory`	`false` or `true`	Determine whether the filter states and coefficients get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any property value that the filter changes during processing. Property values that the filter does not change are not affected. Defaults to `false`.
`States`	`zeros(l-1,1)`	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l-1`).
`StepSize`	0.1	Sets the SE algorithm step size used for each iteration of the adapting algorithm. Determines both how quickly and how closely the adaptive filter converges to the filter solution.

Examples

Demonstrating adaptive line enhancement using a 32-coefficient FIR filter provides a good introduction to the sign-sign algorithm.

```
d = 1;                        % Number of samples of delay
ntr= 5000;                    % Number of iterations
v = sin(2*pi*0.05*(1:ntr+d));    % Sinusoidal signal
n = randn(1,ntr+d);           % Noise signal
x = v(1:ntr)+n(1:ntr);        % Input signal --(delayed desired signal)
d = v(1+d:ntr+d)+n(1+d:ntr+d);  % Desired signal
mu = 0.0001;                     % Sign-error step size
ha = adaptfilt.ss(32,mu);
[y,e] = filter(ha,x,d);
subplot(2,1,1);
plot(1:ntr,[d;y;v(1:end-1)]);
axis([ntr-100 ntr -3 3]);
title('Adaptive Line Enhancement of Noisy Sinusoid');
legend('Observed','Enhanced','Original');
xlabel('Time Index'); ylabel('Signal Value');
[InputPsd,wi] = pwelch(x(ntr-1000:ntr));
[OutputPsd,wo] = pwelch(y(ntr-1000:ntr));
CompPsdEst = [InputPsd/max(InputPsd), OutputPsd/max(OutputPsd)];
subplot(2,1,2); plot(wi/pi,10*log10(CompPsdEst));
axis([0 1 -60 20]); legend('Observed','Enhanced');
xlabel('Normalized Frequency (\times \pi rad/sample)');
ylabel('Power Spectral Density'); grid on;
```

This example is the same as the ones used for the sign-data and sign-error examples. Comparing the figures shown for each of the others lets you assess the performance of each for the same task.

adaptfilt.swftf

Purpose

FIR adaptive filter that uses sliding window fast transversal least squares

Syntax

```
ha = adaptfilt.swftf(l,delta,blocklen,gamma,gstates,
dstates,...coeffs,states)
```

Description

`ha = adaptfilt.swftf(l,delta,blocklen,gamma,gstates, dstates,...coeffs,states)` constructs a sliding window fast transversal least squares adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.swftf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`delta`	Soft-constrained initialization factor. This scalar should be positive and sufficiently large to maintain stability. `delta` defaults to 1.
`blocklen`	Block length of the sliding window. This must be an integer at least as large as the filter length `l`, which is the default value.
`gamma`	Conversion factor. `gamma` defaults to the matrix [1 -1] that specifies soft-constrained initialization.
`gstates`	States of the Kalman gain updates. `gstates` defaults to a zero vector of length (`l` + `blocklen` - 1).

Input Argument	Description
`dstates`	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector of length equal to (`blocklen` - 1). For a default object, `dstates` is (`l`-1).
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to length `l` vector of all zeros.
`states`	Vector of initial filter states. `states` defaults to a zero vector of length equal to (`l` + `blocklen` - 2).

Properties

Since your `adaptfilt.swftf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.swftf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`BkwdPredictions`		Returns the predicted samples generated during adaptation. Refer to [2] in the bibliography for details about linear prediction.
`BlockLength`		Block length of the sliding window. This must be an integer at least as large as the filter length `l`, which is the default value.

Name	Range	Description
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`ConversionFactor`		Conversion factor. Called `gamma` when it is an input argument, it defaults to the matrix [1 -1] that specifies soft-constrained initialization.
`DesiredSignal States`		Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`blocklen` - 1).
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`FwdPrediction`		Contains the predicted values for samples during adaptation. Compare these to the actual samples to get the error and power.
`InitFactor`		Soft-constrained initialization factor. This scalar should be positive and sufficiently large to prevent an excessive number of Kalman gain rescues. `delta` defaults to one.

Name	Range	Description
`KalmanGain`		Empty when you construct the object, this gets populated after you run the filter.
`KalmanGainStates`		Contains the states of the Kalman gains for the adaptive algorithm. Initialized to a vector of double data type entries.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).

Examples

Over 500 iterations, perform a system identification of a 32-coefficient FIR filter.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
L  = 32;               % Adaptive filter length
```

```
del = 0.1;              % Soft-constrained initialization factor
N  = 64;                % block length
ha = adaptfilt.swftf(L,del,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

Review the figure for the results of the example. When you evaluate the example you should get the same results, within the differences in the random noise signal you use.

`adaptfilt.ftf` | `adaptfilt.swrls` | `adaptfilt.ap` | `adaptfilt.apru`

Purpose

FIR adaptive filter that uses window recursive least squares (RLS)

Syntax

```
ha = adaptfilt.swrls(l,lambda,invcov,swblocklen,
dstates,...coeffs,states)
```

Description

`ha = adaptfilt.swrls(l,lambda,invcov,swblocklen, dstates,...coeffs,states)` constructs an FIR sliding window RLS adaptive filter `ha`.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.swrls`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps). It must be a positive integer. `l` defaults to 10.
`lambda`	RLS forgetting factor. This is a scalar and should lie within the range (0, 1]. `lambda` defaults to 1.
`invcov`	Inverse of the input signal covariance matrix. You should initialize `invcov` to a positive definite matrix.
`swblocklen`	Block length of the sliding window. This integer must be at least as large as the filter length. `swblocklen` defaults to 16.
`dstates`	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).

Input Argument	Description
`coeffs`	Vector of initial filter coefficients. It must be a length `l` vector. `coeffs` defaults to length `l` vector of all zeros.
`states`	Vector of initial filter states. `states` defaults to a zero vector of length equal to (`l` + `swblocklen` - 2).

Properties

Since your `adaptfilt.swrls` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.swrls` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`Coefficients`	Any vector of `l` elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`DesiredSignalStates`	Vector	Desired signal states of the adaptive filter. `dstates` defaults to a zero vector with length equal to (`swblocklen` - 1).

Name	Range	Description
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`ForgettingFactor`	Scalar	Forgetting factor of the adaptive filter. This is a scalar and should lie in the range (0, 1]. It defaults to 1. Setting `forgetting factor` = 1 denotes infinite memory while adapting to find the new filter. Note that this is the `lambda` input argument.
`InvCov`	Matrix	Square matrix with each dimension equal to the filter length `1`.
`KalmanGain`	Vector with dimensions (1,1)	Empty when you construct the object, this gets populated after you run the filter.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter if you have not changed the filter since you constructed it. `PersistentMemory` returns to zero any state that the filter changes during processing. Defaults to `false`.

Name	Range	Description
States	Vector of elements, data type double	Vector of the adaptive filter states. states defaults to a vector of zeros which has length equal to (1 + swblocklen - 2)
SwBlockLength	Integer	Block length of the sliding window. This integer must be at least as large as the filter length. swblocklen defaults to 16.

Examples

System Identification of a 32-coefficient FIR filter. Use 500 iterations to adapt to the unknown filter. After the example code, you see a figure that plots the results of the running the code.

```
x  = randn(1,500);     % Input to the filter
b  = fir1(31,0.5);     % FIR system to be identified
n  = 0.1*randn(1,500); % Observation noise signal
d  = filter(b,1,x)+n;  % Desired signal
P0 = 10*eye(32);       % Initial correlation matrix inverse
lam = 0.99;            % RLS forgetting factor
N  = 64;               % Block length
ha = adaptfilt.swrls(32,lam,P0,N);
[y,e] = filter(ha,x,d);
subplot(2,1,1); plot(1:500,[d;y;e]);
 title('System Identification of an FIR Filter');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,1,2); stem([b.',ha.Coefficients.']);
legend('Actual','Estimated');
xlabel('Coefficient #'); ylabel('Coefficient Value');  grid on;
```

In the figure you see clearly that the adaptive filter process successfully identified the coefficients of the unknown FIR filter. You knew it

had to or many things that you take for granted, such as modems on computers, would not work.

`adaptfilt.rls` | `adaptfilt.qrdrls` | `adaptfilt.hswrls`

Purpose

Adaptive filter that uses discrete cosine transform

Syntax

```
ha = adaptfilt.tdafdct(l,step,leakage,offset,delta,lambda,
coeffs,states)
```

Description

`ha = adaptfilt.tdafdct(l,step,leakage,offset,delta,lambda, coeffs,states)` constructs a transform-domain adaptive filter ha object that uses the discrete cosine transform to perform filter adaptation.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.tdafdct`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDCT algorithm. `leakage` defaults to 1 — no leakage.

Input Argument	Description
`offset`	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zero or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.
`delta`	Initial common value of all of the transform domain powers. Its initial value should be positive. `delta` defaults to 5.
`lambda`	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. `lambda` should lie between zero and one. For default filter objects, `lambda` equals (`1 - step`).
`coeffs`	Initial time domain coefficients of the adaptive filter. Set it to be a length `l` vector. `coeffs` defaults to a zero vector of length `l`.
`states`	Initial conditions of the adaptive filter. `states` defaults to a zero vector with length equal to (`l - 1`).

Properties

Since your `adaptfilt.tdafdct` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.tdafdct` objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation.
`AvgFactor`		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. `AvgFactor` should lie between zero and one. For default filter objects, `AvgFactor` equals (1 - `step`). `lambda` is the input argument that represent `AvgFactor`.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps.
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. `leakage` defaults to 1 — no leakage.

Name	Range	Description
`Offset`		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`Power`	`2*l` element vector	A vector of `2*l` elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.

Name	Range	Description
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (1 + `projectord` - 2).
`StepSize`	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.

For checking the values of properties for an adaptive filter object, use `get(ha)` or enter the object name, without a trailing semicolon, at the MATLAB prompt.

Examples

Using 1000 iterations, perform a Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];      % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D)); %QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D)); % Noise signal
r  = filter(b,a,s)+n;           % Received signal
x  = r(1+D:ntr+D);              % Input signal (received signal)
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
L  = 32;                        % filter length
mu = 0.01;                      % Step size
ha = adaptfilt.tdafdct(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1);
plot(1:ntr,real([d;y;e])); title('In-Phase Components');
```

```
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); grid on;
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]');
```

Compare the plots shown in this figure to those in the other time domain filter variations. The comparison should help you select and understand how the variants differ.

adaptfilt.tdafdft

Purpose

Adaptive filter that uses discrete Fourier transform

Syntax

```
ha = adaptfilt.tdafdft(l,step,leakage,offset,
delta,lambda,...coeffs,states)
```

Description

`ha = adaptfilt.tdafdft(l,step,leakage,offset, delta,lambda,...coeffs,states)` constructs a transform-domain adaptive filter object `ha` using a discrete Fourier transform.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.tdafdft`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. `leakage` defaults to 1 — no leakage.

Input Argument	Description
`offset`	Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.
`delta`	Initial common value of all of the transform domain powers. Its initial value should be positive. `delta` defaults to 5.
`lambda`	Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. `lambda` should lie between zero and one. For default filter objects, LAMBDA equals (`1 - step`).
`coeffs`	Initial time domain coefficients of the adaptive filter. Set it to be a length `l` vector. `coeffs` defaults to a zero vector of length `l`.
`states`	Initial conditions of the adaptive filter. `states` defaults to a zero vector with length equal to (`l - 1`).

Properties

Since your `adaptfilt.tdafdft` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.tdafdft` objects. To show you the properties that apply, this table lists and describes each property for the transform domain filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`AvgFactor`		Averaging factor used to compute the exponentially-windowed estimates of the powers in the transformed signal bins for the coefficient updates. `AvgFactor` should lie between zero and one. For default filter objects, `AvgFactor` equals (1 - `step`). `lambda` is the input argument that represent `AvgFactor`.
`Coefficients`	Vector of elements	Vector containing the initial filter coefficients. It must be a length `l` vector where `l` is the number of filter coefficients. `coeffs` defaults to length `l` vector of zeros when you do not provide the argument for input.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the TDAFDFT algorithm. `leakage` defaults to 1 — no leakage.

Name	Range	Description
`Offset`		Offset for the normalization terms in the coefficient updates. You can use this argument to avoid dividing by zeros or by very small numbers when any of the FFT input signal powers become very small. `offset` defaults to zero.
`PersistentMemory`	`false` or `true`	Determines whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.
`Power`	2*`l` element vector	A vector of 2*`l` elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.
`States`	Vector of elements, data type double	Vector of the adaptive filter states. `states` defaults to a vector of zeros which has length equal to (`l` + `projectord` - 2).
`StepSize`	0 to 1	Step size. It must be a nonnegative scalar, greater than zero and less than or equal to 1. `step` defaults to 0.

Examples

Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient FIR filter (1000 iterations).

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1000;                      % Number of iterations
s  = sign(randn(1,ntr+D)) + 1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));      % Noise signal
r  = filter(b,a,s)+n;           % Received signal
x  = r(1+D:ntr+D);              % Input signal (received signal)
d  = s(1:ntr);                  % Desired signal (delayed QPSK signal)
L  = 32;                        % filter length
mu = 0.01;                      % Step size
ha = adaptfilt.tdafdft(L,mu);
[y,e] = filter(ha,x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.');
 axis([-3 3 -3 3]); title('Received Signal Scatter Plot');
axis('square');  xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.');
axis([-3 3 -3 3]); title('Equalized Signal Scatter Plot');
axis('square'); xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

All of the time domain adaptive filter reference pages use this QPSK example. By comparing the results for each variation you get an idea of the differences in the way each one performs.

This figure demonstrates the results of running the example code shown.

adaptfilt.ufdaf

Purpose

FIR adaptive filter that uses unconstrained frequency-domain with quantized step size normalization

Syntax

```
ha = adaptfilt.ufdaf(l,step,leakage,delta,lambda,blocklen,
offset,coeffs,states)
```

Description

```
ha = adaptfilt.ufdaf(l,step,leakage,delta,lambda,blocklen,
offset,coeffs,states)
```

constructs an unconstrained frequency-domain FIR adaptive filter `ha` with quantized step size normalization.

For information on how to run data through your adaptive filter object, see the Adaptive Filter Syntaxes section of the reference page for `filter`.

Input Arguments

Entries in the following table describe the input arguments for `adaptfilt.ufdaf`.

Input Argument	Description
`l`	Adaptive filter length (the number of coefficients or taps) and it must be a positive integer. `l` defaults to 10.
`step`	Adaptive filter step size. It must be a nonnegative scalar. `step` defaults to 0.
`leakage`	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. `leakage` defaults to 1 — no leakage.
`delta`	Initial common value of all of the FFT input signal powers. the initial value of delta should be positive, and it defaults to 1.

Input Argument	Description
`lambda`	Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. `lambda` should lie in the range (0,1]. For default UFDAF filter objects, `lambda` defaults to 0.9.
`blocklen`	Block length for the coefficient updates. This must be a positive integer. For faster execution, (`blocklen` `l`) should be a power of two. `blocklen` defaults to `l`.
`offset`	Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.
`coeffs`	Initial time-domain coefficients of the adaptive filter. It should be a length `l` vector. The filter object uses these coefficients to compute the initial frequency-domain filter coefficients via an FFT computed after zero-padding the time-domain vector by `blocklen`.
`states`	Adaptive filter states. `states` defaults to a zero vector with length equal to `l`.

Properties

Since your `adaptfilt.ufdaf` filter is an object, it has properties that define its behavior in operation. Note that many of the properties are also input arguments for creating `adaptfilt.ufdaf` objects. To show you the properties that apply, this table lists and describes each property for the filter object.

Name	Range	Description
`Algorithm`	None	Defines the adaptive filter algorithm the object uses during adaptation
`AvgFactor`		Specifies the averaging factor used to compute the exponentially-windowed FFT input signal powers for the coefficient updates. `AvgFactor` should lie in the range (0,1]. For default UFDAF filter objects, `AvgFactor` defaults to 0.9. Note that AvgFactor and lambda are the same thing — lambda is an input argument and AvgFactor a property of the object.
`BlockLength`		Block length for the coefficient updates. This must be a positive integer. For faster execution, (`blocklen` + `1`) should be a power of two. `blocklen` defaults to `1`.
`FFTCoefficients`		Stores the discrete Fourier transform of the filter coefficients in `coeffs`.
`FFTStates`		States for the FFT operation.
`FilterLength`	Any positive integer	Reports the length of the filter, the number of coefficients or taps

Name	Range	Description
`Leakage`	0 to 1	Leakage parameter of the adaptive filter. When you set this argument to a value between zero and one, you are implementing a leaky version of the UFDAF algorithm. `leakage` defaults to 1 — no leakage.
`Offset`		Offset for the normalization terms in the coefficient updates. This can help you avoid divide by zero conditions, or divide by very small numbers conditions, when any of the FFT input signal powers become very small. Default value is zero.
`PersistentMemory`	`false` or `true`	Determine whether the filter states get restored to their starting values for each filtering operation. The starting values are the values in place when you create the filter. `PersistentMemory` returns to zero any state that the filter changes during processing. States that the filter does not change are not affected. Defaults to `false`.

Name	Range	Description
`Power`	2*l element vector	A vector of 2*l elements, each initialized with the value `delta` from the input arguments. As you filter data, `Power` gets updated by the filter process.
`StepSize`	0 to 1	Adaptive filter step size. It must be a nonnegative scalar. You can use `maxstep` to determine a reasonable range of step size values for the signals being processed. `step` defaults to 0.

Examples

Show an example of Quadrature Phase Shift Keying (QPSK) adaptive equalization using a 32-coefficient adaptive filter. For fidelity, use 1024 iterations. The figure that follows the code provides the information you need to assess the performance of the equalization process.

```
D  = 16;                        % Number of samples of delay
b  = exp(1j*pi/4)*[-0.7 1];     % Numerator coefficients of channel
a  = [1 -0.7];                  % Denominator coefficients of channel
ntr= 1024;                      % Number of iterations
s = sign(randn(1,ntr+D))+1j*sign(randn(1,ntr+D));% Baseband QPSK signal
n  = 0.1*(randn(1,ntr+D) + 1j*randn(1,ntr+D));
r  = filter(b,a,s)+n;% Received signal
x  = r(1+D:ntr+D);   % Input signal (received signal)
d  = s(1:ntr);       % Desired signal (delayed QPSK signal)
del = 1;            %Initial FFT input powers
mu  = 0.1;           % Step size
lam = 0.9;          % Averaging factor
ha = adaptfilt.ufdaf(32,mu,1,del,lam);
[y,e] = filter(ha,x,d);
subplot(2,2,1);  plot(1:1000,real([d(1:1000);y(1:1000);e(1:1000)]));
```

```
title('In-Phase Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components'); legend('Desired','Output','Error');
xlabel('Time Index'); ylabel('Signal Value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

allpass2wdf

Purpose

Allpass to Wave Digital Filter coefficient transformation

Syntax

```
w = allpass2wdf(a)
W = allpass2wdf(A)
```

Description

`w = allpass2wdf(a)` accepts a vector of real allpass polynomial filter coefficients `a`, and returns the transformed coefficient `w`. `w` can be used with allpass filter objects such as `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`, with Structure set to `'Wave Digital Filter'`.

`W = allpass2wdf(A)` accepts the cell array of allpass polynomial coefficient vectors `A`. Each cell of `A` holds the coefficients of a section of a cascade allpass filter. `W` is also a cell array, and each cell of `W` contains the transformed version of the coefficients in the corresponding cell of `A`. W can be used with allpass filter objects such as `dsp.AllpassFilter` and `dsp.CoupledAllpassFilter`, with structure set to `'Wave Digital Filter'`.

Input Arguments

a - allpass filter coefficients

(default) | vector of real numbers

Numeric vector of allpass filter coefficients, specified as real numbers. `a` can have length only equal to 1,2, and 4. When the length is 4, the first and third components must both be zero. `a` can be a row or a column vector.

Example: `0.7`

Data Types

`double | single`

A - allpass filter coefficients

(default) | vector of cells

Cascade of allpass filter coefficients, specified as a cell vector. Every cell of `A` must contain a real vector of length 1,2, or 4. When the length is

4, the first and third components must both be zero. `A` can be a row or column vector of cells.

Example: `{0.7, [0.1, 0.2]}`

Data Types
`double | single`

Output Arguments

w - transformed version of the coefficients `a`

(default) | vector of real numbers

Numeric vector of transformed coefficients, determined as a real number, to use with single-section allpass filter objects having `Structure` set to `'Wave Digital Filter'`. `W` is always returned as a numeric row vector.

Example: `0.7`

Data Types
`double | single`

W - transformed version of the coefficients cell array `A`

(default) | vector of cell

Cascade of transformed allpass filter coefficients, determined as a cell array, to use with multi-section allpass filter objects having `Structure` set to `'Wave Digital Filter'`. `W` is always returned as a column of cells.

Example: `{0.7;[0.2,-0.0833]}`

Data Types
`double | single`

Examples

Allpass coefficients

This example illustrates the use of allpass2wdf to enable Wave Digital Filter as Structure of dsp.AllpassFilter.

```
a = [0 0.5];    % Original 2nd order allpass coefficients
smm = dsp.AllpassFilter('AllpassCoefficients', a);
```

```
w = allpass2wdf(a); % Convert coefficients to Wave Digital Filter for
swdf = dsp.AllpassFilter('Structure', 'Wave Digital Filter',...
    'WDFCoefficients', w);
in = randn(512, 1);
out_mm = step(smm, in);
out_wdf = step(swdf, in);
max(out_mm-out_wdf);  % Compare numerical difference of filter output
```

Algorithms

In the more general case, the input coefficients A define a cascade or multisection allpass filter. `allpass2wdf` applies separately to each section of the same transformation used in the single-section case. In the single-section case, the numeric coefficients vector a contains a standard polynomial representation of an allpass filter of order 1, 2, or 4. For example, in the first order case,

$$a = \left[a_1\right]$$

represents the first order transfer function:

$$H_1(z) = \frac{z^{-1} + a_1}{1 + a_1 z^{-1}}$$

and in the second order case,

$$a = \left[a_1, a_2\right]$$

represents the second order transfer function:

$$H_2(z) = \frac{z^{-2} + a_1 z^{-1} + a_2}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

.

The allpass transfer functions H_1 and H_2 can also have the following alternative representations, using decoupled coefficients in vector w_1 or w_2 respectively.

$$\tilde{H}_1(z) = \frac{z^{-1} + w_1}{1 + w_1 z^{-1}}$$

$$\tilde{H}_2(z) = \frac{z^{-2} + w_2(1 + w_1)z^{-1} + w_1}{1 + w_2(1 + w_1)z^{-1} + w_1 z^{-2}}$$

For allpass coefficients, w is often used to derive adaptor multipliers for Wave Digital Filter structures, and it is required by a number of allpass based filters in DSP System Toolbox when `Structure` is set to `'Wave Digital Filter'` (e.g. `dsp.AllpassFilter`, and `dsp.CoupledAllpassFilter`).

For a given vector of section coefficients a, `allpass2wdf` computes the corresponding vector w such that

when $i = 1, 2$ *or* 4

$$\tilde{H}_i(z) = H_i(z)$$

This results in using the following formulas:

for order 1:

$$w_1 = a_1$$

for order 2:

$$w_1 = a_2$$

$$w_2 = \frac{a_1}{1 + a_2}$$

for order 4:

$$w_1 = a_4$$

$$w_3 = \frac{a_2}{1 + a_4}$$

$$w_2 = w_4 = 0$$

`wdf2allpass` | `tf2ca` | `tf2latc` | `dsp.AllpassFilter` | `dsp.CoupledAllpassFilter`

Purpose

Allpass filter for complex bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpassbpc2bpc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a complex bandpass to complex bandpass frequency transformation. This transformation effectively places two features of an original filter, located at frequencies W_{o1} and W_{o2}, at the required target frequency locations W_{t1} and W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. In most of the cases the features selected for the transformation are the band edges of the filter passbands. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

This transformation can also be used for transforming other types of filters; e.g., complex notch filters or resonators can be repositioned at two distinct desired frequencies at any place around the unit circle. This is very attractive for adaptive systems.

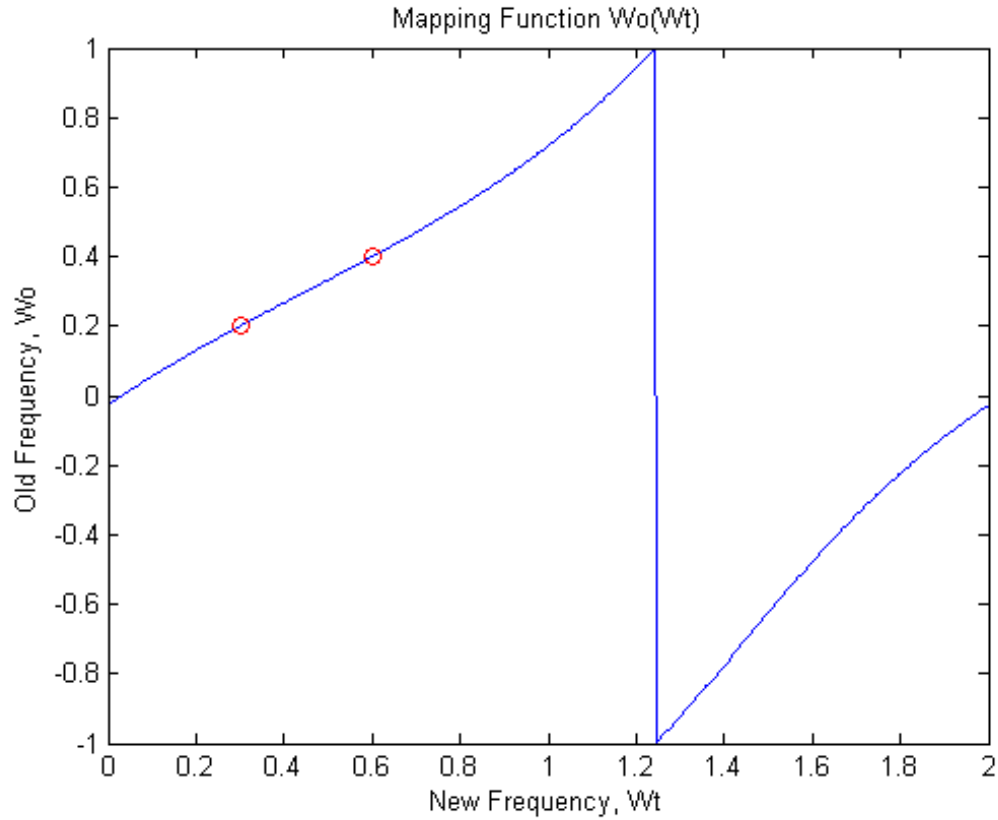
Examples

Design of the allpass mapping filter

This example shows how to design allpass mapping filter, changing the complex bandpass filter with the band edges at $W_{o1} = 0.2$ and $W_{o2} = 0.4$ to the new band edges of $W_{t1} = 0.3$ and $W_{t2} = 0.6$. Find the frequency response of the allpass mapping filter:

```
Wo = [0.2, 0.4]; Wt = [0.3, 0.6];
[AllpassNum, AllpassDen] = allpassbpc2bpc(Wo, Wt);
[ha, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi,-angle(ha)/pi, Wt, Wo, 'ro'); title('Mapping Function Wo(Wt)
```

```
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

allpasslp2bp

Purpose

Allpass filter for lowpass to bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "DC mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

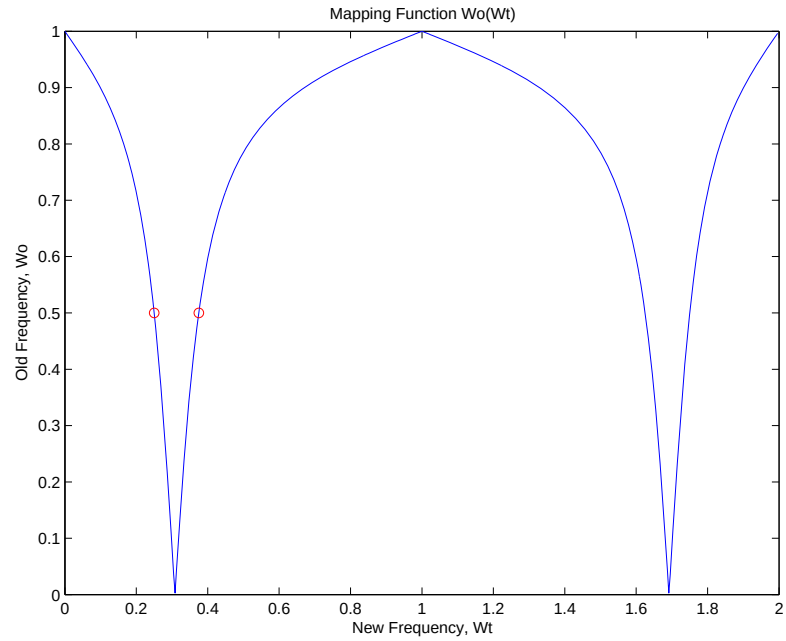
Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and repositioned at two distinct desired frequencies.

Examples

Design the allpass mapping filter changing the lowpass filter with cutoff frequency at W_o=0.5 to the real–valued bandpass filter with cutoff frequencies at W_{t1}0.25 and W_{t2}=0.375.

Compute the frequency response and plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

Purpose

Allpass filter for lowpass to complex bandpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bpc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to complex bandpass frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandpass transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandpass filters for radio receivers from the high-quality prototype lowpass filter.

Examples

Design the allpass mapping filter changing the real lowpass filter with the cutoff frequency of W_o=`0.5` into a complex bandpass filter with band edges of W_{t1}=`0.2` and W_{t2}=`0.4` precisely defined. Calculate the frequency response of the mapping filter in the full range:

```
Wo = 0.5; Wt = [0.2,0.4];
[AllpassNum, AllpassDen] = allpasslp2bpc(Wo, Wt);
```

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Purpose

Allpass filter for lowpass to bandstop transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bs(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real lowpass to real bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. This transformation implements the "Nyquist Mobility," which means that the DC feature stays at DC, but the Nyquist feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

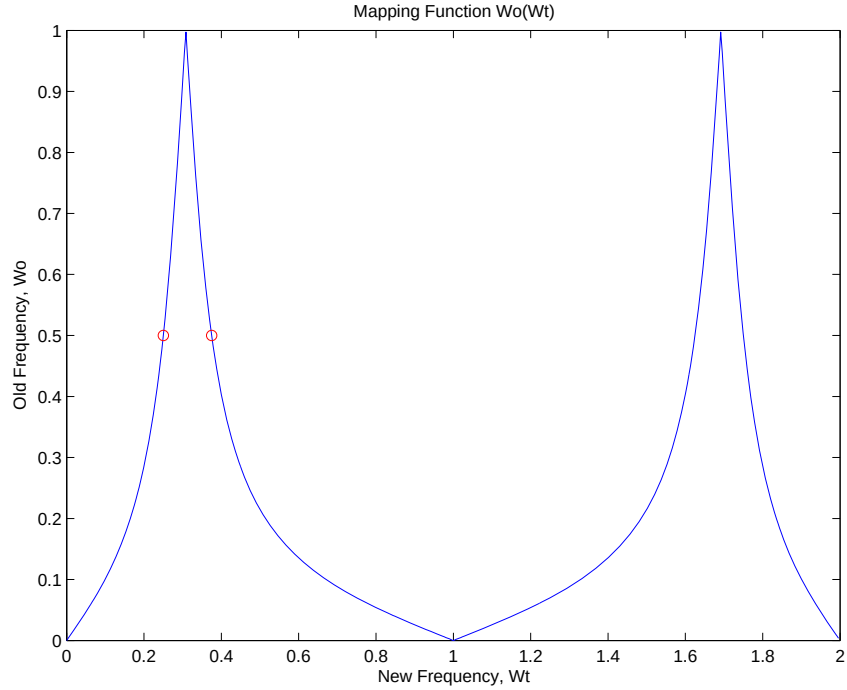
Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Examples

Design the allpass filter changing the lowpass filter with cutoff frequency at W_o=0.5 to the real bandstop filter with cutoff frequencies at W_{t1}=0.25 and W_{t2}=0.375:

```
Wo = 0.5; Wt = [0.25, 0.375];
[AllpassNum, AllpassDen] = allpasslp2bs(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In the figure, you find the mapping filter function as determined by the example. Note the response is normalized to π:



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2bsc

Purpose

Allpass filter for lowpass to complex bandstop transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2bsc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to complex bandstop frequency transformation. This transformation effectively places one feature of an original filter, located at frequency $-W_o$, at the required target frequency location, W_{t1}, and the second feature, originally at $+W_o$, at the new location, W_{t2}. It is assumed that W_{t2} is greater than W_{t1}. Additionally the transformation swaps passbands with stopbands in the target filter.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to bandstop transformation is not restricted only to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

Lowpass to bandpass transformation can also be used for transforming other types of filters; e.g., real notch filters or resonators can be doubled and positioned at two distinct desired frequencies at any place around the unit circle forming a pair of complex notches/resonators. This transformation can be used for designing bandstop filters for band attenuation or frequency equalizers, from the high-quality prototype lowpass filter.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=`0.5` into a complex bandstop filter with band edges of W_{t1}=`0.2` and W_{t2}=`0.4` precisely defined:

```
Wo = 0.5; Wt = [0.2,0.4];
```

```
[AllpassNum, AllpassDen] = allpasslp2bsc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

allpasslp2hp

Purpose

Allpass filter for lowpass to highpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2hp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real highpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency, W_o, at the required target frequency location, W_t, at the same time rotating the whole frequency response by half of the sampling frequency. Result is that the DC and Nyquist features swap places.

Relative positions of other features of an original filter change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. After the transformation feature F_2 will precede F_1 in the target filter. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to highpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband.

Lowpass to highpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by using the lowpass to highpass transformation.

Examples

Design the allpass filter changing the lowpass filter to the highpass filter with its cutoff frequency moved from W_o=0.5 to W_t=0.25.

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2hp(Wo, Wt);
```

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt');
ylabel('Old Frequency, Wo');
```

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2lp

Purpose

Allpass filter for lowpass to lowpass transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2lp(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the first-order allpass mapping filter for performing a real lowpass to real lowpass frequency transformation. This transformation effectively places one feature of an original filter, located originally at frequency W_o, at the required target frequency location, W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the lowpass to lowpass transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband and so on.

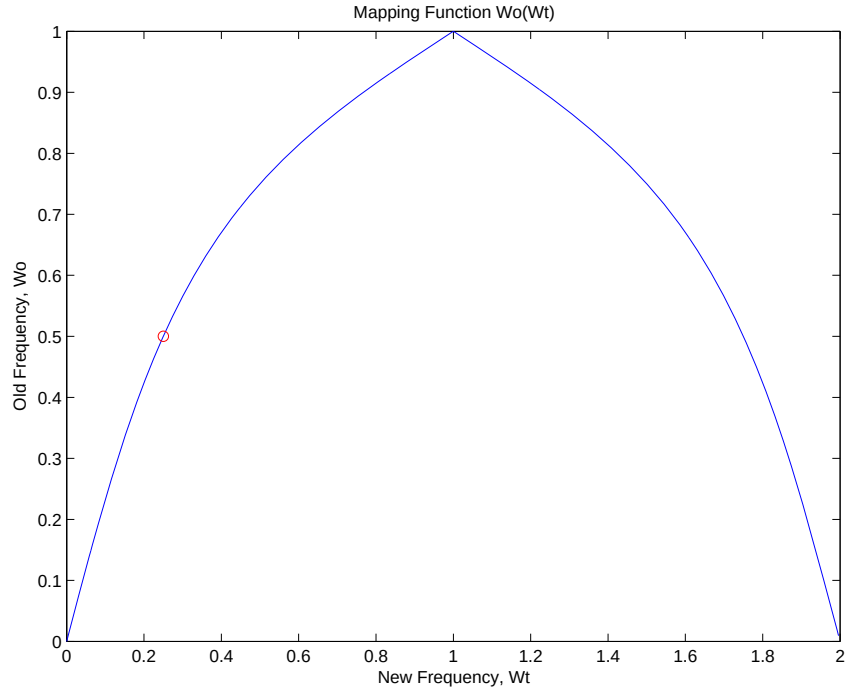
Lowpass to lowpass transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can change their position in a simple way by applying the lowpass to lowpass transformation.

Examples

Design the allpass filter changing the lowpass filter cutoff frequency originally at W_o=0.5 to W_t=0.25. Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = 0.25;
[AllpassNum, AllpassDen] = allpasslp2lp(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
```

```
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



As shown in the figure, `allpasslp2lp` generates a mapping function that converts your prototype lowpass filter to a target lowpass filter with different passband specifications.

Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency location in the transformed target filter

Variable	Description
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`iirlp2lp` | `zpklp2lp`

Purpose

Allpass filter for lowpass to M-band transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `M`th-order allpass mapping filter for performing a real lowpass to real multipassband frequency transformation. Parameter `M` is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, $W_{t1},...,W_{tM}$. By default the DC feature is kept at its original location.

`[AllpassNum,AllpassDen] = allpasslp2mb(Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the “Nyquist Mobility.” In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

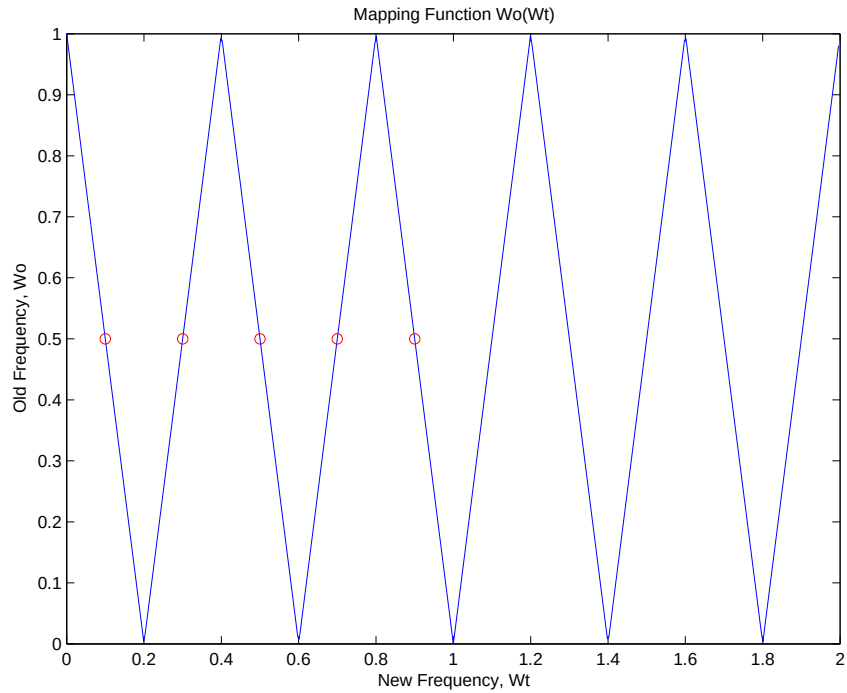
Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without redesigning them. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=0.5 into a real multiband filter with band edges of W_t=[1:2:9]/10 precisely defined. Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
Wo = 0.5; Wt = [1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mb(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
plot(f/pi, abs(angle(h))/pi, Wt, Wo, 'ro');
title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

allpasslp2mbc

Purpose

Allpass filter for lowpass to complex M-band transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2mbc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `M`th-order allpass mapping filter for performing a real lowpass to complex multipassband frequency transformation. Parameter `M` is the number of times an original feature is replicated in the target filter. This transformation effectively places one feature of an original filter, located at frequency W_o, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need to design them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter changing the real lowpass filter with the cutoff frequency of W_o=`0.5` into a complex multiband filter with band edges of W_t=`[-3+1:2:9]/10` precisely defined:

```
Wo = 0.5; Wt = [-3+1:2:9]/10;
[AllpassNum, AllpassDen] = allpasslp2mbc(Wo, Wt);
```

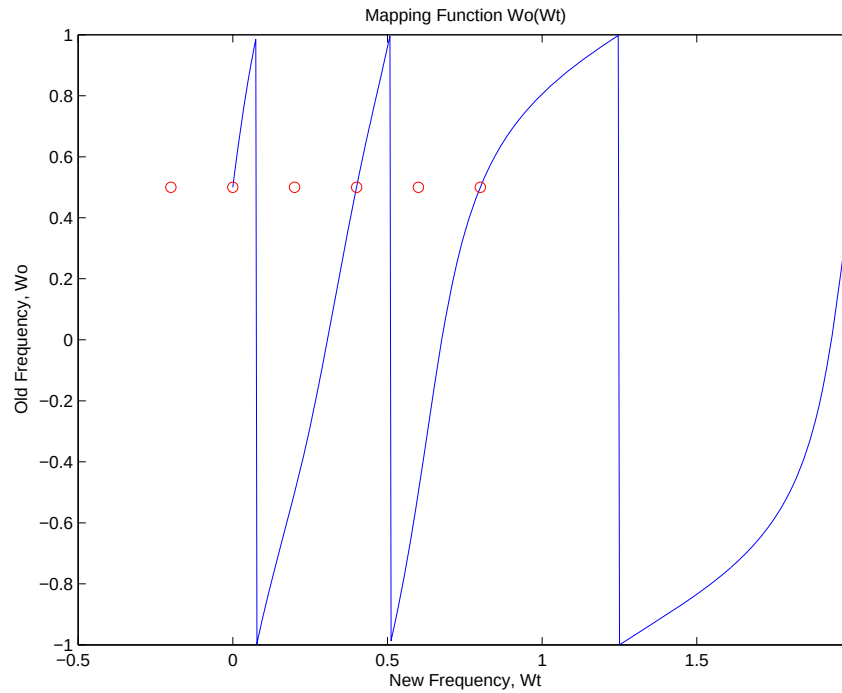
Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Plot the phase response normalized to π, which is in effect the mapping function $W_o(W_t)$. Please note that the transformation works in the same way for both positive and negative frequencies:

```
plot(f/pi, angle(h)/pi, Wt, Wo, 'ro');
 title('Mapping Function Wo(Wt)');
xlabel('New Frequency, Wt'); ylabel('Old Frequency, Wo');
```

In this example, the resulting mapping function converts real filters to multiband complex filters.



Arguments

Variable	Description
Wo	Frequency value to be transformed from the prototype filter. It should be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.
Wt	Desired frequency locations in the transformed target filter. They should be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Purpose

Allpass filter for lowpass to complex N-point transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2xc(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter, where `N` is the allpass filter order, for performing a real lowpass to complex multipoint frequency transformation. Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of the, original filter located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations, $W_{t1},...,W_{tM}$.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Examples

Design the allpass filter moving four features of an original complex filter given in W_o to the new independent frequency locations W_t. Please

note that the transformation creates `N` replicas of an original filter around the unit circle, where `N` is the order of the allpass mapping filter:

```
Wo = [-0.2, 0.3, -0.7, 0.4]; Wt = [0.3, 0.5, 0.7, 0.9];
[AllpassNum, AllpassDen] = allpasslp2xc(Wo, Wt);
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between -1 and 1, with 1 corresponding to half the sample rate.

Purpose

Allpass filter for lowpass to N-point transformation

Syntax

```
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)
[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)
```

Description

`[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter, where `N` is the allpass filter order, for performing a real lowpass to real multipoint frequency transformation. Parameter `N` also specifies the number of replicas of the prototype filter created around the unit circle after the transformation. This transformation effectively places `N` features of an original filter, located at frequencies $W_{o1},...,W_{oN}$, at the required target frequency locations, $W_{t1},...,W_{tM}$. By default the DC feature is kept at its original location.

`[AllpassNum,AllpassDen] = allpasslp2xn(Wo,Wt,Pass)` allows you to specify an additional parameter, `Pass`, which chooses between using the "DC Mobility" and the "Nyquist Mobility." In the first case the Nyquist feature stays at its original location and the DC feature is free to move. In the second case the DC feature is kept at an original frequency and the Nyquist feature is movable.

Relative positions of other features of an original filter are the same in the target filter for the Nyquist mobility and are reversed for the DC mobility. For the Nyquist mobility this means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation. For DC mobility feature F_2 will precede F_1 after the transformation.

Choice of the feature subject to this transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones. The only condition is that the features must be selected in such a way that when creating `N` bands around the unit circle, there will be no band overlap.

This transformation can also be used for transforming other types of filters; e.g., notch filters or resonators can be easily replicated at a number of required frequency locations without the need of designing them again. A good application would be an adaptive tone cancellation circuit reacting to the changing number and location of tones.

Arguments

Variable	Description
Wo	Frequency values to be transformed from the prototype filter
Wt	Desired frequency locations in the transformed target filter
Pass	Choice (`'pass'`/`'stop'`) of passband/stopband at DC, `'pass'` being the default
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

Frequencies must be normalized to be between 0 and 1, with 1 corresponding to half the sample rate.

`iirlp2xn` | `zpklp2xn`

Purpose

Allpass filter for integer upsample transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassrateup(N)
```

Description

`[AllpassNum,AllpassDen] = allpassrateup(N)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the `N`th-order allpass mapping filter for performing the rateup frequency transformation, which creates `N` equal replicas of the prototype filter frequency response.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Examples

Design the allpass filter creating the effect of upsampling the digital filter four times:

Choose any feature from an original filter, say at W_0=`0.2`:

```
N = 4;
Wo = 0.2; Wt = Wo/N + 2*[0:N-1]/N;
[AllpassNum, AllpassDen] = allpassrateup(N);
```

Calculate the frequency response of the mapping filter in the full range:

```
[h, f] = freqz(AllpassNum, AllpassDen, 'whole');
```

Arguments

Variable	Description
N	Frequency replication ratio (upsampling ratio)
AllpassNum	Numerator of the mapping filter
AllpassDen	Denominator of the mapping filter

allpassshift

Purpose

Allpass filter for real shift transformation

Syntax

```
[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)
```

Description

`[AllpassNum,AllpassDen] = allpassshift(Wo,Wt)` returns the numerator, `AllpassNum`, and the denominator, `AllpassDen`, of the second-order allpass mapping filter for performing a real frequency shift transformation. This transformation places one selected feature of an original filter, located at frequency W_o, at the required target frequency location, W_t. This transformation implements the "DC mobility," which means that the Nyquist feature stays at Nyquist, but the DC feature moves to a location dependent on the selection of W_o and W_t.

Relative positions of other features of an original filter do not change in the target filter. This means that it is possible to select two features of an original filter, F_1 and F_2, with F_1 preceding F_2. Feature F_1 will still precede F_2 after the transformation. However, the distance between F_1 and F_2 will not be the same before and after the transformation.

Choice of the feature subject to the real shift transformation is not restricted to the cutoff frequency of an original lowpass filter. In general it is possible to select any feature; e.g., the stopband edge, the DC, the deep minimum in the stopband, or other ones.
