© COPYRIGHT 1984–2014 by The MathWorks, Inc.

The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

December 1996	First printing	For MATLAB 5.0 (Release 8)
June 1997	Online only	Revised for MATLAB 5.1 (Release 9)
October 1997	Online only	Revised for MATLAB 5.2 (Release 10)
January 1999	Online only	Revised for MATLAB 5.3 (Release 11)
June 1999	Second printing	For MATLAB 5.3 (Release 11)
June 2001	Online only	Revised for MATLAB 6.1 (Release 12.1)
July 2002	Online only	Revised for 6.5 (Release 13)
June 2004	Online only	Revised for 7.0 (Release 14)
September 2006	Online only	Revised for 7.3 (Release 2006b)
March 2007	Online only	Revised for 7.4 (Release 2007a)
September 2007	Online only	Revised for Version 7.5 (Release 2007b)
March 2008	Online only	Revised for Version 7.6 (Release 2008a)
October 2008	Online only	Revised for Version 7.7 (Release 2008b)
March 2009	Online only	Revised for Version 7.8 (Release 2009a)
September 2009	Online only	Revised for Version 7.9 (Release 2009b)
March 2010	Online only	Revised for Version 7.10 (Release 2010a)
September 2010	Online only	Revised for Version 7.11 (Release 2010b)
April 2011	Online only	Revised for Version 7.12 (Release 2011a)
September 2011	Online only	Revised for Version 7.13 (Release 2011b)
March 2012	Online only	Revised for Version 7.14 (Release 2012a)
September 2012	Online only	Revised for Version 8.0 (Release 2012b)
March 2013	Online only	Revised for Version 8.1 (Release 2013a)
September 2013	Online only	Revised for Version 8.2 (Release 2013b)
March 2014	Online only	Revised for Version 8.3 (Release 2014a)

Relational Operators < > <= >= == ~=

Purpose Relational operations

Syntax

```
A < B
A > B
A <= B
A >= B
A == B
A ~= B
```

Description The relational operators are <, >, <=, >=, ==, and ~=. Relational operators perform element-by-element comparisons between two arrays. They return a logical array of the same size, with elements set to logical 1 (true) where the relation is true, and elements set to logical 0 (false) where it is not.

The operators <, >, <=, and >= use only the real part of their operands for the comparison. The operators == and ~= test real and imaginary parts.

To test if two strings are equivalent, use strcmp, which allows vectors of dissimilar length to be compared.

Note For some toolboxes, the relational operators are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given operator, type help followed by the operator name. For example, type help lt. The toolboxes that overload lt (<) are listed. For information about using the operator in that toolbox, see the documentation for the toolbox.

Examples If one of the operands is a scalar and the other a matrix, the scalar expands to the size of the matrix. For example, the two pairs of statements

```
X = 5; X >= [1 2 3; 4 5 6; 7 8 10]
X = 5*ones(3,3); X >= [1 2 3; 4 5 6; 7 8 10]
```

produce the same result:

```
ans =
```

Relational Operators < > <= >= == !=

1	1	1
1	1	0
0	0	0

See Also

[all](#) | [any](#) | [find](#) | [strcmp](#) | [Logical Operators: Short Circuit](#)

Purpose Logical operations with short-circuiting

Syntax `expr1 && expr2`
`expr1 || expr2`

Description `expr1 && expr2` represents a logical AND operation that employs short-circuiting behavior. That is, `expr2` is not evaluated if `expr1` is logical 0 (false). Each expression must evaluate to a scalar logical result.

`expr1 || expr2` represents a logical OR operation that employs short-circuiting behavior. That is, `expr2` is not evaluated if `expr1` is logical 1 (true). Each expression must evaluate to a scalar logical result.

Examples **Use Scalar Logical Conditions**

Create two vectors.

```
X = [1 0 0 1 1];  
Y = [0 0 0 0 0];
```

Use the short-circuit OR operator with X and Y.

```
X || Y
```

Operands to the `||` and `&&` operators must be convertible to logical scalars.

The short-circuit operators operate only with scalar logical conditions.

Use the `any` and `all` functions to reduce each vector to a single logical condition.

```
any(X) || any(Y)
```

```
ans =
```

```
1
```

Logical Operators: Short-Circuit && ||

The expression is equivalent to `1 || 0`, so it evaluates to logical 1 (true) after computing only the first condition, any(X).

Specify Dependent Logical Conditions

Specify a logical statement where the second condition depends on the first. In the following statement, it doesn't make sense to evaluate the relation on the right if the divisor, b, is zero.

```
b = 1;  
a = 20;  
x = (b ~= 0) && (a/b > 18.5)
```

```
x =
```

```
1
```

The result is logical 1 (true). However, if `(b ~= 0)` evaluates to false, MATLAB® assumes the entire expression to be false and terminates its evaluation of the expression early.

Specify `b = 0` and evaluate the same expression.

```
b = 0;  
x = (b ~= 0) && (a/b > 18.5)
```

```
x =
```

```
0
```

The result is logical 0 (false). The first statement evaluates to logical 0 (false), so the expression short-circuits.

Change Structure Field Value

Create a structure with fields named 'File' and 'Format'.

```
S = struct('File',{'myGraph'},'Format',[])
```

```
S =
```

```
File: 'myGraph'  
Format: []
```

Short-circuit expressions are useful in *if* statements when you want multiple conditions to be true. The conditions can build on one another in such a way that it only makes sense to evaluate the second expression if the first expression is true.

Specify an *if* statement that executes only when *S* contains an empty field named 'Format'.

```
if isfield(S,'Format') && isempty(S.Format)  
    S.Format = '.png';  
end  
S  
  
S =
```

```
File: 'myGraph'  
Format: '.png'
```

The first condition tests if the string 'Format' is the name of a field in structure *S*. The second statement then tests whether the *Format* field is empty. The truth of the second condition depends on the first. The second condition can never be true if the first condition is not true. Since *S* has an empty field named 'Format', the body statement executes and assigns *S.Format* the value '.png'.

Definitions

Logical Short-Circuiting

With logical short-circuiting, the second operand, *expr2*, is evaluated only when the result is not fully determined by the first operand, *expr1*.

Due to the properties of logical AND and OR, the result of a logical expression is sometimes fully determined before evaluating all of the conditions. The logical and operator returns logical 0 (false) if even a single condition in the expression is false. The logical or operator returns logical 1 (true) if even a single condition in the expression is

Logical Operators: Short-Circuit && ||

true. When the evaluation of a logical expression terminates early by encountering one of these values, the expression is said to have *short-circuited*.

For example, in the expression `A && B`, MATLAB does not evaluate condition `B` at all if condition `A` is false. If `A` is false, then the value of `B` does not change the outcome of the operation.

When you use the element-wise `&` and `|` operators in the context of an `if` or `while` loop expression (and *only* in that context), they use short-circuiting to evaluate expressions.

Note Always use the `&&` and `||` operators to enable short-circuit evaluation. Using the `&` and `|` operators for short-circuiting can yield unexpected results when the expressions do not evaluate to logical scalars.

Special Characters [] () { } = ' , ; : % ! @

Purpose

Special characters

Syntax

[]
{ }
()
=
'
.
...
,
;
:
%
%{ %}
!
@

Description

[] Brackets are used to form vectors and matrices. $[6.9 \ 9.64 \ \text{sqrt}(-1)]$ is a vector with three elements separated by blanks. $[6.9, \ 9.64, \ i]$ is the same thing. $[1+j \ 2-j \ 3]$ and $[1 \ +j \ 2 \ -j \ 3]$ are not the same. The first has three elements, the second has five.

$[11 \ 12 \ 13; \ 21 \ 22 \ 23]$ is a 2-by-3 matrix. The semicolon ends the first row.

Vectors and matrices can be used inside [] brackets. $[A \ B;C]$ is allowed if the number of rows of A equals the number of rows of B and the number of columns of A plus the number of columns of B equals the number of columns of C. This rule generalizes to allow fairly complicated constructions.

Special Characters [] () { } = ' , ; : % ! @

`A = []` stores an empty matrix in `A`. `A(m,:) = []` deletes row `m` of `A`. `A(:,n) = []` deletes column `n` of `A`. `A(n) = []` reshapes `A` into a column vector and deletes the `n`th element.

`[A1,A2,A3...]` = function assigns function output to multiple variables.

For the use of `[` and `]` on the left of an “=” in multiple assignment statements, see `lu`, `eig`, `svd`, and so on.

`{ }` Curly braces are used in cell array assignment statements. For example, `A(2,1) = {[1 2 3; 4 5 6]}`, or `A{2,2} = ('str')`. See `help paren` for more information about `{ }`.

`()` Parentheses are used to indicate precedence in arithmetic expressions in the usual way. They are used to enclose arguments of functions in the usual way. They are also used to enclose subscripts of vectors and matrices in a manner somewhat more general than usual. If `X` and `V` are vectors, then `X(V)` is `[X(V(1)), X(V(2)), ..., X(V(n))]`. The components of `V` must be integers to be used as subscripts. An error occurs if any such subscript is less than 1 or greater than the size of `X`. Some examples are

- `X(3)` is the third element of `X`.
- `X([1 2 3])` is the first three elements of `X`.

See `help paren` for more information about `()`.

If `X` has `n` components, `X(n: 1:1)` reverses them. The same indirect subscripting works in matrices. If `V` has `m` components and `W` has `n` components, then `A(V,W)` is the `m`-by-`n` matrix formed from the elements of `A` whose subscripts are the elements of `V` and `W`. For example, `A([1,5],:) = A([5,1],:)` interchanges rows 1 and 5 of `A`.

`=` Used in assignment statements. `B = A` stores the elements of `A` in `B`. `==` is the relational equals operator. See the Relational Operators page.

Special Characters [] () { } = ' , ; : % ! @

- ' Matrix transpose. X' is the complex conjugate transpose of X . $X.'$ is the nonconjugate transpose.
- Quotation mark. 'any text' is a vector whose components are the ASCII codes for the characters. A quotation mark within the text is indicated by two quotation marks.
- . Decimal point. $314/100$, 3.14 , and $.314e1$ are all the same.
- . Element-by-element operations. These are obtained using $.*$, $.^$, $./$, or $.\$. See the Arithmetic Operators page.
- . Field access. $S(m).f$ when S is a structure, accesses the contents of field f of that structure.
- .() Dynamic Field access. $S.(df)$ when S is a structure, accesses the contents of dynamic field df of that structure. Dynamic field names are defined at runtime.
- .. Parent folder. See `cd`.
- ... Continuation. Three or more periods at the end of a line continue the current function on the next line. Three or more periods before the end of a line cause the MATLAB software to ignore the remaining text on the current line and continue the function on the next line. This effectively makes a comment out of anything on the current line that follows the three periods. For an example, see “Continue Long Statements on Multiple Lines”.
- , Comma. Used to separate matrix subscripts and function arguments. Used to separate statements in multistatement lines. For multistatement lines, the comma can be replaced by a semicolon to suppress printing.
- ; Semicolon. Used inside brackets to end rows. Used after an expression or statement to suppress printing or to separate statements.
- : Colon. Create vectors, array subscripting, and for loop iterations. See `colon (:)` for details.

Special Characters [] () { } = ' , ; : % ! @

- % Percent. The percent symbol denotes a comment; it indicates a logical end of line. Any following text is ignored. MATLAB displays the first contiguous comment lines in a function or script file in response to a `help` command.
- %{
%} Percent-brace. The text enclosed within the `%{` and `%}` symbols is a comment block. Use these symbols to insert comments that take up more than a single line in your script of function code. Any text between these two symbols is ignored by MATLAB.

With the exception of whitespace characters, the `%{` and `%}` operators must appear alone on the lines that immediately precede and follow the block of help text. Do not include any other text on these lines.
- ! Exclamation point. Indicates that the rest of the input line is issued as a command to the operating system. See “Run External Commands, Scripts, and Programs” for more information.
- @ Function handle. MATLAB data type that is a handle to a function. See `function_handle (@)` for details.

Tips

Some uses of special characters have function equivalents, as shown:

Horizontal concatenation	<code>[A,B,C...]</code> <code>horzcat(A,B,C...)</code>
Vertical concatenation	<code>[A;B;C...]</code> <code>vertcat(A,B,C...)</code>
Subscript reference	<code>A(i,j,k...)</code> <code>subsref(A,S)</code> . See help <code>subsref</code> .
Subscript assignment	<code>A(i,j,k...)=B</code> <code>subsasgn(A,S,B)</code> . See help <code>subsasgn</code> .

Special Characters [] () { } = ' , ; : % ! @

Note For some toolboxes, the special characters are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given character, type `help` followed by the character name. For example, type `help transpose`. The toolboxes that overload `transpose` (`.`) are listed. For information about using the character in that toolbox, see the documentation for the toolbox.

“Array vs. Matrix Operations”

Concepts

- “Logical Operations”
- “Relational Operations”

colon (:)

Purpose

Create vectors, array subscripting, and for-loop iterators

Description

The colon is one of the most useful operators in MATLAB. It can create vectors, subscript arrays, and specify for iterations.

The colon operator uses the following rules to create regularly spaced vectors for scalar values i , j , and k :

$j:k$ is the same as $[j, j+1, j+2, \dots, j+m]$, where $m = \text{fix}(k-j)$. In the case where both j and k are integers, this is simply $[j, j+1, \dots, k]$. This syntax returns an empty matrix when $j > k$.

$j:i:k$ is the same as $[j, j+i, j+2i, \dots, j+m*i]$, where $m = \text{fix}((k-j)/i)$. This syntax returns an empty matrix when $i == 0$, $i > 0$ and $j > k$, or $i < 0$ and $j < k$.

If you specify nonscalar arrays, MATLAB interprets $j:i:k$ as $j(1):i(1):k(1)$.

You can use the colon to create a vector of indices to select rows, columns, or elements of arrays, where:

$A(:,j)$ is the j th column of A .

$A(i,:)$ is the i th row of A .

$A(:,:)$ is the equivalent two-dimensional array. For matrices this is the same as A .

$A(j:k)$ is $A(j), A(j+1), \dots, A(k)$.

$A(:,j:k)$ is $A(:,j), A(:,j+1), \dots, A(:,k)$.

$A(:,:,k)$ is the k th page of three-dimensional array A .

`A(i,j,k,:)` is a vector in four-dimensional array `A`. The vector includes `A(i,j,k,1)`, `A(i,j,k,2)`, `A(i,j,k,3)`, and so on.

`A(:)` is all the elements of `A`, regarded as a single column. On the left side of an assignment statement, `A(:)` fills `A`, preserving its shape from before. In this case, the right side must contain the same number of elements as `A`.

When you create a vector to index into a cell array or structure array (such as `cellName{:}` or `structName(:).fieldName`), MATLAB returns multiple outputs in a comma-separated list. For more information, see “How to Use the Comma-Separated Lists” in the MATLAB Programming Fundamentals documentation.

Examples

Using the colon with integers,

```
D = 1:4
```

results in

```
D =  
    1    2    3    4
```

Using two colons to create a vector with arbitrary real increments between the elements,

```
E = 0:.1:.5
```

results in

```
E =  
    0    0.1000    0.2000    0.3000    0.4000    0.5000
```

The command

```
A(:,:,2) = pascal(3)
```

colon (:)

generates a three-dimensional array whose first page is all zeros.

```
A(:,:,1) =  
    0    0    0  
    0    0    0  
    0    0    0
```

```
A(:,:,2) =  
    1    1    1  
    1    2    3  
    1    3    6
```

Using a colon with characters to iterate a for-loop,

```
for x='a':'d',x,end
```

results in

```
x =  
    a  
x =  
    b  
x =  
    c  
x =  
    d
```

See Also

[for](#) | [linspace](#) | [logspace](#) | [reshape](#) | [varargin](#)

Purpose Absolute value and complex magnitude

Syntax `abs(X)`

Description `abs(X)` returns an array Y such that each element of Y is the absolute value of the corresponding element of X.

If X is complex, `abs(X)` returns the complex modulus (magnitude), which is the same as

```
sqrt(real(X).^2 + imag(X).^2)
```

Examples

```
abs(-5)
ans =
    5
```

```
abs(3+4i)
ans =
    5
```

See Also `angle` | `sign` | `unwrap`

accumarray

Purpose Construct array with accumulation

Syntax

```
A = accumarray(subs, val)
A = accumarray(subs, val, sz)
A = accumarray(subs, val, sz, fun)
A = accumarray(subs, val, sz, fun, fillval)
A = accumarray(subs, val, sz, fun, fillval, issparse)
```

Description `A = accumarray(subs, val)` returns an array, `A`, by accumulating elements of vector `val` using the subscripts in `subs`. The values in each row of the m -by- n matrix `subs` define an n -dimensional subscript into the output, `A`. If `subs` is a column vector, the value in each row defines a row subscript into the output, which is also a column vector.

The i th row of `subs` corresponds to the i th element in the vector, `val`. The function collects all elements of `val` that have identical subscripts in `subs`, applies the function `@sum`, and then stores the result in the location of `A` corresponding to the subscript. Elements of `A` that are not referred to by any row of `subs` contain the value 0.

`A = accumarray(subs, val, sz)` returns an array, `A`, with size `sz`. Specify `sz` as a vector of positive integers to define the size of the output, or as `[]` to let the subscripts in `subs` determine the size of the output. Use `sz` when `subs` does not reference trailing rows, columns, or dimensions that you would like to be present in the output.

`A = accumarray(subs, val, sz, fun)` applies the function `fun` to each subset of elements in `val` that have identical subscripts in `subs`. Specify `fun` using the `@` symbol (e.g., `@mean`), or as `[]` to use the default function, `@sum`.

`A = accumarray(subs, val, sz, fun, fillval)` fills all elements of `A` that are not referred to by any subscript in `subs` with the scalar value, `fillval`. The `fillval` input must have the same class as the values returned by `fun`. Specify `fillval` as `[]` to use the default value, 0.

`A = accumarray(subs, val, sz, fun, fillval, issparse)` returns an array, `A`, that is sparse if the scalar `issparse` is true or 1, and full if `issparse` is false or 0. The output, `A`, is full by default.

Input Arguments

subs - Subscript matrix

vector of indices | matrix of indices | cell array of index vectors

Subscript matrix, specified as a vector of indices, matrix of indices, or cell array of index vectors. The indices must be positive integers:

- The value in each row of the m -by- n matrix, `subs`, specifies an n -dimensional index into the output, `A`. For example, if `subs` is a 3-by-2 matrix, it contains three 2-D subscripts. `subs` also can be a column vector of indices, in which case the output, `A`, is also a column vector.
- The i th row in `subs` corresponds to the i th data value in `val`.

Thus, `subs` determines which data in `val` to group, as well as its final destination in the output. If `subs` is a cell array of index vectors, each vector must have the same length, and the function treats the vectors as columns of a subscript matrix.

val - Data

vector | scalar

Data, specified as a vector or scalar:

- If `val` is a vector, it must have the same length as the number of rows in `subs`.
- If `val` is a scalar, it is scalar expanded.

In both cases, a one-to-one pairing is present between the subscripts in each row of `subs` and the data values in `val`.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

Complex Number Support: Yes

sz - Size of output array

vector of positive integers | [] (default)

Size of output array, specified as a vector of positive integers or [] (default). When you specify [] for the default size, the values in `subs` determine the size of the output array, `A`.

When you specify `sz` as a vector of positive integers, it must satisfy these properties:

- If `subs` is a nonempty m -by- n matrix with $n > 1$ columns, then `sz` must have n elements and pass the logical test `all(sz >= max(subs, [], 1))`.
- If `subs` is a nonempty column vector, then `sz` must be `[m 1]` where $m \geq \max(\text{subs})$.

Example: `sz = [3 3]`

fun - Function

function handle | [] (default)

Function, specified as a function handle or [] (default). The default function is `@sum`. The `fun` function must accept a column vector and return a numeric, logical, or char scalar, or a scalar cell. If the subscripts in `subs` are not sorted with respect to their linear indices, `fun` should not depend on the order of the values in its input data.

Example: `fun = @max`

Data Types

function_handle

fillval - Fill value

scalar | [] (default)

Fill value, specified as a scalar or [] (default). The default value of `fillval` is 0. If `subs` does not reference each element in the output, `accumarray` fills in the output with the value specified by `fillval`. The class of `fillval` must be the same as the values returned by `fun`.

issparse - Output sparsity

false (default) | true | 1 | 0

Output sparsity, specified as true, 1, 0, or false (default). Specify true or 1 when you want the output array to be sparse. If issparse is true or 1:

- fillval must be 0 or [].
- The values in val and the output values of fun must both have type double.

Output Arguments

A - Output array

vector | matrix | multidimensional array

Output array, returned as a vector, matrix, or multidimensional array. A has the same class as the values returned by fun.

When sz is not specified, the size of A depends on the input subs:

- If subs is a nonempty matrix with $n > 1$ columns, then A is an n -dimensional array of size $\max(\text{subs}, [], 1)$.
- If subs is an empty matrix with $n > 1$ columns, then A is an n -dimensional empty array with size 0-by-0-by-...-by-0.
- If subs is a nonempty column vector, then A is a column vector of length $\max(\text{subs}, [], 1)$. The length of A is 0 when subs is empty.

Examples

Find Bin Counts

Create a vector of subscripts, subs.

```
subs = [1; 2; 4; 2; 4]
```

```
subs =
     1
     2
     4
     2
     4
```

accumarray

Use `accumarray` with `val = 1` to count the number of identical subscripts in `subs`.

```
A = accumarray(subs,1)
```

```
A =
```

```
1
2
0
2
```

The result is a vector of bin counts. You can obtain the same answer with `histc(subs,1:4)`. However, `accumarray` also can compute bin counts over higher dimensional grids.

Accumulate Data

Create a vector of data, `val`, and a vector of subscript values with the same length, `subs`.

```
val = 101:105';
subs = [1; 3; 4; 3; 4]
```

```
subs =
```

```
1
3
4
3
4
```

Use `accumarray` to sum the values in `val` that have identical subscripts in `subs`.

```
A = accumarray(subs,val)
```

```
A =
```

```

101
  0
206
208

```

The result is a vector of accumulated values. Since the second and fourth elements of `subs` are equal to 3, $A(3)$ is the sum of the second and fourth elements of `val`, that is, $A(3) = 102 + 104 = 206$. Also, $A(2) = 0$ because `subs` does not contain the value 2. Since `subs` is a vector, the output, `A`, is also a vector. The length of `A` is $\max(\text{subs}, [], 1)$.

Specify Output Size

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```

val = 101:106';
subs = [1 1; 2 2; 3 2; 1 1; 2 2; 4 1]

```

```

subs =

     1     1
     2     2
     3     2
     1     1
     2     2
     4     1

```

The subscripts in `subs` define a 4-by-2 matrix for the output.

Use `accumarray` to sum the values in `val` that have identical subscripts in `subs`.

```

A = accumarray(subs, val)

```

```

A =

    205     0
     0    207
     0    103

```

accumarray

```
106    0
```

The result is a 4-by-2 matrix of accumulated values.

Use the `sz` input of `accumarray` to return a 4-by-4 matrix. You can specify a size with each dimension equal to or greater than the default size, in this case 4-by-2, but not smaller.

```
A = accumarray(subs, val, [4 4])
```

```
A =
```

```
205    0    0    0
    0   207    0    0
    0   103    0    0
106    0    0    0
```

The result is a 4-by-4 matrix of accumulated values.

Use Custom Functions

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = [100.1 101.2 103.4 102.8 100.9 101.5]';
subs = [1 1; 1 1; 2 2; 3 2; 2 2; 3 2]
```

```
subs =
```

```
1    1
1    1
2    2
3    2
2    2
3    2
```

The subscripts in `subs` define a 3-by-2 matrix for the output.

Use the fun input of `accumarray` to calculate the within-group variances of data in `val` that have identical subscripts in `subs`. Specify `fun` as `@var`.

```
A1 = accumarray(subs, val, [], @var)
```

```
A1 =
```

```
    0.6050         0
         0    3.1250
         0    0.8450
```

The result is a 3-by-2 matrix of variance values.

Alternatively, you can specify `fun` as an anonymous function so long as it accepts vector inputs and returns a scalar. A common situation where this is useful is when you want to pass additional parameters to a function. In this case, use the `var` function with a normalization parameter.

```
A2 = accumarray(subs, val, [], @(x) var(x, 1))
```

```
A2 =
```

```
    0.3025         0
         0    1.5625
         0    0.4225
```

The result is a 3-by-2 matrix of normalized variance values.

Sum Values Natively

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = int8(10:15);
subs = [1 1 1; 1 1 1; 1 1 2; 1 1 2; 2 3 1; 2 3 2]
```

```
subs =
```

accumarray

```
1     1     1
1     1     1
1     1     2
1     1     2
2     3     1
2     3     2
```

The subscripts in `subs` define a 2-by-3-by-2 multidimensional array for the output.

Use `accumarray` to sum the data values in `val` that have identical subscripts in `subs`. You can use a function handle to sum the values in their native, `int8`, integer class by using the 'native' option of the `sum` function.

```
A = accumarray(subs,val,[],@(x) sum(x,'native'))
```

```
A(:,:,1) =
```

```
21     0     0
 0     0    14
```

```
A(:,:,2) =
```

```
25     0     0
 0     0    15
```

The result is a 2-by-3-by-2 multidimensional array of class `int8`.

Group Values in Cell Array

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 1:10;
subs = [1 1;1 1;1 1;1 1;2 1;2 1;2 1;2 1;2 1;2 1;2 2]
```

```
subs =
```

```

1     1
1     1
1     1
1     1
2     1
2     1
2     1
2     1
2     1
2     1
2     2

```

The subscripts in `subs` define a 2-by-2 matrix for the output.

Use `accumarray` to group the elements of `val` into a cell array.

```
A = accumarray(subs, val, [], @(x) {x})
```

```
A =
```

```

[4x1 double]     []
[5x1 double]     [10]

```

The result is a 2-by-2 cell array.

Verify that the vector elements are in the same order as they appear in `val`.

```
A{2,1}
```

```
ans =
```

```

5
6
7
8
9

```

Since the subscripts in `subs` are sorted, the elements of the numeric vectors in the cell array are in the same order as they appear in `val`.

Using Functions That Depend on Data Order

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 1:5;  
subs = [1 2; 1 1; 1 2; 1 1; 2 3]
```

```
subs =  
  
     1     2  
     1     1  
     1     2  
     1     1  
     2     3
```

The subscripts in `subs` define a 2-by-3 matrix for the output, but are unsorted with respect to the linear indices in the output, `A`.

Group the values in `val` into a cell array by specifying `fun = @(x) {x}`.

```
A = accumarray(subs, val, [], @(x) {x})
```

```
A =  
  
     [2x1 double]     [2x1 double]     []  
     []           []           [5]
```

The result is a 2-by-3 cell array.

Examine the vector in `A{1,2}`.

```
A{1,2}
```

```
ans =  
  
     3
```

```
1
```

The elements of the `A{1,2}` vector are in a different order than in `val`. The first element of the vector is 3 instead of 1. If the subscripts in `subs` are not sorted with respect to their linear indices, then `accumarray` might not always preserve the order of the data in `val` when it passes them to `fun`. In the unusual case that `fun` requires that its input values be in the same order as they appear in `val`, sort the indices in `subs` with respect to the linear indices of the output.

Use the two-output syntax of the `sortrows` function to reorder `subs` and `val` concurrently with respect to the linear indices of the output, `A`.

```
[S,I] = sortrows(subs);
A = accumarray(S,val(I),[],@(x) {x});
A{3}
```

```
ans =
```

```
1
3
```

The elements of the `A{3}` vector are now in sorted order.

Fill Output with NaN Values

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 101:106';
subs = [1 1; 2 2; 3 3; 1 1; 2 2; 4 4]
```

```
subs =
```

```
1 1
2 2
3 3
1 1
2 2
4 4
```

accumarray

The subscripts in `subs` define a 4-by-4 matrix for the output, but only reference 4 out of the 16 elements. By default, the other 12 elements are 0 in the output.

Use the `fillval` input of `accumarray` to fill in the extra output elements with NaN values.

```
A = accumarray(subs, val, [], [], NaN)
```

```
A =
```

```
    205    NaN    NaN    NaN
    NaN    207    NaN    NaN
    NaN    NaN    103    NaN
    NaN    NaN    NaN    106
```

The result is a 4-by-4 matrix padded with NaN values.

Change Output Sparsity

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = [34 22 19 85 53 77 99 6];
subs = [1 1; 400 400; 80 80; 1 1; 400 400; 400 400; 80 80; 1 1]
```

```
subs =
```

```
     1     1
   400   400
     80    80
     1     1
   400   400
   400   400
     80    80
     1     1
```

The subscripts in `subs` define a 400-by-400 matrix for the output, but only reference 3 out of the 160,000 elements. When the result of an operation with `accumarray` leads to a large output array with low

density of nonzero elements, you can save storage space by storing the output as a sparse matrix.

Use the `issparse` input of `accumarray` to return a sparse matrix.

```
A = accumarray(subs, val, [], [], [], true)
```

```
A =
```

```

(1,1)      125
(80,80)     118
(400,400)   152

```

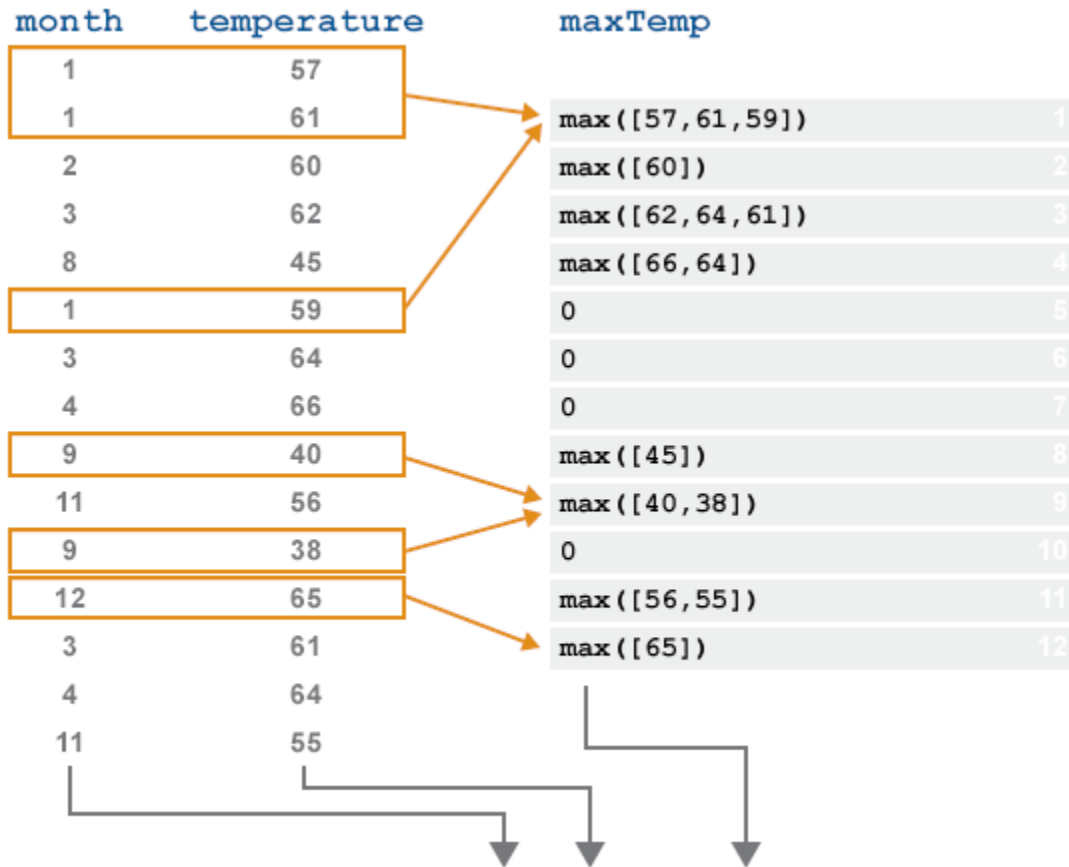

The result is a sparse matrix. You can obtain the same answer with `sparse(subs(:,1), subs(:,2), val)`.

Definitions

Accumulating Elements

The following graphic illustrates the behavior of `accumarray` on a vector of temperature data taken over a 12-month period. To find the maximum temperature reading for each month, `accumarray` applies the `max` function to each group of values in `temperature` that have identical subscripts in `month`.

accumarray

```
maxTemp = accumarray(subs, val, [], @max)
```

No values in month point to the 5, 6, 7, or 10 positions of the output. These elements are 0 in the output by default, but you can specify a value to fill in using fillval.

Tips

- The behavior of accumarray is similar to that of the histc function. Both functions group data into bins.

- `histc` groups continuous values into a 1-D range using bin edges.
- `accumarray` groups data using n -dimensional subscripts.
- `histc` returns the bin counts using `@sum`.
- `accumarray` can apply any function to the bins.

You can mimic the behavior of `histc` using `accumarray` with `val = 1`.

- The `sparse` function also has accumulation behavior similar to that of `accumarray`.
 - `sparse` groups data into bins using 2-D subscripts, whereas `accumarray` groups data into bins using n -dimensional subscripts.
 - `sparse` adds elements that have identical subscripts into the output. `accumarray` adds elements that have identical subscripts into the output by default, but can optionally apply any function to the bins.

Purpose Inverse cosine in radians

Syntax $Y = \text{acos}(X)$

Description $Y = \text{acos}(X)$ returns the inverse cosine (arccosine) for each element of X . For real elements of X in the domain $[-1, 1]$, $\text{acos}(X)$ is real and in the range $[0, \pi]$. For real elements of X outside the domain $[-1, 1]$, $\text{acos}(X)$ is complex.

The `acos` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Cosine Function**

Graph the inverse cosine function over the domain $-1 \leq x \leq 1$.

```
x = -1:.05:1;  
plot(x,acos(x)), grid on
```

Definitions Inverse Cosine

The inverse can be defined as

$$\cos^{-1}(z) = -i \log \left[z + i(1 - z^2)^{1/2} \right].$$

See Also `acosd` | `acosh` | `cos`

acosd

Purpose Inverse cosine in degrees

Syntax $Y = \text{acosd}(X)$

Description $Y = \text{acosd}(X)$ returns the inverse cosine (\cos^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain $[-1,1]$, acosd returns values in the range $[0, 180]$. For values of X outside this range, acosd returns complex values.

Input Arguments **X - Cosine of angle**
scalar value | vector | matrix | N-D array

Cosine of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The acosd operation is element-wise when X is non-scalar.

Data Types

single | double

Complex Number Support: Yes

Output Arguments **Y - Angle in degrees**
scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .

Examples **Inverse Cosine of 0**

Verify that inverse cosine of 0 is exactly 90.

```
acosd(0)
```

```
ans =
```

```
90
```

Round-Trip Calculation for Complex Angles

Show that the inverse cosine, followed by cosine, returns the original values of X.

```
cosd(acosd([2 3]))
```

```
ans =
```

```
2.0000 3.0000
```

`acosd([2 3])` returns two complex angles, which are then passed to the `cosd` function. `cosd` returns the original values, 2 and 3.

`cosd` | `acos` | `cos`

acosh

Purpose Inverse hyperbolic cosine

Syntax $Y = \text{acosh}(X)$

Description $Y = \text{acosh}(X)$ returns the inverse hyperbolic cosine for each element of X .

The `acosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Hyperbolic Cosine Function**

Graph the inverse hyperbolic cosine function over the domain $-1 \leq x \leq \pi$.

```
x = 1:pi/40:pi;  
plot(x,acosh(x)), grid on
```

**Definitions** **Inverse Hyperbolic Cosine**

The inverse hyperbolic cosine can be defined as

$$\cosh^{-1}(z) = \log \left[z + (z^2 - 1)^{1/2} \right].$$

See Also [acos](#) | [cosh](#) | [asinh](#) | [atanh](#)

acot

Purpose Inverse cotangent in radians

Syntax $Y = \text{acot}(X)$

Description $Y = \text{acot}(X)$ returns the inverse cotangent (arccotangent) for each element of X .

The `acot` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Cotangent Function**

Graph the inverse cotangent function over the domains $-2\pi \leq x < 0$ and $0 < x \leq 2\pi$.

```
x1 = -2*pi:pi/30:-0.1;  
x2 = 0.1:pi/30:2*pi;  
plot(x1,acot(x1),x2,acot(x2)), grid on
```

**Definitions** **Inverse Cotangent**

The inverse cotangent can be defined as

$$\cot^{-1}(z) = \tan^{-1}\left(\frac{1}{z}\right).$$

See Also [cot](#) | [acotd](#) | [acoth](#)

acotd

Purpose Inverse cotangent in degrees

Syntax $Y = \text{acotd}(X)$

Description $Y = \text{acotd}(X)$ returns the inverse cotangent (\cot^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the range $[-\text{Inf}, \text{Inf}]$, acotd returns values in the range $[-90, 90]$. For complex values of X , acotd returns complex values.

Input Arguments **X - Cotangent of angle**
scalar value | vector | matrix | N-D array

Cotangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The acotd operation is element-wise when X is non-scalar.

Data Types

single | double

Complex Number Support: Yes

Output Arguments **Y - Angle in degrees**
scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .

Examples **Inverse Cotangent of Vector**

```
x = [0 20 Inf];
```

```
y = acotd(x)
```

```
y =
```

```
    90.0000    2.8624         0
```

The acotd operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Cotangent of Complex Value`acotd(1+i)``ans =``31.7175 -23.0535i`**See Also**`cotd | cot | acot`

acoth

Purpose Inverse hyperbolic cotangent

Syntax $Y = \operatorname{acoth}(X)$

Description $Y = \operatorname{acoth}(X)$ returns the inverse hyperbolic cotangent for each element of X .
The `acoth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Hyperbolic Cotangent Function**

Graph the inverse hyperbolic cotangent function over the domains $-30 \leq x < -1$ and $1 < x \leq 30$.

```
x1 = -30:0.1:-1.1;  
x2 = 1.1:0.1:30;  
plot(x1,acoth(x1),x2,acoth(x2)), grid on
```

Definitions Inverse Hyperbolic Cotangent

The inverse hyperbolic cotangent can be defined as

$$\operatorname{coth}^{-1}(z) = \tanh^{-1}\left(\frac{1}{z}\right).$$

See Also `acot` | `coth` | `atanh` | `asinh` | `acosh`

Purpose Inverse cosecant in radians

Syntax $Y = \text{acsc}(X)$

Description $Y = \text{acsc}(X)$ returns the inverse cosecant (arccosecant) for each element of X .

The `acsc` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Cosecant Function**

Graph the inverse cosecant function over the domains $-10 \leq x < -1$ and $1 < x \leq 10$.

```
x1 = -10:0.01:-1.01;  
x2 = 1.01:0.01:10;  
plot(x1,acsc(x1),x2,acsc(x2)), grid on
```

**Definitions** **Inverse Cosecant**

The inverse cosecant can be defined as

$$\text{csc}^{-1}(z) = \sin^{-1}\left(\frac{1}{z}\right).$$

See Also [csc](#) | [acscd](#) | [acsch](#)

Purpose Inverse cosecant in degrees

Syntax $Y = \text{acscd}(X)$

Description $Y = \text{acscd}(X)$ returns the inverse cosecant (cosec^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain $[-\text{Inf},1]$ and $[1,\text{Inf}]$, acscd returns values in the range $[-90,90]$. For values of X outside this range, acscd returns complex values.

Input Arguments **X - Cosecant of angle**
scalar value | vector | matrix | N-D array

Cosecant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The acscd operation is element-wise when X is non-scalar.

Data Types

single | double

Complex Number Support: Yes

Output Arguments **Y - Angle in degrees**
scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .

Examples **Inverse Cosecant of Vector**

```
x = [20 10 Inf];
```

```
y = acscd(x)
```

```
y =
```

```
2.8660    5.7392    0
```

The acscd operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Cosecant of Complex Value

[acsc](#) | [csch](#) | [asinh](#) | [acosh](#)

actxcontrol

Purpose Create Microsoft ActiveX control in figure window

Syntax

```
h = actxcontrol('progid')
h = actxcontrol('progid','param1',value1,...)
h = actxcontrol('progid',position)
h = actxcontrol('progid', position, fig_handle)
h = actxcontrol('progid',position,fig_handle,event_handler)
h = actxcontrol('progid',position,fig_handle,event_handler,
    'filename')
```

Description `h = actxcontrol('progid')` creates an ActiveX[®] control in a figure window. The programmatic identifier (`progid`) for the control determines the type of control created. (See the documentation provided by the control vendor to get this string.) The returned object, `h`, represents the default interface for the control.

You cannot use an ActiveX server for the `progid` because MATLAB software cannot insert ActiveX servers in a figure. See `actxserver` for use with ActiveX servers.

`h = actxcontrol('progid','param1',value1,...)` creates an ActiveX control using the optional parameter name/value pairs. Parameter names include:

- `position` — MATLAB position vector specifying the position of the control. The format is [left, bottom, width, height] using pixel units.
- `parent` — Handle to parent figure, model, or Command Window.
- `callback` — Name of event handler. To use the same handler for all events, specify a single name. To handle specific events, specify a cell array of event name/event handler pairs.
- `filename` — Sets the initial conditions to the previously saved control.
- `licensekey` — License key to create licensed ActiveX controls that require design-time licenses. See “Deploy ActiveX Controls Requiring Run-Time Licenses” for information on how to use controls that require run-time licenses.

One possible format is:

```
h = actxcontrol('myProgid','newPosition',[0 0 200 200],...
    'myFigHandle',gcf,...
    'myCallback',{ 'Click' 'myClickHandler';...
    'DbtClick' 'myDbtClickHandler';...
    'MouseDown' 'myMouseDownHandler'});
```

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the previous syntaxes are preferred.

`h = actxcontrol('progid',position)` creates an ActiveX control having the location and size specified in the vector, `position`. The format of this vector is:

```
[x y width height]
```

The first two elements of the vector determine where the control is placed in the figure window, with `x` and `y` being offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control. The last two elements, `width` and `height`, determine the size of the control itself.

The default position vector is `[20 20 60 60]`.

`h = actxcontrol('progid', position, fig_handle)` creates an ActiveX control at the specified position in an existing figure window. The Handle Graphics® handle, `fig_handle`, identifies this window.

The `gcf` command returns the current figure handle.

Note If the figure window designated by `fig_handle` is invisible, the control is invisible. If you want the control you are creating to be invisible, use the handle of an invisible figure window.

`h = actxcontrol('progid',position,fig_handle,event_handler)` creates an ActiveX control that responds to events. Controls respond to events by invoking a MATLAB function whenever an event (such

as clicking a mouse button) is fired. The `event_handler` argument identifies one or more functions to be used in handling events. For more information, see “Specifying Event Handlers” on page 1-122.

`h = actxcontrol('progid', position, fig_handle, event_handler, 'filename')` creates an ActiveX control with the first four arguments, and sets its initial state to that of a previously saved control. MATLAB loads the initial state from the file specified in the string `filename`.

If you do not want to specify an `event_handler`, you can use an empty string (`' '`) as the fourth argument.

The `progid` argument must match the `progid` of the saved control.

Specifying Event Handlers

There is more than one valid format for the `event_handler` argument. Use this argument to specify one of the following:

- A different event handler routine for each event supported by the control
- One common routine to handle selected events
- One common routine to handle all events

In the first case, use a cell array for the `event_handler` argument, with each row of the array specifying an event and handler pair:

```
{'event' 'eventhandler'; 'event2' 'eventhandler2'; ...}
```

`event` is either a string containing the event name or a numeric event identifier (see Example 2), and `eventhandler` is a string identifying the function you want the control to use in handling the event. Include only those events that you want enabled.

In the second case, use the same cell array syntax described, but specify the same `eventhandler` for each event. Again, include only those events that you want enabled.

In the third case, make `event_handler` a string (instead of a cell array) that contains the name of the one function that is to handle all events for the control.

There is no limit to the number of event and handler pairs you can specify in the `event_handler` cell array. However, if you register the same event name to the same callback handler multiple times, MATLAB executes the event only once.

Event handler functions accept a variable number of arguments.

Strings used in the `event_handler` argument are not case-sensitive.

Note Although using a single handler for all events might be easier in some cases, specifying an individual handler for each event creates more efficient code, resulting in better performance.

Tips

If the control implements any custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

When you no longer need the control, call `release` to release the interface and free memory and other resources used by the interface. Releasing the interface does not delete the control itself. To release the interface, use the `delete` function.

For more information on handling control events, see [Writing Event Handlers](#).

For an example event handler, see the file `sampev.m` in the `toolbox\matlab\winfun\comcli` folder.

COM functions are available on Microsoft® Windows® systems only.

Note If you encounter problems creating Microsoft Forms 2.0 controls in MATLAB or other non-VBA container applications, see “Use Microsoft Forms 2.0 Controls”.

Examples

Handling Events

The `event_handler` argument specifies how you want the control to handle any events that occur. The control can handle all events with one common handler function, selected events with a common handler function, or each type of event can be handled by a separate function.

This command creates an `mwsamp` control that uses one event handler, `sampev`, to respond to all events:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...  
    gcf, 'sampev');
```

The next command also uses a common event handler, but will only invoke the handler when selected events, `Click` and `Db1Click` are fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...  
    gcf, {'Click' 'sampev'; 'Db1Click' 'sampev'});
```

This command assigns a different handler routine to each event. For example, `Click` is an event, and `myclick` is the routine that executes whenever a `Click` event is fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...  
    gcf, {'Click', 'myclick'; 'Db1Click' 'my2click'; ...  
    'MouseDown' 'mymoused'});
```

The next command does the same thing, but specifies the events using numeric event identifiers:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...  
    gcf, {-600, 'myclick'; -601 'my2click'; -605 'mymoused'});
```

For examples of event handler functions and how to register them with MATLAB, see “Sample Event Handlers”.

See Also

`actxserver` | `release` | `delete` (COM) | `save` (COM) | `load` (COM) | `interfaces`

Purpose List currently installed Microsoft ActiveX controls

Syntax `info = actxcontrollist`

Description `info = actxcontrollist` returns a list of controls in `info`, a 1-by-3 cell array containing the name, programmatic identifier (ProgID), and file name for the control. Each control has one row, which MATLAB software sorts by file name.

COM functions are available on Microsoft Windows systems only.

Examples Show information for two controls:

```
list = actxcontrollist;
for k = 1:2
    sprintf(' Name = %s\n ProgID = %s\n File = %s\n', list{k,:})
end
```

MATLAB displays information like:

```
ans =
  Name = Calendar Control 11.0
  ProgID = MSCAL.Calendar.7
  File = C:\Program Files\MSOffice\OFFICE11\MSCAL.OCX
```

```
ans =
  Name = CTreeView Control
  ProgID = CTREEVIEW.CTreeViewCtrl.1
  File = C:\WINNT\system32\dmocx.dll
```

See Also `actxcontrolselect` | `actxcontrol`

actxcontrolselect

Purpose Create Microsoft ActiveX control from GUI

Syntax `h = actxcontrolselect`
`[h, info] = actxcontrolselect`

Description `h = actxcontrolselect` displays a GUI listing all ActiveX controls installed on the system and creates the one you select from the list. Returns handle `h` for the object. Use the handle to identify this control when calling MATLAB COM functions.

`[h, info] = actxcontrolselect` returns a 1-by-3 cell array `info` containing the name, programmatic identifier (ProgID), and file name for the control.

COM functions are available on Microsoft Windows systems only.

See Also `actxcontrollist` | `actxcontrol`

How To

- “Creating Control Objects Using a GUI”

Purpose

Handle to running instance of Automation server

Syntax

```
h = actxGetRunningServer('progid')
```

Description

`h = actxGetRunningServer('progid')` gets a reference to a running instance of the OLE Automation server. `progid` is the programmatic identifier of the Automation server object and `h` is the handle to the default interface of the server object.

The function returns an error if the server specified by `progid` is not currently running or if the server object is not registered. When multiple instances of the Automation server are running, the operating system controls the behavior of this function.

COM functions are available on Microsoft Windows systems only.

Examples

Get a handle to the MATLAB application:

```
h = actxGetRunningServer('matlab.application')
```

See Also

`actxcontrol` | `actxserver`

How To

- “MATLAB COM Automation Server Interface”

Purpose Create COM server

Syntax

```
h = actxserver('progid')
h = actxserver('progid','machine','machineName')
h = actxserver('progid','interface','interfaceName')
h = actxserver('progid','machine','machineName','interface',
    'interfaceName')
h = actxserver('progid',machine)
```

Description `h = actxserver('progid')` creates a local OLE Automation server, where `progid` is the programmatic identifier of an OLE-compliant COM server, and `h` is the handle of the server's default interface.

Get `progid` from the control or server vendor's documentation. To see the `progid` values for MATLAB software, refer to "Programmatic Identifiers".

`h = actxserver('progid','machine','machineName')` creates an OLE Automation server on a remote machine, where `machineName` is a string specifying the name of the machine on which to start the server.

`h = actxserver('progid','interface','interfaceName')` creates a Custom interface server, where `interfaceName` is a string specifying the interface name of the COM object. Values for `interfaceName` are

- `IUnknown` — Use the `IUnknown` interface.
- The Custom interface name

You must know the name of the interface and have the server vendor's documentation in order to use the `interfaceName` value. For information about custom COM servers and interfaces, see "COM Server Types".

Note The MATLAB COM Interface does not support invoking functions with optional parameters.

```
h =  
actxserver('progid','machine','machineName','interface',  
'interfaceName') creates a Custom interface server on a  
remote machine.
```

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the syntaxes described earlier are preferred:

```
h = actxserver('progid',machine) creates a COM server running  
on the remote system named by the machine argument. This can be an  
IP address or a DNS name. Use this syntax only in environments that  
support Distributed Component Object Model (for more information,  
see “Using MATLAB Application as DCOM Server”).
```

Tips

For components implemented in a dynamic link library (DLL), `actxserver` creates an in-process server. For components implemented as an executable (EXE), `actxserver` creates an out-of-process server. Out-of-process servers can be created either on the client system or on any other system on a network that supports DCOM.

If the control implements any Custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

You can register events for COM servers.

COM functions are available on Microsoft Windows systems only.

Examples

Microsoft Excel® Workbook Example

This example creates an OLE Automation server, Excel version 9.0, and manipulates a workbook in the application.

Create a COM server running Microsoft Excel.

```
e = actxserver ('Excel.Application')
```

```
e =  
    COM.Excel.application
```

Make the Excel frame window visible.

```
e.Visible = 1;
```

Use the `get` method on the Excel object `e` to list all properties of the application.

```
e.get
```

```
Application: [1x1
Interface.Microsoft_Excel_9.0_Object_Library._Application]
  Creator: 'xlCreatorCode'
  .
  .
  .
  Workbooks: [1x1
Interface.Microsoft_Excel_9.0_Object_Library.Workbooks]
  .
  .
  .
  Caption: 'Microsoft Excel - Book1'
  CellDragAndDrop: 0
  ClipboardFormats: {3x1 cell}
  .
  .
  .
  Cursor: 'xlNorthwestArrow'
  .
  .
  .
```

Create an interface `eWorkBooks`.

```
eWorkbooks = e.Workbooks
```

```
eWorkbooks =
  Interface.Microsoft_Excel_9.0_Object_Library.Workbooks
```

List all methods for that interface.

```
eWorkbooks.invoke
```

```

    Add: 'handle Add(handle, [Optional]Variant)'
    Close: 'void Close(handle)'
    Item: 'handle Item(handle, Variant)'
    Open: 'handle Open(handle, string, [Optional]Variant)'
    OpenText: 'void OpenText(handle, string, [Optional]Variant)'
    .
    .
    .

```

Add a new workbook w, also creating a new interface.

```
w = eWorkbooks.Add
```

```

w =
    Interface.Microsoft_Excel_9.0_Object_Library._Workbook

```

Close Excel and delete the object.

```

e.Quit;
e.delete;

```

matlab.apputil.create

Purpose Create or modify app project file for packaging app into .mlappinstall file using interactive dialog box

Syntax matlab.apputil.create
matlab.apputil.create(prjfile)

Description matlab.apputil.create opens the Package App dialog box that steps you through the process of creating an .mlappinstall file.

matlab.apputil.create(prjfile) loads the specified .prj file and populates the Package App dialog box with the information from the specified project file. Use this option if you need to update an existing app.

Input Arguments **prjfile - Full or partial path to the .prj file**
string

Full or partial path to the .prj file you created previously with the Package App dialog box, specified as a string

Example: 'C:\myapp.prj'

Examples **Open Dialog Box for Creating an App Package**

matlab.apputil.create

Package App
H:\Untitled1.prj

Pick main file | **Describe your app**

Main file
Add main function file (program's entry point).
[Add main file](#)

Files included through analysis
These are the files found through dependency analysis.
[Refresh](#)

Shared resources and helper files
Place images, data files, and GUIs (.fig files) here if referenced by any functions.
Also place here:

- Functions called using `eval` (and its variants)
- Functions not on the MATLAB path
- Private functions

[Add files/folders](#)

Describe your app

Version

matlab.apputil.create

Minimally, add a main file and specify an app name. MATLAB creates and continuously saves a .prj file, regardless of whether you click **Package**. However, MATLAB does not create a .mlappinstall file if you do not click **Package**.

Update Existing App Package

Assume you have an existing project file, myapp.prj. You want to add a file and update the description.

Open the Package App dialog box, specifying the previously created .prj file:

```
matlab.apputil.create('myapp.prj')
```

The dialog box opens populated with the data you previously specified for myapp. Adjust the information in the dialog box, as needed.

matlab.apputil.package

Concepts

- “MATLAB App Installer File — mlappinstall”

Purpose

List installed app information

Syntax

```
matlab.apputil.getInstalledAppInfo
```

```
appinfo = matlab.apputil.getInstalledAppInfo
```

Description

`matlab.apputil.getInstalledAppInfo` displays the ID and name of all installed custom apps. It does not display this information for apps packaged with MathWorks® products.

`appinfo = matlab.apputil.getInstalledAppInfo` returns structure to `appinfo`, which includes the status, ID, location, and name of all installed custom apps. It does not return this information for apps packaged with MathWorks products.

Output Arguments

appinfo - Information about installed apps

structure array

Information about the installed app, returned as a structure array, with one element for each installed app. Each element of the structure array has the following fields:

status - Installation status

'installed'

Status of the installation, returned as the string 'installed'.

id - Unique identifier for the installed app

string

Unique identifier for the installed app, returned as a string

The ID is for use when running or uninstalling the app programmatically.

location - Folder where the app is installed

string

matlab.apputil.getInstalledAppInfo

Folder where the app is installed, returned as a string

name - Name of the installed app

string

Name of the installed app as it appears in the apps gallery, returned as a string

Examples

Display Installed Apps Information in the Command Window

Assume you installed two apps, LinePlotter and PlotRandNumbers. Display the app information in the Command Window.

```
matlab.apputil.getInstalledAppInfo
```

```
ID                               Name
-----
LinePlotterAPP                  LinePlotter
PlotRandNumbersAPP             PlotRandNumbers
```

Store Installed App Information in a Variable

Assume you installed an app, ColorPalette. Get the app information and store it in a variable, myappinfo.

```
myappinfo = matlab.apputil.getInstalledAppInfo;
```

Store Installed App Information in a Variable and Display IDs

Assume you installed two apps, LinePlotter and PlotRandNumbers. Get and store the app information for both installed apps in a variable, myappinfo. Then, get the id for each app.

```
myappinfo = matlab.apputil.getInstalledAppInfo
```

```
myappinfo =
```

```
1x2 struct array with fields:
    id
```

```
name  
status  
location
```

Get the id of each installed app:

```
appids={myappinfo.id}
```

```
appids =
```

```
    'LinePlotterAPP'    'PlotRandNumbersAPP'
```

Concepts

- “MATLAB App Installer File — mlappinstall”

matlab.apputil.install

Purpose	Install app from a <code>.mlappinstall</code> file
Syntax	<code>appinfo = matlab.apputil.install(appfile)</code>
Description	<code>appinfo = matlab.apputil.install(appfile)</code> installs the specified app file and returns information about the app.
Input Arguments	<p>appfile - Full or partial path to <code>.mlappinstall</code> file string</p> <p>Full or partial path of the app file you want to install, specified as a string.</p> <p>Example: <code>'C:\myguis\myapps\myapp.mlappinstall'</code></p>
Output Arguments	<p>appinfo - Information about installed app structure</p> <p>Information about the installed app, returned as a structure with the fields:</p> <p>status - Installation status <code>'installed' 'updated'</code></p> <p>Installation status, returned as a string:</p> <ul style="list-style-type: none">• <code>'installed'</code> — New app is installed.• <code>'updated'</code> — Previously installed app is updated. <p>id - Unique identifier string</p> <p>Unique identifier for the installed app, returned as a string</p> <p>The ID is for use when running or uninstalling the app programmatically.</p> <p>location - Folder where app is installed string</p>

Folder where app is installed, returned as a string

name - Name of installed app

string

Name of installed app as it appears in the apps gallery, returned as a string

Examples

Install App and Display Information About the Installation

Assume you have downloaded an app from File Exchange named EmployeeData. Install it and return information about the installation to the variable `appinfo`. Later, if you decide to uninstall the app programmatically, you have the app id required to do so.

```
appinfo = matlab.apputil.install...  
    ('C:\myguis\myapps\EmployeeData.mlappinstall')  
  
appinfo =  
  
        id: 'EmployeeDataApp'  
       name: 'EmployeeData'  
      status: 'installed'  
 location: 'C:\myguis\myapps\EmployeeData.mlappinstall'
```

Concepts

- “MATLAB App Installer File — `mlappinstall`”

matlab.apputil.package

Purpose	Package app files into .mlappinstall file
Syntax	<code>matlab.apputil.package(prjfile)</code>
Description	<code>matlab.apputil.package(prjfile)</code> creates a .mlappinstall file based on the information in the specified <code>prjfile</code> .
Input Arguments	prjfile - Full or partial path to app project (.prj) file string Full or partial path to app project (.prj) file, specified as a string. Example: 'plotdata.prj'
Examples	Create mlappinstall File for Previously Created Project File Assume you previously created <code>myprjfile.prj</code> using <code>matlab.apputil.create</code> . The following command creates the corresponding .mlappinstall file. <code>matlab.apputil.package('myprjfile.prj')</code>
Tips	<ul style="list-style-type: none">• To create a .prj file, use <code>matlab.apputil.create</code>.
See Also	<code>matlab.apputil.create</code> <code>matlab.apputil.install</code> <code>matlab.apputil.run</code>

Purpose Run app programmatically

Syntax `matlab.apputil.run(appid)`

Description `matlab.apputil.run(appid)` runs the custom app specified by the unique identifier, `appid`.

Input Arguments **appid - ID of custom app**
string

ID of custom app you want to run, specified as a string.

Example: `'DataExplorationAPP'`

- Tips**
- The ID of a custom app is returned when you install it. You can use `matlab.apputil.getInstalledAppInfo` to get the ID after you have installed an app.
 - When a custom app runs, MATLAB adds any folders it needs to have added to the path, as identified when the app was packaged. When the app exits, MATLAB removes those folders from the path.
 - You can run multiple, different custom apps concurrently. However, you cannot run two instances of the same app concurrently.

Examples **Run Previously Installed App**

Assume you installed two apps, `PlotData` and `setslider`. Run `PlotData` programmatically, using its ID.

Get IDs of all installed apps.

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
-----	-----
setsliderAPP	setslider
PlotDataAPP	PlotData

matlab.apputil.run

Run PlotData.

```
matlab.apputil.run('PlotDataAPP')
```

See Also

[matlab.apputil.create](#) | [matlab.apputil.install](#) |
[matlab.apputil.getInstalledAppInfo](#)

Purpose Uninstall app

Syntax `matlab.apputil.uninstall(appid)`

Description `matlab.apputil.uninstall(appid)` removes the app specified by the unique identifier, `appid`. MATLAB removes all files corresponding to the app and removes the app from the app gallery.

Input Arguments **appid - ID of app**
string

ID of app to be uninstalled, specified as a string.

Example: 'DataExplorationAPP'

Tips

- To determine the `appid` of an installed app, preserve the value returned when you install the app programmatically with `matlab.apputil.install`, or use `matlab.apputil.getInstalledAppInfo`.

Examples **Uninstall App**

Assume you previously installed two apps, `setslider` and `simplegui`. Get the IDs of all installed apps, and then use the ID for `simplegui` to uninstall it.

View the IDs of all apps

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
setsliderAPP	setslider
simpleguiAPP	simplegui

Uninstall the `simplegui` app.

```
matlab.apputil.uninstall('simpleguiAPP')
```

matlab.apputil.uninstall

Confirm the app was removed, by running
`matlab.apputil.getInstalledAppInfo` again.

```
matlab.apputil.getInstalledAppInfo
```

ID	Name
-----	-----
setsliderAPP	setslider

See Also

`matlab.apputil.install` | `matlab.apputil.getInstalledAppInfo`

Purpose

Record additional causes of exception

Syntax

```
baseExcep = addCause(baseExcep, causeExcep)
```

Description

baseExcep = addCause(*baseExcep*, *causeExcep*) adds information to existing exception *baseExcep* to help determine its cause. The added information is in the form of a second exception *causeExcep*. Both *baseExcep* and *causeExcep* are objects of the MException class. The *baseExcep* and *causeExcep* inputs are scalar objects of the mException class.

The exception has a property called *cause* in which you can store a series of additional exceptions, each saving information on what caused the initial error. (See the figure in the documentation for “The MException Class”.) When your program calls addCause, MATLAB appends a new exception *cause* to this field in the base exception *exception*. When your error handling code catches the error in a try/catch statement, execution of the catch part of this statement makes the base exception, along with all of the appended cause records, available to help diagnose the error.

Examples

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested try-catch block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second using addCause:

```
function data = read_it(filename);
try
    % Attempt to open and read from a file.
    fid = fopen(filename, 'r');
    data = fread(fid);
catch exception1
    % If the error was caused by an invalid file ID, try
    % reading from another location.
    if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
        msg = sprintf( ...
```

addCause (MException)

```
        '\nCannot open file %s. Try another location? ', ...
        filename);
    reply = input(msg, 's')
    if reply(1) == 'y'
        newFolder = input('Enter folder name: ', 's');
    else
        throw(exception1);
    end
    oldpath = addpath(newFolder);
    try
        fid = fopen(filename, 'r');
        data = fread(fid);
    catch exception2
        exception3 = addCause(exception2, exception1)
        path(oldpath);
        throw(exception3);
    end
    path(oldpath);
end
end
fclose(fid);

try
    d = read_it('anytextfile.txt');
catch exception
end

exception
exception =
    MException object with properties:

    identifier: 'MATLAB:FileIO:InvalidFid'
    message: 'Invalid file identifier. Use fopen
             to generate a valid file identifier.'
    stack: [1x1 struct]
    cause: {[1x1 MException]}
```

```
Cannot open file anytextfile.txt. Try another location?y
Enter folder name: xxxxxxx
Warning: Name is nonexistent or not a directory: xxxxxxx.
> In path at 110
  In addpath at 89
```

getReport(MException) | MException | assert | error |
try, catch
```

addevent

Purpose Add event to `timeseries` object

Syntax
`ts = addevent(ts,e)`
`ts = addevent(ts,Name,Time)`

Description `ts = addevent(ts,e)` adds one or more `tsdata.event` objects, `e`, to the `timeseries` object `ts`. `e` is either a single `tsdata.event` object or an array of `tsdata.event` objects.

`ts = addevent(ts,Name,Time)` constructs one or more `tsdata.event` objects and adds them to the `Events` property of `ts`. `Name` is a cell array of event name strings. `Time` is a cell array of event times.

Examples Create a time-series object and add an event to this object.

```
%% Import the sample data
load count.dat

%% Create time-series object
count1=timeseries(count(:,1),1:24,'name','data');

%% Modify the time units to be 'hours' ('seconds' is default)
count1.TimeInfo.Units = 'hours';

%% Construct and add the first event at 8 AM
e1 = tsdata.event('AMCommute',8);

%% Specify the time units of the time
e1.Units = 'hours';

View the properties (EventData, Name, Time, Units, and StartDate)
of the event object.

get(e1)

MATLAB software responds with

    EventData: []
```

```
        Name: 'AMCommute'  
        Time: 8  
        Units: 'hours'  
        StartDate: ''  
%% Add the event to count1  
count1 = addevent(count1,e1);
```

An alternative syntax for adding two events to the time series count1 is as follows:

```
count1 = addevent(count1,{'AMCommute' 'PMCommute'},{8 18})
```

See Also

[timeseries](#) | [tsdata.event](#)

audioinfo

Purpose Information about audio file

Syntax `info = audioinfo(filename)`

Description `info = audioinfo(filename)` returns information about the contents of the audio file specified by `filename`.

Input Arguments **filename - Name of file**
string

Name of file, specified as a string. If a path is specified, it can be absolute, relative, or partial.

Example: `'myFile.mp3'`

Example: `'../myFile.mp3'`

Example: `'C:\temp\myFile.mp3'`

`audioinfo` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
	AU (.au)
Windows 7 (or later), Macintosh, and Linux®	MP3 (.mp3)
	MPEG-4 AAC (.m4a, .mp4)

On Windows 7 platforms (or later), `audioinfo` might also return information about the contents of any files supported by Windows Media® Foundation.

On Linux platforms, `audioinfo` might also return information about the contents of any files supported by GStreamer.

audioinfo can extract audio metadata from MPEG-4 (.mp4, .m4v) video files on Windows 7 or later, Mac OS X 10.7 Lion or higher, and Linux, and from Windows Media Video (.wmv) and AVI (.avi) files on Windows 7 (or later) and Linux platforms.

Output Arguments

info - Information about audio file

structure

Information about audio file, returned as a structure. info can contain the following fields.

Field Name	Description	Data Type
Filename	Filename including the absolute path to the file and the file extension.	string
CompressionMethod	Compression method used.	string
NumChannels	Number of audio channels encoded in	double
SampleRate	Sample rate of the audio data in the file, in hertz.	double
TotalSamples	Total number of audio samples in the file.	double
Duration	Duration of the file, in seconds.	double
BitsPerSample	Number of bits per sample encoded in the audio file. Only valid for WAVE (.wav) and FLAC (.flac) files.	double

Field Name	Description	Data Type
BitRate	Number of kilobits per second (kbit/s) used for compressed audio files. Only valid for MP3 (.mp3) and MPEG-4 Audio (.m4a, .mp4) files.	double
Title	Value of 'Title', if any.	string
Artist	Value of 'Artist', if any.	string
Comment	Value of 'Comment', if any.	string

Note The BitRate property returns the actual bit rate on Mac platforms, and not the encoded bit rate. This means that bit rate values might be lower than specified at the time of the encoding, depending on the source data.

Note On Mac platforms, audioinfo returns metadata from .m4a and .mp4 files only on Mac OS X 10.7 Lion or higher. Previous versions of Mac OS X will not read the 'Title', 'Author', or 'Comment' fields.

Examples

Get Information About Audio File

Create a WAVE file from the example file handel.mat, and get information about the file.

Create a WAVE (.wav) file in the current folder.

```
load handel.mat
filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Use `audioinfo` to return information about the WAVE file.

```
info = audioinfo(filename)

info =
    Filename: 'S:\handel.wav'
    CompressionMethod: 'Uncompressed'
    NumChannels: 1
    SampleRate: 8192
    TotalSamples: 73113
    Duration: 8.9249
    Title: []
    Comment: []
    Artist: []
    BitsPerSample: 16
```

Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 or later and Linux platforms, `audioinfo` might report fewer samples than expected. On Linux platforms, this is due to a limitation in the underlying GStreamer framework.
- On Linux platforms, `audioinfo` interprets single channel data in MPEG-4 AAC files as stereo data.

See Also

`audioread` | `audiowrite`

audioread

Purpose Read audio file

Syntax

```
[y,Fs] = audioread(filename)
[y,Fs] = audioread(filename,samples)

[y,Fs] = audioread( ___,dataType)
```

Description [y,Fs] = audioread(filename) reads data from the file named filename, and returns sampled data,y, and a sample rate for that data, Fs.

[y,Fs] = audioread(filename,samples) reads the selected range of audio samples in the file, where samples is a vector of the form [start,finish].

[y,Fs] = audioread(___,dataType) returns sampled data in the data range corresponding to the dataType of 'native' or 'double', and can include any of the input arguments in previous syntaxes.

Input Arguments

filename - Name of file to read

string

Name of file to read, specified as a string that includes the file extension. If a path is specified, it can be absolute, relative or partial.

Example: 'myFile.mp3'

Example: '../myFile.mp3'

Example: 'C:\temp\myFile.mp3'

audioread supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
	AU (.au)
Windows 7 (or later), Macintosh, and Linux	MP3 (.mp3)
	MPEG-4 AAC (.m4a, .mp4)

On Windows platforms prior to Windows 7, audioread does not read WAVE files with MP3 encoded data.

On Windows 7 (or later) platforms, audioread might also read any files supported by Windows Media Foundation.

On Linux platforms, audioread might also read any files supported by GStreamer.

audioread can extract audio from MPEG-4 (.mp4, .m4v) video files on Windows 7 or later, Macintosh, and Linux, and from Windows Media Video (.wmv) and AVI (.avi) files on Windows 7 (or later) and Linux platforms.

samples - Audio samples to read

[1, inf] (default) | two-element vector of positive scalar integers

Audio samples to read, specified as a two-element vector of the form [start, finish], where start and finish are the first and last samples to read, and are positive scalar integers.

- start must be less than or equal to finish.
- start and finish must be less than the number of audio samples in the file,
- You can use inf to indicate the last sample in the file.

Note When reading a portion of some MP3 files on Windows 7 platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying Windows Media Foundation framework.

When reading a portion of MP3 and M4A files on Linux platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying GStreamer framework.

Example: `[1,100]`

Data Types

`double`

dataType - Data format of audio data, *y*

`'double'` (default) | `'native'`

Data format of audio data,*y*, specified as one of the following strings:

- `'double'` Double-precision normalized samples.
- `'native'` Samples in the native format found in the file.

For compressed audio formats, such as MP3 and MPEG-4 AAC that do not store data in integer form, `'native'` defaults to `'single'`.

Output Arguments

y - Audio data

`matrix`

Audio data in the file, returned as an *m*-by-*n* matrix, where *m* is the number of audio samples read and *n* is the number of audio channels in the file.

- If you do not specify `dataType`, or `dataType` is `'double'`, then *y* is of type `double`, and matrix elements are normalized values between `-1.0` and `1.0`.

- If `dataType` is 'native', then `y` can be one of several MATLAB data types, depending on the file format and the `BitsPerSample` value of the input file. Call `audioinfo` to determine the `BitsPerSample` value of the file.

File Format	BitsPerSample	Data Type of <code>y</code>	Data Range of <code>y</code>
WAVE (.wav)	8	uint8	$0 \leq y \leq 255$
	16	int16	$-32768 \leq y \leq +32767$
	24	int32	$-2^{32} \leq y \leq 2^{32}-1$
	32	int32	$-2^{32} \leq y \leq 2^{32}-1$
	32	single	$-1.0 \leq y \leq +1.0$
	64	double	$-1.0 \leq y \leq +1.0$
FLAC (.flac)	8	uint8	$0 \leq y \leq 255$
	16	int16	$-32768 \leq y \leq +32767$
	24	int32	$-2^{32} \leq y \leq 2^{32}-1$
MP3 (.mp3), MPEG-4 AAC (.m4a, .mp4), OGG (.ogg), and certain compressed WAVE files	N/A	single	$-1.0 \leq y \leq +1.0$

Note Where `y` is `single` or `double` and the `BitsPerSample` is 32 or 64, values in `y` might exceed `-1.0` or `+1.0`.

Fs - Sample rate

positive scalar

Sample rate, in hertz, of audio data `y`, returned as a positive scalar.

Examples

Read Complete Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Create a WAVE (`.wav`) file in the current folder.

```
load handel.mat
```

```
filename = 'handel.wav';  
audiowrite(filename,y,Fs);  
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread('handel.wav');
```

Play the audio.

```
sound(y,Fs);
```

Read Portion of Audio File

Create a FLAC file from the example file `handel.mat`, and then read only the first 2 seconds.

Create a FLAC (`.flac`) file in the current folder.

```
load handel.mat
```

```
filename = 'handel.flac';  
audiowrite(filename,y,Fs);
```

Read only the first 2 seconds.

```
samples = [1,2*Fs];  
clear y Fs  
[y,Fs] = audioread(filename,samples);
```

Play the samples.

```
sound(y,Fs);
```

Return Audio in Native Integer Format

Create a FLAC file and read the first 2 seconds according to the previous Example. Then, view the data type of the sampled data `y`.

```
whos y
```

Name	Size	Bytes	Class	Attributes
y	16384x1	131072	double	

The data type of `y` is `double`.

Request audio data in the native format of the file, and then view the data type of the sampled data `y`.

```
[y,Fs] = audioread(filename,'native');  
whos y
```

Name	Size	Bytes	Class	Attributes
y	16384x1	32768	int16	

The data type of `y` is now `int16`.

audioread

Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 or later and Linux platforms, `audioread` might read fewer samples than expected. On Windows 7 platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.
- On Linux platforms, `audioread` reads MPEG-4 AAC files that contain single-channel data as stereo data.

See Also

`audiowrite` | `audioinfo`

Purpose

Write audio file

Syntax

```
audiowrite(filename,y,Fs)
audiowrite(filename,y,Fs,Name,Value)
```

Description

`audiowrite(filename,y,Fs)` writes a matrix of audio data, `y`, with sample rate `Fs` to a file called `filename`. The `filename` input also specifies the output file format. The output data type depends on the output file format and the data type of the audio data, `y`.

`audiowrite(filename,y,Fs,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Input Arguments**filename - Name of file to write**

string

Name of file to write, or the full path to the file, specified as a string that includes the file extension. If a path is specified, it can be absolute or relative. If you do not specify the path, then the destination directory is the current working directory.

`audiowrite` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (.wav)
	OGG (.ogg)
	FLAC (.flac)
Windows and Mac	MPEG-4 AAC (.m4a, .mp4)

Example: 'myFile.m4a'

Example: '../myFile.m4a'

Example: 'C:\temp\myFile.m4a'

When writing AAC files on Windows, `audiowrite` pads the front and back of the output signal with extra samples of silence. The Windows

AAC encoder also places a very sharp fade-in and fade-out on the audio. This results in audio with an increased number of samples after being written to disk.

y - Audio data to write

matrix

Audio data to write, specified as an m -by- n matrix, where m is the number of audio samples to write and n is the number of audio channels to write.

If either m or n is 1, then `audiowrite` assumes that this dimension specifies the number of audio channels, and the other dimension specifies the number of audio samples.

The maximum number of channels depends on the file format.

File Format	Maximum Number of Channels
WAVE (.wav)	256
OGG (.ogg)	255
FLAC (.flac)	8
MPEG-4 AAC (.m4a, .mp4)	2

The valid range for the data in y depends on the data type of y .

Data Type of y	Valid Range for y
uint8	$0 \leq y \leq 255$
int16	$-32768 \leq y \leq +32767$
int32	$-2^{32} \leq y \leq 2^{32}-1$
single	$-1.0 \leq y \leq +1.0$
double	$-1.0 \leq y \leq +1.0$

Data beyond the valid range is clipped.

If `y` is `single` or `double`, then audio data in `y` should be normalized to values in the range -1.0 and 1.0 , inclusive.

Data Types

`single` | `double` | `int16` | `int32` | `uint8`

F_s - Sample rate

positive scalar

Sample rate, in hertz, of audio data `y`, specified as a positive scalar greater than 0. Values of `Fs` are truncated to integer boundaries. When writing to `.m4a` or `.mp4` files on Windows platforms, `audiowrite` supports only samples rates of 44100 and 48000.

Example: 44100

Data Types

`double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Title','Symphony No. 9','Artist','My Orchestra'` instructs `audiowrite` to write an audio file with the title “Symphony No. 9” and the artist information “My Orchestra.”

'BitsPerSample' - Number of output bits per sample

16 (default) | 8 | 24 | 32 | 64

Number of output bits per sample, specified as the comma-separated pair consisting of `'BitsPerSample'` and a number.

Only available for WAVE (`.wav`) and FLAC (`.flac`) files. For FLAC files, only 8, 16, or 24 bits per sample are supported.

Example: `'BitsPerSample',32`

'BitRate' - Kilobits per second (kbit/s)

128 (default) | 64 | 96 | 160 | 192 | 256 | 320

Number of kilobits per second (kbit/s) used for compressed audio files, specified as the comma-separated pair consisting of 'BitRate' and an integer. Noninteger values are truncated. On Windows 7 or later, the only valid values are 96, 128, 160, and 192.

In general, a larger BitRate value results in higher compression quality.

Only available for MPEG-4 (.m4a, .mp4) files.

Example: 'BitRate',96

'Quality' - Quality setting for the Ogg Vorbis Compressor

75 (default) | value in the range [0 100]

Quality setting for the Ogg Vorbis Compressor, specified as the comma-separated pair consisting of 'Quality' and a number in the range [0 100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression.

Only available for OGG (.ogg) files.

Example: 'Quality',25

'Title' - Title information

[] (default) | string

Title information, specified as the comma-separated pair consisting of 'Title' and a string.

'Artist' - Artist information

[] (default) | string

Artist information, specified as the comma-separated pair consisting of 'Artist' and a string.

'Comment' - Additional information

[] (default) | string

Additional information, specified as the comma-separated pair consisting of 'Comment' and a string.

Note On Mac platforms, `audiowrite` writes metadata to WAVE, OGG, and FLAC files only, and will not write the 'Title', 'Author', or 'Comment' fields to MPEG-4 AAC files.

Examples

Write an Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Write a WAVE (.wav) file in the current folder.

```
load handel.mat

filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread(filename);
```

Listen to the audio.

```
sound(y,Fs);
```

Specify Bits Per Sample and Metadata

Create a FLAC file from the example file `handel.mat` and specify the number of output bits per sample and a comment.

```
load handel.mat

filename = 'handel.flac';
```

audiowrite

```
audiowrite(filename,y,Fs,'BitsPerSample',24,...  
'Comment','This is my new audio file.');
```

```
clear y Fs
```

View information about the new FLAC file.

```
info = audioinfo(filename)
```

```
info =
```

```
      Filename: 'S:\handel.flac'  
CompressionMethod: 'FLAC'  
      NumChannels: 1  
      SampleRate: 8192  
TotalSamples: 73113  
      Duration: 8.9249  
      Title: []  
      Comment: 'This is my new audio file.'  
      Artist: []  
BitsPerSample: 24
```

Algorithms

The output data type is determined by the file format, the data type of `y`, and the specified output `BitsPerSample`.

File Formats	Data Type of <code>y</code>	Output <code>BitsPerSample</code>	Output Data Type
WAVE (.wav),	uint8, int16, int32, single, double	8	uint8
		16	int16
		24	int32
	uint8, int16, int32	32	int32
	single, double	32	single
	single, double	64	double

File Formats	Data Type of y	Output BitsPerSample	Output Data Type
FLAC (.flac)	uint8, int16, int32, single, double	8	int8
		16	int16
		24	int32
MPEG-4 (.m4a, .mp4), OGG (.ogg)	uint8, int16, int32, single, double	N/A	single

audioinfo | audioread

addframe (avifile)

Purpose Add frame to Audio/Video Interleaved (AVI) file

Syntax

```
aviobj = addframe(aviobj,frame)
aviobj = addframe(aviobj,frame1,frame2,frame3,...)
aviobj = addframe(aviobj,mov)
aviobj = addframe(aviobj,h)
```

Description `aviobj = addframe(aviobj,frame)` appends the data in `frame` to the AVI file identified by `aviobj`, which was created by a previous call to `avifile`. `frame` can be either an indexed image (m-by-n) or a truecolor image (m-by-n-by-3) of double or uint8 precision. If `frame` is not the first frame added to the AVI file, it must be consistent with the dimensions of the previous frames.

`addframe` returns a handle to the updated AVI file object, `aviobj`. For example, `addframe` updates the `TotalFrames` property of the AVI file object each time it adds a frame to the AVI file.

`aviobj = addframe(aviobj,frame1,frame2,frame3,...)` adds multiple frames to an AVI file.

`aviobj = addframe(aviobj,mov)` appends the frames contained in the MATLAB movie `mov` to the AVI file `aviobj`. MATLAB movies that store frames as indexed images use the colormap in the first frame as the colormap for the AVI file, unless the colormap has been previously set.

`aviobj = addframe(aviobj,h)` captures a frame from the figure or axis handle `h` and appends this frame to the AVI file. `addframe` renders the figure into an offscreen array before appending it to the AVI file. This ensures that the figure is written correctly to the AVI file even if the figure is obscured on the screen by another window or screen saver.

Tips

- `avifile` cannot write files larger than 2 GB. Use `VideoWriter` and `writeVideo` to create larger files.
- If you are creating an animation from a figure with an `EraseMode` property set to `'xor'`, you must use `getframe` to capture the graphics into a frame of a MATLAB movie. Add the frame to the AVI file using

the syntax `aviobj = addframe(aviobj, mov)`. See the example for an illustration.

Examples

This example calls `addframe` to add frames to the AVI file object `aviobj`.

```
aviobj = avifile('example.avi','compression','None');

t = linspace(0,2.5*pi,40);
fact = 10*sin(t);
fig=figure;
[x,y,z] = peaks;
for k=1:length(fact)
    h = surf(x,y,fact(k)*z);
    axis([-3 3 -3 3 -80 80])
    axis off
    caxis([-90 90])

    F = getframe(fig);
    aviobj = addframe(aviobj,F);
end
close(fig);
aviobj = close(aviobj);
```

See Also

[VideoWriter](#) | [avifile](#) | [close \(avifile\)](#) | [movie2avi](#)

addlistener (handle)

Purpose

Create event listener

Syntax

```
lh = addlistener(Hsource, 'EventName', callback)
lh = addlistener(Hsource, property, 'EventName', callback)
```

Description

`lh = addlistener(Hsource, 'EventName', callback)` creates a listener for the specified event.

`lh = addlistener(Hsource, property, 'EventName', callback)` creates a listener for one of the predefined property events. There are four property events:

- **PreSet** — triggered just before the property value is set, before calling its set access method.
- **PostSet** — triggered just after the property value is set.
- **PreGet** — triggered just before a property value query is serviced, before calling its get access method.
- **PostGet** — triggered just after returning the property value to the query

See “Events and Listeners — Syntax and Techniques” for more information.

Input Arguments

Hsource

Handle of the object that is the source of the event, or an array of source handles.

EventName

Name of the event, which is triggered by the source objects.

callback

Function handle referencing a function to execute when the event is triggered.

property

Character string that can be:

- the name of the property

- a cell array of strings where each string is the name of a property that exists in object array `Hsource`
- a `meta.property` object or an array of `meta.property` objects
- a cell array of `meta.property` objects

If `Hsource` is a scalar, then any of the properties can be dynamic properties. If `Hsource` is non-scalar, then the properties must belong to the class of `Hsource` and can not include dynamic properties (which are not part of the class definition).

For more information, see the following sections:

- The `GetObservable` and `SetObservable` property attributes in the “Property Attributes” table.
- “Creating Property Listeners”
- “Dynamic Properties — Adding Properties to an Instance”

Output Arguments

`lh`

Handle of the `event.listener` object returned by `addlistener`.

Removing a Listener

To remove a listener, delete the listener object returned by `addlistener`. For example,

```
delete(lh)
```

calls the handle class `delete` method to delete the object from the workspace and remove the listener.

When you use `addlistener` to create a listener, redefining the variable containing the handle to the listener does not delete the listener because the event object still has a reference to the `event.listener` object. `addlistener` ties the listener’s lifecycle to the object that is the source of the event. If you want to define a listener that is not tied to the event object, use the `event.listener` constructor directly to create the listener.

addListener (handle)

See Also

delete (handle) | handle | notify (handle)

How To

- “Limiting Listener Scope — Constructing event.listener Objects Directly”

Purpose

Add optional positional argument to input parser scheme

Syntax

```
addOptional(p, argName, default)
addOptional(p, argName, default, validationFcn)
```

Description

`addOptional(p, argName, default)` adds optional input, `argName`, to the input parser scheme of `inputParser` object, `p`. When the inputs that you are checking do not include a value for this optional input, the input parser assigns the `default` value to the input.

`addOptional(p, argName, default, validationFcn)` specifies a validation function for the input argument.

Tips

- For optional string inputs, specify a validation function. Without a validation function, the input parser interprets valid string inputs as invalid parameter names and throws an error.
- Use `addOptional` to add an individual argument into the input parser scheme. If you want to parse an optional name-value pair, use `addParameter`.

Input Arguments

p

Object of class `inputParser`.

argName

String that specifies the internal name for the input argument.

Arguments added with `addOptional` are positional. When you call a function with positional inputs:

- Specify inputs in the same order that they are added into the input parser scheme.
- Specify a value for the k th argument by assigning values for the first $(k - 1)$ arguments in the input scheme.

default

inputParser.addOptional

Default value for the input. This value can be of any data type.

validationFcn

Handle to a function that checks if the input argument is valid.

inputParser accepts two types of validation functions: functions that return true or false, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Input

Create an inputParser object and add an optional input named myinput with a default value of 0 to the input scheme.

```
p = inputParser;  
argName = 'myinput';  
default = 0;  
addOptional(p,argName,default);
```

Validate Optional Input

Check whether an optional input named num with a default value of 1 is a numeric scalar greater than zero.

```
p = inputParser;  
argName = 'num';  
default = 1;  
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);  
addOptional(p,argName,default,validationFcn);
```

The syntax @(x) creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as -1:

```
parse(p, -1)
```

```
The value of 'num' is invalid. It must satisfy the function: @(x)isnumeric(x)&&isscalar(x)&&(x>0).
```

Validate Optional Input with validateattributes

Create an inputParser object and define a validation function using validateattributes to test that optional input is numeric, positive, and even. Add the required input to the scheme.

```
p = inputParser;  
argName = 'evenPosNum';  
default = 1;  
validationFcn = @(x) validateattributes(x,{'numeric'},...  
    {'even','positive'});  
addOptional(p,argName,default,validationFcn);
```

Parse an input string. Parse will fail.

```
parse(p, 'hello')
```

The value of 'evenPosNum' is invalid. Expected input to be one of these types:

```
double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64
```

Instead its type was char.

Parse an odd number. Parse will fail.

```
parse(p, 13)
```

The value of 'evenPosNum' is invalid. Expected input to be even.

Parse an even, positive number. Parse will pass.

```
parse(p, 42)
```

See Also

[addParameter](#) | [addRequired](#) | [inputParser](#) | [function_handle](#) | [validateattributes](#)

Concepts

- “Anonymous Functions”

inputParser.addParameter

Purpose Add optional parameter name-value pair argument to input parser scheme

Syntax

```
addParameter(p,paramName,default)
addParameter(p,paramName,default,validationFcn)
addParameter(__,'PartialMatchPriority',
matchPriorityValue)
```

Description

`addParameter(p,paramName,default)` adds parameter name and value argument `paramName` to the input parser scheme of `inputParser` object, `p`. When the inputs that you are checking do not include a value for this optional parameter, the input parser assigns the `default` value.

`addParameter(p,paramName,default,validationFcn)` specifies a validation function for the input argument.

`addParameter(__,'PartialMatchPriority',matchPriorityValue)` allows specification of `matchPriorityValue` to indicate priority for matching of conflicting partial parameter names and can include any of the input arguments in the previous syntaxes.

Input Arguments

p

Object of class `inputParser`.

paramName

String that specifies the internal name for the input parameter.

Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form `Name1, Value1, . . . , NameN, ValueN`.

default

Default value for the input. This value can be of any data type.

matchPriorityValue

Positive integer value indicating the priority for matching of conflicting partial parameter names. The input parser selects

lower priority values over higher ones. If, within an input parser scheme, partial parameter names are ambiguous and have the same priority, `inputParser` will throw an error. If the names are ambiguous, but have different `PartialMatchPriority` values, `inputParser` issues a warning indicating the matched name.

Default: 1

validationFcn

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Parameter Value Input

Create an `inputParser` object and add an optional input named `myparam` with a default value of 0 to the input scheme.

```
p = inputParser;  
paramName = 'myparam';  
default = 0;  
addParameter(p,paramName,default);
```

Unlike the positional inputs added with the `addRequired` and `addOptional` methods, each parameter added with `addParameter` corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the `parse` method.

```
parse(p, 'myparam', 100);  
p.Results
```

```
ans =
```

inputParser.AddParameter

```
myparam: 100
```

Validate Parameter Value

Check whether the value corresponding to `myparam` is a numeric scalar greater than zero.

```
p = inputParser;
paramName = 'myparam';
default = 1;
errorStr = 'Value must be positive, scalar, and numeric.';
validationFcn = @(x) assert(isnumeric(x) && isscalar(x) ...
    && (x > 0),errorStr);
addParameter(p,paramName,default,validationFcn);
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as `-1`:

```
parse(p, 'myparam', -1)
```

```
The value of 'myparam' is invalid. Value must be positive, scalar, and numeric.
```

Validate Parameter Value Input with validateattributes

Create an `inputParser` object and define a validation function using `validateattributes` to test that input parameter `myName` is a nonempty string.

```
p = inputParser;
paramName = 'myName';
default = 'John Doe';
validationFcn = @(x) validateattributes(x,{'char'},{'nonempty'});
addParameter(p,paramName,default,validationFcn);
```

Define `myName` as a number. The attempt to parse fails.

```
parse(p, 'myName ', 1138)
```

The value of 'myName' is invalid. Expected input to be one of these types:

char

Instead its type was double.

Parse a string. The attempt to parse passes.

```
parse(p, 'myName ', 'George ')
```

[addOptional](#) | [addRequired](#) | [inputParser](#) | [function_handle](#) | [validateattributes](#)

Concepts

- “Anonymous Functions”

inputParser.addParamValue

Purpose (Not recommended) Add parameter name and value argument to Input Parser scheme

Compatibility addParamValue is not recommended. Use addParameter instead.

Syntax
addParamValue(p,paramName,default)
addParamValue(p,paramName,default,validationFcn)

Description
addParamValue(p,paramName,default) adds parameter name and value argument paramName to the input scheme of inputParser object p. When the inputs that you are checking do not include a value for this optional parameter, the parser assigns the default value.
addParamValue(p,paramName,default,validationFcn) specifies a validation function for the input argument.

Tips

- If your parameter values do not require validation, you do not have to include them in the input scheme with addParamValue. As an alternative, set the KeepUnmatched property of the inputParser object to true. The parser stores extra parameter names and values in the Unmatched property rather than in the Results property of the object. For an example, see the inputParser reference page.

Input Arguments

p
Object of class inputParser.

paramName
String that specifies the internal name for the input parameter.
Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form Name1, Value1, . . . , NameN, ValueN.

default
Default value for the input. This value can be of any data type.

validationFcn

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Parameter Value Input

Create an `inputParser` object and add an optional input named `myparam` with a default value of 0 to the input scheme.

```
p = inputParser;  
paramName = 'myparam';  
default = 0;  
addParameter(p,paramName,default);
```

Unlike the positional inputs added with the `addRequired` and `addOptional` methods, each parameter added with `addParameter` corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the `parse` method.

```
parse(p, 'myparam', 100);  
p.Results
```

```
ans =
```

```
    myparam: 100
```

Validate Parameter Value

Check whether the value corresponding to `myparam` is a numeric scalar greater than zero.

```
p = inputParser;
```

inputParser.addParamValue

```
paramName = 'myparam';  
default = 1;  
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);  
addParamValue(p,paramName,default,validationFcn);
```

The syntax @(x) creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as -1:

```
parse(p, 'myparam', -1)
```

```
Argument 'myparam' failed validation @(x)isnumeric(x)&&isscalar(x)&&(x>0)
```

Concepts

- “Anonymous Functions”

Purpose	Add categories to categorical array
Syntax	<pre>B = addcats(A,newcats) B = addcats(A,newcats, 'Before',beforewhere) B = addcats(A,newcats, 'After',afterwhere)</pre>
Description	<p><code>B = addcats(A,newcats)</code> adds categories to the end of the category list for the input categorical array, <code>A</code>. The output categorical array, <code>B</code>, contains the same values as <code>A</code>. The output, <code>B</code>, does not contain any elements equal to the new categories until you assign values from <code>newcats</code> to elements in <code>B</code>.</p> <p>If <code>A</code> is an ordinal categorical array, you must specify the <code>'Before',beforewhere</code> or <code>'After',afterwhere</code> input arguments.</p> <p><code>B = addcats(A,newcats, 'Before',beforewhere)</code> adds categories before the category specified by <code>beforewhere</code>.</p> <p><code>B = addcats(A,newcats, 'After',afterwhere)</code> adds categories after the category specified by <code>afterwhere</code>.</p>
Input Arguments	<p>A - Categorical array vector matrix multidimensional array</p> <p>Categorical array, specified as a vector, matrix, or multidimensional array.</p> <p>newcats - New categories string cell array of strings</p> <p>New categories, specified as a string or a cell array of strings.</p> <p>beforewhere - Category to precede string</p> <p>Category to precede, specified as a string.</p>

afterwhere - Category to follow

string

Category to follow, specified as a string.

Examples

Add Categories at End

Create a nonordinal categorical array.

```
A = categorical({'republican' 'democrat' 'republican';...  
              'democrat' 'republican' 'democrat'})
```

A =

```
      republican      democrat      republican  
      democrat      republican      democrat
```

Display the categories of A.

```
categories(A)
```

ans =

```
      'democrat'  
      'republican'
```

A is a 2-by-3 categorical array with two categories.

Add the categories, `independent` and `undeclared`, to the end of the category list

```
B = addcats(A,{'independent' 'undeclared'})
```

B =

```
      republican      democrat      republican  
      democrat      republican      democrat
```

B contains the same values as A.

Display the categories of B.

```
categories(B)

ans =

    'democrat'
    'republican'
    'independent'
    'undeclared'
```

B is a 2-by-3 categorical array with four categories.

Add Categories and Specify Category to Precede

Create an ordinal categorical array.

```
A = categorical({'medium' 'large'; 'small' 'xlarge'; 'large' 'medium'},...
    {'small' 'medium' 'large' 'xlarge'}, 'Ordinal', true)
```

```
A =

    medium    large
    small     xlarge
    large     medium
```

Display the categories of A.

```
categories(A)

ans =

    'small'
    'medium'
    'large'
    'xlarge'
```

Since A is ordinal, the categories have the mathematical ordering `small < medium < large < xlarge`.

addcats

Add the category `xsmall` before `small`.

```
B = addcats(A, 'xsmall', 'Before', 'small')
```

```
B =
```

```
      medium      large  
      small      xlarge  
      large      medium
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
'xsmall'  
'small'  
'medium'  
'large'  
'xlarge'
```

The categories have the mathematical ordering `xsmall < small < medium < large < xlarge`.

| reordercats
```

Purpose

Add folders to search path

Syntax

```
addpath(folderName1,...,folderNameN)
addpath(folderName1,...,folderNameN,position)

addpath( ____, '-frozen' )

oldpath = addpath( ____ )
```

Description

`addpath(folderName1,...,folderNameN)` adds the specified folders to the top of the search path. Use `addpath` statements in a `startup.m` file to modify the search path programmatically at startup.

`addpath(folderName1,...,folderNameN,position)` adds the specified folders to the top or bottom of the search path, as specified by `position`.

`addpath(____, '-frozen')` additionally disables folder change detection on Windows for folders being added, which conserves Windows change notification resources (Windows only). Type `help changenotification` in the Command Window for more information.

Add `'-frozen'` to the input arguments in any of the previous syntaxes. You can specify `'-frozen'` and `position` in either order.

`oldpath = addpath(____)` additionally returns the path prior to adding the specified folders.

Input Arguments

folderName1,...,folderNameN - Names of folders to add to search path

string

Names of folders to add to the search path, specified as strings. Use the full path name for each folder. Use `genpath` with `addpath` to add all subfolders of `folderName`.

addpath

Example: 'c:\matlab\work'

Example: '/home/user/matlab'

Example: '/home/user/matlab', '/home/user/matlab/test'

position - Position on the search path

'-begin' (default) | '-end'

Position on the search path, specified as one of the following strings.

Value of position	Description
'-begin'	Add specified folders to the top of the search path.
'-end'	Add specified folders to the bottom of the search path.

Output Arguments

oldpath - Path prior to addition of folders

string

Path prior to the addition of folders, returned as a string.

Examples

Add Folder to Top of Search Path

If you do not have a folder called `c:/matlab/myfiles`, create the folder.

```
mkdir('c:/matlab/myfiles')
```

Add `c:/matlab/myfiles` to the top of the search path.

```
addpath('c:/matlab/myfiles')
```

Add Folder to End of Search Path

Add `c:/matlab/myfiles` to the end of the search path.

```
addpath('c:/matlab/myfiles', '-end')
```

Add Folder and Its Subfolders to Search Path

Add `c:/matlab/myfiles` and its subfolders to the search path.

Call `genpath` inside of `addpath` to add all subfolders of `c:/matlab/myfiles` to the search path.

```
addpath(genpath('c:/matlab/myfiles'))
```

Add Folder to Search Path and Disable Folder Change Notification

On Windows, add the folder `c:/matlab/myfiles` to the top of the search path, disable folder change notification, and return the search path before adding the folder.

```
oldpath = addpath('c:/matlab/myfiles', '-frozen');
```

Tips

- If you use `addpath` within a local function, the path change persists after program control returns from the function. That is, the scope of the path change is global.

Concepts

- “What Is the MATLAB Search Path?”
- “Files and Folders that MATLAB Accesses”
- “Specify File Names”
- “Specifying Startup Options in MATLAB Startup File”

addpref

Purpose

Add preference

Syntax

```
addpref('group','pref',val)
addpref('group',{'pref1','pref2',... 'prefn'},{val1,val2,...valn})
```

Description

`addpref('group','pref',val)` creates the preference specified by `group` and `pref` and sets its value to `val`. It is an error to add a preference that already exists. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`addpref('group',{'pref1','pref2',... 'prefn'},{val1,val2,...valn})` creates the preferences specified by the cell array of names `'pref1'`, `'pref2'`, ..., `'prefn'`, setting each to the corresponding value.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Add a preference called `version` to the `mytoolbox` group of preferences, setting its value to the cell array `{'1.0','beta'}`.

```
addpref('mytoolbox','version',{'1.0','beta'})
```

Add a preference called `documentation` to the `mytoolbox` group of preferences, setting its value to a struct you define as having four fields:

```
mydoc.docexists = 1;
mydoc.docpath = fullfile(docroot,'techdoc',...
    'matlab_env','examples');
```

```
mydoc.demoexists = 1;
mydoc.demopath = fullfile(docroot,'techdoc',...
    'matlab_env','examples','demo_examples');
addpref('mytoolbox','documentation',mydoc)
% Retrieve the preference with GETPREF
p = getpref('mytoolbox','documentation')

p =
    docexists: 1
    docpath: [1x109 char]
    demoexists: 1
    demopath: [1x123 char]
```

See Also

[getpref](#) | [ispref](#) | [rmpref](#) | [setpref](#) | [uigetpref](#) | [uisetpref](#)

addprop (dynamicprops)

Purpose Add dynamic property

Syntax `P = addprop(Hobj, 'PropName')`

Description `P = addprop(Hobj, 'PropName')` adds a property named `PropName` to each object in array `Hobj`. The class definition is not affected by the addition of dynamic properties. Note that you can add dynamic properties only to objects derived from the `dynamicprops` class. You can set and retrieve the data in dynamic properties as you would any property.

The output argument `P` is an array the same size as `Hobj` of `meta.DynamicProperty` objects, which you can use to assign `SetMethod` and `GetMethod` functions to the property. These functions operate just like property set and get access methods.

See “Dynamic Properties — Adding Properties to an Instance” for more information and examples.

See Also `handle` | `dynamicprops`

Purpose Add custom property to COM object

Syntax `h.addproperty('propertyname')`
`addproperty(h,'propertyname')`

Description `h.addproperty('propertyname')` adds the custom property specified in the string `propertyname` to the object or interface `h`. Use the `COM set` function to assign a value to the property.

`addproperty(h,'propertyname')` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

Examples Add a custom property to an instance of the MATLAB sample control:

1 Create an instance of the control:

```
f = figure('position', [100 200 200 200]);  
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);  
h.get
```

MATLAB displays its properties:

```
Label: 'Label'  
Radius: 20
```

2 Add a custom property named `Position` and assign a value:

```
h.addproperty('Position');  
h.Position = [200 120];  
h.get
```

MATLAB displays (in part):

```
Label: 'Label'  
Radius: 20  
Position: [200 120]
```

3 Delete the custom property `Position`:

addproperty

```
h.deleteproperty('Position');  
h.get
```

MATLAB displays the original list of properties:

```
Label: 'Label'  
Radius: 20
```

How To

- “Use Object Properties”

Purpose	Add required positional argument to input parser scheme
Syntax	<pre>addRequired(p, argName) addRequired(p, argName, validationFcn)</pre>
Description	<p><code>addRequired(p, argName)</code> adds required argument, <code>argName</code>, to the input parser scheme of <code>inputParser</code> object, <code>p</code>.</p> <p><code>addRequired(p, argName, validationFcn)</code> includes a validation function for the input argument.</p>
Input Arguments	<p>p Object of class <code>inputParser</code>.</p> <p>argName String that specifies the internal name for the input argument. Arguments added with <code>addRequired</code> are positional. When you call a function with positional inputs, you must specify inputs in the order that they are added to the input parser scheme.</p> <p>validationFcn Handle to a function that checks if the input argument is valid. <code>inputParser</code> accepts two types of validation functions: functions that return <code>true</code> or <code>false</code>, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.</p>
Examples	<p>Add Required Input</p> <p>Create an <code>inputParser</code> object and add a required input named <code>myinput</code> to the input scheme.</p> <pre>p = inputParser; argName = 'myinput'; addRequired(p, argName);</pre>

inputParser.addRequired

Validate Required Input

Check whether a required input named `num` is a numeric scalar greater than zero.

```
p = inputParser;
argName = 'num';
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);
addRequired(p, argName, validationFcn);
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as `-1`:

```
parse(p, -1)
```

The value of 'num' is invalid. It must satisfy the function: `@(x)isnumeric(x)&&isscalar(x)&&(x>0)`.

Validate Required Input with `validateattributes`

Create an `inputParser` object and define a validation function using `validateattributes` to test that required input is numeric, positive, and even. Add the required input to the scheme.

```
p = inputParser;
argName = 'evenPosNum';
validationFcn = @(x) validateattributes(x, {'numeric'}, ...
    {'even', 'positive'});
addRequired(p, argName, validationFcn);
```

Parse an input string. Parse will fail.

```
parse(p, 'hello')
```

The value of 'evenPosNum' is invalid. Expected input to be one of these types:

```
double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64
```

Instead its type was char.

Parse an odd number. Parse will fail.

```
parse(p,13)
```

The value of 'evenPosNum' is invalid. Expected input to be even.

Parse an even, positive number. Parse will pass.

```
parse(p,42)
```

Concepts

- “Anonymous Functions”

addsampletocollection

Purpose Add sample to `tscollection` object

Syntax `tsc = addsampletocollection(tsc, 'time', Time, TS1Name, TS1Data, TSnName, TSnData)`

Description `tsc = addsampletocollection(tsc, 'time', Time, TS1Name, TS1Data, TSnName, TSnData)` adds data samples `TSnData` to the collection member `TSnName` in the `tscollection` object `tsc` at one or more `Time` values. Here, `TSnName` is the string that represents the name of a time series in `tsc`, and `TSnData` is an array containing data samples.

Tips If you do not specify data samples for a time-series member in `tsc`, that time-series member will contain missing data at the times given by `Time` (for numerical time-series data), NaN values, or (for logical time-series data) false values.

When a time-series member requires `Quality` values, you can specify data quality codes together with the data samples by using the following syntax:

```
tsc = addsampletocollection(tsc, 'time', time, TS1Name, ...
    ts1cellarray, TS2Name, ts2cellarray, ...)
```

Specify data in the first cell array element and `Quality` in the second cell array element.

Note If a time-series member already has `Quality` values but you only provide data samples, 0s are added to the existing `Quality` array at the times given by `Time`.

Examples The following example shows how to create a `tscollection` that consists of two `timeseries` objects, where one `timeseries` does not have quality codes and the other does. The final step of the example adds a sample to the `tscollection`.

- 1 Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...  
                'name','acceleration');  
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...  
                'name','speed');
```

- 2 Define a dictionary of quality codes and descriptions for `ts2`.

```
ts2.QualityInfo.Code = [0 1];  
ts2.QualityInfo.Description = {'bad','good'};
```

- 3 Assign a quality of code of 1, which is equivalent to 'good', to each data value in `ts2`.

```
ts2.Quality = ones(5,1);
```

- 4 Create a time-series collection `tsc`, which includes time series `ts1` and `ts2`.

```
tsc = tscollection({ts1,ts2});
```

- 5 Add a data sample to the collection `tsc` at 3.5 seconds.

```
tsc = addsampletocollection(tsc,'time',3.5,'acceleration',10,'speed',{5 1});
```

The cell array for the `timeseries` object 'speed' specifies both the data value 5 and the quality code 1.

Note If you do not specify a quality code when adding a data sample to a time series that has quality codes, then the lowest quality code is assigned to the new sample by default.

See Also

`delsamplefromcollection` | `timeseries` | `tscollection`

addtodate

Purpose Modify date number by field

Syntax `R = addtodate(D, Q, F)`

Description `R = addtodate(D, Q, F)` adds quantity `Q` to the indicated date field `F` of a scalar serial date number `D`, returning the updated date number `R`.

The quantity `Q` to be added can be a positive or negative integer. The absolute value of `Q` must be less than or equal to $1e16$. The date field `F` must be a 1-by-`N` character array equal to one of the following: 'year', 'month', 'day', 'hour', 'minute', 'second', or 'millisecond'.

If the addition to the date field causes the field to roll over, the MATLAB software adjusts the next more significant fields accordingly. Adding a negative quantity to the indicated date field rolls back the calendar on the indicated field. If the addition causes the field to roll back, MATLAB adjusts the next less significant fields accordingly.

Examples Modify the hours, days, and minutes of a given date:

```
t = datenum('07-Apr-2008 23:00:00');
datestr(t)
ans =
    07-Apr-2008 23:00:00
```

```
t= addtodate(t, 2, 'hour');
datestr(t)
ans =
    08-Apr-2008 01:00:00
```

```
t= addtodate(t, -7, 'day');
datestr(t)
ans =
    01-Apr-2008 01:00:00
```

```
t= addtodate(t, 59, 'minute');
datestr(t)
ans =
```

```
01-Apr-2008 01:59:00
```

Adding 20 days to the given date in late December causes the calendar to roll over to January of the next year:

```
R = addtodate(datenum('12/24/2007 12:45'), 20, 'day');
```

```
datestr(R)
```

```
ans =
```

```
13-Jan-2008 12:45:00
```

See Also

[date](#) | [datenum](#) | [datestr](#) | [datevec](#)

addts

Purpose Add timeseries object to tscollection object

Syntax

```
tsc = addts(tsc,ts)
tsc = addts(tsc,ts)
tsc = addts(tsc,ts,Name)
tsc = addts(tsc,Data,Name)
```

Description `tsc = addts(tsc,ts)` adds the timeseries object `ts` to tscollection object `tsc`.

`tsc = addts(tsc,ts)` adds a cell array of timeseries objects `ts` to the tscollection `tsc`.

`tsc = addts(tsc,ts,Name)` adds a cell array of timeseries objects `ts` to tscollection `tsc`. `Name` is a cell array of strings that gives the names of the timeseries objects in `ts`.

`tsc = addts(tsc,Data,Name)` creates a new timeseries object from `Data` with the name `Name` and adds it to the tscollection object `tsc`. `Data` is a numerical array and `Name` is a string.

Tips The timeseries objects you add to the collection must have the same time vector as the collection. That is, the time vectors must have the same time values and units.

Suppose that the time vector of a timeseries object is associated with calendar dates. When you add this timeseries to a collection with a time vector without calendar dates, the time vectors are compared based on the units and the values relative to the `StartDate` property. For more information about properties, see the timeseries reference page.

Examples The following example shows how to add a time series to a time-series collection:

1 Create two timeseries objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...
                'name','acceleration');
```

```
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...  
                'name','speed');
```

- 2** Create a time-series collection `tsc`, which includes `ts1`.

```
tsc = tscollection(ts1);
```

- 3** Add `ts2` to the `tsc` collection.

```
tsc = addts(tsc, ts2);
```

- 4** To view the members of `tsc`, type

```
tsc
```

at the MATLAB prompt. the response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time      1 seconds  
End time        5 seconds
```

```
Member Time Series Objects:
```

```
acceleration  
speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of the `timeseries` objects `ts1` and `ts2`, respectively.

`removets` | `tscollection`

airy

Purpose Airy Functions

Syntax
 $W = \text{airy}(Z)$
 $W = \text{airy}(k, Z)$
 $W = \text{airy}(k, Z, \text{scale})$

Description $W = \text{airy}(Z)$ returns the Airy function, $Ai(Z)$, for each element of Z .

$W = \text{airy}(k, Z)$ returns any of four different Airy functions, depending on the value of k , such as the Airy function of the second kind or the first derivative of an Airy function.

$W = \text{airy}(k, Z, \text{scale})$ scales the resulting Airy function. `airy` applies a specific scaling function to W depending on your choice of k and `scale`.

Input Arguments

Z - System variable

vector | matrix | N-D Array

System variable, specified as a real or complex vector, matrix, or N-D array.

Data Types

single | double

Complex Number Support: Yes

k - Type of Airy function

0 (default) | 1 | 2 | 3

Type of Airy function, specified as one of four values.

k	Returns
0	Airy function, $Ai(Z)$, which is the same as <code>airy(Z)</code> .
1	First derivative of Airy function, $Ai'(Z)$.

k	Returns
2	Airy function of the second kind, $Bi(Z)$
3	First derivative of Airy function of the second kind, $Bi'(Z)$

Data Types

single | double

scale - Scaling option

0 (default) | 1

Scaling option, specified as 0 or 1. Use `scale = 1` to enable the scaling of Z. The values you specify for k and scale determine the scaling function airy applies to Z.

scale	k	Scaling applied to output
0	Any	None
1	0 or 1	$e^{\frac{2}{3}Z^{(3/2)}}$
1	2 or 3	$e^{-\left \frac{2}{3}Re(Z^{(3/2)})\right }$

Data Types

single | double

Output Arguments

W - Airy function of z

vector | matrix | N-D Array

Airy function of Z, returned as an array the same size as Z.

Definitions

Airy Functions

The Airy functions form a pair of linearly independent solutions to

$$\frac{d^2W}{dZ^2} - ZW = 0.$$

The relationship between the Airy and modified Bessel functions is

$$Ai(Z) = \left[\frac{1}{\pi} \sqrt{\frac{Z}{3}} \right] K_{1/3}(\zeta)$$
$$Bi(Z) = \sqrt{\frac{Z}{3}} [I_{-1/3}(\zeta) + I_{1/3}(\zeta)],$$

where

$$\zeta = \frac{2}{3} Z^{3/2}.$$

Examples

Airy Function of Real-Valued x

Define x.

```
x = -10:0.01:1;
```

Calculate $Ai(x)$

```
ai = airy(x);
```

Calculate $Bi(x)$ using $k = 2$.

```
bi = airy(2,x);
```

Plot both results together on the same axes.

```
figure  
plot(x,ai,'-b',x,bi,'-r');
```

```
axis([-10 1 -0.6 1.4]);
xlabel('x');
legend('Ai(x)', 'Bi(x)', 'Location', 'NorthWest');
```

Airy Function of Complex-Valued x

Compute the Airy function at a slice through the complex plane at $x + i$.

Take a slice through the complex plane.

```
x = -4:0.1:4;  
z = x+1i;
```

Calculate $Ai(z)$.

```
w = airy(z);
```

Plot the real part of the result.

```
figure  
plot(x, real(w));  
axis([-4 4 -1.5 1]);  
xlabel('real(z)');
```

Scaled Airy Function

Define x.

```
x = -10:0.01:1;
```

Calculate the scaled and unscaled Airy function.

```
scaledAi = airy(0,x,1);
noscaleAi = airy(0,x,0);
```

Plot the real part of each result.

```
rscaled = real(scaledAi);  
rnoscale = real(noscaleAi);  
figure  
plot(x,rscaled,'-b',x,rnoscale,'-r');  
axis([-10 1 -0.60 0.60]);  
xlabel('x');  
legend('scaled','not scaled','Location','SouthEast');
```

**See Also**[besseli](#) | [besselj](#) | [besselk](#) | [bessely](#) | [besselh](#)

align

Purpose

Align user interface controls (uicontrols) and axes

Syntax

```
align(HandleList,'HorizontalAlignment','VerticalAlignment')
Positions = align(HandleList, 'HorizontalAlignment',
    'VerticalAlignment')
Positions = align(CurPositions, 'HorizontalAlignment',
    'VerticalAlignment')
```

Description

`align(HandleList,'HorizontalAlignment','VerticalAlignment')` aligns the `uicontrol` and `axes` objects in `HandleList`, a vector of handles, according to the options `HorizontalAlignment` and `VerticalAlignment`. The following tables show the possible values for `HorizontalAlignment` and `VerticalAlignment`.

HorizontalAlignment	Definition
None	No horizontal alignment
Left	Shifts the objects' left edges to that of the first object selected
Center	Shifts objects to center their positions to the average of the extreme <i>x</i> -values of the group
Right	Shifts the objects' right edges to that of the first object selected
Distribute	Equalizes <i>x</i> -distances between all objects within the span of the extreme <i>x</i> -values
Fixed	Spaces objects to have a specified number of points between them in the <i>y</i> -direction

VerticalAlignment	Definition
None	No vertical alignment
Top	Shifts the objects' top edges to that of the first object selected

VerticalAlignment	Definition
Middle	Shifts objects to center their positions to the average of the extreme <i>y</i> -values of the group
Bottom	Shifts the objects' bottom edges to that of the first object selected
Distribute	Equalizes <i>y</i> -distances between all objects within the span of the extreme <i>y</i> -values
Fixed	Spaces objects to have a specified number of points between them in the <i>x</i> -direction

Aligning objects does not change their absolute sizes. All alignment options align the objects within the bounding box that encloses the objects. `Distribute` and `Fixed` align objects to the bottom left of the bounding box. `Distribute` evenly distributes the objects while `Fixed` distributes the objects with a fixed distance (in points) between them. When you specify both horizontal and vertical distance together, the keywords '`HorizontalAlignment`' and '`VerticalAlignment`' are not necessary.

If you use `Fixed` for `HorizontalAlignment` or `VerticalAlignment`, you must also specify the distance, in points, where 72 points equals 1 inch. For example:

```
align(HandleList, 'Fixed', Distance, 'VerticalAlignment')
```

distributes the specified components *Distance* points horizontally and aligns them vertically as specified.

```
align(HandleList, 'HorizontalAlignment', 'Fixed', Distance)
```

aligns the specified components horizontally as specified and distributes them *Distance* points vertically.

```
align(HandleList, 'Fixed', HorizontalDistance, ...
      'Fixed', VerticalDistance)
```

distributes the specified components `HorizontalDistance` points horizontally and distributes them `VerticalDistance` points vertically.

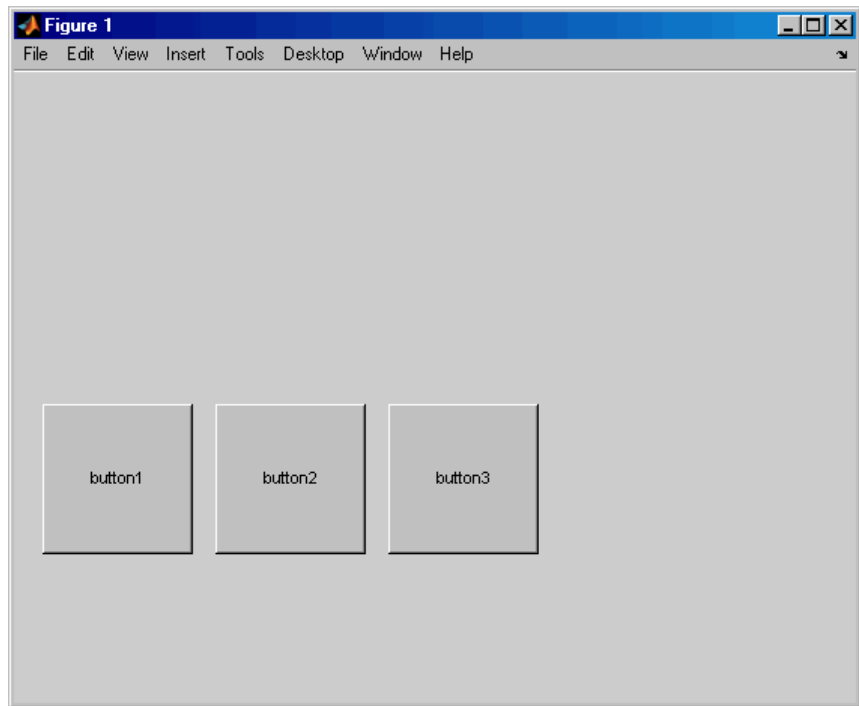

`Positions = align(HandleList, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the specified objects as a vector of `Position` vectors. The position of the objects on the figure does not change.

`Positions = align(CurPositions, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the objects whose positions are contained in `CurPositions`, where `CurPositions` is a vector of `Position` vectors. The position of the objects on the figure does not change.

Examples

Create a GUI with three buttons and use `align` to line up the buttons.

```
% Create a figure window and one button object:
f=figure;
u1 = uicontrol('Style','push', 'parent', f,'pos',...
[20 100 100 100],'string','button1');
% Create two more button objects, not aligned with
% each other or any part of the figure window:
u2 = uicontrol('Style','push', 'parent', f,'pos',...
[150 250 100 100],'string','button2');
u3 = uicontrol('Style','push', 'parent', f,'pos',...
[250 100 100 100],'string','button3');
% Align the button objects with the bottom of the first
% button object, equalizing the distance between the
% objects within the span of the extreme x-values:
align([u1 u2 u3],'distribute','bottom');
```

**Alternatives**

See “Alignment Tool — Aligning and Distributing Objects” for the GUI alternative.

Purpose Set or query axes alpha limits

Syntax

```
alpha_limits = alim
alim([amin amax])
alim_mode = alim('mode')
alim('alim_mode')
alim(axes_handle,...)
```

Description `alpha_limits = alim` returns the alpha limits (ALim property) of the current axes.

`alim([amin amax])` sets the alpha limits to the specified values. `amin` is the value of the data mapped to the first alpha value in the alphamap, and `amax` is the value of the data mapped to the last alpha value in the alphamap. Data values in between are linearly interpolated across the alphamap, while data values outside are clamped to either the first or last alphamap value, whichever is closest.

`alim_mode = alim('mode')` returns the alpha limits mode (ALimMode property) of the current axes.

`alim('alim_mode')` sets the alpha limits mode on the current axes. `alim_mode` can be

- `auto` — MATLAB automatically sets the alpha limits based on the alpha data of the objects in the axes.
- `manual` — MATLAB does not change the alpha limits.

`alim(axes_handle,...)` operates on the specified axes.

Examples

Map transparency to a surface plot of z-data and change the `alim` property to make all values below zero transparent:

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2-y.^2);
% Plot the data, using the gradient of z as
% the alphamap:
surf(x,y,z+.001,'FaceAlpha','flat',...
'AlphaDataMapping','scaled',...)
```

```
'AlphaData',gradient(z),...  
'FaceColor','blue');  
axis tight  
% Adjust the alim property to see only where  
% the gradient is between 0 and 0.15:  
alim([0 .15])
```

all

Purpose Determine if all array elements are nonzero or true

Syntax
B = all(A)
B = all(A,dim)

Description B = all(A) tests along the first array dimension of A whose size does not equal 1, and determines if the elements are all nonzero or logical 1 (true). In practice, all is a natural extension of the logical AND operator.

- If A is a vector, then all(A) returns logical 1 (true) if all the elements are nonzero and returns logical 0 (false) if one or more elements are zero.
- If A is a nonempty, nonvector matrix, then all(A) treats the columns of A as vectors and returns a row vector of logical 1s and 0s.
- If A is an empty 0-by-0 matrix, then all(A) returns logical 1 (true).
- If A is a multidimensional array, then all(A) acts along the first array dimension whose size does not equal 1 and returns an array of logical values. The size of this dimension becomes 1, while the sizes of all other dimensions remain the same.

B = all(A,dim) tests elements along dimension dim. The dim input is a positive integer scalar.

Input Arguments

A - Input Array
scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types
single | double | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64 | logical | char

Complex Number Support: Yes

dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A:

- `all(A,1)` works on successive elements in the columns of A and returns a row vector of logical values.
- `all(A,2)` works on successive elements in the rows of A and returns a column vector of logical values.

Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64

Output Arguments

B - Logical array

scalar | vector | matrix | multidimensional array

Logical array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of A acted on by `all` has size 1 in B.

Examples

Test Matrix Columns

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =  
  
    0     0     3  
    0     0     3  
    0     0     3
```

Test each column for all nonzero elements.

```
B = all(A)
```

```
B =  
  
    0     0     1
```

Reduce a Logical Vector to a Single Condition

Create a vector of decimal values and test which values are less than 0.5.

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69];  
B = (A < 0.5)
```

```
B =  
  
0  0  1  1  1  1  0
```

The output is a vector of logical values. The `all` function reduces such a vector of logical values to a single condition. In this case, `B = all(A < 0.5)` yields logical 0.

This makes `all` particularly useful in `if` statements.

```
if all(A < 0.5)  
    %do something  
else  
    %do something else  
end
```

The code is executed depending on a single condition, rather than a vector of possibly conflicting conditions.

Test Arrays of Any Dimension

Create a 3-by-7-by-5 multidimensional array and test to see if all of its elements are less than 3.

```
A = rand(3,7,5) * 5;  
B = all(A(:) < 3)
```

```
B =
```

```
0
```

You can also test the array for elements that are greater than zero.

```
B = all(A(:) > 0)
```

```
B =
```

```
1
```

The syntax `A(:)` turns the elements of `A` into a single column vector, so you can use this type of statement on an array of any size.

Test Matrix Rows

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
0     0     3  
0     0     3  
0     0     3
```

Test the rows of `A` for all nonzero elements by specifying `dim = 2`.

all

```
B = all(A,2)
```

```
B =
```

```
0  
0  
0
```

Concepts

- “Reduce Logical Arrays to Single Value”

Purpose Find all children of specified objects

Syntax `child_handles = allchild(handle_list)`

Description `child_handles = allchild(handle_list)` returns the list of all children (including ones with hidden handles) for each handle. If `handle_list` is a single element, `allchild` returns the output in a vector. If `handle_list` is a vector of handles, the output is a cell array.

Examples Compare the results these two statements return:

```
axes  
get(gca, 'Children')  
allchild(gca)
```

See Also `findall` | `findobj`

alpha

Purpose Set transparency properties for objects in current axes

Syntax

```
alpha
alpha(object_handle,value)
alpha(face_alpha)
alpha(alpha_data)
alpha(alpha_data)
alpha(alpha_data_mapping)
```

Description alpha sets one of three transparency properties, depending on what arguments you specify with the call to this function. For available arguments, see Inputs.

alpha(object_handle,value) sets the transparency property only on the object identified by object_handle.

Input Arguments

Face Alpha

alpha(face_alpha) sets the FaceAlpha property of all image, patch, and surface objects in the current axes. You can set face_alpha to

scalar	Set the FaceAlpha property to the specified value (for images, set the AlphaData property to the specified value).
'flat'	Set the FaceAlpha property to flat.
'interp'	Set the FaceAlpha property to interp.
'texture'	Set the FaceAlpha property to texture.
'opaque'	Set the FaceAlpha property to 1.
'clear'	Set the FaceAlpha property to 0.

See “Specifying Transparency” for more information.

AlphaData (Surface Objects)

alpha(alpha_data) sets the AlphaData property of all surface objects in the current axes. You can set alpha_data to

matrix the same size as CData	Set the AlphaData property to the specified values.
'x'	Set the AlphaData property to be the same as XData.
'y'	Set the AlphaData property to be the same as YData.
'z'	Set the AlphaData property to be the same as ZData.
'color'	Set the AlphaData property to be the same as CData.
'rand'	Set the AlphaData property to a matrix of random values equal in size to CData.

AlphaData (Image Objects)

`alpha(alpha_data)` sets the AlphaData property of all image objects in the current axes. You can set `alpha_data` to

matrix the same size as CData	Set the AlphaData property to the specified value.
'x'	Ignored.
'y'	Ignored.
'z'	Ignored.
'color'	Set the AlphaData property to be the same as CData.
'rand'	Set the AlphaData property to a matrix of random values equal in size to CData.

AlphaDataMapping

`alpha(alpha_data_mapping)` sets the AlphaDataMapping property of all image, patch, and surface objects in the current axes. You can set `alpha_data_mapping` to

alpha

- 'scaled' Set the AlphaDataMapping property to scaled.
- 'direct' Set the AlphaDataMapping property to direct.
- 'none' Set the AlphaDataMapping property to none.

Examples

Create a surface plot and change its transparency using alpha:

```
surf(peaks);  
alpha(0.5);
```

Tutorials

- “Making Objects Transparent”

alphamap

Purpose Specify figure alphamap (transparency)

Syntax

```
alphamap(alpha_map)
alphamap('parameter')
alphamap('parameter',length)
alphamap('parameter',delta)
alphamap(figure_handle,...)
alpha_map = alphamap
alpha_map = alphamap(figure_handle)
alpha_map = alphamap('parameter')
```

Description `alphamap(alpha_map)` sets the AlphaMap of the current figure to the specified m-by-1 array of alpha values, `alpha_map`.

`alphamap('parameter')` creates a new alphamap or modifies the current alphamap. You can specify the following parameters:

- 'default' — Set the AlphaMap property to the figure's default alphamap.
- 'rampup' — Create a linear alphamap with increasing opacity (default length equals the current alphamap length).
- 'rampdown' — Create a linear alphamap with decreasing opacity (default length equals the current alphamap length).
- 'vup' — Create an alphamap that is opaque in the center and becomes more transparent linearly towards the beginning and end (default length equals the current alphamap length).
- 'vdown' — Create an alphamap that is transparent in the center and becomes more opaque linearly towards the beginning and end (default length equals the current alphamap length).
- 'increase' — Modify the alphamap making it more opaque (default delta is .1, added to the current values).
- 'decrease' — Modify the alphamap making it more transparent (default delta is .1, subtracted from the current values).

- 'spin' — Rotate the current alphamap (default delta is 1; delta must be an integer).

`alphamap('parameter',length)` creates a new alphamap with the length specified by the integer `length` (used with parameters 'rampup', 'rampdown', 'vup', 'vdown').

`alphamap('parameter',delta)` modifies the existing alphamap using the value specified by the integer `delta` (used with parameters 'increase', 'decrease', 'spin').

`alphamap(figure_handle,...)` performs the operation on the alphamap of the figure identified by `figure_handle`.

`alpha_map = alphamap` returns the current alphamap.

`alpha_map = alphamap(figure_handle)` returns the current alphamap from the figure identified by `figure_handle`.

`alpha_map = alphamap('parameter')` returns the alphamap modified by the parameter, but does not set the AlphaMap property.

Examples

Create a surface plot and change the alphamap

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2-y.^2);
% Plot the data, using the gradient of z as
% the alphamap:
surf(x,y,z+.001,'FaceAlpha','flat',...
'AlphaDataMapping','scaled',...
'AlphaData',gradient(z),...
'FaceColor','blue');
% Change the alphamap to be opaque at the middle and
% transparent towards the ends:
alphamap('vup')
```

Purpose

Approximate minimum degree permutation

Syntax

```
P = amd(A)
P = amd(A,opts)
```

Description

`P = amd(A)` returns the approximate minimum degree permutation vector for the sparse matrix $C = A + A'$. The Cholesky factorization of $C(P,P)$ or $A(P,P)$ tends to be sparser than that of C or A . The `amd` function tends to be faster than `symamd`, and also tends to return better orderings than `symamd`. Matrix A must be square. If A is a full matrix, then `amd(A)` is equivalent to `amd(sparse(A))`.

`P = amd(A,opts)` allows additional options for the reordering. The `opts` input is a structure with the two fields shown below. You only need to set the fields of interest:

- **dense** — A nonnegative scalar value that indicates what is considered to be dense. If A is n -by- n , then rows and columns with more than $\max(16, (\text{dense} * \sqrt{n}))$ entries in $A + A'$ are considered to be "dense" and are ignored during the ordering. MATLAB software places these rows and columns last in the output permutation. The default value for this field is 10.0 if this option is not present.
- **aggressive** — A scalar value controlling aggressive absorption. If this field is set to a nonzero value, then aggressive absorption is performed. This is the default if this option is not present.

MATLAB software performs an assembly tree post-ordering, which is typically the same as an elimination tree post-ordering. It is not always identical because of the approximate degree update used, and because "dense" rows and columns do not take part in the post-order. It is well-suited for a subsequent `chol` operation, however, If you require a precise elimination tree post-ordering, you can use the following code:

```
P = amd(S);
C = spones(S)+spones(S');
[ignore, Q] = etree(C(P,P));
P = P(Q);
```

If S is already symmetric, omit the second line, $C = \text{spones}(S) + \text{spones}(S')$.

Examples

This example constructs a sparse matrix and computes a two Cholesky factors: one of the original matrix and one of the original matrix preordered by `amd`. Note how much sparser the Cholesky factor of the preordered matrix is compared to the factor of the matrix in its natural ordering:

```
A = gallery('wathen',50,50);
p = amd(A);
L = chol(A,'lower');
Lp = chol(A(p,p),'lower');

figure;
subplot(2,2,1); spy(A);
title('Sparsity structure of A');

subplot(2,2,2); spy(A(p,p));
title('Sparsity structure of AMD ordered A');

subplot(2,2,3); spy(L);
title('Sparsity structure of Cholesky factor of A');

subplot(2,2,4); spy(Lp);
title('Sparsity structure of Cholesky factor of AMD ordered A');

set(gcf,'Position',[100 100 800 700]);
```

`colamd` | `colperm` | `symamd` | `symrcm`

Purpose

Ancestor of graphics object

Syntax

```
p = ancestor(h,type)
p = ancestor(h,type,'toplevel')
```

Description

`p = ancestor(h,type)` returns the handle of the closest ancestor of `h`, if the ancestor is one of the types of graphics objects specified by `type`. `type` can be:

- a string that is the name of a single type of object. For example, 'figure'
- a cell array containing the names of multiple objects. For example, {'hgtransform','hgroup','axes'}

If MATLAB cannot find an ancestor of `h` that is one of the specified types, then `ancestor` returns `p` as empty. When `ancestor` searches the hierarchy, it includes the object itself in the search. Therefore, if the object with handle `h` is of one of the types listed in `type`, `ancestor` will return object `h`.

`ancestor` returns `p` as empty but does not issue an error if `h` is not the handle of a Handle Graphics object.

`p = ancestor(h,type,'toplevel')` returns the highest-level ancestor of `h`, if this type appears in the `type` argument.

Examples

Find the ancestors of a line object:

```
% Create some line objects and parent them
% to an hgroup object.
hgg = hgroup;
hgl = line(randn(5),randn(5),'Parent',hgg);
% Now get the ancestor of the lines:
p = ancestor(hgg,{'figure','axes','hgroup'});
get(p,'Type')
% Now get the top-level ancestor:
ptop=ancestor(hgg,{'figure','axes','hgroup'],'toplevel');
get(ptop,'type')
```

ancestor

`findobj`

Purpose Find logical AND

Syntax A & B & ...
and(A, B)

Description A & B & ... performs a logical AND of all input arrays A, B, etc., and returns an array containing elements set to either logical 1 (true) or logical 0 (false). An element of the output array is set to 1 if all input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input A is a 3-by-5 matrix and input B is the number 1, then B is treated as if it were a 3-by-5 matrix of ones.

and(A, B) is called for the syntax A & B when either A or B is an object.

Note The symbols & and && perform different operations in the MATLAB software. The element-wise AND operator described here is &. The short-circuit AND operator is &&.

Examples If matrix A is

0.4235	0.5798	0	0.7942	0
0.5155	0	0.7833	0.0592	0.8744
0.3340	0	0	0	0.0150
0.4329	0.6405	0.6808	0.0503	0

and matrix B is

and, &

0	1	0	1	0
1	1	1	0	1
0	1	1	1	0
0	1	0	0	1

then

A & B

ans =

0	1	0	1	0
1	0	1	0	1
0	0	0	0	0
0	1	0	0	0

annotation

Purpose Create annotation objects

Syntax

```
annotation(annotation_type)
annotation('line',x,y)
annotation('arrow',x,y)
annotation('doublearrow',x,y)
annotation('textarrow',x,y)
annotation('textbox',[x y w h])
annotation('ellipse',[x y w h])
annotation('rectangle',[x y w h])
annotation(figure_handle,...)
annotation(...,'PropertyName',PropertyValue,...)
anno_obj_handle = annotation(...)
```

Description `annotation(annotation_type)` creates the specified annotation type using default values for all properties. *annotation_type* can be one of the following strings:

- 'line'
- 'arrow'
- 'doublearrow' (two-headed arrow),
- 'textarrow' (arrow with attached text box),
- 'textbox'
- 'ellipse'
- 'rectangle'

`annotation('line',x,y)` creates a line annotation object that extends from the point defined by $x(1),y(1)$ to the point defined by $x(2),y(2)$, specified in normalized figure units.

`annotation('arrow',x,y)` creates an arrow annotation object that extends from the point defined by $x(1),y(1)$ to the point defined by $x(2),y(2)$, specified in normalized figure units.

`annotation('doublearrow',x,y)` creates a two-headed annotation object that extends from the point defined by $x(1),y(1)$ to the point defined by $x(2),y(2)$, specified in normalized figure units.

`annotation('textarrow',x,y)` creates a `textarrow` annotation object that extends from the point defined by $x(1),y(1)$ to the point defined by $x(2),y(2)$, specified in normalized figure units. The tail end of the arrow is attached to an editable text box.

`annotation('textbox',[x y w h])` creates an editable text box annotation with its lower left corner at the point x,y , a width w , and a height h , specified in normalized figure units. Specify x, y, w , and h in a single vector.

To type in the text box, enable plot edit mode (`plotedit`) and double-click within the box.

`annotation('ellipse',[x y w h])` creates an ellipse annotation with the lower left corner of the bounding rectangle at the point x,y , a width w , and a height h , specified in normalized figure units. Specify x, y, w , and h in a single vector.

`annotation('rectangle',[x y w h])` creates a rectangle annotation with the lower left corner of the rectangle at the point x,y , a width w , and a height h , specified in normalized figure units. Specify x, y, w , and h in a single vector.

`annotation(figure_handle,...)` creates the annotation in the specified figure.

`annotation(...,'PropertyName',PropertyValue,...)` creates the annotation and sets the specified properties to the specified values.

`anno_obj_handle = annotation(...)` returns the handle to the “Annotation Objects”.

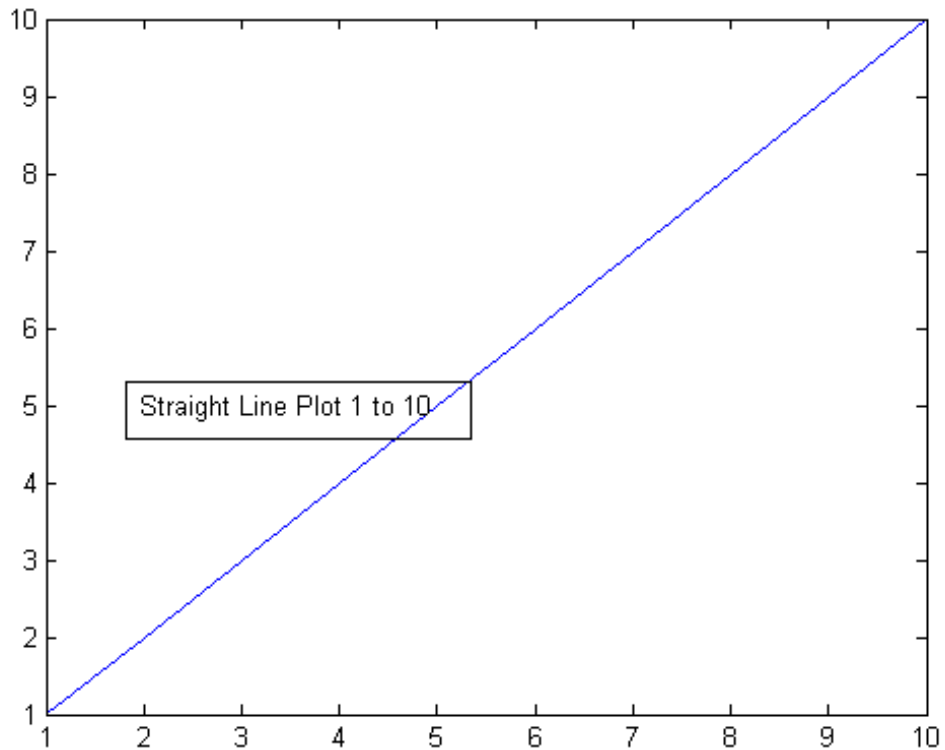

Examples

Add Text Box to Graph

Annotate the graph with a text box. Specify the text box location in normalized figure coordinates.

annotation

```
figure; % new figure window
plot(1:10);
annotation('textbox', [0.2,0.4,0.1,0.1],...
           'String', 'Straight Line Plot 1 to 10');
```

Add Text Box with Multiple Lines to Graph

Insert multiple lines in a text box by creating a cell array of strings. Each element is used as a separate line.

```
figure
plot(1:10);
str = {'Straight Line', 'Plot of 1 to 10'};
annotation('textbox', [0.2,0.4,0.1,0.1],...
           'String', str);
```

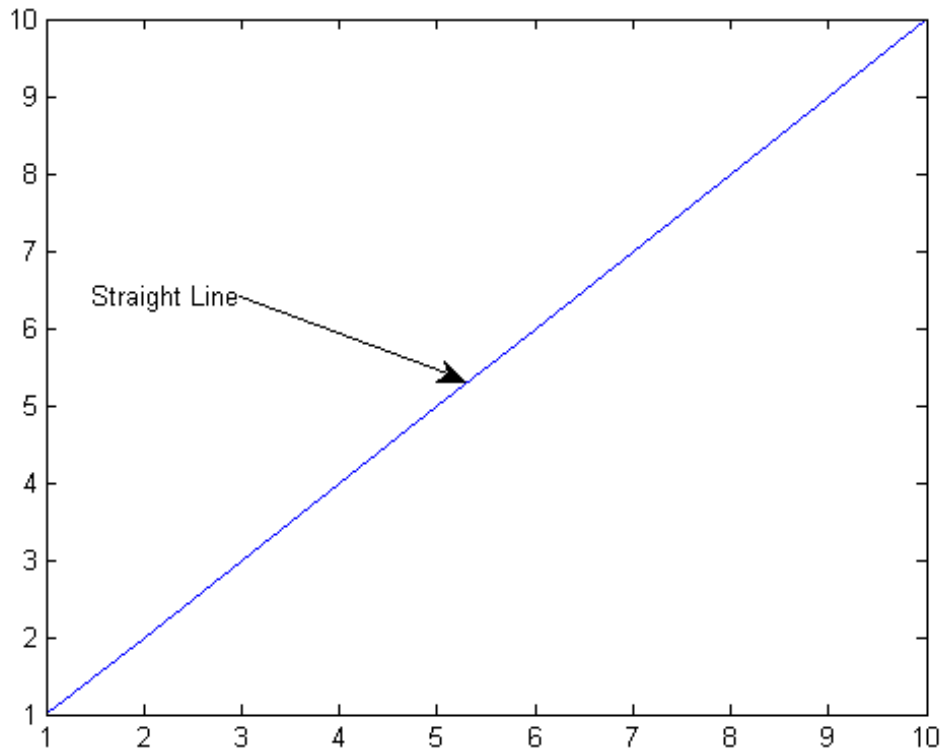

Add Text Arrow to Graph

Add a text arrow to the graph. Define the text arrow to start from (0.3,0.6) and extend to (0.5,0.5) in normalized figure coordinates.

annotation

```
figure
plot(1:10);
annotation('textarrow', [0.3,0.5], [0.6,0.5],...
          'String' , 'Straight Line');
```

Adding Annotations Interactively

It is often convenient to place annotations interactively. For details, see “Customize Graph Using Plot Tools”.

How To

- [“How to Annotate Graphs”](#)
- [“Annotation Objects”](#)

Annotation Arrow Properties

Purpose Define annotation arrow properties

Modifying Properties You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

Annotation Arrow Property Descriptions

Color
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object’s color. The default value is `[0 0 0]` (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

HeadLength
size in points

Length of the arrowhead. Specify this property in points. 1 point = $\frac{1}{72}$ inch. The default value is 10. See also `HeadWidth`.

HeadStyle
string

Style of arrowhead. Specify this property as one of the strings from the following table.

Annotation Arrow Properties

Arrow Head Style Table

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	
cback1		deltoid	
cback2			
cback3			

HeadWidth
size in points

Width of arrowhead. Specify in points. 1 point = $\frac{1}{72}$ inch. The default value is 10. See also HeadLength.

Annotation Arrow Properties

LineStyle

{-} | -- | : | -. | none

Style of arrow stem.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of arrow stem. Specify in points. 1 point = $\frac{1}{72}$ inch. The default is 0.5 points.

Position

four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point x, y in units normalized to the figure (when Units property is normalized). width and height specify the object's dx and dy , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

Units

{normalized} | inches | centimeters | characters |
points | pixels

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $1/72$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one characters unit is the width of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.

X

vector [X_{begin} X_{end}]

x-coordinates of beginning and ending points for line. A vector of x-axis (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is [0.3 0.4].

Y

vector [Y_{begin} Y_{end}]

y-coordinates of beginning and ending points for line. A vector of y-axis (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is [0.3 0.4].

Annotation Doublearrow Properties

Purpose Define annotation doublearrow properties

Modifying Properties You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

Annotation Doublearrow Property Descriptions This section provides a description of properties. Curly braces { } enclose default values.

Color
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object’s color. The default value is [0 0 0] (black).

See the ColorSpec reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

Head1Length
size in points

Length of first arrowhead. Specify in points. 1 point = $1/72$ inch. The default value is 10.

The first arrowhead is located at the end defined by the point `x(1)`, `y(1)`.

See also the `Head1Style`, `Head1Width`, `X` and `Y` properties.

Head2Length
size in points

Annotation Doublearrow Properties

Length of second arrowhead. Specify in points. 1 point = $\frac{1}{72}$ inch. The default value is 10.

The first arrowhead is located at the end defined by the point $x(\text{end})$, $y(\text{end})$.

See also the `Head1Style`, `Head1Width`, `X` and `Y` properties.

`Head1Style`
string

Style of first arrowhead. Specify this property as one of the strings from the following table.

Arrow Head Style Table

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	

Annotation Doublearrow Properties

Head Style String	Head	Head Style String	Head
cback1		deltoid	
cback2			
cback3			

See also Head1Width, Head1Length, and LineWidth.

Head2Style
string

Style of second arrowhead. Specify this property as one of the strings shown in the table for the Head1Style property.

See also Head2Width, Head2Length, LineWidth.

Head1Width
size in points

Width of first arrowhead. Specify in points. 1 point = $\frac{1}{72}$ inch.
See also Head1Length.

Head2Width
size in points

Width of second arrowhead. Specify in points. 1 point = $\frac{1}{72}$ inch.
See also Head2Length.

LineStyle
{-} | -- | : | -. | none

Style of arrow stem.

Annotation Doublearrow Properties

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

See also `Head1Style`, `Head1Length`, and `LineWidth`.

`LineWidth`

size in points

Width of arrow stem. Specify in points. 1 point = $1/72$ inch. The default is 0.5 points.

`Position`

four-element vector [`x`, `y`, `width`, `height`]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point x , y in units normalized to the figure (when `Units` property is normalized). `width` and `height` specify the object's dx and dy , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

`Units`

{normalized} | inches | centimeters | characters |
points | pixels

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

Annotation Doublearrow Properties

- **normalized** — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- **pixels, inches, centimeters, and points** — Absolute units. 1 point = $1/72$ inch.
- **characters** — Based on the size of characters in the default system font. The width of one characters unit is the width of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.

X

vector [X_{begin} X_{end}]

x-coordinates of beginning and ending points for line. A vector of *x-axis* (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is [0.3 0.4].

Y

vector [Y_{begin} Y_{end}]

y-coordinates of beginning and ending points for line. A vector of *y-axis* (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is [0.3 0.4].

annotation

How To

- “Annotation Objects”
- “Adding Arrows and Lines to Graphs”

Purpose

Define annotation ellipse properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

Annotation Ellipse Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`EdgeColor`
ColorSpec | none

Edge color of object. A three-element RGB vector or one of the MATLAB predefined names, specifying the edge color. The default value is [0 0 0] (black).

See the `ColorSpec` reference page for more information on specifying color.

`FaceColor`
{flat} | none | ColorSpec

Color of filled areas.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- `none` — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.
- `flat` — The object uses the figure `colormap` to determine the color of the filled areas.

`LineStyle`
{-} | -- | : | -. | none

Annotation Ellipse Properties

Line style of ellipse.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
'.'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $\frac{1}{72}$ inch. The default is 0.5 points.

Position

four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point x, y in units normalized to the figure (when Units property is normalized). width and height specify the object's dx and dy , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

Units

{normalized} | inches | centimeters | characters |
points | pixels

Position units. MATLAB uses this property to determine the units used by the Position property. All positions are measured from the lower left corner of the figure window.

- **normalized** — Interpret **Position** as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- **pixels, inches, centimeters, and points** — Absolute units. 1 point = $\frac{1}{72}$ inch.
- **characters** — Based on the size of characters in the default system font. The width of one **characters** unit is the width of the letter x, and the height of one **characters** unit is the distance between the baselines of two lines of text.

Annotation Line Properties

Purpose Define annotation line properties

Modifying Properties You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

Annotation Line Property Descriptions This section provides a description of properties. Curly braces { } enclose default values.

Color
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object’s color. The default value is [0 0 0] (black).

See the ColorSpec reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

LineStyle
{-} | -- | : | -. | none

Line style of annotation line object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line

Annotation Line Properties

Specifier	Line Style
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $1/72$ inch. The default is 0.5 points.

Position

four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point x, y in units normalized to the figure (when `Units` property is `normalized`). `width` and `height` specify the object's dx and dy , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

Units

{normalized} | inches | centimeters | characters |
points | pixels

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $1/72$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one characters unit is the width

Annotation Line Properties

of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.

X

vector $[X_{\text{begin}} X_{\text{end}}]$

x-coordinates of beginning and ending points for line. A vector of *x-axis* (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is $[0.3 0.4]$.

Y

vector $[Y_{\text{begin}} Y_{\text{end}}]$

y-coordinates of beginning and ending points for line. A vector of *y-axis* (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is $[0.3 0.4]$.

annotation

How To

- “Annotation Objects”
- “Adding Arrows and Lines to Graphs”

Purpose

Define annotation rectangle properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

Annotation Rectangle Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

EdgeColor
ColorSpec | none

Edge color of object. A three-element RGB vector or one of the MATLAB predefined names, specifying the edge color. The default value is [0 0 0] (black).

See the ColorSpec reference page for more information on specifying color.

FaceAlpha
Scalar alpha value in range [0 1]

Transparency of object background. Defines the degree to which the object’s background color is transparent. A value of 1 (the default) makes the background opaque, a value of 0 makes the background completely transparent (that is, invisible). The default value is 1.

FaceColor
{flat} | none | ColorSpec

Color of filled areas.

Annotation Rectangle Properties

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- **none** — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.
- **flat** — The object uses the figure colormap to determine the color of the filled areas.

LineStyle

{-} | -- | : | -. | none

Line style of annotation rectangle object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $1/72$ inch. The default is 0.5 points.

Position

four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point x, y in units normalized to the figure (when `Units` property is normalized). $width$ and $height$ specify the object's dx and dy ,

Annotation Rectangle Properties

respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

Units

{normalized} | inches | centimeters | characters | points | pixels

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $\frac{1}{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter x, and the height of one `characters` unit is the distance between the baselines of two lines of text.

`annotation`

Annotation Textarrow Properties

Purpose

Define annotation textarrow properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

Annotation Textarrow Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

Color

ColorSpec

Color of the arrow, text and text border. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the arrow, the color of the text (`TextColor` property), and the rectangle enclosing the text (`TextEdgeColor` property). The default value is `[0 0 0]` (black).

Setting the `Color` property also sets the `TextColor` and `TextEdgeColor` properties to the same color. However, if the value of the `TextEdgeColor` is `none`, it remains `none` and the text box is not displayed. You can set `TextColor` or `TextEdgeColor` independently without affecting other properties.

For example, if you want to create a textarrow with a red arrow and black text in a black box, you must:

- 1 Set the `Color` property to red — `set(h, 'Color', 'r')`
- 2 Set the `TextColor` to black — `set(h, 'TextColor', 'k')`
- 3 Set the `TextEdgeColor` to black. —
`set(h, 'TextEdgeColor', 'k')`

Annotation Textarrow Properties

If you do not want display the text box, set the `TextEdgeColor` to `none`.

See the `ColorSpec` reference page for more information on specifying color.

FontAngle

`{normal} | italic | oblique`

Character slant. MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

FontName

string

Font family. A string specifying the name of the font to use for the text. To display and print properly, this font must be supported on your system. The default font is Helvetica.

FontSize

size in points

Approximate size of text characters. Specify in points. 1 point = $\frac{1}{72}$ inch. The default size is 10.

FontUnits

`{points} | normalized | inches | centimeters | pixels`

Font size units. MATLAB uses this property to determine the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units. 1 point = $\frac{1}{72}$ inch.

FontWeight

`{normal} | bold | light | demi`

Annotation Textarrow Properties

Weight of text characters. MATLAB uses this property to select a font from those available on your system. Generally, setting this property to bold or demi causes MATLAB to use a bold font.

HeadLength
size in points

Length of the arrowhead. Specify this property in points. 1 point = $\frac{1}{72}$ inch. The default value is 10. See also HeadWidth.

HeadStyle
string

Style of arrowhead. Specify this property as one of the strings from the following table.

Arrow Head Style Table

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	

Annotation Textarrow Properties

Head Style String	Head	Head Style String	Head
cback1		deltoid	
cback2			
cback3			

HeadWidth

size in points

Width of arrowhead. Specify in points. 1 point = $1/72$ inch. The default value is 10. See also HeadLength.

HorizontalAlignment

left | center | {right}

Horizontal alignment of text. Specifies the horizontal justification of the text string. This property determines where MATLAB places the string horizontally with regard to the points specified by the Position property.

Interpreter

latex | {tex} | none

Interpret TeX instructions. This property controls whether MATLAB interprets certain characters in the String property as TeX instructions (default) or displays all characters literally. The options are:

- latex — Supports a basic subset of the LaTeX markup language.
- tex — Supports a subset of plain TeX markup language. See the String property for a list of supported TeX instructions.

Annotation Textarrow Properties

- none — Displays literal characters.

LineStyle

{-} | -- | : | -. | none

Line style of arrow stem.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of arrow stem. Specify in points 1 point = $1/72$ inch. The default is 0.5 points.

Position

four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point x, y in units normalized to the figure (when Units property is normalized). width and height specify the object's dx and dy , respectively, in units normalized to the figure. The default value is [0.3 0.3 0.1 0.1].

String

string

Annotation Textarrow Properties

Text string. Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See Mathematical Symbols, Greek Letters, and TeX Characters for an example.

Note The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

When the text Interpreter property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. This table lists these characters and the character sequences used to define them.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	α	<code>\upsilon</code>	υ	<code>\sim</code>	\sim

<code>\langle</code>	⟨				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers.

`TextBackgroundColor`
`ColorSpec | {none}`

Color of text background rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color.

See the `ColorSpec` reference page for more information on specifying color.

`TextColor`
`ColorSpec`

Color of text. A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color. The default value is `[0 0 0]` (black).

Annotation Textarrow Properties

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`TextEdgeColor`
ColorSpec | {none}

Color of edge of text rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the rectangle that encloses the text.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`TextLineWidth`
width in points

Width of text rectangle edge. Specify in points. 1 point = $\frac{1}{72}$ inch. The default value is 0.5.

`TextMargin`
size in pixels

Space around text. A value in pixels that defines the space around the text string, but within the rectangle. Default value is 5 pixels.

`TextRotation`
rotation angle in degrees

Text orientation. Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation). Angles are absolute and not relative to previous rotations; a rotation of 0 degrees is always horizontal. Default is 0.

`Units`
{normalized} | inches | centimeters | characters |
points | pixels

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $1/72$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one characters unit is the width of the letter x, and the height of one characters unit is the distance between the baselines of two lines of text.

VerticalAlignment

`top` | `cap` | `{middle}` | `baseline` | `bottom`

Vertical alignment of text. Specifies the vertical justification of the text string. It determines where MATLAB places the string vertically with regard to the points specified by the `Position` property.

Note that `top` and `cap` both place the text at the top, while `baseline` and `bottom` both align the text on the bottom.

X

vector $[X_{\text{begin}} \ X_{\text{end}}]$

x-coordinates of beginning and ending points for line. A vector of *x*-axis (horizontal) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is `[0.3 0.4]`.

Y

vector $[Y_{\text{begin}} \ Y_{\text{end}}]$

Annotation Textarrow Properties

y-coordinates of beginning and ending points for line. A vector of *y*-axis (vertical) values specifying the beginning and ending points of the line, units normalized to the figure. The default value is [0.3 0.4].

Purpose

Define annotation textbox properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see “Annotation Objects” in the MATLAB Graphics documentation.

Annotation Textbox Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`BackgroundColor`
`ColorSpec` | {none}

Color of text background rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the rectangle background color. The default value is none.

See the `ColorSpec` reference page for more information on specifying color.

`Color`
`ColorSpec`

Text color. A three-element RGB vector or one of the predefined names, specifying the text color. The default value is black. See `ColorSpec` for more information on specifying color.

`EdgeColor`
`ColorSpec` | {none}

Color of edge of text rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the rectangle that encloses the text.

Annotation Textbox Properties

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

FaceAlpha

Scalar alpha value in range [0 1]

Transparency of object background. Defines the degree to which the object's background color is transparent. A value of 1 (the default) makes the background opaque, a value of 0 makes the background completely transparent (that is, invisible). The default value is 1.

FitBoxToText

{on} | off

Automatically adjust text box width and height to fit text. When this property is on (the default), MATLAB automatically resizes textboxes to fit the *x*-extents and *y*-extents of the text strings they contain. When it is off, text strings are wrapped to fit the width of their textboxes, which can cause them to extend below the bottom of the box.

If you resize a textbox in plot edit mode or change the width or height of its `Position` property directly, MATLAB sets the object's `FitBoxToText` property to off. You can toggle this property with `set`, with the Property Inspector, or in plot edit mode via the object's context menu.

FitHeightToText

on | off

Automatically adjust text box width and height to fit text. MATLAB automatically wraps text strings to fit the width of the text box. However, if the text string is long enough, it can extend beyond the bottom of the text box.

Annotation Textbox Properties

Note The property is obsolete. To control line wrapping behavior in textboxes, use `FitBoxToText` instead.

When you set this mode to on, MATLAB automatically adjusts the height of the text box to accommodate the string, doing so as you create or edit the string.

The fit-size-to-text behavior turns off if you resize the text box programmatically or manually in plot edit mode.

Annotation Textbox Properties

However, if you resize the text box from any other handles, the position you set is honored without regard to how the text fits the box.

FontAngle

{normal} | italic | oblique

Character slant. MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

FontName

string

Font family. A string specifying the name of the font to use for the text. To display and print properly, this font must be supported on your system. The default font is Helvetica.

FontSize

size in points

Approximate size of text characters. Specify in points. 1 point = $\frac{1}{72}$ inch. The default size is 10.

FontUnits

{points} | normalized | inches | centimeters | pixels

Font size units. MATLAB uses this property to determine the units used by the FontSize property. Normalized units interpret FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. pixels, inches, centimeters, and points are absolute units. 1 point = $\frac{1}{72}$ inch.

FontWeight

{normal} | bold | light | demi

Weight of text characters. MATLAB uses this property to select a font from those available on your system. Generally, setting this property to bold or demi causes MATLAB to use a bold font.

HorizontalAlignment

{left} | center | right

Horizontal alignment of text. Specifies the horizontal justification of the text string within the textbox. It determines where MATLAB places the string horizontally with regard to the points specified by the Position property.

Interpreter

latex | {tex} | none

Interpret TeX instructions. This property controls whether MATLAB interprets certain characters in the String property as TeX instructions (default) or displays all characters literally. The options are:

Annotation Textbox Properties

- `latex` — Supports a basic subset of the LaTeX markup language.
- `tex` — Supports a subset of plain TeX markup language. See the `String` property for a list of supported TeX instructions.
- `none` — Displays literal characters.

LineStyle

{-} | -- | : | -. | none

Line style of annotation textbox object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $1/72$ inch. The default is 0.5 points.

Margin

size in pixels

Space around text. A value in pixels that defines the space around the text string, but within the rectangle. Default value is 5 pixels.

Position

four-element vector [x, y, width, height]

Annotation Textbox Properties

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point x, y in units normalized to the figure (when `Units` property is normalized). `width` and `height` specify the object's dx and dy , respectively, in units normalized to the figure. The default value is `[0.3 0.3 0.1 0.1]`.

String
string

Text string. Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See *Mathematical Symbols*, *Greek Letters*, and *TeX Characters* for an example.

Note The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

When the text `Interpreter` property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. This table lists these characters and the character sequences used to define them.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	α	<code>\upsilon</code>	υ	<code>\sim</code>	\sim
<code>\angle</code>	\angle	<code>\phi</code>	Φ	<code>\leq</code>	\leq

<code>\rceil</code>	\rceil	<code>\rangle</code>	\rangle	<code>\mid</code>	$ $
<code>\vee</code>	\vee			<code>\copyright</code>	\copyright
<code>\langle</code>	\langle				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers.

Units

`{normalized} | inches | centimeters | characters | points | pixels`

Position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window.

Annotation Textbox Properties

- `normalized` — Interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point = $\frac{1}{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.

`VerticalAlignment`

`top` | `cap` | `{middle}` | `baseline` |
`bottom`

Vertical alignment of text. Specifies the vertical justification of the text string within the textbox. It determines where MATLAB places the string vertically with regard to the points specified by the `Position` property.

Note that `top` and `cap` both place the text at the top of the box, while `baseline` and `bottom` both align the text on the bottom.

`annotation`

Purpose	Most recent answer
Syntax	<code>ans</code>
Description	The MATLAB software creates the <code>ans</code> variable automatically when you specify no output argument.
Examples	<p>The statement</p> <pre>2+2</pre> <p>is the same as</p> <pre>ans = 2+2</pre>
See Also	<code>display</code>

any

Purpose Determine if any array elements are nonzero

Syntax
B = any(A)
B = any(A,dim)

Description B = any(A) tests along the first array dimension of A whose size does not equal 1, and determines if any element is a nonzero number or logical 1 (true). In practice, any is a natural extension of the logical OR operator.

- If A is a vector, then B = any(A) returns logical 1 (true) if any of the elements of A is a nonzero number or is logical 1, and returns logical 0 (false) if all the elements are zero.
- If A is a nonempty, nonvector matrix, then B = any(A) treats the columns of A as vectors, returning a row vector of logical 1s and 0s.
- If A is an empty 0-by-0 matrix, any(A) returns logical 0 (false).
- If A is a multidimensional array, any(A) acts along the first array dimension whose size does not equal 1 and returns an array of logical values. The size of this dimension becomes 1, while the sizes of all other dimensions remain the same.

B = any(A,dim) tests elements along dimension dim. The dim input is a positive integer scalar.

Input Arguments

A - Input array
scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. The any function ignores elements of A that are NaN (Not a Number).

Data Types
single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

Complex Number Support: Yes

dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A:

- `any(A,1)` works on successive elements in the columns of A and returns a row vector of logical values.
- `any(A,2)` works on successive elements in the rows of A and returns a column vector of logical values.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64

Output Arguments**B - Logical array**

scalar | vector | matrix | multidimensional array

Logical array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of A acted on by `any` has size 1 in B.

Examples**Test Matrix Columns**

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
    0    0    3
    0    0    3
    0    0    3
```

Test each column for nonzero elements.

```
B = any(A)
```

```
B =
```

```
    0    0    1
```

Reduce a Logical Vector to a Single Condition

Create a vector of decimal values and test which values are less than 0.5.

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69];
```

```
B = (A < 0.5)
```

```
B =
```

```
0  0  1  1  1  1  0
```

The output is a vector of logical values. The `any` function reduces such a vector of logical values to a single condition. In this case, `B = any(A < 0.5)` yields logical 1.

This makes `any` particularly useful in `if` statements.

```
if any(A < 0.5)
    %do something
else
    %do something else
end
```

The code is executed depending on a single condition, rather than a vector of possibly conflicting conditions.

Test Arrays of Any Dimension

Create a 3-by-7-by-5 multidimensional array and test to see if any of its elements are greater than 3.

```
A = rand(3,7,5) * 5;  
B = any(A(:) > 3)
```

```
B =
```

```
1
```

You can also test the array for elements that are less than zero.

```
B = any(A(:) < 0)
```

```
B =
```

```
0
```

The syntax `A(:)` turns the elements of `A` into a single column vector, so you can use this type of statement on an array of any size.

Test Matrix Rows

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
0     0     3  
0     0     3  
0     0     3
```

Test the rows of `A` for nonzero elements by specifying `dim = 2`.

any

```
B = any(A,2)
```

```
B =
```

```
    1  
    1  
    1
```

Concepts

- “Reduce Logical Arrays to Single Value”

Purpose Filled area 2-D plot

Syntax

```
area(Y)
area(X,Y)
area(...,basevalue)
area(...,'PropertyName',PropertyValue,...)
area(axes_handle,...)
h = area(...)
```

Description

An area graph displays elements in *Y* as one or more curves and fills the area beneath each curve. When *Y* is a matrix, the curves are stacked showing the relative contribution of each row element to the total height of the curve at each *x* interval.

`area(Y)` plots the vector *Y* or plots each column in matrix *Y* as a separate curve and stacks the curves. The *x*-axis automatically scales to `1:size(Y,1)`.

`area(X,Y)` For vectors *X* and *Y*, `area(X,Y)` is the same as `plot(X,Y)` except that the area between 0 and *Y* is filled. When *Y* is a matrix, `area(X,Y)` plots the columns of *Y* as filled areas. For each *X*, the net result is the sum of corresponding values from the rows of *Y*.

If *X* is a vector, `length(X)` must equal `length(Y)`. If *X* is a matrix, `size(X)` must equal `size(Y)`.

`area(...,basevalue)` specifies the base value for the area fill. The default basevalue is 0. See the `BaseValue` property for more information.

`area(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the patch graphics object created by `area`.

`area(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = area(...)` returns handles of `areaseries` graphics objects.

Creating an area graph of an m -by- n matrix creates n `areaseries` objects (that is, one per column), whereas a 1-by- n vector creates one `areaseries` object.

Some `areaseries` object properties that you set on an individual `areaseries` object set the values for all `areaseries` objects in the graph. See the property descriptions for information on specific properties.

Examples

Create Area Graph

Plot the data in matrix `Y` as an area graph.

```
Y = [1, 5, 3;  
     3, 2, 7;  
     1, 5, 3;  
     2, 6, 1];  
figure  
area(Y)
```

Adjust Base Value of Area Graph

By default, `area` uses the y -axis as the base value. Change the base value by setting the `basevalue` input argument to `-4`.

```
Y = [1, 5, 3;  
     3, 2, 7;  
     1, 5, 3;  
     2, 6, 1];  
figure
```

area

```
basevalue = -4;  
area(Y,basevalue)
```

Specify Color and Line Styles for Area Plot

Create an area plot of the data in matrix Y . Set the line style and line width for the three areaseries objects created, one for each column in Y . Store the areaseries object handles in vector h .

```
Y = [1, 5, 3;
```

```
3, 2, 7;  
1, 5, 3;  
2, 6, 1];  
  
figure  
h = area(Y,'LineStyle',':',...  
        'LineWidth',2);
```

Use the areaseries object handles to specify a different face color for each object.

area

```
set(h(1), 'FaceColor', [0,0.25,0.25]);  
set(h(2), 'FaceColor', [0,0.5,0.5]);  
set(h(3), 'FaceColor', [0,0.75,0.75]);
```

How To

- “Compare Data Sets Using Overlaid Area Graphs”

Purpose

Define areaseries properties

Modifying Properties

You can set and query graphics object properties using the set and get commands or with the property editor (propertyeditor).

Note that you cannot define default properties for areaseries objects.

See “Plot Objects” for more information on areaseries objects.

Areaseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

Annotation

hg.Annotation object (read-only)

Control the display of areaseries objects in legends. Specifies whether this areaseries object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the areaseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the areaseries object in a legend as one entry, but not its children objects
off	Do not include the areaseries or its children in a legend (default)
children	Include only the children of the areaseries as separate entries in the legend

Areaseries Properties

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

Using the IconDisplayStyle Property

See “Control Legend Content” for more information and examples.

BaseValue

double: *y*-axis value

Value where filled area base is drawn. Specify the value along the *y*-axis at which the MATLAB software draws the baseline of the bottommost filled area. The default is 0.

BeingDeleted

on | {off} (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

BusyAction

cancel | {queue}

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

Areaseries Properties

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

Children

array of graphics object handles

Children of this object. The handle of a patch object that is the child of this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

Clipping

{on} | off

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

See the `BeingDeleted` property for related information.

DisplayName

string

Areaseries Properties

String used by legend. The `legend` function uses the `DisplayName` property to label the areaseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

EdgeColor

`{[0 0 0]} | none | ColorSpec`

Color of line separating filled areas. You can set the color of the edges of filled areas to a three-element RGB vector or one of the MATLAB predefined names, including the string `none`. The default value is `[0 0 0]` (black). See the `ColorSpec` reference page for more information on specifying color.

EraseMode

`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated

sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

Areaseries Properties

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

FaceColor

{flat} | none | ColorSpec

Color of filled areas.

- **ColorSpec** — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- **none** — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.
- **flat** — The object uses the figure colormap to determine the color of the filled areas.

HandleVisibility

{on} | callback | off

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- **on** — Handles are always visible.
- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

```
HitTest  
    {on} | off
```

Areaseries Properties

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`
`on` | `{off}`

Select areaseries object on filled area or extent of graph. Select plot objects by:

- Clicking an area (default).
- Clicking anywhere in the extent of the area plot.

When `HitTestArea` is `off`, you must click an area to select the `areaseries` object. When `HitTestArea` is `on`, you can select the `areaseries` object by clicking anywhere within the extent of the area graph (that is, anywhere within a rectangle that encloses all the area plots).

`Interruptible`
`off` | `{on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
 - If there is a *drawnow*, *figure*, *getframe*, *waitfor*, or *pause* command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
 - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`

{-} | -- | : | -. | none

Line style of edges of filled areas.

Areaseries Properties

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
'.'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $1/72$ inch. The default is 0.5 points.

Parent

handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

Selected

on | {off}

Object selection state. When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

SelectionHighlight

{on} | off

Object highlighted when selected.

- **on** — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- **off** — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

Tag

string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

Type

string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For `areaseries` objects, `Type` is `'hgroup'`.

The following statement finds all the `hgroup` objects in the current axes.

```
t = findobj(gca, 'Type', 'hgroup');
```

Areaseries Properties

UIContextMenu

handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

UserData

array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

Visible

{on} | off

Visibility of object and its children.

- on — Object and all children of the object are visible unless the child object's Visible property is off.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

XData

vector | matrix

x-axis values for graph. The x-axis values for graphs are specified by the X input argument. If XData is a vector, length(XData) must equal length(YData) and must be monotonic. If XData is a matrix, size(XData) must equal size(YData) and each column must be monotonic.

You can use XData to define meaningful coordinates for an underlying surface whose topography is being mapped.

XDataMode

{auto} | manual

Use automatic or user-specified x-axis values. If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the x-axis.

If you set XDataMode to auto after specifying XData, MATLAB resets the x-axis ticks to `1:size(YData,1)` or to the column indices of the ZData, overwriting any previous values for XData.

XDataSource

MATLAB variable, as a string

Link XData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatabasename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's XDataSource does not change the object's XData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

YData

vector | matrix

Areaseries Properties

Area plot data. `YData` contains the data plotted as filled areas (the `Y` input argument). If `YData` is a vector, `area` creates a single filled area whose upper boundary is defined by the elements of `YData`. If `YData` is a matrix, `area` creates one filled area per column, stacking each on the previous plot. The default value is the `Y` input argument.

The input argument `Y` in the `area` function calling syntax assigns values to `YData`.

`YDataSource`

MATLAB variable, as a string

Link YData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

How To

- “Plot Objects”
- “Setting Default Property Values”

Purpose	Convert homogeneous array to table
Syntax	<pre>T = array2table(A) T = array2table(A,Name,Value)</pre>
Description	<p><code>T = array2table(A)</code> converts the m-by-n array, <code>A</code>, to an m-by-n table, <code>T</code>. Each column of <code>A</code> becomes a variable in <code>T</code>.</p> <p><code>array2table</code> uses the input array name appended with the column number for the variable names in the table. If these names are not valid MATLAB identifiers, <code>array2table</code> uses strings of the form <code>'Var1'</code>, ..., <code>'VarN'</code>, where N is the number of columns in <code>A</code>.</p> <p><code>T = array2table(A,Name,Value)</code> creates a table from an array, <code>A</code>, with additional options specified by one or more <code>Name,Value</code> pair arguments.</p> <p>For example, you can specify row names or variable names to include in the table.</p>
Input Arguments	<p>A - Input array <i>matrix</i></p> <p>Input array, specified as a matrix.</p> <p>Data Types <code>single</code> <code>double</code> <code>int8</code> <code>int16</code> <code>int32</code> <code>int64</code> <code>uint8</code> <code>uint16</code> <code>uint32</code> <code>uint64</code> <code>logical</code> <code>char</code> <code>struct</code> <code>cell</code></p> <p>Complex Number Support: Yes</p> <p>Name-Value Pair Arguments</p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes (<code>' '</code>). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p>

array2table

Example: 'RowNames', {'row1', 'row2', 'row3'} uses the row names, row1, row2, and row3 for the table, T.

'RowNames' - Row names for T

{} (default) | cell array of nonempty, distinct strings

Row names for T, specified as the comma-separated pair consisting of 'RowNames' and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows, `size(A,1)`.

'VariableNames' - Variable names for T

cell array of nonempty, distinct strings

Variable names for T, specified as the comma-separated pair consisting of 'VariableNames' and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables, `size(A,2)`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of N strings of the form {'Var1' ... 'Var N '} where N is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

Output Arguments

T - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

Examples

Convert Numeric Array to Table

Create an array of numeric data.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

```
A =
```

```
     1     4     7
```

```

     2     5     8
     3     6     9

```

Convert the array, A, to a table.

```
T = array2table(A)
```

```
T =
```

```

     A1     A2     A3
     —     —     —
     1     4     7
     2     5     8
     3     6     9

```

The table has variable names that append the column number to the input array name, A.

Convert Array to Table Including Variable Names

Create an array of numeric data.

```
A = [1 12 30.48; 2 24 60.96; 3 36 91.44]
```

```
A =
```

```

     1.0000     12.0000     30.4800
     2.0000     24.0000     60.9600
     3.0000     36.0000     91.4400

```

Convert the array, A, to a table and include variable names.

```
T = array2table(A,...
    'VariableNames',{'Feet' 'Inches' 'Centimeters'})
```

```
T =
```

```

     Feet     Inches     Centimeters

```

array2table

1	12	30.48
2	24	60.96
3	36	91.44

Tips

- If A is a cell array, use `cell2table(A)` to create a table from the contents of the cells in A. Each variable in the table is numeric or a cell array of strings. `array2table(A)` creates a table where each variable is a column of cells.

Purpose

Apply function to each element of array

Syntax

```
[B1,...,Bm] = arrayfun(func,A1,...,An)
[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value)
```

Description

[B1,...,Bm] = arrayfun(func,A1,...,An) calls the function specified by function handle `func` and passes elements from arrays A1,...,An, where `n` is the number of inputs to function `func`. Output arrays B1,...,Bm, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The `i`th iteration corresponds to the syntax [B1(i),...,Bm(i)] = func(A1{i},...,An{i}). The arrayfun function does not perform the calls to function `func` in a specific order.

[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value) calls function `func` with additional options specified by one or more Name,Value pair arguments. Possible values for Name are 'UniformOutput' or 'ErrorHandler'.

Input Arguments**func**

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

A1,...,An

Arrays that contain the `n` inputs required for function `func`. Each array must have the same dimensions. Arrays can be numeric, character, logical, cell, structure, or user-defined object arrays.

If any input `A` is a user-defined object array, and you overloaded the `subsref` or `size` methods, arrayfun requires that:

- The `size` method returns an array of type `double`.
- The object array supports linear indexing.

- The product of the sizes returned by the `size` method does not exceed the limit of the array, as defined by linear indexing into the array.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'UniformOutput'

Logical value, as follows:

- | | |
|------------------------|---|
| <code>true</code> (1) | Indicates that for all inputs, each output from function <code>func</code> is a cell array or a scalar value that is always of the same type and size. The <code>arrayfun</code> function combines the outputs in arrays <code>B1, ..., Bm</code> , where <code>m</code> is the number of function outputs. Each output array is of the same type as the individual function outputs. |
| <code>false</code> (0) | Requests that the <code>arrayfun</code> function combine the outputs into cell arrays <code>B1, ..., Bm</code> . The outputs of function <code>func</code> can be of any size or type. |

Default: `true`

'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

identifier	Error identifier.
message	Error message text.
index	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

Output Arguments

B1,...,Bm

Arrays that collect the m outputs from function `func`. Each array `B` is the same size as each of the inputs `A1, . . . , An`.

Function `func` can return output arguments of different classes. However, if `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

Examples

To run the examples in this section, create a nonscalar structure array with arrays of different sizes in field `f1`.

```
s(1).f1 = rand(3, 6);
s(2).f1 = magic(12);
s(3).f1 = ones(5, 10);
```

Count the number of elements in each `f1` field.

```
counts = arrayfun(@(x) numel(x.f1), s)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
counts =
```

```
18  144  50
```

Compute the size of each array in the f1 fields.

```
[nrows, ncols] = arrayfun(@(x) size(x.f1), s)
```

This code returns

```
nrows =  
     3     12     5  
ncols =  
     6     12    10
```

Compute the mean of each column in the f1 fields of s. Because the output is nonscalar, set UniformOutput to false.

```
averages = arrayfun(@(x) mean(x.f1), s, 'UniformOutput', false)
```

This code returns

```
averages =  
    [1x6 double]    [1x12 double]    [1x10 double]
```

Create additional nonscalar structures t and u, and test for equality between the arrays in fields f1 across structures s, t, and u.

```
t = s; t(1).f1(:)=0;  
u = s; u(2).f1(:)=0;
```

```
same = arrayfun(@(x,y,z) isequal(x.f1, y.f1, z.f1), s, t, u)
```

This code returns

```
same =  
     0     0     1
```

Tutorials

- “Anonymous Functions”

FTP.ascii

Purpose Set FTP transfer type to ASCII

Syntax `ascii(ftpobj)`

Description `ascii(ftpobj)` sets the download and upload FTP mode to ASCII, which converts new line characters. Use this method only for text files, including HTML pages and Rich Text Format (RTF) files.

Input Arguments **ftpobj**
FTP object created by `ftp`.

Examples Connect to the MathWorks FTP server, and switch from binary (default) to ASCII mode:

```
mw=ftp('ftp.mathworks.com');  
ascii(mw)
```

See Also `binary` | `ftp`

Purpose Inverse secant in radians

Syntax $Y = \text{asec}(X)$

Description $Y = \text{asec}(X)$ returns the inverse secant (arcsecant) for each element of X .

The `asec` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Secant Function**

Graph the inverse secant over the domains $-5 \leq x \leq -1$ and $1 \leq x \leq 5$.

```
x1 = -5:0.01:-1;  
x2 = 1:0.01:5;  
plot(x1,asec(x1),x2,asec(x2)), grid on
```

Definitions Inverse Secant

The inverse secant can be defined as

$$\sec^{-1}(z) = \cos^{-1}\left(\frac{1}{z}\right).$$

See Also [asecd](#) | [asech](#) | [sec](#)

Purpose	Inverse secant in degrees
Syntax	$Y = \text{asecd}(X)$
Description	$Y = \text{asecd}(X)$ returns the inverse secant (sec^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain $[-\text{Inf}, 1]$ and $[1, \text{Inf}]$, asecd returns values in the range $[0, 180]$. For values of X outside this range, asecd returns complex values.
Input Arguments	<p>X - Secant of angle scalar value vector matrix N-D array</p> <p>Secant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The asecd operation is element-wise when X is non-scalar.</p> <p>Data Types single double</p> <p>Complex Number Support: Yes</p>
Output Arguments	<p>Y - Angle in degrees scalar value vector matrix N-D array</p> <p>Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X.</p>
Examples	<p>Inverse Secant of Vector</p> <pre>x = [10 1 Inf]; y = asecd(x) y = 84.2608 0 90.0000</pre> <p>The asecd operation is element-wise when you pass a vector, matrix, or N-D array.</p>

Inverse Secant of Complex Value

```
asecd(1+i)
```

```
ans =
```

```
64.0864 +30.4033i
```

[secd](#) | [asec](#) | [sec](#)

Purpose Inverse hyperbolic secant

Syntax $Y = \operatorname{asech}(X)$

Description $Y = \operatorname{asech}(X)$ returns the inverse hyperbolic secant for each element of X .

The `asech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Hyperbolic Secant Function**

Graph the inverse hyperbolic secant over the domain $0.01 \leq x \leq 1$.

```
x = 0.01:0.001:1;  
plot(x,asech(x)), grid on
```

Definitions Inverse Hyperbolic Secant

The inverse hyperbolic secant can be defined as

$$\operatorname{sech}^{-1}(z) = \cosh^{-1}\left(\frac{1}{z}\right).$$

See Also [asec](#) | [sech](#) | [asinh](#) | [acosh](#)

Purpose Inverse sine in radians

Syntax `Y = asin(X)`

Description `Y = asin(X)` returns the inverse sine (arcsine) for each element of `X`. The `asin` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians. For real elements of `X` in the domain $[-1, 1]$, `asin(X)` is in the range

$$\left[-\frac{\pi}{2}, \frac{\pi}{2}\right].$$

For real elements of `x` outside the range $[-1, 1]$, `asin(X)` is complex.

Examples **Graph of Inverse Sine Function**

Graph the inverse sine over the domain $-1 \leq x \leq 1$.

```
x = -1:.01:1;  
plot(x,asin(x)), grid on
```

Definitions Inverse Sine

The inverse sine can be defined as

$$\sin^{-1}(z) = -i \log \left[iz + (1 - z^2)^{1/2} \right].$$

See Also `asind` | `sin` | `sind`

Purpose	Inverse sine in degrees
Syntax	$Y = \text{asind}(X)$
Description	$Y = \text{asind}(X)$ returns the inverse sine (\sin^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain $[-1,1]$, asind returns values in the range $[-90,90]$. For values of X outside this range, asind returns complex values.
Input Arguments	X - Sine of angle scalar value vector matrix N-D array Sine of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The asind operation is element-wise when X is nonscalar. Data Types single double Complex Number Support: Yes
Output Arguments	Y - Angle in degrees scalar value vector matrix N-D array Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .
Examples	Inverse Sine of Scalar Show that the inverse sine of 1 is exactly 90° . <code>asind(1)</code> <code>ans =</code> 90

Round-Trip Calculation for Complex Angles

Show that the inverse sine, followed by sine, returns the original values of X .

```
sind(asind([2 3]))
```

```
ans =
```

```
2.0000 3.0000
```

Graph of Inverse Sine Function

Plot the inverse sine function over the domain $-1 \leq x \leq 1$.

```
x = -1:.01:1;  
plot(x,asind(x))  
grid on
```

See Also [sind](#) | [sin](#) | [asin](#)

asinh

Purpose Inverse hyperbolic sine

Syntax $Y = \operatorname{asinh}(X)$

Description $Y = \operatorname{asinh}(X)$ returns the inverse hyperbolic sine for each element of X . The `asinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Hyperbolic Sine Function**

Graph the inverse hyperbolic sine over the domain $-5 \leq x \leq 5$.

```
x = -5:.01:5;  
plot(x,asinh(x)), grid on
```

Definitions Inverse Hyperbolic Sine

The inverse hyperbolic sine can be defined as

$$\sinh^{-1}(z) = \log \left[z + (z^2 + 1)^{1/2} \right].$$

See Also [asin](#) | [sinh](#) | [acosh](#)

assert

Purpose Generate error when condition is violated

Syntax

```
assert(expression)
assert(expression, 'msgString')
assert(expression, 'msgString', value1, value2, ...)
assert(expression, 'msgIdent', 'msgString',
value1, value2, ...)
```

Description `assert(expression)` evaluates *expression* and, if it is false, generates an exception. Depending on how the program has been designed to respond to the assertion failure, MATLAB either enters a catch block to handle the condition, or exits the program.

`assert(expression, 'msgString')` evaluates *expression* and, if it is false, generates an exception and displays the string contained in *msgString*. This string must be enclosed in single quotation marks. When *msgString* is the last input to `assert`, the MATLAB software displays it literally, without performing any substitutions on the characters in *msgString*.

`assert(expression, 'msgString', value1, value2, ...)` evaluates *expression* and, if it is false, generates an exception and displays the formatted string contained in *msgString*. The *msgString* string can include escape sequences such as `\t` or `\n`, as well as any of the C language conversion operators supported by the `sprintf` function (e.g., `%s` or `%d`). Additional arguments *value1*, *value2*, etc. provide values that correspond to and replace the conversion operators.

See “Formatting Strings” in the MATLAB Programming Fundamentals documentation for more detailed information on using string formatting commands.

MATLAB makes substitutions for escape sequences and conversion operators in *msgString* in the same way that it does for the `sprintf` function.

`assert(expression, 'msgIdent', 'msgString', value1, value2, ...)` evaluates *expression* and, if it is false, generates an exception and displays the formatted string *msgString*, also tagging the error

with the message identifier *msgIdent*. See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for information.

Examples

This function tests input arguments using `assert`:

```
function write2file(varargin)
min_inputs = 3;
assert(nargin >= min_inputs, ...
    'You must call function %s with at least %d inputs', ...
    mfilename, min_inputs)

infile = varargin{1};
assert(ischar(infile), ...
    'First argument must be a filename.')
assert(exist(infile)~=0, 'File %s not found.', infile)

fid = fopen(infile, 'w');
assert(fid > 0, 'Cannot open file %s for writing', infile)

fwrite(fid, varargin{2}, varargin{3});
```

MException | rethrow(MException) | throwAsCaller(MException) |
throw(MException) | addCause(MException) | last(MException) |
getReport(MException)
```

assignin

Purpose Assign value to variable in specified workspace

Syntax `assignin(ws, 'var', val)`

Description `assignin(ws, 'var', val)` assigns the value `val` to the variable `var` in the workspace `ws`. The `var` input must be the array name only; it cannot contain array indices. If `var` does not exist in the specified workspace, `assignin` creates it. `ws` can have a value of 'base' or 'caller' to denote the MATLAB base workspace or the workspace of the caller function.

The `assignin` function is particularly useful for these tasks:

- Exporting data from a function to the MATLAB workspace
- Within a function, changing the value of a variable that is defined in the workspace of the caller function (such as a variable in the function argument list)

Tips The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line. For more information, see “Base and Function Workspaces”.

Examples **Example 1**

This example creates a dialog box for the image display function, prompting a user for an image name and a colormap name. The `assignin` function is used to export the user-entered values to the MATLAB workspace variables `imfile` and `cmap`.

```
prompt = {'Enter image name:', 'Enter colormap name:'};
title = 'Image display - assignin example';
lines = 1;
def = {'my_image', 'hsv'};
answer = inputdlg(prompt, title, lines, def);
```

```
assignin('base', 'imfile', answer{1});
assignin('base', 'cmap', answer{2});
```

Example 2

`assignin` does not assign to specific elements of an array. The following statement generates an error:

```
X = 1:8;
assignin('base', 'X(3:5)', -1);
```

However, you can use the `evalin` function to do this:

```
evalin('base', 'X(3:5) = -1')
X =
     1     2    -1    -1    -1     6     7     8
```

See Also

`evalin`

atan

Purpose Inverse tangent in radians

Syntax $Y = \text{atan}(X)$

Description $Y = \text{atan}(X)$ returns the inverse tangent (arctangent) for each element of X . For real elements of X , $\text{atan}(X)$ is in the range $[-\pi/2, \pi/2]$.

The `atan` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples **Graph of Inverse Tangent Function**

Graph the inverse tangent over the domain $-20 \leq x \leq 20$.

```
x = -20:0.01:20;  
plot(x,atan(x)), grid on
```

**Definitions** **Inverse Tangent**

The inverse tangent can be defined as

$$\tan^{-1}(z) = \frac{i}{2} \log\left(\frac{i+z}{i-z}\right).$$

See Also atan2 | tan | atand | atanh

atan2

Purpose Four-quadrant inverse tangent

Syntax $P = \text{atan2}(Y,X)$

Description $P = \text{atan2}(Y,X)$ returns an array P the same size as X and Y containing the element-by-element, four-quadrant inverse tangent (arctangent) of Y and X , which must be real.

Elements of P lie in the closed interval $[-\pi, \pi]$, where π is the MATLAB floating-point representation of π . atan uses $\text{sign}(Y)$ and $\text{sign}(X)$ to determine the specific quadrant.

$\text{atan2}(Y,X)$ contrasts with $\text{atan}(Y/X)$, whose results are limited to the interval $[-\pi/2, \pi/2]$, or the right side of this diagram.

Examples Any complex number $z = x + iy$ is converted to polar coordinates with

```
r = abs(z)
theta = atan2(imag(z), real(z))
```

For example,

```
z = 4 + 3i;
```

```
r = abs(z)
theta = atan2(imag(z),real(z))
```

```
r =
    5
```

```
theta =
    0.6435
```

This is a common operation, so MATLAB software provides a function, `angle(z)`, that computes `theta = atan2(imag(z),real(z))`.

To convert back to the original complex number

```
z = r * exp(i * theta)
z =
```

```
    4.0000 + 3.0000i
```

See Also

`angle` | `atan` | `atanh` | `atan2d`

atan2d

Purpose Four-quadrant inverse tangent in degrees

Syntax $D = \text{atan2d}(Y,X)$

Description $D = \text{atan2d}(Y,X)$ returns the four-quadrant inverse tangent of points specified in the x - y plane. The result, D , is expressed in degrees.

Input Arguments

Y - y-coordinates

scalar value | vector | matrix | N-D array

y -coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

Data Types

single | double

X - x-coordinates

scalar value | vector | matrix | N-D array

x -coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

Data Types
single | double

Output Arguments

D - Angles in degrees
scalar value | vector | matrix | N-D array

Angles in degrees, returned as a scalar, vector, matrix, or N-D array. These angles correspond to the points defined by X and Y, and they lie in the closed interval $[-180,180]$.

Examples

Inverse Tangent of Four Points on the Unit Circle

```
x = [1 0 -1 0];  
y = [0 1 0 -1];  
d = atan2d(y,x)
```

```
d =
```

```
0    90   180  -90
```

Tips

- Use `atan2d(Y/X)` for the inverse tangent with results on the interval $[-90, 90]$.

See Also

`atan2` | `atan` | `atan2d` | `tan` | `tand`

atand

Purpose Inverse tangent in degrees

Syntax $Y = \text{atand}(X)$

Description $Y = \text{atand}(X)$ returns the inverse tangent (\tan^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain $[-\text{Inf}, \text{Inf}]$, atand returns values in the range $[-90, 90]$. For complex values of X , atand returns complex values.

Input Arguments **X - Tangent of angle**
scalar value | vector | matrix | N-D array

Tangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The atand operation is element-wise when X is non-scalar.

Data Types

single | double

Complex Number Support: Yes

Output Arguments **Y - Angle in degrees**
scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .

Examples **Inverse Tangent of Vector**

```
x = [-50 -20 0 20 50];
```

```
y = atand(x)
```

```
y =
```

```
   -88.8542   -87.1376         0    87.1376    88.8542
```

The atand operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Tangent of Complex Value

```
atand(10+i)
```

```
ans =
```

```
84.3450 + 0.5618i
```

See Also

```
tand | atan | tan | atan2d
```

atanh

Purpose Inverse hyperbolic tangent

Syntax $Y = \operatorname{atanh}(X)$

Description The `atanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians. $Y = \operatorname{atanh}(X)$ returns the inverse hyperbolic tangent for each element of X .

Examples **Graph of Inverse Hyperbolic Tangent Function**

Graph the inverse hyperbolic tangent over the domain $-1 < x < 1$.

```
x = -0.99:0.01:0.99;  
plot(x,atanh(x)), grid on
```

Definitions **Inverse Hyperbolic Tangent**

The inverse hyperbolic tangent can be defined as

$$\tanh^{-1}(z) = \frac{1}{2} \log\left(\frac{1+z}{1-z}\right).$$

See Also atan2 | atan | tanh | asinh | acosh | tan

audiodevinfo

Purpose Information about audio device

Syntax

```
info = audiodevinfo
nDevices = audiodevinfo(IO)
name = audiodevinfo(IO, ID)
DriverVersion = audiodevinfo(IO, ID, 'DriverVersion')
support = audiodevinfo(IO, ID, Fs, nBits, nChannels)

ID = audiodevinfo(IO, name)
ID = audiodevinfo(IO, Fs, nBits, nChannels)
```

Description info = audiodevinfo returns information about the input and output audio devices on the system.

nDevices = audiodevinfo(IO) returns the number of input devices on the system if IO is 1, and returns the number of output devices on the system if IO is 0.

name = audiodevinfo(IO, ID) returns the name of the audio device specified by the device identifier, ID.

DriverVersion = audiodevinfo(IO, ID, 'DriverVersion') returns the name of the driver for the audio device specified by ID.

support = audiodevinfo(IO, ID, Fs, nBits, nChannels) returns 1 if the input or output audio device specified by ID supports the sample rate, number of bits, and number of channels specified by the values of Fs, nBits, and nChannels, respectively. Otherwise, support is 0.

ID = audiodevinfo(IO, name) returns the device identifier of the input or output audio device identified by the device name, name. If no device is found with the specified name, then ID is -1.

`ID = audiodevinfo(IO, Fs, nBits, nChannels)` returns the device identifier of the first input or output device that supports the sample rate, number of bits, and the number of channels specified by the values of `Fs`, `nBits`, and `nChannels`, respectively. If no supporting device is found, then `ID` is `-1`.

Input Arguments

IO - Input or output device

1 | 0

Input or output device, specified as 1 to indicate input, or 0 to indicate output.

ID - Audio device identifier

integer

Audio device identifier, specified as an integer. The device can be an input or output audio device.

Fs - Sample rate

scalar

Sample rate, in hertz, specified as a positive scalar.

Example: 44100

Data Types

single | double

nBits - Number of bits per sample

scalar

Number of bits per sample, specified as a scalar.

Example: 16

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64

nChannels - Number of audio channels

1 | 2

audiodevinfo

Number of audio channels, specified as 1 (mono) or 2 (stereo).

name - Name of input or output device

string

Name of the input or output audio device, specified as a string.

Data Types

char

Output Arguments

info - Information about audio devices

structure array

Information about audio devices, returned as a structure array containing two fields, `input` and `output`. Each field is an array of structures, with each structure containing information about one of the audio input or output devices on the system. The individual device structure fields are:

- `Name` — Name of the device, returned as a string.
- `DriverVersion` — Name of the driver used to communicate with the device, returned as a string.
- `ID` — Device identifier, returned as a scalar.

Examples

View Information About Audio Devices

Call `audiodevinfo` with no inputs to view information about the input and output audio devices on a system.

```
info = audiodevinfo
```

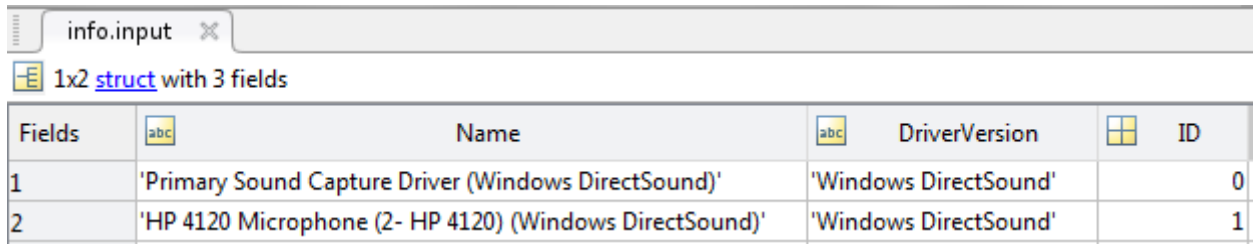

```
info =
```

```
    input: [1x2 struct]  
    output: [1x3 struct]
```

`audiodevinfo` returns a structure containing two fields, `input` and `output`.

View the contents of the input field in the Variables editor.

```
openvar info.input
```

Fields	Name	DriverVersion	ID
1	'Primary Sound Capture Driver (Windows DirectSound)'	'Windows DirectSound'	0
2	'HP 4120 Microphone (2- HP 4120) (Windows DirectSound)'	'Windows DirectSound'	1

The Variables editor displays the input audio device names, driver used, and device identifiers. The values on your system might differ from this example.

View Number of Output Devices

View the number of output audio devices on the system, using an IO value of 0 to indicate output.

```
nDevices = audiodevinfo(0)
```

```
nDevices =
```

```
3
```

This example shows three output devices, but your system might vary.

Check Support for Input Device

Check if the input audio device identified by the ID value, 0, supports a sample rate of 44100 hertz, with 16 bits per sample, and two channels.

```
support = audiodevinfo(1,0,44100,16,2)
```

```
support =
```

```
1
```

audiodevinfo

The input device supports the specified sample rate, number of bits and number of channels.

See Also

[audioplayer](#) | [audiorecorder](#)

Purpose Create object for playing audio

Syntax

```
player = audioplayer(Y,Fs)
player = audioplayer(Y,Fs,nBits)
player = audioplayer(Y,Fs,nBits,ID)
player = audioplayer(recorder)
player = audioplayer(recorder,ID)
```

Description

`player = audioplayer(Y,Fs)` creates an `audioplayer` object for signal `Y`, using sample rate `Fs`. The function returns a handle to the `audioplayer` object, `player`.

`player = audioplayer(Y,Fs,nBits)` uses `nBits` bits per sample for signal `Y`.

`player = audioplayer(Y,Fs,nBits,ID)` uses the audio device identified by `ID` for output.

`player = audioplayer(recorder)` creates an `audioplayer` object using audio recorder object `recorder`.

`player = audioplayer(recorder , ID)` creates an object from `recorder` that uses the audio device identified by `ID` for output.

Input Arguments

Y

Audio signal represented by a vector or two-dimensional array containing `single`, `double`, `int8`, `uint8`, or `int16` values.

The value range of the input sample depends on the data type. The following table lists these ranges.

Data Type	Sample Value Range
<code>int8</code>	-128 to 127
<code>uint8</code>	0 to 255
<code>int16</code>	-32768 to 32767

audioplayer

Data Type	Sample Value Range
single	-1 to 1
double	-1 to 1

F_s

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

nBits

Bits per sample. Specify only when signal Y is represented by floating-point values. Valid values depend on the audio hardware installed: 8, 16, or 24.

Default: 16

ID

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

Default: -1 (default device)

recorder

Audio recorder object created by `audiorecorder`.

Methods

Note When calling any method, include the `audioplayer` object name using function syntax, such as `stop(player)`.

<code>get</code>	Query properties of <code>audioplayer</code> object.
<code>isplaying</code>	Query whether playback is in progress: returns true or false.

<code>pause</code>	Pause playback.
<code>play</code>	Play audio from beginning to end.
<code>playblocking</code>	Play, and do not return control until playback completes.
<code>resume</code>	Restart playback from paused position.
<code>set</code>	Set properties of <code>audioplayer</code> object.
<code>stop</code>	Stop playback.

See the reference pages for `get`, `play`, `playblocking`, and `set` for additional syntax options.

Properties

<code>BitsPerSample</code>	Number of bits per sample. (Read-only)
<code>CurrentSample</code>	Current sample that the audio output device is playing. If the device is not playing, <code>CurrentSample</code> is the next sample to play with <code>play</code> or <code>resume</code> . (Read-only)
<code>DeviceID</code>	Identifier for audio device. (Read-only)
<code>NumberOfChannels</code>	Number of audio channels. (Read-only)
<code>Running</code>	Status of the audio player: 'on' or 'off'. (Read-only)
<code>SampleRate</code>	Sampling frequency in Hz.
<code>TotalSamples</code>	Total length of the audio data in samples. (Read-only)
<code>Tag</code>	String that labels the object.
<code>Type</code>	Name of the class: 'audioplayer'. (Read-only)
<code>UserData</code>	Any type of additional data to store with the object.

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audioplayer` object and an *event* structure.

audioplayer

StartFcn	Function to execute one time when playback starts.
StopFcn	Function to execute one time when playback stops.
TimerFcn	Function to execute repeatedly during playback. To specify time intervals for the repetitions, use the <code>TimerPeriod</code> property.
TimerPeriod	Time in seconds between <code>TimerFcn</code> callbacks. Default: <code>.05</code>

Examples

Load and play a sample audio file of Handel’s “Hallelujah Chorus:”

```
load handel;  
player = audioplayer(y, Fs);  
play(player);
```

See Also

[audiodevinfo](#) | [audiorecorder](#) | [sound](#)

How To

- “Characteristics of Audio Files”
- “Play Audio”

Purpose

Create object for recording audio

Syntax

```
recorder = audiorecorder  
recorder = audiorecorder(Fs,nBits,nChannels)  
recorder = audiorecorder(Fs,nBits,nChannels,ID)
```

Description

`recorder = audiorecorder` creates an 8000 Hz, 8-bit, 1-channel `audiorecorder` object.

`recorder = audiorecorder(Fs,nBits,nChannels)` sets the sample rate `Fs` (in Hz), the sample size `nBits`, and the number of channels `nChannels`.

`recorder = audiorecorder(Fs,nBits,nChannels,ID)` sets the audio input device to the device specified by `ID`.

Tips

- To use an `audiorecorder` object, your system must have a properly installed and configured sound card.
- `audiorecorder` is not intended for long, high-sample-rate recording. `audiorecorder` uses system memory for storage and does not use disk buffering. When you attempt a large recording, your MATLAB performance sometimes degrades over time.

Input Arguments

Fs

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

Default: 8000

nBits

Bits per sample. Valid values depend on the audio hardware installed: 8, 16, or 24.

Default: 8

audiorecorder

nChannels

The number of channels: 1 (mono) or 2 (stereo).

Default: 1

ID

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

Default: -1 (default device)

Methods

Note When calling any method, include the `audiorecorder` object name using function syntax, such as `stop(recorder)`.

<code>get</code>	Query properties of <code>audiorecorder</code> object.
<code>getaudiodata</code>	Create an array that stores the recorded signal values.
<code>getplayer</code>	Create an <code>audioplayer</code> object.
<code>isrecording</code>	Query whether recording is in progress: returns <code>true</code> or <code>false</code> .
<code>pause</code>	Pause recording.
<code>play</code>	Play recorded audio. This method returns an <code>audioplayer</code> object.
<code>record</code>	Start recording.
<code>recordblocking</code>	Record, and do not return control until recording completes. This method requires a second input for the length of the recording in seconds: <code>recordblocking(recorder, length)</code>
<code>resume</code>	Restart recording from paused position.
<code>set</code>	Set properties of <code>audiorecorder</code> object.
<code>stop</code>	Stop recording.

See the reference pages for `get`, `getaudiodata`, `play`, `record`, `recordblocking`, and `set` for additional syntax options.

Properties

<code>BitsPerSample</code>	Number of bits per sample. (Read-only)
<code>CurrentSample</code>	Current sample that the audio input device is recording. If the device is not recording, <code>CurrentSample</code> is the next sample to record with <code>record</code> or <code>resume</code> . (Read-only)
<code>DeviceID</code>	Identifier for audio device. (Read-only)
<code>NumberOfChannels</code>	Number of audio channels. (Read-only)
<code>Running</code>	Status of the audio recorder: 'on' or 'off'. (Read-only)
<code>SampleRate</code>	Sampling frequency in Hz. (Read-only)
<code>TotalSamples</code>	Total length of the audio data in samples. (Read-only)
<code>Tag</code>	String that labels the object.
<code>Type</code>	Name of the class: 'audiorecorder'. (Read-only)
<code>UserData</code>	Any type of additional data to store with the object.

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audiorecorder` object and an *event* structure.

<code>StartFcn</code>	Function to execute one time when recording starts.
<code>StopFcn</code>	Function to execute one time when recording stops.

audiorecorder

TimerFcn	Function to execute repeatedly during recording. To specify time intervals for the repetitions, use the TimerPeriod property.
TimerPeriod	Time in seconds between TimerFcn callbacks. Default: .05

audiorecorder ignores any specified values for these properties, which will be removed in a future release.

BufferLength	Length of buffer in seconds.
NumberOfBuffers	Number of buffers.

Examples

Create an audiorecorder object for CD-quality audio in stereo, and view its properties:

```
recObj = audiorecorder(44100, 16, 2);  
get(recObj)
```

Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.  
recObj = audiorecorder;  
disp('Start speaking.')
```

```
recordblocking(recObj, 5);  
disp('End of Recording.');
```

```
% Play back the recording.  
play(recObj);
```

```
% Store data in double-precision array.  
myRecording = getaudiodata(recObj);
```

```
% Plot the waveform.  
plot(myRecording);
```

See Also

[audiodevinfo](#) | [audioplayer](#) | [sound](#)

How To

- “Characteristics of Audio Files”
- “Record Audio”
- “Record or Play Audio within a Function”

aufinfo

Purpose Information about NeXT/SUN (.au) sound file

Note aufinfo will be removed in a future release. Use audioinfo instead.

Syntax `[m d] = aufinfo(aufile)`

Description `[m d] = aufinfo(aufile)` returns information about the contents of the AU sound file specified by the string `aufile`.

`m` is the string 'Sound (AU) file', if `filename` is an AU file. Otherwise, it contains an empty string ('').

`d` is a string that reports the number of samples in the file and the number of channels of audio data. If `filename` is not an AU file, it contains the string 'Not an AU file'.

See Also `audioread` | `audioinfo`

Purpose Read NeXT/SUN (.au) sound file

Note auread will be removed in a future release. Use audioread instead.

Syntax

```
y = auread(aufile)
[y,Fs] = auread(aufile)
[y,Fs,nbits] = auread(aufile)
[ ___ ] = auread(aufile,N)
[ ___ ] = auread(aufile,[N1 N2])
siz = auread(aufile,'size')
```

Description `y = auread(aufile)` loads a sound file specified by the string `aufile`, returning the sampled data in `y`. The `.au` extension is appended if no extension is given. Amplitude values are in the range `[-1,+1]`. `auread` supports multichannel data in the following formats:

- 8-bit mu-law
- 8-, 16-, and 32-bit linear
- Floating-point

`[y,Fs] = auread(aufile)` returns the sample rate (`Fs`) in Hertz used to encode the data in the file.

`[y,Fs,nbits] = auread(aufile)` returns the number of bits per sample (`nbits`).

`[___] = auread(aufile,N)` returns only the first `N` samples from each channel in the file.

`[___] = auread(aufile,[N1 N2])` returns only samples `N1` through `N2` from each channel in the file.

`siz = auread(aufile,'size')` returns the size of the audio data contained in the file in place of the actual audio data, returning the vector `siz = [samples channels]`.

Examples

Create a sound file from the example file `handel.mat`, and read portions of the file back into MATLAB:

```
% Create .au file in current folder.
load handel.mat

hfile = 'handel.au';
auwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits] = auread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = auread(hfile, nsamples);
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = auread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = auread(hfile, [startpos endpos]);
sound(y3, Fs);
```

See Also

[audiowrite](#) | [audioinfo](#) | [audioplayer](#) | [audiorecorder](#) | [sound](#) | [audioread](#)

Purpose Write NeXT/SUN (.au) sound file

Note auwrite will be removed in a future release.

Syntax

```
auwrite(y, aufile)
auwrite(y, Fs, aufile)
auwrite(y, Fs, N, aufile)
auwrite(y, Fs, N, method, aufile)
```

Description `auwrite(y, aufile)` writes a sound file specified by the string *aufile*. The data should be arranged with one channel per column. Amplitude values outside the range $[-1, +1]$ are clipped prior to writing. `auwrite` supports multichannel data for 8-bit mu-law and 8- and 16-bit linear formats.

`auwrite(y, Fs, aufile)` specifies the sample rate of the data in Hertz.

`auwrite(y, Fs, N, aufile)` selects the number of bits in the encoder. Allowable settings are $N = 8$ and $N = 16$.

`auwrite(y, Fs, N, method, aufile)` allows selection of the encoding method, which can be either 'mu' or 'linear'. Note that mu-law files must be 8-bit. By default, *method* = 'mu'.

See Also audioread | audiowrite

avifile

Purpose

Create new Audio/Video Interleaved (AVI) file

Note `avifile` will be removed in a future release. Use `VideoWriter` instead.

Syntax

```
aviobj = avifile(filename)  
avifile(filename, ParameterName, ParameterValue)
```

Description

`aviobj = avifile(filename)` creates an `avifile` object, giving it the name specified in `filename`, using default values for all `avifile` object properties. If `filename` does not include an extension, `avifile` appends `.avi` to the file name. AVI is a file format for storing audio and video data.

`avifile` returns a handle to an AVI file object `aviobj`. Use this object to refer to the AVI file in other functions. An AVI file object supports properties and methods that control aspects of the AVI file created.

`aviobj = avifile(filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. Set parameter values before any calls to `addframe`. The following table lists the available parameters and values.

Parameter Name	Value	Default
'colormap'	An m -by-3 matrix defining the colormap for indexed AVI movies, where m is no more than 256 (236 for Indeo compression). Valid only when the 'compression' is 'MSVC', 'RLE', or 'None'.	No default
'compression'	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of 'None'.	'Indeo5' on Windows systems.

Parameter Name	Value	Default
	<p>On UNIX[®] operating systems, the only valid value is 'None'.</p> <p>On Windows systems, valid values include:</p> <ul style="list-style-type: none"> • 'MSVC' • 'RLE' • 'Cinepak' on 32-bit systems. • 'Indeo3' or 'Indeo5' on 32-bit Windows XP systems. <p>Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.</p>	'None' on UNIX systems.
'fps'	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
'keyframe'	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
'quality'	<p>A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.</p> <p>Valid only for compressed movies.</p>	75
'videoname'	A descriptive name for the video stream, no more than 64 characters.	<i>filename</i>

Tips

- On some Windows systems, including all 64-bit systems, the default Indeo® 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer®. Consider specifying a compression value of 'None'.
- avifile cannot write files larger than 2 GB.
- You can use dot notation to set avifile object properties. For example, set the quality property to 100:

```
aviobj = avifile('myavifile');  
aviobj.quality = 100;
```

All property names of an avifile object are the same as the parameter names, except for the keyframe parameter, which corresponds to the KeyFramePerSec property. For example, change keyframe to 2.5:

```
aviobj.KeyFramePerSec = 2.5;
```

Examples

Create the AVI file example.avi:

```
aviobj = avifile('example.avi','compression','None');  
  
t = linspace(0,2.5*pi,40);  
fact = 10*sin(t);  
fig=figure;  
[x,y,z] = peaks;  
for k=1:length(fact)  
    h = surf(x,y,fact(k)*z);  
    axis([-3 3 -3 3 -80 80])  
    axis off  
    caxis([-90 90])  
end
```

```
F = getframe(fig);
aviobj = addframe(aviobj,F);
end
close(fig);
aviobj = close(aviobj);
```

Alternatives

Use VideoWriter rather than avifile to create AVI files. VideoWriter supports files larger than 2 GB, and by default, creates files with Motion JPEG compression, which all platforms support.

VideoWriter | addframe (avifile) | close (avifile) | movie2avi

Purpose

Information about Audio/Video Interleaved (AVI) file

Note `aviinfo` will be removed in a future release. Use `VideoReader` and the `get` method instead.

Syntax

```
fileinfo = aviinfo(filename)
```

Description

`fileinfo = aviinfo(filename)` returns a structure whose fields contain information about the AVI file specified in the string `filename`. If `filename` does not include an extension, then `.avi` is used. The file must be in the current working directory or in a directory on the MATLAB path.

The set of fields in the `fileinfo` structure is shown below.

Field Name	Description
AudioFormat	String containing the name of the format used to store the audio data, if audio data is present
AudioRate	Integer indicating the sample rate in Hertz of the audio stream, if audio data is present
Filename	String specifying the name of the file
FileModDate	String containing the modification date of the file
FileSize	Integer indicating the size of the file in bytes
FramesPerSecond	Integer indicating the desired frames per second
Height	Integer indicating the height of the AVI movie in pixels

Field Name	Description
ImageType	String indicating the type of image. Either 'truecolor' for a truecolor (RGB) image, or 'indexed' for an indexed image.
NumAudioChannels	Integer indicating the number of channels in the audio stream, if audio data is present
NumFrames	Integer indicating the total number of frames in the movie
NumColormapEntries	Integer specifying the number of colormap entries. For a truecolor image, this value is 0 (zero).
Quality	Number between 0 and 100 indicating the video quality in the AVI file. Higher quality numbers indicate higher video quality; lower quality numbers indicate lower video quality. This value is not always set in AVI files and therefore can be inaccurate.
VideoCompression	String containing the compressor used to compress the AVI file. If the compressor is not Microsoft Video 1, Run Length Encoding (RLE), Cinepak, or Intel® Indeo, aviinfo returns the four-character code that identifies the compressor.
Width	Integer indicating the width of the AVI movie in pixels

mmfileinfo, VideoReader, VideoWriter

aviread

Purpose Read Audio/Video Interleaved (AVI) file

Note `aviread` will be removed in a future release. Use `VideoReader` instead.

Syntax

```
mov = aviread(filename)  
mov = aviread(filename, index)
```

Description `mov = aviread(filename)` reads the AVI movie *filename* into the MATLAB movie structure *mov*. If *filename* does not include an extension, then `.avi` is used. Use the `movie` function to view the movie *mov*. On UNIX platforms, *filename* must be an uncompressed AVI file. *mov* has two fields, `cdata` and `colormap`. The content of these fields varies depending on the type of image.

Image Type	cdata Field	colormap Field
Truecolor	Height-by-width-by-3 array of uint8 values	Empty
Indexed	Height-by-width array of uint8 values	m-by-3 array of double values

`aviread` supports 8-bit frames, for indexed and grayscale images, 16-bit grayscale images, or 24-bit truecolor images. Note, however, that `movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale image frames.

`mov = aviread(filename, index)` reads only the frames specified by *index*. *index* can be a single index or an array of indices into the video stream. In AVI files, the first frame has the index value 1, the second frame has the index value 2, and so on.

See also `mmfileinfo`, `movie`, `VideoReader`, `VideoWriter`

Purpose Create axes graphics object

Syntax

```
axes  
axes('PropertyName',propertyvalue,...)  
axes(h)  
h = axes(...)
```

Properties For a list of properties, see Axes Properties.

Description `axes` creates an axes graphics object in the current figure using default property values. `axes` is the low-level function for creating axes graphics objects. MATLAB automatically creates an axes, if one does not already exist, when you issue a command that creates a graph.

`axes('PropertyName',propertyvalue,...)` creates an axes object having the specified property values. For a description of the properties, see Axes Properties. MATLAB uses default values for any properties that you do not explicitly define as arguments. The `axes` function accepts property name/property value pairs, structure arrays, and cell arrays as input arguments (see the `set` and `get` commands for examples of how to specify these data types). While the basic purpose of an axes object is to provide a coordinate system for plotted data, axes properties provide considerable control over the way MATLAB displays data.

`axes(h)` makes existing axes `h` the current axes and brings the figure containing it into focus. It also makes `h` the first axes listed in the figure's `Children` property and sets the figure's `CurrentAxes` property to `h`. The current axes is the target for functions that draw image, line, patch, rectangle, surface, and text graphics objects.

If you want to make an axes the current axes without changing the state of the parent figure, set the `CurrentAxes` property of the figure containing the axes:

```
set(figure_handle,'CurrentAxes',axes_handle)
```

This command is useful if you want a figure to remain minimized or stacked below other figures, but want to specify the current axes.

`h = axes(...)` returns the handle of the created axes object.

Use the `set` function to modify the properties of an existing axes or the `get` function to query the current values of axes properties. Use the `gca` command to obtain the handle of the current axes.

The `axis` (not `axes`) function provides simplified access to commonly used properties that control the scaling and appearance of axes.

Set default axes properties on the figure and root object levels:

```
set(0, 'DefaultAxesPropertyName', PropertyValue, ...)  
set(gcf, 'DefaultAxesPropertyName', PropertyValue, ...)
```

PropertyName is the name of the axes property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access axes properties.

Stretch-to-Fill

By default, MATLAB stretches the axes to fill the axes position rectangle (the rectangle defined by the last two elements in the `Position` property). This results in graphs that use the available space in the rectangle. However, some 3-D graphs (such as a sphere) appear distorted because of this stretching, and are better viewed with a specific three-dimensional aspect ratio.

Stretch-to-fill is active when the `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto` (the default). However, stretch-to-fill is turned off when the `DataAspectRatio`, `PlotBoxAspectRatio`, or `CameraViewAngle` is user-specified, or when one or more of the corresponding modes is set to `manual` (which happens automatically when you set the corresponding property value).

This picture shows the same sphere displayed both with and without the stretch-to-fill. The dotted lines show the axes rectangle.

When stretch-to-fill is disabled, MATLAB sets the size of the axes to be as large as possible within the constraints imposed by the `Position` rectangle without introducing distortion. In the picture above, the height of the rectangle constrains the axes size.

Examples

Define Multiple Axes in Figure Window

Define multiple axes in a single figure window.

```
figure
axes('Position',[0.1,0.1,0.7,0.7])
contour(peaks(20))

axes('Position',[0.7,0.7,0.28,0.28])
surf(peaks(20))
```

Alternatives

To create a figure select **New > Figure** from the figure window **File** menu. To add an axes to a figure, click one of the *New Subplots* icons in the Figure Palette, and slide right to select an arrangement of new axes. For details, see “Customize Graph Using Plot Tools”.

Tutorials

- “Axes Objects — Defining Coordinate Systems for Graphs”
- “Axes Property Operations”

Axes Properties

Purpose Modify axes properties

Creating Axes Objects Use axes to create axes objects.

Modifying Properties You can set and query graphics object properties in two ways:

- “Customize Objects in Graph” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands let you set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values” in the Handle Graphics Objects documentation.

Axes Property Descriptions This section provides a description of properties. Curly braces { } enclose default values.

`ActivePositionProperty`
{outerposition} | position

Use OuterPosition or Position property for resize. Specifies which property (`Position` or `OuterPosition`) MATLAB holds constant as you resize the figure (interactively or during a printing or exporting operation).

Setting a value for the `Position` property makes `position` the value of the `ActivePositionProperty`. The same is also true of setting a value for the `OuterPosition` property; `outerposition` becomes the value of the `ActivePositionProperty`.

See `OuterPosition` and `Position` for related properties.

See `Automatic Axes Resize` for a discussion of how to use axes positioning properties.

ALim

[amin, amax]

Alpha axis limits. Determines how MATLAB maps the AlphaData values of surface, patch, and image objects to the figure's alphamap.

- **amin** — Value of the data mapped to the first alpha value in the alphamap.
- **amax** — Value of the data mapped to the last alpha value in the alphamap.

MATLAB linearly interpolates data values in between across the alphamap and clamps data values outside to either the first or last alphamap value, whichever is closest.

If the axes contains multiple graphics objects, MATLAB sets ALim to span the range of all objects' AlphaData (or FaceVertexAlphaData for patch objects).

See the alpha function reference page for additional information.

ALimMode

{auto} | manual

Alpha axis limits mode.

- **auto** — MATLAB sets the ALim property to span the AlphaData limits of the graphics objects displayed in the axes.
- **manual** — MATLAB does not change the value of ALim when the AlphaData limits of axes children change.

Setting the ALim property sets ALimMode to manual.

AmbientLightColor

ColorSpec

Axes Properties

Background light in a scene. Ambient light is a directionless light that shines uniformly on all objects in the axes. However, if there are no visible light objects in the axes, MATLAB does not use `AmbientLightColor`. If there are light objects in the axes, MATLAB adds the `AmbientLightColor` to the other light sources.

`AspectRatio`
(Obsolete)

This property produces a warning message when queried or changed. The `DataAspectRatio[Mode]` and `PlotBoxAspectRatio[Mode]` properties have superseded it.

`BeingDeleted`
on | {off} (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

See the `close` and `delete` function reference pages for related information.

`Box`
on | {off}

Axes box mode. Specifies whether to enclose the axes extent in a box for 2-D views or a cube for 3-D views. The default is to not display the box.

`BusyAction`
cancel | {queue}

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

Button press callback function. Executes whenever you press a mouse button while the pointer is within the axes, but not over another graphics object parented to the axes. For 3-D views, the active area is a rectangle that encloses the axes.

See the figure's `SelectionType` property to determine whether modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of axes associated with the button down event and an event structure, which is empty for this property).

Axes Properties

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

Some Plotting Functions Reset the `ButtonDownFcn`

Most MATLAB plotting functions clear the axes and reset a number of axes properties, including the `ButtonDownFcn` before plotting data. To create an interface that lets users plot data interactively, consider using a control device such as a push button (`uicontrol`), which plotting functions do not affect.

If you must use the axes `ButtonDownFcn` to plot data, then you should use low-level functions such as `line`, `patch`, and `surface` and manage the process with the figure and axes `NextPlot` properties.

See “High-Level Versus Low-Level Functions” for information on how plotting functions behave.

See “Preparing Figures and Axes for Graphics” for more information.

Camera Properties

See [View Control with the Camera Toolbar](#) for information related to the Camera properties.

See [Defining Scenes with Camera Graphics](#) for information on the camera properties.

See [View Projection Types](#) for information on orthogonal and perspective projections.

`CameraPosition`

[*x*, *y*, *z*] axes coordinates

Location of the camera. Position from which the camera views the scene. Specify the point in axes coordinates.

If you fix `CameraViewAngle`, you can zoom in and out on the scene by changing the `CameraPosition`, moving the camera closer to the `CameraTarget` to zoom in and farther away from the `CameraTarget` to zoom out. As you change the `CameraPosition`, the amount of perspective also changes, if `Projection` is perspective. You can also zoom by changing the `CameraViewAngle`; however, this does not change the amount of perspective in the scene.

`CameraPositionMode`
{auto} | manual

Auto or manual CameraPosition. When set to `auto`, MATLAB automatically calculates the `CameraPosition` such that the camera lies a fixed distance from the `CameraTarget` along the azimuth and elevation specified by `view`. Setting a value for `CameraPosition` sets this property to `manual`.

`CameraTarget`
[x, y, z] axes coordinates

Camera aiming point. Specifies the location in the axes that the camera points to. The `CameraTarget` and the `CameraPosition` define the vector (the view axis) along which the camera looks.

`CameraTargetMode`
{auto} | manual

Auto or manual CameraTarget placement. When this property is `auto`, MATLAB automatically positions the `CameraTarget` at the centroid of the axes plot box. Specifying a value for `CameraTarget` sets this property to `manual`.

`CameraUpVector`
[x, y, z] axes coordinates

Camera rotation. Specifies the rotation of the camera around the viewing axis defined by the `CameraTarget` and the `CameraPosition` properties. Specify `CameraUpVector` as a

Axes Properties

three-element array containing the x , y , and z components of the vector. For example, $[0\ 1\ 0]$ specifies the positive y -axis as the up direction.

The default `CameraUpVector` is $[0\ 0\ 1]$, which defines the positive z -axis as the up direction.

`CameraUpVectorMode`
{auto} | manual

Default or user-specified up vector. When `CameraUpVectorMode` is `auto`, MATLAB uses a value of $[0\ 0\ 1]$ (positive z -direction is up) for 3-D views and $[0\ 1\ 0]$ (positive y -direction is up) for 2-D views. Setting a value for `CameraUpVector` sets this property to `manual`.

`CameraViewAngle`
scalar greater than 0 and less than or equal to 180 (angle in degrees)

Field of view. Determines the camera field of view. Changing this value affects the size of graphics objects displayed in the axes, but does not affect the degree of perspective distortion. The greater the angle, the larger the field of view, and the smaller objects appear in the scene.

`CameraViewAngleMode`
{auto} | manual

Auto or manual CameraViewAngle. When in `auto` mode, MATLAB sets `CameraViewAngle` to the minimum angle that captures the entire scene (up to 180°).

The following table summarizes MATLAB camera behavior using various combinations of `CameraViewAngleMode`, `CameraTargetMode`, and `CameraPositionMode`:

Axes Properties

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
auto	auto	auto	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
auto	auto	manual	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene.
auto	manual	auto	Sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
auto	manual	manual	Sets CameraViewAngle to capture entire scene.
manual	auto	auto	Sets CameraTarget to plot box centroid, sets CameraPosition along the view axis.
manual	auto	manual	Sets CameraTarget to plot box centroid.

Axes Properties

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
manual	manual	auto	Sets CameraPosition along the view axis.
manual	manual	manual	User specifies all camera properties.

Children

vector of graphics object handles

Handles of all graphics objects rendered within the axes (whether visible or not). The graphics objects that can be children of axes are `image`, `light`, `line`, `patch`, `rectangle`, `surface`, and `text`. Change the order of the handles to change the stacking of the objects on the display.

The text objects used to label the x -, y -, and z -axes and the title are also children of axes, but their `HandleVisibility` properties are set to `off`. This means their handles do not show up in the axes `Children` property unless you set the `Root ShowHiddenHandles` property to `on`.

When an object's `HandleVisibility` property is `off`, its parent's `Children` property does not list it. See `HandleVisibility` for more information.

CLim

[`cmin`, `cmax`]

Color axis limits. Determines how MATLAB maps the `CData` values of `surface` and `patch` objects to the figure's `Colormap`. `cmin` is the value of the data mapped to the first color in the `colormap`. `cmax` is the value of the data mapped to the last color in the `colormap`. MATLAB linearly interpolates data values in between across the `colormap` and clamps data values outside to either the first or last `colormap` color, whichever is closest.

When `CLimMode` is `auto` (the default), MATLAB assigns `cmin` the minimum data value and `cmax` the maximum data value in the graphics object's `CData`. This maps `CData` elements with minimum data value to the first `colormap` entry and with maximum data value to the last `colormap` entry.

If the axes contains multiple graphics objects, MATLAB sets `CLim` to span the range of all objects' `CData`.

See the `caxis` function reference page for related information.

`CLimMode`

`{auto} | manual`

Color axis limits mode.

- `auto` — MATLAB sets the `CLim` property to span the `CData` limits of the graphics objects displayed in the axes.
- `manual` — MATLAB does not change the value of `CLim` when the `CData` limits of axes children change.

Setting the `CLim` property sets this property to `manual`.

`Clipping`

`{on} | off`

Clipping mode. This property has no effect on axes.

`Color`

`{[1,1,1]} | ColorSpec`

Color of the axes back planes. Setting this property to `none` means that the axes is transparent and the figure color shows through. A `ColorSpec` is a three-element RGB vector or one of the MATLAB predefined names.

`ColorOrder`

`m-by-3` matrix of RGB values

Axes Properties

Colors to use for multiline plots. Defines the colors used by the `plot` and `plot3` functions to color each line plotted. If you do not specify a line color with `plot` and `plot3`, these functions cycle through the `ColorOrder` property to obtain the color for each line plotted. To obtain the current `ColorOrder`, which might be set during startup, get the property value:

```
get(gca, 'ColorOrder')
```

Note that if the axes `NextPlot` property is `replace` (the default), high-level functions like `plot` reset the `ColorOrder` property before determining the colors to use. If you want MATLAB to use a `ColorOrder` that is different from the default, set `NextPlot` to `replacechildren`. You can also specify your own default `ColorOrder`.

CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Executes when MATLAB creates an axes object. You must define this property as a default value for axes. For example, the statement:

```
set(0, 'DefaultAxesCreateFcn', @ax_create)
```

defines a default value on the Root level that sets axes properties whenever you (or MATLAB) create an axes.

```
function ax_create(src, evnt)
    set(src, 'Color', 'b', ...
        'XLim', [1 10], ...
        'YLim', [0 100])
end
```

MATLAB executes this function after setting all properties for the axes. Setting the `CreateFcn` property on an existing axes object has no effect.

MATLAB passes the handle of the object whose `CreateFcn` is being executed as the first argument to the callback function and is also accessible through the `Root CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

CurrentPoint
2-by-3 matrix

Location of last button click, in axes data units. Contains the coordinates of two points defined by the location of the pointer at the last mouse click. MATLAB returns the coordinates with respect to the requested axes.

Clicking Within the Axes — Orthogonal Projection

The two points lie on the line that is perpendicular to the plane of the screen and passes through the pointer. This is true for both 2-D and 3-D views.

The 3-D coordinates are the points, in the axes coordinate system, where this line intersects the front and back surfaces of the axes volume (which is defined by the axes x , y , and z limits).

The returned matrix is of the form:

$$\begin{bmatrix} x_{front} & y_{front} & z_{front} \\ x_{back} & y_{back} & z_{back} \end{bmatrix}$$

where *front* defines the point nearest to the camera position. Therefore, if the `CurrentPoint` property returns the `cp` matrix, then the first row,

`cp(1, :)`

specifies the point nearest the viewer and the second row,

`cp(2, :)`

specifies the point furthest from the viewer.

Clicking Outside the Axes — Orthogonal Projection

When you click outside the axes volume, but within the figure, the returned values are:

- Back point — a point in the plane of the camera target (which is perpendicular to the viewing axis).
- Front point — a point in the camera position plane (which is perpendicular to the viewing axis).

These points lie on a line that passes through the pointer and is perpendicular to the camera target and camera position planes.

Clicking Within the Axes — Perspective Projection

The values of the current point when using perspective project can be different from the same point in orthographic projection because the shape of the axes volume can be different.

Clicking Outside the Axes — Perspective Projection

Clicking outside of the axes volume returns the front point as the current camera position at all times. Only the back point updates with the coordinates of a point that lies on a line extending from the camera position through the pointer and intersecting the camera target at the point.

Related Information

See the figure `CurrentPoint` property for more information.

DataAspectRatio
[dx dy dz]

Relative scaling of data units. Controls the relative scaling of data units in the x , y , and z directions. For example, setting this property to [1 2 1] causes the length of one unit of data in the x -direction to be the same length as two units of data in the y -direction and one unit of data in the z -direction.

Note that the DataAspectRatio property interacts with the PlotBoxAspectRatio, XLimMode, YLimMode, and ZLimMode properties to control how MATLAB scales the x -, y -, and z -axis. Setting the DataAspectRatio disables the stretch-to-fill behavior if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all auto.

The following table describes the interaction between properties when you disable stretch-to-fill behavior.

Interaction Between Properties With Stretch-to-Fill Disabled

X-, Y-, Z-LimitModes	DataAspectRatio	PlotBoxAspectRatio	Behavior
auto	auto	auto	Limits chosen to span data range in all dimensions.
auto	auto	manual	Limits chosen to span data range in all dimensions. MATLAB modifies DataAspectRatio to achieve the requested PlotBoxAspectRatio

Axes Properties

X-, Y-, Z-LimitModes	DataAspectRatio	PlotBoxAspectRatio	Behavior
			within the limits the software selected.
auto	manual	auto	Limits chosen to span data range in all dimensions. MATLAB modifies <code>PlotBoxAspectRatio</code> to achieve the requested <code>DataAspectRatio</code> within the limits the software selected.
auto	manual	manual	Limits chosen to completely fit and center the plot within the requested <code>PlotBoxAspectRatio</code> given the requested <code>DataAspectRatio</code> (this might produce empty space around 2 of the 3 dimensions).
manual	auto	auto	MATLAB honors limits and modifies the <code>DataAspectRatio</code> and <code>PlotBoxAspectRatio</code> as necessary.

X-, Y-, Z-LimitModes	DataAspectRatio	PlotBoxAspectRatio	Behavior
manual	auto	manual	MATLAB honors limits and <code>PlotBoxAspectRatio</code> and modifies <code>DataAspectRatio</code> as necessary.
manual	manual	auto	MATLAB honors limits and <code>DataAspectRatio</code> and modifies the <code>PlotBoxAspectRatio</code> as necessary.
1 manual 2 auto	manual	manual	MATLAB selects the 2 automatic limits to honor the specified aspect ratios and limit. See "Examples."
2 or 3 manual	manual	manual	MATLAB honors limits and <code>DataAspectRatio</code> while ignoring <code>PlotBoxAspectRatio</code> .

See “Understanding Axes Aspect Ratio” for more information.

`DataAspectRatioMode`
{auto} | manual

User or MATLAB controlled data scaling. Controls whether the values of the `DataAspectRatio` property are user-defined or selected automatically by MATLAB. Setting values for the `DataAspectRatio` property automatically sets this property

Axes Properties

to manual. Changing `DataAspectRatioMode` to manual disables the stretch-to-fill behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto.

DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

Delete axes callback function. Executes when you delete the axes object (for example, when you issue a `delete` or `clf` command). MATLAB executes the routine before destroying the object's properties so the callback can query these values.

MATLAB passes the handle of the object whose `DeleteFcn` is executing as the first argument to the callback function. The handle is also accessible through the `Root CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

DrawMode

{normal} | fast

Rendering mode. Controls the way MATLAB renders graphics objects displayed in the axes when the figure `Renderer` property is `painters`.

- `normal` — Draws objects in back to front ordering based on the current view in order to handle hidden surface elimination and object intersections.
- `fast` — Draws objects in the order in which you specify the drawing commands, without considering the relationships of the objects in three dimensions. This results in faster rendering because it requires no sorting of objects according to location in the view, but can produce undesirable results because it

bypasses the hidden surface elimination and object intersection handling provided by `normal` `DrawMode`.

When the figure `Renderer` property is `zbuffer`, MATLAB ignores `DrawMode` and always provides hidden surface elimination and object intersection handling.

FontAngle

`{normal} | italic | oblique`

Select italic or normal font. Selects the character slant for axes text. `normal` specifies a nonitalic font. `italic` and `oblique` specify italic font.

FontName

`name (such as Courier) | FixedWidth`

Font family name. Specifies the font to use for axes labels. To display and print properly, `FontName` must be a font that your system supports. Note that MATLAB does not display the x -, y -, and z -axis labels in a new font until you manually reset them (by setting the `XLabel`, `YLabel`, and `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` command). Tick mark labels change immediately.

Specifying a Fixed-Width Font

If you want an axes to use a fixed-width font that looks good in any locale, set `FontName` to the string `FixedWidth`:

```
set(axes_handle, 'FontName', 'FixedWidth')
```

This eliminates the need to hardcode the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding (such as in Japan, where character sets can be multibyte). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` (note that this string is case sensitive) and rely

Axes Properties

on `FixedWidthFontName` to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`.

Note that setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

FontSize

Font size specified in `FontUnits`

Font size. An integer specifying the font size to use for axes labels and titles, in units determined by the `FontUnits` property. The default point size is 12 and the maximum allowable font size depends on your operating system. MATLAB does not display *x*-, *y*-, and *z*-axis text labels in a new font size until you manually reset them (by setting the `XLabel`, `YLabel`, or `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` command). Tick mark labels change immediately.

FontUnits

{points} | normalized | inches | centimeters | pixels

Units used to interpret the FontSize property. When set to `normalized`, MATLAB interprets the value of `FontSize` as a fraction of the height of the axes. For example, a `normalized FontSize` of 0.1 sets the text characters to a font whose height is one tenth of the axes' height. The default units (`points`), are equal to 1/72 of an inch.

If you set both the `FontSize` and the `FontUnits` in one function call, you must set the `FontUnits` property first so that MATLAB correctly interprets the specified `FontSize`.

FontWeight

{normal} | bold | light | demi

Select bold or normal font. The character weight for axes text. MATLAB does not display the x -, y -, and z -axis text labels in bold until you manually reset them (by setting the `XLabel`, `YLabel`, and `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` commands). Tick mark labels change immediately.

GridLineStyle

- | -- | {:} | -. | none

Line style used to draw grid lines. The line style is a string consisting of a character, in quotes, specifying solid lines (-), dashed lines (--), dotted lines(:), or dash-dot lines (-.). The default grid line style is dotted. To turn on grid lines, use the `grid` command.

HandleVisibility

{on} | callback | off

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, functions that obtain handles by searching the object hierarchy or

Axes Properties

querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When you restrict a handle's visibility by using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the Root's `CurrentFigure` property, objects do not appear in the Root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the Root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`
`{on} | off`

Selectable by mouse click. Determines if the axes can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click the axes. If `HitTest` is `off`, clicking the axes selects the object below it (which is usually the figure containing it).

`Interruptible`
`off | {on}`

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is

the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
 - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
 - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to `on` (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

Axes Properties

For more information, see “Control Callback Execution and Interruption”.

Layer

{bottom} | top

Draw axis lines below or above graphics objects. Determines whether to draw axis lines and tick marks on top or below axes children objects for any 2-D view (for example, when you are looking along the x -, y -, or z -axis). Use this property to place grid lines and tick marks on top of images.

LineStyleOrder

LineStyleSpec {a solid line '-'} }

Order of line styles and markers used in a plot. Specifies which line styles and markers to use and in what order when creating multiple-line plots. For example:

```
set(gca, 'LineStyleOrder', '-*|:|o')
```

sets `LineStyleOrder` to solid line with asterisk marker, dotted line, and hollow circle marker. The default is (-), which specifies a solid line for all data plotted. Alternatively, you can create a cell array of character strings to define the line styles:

```
set(gca, 'LineStyleOrder', {'-*', ':', 'o'})
```

MATLAB supports four line styles, which you can specify any number of times in any order. MATLAB cycles through the line styles only after using all colors defined by the `ColorOrder` property. For example, the first eight lines plotted use the different colors defined by `ColorOrder` with the first line style. MATLAB then cycles through the colors again, using the second line style specified, and so on.

You can also specify line style and color directly with the `plot` and `plot3` functions or by altering the properties of the `line` or `lineseries` objects after creating the graph.

High-Level Functions and LineStyleOrder

Note that, if the axes `NextPlot` property is `replace` (the default), high-level functions like `plot` reset the `LineStyleOrder` property before determining the line style to use. If you want MATLAB to use a `LineStyleOrder` that is different from the default, set `NextPlot` to `replacechildren`.

Specifying a Default LineStyleOrder

You can specify your own default `LineStyleOrder`. For example:

```
set(0, 'DefaultAxesLineStyleOrder', {'-*', ':', 'o'})
```

creates a default value for the axes `LineStyleOrder` that high-level plotting functions will not reset.

LineWidth

line width in points

Width of axis lines. Specifies the width, in points, of the x -, y -, and z -axis lines. The default line width is 0.5 points 1 point = $1/72$ inch.

MinorGridLineStyle

- | -- | {:} | -. | none

Line style used to draw minor grid lines. The line style is a string consisting of one or more characters, in quotes, specifying solid lines (-), dashed lines (--), dotted lines (:{), or dash-dot lines (-.). The default minor grid line style is dotted. To turn on minor grid lines, use the `grid minor` command.

NextPlot

add | {replace} | replacechildren

Where to draw the next plot. Determines how high-level plotting functions draw into an existing axes.

- `add` — Use the existing axes to draw graphics objects.

Axes Properties

- `replace` — Reset all axes properties except `Position` to their defaults and delete all axes children before displaying graphics (equivalent to `cla reset`).
- `replacechildren` — Remove all child objects, but do not reset axes properties (equivalent to `cla`).

The `newplot` function simplifies the use of the `NextPlot` property and is useful for functions that draw graphs using only low-level object creation routines. Note that figure graphics objects also have a `NextPlot` property.

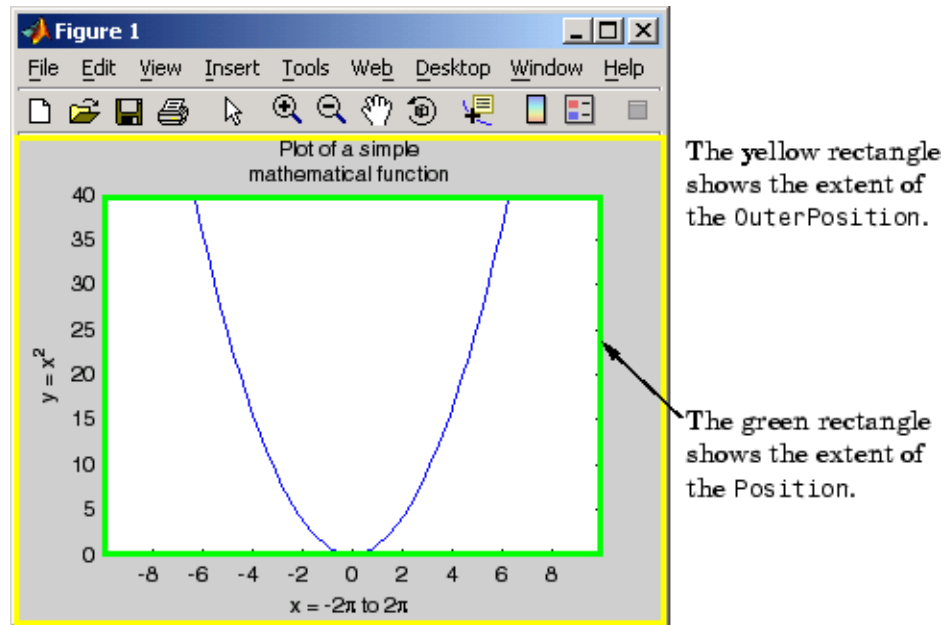

`OuterPosition`
four-element vector

Position of axes including labels, title, and a margin. Specifies a rectangle that locates the outer bounds of the axes, including axis labels, the title, and a margin. The vector is as follows:

[left bottom width height]

where `left` and `bottom` define the distance from the lower-left corner of the figure window to the lower-left corner of the rectangle. `width` and `height` are the dimensions of the rectangle.

The following picture shows the region defined by the `OuterPosition` enclosed in a yellow rectangle.

When `ActivePositionProperty` is `OuterPosition` (the default), resizing the figure will not clip any of the text. The default value of `[0 0 1 1]` (normalized units) includes the interior of the figure.

The `Units` property specifies all measurement units.

See the property for related information.

See “Automatic Axes Resize” for a discussion of how to use axes positioning properties.

Parent

figure or uipanel handle

Axes parent. The handle of the axes’ parent object. The parent of an axes object is the figure which displays it or the uipanel object that contains it. The utility function `gcf` returns the handle of

Axes Properties

the current axes Parent. You can reparent axes to other figure or uipanel objects.

`PlotBoxAspectRatio`
[px py pz]

Relative scaling of axes plot box. Controls the relative scaling of the plot box in the x , y , and z directions. The plot box is a box enclosing the axes data region as defined by the x -, y -, and z -axis limits.

Note that the `PlotBoxAspectRatio` property interacts with the `DataAspectRatio`, `XLimMode`, `YLimMode`, and `ZLimMode` properties to control the way MATLAB displays graphics objects. Setting the `PlotBoxAspectRatio` disables stretch-to-fill behavior, if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto.

`PlotBoxAspectRatioMode`
{auto} | manual

User or MATLAB controlled axis scaling. Controls whether the values of the `PlotBoxAspectRatio` property are user-defined or selected automatically by MATLAB. Setting values for the `PlotBoxAspectRatio` property automatically sets this property to manual. Changing the `PlotBoxAspectRatioMode` to manual disables stretch-to-fill behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto.

`Position`
four-element vector

Position of axes. Specifies a rectangle that locates the axes within its parent container (figure or uipanel). The vector is of the form:

[left bottom width height]

where `left` and `bottom` define the distance from the lower-left corner of the container to the lower-left corner of the rectangle. `width` and `height` are the dimensions of the rectangle. The `Units` property specifies the units for all measurements.

When you enable axes stretch-to-fill behavior (when `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`), MATLAB stretches the axes to fill the `Position` rectangle. When you disable stretch-to-fill, MATLAB makes the axes as large as possible, while obeying all other properties, without extending outside the `Position` rectangle.

See the `OuterPosition` property for related information.

See “Automatic Axes Resize” for a discussion of how to use axes positioning properties.

Projection

`{orthographic} | perspective`

Type of projection. Selects one of the following projection types:

- `orthographic` — Maintains the correct relative dimensions of graphics objects regarding the distance a given point is from the viewer and draws parallel lines in the data parallel on the screen.
- `perspective` — Incorporates foreshortening, which allows you to perceive depth in 2-D representations of 3-D objects. Perspective projection does not preserve the relative dimensions of objects; it displays a distant line segment smaller than a nearer line segment of the same length. Parallel lines in the data might not appear parallel on screen.

Selected

`on | {off}`

Axes Properties

Is object selected? When you set this property to on, MATLAB displays selection “handles” at the corners and midpoints if the `SelectionHighlight` property is also on (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to on, thereby indicating that the axes has been selected.

`SelectionHighlight`
{on} | off

Highlights objects when selected. When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

`Tag`
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, suppose you want to direct all graphics output from a file to a particular axes, regardless of user actions that might have changed the current axes. To do this, identify the axes with a `Tag`:

```
axes('Tag','Special Axes')
```

Then make that axes the current axes before drawing by searching for the `Tag` with `findobj`:

```
axes(findobj('Tag','Special Axes'))
```

`TickDir`
in | out

Direction of tick marks. For 2-D views, the default is to direct tick marks inward from the axis lines; 3-D views direct tick marks outward from the axis line.

TickDirMode
{auto} | manual

Automatic tick direction control. In auto mode, MATLAB directs tick marks inward for 2-D views and outward for 3-D views. When you specify a setting for TickDir, MATLAB sets TickDirMode to manual. In manual mode, MATLAB does not change the specified tick direction.

TickLength
[2DLength 3DLength]

Length of tick marks. Specifies the length of axes tick marks. The first element is the length of tick marks used for 2-D views and the second element is the length of tick marks used for 3-D views. Specify tick mark lengths in units normalized relative to the longest of the visible x -, y -, or z -axis annotation lines.

TightInset
[left bottom right top] Read only

Margins added to Position to include text labels. The distances between the bounds of the Position property and the extent of the axes text labels and title. When added to the Position width and height values, the TightInset defines the tightest bounding box that encloses the axes and its labels and title.

See “Automatic Axes Resize” for more information.

Title
handle of text object

Axes title. The handle of the text object used for the axes title. Use this handle to change the properties of the title text or you can

Axes Properties

set `Title` to the handle of an existing text object. For example, the following statement changes the color of the current title to red:

```
set(get(gca,'Title'),'Color','r')
```

To create a new title, set this property to the handle of the text object you want to use:

```
set(gca,'Title',text('String','New Title'),'Color','r')
```

However, it is simpler to use the `title` command to create or replace an axes title:

```
title('New Title','Color','r') % Make text color red  
title({'This title','has 2 lines'}) % Two line title
```

Type

string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For axes objects, `Type` is always 'axes'.

UIContextMenu

handle of uicontextmenu object

Associate a context menu with the axes. Assign this property the handle of a `uicontextmenu` object created in the axes' parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the axes.

Units

inches | centimeters | {normalized} | points | pixels
| characters

Axes position units. The units used to interpret the `Position` property. MATLAB measures all units from the lower left corner of the figure window.

Note The `Units` property controls the positioning of the axes within the figure. This property does not affect the data units used for graphing. See the axes `XLim`, `YLim`, and `ZLim` properties to set the limits of each axis data units.

- `normalized` — Units map the lower left corner of the figure window to (0,0) and the upper right corner to (1.0, 1.0).
- `inches`, `centimeters`, and `points` — Absolute units. 1 point = $\frac{1}{72}$ inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter x, and the height of one `characters` unit is the distance between the baselines of two lines of text.

When specifying the units as property/value pairs during object creation, you must set the `Units` property before specifying the properties that you want to use these units.

`UserData`
matrix

User-specified data. Data you want to associate with the axes object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`View`
Obsolete

The axes camera properties now controls the functionality provided by the `View` property — `CameraPosition`, `CameraTarget`, `CameraUpVector`, and `CameraViewAngle`. See the `view` command.

Axes Properties

Visible

{on} | off

Visibility of axes. By default, axes are visible. Setting this property to `off` prevents axis lines, tick marks, and labels from being displayed. The `Visible` property does not affect children of axes.

XAxisLocation

top | {bottom}

Location of x-axis tick marks and labels. Controls where MATLAB displays the *x*-axis tick marks and labels. Setting this property to `top` moves the *x*-axis to the top of the plot from its default position at the bottom. This property applies to 2-D views only.

YAxisLocation

right | {left}

Location of y-axis tick marks and labels. Controls where MATLAB displays the *y*-axis tick marks and labels. Setting this property to `right` moves the *y*-axis to the right side of the plot from its default position on the left side. This property applies to 2-D views only. See the `plotyy` function for a simple way to use two *y*-axes.

Properties That Control the X-, Y-, or Z-Axis

XColor

YColor

ZColor

ColorSpec

Color of axis lines. A three-element vector specifying an RGB triple, or a predefined MATLAB color string. This property determines the color of the axis lines, tick marks, tick mark labels, and the axis grid lines of the respective *x*-, *y*-, and *z*-axis. The default axis color is black. See `ColorSpec` for details on specifying colors.

XDir
YDir
ZDir
{normal} | reverse

Direction of increasing values. A mode controlling the direction of increasing axis values. Axes form a right-hand coordinate system. By default:

- x -axis values increase from left to right. To reverse the direction of increasing x values, set this property to reverse.

```
set(gca, 'XDir', 'reverse')
```

- y -axis values increase from bottom to top (2-D view) or front to back (3-D view). To reverse the direction of increasing y values, set this property to reverse.

```
set(gca, 'YDir', 'reverse')
```

- z -axis values increase pointing out of the screen (2-D view) or from bottom to top (3-D view). To reverse the direction of increasing z values, set this property to reverse.

```
set(gca, 'ZDir', 'reverse')
```

XGrid
YGrid
ZGrid
on | {off}

Axis gridline mode. When you set any of these properties to on, MATLAB draws grid lines perpendicular to the respective axis (for example, along lines of constant x , y , or z values). Use the `grid` command to set all three properties on or off at once.

```
set(gca, 'XGrid', 'on')
```

Axes Properties

XLabel

YLabel

ZLabel

handle of text object

Axis labels. The handle of the `text` object used to label the x -, y -, or z -axis, respectively. To assign values to any of these properties, you must obtain the handle to the text string you want to use as a label. This statement defines a text object and assigns its handle to the XLabel property:

```
set(get(gca,'XLabel'),'String','axis label')
```

MATLAB places the string 'axis label' appropriately for an x -axis label and moves any text object whose handle you specify as an XLabel, YLabel, or ZLabel property to the appropriate location for the respective label.

Alternatively, you can use the `xlabel`, `ylabel`, and `zlabel` functions, which generally provide a simpler means to label axis lines.

Note that using a bitmapped font (for example, Courier is usually a bitmapped font) might cause the labels to rotate improperly. As a workaround, use a TrueType font (for example, Courier New) for axis labels. See your system documentation to determine the types of fonts installed on your system.

XLim

YLim

ZLim

[minimum maximum]

Axis limits. Specifies the minimum and maximum values of the respective axis. The data you plot determines these values.

Changing these properties affects the scale of the x -, y -, or z -dimension as well as the placement of labels and tick marks on the axis. The default values for these properties are [0 1].

See the `axis`, `datetick`, `xlim`, `ylim`, and `zlim` commands to set these properties.

`XLimMode`
`YLimMode`
`ZLimMode`
 {auto} | manual

MATLAB or user-controlled limits. The axis limits mode determines whether MATLAB calculates axis limits based on the data plotted (for example, the `XData`, `YData`, or `ZData` of the axes children) or uses the values explicitly set with the `XLim`, `YLim`, or `ZLim` property, in which case, the respective limits mode is set to manual.

`XMinorGrid`
`YMinorGrid`
`ZMinorGrid`
 on | {off}

Enable or disable minor gridlines. When set to on, MATLAB draws gridlines aligned with the minor tick marks of the respective axis. Note that you do not have to enable minor ticks to display minor grids.

`XMinorTick`
`YMinorTick`
`ZMinorTick`
 on | {off}

Enable or disable minor tick marks. When set to on, MATLAB draws tick marks between the major tick marks of the respective axis. MATLAB automatically determines the number of minor ticks based on the space between the major ticks.

Axes Properties

XScale
YScale
ZScale
 {linear} | log

Axis scaling. Linear or logarithmic scaling for the respective axis. See also `loglog`, `semilogx`, and `semilogy`.

XTick
YTick
ZTick
 vector of data values locating tick marks

Tick spacing. A vector of x -, y -, or z -data values that determine the location of tick marks along the respective axis. If you do not want tick marks displayed, set the respective property to the empty vector, `[]`. These vectors must contain monotonically increasing values.

XTickLabel
YTickLabel
ZTickLabel
 string

Tick labels. A matrix of strings to use as labels for tick marks along the respective axis. These labels replace the numeric labels generated by MATLAB. If you do not specify enough text labels for all the tick marks, MATLAB uses all of the labels specified, then reuses the specified labels.

For example, the statement:

```
set(gca, 'XTickLabel', {'One'; 'Two'; 'Three'; 'Four'})
```

labels the first four tick marks on the x -axis and then reuses the labels for the remaining ticks.

Labels can be cell arrays of strings, padded string matrices, string vectors separated by vertical slash characters, or numeric vectors (where MATLAB implicitly converts each number to the equivalent string using `num2str`). All of the following are equivalent:

```
set(gca,'XTickLabel',{'1';'10';'100'})
set(gca,'XTickLabel','1|10|100')
set(gca,'XTickLabel',[1;10;100])
set(gca,'XTickLabel',['1 ','10 ','100'])
```

Note that tick labels do not interpret TeX character sequences (however, the `Title`, `XLabel`, `YLabel`, and `ZLabel` properties do).

```
XTickMode
YTickMode
ZTickMode
    {auto} | manual
```

MATLAB or user-controlled tick spacing. The axis tick modes determine whether MATLAB calculates the tick mark spacing based on the range of data for the respective axis (auto mode) or uses the values explicitly set for any of the `XTick`, `YTick`, and `ZTick` properties (manual mode). Setting values for the `XTick`, `YTick`, or `ZTick` properties sets the respective axis tick mode to manual.

```
XTickLabelMode
YTickLabelMode
ZTickLabelMode
    {auto} | manual
```

MATLAB or user-determined tick labels. The axis tick mark labeling modes determine whether MATLAB uses numeric tick mark labels that span the range of the plotted data (auto mode) or uses the tick mark labels specified with the `XTickLabel`, `YTickLabel`, or `ZTickLabel` property (manual mode). Setting

Axes Properties

values for the `XTickLabel`, `YTickLabel`, or `ZTickLabel` property sets the respective axis tick label mode to manual.

See Also `axes`

Purpose

Axis scaling and appearance

Syntax

```
axis([xmin xmax ymin ymax])
axis([xmin xmax ymin ymax zmin zmax cmin cmax])
v = axis
axis auto
axis manual
axis tight
axis fill
axis ij
axis xy
axis equal
axis image
axis square
axis vis3d
axis normal
axis off
axis on
axis(axes_handles,...)
[mode,visibility,direction] = axis('state')
```

Description

`axis` manipulates commonly used axes properties. (See Algorithm section.)

`axis([xmin xmax ymin ymax])` sets the limits for the x - and y -axis of the current axes.

`axis([xmin xmax ymin ymax zmin zmax cmin cmax])` sets the x -, y -, and z -axis limits and the color scaling limits (see `caxis`) of the current axes.

`v = axis` returns a row vector containing scaling factors for the x -, y -, and z -axis. `v` has four or six components depending on whether the current axes is 2-D or 3-D, respectively. The returned values are the current axes `XLim`, `Ylim`, and `ZLim` properties.

`axis auto` sets MATLAB default behavior to compute the current axes limits automatically, based on the minimum and maximum values of x , y , and z data. You can restrict this automatic behavior to a specific

`axis`. For example, `axis 'auto x'` computes only the x -axis limits automatically; `axis 'auto yz'` computes the y - and z -axis limits automatically.

`axis manual` and `axis(axis)` freezes the scaling at the current limits, so that if `hold` is on, subsequent plots use the same limits. This sets the `XLimMode`, `YLimMode`, and `ZLimMode` properties to `manual`.

`axis tight` sets the axis limits to the range of the data.

`axis fill` sets the axis limits and `PlotBoxAspectRatio` so that the axes fill the position rectangle. This option has an effect only if `PlotBoxAspectRatioMode` or `DataAspectRatioMode` is `manual`.

`axis ij` places the coordinate system origin in the upper left corner. The i -axis is vertical, with values increasing from top to bottom. The j -axis is horizontal with values increasing from left to right.

`axis xy` draws the graph in the default Cartesian axes format with the coordinate system origin in the lower left corner. The x -axis is horizontal with values increasing from left to right. The y -axis is vertical with values increasing from bottom to top.

`axis equal` sets the aspect ratio so that the data units are the same in every direction. The aspect ratio of the x -, y -, and z -axis is adjusted automatically according to the range of data units in the x , y , and z directions.

`axis image` is the same as `axis equal` except that the plot box fits tightly around the data.

`axis square` makes the current axes region square (or cubed when three-dimensional). This option adjusts the x -axis, y -axis, and z -axis so that they have equal lengths and adjusts the increments between data units accordingly.

`axis vis3d` freezes aspect ratio properties to enable rotation of 3-D objects and overrides `stretch-to-fill`.

`axis normal` automatically adjusts the aspect ratio of the axes and the relative scaling of the data units so that the plot fits the figure's shape as well as possible.

`axis off` turns off all axis lines, tick marks, and labels.

`axis on` turns on all axis lines, tick marks, and labels.

`axis(axes_handles,...)` applies the axis command to the specified axes. For example, the following statements

```
h1 = subplot(221);
h2 = subplot(222);
axis([h1 h2], 'square')
```

set both axes to square.

`[mode,visibility,direction] = axis('state')` returns three strings indicating the current setting of axes properties:

Output Argument	Strings Returned
mode	'auto' 'manual'
visibility	'on' 'off'
direction	'xy' 'ij'

mode is auto if `XLimMode`, `YLimMode`, and `ZLimMode` are all set to auto. If `XLimMode`, `YLimMode`, or `ZLimMode` is manual, mode is manual.

Keywords to `axis` can be combined, separated by a space (e.g., `axis tight equal`). These are evaluated from left to right, so subsequent keywords can overwrite properties set by prior ones.

Tips

You can create an axes (and a figure for it) if none exists with the `axis` command. However, if you specify non-default limits or formatting for the axes when doing this, such as `[4 8 2 9]`, `square`, `equal`, or `image`, the property is ignored because there are no axis limits to adjust in the absence of plotted data. To use `axis` in this manner, you can set `hold on` to keep preset axes limits from being overridden.

Examples

Set Axis Limits

Plot the tan function from 0 to $\pi/2$.

```
x = 0:.01:pi/2;  
y = tan(x);
```

```
figure  
plot(x,y,'-o')
```

Change the axis limits so that the x -axis ranges from 0 to $\pi/2$ and the y -axis ranges from 0 to 5.

```
axis([0,pi/2,0,5])
```

Algorithms

When you specify minimum and maximum values for the x -, y -, and z -axes, `axis` sets the `XLim`, `Ylim`, and `ZLim` properties for the current axes to the respective minimum and maximum values in the argument

list. Additionally, the `XLimMode`, `YLimMode`, and `ZLimMode` properties for the current axes are set to `manual`.

`axis auto` sets the current axes `XLimMode`, `YLimMode`, and `ZLimMode` properties to `'auto'`.

`axis manual` sets the current axes `XLimMode`, `YLimMode`, and `ZLimMode` properties to `'manual'`.

The following table shows the values of the axes properties set by `axis equal`, `axis normal`, `axis square`, and `axis image`.

Axes Property or Behavior	axis equal	axis normal	axis square	axis image
DataAspectRatio property	[1 1 1]	not set	not set	[1 1 1]
DataAspectRatioMode property	manual	auto	auto	manual
PlotBoxAspectRatio property	[3 4 4]	not set	[1 1 1]	auto
PlotBoxAspectRatioMode property	manual	auto	manual	auto
<i>Stretch-to-fill</i> behavior;	disabled	active	disabled	disabled

Purpose

Diagonal scaling to improve eigenvalue accuracy

Syntax

```
[T,B] = balance(A)
[S,P,B] = balance(A)
B = balance(A)
B = balance(A, 'noperm')
```

Description

`[T,B] = balance(A)` returns a similarity transformation T such that $B = T \backslash A * T$, and B has, as nearly as possible, approximately equal row and column norms. T is a permutation of a diagonal matrix whose elements are integer powers of two to prevent the introduction of roundoff error. If A is symmetric, then $B == A$ and T is the identity matrix.

`[S,P,B] = balance(A)` returns the scaling vector S and the permutation vector P separately. The transformation T and balanced matrix B are obtained from A , S , and P by $T(:,P) = \text{diag}(S)$ and $B(P,P) = \text{diag}(1./S) * A * \text{diag}(S)$.

`B = balance(A)` returns just the balanced matrix B .

`B = balance(A, 'noperm')` scales A without permuting its rows and columns.

Tips

-

Nonsymmetric matrices can have poorly conditioned eigenvalues. Small perturbations in the matrix, such as roundoff errors, can lead to large perturbations in the eigenvalues. The condition number of the eigenvector matrix,

$$\text{cond}(V) = \text{norm}(V) * \text{norm}(\text{inv}(V))$$

where

$$[V,T] = \text{eig}(A)$$

balance

relates the size of the matrix perturbation to the size of the eigenvalue perturbation. Note that the condition number of A itself is irrelevant to the eigenvalue problem.

Balancing is an attempt to concentrate any ill conditioning of the eigenvector matrix into a diagonal scaling. Balancing usually cannot turn a nonsymmetric matrix into a symmetric matrix; it only attempts to make the norm of each row equal to the norm of the corresponding column.

Note The MATLAB eigenvalue function, `eig(A)`, automatically balances A before computing its eigenvalues. Turn off the balancing with `eig(A, 'nobalance')`.

Examples

This example shows the basic idea. The matrix A has large elements in the upper right and small elements in the lower left. It is far from being symmetric.

```
A = [1 100 10000; .01 1 100; .0001 .01 1]
A =
  1.0e+04 *
  0.0001    0.0100    1.0000
  0.0000    0.0001    0.0100
  0.0000    0.0000    0.0001
```

Balancing produces a diagonal matrix T with elements that are powers of two and a balanced matrix B that is closer to symmetric than A .

```
[T,B] = balance(A)
T =
  1.0e+03 *
  2.0480         0         0
         0    0.0320         0
         0         0    0.0003
B =
  1.0000    1.5625    1.2207
```

```

0.6400    1.0000    0.7813
0.8192    1.2800    1.0000

```

To see the effect on eigenvectors, first compute the eigenvectors of A, shown here as the columns of V.

```

[V,E] = eig(A); V
V =
0.9999          -0.9999          -0.9999
0.0100          0.0059 + 0.0085i    0.0059 - 0.0085i
0.0001          0.0000 - 0.0001i    0.0000 + 0.0001i

```

Note that all three vectors have the first component the largest. This indicates V is badly conditioned; in fact $\text{cond}(V)$ is $8.7766e+003$. Next, look at the eigenvectors of B.

```

[V,E] = eig(B); V
V =
0.6933          -0.6993          -0.6993
0.4437          0.2619 + 0.3825i    0.2619 - 0.3825i
0.5679          0.2376 - 0.4896i    0.2376 + 0.4896i

```

Now the eigenvectors are well behaved and $\text{cond}(V)$ is 1.4421. The ill conditioning is concentrated in the scaling matrix; $\text{cond}(T)$ is 8192.

This example is small and not really badly scaled, so the computed eigenvalues of A and B agree within roundoff error; balancing has little effect on the computed results.

Limitations

Balancing can destroy the properties of certain matrices; use it with some care. If a matrix contains small elements that are due to roundoff error, balancing might scale them up to make them as significant as the other elements of the original matrix.

`eig`

bandwidth

Purpose Lower and upper matrix bandwidth

Syntax `B = bandwidth(A,type)`

`[lower,upper] = bandwidth(A)`

Description `B = bandwidth(A,type)` returns the bandwidth of matrix `A` specified by type. Specify type as 'lower' for the lower bandwidth, or 'upper' for the upper bandwidth.

`[lower,upper] = bandwidth(A)` returns the lower bandwidth, lower, and upper bandwidth, upper, of matrix `A`.

Input Arguments

A - Input matrix
2-D numeric matrix

Input matrix, specified as a 2-D numeric matrix. `A` can be either full or sparse.

Data Types

single | double

Complex Number Support: Yes

type - Bandwidth type

'lower' | 'upper'

Bandwidth type, specified as 'lower' or 'upper'.

- Specify 'lower' for the lower bandwidth. The lower bandwidth is the number of nonzero diagonals below the main diagonal.
- Specify 'upper' for the upper bandwidth. The upper bandwidth is the number of nonzero diagonals above the main diagonal.

Data Types

char

Output Arguments**B - Lower or upper bandwidth**

nonnegative integer scalar

Lower or upper bandwidth, returned as a nonnegative integer scalar.

- If type is 'lower', then B is the number of nonzero diagonals below the main diagonal and $0 \leq B \leq \text{size}(A,1) - 1$.
- If type is 'upper', then B is the number of nonzero diagonals above the main diagonal and $0 \leq B \leq \text{size}(A,2) - 1$.

lower - Lower bandwidth

nonnegative integer scalar

Lower bandwidth, returned as a nonnegative integer scalar. The lower bandwidth is the number of nonzero diagonals below the main diagonal. lower is in the range $0 \leq \text{lower} \leq \text{size}(A,1) - 1$.

upper - Upper bandwidth

nonnegative integer scalar

Upper bandwidth, returned as a nonnegative integer scalar. The upper bandwidth is the number of nonzero diagonals above the main diagonal. upper is in the range $0 \leq \text{upper} \leq \text{size}(A,2) - 1$.

Examples**Find Bandwidth of Triangular Matrix**

Create a 6-by-6 lower triangular matrix.

```
A = tril(magic(6))
```

```
A =
```

```

35     0     0     0     0     0
 3    32     0     0     0     0
31     9     2     0     0     0
 8    28    33    17     0     0
30     5    34    12    14     0
 4    36    29    13    18    11
```

bandwidth

Find the lower bandwidth of A by specifying type as 'lower'.

```
B = bandwidth(A, 'lower')
```

```
B =
```

```
5
```

The result is 5 because every diagonal below the main diagonal has nonzero elements.

Find the upper bandwidth of A by specifying type as 'upper'.

```
B = bandwidth(A, 'upper')
```

```
B =
```

```
0
```

The result is 0 because there are no nonzero elements above the main diagonal.

Find Bandwidth of Sparse Block Matrix

Create a 100-by-100 sparse block matrix.

```
B = kron(speye(25), ones(4));
```

View a 10-by-10 section of elements from the top left of B.

```
full(B(1:10, 1:10))
```

```
ans =
```

```
1 1 1 1 0 0 0 0 0 0
1 1 1 1 0 0 0 0 0 0
1 1 1 1 0 0 0 0 0 0
1 1 1 1 0 0 0 0 0 0
0 0 0 0 1 1 1 1 0 0
0 0 0 0 1 1 1 1 0 0
```

```
0 0 0 0 1 1 1 1 0 0
0 0 0 0 1 1 1 1 0 0
0 0 0 0 0 0 0 0 1 1
0 0 0 0 0 0 0 0 1 1
```

B has 4-by-4 blocks of ones centered on the main diagonal.

Find both the lower and upper bandwidths of B by specifying two output arguments.

```
[lower,upper] = bandwidth(B)
```

```
lower =
```

```
3
```

```
upper =
```

```
3
```

The lower and upper bandwidths are both 3.

Bandwidth

The upper and lower bandwidths of a matrix are the number of nonzero diagonals above and below the main diagonal, respectively.

In terms of the upper and lower bandwidths, the total bandwidth of the matrix is equal to `upper + lower + 1`.

Tips

- Use the `isbanded` function to test if a matrix is within a specific lower and upper bandwidth.

bar

Purpose Bar graph

Syntax

```
bar(Y)
bar(x,Y)

bar( __ ,width)
bar( __ ,style)
bar( __ ,bar_color)
bar( __ ,Name,Value)

bar(axes_handle, __ )

h = bar( __ )
```

Description `bar(Y)` draws one bar for each element in `Y`.

`bar(x,Y)` draws bars for each column in `Y` at locations specified in `x`.

`bar(__ ,width)` sets the relative bar width and controls the separation of bars within a group and can include any of the input arguments in previous syntaxes.

`bar(__ ,style)` specifies the style of the bars and can include any of the input arguments in previous syntaxes.

`bar(__ ,bar_color)` displays all bars using the color specified by the single-letter abbreviation of `bar_color` and can include any of the input arguments in previous syntaxes.

`bar(__ ,Name,Value)` sets the property names to the specified values and can include any of the input arguments in previous syntaxes.

Note You cannot specify names and values when using `hist` or `histc` options.

`bar(axes_handle, ___)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar(___)` returns a vector of handles to `barseries` graphics objects, one for each created.

Change the colormap to use a different color scheme. Use the `colormap` function to specify the figure colormap.

Use shading `flat` to turn off bar edges. Use shading `faceted` to turn on bar edges. See the `shading` function for more information.

Input Arguments

x - x-axis intervals

vector | 2-D array

x-axis intervals for vertical bars, specified as a vector or a 2-D array..

The *x*-values can be nonmonotonic, but cannot contain duplicate values.

Example: `x = 1:10;`

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Y - Bar lengths

vector | 2-D array

Bar lengths, specified as a vector or a 2-D array.

- If *Y* is a vector, then `bar` creates `length(Y)` bars. The `bar` function treats all vectors as column vectors.
- If *Y* is a 2-D array, then `bar` groups the bars produced by the elements in each row.

bar

- If Y is complex, then `bar(Y)` plots the imaginary parts of Y versus the index of each entry. If either x or Y is complex, then `bar(x,Y)` ignores the imaginary parts and plots the real parts of Y versus the real parts of x .

Example: `y = [10,8,5,7,3,9,1];`

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` |
`uint16` | `uint32` | `uint64`

width - Bar width

`0.8` (default) | `scalar`

Bar width of each bar, specified as a fraction of the total width of a bar and the space between bars. The default of 0.8 means the a bar width is 80% of the space from the previous bar to the next bar, with 10% of that space on each side.

If width is 1, the bars within a group touch one another.

Example: `bar(y,0.5);`

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` |
`uint16` | `uint32` | `uint64`

style - Bar style, specified as one of the following strings

`'grouped'` (default) | `'stacked'` | `'hist'` | `'histc'`

Bar style, specified by one of these values.

Style	Purpose
'grouped'	<p data-bbox="911 317 1317 378">Displays one group for each row in Y.</p> <ul data-bbox="911 413 1332 713" style="list-style-type: none"><li data-bbox="911 413 1332 569">• If Y is an m-by-n matrix, then MATLAB displays m groups of n vertical bars, where m is the number of rows and n is the number of columns in Y.<li data-bbox="911 586 1332 713">• If Y is a vector of length n, then MATLAB treats Y as a column vector and displays one group of n bars.
'stacked'	<p data-bbox="911 734 1317 795">Displays one bar for each row in Y.</p> <ul data-bbox="911 817 1332 1211" style="list-style-type: none"><li data-bbox="911 817 1332 1098">• If Y is an m-by-n matrix, then MATLAB displays m bars where each bar height is the sum of the elements in the row. Each bar is multicolored. Colors correspond to distinct elements and show the relative contribution each row element makes to the total sum.<li data-bbox="911 1116 1332 1211">• If Y is a vector of length n, then MATLAB treats Y as a column vector and displays n bars.

bar

Style	Purpose
'histc'	Displays the graph in histogram format, in which bars touch one another.
'hist'	Displays the graph in histogram format, but centers each bar over the <i>x</i> -ticks, rather than making bars span <i>x</i> -ticks as the <code>histc</code> option does.

Example: `bar(Y, 'hist')`

Data Types

char

bar_color - Bar color

'b' | 'r' | 'g' | 'b' | 'c' | 'm' | 'y' | 'k' | 'w'

Bar color, specified as a single-letter abbreviation, assigns the color specified to all bars.

Example: `bar(Y, 'r')`

Data Types

char

axes_handle - Axes handle

current axes (default) | axes handle

Axes handle specifying the target axes for the bar graph.

Example: `bar(ah, Y);`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

For more information see “Barseries Property Descriptions” on page 1-478.

Example: `bar(Y, 'EdgeColor', 'g')`

‘BarLayout’ - Arrangement of bars

grouped (default) | stacked

Arrangement of bars, specified as the comma-separated pair consisting of 'BarLayout' and one of these values:

- **grouped** — Display m groups of n vertical bars, where m is the number of rows and n is the number of columns in the input argument Y . The group contains one bar per column in Y .
- **stacked** — Display one bar for each row in the input argument Y . The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

‘BaseValue’ - Base line location

0 (default) | scalar

Base line location, specified as the comma-separated pair consisting of 'BaseValue' and the value along the y -axis (vertical bars) or x -axis (horizontal bars) at which MATLAB draws the baseline.

‘BarWidth’ - Relative width of bars

0.8 (default) | scalar

Relative bar width, specified as the comma-separated pair consisting of 'BarWidth' and a value relative to width and spacing. `BarWidth` controls the separation of bars within a group. By default, the bars within a group have a slight separation. A value of 1 makes bars touch with no space. A value greater than 1 makes the bars overlap.

‘EdgeColor’ - Color of bar edges

[0,0,0] (default) | none | ColorSpec

Color of bar edges, specified as the comma-separated pair consisting of 'EdgeColor' and a three-element RGB vector, or one of the MATLAB predefined color specifier names.

'FaceColor' - Color of bars

flat (default) | none | ColorSpec

Color of bars, specified as the comma-separated pair consisting of 'FaceColor' and one of these values:

- flat — Use the figure colormap to determine the color of the bars.
- ColorSpec — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all bars.
- none — Do not draw faces. Note that MATLAB draws EdgeColor independently of FaceColor.

'LineStyle' - Line style of bar edges

— (default) | - | -- | : | -. | none

Line style of bar edges, specified as the comma-separated pair consisting of 'LineStyle' and one of the predefined line style strings.

'LineWidth' - Width of bar edges

0.5 points (default) | scalar width specified in points

Width of bar edges, specified as the comma-separated pair consisting of 'LineWidth' and a scalar value representing the line width in points.

Output Arguments

h - Handle to barseries objects

array of one or more handles

Handle to barseries objects, returned as an array of one or more handles.

Examples

Single Data Series

Use the bar function to plot vector data.

```
y = [75.995,91.972,105.711,123.203,131.669,...  
     150.697,179.323,203.212,226.505,249.633,281.422];
```

```
figure;  
bar(y);
```

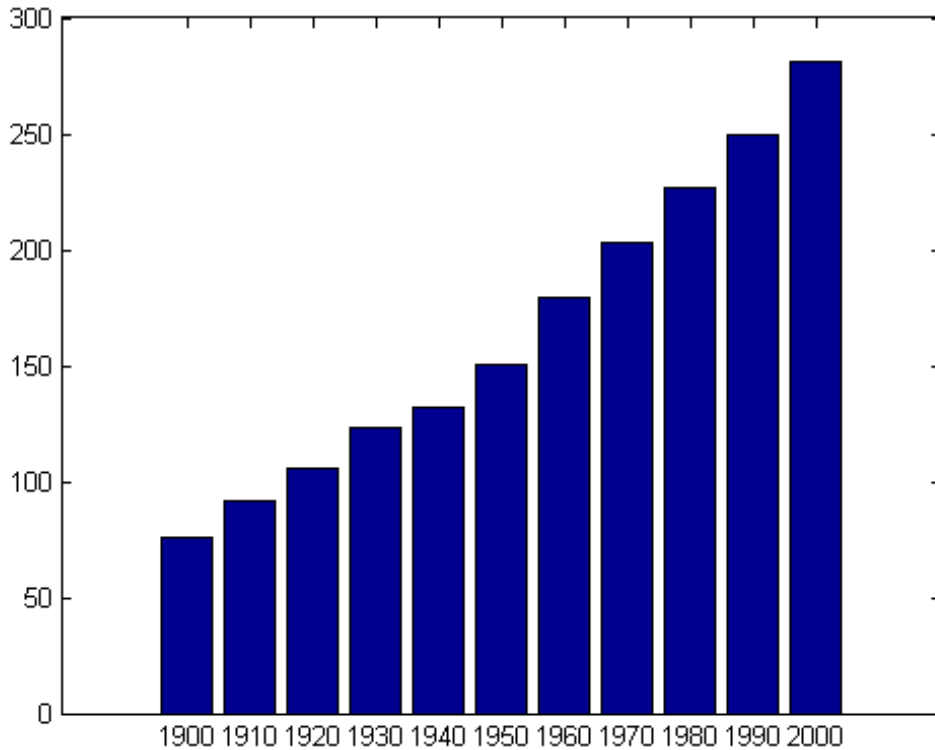

X-Axis Tick Labels

Specify the numeric values of the *x*-axis tick labels.

```
x = 1900:10:2000;  
y = [75.995,91.972,105.711,123.203,131.669,...  
     150.697,179.323,203.212,226.505,249.633,281.422];
```

bar

```
figure;  
bar(x,y);
```

Plot the y -values at each x -value. Notice that the `length(x)` and `length(y)` have to be same.

Bar Width

Set width of each bar to 40 percent of the total space available for each bar.

```
y = [75.995,91.972,105.711,123.203,131.669,...  
     150.697,179.323,203.212,226.505,249.633,281.422];  
figure;  
bar(y,0.4);
```

Bar Graph Styles

Create a figure with four subplots containing bar graphs. In each subplot, apply a different style to the bar graph.

bar

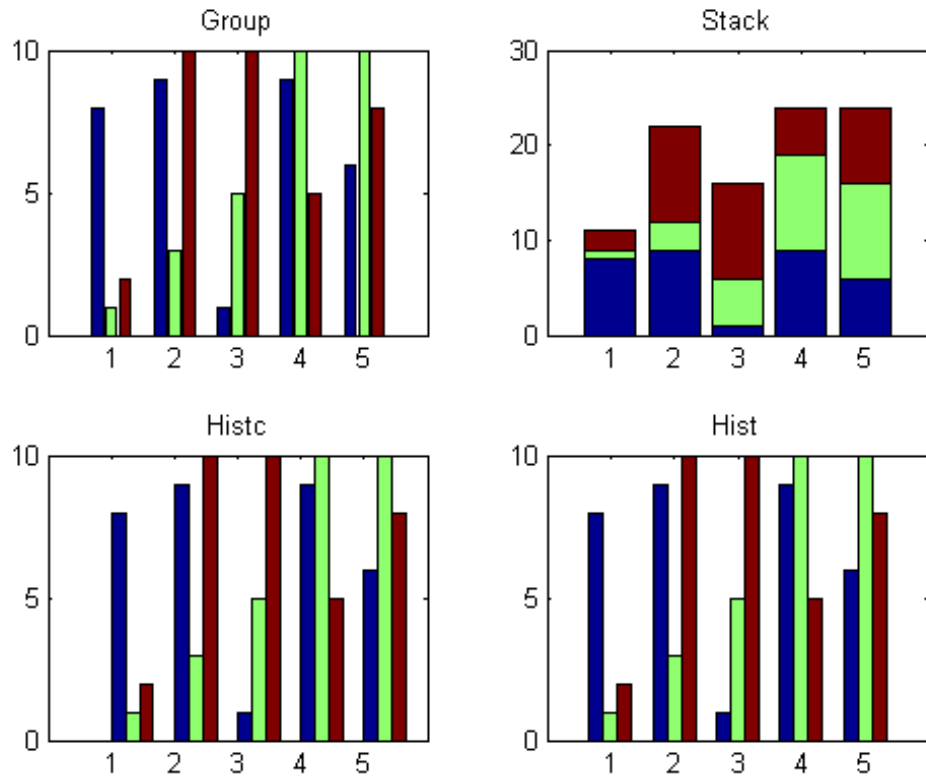

```
Y = round(rand(5,3)*10);

figure;
subplot(2,2,1);
bar(Y, 'grouped');
title('Group')

subplot(2,2,2);
bar(Y, 'stacked');
title('Stack')

subplot(2,2,3);
bar(Y, 'histc');
title('Histic')

subplot(2,2,4);
bar(Y, 'hist');
title('Hist')
```

Specify Axes

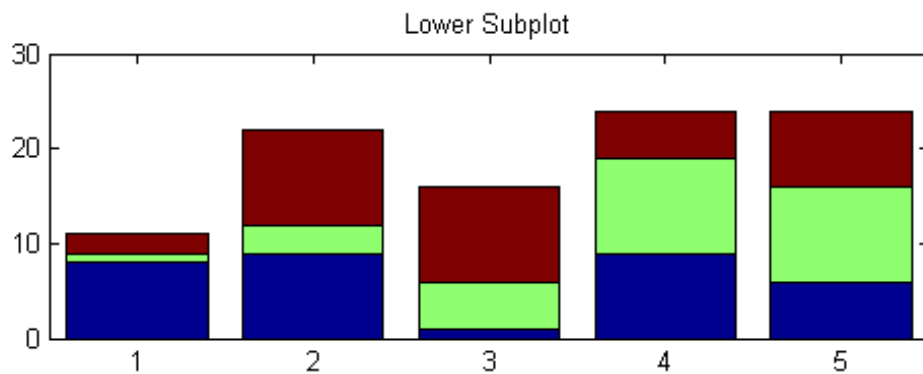

Specify the axes for the bar graph by passing an axes handle to `bar`.

```
rng(0,'twister'); % initialize random number generator
Y = round(rand(5,3)*10);
```

```
figure;
ax = subplot(2,1,2);
bar(ax,Y,'stacked');
```

bar

```
title('Lower Subplot')
```

Bar Color

Specify a red color for the bar graph.

```
y = [75.995,91.972,105.711,123.203,131.669,...  
      150.697,179.323,203.212,226.505,249.633,281.422];  
figure;  
bar(y,'r');
```

Bar Face and Edge Color

Specify green bars and use an RGB color specification for the bar edge color.

```
y = [75.995,91.972,105.711,123.203,131.669,...  
      150.697,179.323,203.212,226.505,249.633,281.422];  
figure;  
bar(y, 'g', 'EdgeColor', [1,0.5,0.5]);
```

bar

Bar Graph of 2-D Array

Plot a 6-by-3 array as six groups with three bars each.

```
c = load('count.dat');  
Y = c(1:6,:);  
figure;  
bar(Y);
```

Emphasize Subset of Data

Set appearance of one column of data.

Set `LineWidth` and `EdgeColor` for the bars representing the second column in the data array `y`. Pass the handles returned by `bar` to the `set` function to set the barseries properties.

```
c = load('count.dat');  
Y = c(1:6,:);
```

bar

```
figure
hArray = bar(Y);
set(hArray(2),'LineWidth',2,'EdgeColor','red');
```

barh

Purpose

Plot bar graph horizontally

Syntax

```
barh(Y)
barh(X,Y)
barh(...,width)
barh(...,'style')
barh(...,'bar_color')
barh(...,'PropertyName',PropertyValue,...)
barh(axes_handle,...)
h = barh(...)
```

Description

A barh graph displays the values in a vector or matrix as horizontal bars.

`barh(Y)` draws one horizontal bar for each element in `Y`. If `Y` is a matrix, `barh` groups the bars produced by the elements in each row. The `x`-axis scale ranges from 1 up to `length(Y)` when `Y` is a vector, and 1 to `size(Y,1)`, which is the number of rows, when `Y` is a matrix. The default is to assign an appropriate progression of tick values according to the data. If you want the `x`-axis scale to end exactly at the last bar, set the axis limits as,

```
set(gca,'XLim',[1 length(Y)])
```

`barh(X,Y)` draws a bar for each element in `Y` at locations specified in `x`, where `X` is a vector defining the `x`-axis intervals for the vertical bars. The `x`-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `barh` groups the elements of each row in `Y` at corresponding locations in `X`.

`barh(...,width)` sets the relative bar width and controls the separation of bars within a group. The default `width` is 0.8, so if you do not specify `X`, the bars within a group have a slight separation. If

width is 1, the bars within a group touch one another. The value of width must be a scalar.

`barh(..., 'style')` specifies the style of the bars. `'style'` is `'grouped'` or `'stacked'`. Default mode of display is `'grouped'`.

- `'grouped'` displays m groups of n vertical bars, where m is the number of rows and n is the number of columns in Y . The group contains one bar per column in Y .
- `'stacked'` displays one bar for each row in Y . The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.
- `'histc'` displays the graph in histogram format, in which bars touch one another.
- `'hist'` also displays the graph in histogram format, but centers each bar over the x -ticks, rather than making bars span x -ticks as the `histc` option does.

Note When you use either the `hist` or `histc` option, you cannot also use parameter/value syntax. These two options create graphic objects that are patches rather than barseries.

`barh(..., 'bar_color')` displays all bars using the color specified by the single-letter abbreviation `'r'`, `'g'`, `'b'`, `'c'`, `'m'`, `'y'`, `'k'`, or `'w'`.

`barh(..., 'PropertyName', PropertyValue, ...)` sets the named property or properties to the specified values. You cannot specify properties when `hist` or `histc` options are used. See the barseries property descriptions for information on what properties you can set.

`barh(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

barh

`h = barh(...)` returns a vector of handles to `barseries` graphics objects, one for each created. When `Y` is a matrix, `barh` creates one `barseries` graphics object per column in `Y`.

Barseries Objects

Creating a bar graph of an m -by- n matrix creates m groups of n `barseries` objects. Each `barseries` object contains the data for corresponding x values of each bar group (as indicated by the coloring of the bars).

Examples

Horizontal Bar Graph of Single Data Series

Create a horizontal bar graph of vector data.

```
y = [57,91,105,123,131,150,...  
     170,203,226.5,249,281.4];  
figure;  
barh(y);
```

`barh` draws one horizontal bar for each element in `y`.

Specify Width for Horizontal Bar Graph

Specify the bar width to 0.4.

```
y = [57,91,105,123,131,150,...  
      170,203,226.5,249,281.4];
```

```
figure;
```

barh

```
width = 0.4;  
barh(y,width);
```

Specify Style for Horizontal Bar Graph

Create a figure with four subplots. In each subplot, create a horizontal bar graph using a different style option for each graph.

```
x = [2,4];  
y = [1,2,3,4;...]
```

```
    5,6,7,8];

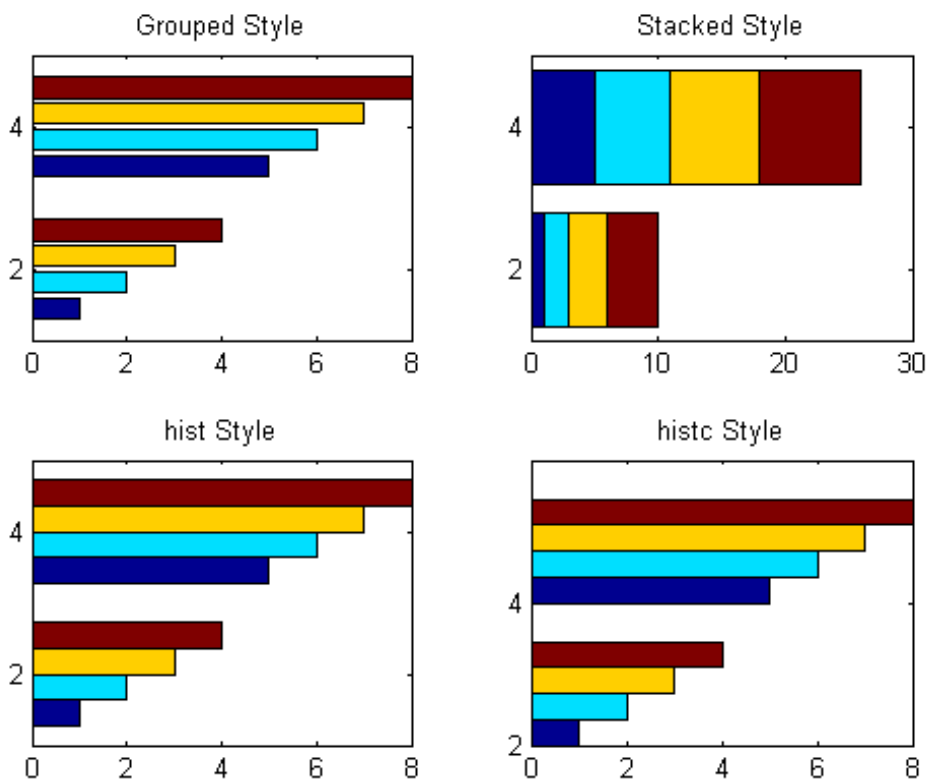

figure;
subplot(2,2,1);
barh(x,y,'grouped'); % groups by row
title('Grouped Style')

subplot(2,2,2);
barh(x,y,'stacked'); % stacks values in each row together
title('Stacked Style')

subplot(2,2,3);
barh(x,y,'hist'); % centers bars over x values
title('hist Style')

subplot(2,2,4);
barh(x,y,'histc'); % spans bars over x values
title('histc Style')
```

barh

Specify Color for Horizontal Bar Graph

Create a horizontal bar graph and change the color of the bars to red.

```
y = [57,91,105,123,131,150,...  
      170,203,226.5,249,281.4];  
figure  
barh(y, 'r')
```

Specify Bar Properties Using Name-Value Pairs

Create a horizontal bar graph and set the line width to 2. Use RGB triplets to set the face color and edge color for the bars.

```
y = [57,91,105,123,131,150,...  
      170,203,226.5,249,281.4];  
  
figure  
barh(y, 'FaceColor', [0,0.5,0.5], ...
```

barh

```
'EdgeColor',[0,0,0.9],...  
'LineWidth',2)
```

Specify Horizontal Bar Locations

Define x and y as vectors of data.

```
x = 1900:10:2000;  
y = [57,91,105,123,131,150,...  
     170,203,226.5,249,281.4];
```

Create a horizontal bar graph of the data in `y`. Use `x` to specify the bar locations along the `y`-axis.

```
figure  
barh(x,y)
```

Horizontal Bar Graph of Matrix Data

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `y` as the first six rows of `count`.

```
load count.dat;  
y = count(1:6,:);
```

Create a horizontal bar graph of matrix `y`.

```
figure;  
barh(y);
```

By default, `barh` groups the bars by row.

Specify Bar Properties for Multiple Barseries Objects

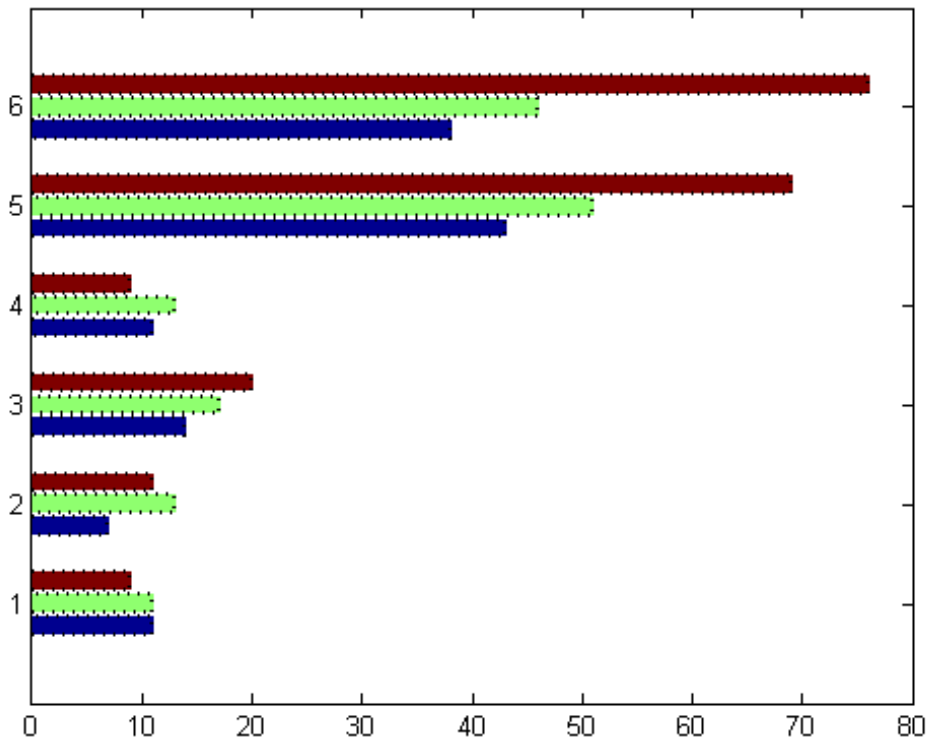

Load the data set, `count.dat`, which returns a three-column array, `count`. Store `y` as the first six rows of `count`.

```
load count.dat;  
y = count(1:6,:);
```

barh

Create a horizontal bar graph of `y` and return the handles to the three barseries objects. Set the line width and line style for all three sets of bars.

```
figure  
h = barh(y,'LineWidth',2,...  
         'LineStyle',':');
```

Use the barseries object handles to set Name-Value pairs for a specific barseries object. Set the face color for the first barseries object to cyan. Set the face color for the last barseries object to an RGB color value.

```
set(h(1), 'FaceColor', 'c')  
set(h(3), 'FaceColor', [0,0.5,0.5])
```

Change Baseline Value for Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `y` as the first six rows of `count`.

```
load count.dat;  
y = count(1:6,:);
```

Create a horizontal bar graph of `y` and set the basevalue to 25.

```
figure  
barh(y, 'BaseValue', 25);
```

How To

- “Modify Baseline of Bar Graph”
- “Overlay Bar Graphs”
- “Overlay Line Plot on Bar Graph Using Two y-Axes”

bar3

Purpose

Plot 3-D bar graph

Syntax

```
bar3(Y)
bar3(x,Y)
bar3(...,width)
bar3(...,'style')
bar3(...,LineStyle)
bar3(axes_handle,...)
h = bar3(...)
```

Description

`bar3` draws a three-dimensional bar graph.

`bar3(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the `x`-axis scale ranges from 1 to `length(Y)`. When `Y` is a matrix, the `x`-axis scale ranges from 1 to `size(Y,1)` and the elements in each row are grouped together.

`bar3(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the `y`-axis intervals for vertical bars. The `x`-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3(...,width)` sets the width of the bars and controls the separation of bars within a group. The default `width` is 0.8, so if you do not specify `x`, bars within a group have a slight separation. If `width` is 1, the bars within a group touch one another.

`bar3(...,'style')` specifies the style of the bars. `'style'` is `'detached'`, `'grouped'`, or `'stacked'`. Default mode of display is `'detached'`.

- 'detached' displays the elements of each row in Y as separate blocks behind one another in the x direction.
- 'grouped' displays n groups of m vertical bars, where n is the number of rows and m is the number of columns in Y . The group contains one bar per column in Y .
- 'stacked' displays one bar for each row in Y . The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3(...,LineStyle)` displays all bars using the color specified by `LineStyle`.

`bar3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3(...)` returns a vector of handles to surface objects, one for each created. When Y is a matrix, `bar3` creates one surface object per column in Y .

Examples

Create 3-D Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store Y as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of Y . By default, the style is `detached`.

```
figure
bar3(Y)
title('Detached Style')
```

Specify Bar Width for 3-D Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat  
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y` and set the bar width to 0.5.

```
width = 0.5;  
  
figure  
bar3(Y,width)  
title('Bar Width of 0.5')
```

3-D Bar Graph with Grouped Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

bar3

```
load count.dat  
Y = count(1:10,:);
```

Create a 3-D bar graph of Y. Group the elements in each row of Y by specifying the style option as grouped.

```
figure  
bar3(Y, 'grouped')  
title('Grouped Style')
```

3-D Bar Graph with Stacked Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y`. Stack the elements in each row of `Y` by specifying the style option as `stacked`.

```
figure
bar3(Y,'stacked')
title('Stacked Style')
```

bar3

See Also

`bar` | `barh` | `bar3h` | `LineStyle`

How To

- “Color 3-D Bars by Height”

Purpose Plot horizontal 3-D bar graph

Syntax

```
bar3h(Y)
bar3h(x,Y)
bar3h(...,width)
bar3h(...,'style')
bar3h(...,LineStyle)
bar3h(axes_handle,...)
h = bar3h(...)
```

Description bar3h draws three-dimensional horizontal bar charts.

bar3h(Y) draws a three-dimensional bar chart, where each element in Y corresponds to one bar. When Y is a vector, the y-axis scale ranges from 1 to length(Y). When Y is a matrix, the y-axis scale ranges from 1 to size(Y,1) and the elements in each row are grouped together.

bar3h(x,Y) draws a bar chart of the elements in Y at the locations specified in x, where x is a vector defining the y-axis intervals for horizontal bars. The x-values can be nonmonotonic, but cannot contain duplicate values. If Y is a matrix, bar3 clusters elements from the same row in Y at locations corresponding to an element in x. Values of elements in each row are grouped together.

bar3h(...,width) sets the width of the bars and controls the separation of bars within a group. The default width is 0.8, so if you do not specify x, bars within a group have a slight separation. If width is 1, the bars within a group touch one another.

bar3h(...,'style') specifies the style of the bars. 'style' is 'detached', 'grouped', or 'stacked'. Default mode of display is 'detached'.

- 'detached' displays the elements of each row in Y as separate blocks behind one another in the y direction.

bar3h

- 'grouped' displays n groups of m vertical bars, where n is the number of rows and m is the number of columns in Y . The group contains one bar per column in Y .
- 'stacked' displays one bar for each row in Y . The bar length is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3h(...,LineStyle)` displays all bars using the color specified by `LineStyle`.

`bar3h(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3h(...)` returns a vector of handles to surface objects, one for each created. When Y is a matrix, `bar3h` creates one surface object per column in Y .

Examples

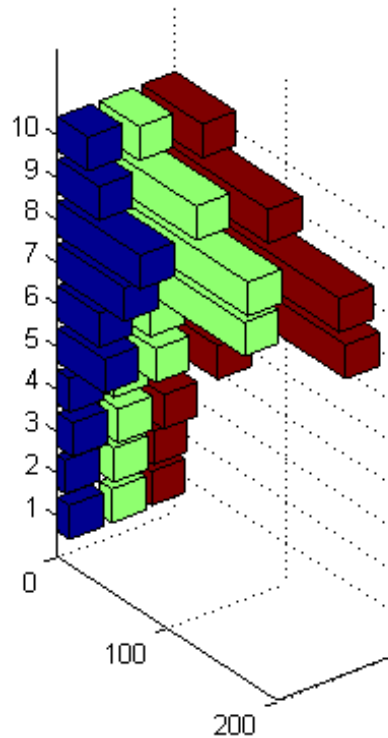

Create 3-D Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store Y as the first ten rows of `count`.

```
load count.dat;  
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of Y . By default, the style is `detached`.

```
figure  
bar3h(Y)
```

Specify Bar Width for 3-D Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat;  
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of `Y` and set the bar width to 0.5.

bar3h

```
width = 0.5;  
  
figure  
bar3h(Y,width)  
title('Width of 0.5')
```

3-D Horizontal Bar Graph with Grouped Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat;  
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of Y and specify the style option as grouped.

```
figure  
bar3h(Y,'grouped')  
title('Grouped Style Option')
```

3-D Horizontal Bar Graph with Stacked Option

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat;  
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of `Y` and specify the style option as `stacked`.

```
figure  
bar3h(Y, 'stacked')  
title('Stacked Style Option')
```

Barseries Properties

Purpose Define barseries properties

Modifying Properties You can set and query graphics object properties using the set and get commands or the Property Editor (propertyeditor).

Note that you cannot define default properties for barseries objects.

See “Plot Objects” for more information on barseries objects.

Barseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

Annotation

hg.Annotation object (read-only)

Control the display of barseries objects in legends. Specifies whether this barseries object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the barseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the barseries object in a legend as one entry, but not its children objects
off	Do not include the barseries or its children in a legend (default)
children	Include only the children of the barseries as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

Using the IconDisplayStyle Property

See “Control Legend Content” for more information and examples.

`BarLayout`
`{grouped} | stacked`

Specify grouped or stacked bars.

- `grouped` — Display m groups of n vertical bars, where m is the number of rows and n is the number of columns in the input argument Y . The group contains one bar per column in Y .
- `stacked` — Display one bar for each row in the input argument Y . The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`BarWidth`
scalar in range [0 1]

Width of individual bars. `BarWidth` specifies the relative bar width and controls the separation of bars within a group. The default is 0.8, so if you do not specify `x`, the bars within a group have a slight separation. If `BarWidth` is 1, the bars within a group touch one another.

`BaseLine`
handle

Barseries Properties

Handle of the baseline line object. Handle of the line object used as the baseline. You can set the properties of this line using its handle.

Create a bar graph, obtain the handle of the baseline from the barseries object, and then set line properties that make the baseline a dashed, red line:

```
bar_handle = bar(randn(10,1));  
baseline_handle = get(bar_handle,'BaseLine');  
set(baseline_handle,'LineStyle','--','Color','red')
```

BaseValue
double: y-axis value

Baseline location. You can specify the value along the y -axis (vertical bars) or x -axis (horizontal bars) at which the MATLAB software draws the baseline. The default is 0.

BeingDeleted
on | {off} (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the **BeingDeleted** property to **on** when the object's delete function callback is called (see the **DeleteFcn** property). It remains set to **on** while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's **BeingDeleted** property before acting.

BusyAction
cancel | {queue}

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

Barseries Properties

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

For information on the syntax of callback functions, see `Function Handle Callbacks`.

`Children`
array of graphics object handles

Children of the barseries object. The handle of a patch object that is the child of this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

Clipping

```
{on} | off
```

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

CreateFcn

```
function handle | cell array containing function handle and  
additional arguments | string (not recommended)
```

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

Barseries Properties

DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

See the `BeingDeleted` property for related information.

DisplayName

string

String used by legend. The `legend` function uses the `DisplayName` property to label the barseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

EdgeColor

`{[0 0 0]} | none | ColorSpec`

Color of line separating filled areas. You can set the color of the edges of filled areas to a three-element RGB vector or one of the MATLAB predefined names, including the string `none`. The default value is `[0 0 0]` (black). See the `ColorSpec` reference page for more information on specifying color.

EraseMode

`{normal} | none | xor | background`

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However,

Barseries Properties

the object's color depends on the color of whatever is beneath it on the display.

- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`

`{flat}` | `none` | `ColorSpec`

Color of filled areas.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas.
- `none` — Do not draw faces. Note that MATLAB draws `EdgeColor` independently of `FaceColor`.

- `flat` — The object uses the figure colormap to determine the color of the filled areas.

HandleVisibility

`{on} | callback | off`

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Barseries Properties

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

HitTest

`{on}` | `off`

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the bar graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

HitTestArea

`on` | `{off}`

Select barseries object on bars or area of extent. This property enables you to select barseries objects in two ways:

- Select by clicking bars (default).

- Select by clicking anywhere in the extent of the bar graph.

When `HitTestArea` is off, you must click the bars to select the `barseries` object. When `HitTestArea` is on, you can select the `barseries` object by clicking anywhere within the extent of the bar graph (that is, anywhere within a rectangle that encloses all the bars).

`Interruptible`
off | {on}

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
 - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
 - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

Barseries Properties

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the gca or(gcf) command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

Line style of barseries object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $1/72$ inch. The default is 0.5 points.

Parent

handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

Selected

on | {off}

Object selection state. When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

SelectionHighlight

{on} | off

Object highlighted when selected.

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

ShowBaseLine

{on} | off

Barseries Properties

Turn baseline display on or off. This property determines whether bar plots display a baseline from which the bars are drawn. By default, the baseline is displayed.

Tag

string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create a barseries object and set the Tag property:

```
t = bar(Y, 'Tag', 'bar1')
```

To access the barseries object, use `findobj` to find the barseries object's handle. The following statement changes the `FaceColor` property of the object whose Tag is bar1.

```
set(findobj('Tag', 'bar1'), 'FaceColor', 'red')
```

Type

string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For barseries objects, Type is 'hggroup'.

The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

UIContextMenu

handle of uicontextmenu object

Associate context menu with object. Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

UserData
array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

Visible
{on} | off

Visibility of object and its children.

- **on** — Object and all children of the object are visible unless the child object's **Visible** property is **off**.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

XData
array

Location of bars. The *x*-axis intervals for the vertical bars or *y*-axis intervals for horizontal bars (as specified by the *X* input argument). If *YData* is a vector, *XData* must be the same size. If *YData* is a matrix, the length of *XData* must be equal to the number of rows in *YData*.

XDataMode
{auto} | manual

Use automatic or user-specified x-axis values. If you specify *XData* (by setting the *XData* property or specifying the *X* input

Barseries Properties

argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`

MATLAB variable, as a string

Link XData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`

scalar | vector | matrix

Bar plot data. `YData` contains the data plotted as bars (the *Y* input argument). Each value in `YData` is represented by a bar in the bar graph. If `XYData` is a matrix, the `bar` function creates a "group"

or a "stack" of bars for each column in the matrix. See the bar reference page for examples of grouped and stacked bar graphs.

The input argument *Y* in the bar function calling syntax assigns values to *YData*.

YDataSource

MATLAB variable, as a string

Link YData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the *YData*. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's *YDataSource* does not change the object's *YData* values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

TriRep.baryToCart

Purpose (Will be removed) Convert point coordinates from barycentric to Cartesian

Note `baryToCart(TriRep)` will be removed in a future release. Use `barycentricToCartesian(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax `XC = baryToCart(TR, SI, B)`

Description `XC = baryToCart(TR, SI, B)` returns the Cartesian coordinates `XC` of each point in `B` that represents the barycentric coordinates with respect to its associated simplex `SI`.

Input Arguments

TR	Triangulation representation.
SI	Column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code>
B	<code>B</code> is a matrix that represents the barycentric coordinates of the points to convert with respect to the simplices <code>SI</code> . <code>B</code> is of size <code>m-by-k</code> , where <code>m = length(SI)</code> , the number of points to convert, and <code>k</code> is the number of vertices per simplex.

Output Arguments

XC	Matrix of cartesian coordinates of the converted points. <code>XC</code> is of size <code>m-by-n</code> , where <code>n</code> is the dimension of the space where the triangulation resides. That is, the Cartesian coordinates of the point <code>B(j)</code> with respect to simplex <code>SI(j)</code> is <code>XC(j)</code> .
----	--

Definitions A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(dt); hold on;
plot(cc(:,1), cc(:,2), '*r'); hold off;
axis equal;
```

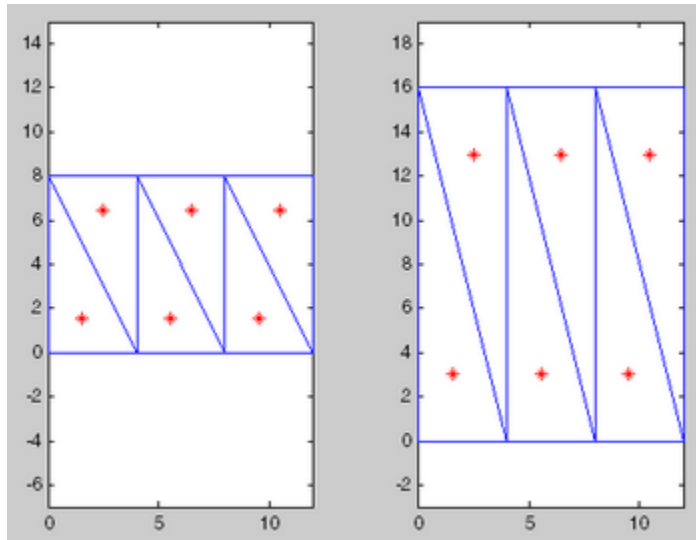

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);
y = [0 0 0 0 16 16 16 16]';
tr = TriRep(tri,x,y)
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(tr); hold on;
plot(xc(:,1), xc(:,2), '*r'); hold off;
axis equal;
```

TriRep.baryToCart

Purpose Convert base N number string to decimal number

Syntax `d = base2dec('strn', base)`

Description `d = base2dec('strn', base)` converts the string number *strn* of the specified base into its decimal (base 10) equivalent. *base* must be an integer between 2 and 36. If *'strn'* is a character array, each row is interpreted as a string in the specified base.

Examples The expression `base2dec('212',3)` converts 212_3 to decimal, returning 23.

See Also `dec2base`

beep

Purpose Produce operating system beep sound

Syntax

```
beep
beep on
beep off

status = beep
```

Description beep produces your computer's default beep sound, if it is enabled.

beep on turns the beep on.

beep off turns the beep off.

status = beep returns the current beep mode (on or off).

Examples **Produce Beep Sound**

Produce your system's default beep sound after a period of silence.

Pause for 5 seconds of silence, and then produce your system's default beep sound.

```
pause(5)
beep
```

Tips

- If you have configured your system not to produce any sound, then beep is silent.
- beep produces the operating system's default beep sound. To produce a sound and specify its pitch and duration in MATLAB, use the sound function.

See Also sound

Purpose	Initiate asynchronous .NET delegate call
Syntax	<code>result = BeginInvoke(arg1, ..., argN, callback, object)</code>
Description	<code>result = BeginInvoke(arg1, ..., argN, callback, object)</code> initiates asynchronous call to a .NET delegate. You must call <code>EndInvoke</code> to complete the asynchronous call.
Input Arguments	<p>arg1, ..., argN Input arguments for delegate. The type and number of arguments must agree with the delegate signature.</p> <p>callback .NET <code>System.AsyncCallback</code> delegate, or [] null value.</p> <p>object User-defined object, or [] null value.</p>
Output Arguments	<p>result .NET <code>System.IAsyncResult</code> object. Used to monitor the progress of the asynchronous call. Input argument to <code>EndInvoke</code>.</p>
See Also	<code>EndInvoke</code>

Related Links	<ul style="list-style-type: none">• MSDN® Calling Synchronous Methods Asynchronously

bench

Purpose MATLAB benchmark

Syntax
bench
bench(N)
bench(0)
t = bench(N)

Description bench times six different MATLAB tasks and compares the execution speed with the speed of several other computers. The six tasks are:

Test	Description	Performance Factors
LU	Perform LU of a full matrix	Floating-point, regular memory access
FFT	Perform FFT of a full vector	Floating-point, irregular memory access
ODE	Solve van der Pol equation with ODE45	Data structures and MATLAB function files
Sparse	Solve a symmetric sparse linear system	Mixed integer and floating-point
2-D	Plot Bernstein polynomial graph	2-D line drawing graphics
3-D	Display animated L-shape membrane logo	3-D animated OpenGL graphics

A final bar chart shows speed, which is inversely proportional to time. The longer bars represent faster machines, and the shorter bars represent the slower ones.

bench(N) runs each of the six tasks N times.

bench(0) just displays the results from other machines.

t = bench(N) returns an N-by-6 array with the execution times.

Tips

Note A benchmark is intended to compare performance of one particular version of MATLAB on different machines. It does not offer direct comparisons between different versions of MATLAB as tasks and problem sizes change from version to version.

The LU and FFT tasks involve large matrices and long vectors. The 2-D and 3-D tasks measure graphics performance, including software or hardware support for OpenGL. The command

```
opengl info
```

describes the OpenGL support available on a particular machine.

Fluctuations of five or ten percent in the measured times of repeated runs on a single machine are not uncommon. Your own mileage may vary.

besselh

Purpose Bessel function of third kind (Hankel function)

Syntax
H = besselh(nu,K,Z)
H = besselh(nu,Z)
H = besselh(nu,K,Z,1)

Definitions The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + (z^2 - \nu^2) y = 0,$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*. $J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν . $Y_\nu(z)$ is a second solution of Bessel's equation—linearly independent of $J_\nu(z)$ —defined by

$$Y_\nu(z) = \frac{J_\nu(z) \cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}.$$

The relationship between the Hankel and Bessel functions is

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z),$$

where $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`.

Description H = besselh(nu,K,Z) computes the Hankel function $H_\nu^{(K)}(z)$ where K = 1 or 2, for each element of the complex array Z. If nu and Z are arrays of the same size, the result is also that size. If either input is a scalar, besselh expands it to the other input's size.

H = besselh(nu,Z) uses K = 1.

H = besselh(nu,K,Z,1) scales $H_\nu^{(K)}(z)$ by $\exp(-i*Z)$ if K = 1, and by $\exp(+i*Z)$ if K = 2.

Examples**Modulus and Phase of Hankel Function**

This example generates the contour plots of the modulus and phase of the Hankel function $H_0^{(1)}(z)$ shown on page 359 of Abramowitz and Stegun, *Handbook of Mathematical Functions* [1].

Create a grid of values for the domain.

```
[X,Y] = meshgrid(-4:0.025:2,-1.5:0.025:1.5);
```

Calculate the Hankel function over this domain and generate the modulus contour plot.

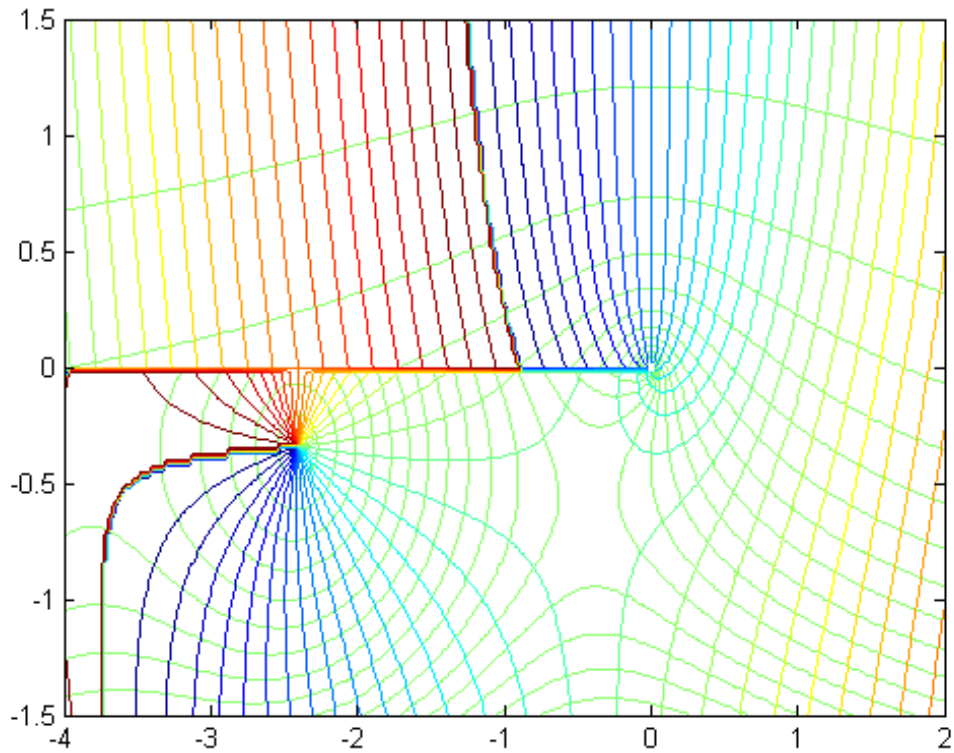

```
H = besselh(0,1,X+1i*Y);  
contour(X,Y,abs(H),0:0.2:3.2), hold on
```

besselh

In the same figure, add the contour plot of the phase.

```
contour(X,Y,(180/pi)*angle(H),-180:10:180); hold off
```

besselj | bessely | besseli | besselk

besseli

Purpose Modified Bessel function of first kind

Syntax
`I = besseli(nu,Z)`
`I = besseli(nu,Z,1)`

Definitions The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} - (z^2 + \nu^2) y = 0,$$

where ν is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

$I_\nu(z)$ and $I_{-\nu}(z)$ form a fundamental set of solutions of the modified Bessel's equation. $I_\nu(z)$ is defined by

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{(k=0)}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k! \Gamma(\nu + k + 1)},$$

where $\Gamma(a)$ is the gamma function.

$K_\nu(z)$ is a second solution, independent of $I_\nu(z)$. It can be computed using `besselk`.

Description `I = besseli(nu,Z)` computes the modified Bessel function of the first kind, $I_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`I = besseli(nu,Z,1)` computes `besseli(nu,Z) .* exp(-abs(real(Z)))`.

Examples**Vector of Function Values**

Create a column vector of domain values.

```
z = (0:0.2:1)';
```

Calculate the function values using `besseli` with `nu = 1`.

```
format long

besselj

Purpose Bessel function of first kind

Syntax
`J = besselj(nu,Z)`
`J = besselj(nu,Z,1)`

Definitions The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + (z^2 - \nu^2) y = 0,$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

$J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν . $J_\nu(z)$ is defined by

$$J_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{(k=0)}^{\infty} \frac{\left(\frac{-z^2}{4}\right)^k}{k! \Gamma(\nu + k + 1)}$$

where $\Gamma(a)$ is the gamma function.

$Y_\nu(z)$ is a second solution of Bessel's equation that is linearly independent of $J_\nu(z)$. It can be computed using `bessely`.

Description `J = besselj(nu,Z)` computes the Bessel function of the first kind, $J_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`J = besselj(nu,Z,1)` computes `besselj(nu,Z) .* exp(-abs(imag(Z)))`.

Tips

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z)$$

where $H_\nu^{(K)}(z)$ is `besselh`, $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

Examples**Vector of Function Values**

Create a column vector of domain values.

See Also

`airy` | `besselh` | `besseli` | `besselj` | `bessely`

Purpose Bessel function of second kind

Syntax
`Y = bessely(nu,Z)`
`Y = bessely(nu,Z,1)`

Definitions The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + (z^2 - \nu^2) y = 0,$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

A solution $Y_\nu(z)$ of the second kind can be expressed as

$$Y_\nu(z) = \frac{J_\nu(z) \cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}$$

where $J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν

$$J_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(-\frac{z^2}{4}\right)^k}{k! \Gamma(\nu + k + 1)},$$

and $\Gamma(a)$ is the gamma function. $Y_\nu(z)$ is linearly independent of $J_\nu(z)$.

$J_\nu(z)$ can be computed using `besselj`.

Description

`Y = bessely(nu,Z)` computes Bessel functions of the second kind, $Y_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

bessely

```
Y = bessely(nu,Z,1) computes  
bessely(nu,Z).*exp(-abs(imag(Z))).
```

Tips

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_v^{(1)}(z) = J_v(z) + iY_v(z)$$

$$H_v^{(2)}(z) = J_v(z) - iY_v(z),$$

where $H_v^{(K)}(z)$ is `besselh`, $J_v(z)$ is `besselj`, and $Y_v(z)$ is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

Examples

Vector of Function Values

Create a column vector of domain values.

```
z = (0:0.2:1)';
```

Calculate the function values using `bessely` with `nu = 1`.

Purpose Beta function

Syntax B = beta(Z,W)

Definitions The beta function is

$$B(z,w) = \int_0^1 t^{z-1} (1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

where $\Gamma(z)$ is the gamma function.

Description B = beta(Z,W) computes the beta function for corresponding elements of arrays Z and W. The arrays must be real and nonnegative. They must be the same size, or either can be scalar.

Examples In this example, which uses integer arguments,

```
beta(n,3)
= (n-1)!*2!/(n+2)!
= 2/(n*(n+1)*(n+2))
```

is the ratio of fairly small integers, and the rational format is able to recover the exact result.

```
format rat
beta((0:10)',3)
```

```
ans =

    1/0
    1/3
    1/12
    1/30
    1/60
    1/105
    1/168
    1/252

Algorithms

`beta(z,w) = exp(gammaIn(z)+gammaIn(w)-gammaIn(z+w))`

See Also

`betainc` | `betaIn` | `gammaIn`

betainc

Purpose Incomplete beta function

Syntax
`I = betainc(X,Z,W)`
`I = betainc(X,Z,W,tail)`

Definitions The incomplete beta function is

$$I_x(z,w) = \frac{1}{B(z,w)} \int_0^x t^{z-1} (1-t)^{w-1} dt$$

where $B(z,w)$, the beta function, is defined as

$$B(z,w) = \int_0^1 t^{z-1} (1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

and $\Gamma(z)$ is the gamma function.

Description `I = betainc(X,Z,W)` computes the incomplete beta function for corresponding elements of the arrays `X`, `Z`, and `W`. The elements of `X` must be in the closed interval $[0,1]$. The arrays `Z` and `W` must be nonnegative and real. All arrays must be the same size, or any of them can be scalar.

`I = betainc(X,Z,W,tail)` specifies the tail of the incomplete beta function. Choices are:

'lower' (the default)	Computes the integral from 0 to x
'upper'	Computes the integral from x to 1

These functions are related as follows:

$$1 - \text{betainc}(X,Z,W) = \text{betainc}(X,Z,W, \text{'upper'})$$

Note that especially when the upper tail value is close to 0, it is more accurate to use the 'upper' option than to subtract the 'lower' value from 1.

Examples

```
format long  
betainc(.5, (0:10)', 3)
```

```
ans =  
1.000000000000000

[beta](#) | [betaIn](#)

betaincinv

Purpose Beta inverse cumulative distribution function

Syntax
`x = betaincinv(y,z,w)`
`x = betaincinv(y,z,w,tail)`

Description `x = betaincinv(y,z,w)` computes the inverse incomplete beta function for corresponding elements of `y`, `z`, and `w`, such that `y = betainc(x,z,w)`. The elements of `y` must be in the closed interval `[0,1]`, and those of `z` and `w` must be nonnegative. `y`, `z`, and `w` must all be real and the same size (or any of them can be scalar).

`x = betaincinv(y,z,w,tail)` specifies the tail of the incomplete beta function. Choices are 'lower' (the default) to use the integral from 0 to `x`, or 'upper' to use the integral from `x` to 1. These two choices are related as follows: `betaincinv(y,z,w,'upper') = betaincinv(1-y,z,w,'lower')`. When `y` is close to 0, the 'upper' option provides a way to compute `x` more accurately than by subtracting from `y` from 1.

Definitions The incomplete beta function is defined as

$$I_x(z,w) = \frac{1}{\beta(z,w)} \int_0^x t^{z-1} (1-t)^{w-1} dt$$

`betaincinv` computes the inverse of the incomplete beta function with respect to the integration limit `x` using Newton's method.

Purpose	Logarithm of beta function
Syntax	<code>L = betaIn(Z,W)</code>
Description	<p><code>L = betaIn(Z,W)</code> computes the natural logarithm of the beta function <code>log(beta(Z,W))</code>, for corresponding elements of arrays <code>Z</code> and <code>W</code>, without computing <code>beta(Z,W)</code>. Since the beta function can range over very large or very small values, its logarithm is sometimes more useful.</p> <p><code>Z</code> and <code>W</code> must be real and nonnegative. They must be the same size, or either can be scalar.</p>
Examples	<pre>x = 510 betaIn(x,x) ans = -708.8616</pre> <p><code>-708.8616</code> is slightly less than <code>log(realmin)</code>. Computing <code>beta(x,x)</code> directly would underflow (or be denormal).</p>
Algorithms	<code>betaIn(z,w) = gammaIn(z)+gammaIn(w)-gammaIn(z+w)</code>
See Also	<code>beta</code> <code>betainc</code> <code>gammaIn</code>

Purpose

Biconjugate gradients method

Syntax

```
x = bicg(A,b)
bicg(A,b,tol)
bicg(A,b,tol,maxit)
bicg(A,b,tol,maxit,M)
bicg(A,b,tol,maxit,M1,M2)
bicg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicg(A,b,...)
[x,flag,relres] = bicg(A,b,...)
[x,flag,relres,iter] = bicg(A,b,...)
[x,flag,relres,iter,resvec] = bicg(A,b,...)
```

Description

`x = bicg(A,b)` attempts to solve the system of linear equations $A*x = b$ for x . The n -by- n coefficient matrix A must be square and should be large and sparse. The column vector b must have length n . A can be a function handle, `afun`, such that `afun(x, 'notransp')` returns $A*x$ and `afun(x, 'transp')` returns $A'*x$.

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicg` converges, it displays a message to that effect. If `bicg` fails to converge after the maximum number of iterations or halts for any reason, it prints a warning message that includes the relative residual $\text{norm}(b-A*x)/\text{norm}(b)$ and the iteration number at which the method stopped or failed.

`bicg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicg` uses the default, $1e-6$.

`bicg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicg` uses the default, $\min(n,20)$.

`bicg(A,b,tol,maxit,M)` and `bicg(A,b,tol,maxit,M1,M2)` use the preconditioner M or $M = M1*M2$ and effectively solve the system $\text{inv}(M)*A*x = \text{inv}(M)*b$ for x . If M is `[]` then `bicg` applies

no preconditioner. M can be a function handle `mfun`, such that `mfun(x, 'notransp')` returns $M \backslash x$ and `mfun(x, 'transp')` returns $M' \backslash x$.

`bicg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If x_0 is `[]`, then `bicg` uses the default, an all-zero vector.

`[x,flag] = bicg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>bicg</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>bicg</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner M was ill-conditioned.
3	<code>bicg</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>bicg</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution x returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicg(A,b,...)` also returns the relative residual norm $\|b - A \cdot x\| / \|b\|$. If `flag` is 0, `relres` \leq `tol`.

`[x,flag,relres,iter] = bicg(A,b,...)` also returns the iteration number at which x was computed, where $0 \leq \text{iter} \leq \text{maxit}$.

`[x,flag,relres,iter,resvec] = bicg(A,b,...)` also returns a vector of the residual norms at each iteration including $\|b - A \cdot x_0\|$.

Examples

Using `bicg` with a Matrix Input

This example shows how to use `bicg` with a matrix input. `bicg`. The following code:

```
n = 100;
on = ones(n,1);
```

```
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = bicg(A,b,tol,maxit,M1,M2);
```

displays this message:

```
bicg converged at iteration 9 to a solution with relative
residual 5.3e-009
```

Using bicg with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_bicg` that

- Calls `bicg` with the `@afun` function handle as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_bicg` are available to `afun`.

Place the following into a file called `run_bicg`:

```
function x1 = run_bicg
n = 100;
on = ones(n,1);
b = afun(on,'notransp');
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = bicg(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)           % y = A'*x
    if strcmp(transp_flag,'transp')
        y = 4 * x;
```

```

        y(1:n-1) = y(1:n-1) - 2 * x(2:n);
        y(2:n) = y(2:n) - x(1:n-1);
    elseif strcmp(transp_flag,'notransp') % y = A*x
        y = 4 * x;
        y(2:n) = y(2:n) - 2 * x(1:n-1);
        y(1:n-1) = y(1:n-1) - x(2:n);
    end
end
end
end

```

When you enter

```
x1 = run_bicg;
```

MATLAB software displays the message

```

bicg converged at iteration 9 to a solution with ...
relative residual
5.3e-009

```

Using bicg with a Preconditioner

This example demonstrates the use of a preconditioner.

Load A = west0479, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define b so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12; maxit = 20;
```

Use bicg to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = bicg(A,b,tol,maxit);
```

f10 is 1 because `bicg` does not converge to the requested tolerance $1e-12$ within the requested 20 iterations. In fact, the behavior of `bicg` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicg`.

```
semilogy(0:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = bicg(A,b,tol,maxit,L,U);
```

f11 is 0 because bicg drives the relative residual to $4.1410e-014$ (the value of rr1). The relative residual is less than the prescribed tolerance of $1e-12$ at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of $1e-6$. The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A*x2).

You can follow the progress of bicg by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

bicgstab

Purpose Biconjugate gradients stabilized method

Syntax

```
x = bicgstab(A,b)
bicgstab(A,b,tol)
bicgstab(A,b,tol,maxit)
bicgstab(A,b,tol,maxit,M)
bicgstab(A,b,tol,maxit,M1,M2)
bicgstab(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstab(A,b,...)
[x,flag,relres] = bicgstab(A,b,...)
[x,flag,relres,iter] = bicgstab(A,b,...)
[x,flag,relres,iter,resvec] = bicgstab(A,b,...)
```

Description `x = bicgstab(A,b)` attempts to solve the system of linear equations $A*x=b$ for x . The n -by- n coefficient matrix A must be square and should be large and sparse. The column vector b must have length n . A can be a function handle, `afun`, such that `afun(x)` returns $A*x$.

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicgstab` converges, a message to that effect is displayed. If `bicgstab` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual $\text{norm}(b-A*x)/\text{norm}(b)$ and the iteration number at which the method stopped or failed.

`bicgstab(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicgstab` uses the default, $1e-6$.

`bicgstab(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicgstab` uses the default, $\min(n,20)$.

`bicgstab(A,b,tol,maxit,M)` and `bicgstab(A,b,tol,maxit,M1,M2)` use preconditioner M or $M = M1*M2$ and effectively solve the system $\text{inv}(M)*A*x = \text{inv}(M)*b$ for x . If M is `[]` then `bicgstab` applies no preconditioner. M can be a function handle `mfun`, such that `mfun(x)` returns $M*x$.

`bicgstab(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicgstab` uses the default, an all zero vector.

`[x,flag] = bicgstab(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>bicgstab</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>bicgstab</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>bicgstab</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>bicgstab</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicgstab(A,b,...)` also returns the relative residual $\text{norm}(b-A*x)/\text{norm}(b)$. If `flag` is 0, `relres` \leq `tol`.

`[x,flag,relres,iter] = bicgstab(A,b,...)` also returns the iteration number at which `x` was computed, where $0 \leq \text{iter} \leq \text{maxit}$. `iter` can be an integer + 0.5, indicating convergence halfway through an iteration.

`[x,flag,relres,iter,resvec] = bicgstab(A,b,...)` also returns a vector of the residual norms at each half iteration, including $\text{norm}(b-A*x0)$.

Examples

Using `bicgstab` with a Matrix Input

This example first solves $Ax = b$ by providing `A` and the preconditioner `M1` directly as arguments.

The code:

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = bicgstab(A,b,tol,maxit,M1);
```

displays the message:

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

Using bicgstab with a Function Handle

This example replaces the matrix *A* in the previous example with a handle to a matrix-vector product function *afun*, and the preconditioner *M1* with a handle to a backsolve function *mfun*. The example is contained in a file `run_bicgstab` that

- Calls `bicgstab` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_bicgstab` are available to `afun` and `mfun`.

The following shows the code for `run_bicgstab`:

```
function x1 = run_bicgstab
n = 21;
b = afun(ones(n,1));
tol = 1e-12;
maxit = 15;
x1 = bicgstab(@afun,b,tol,maxit,@mfun);

function y = afun(x)
    y = [0; x(1:n-1)] + ...
        [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
        [x(2:n); 0];
end
```

```
function y = mfun(r)
    y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
end
end
```

When you enter

```
x1 = run_bicgstab;
```

MATLAB software displays the message

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

Using bicgstab with a Preconditioner

This example demonstrates the use of a preconditioner.

Load west0479, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define b so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12; maxit = 20;
```

Use bicgstab to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = bicgstab(A,b,tol,maxit);
```

f10 is 1 because bicgstab does not converge to the requested tolerance 1e-12 within the requested 20 iterations. In fact, the behavior of bicgstab is so bad that the initial guess (x0 = zeros(size(A,2),1))

bicgstab

is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicgstab`.

```
semilogy(0:0.5:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = bicgstab(A,b,tol,maxit,L,U);
```

`f11` is 0 because `bicgstab` drives the relative residual to $5.9829e-014$ (the value of `rr1`). The relative residual is less than the prescribed tolerance of $1e-12$ at the third iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of $1e-6$. The output `rv1(1)` is `norm(b)` and the output `rv1(7)` is `norm(b-A*x2)` since `bicgstab` uses half iterations.

You can follow the progress of `bicgstab` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.5:it1,rv1/norm(b),'-o');  
xlabel('Iteration Number');  
ylabel('Relative Residual');
```

bicgstabl

Purpose Biconjugate gradients stabilized (l) method

Syntax

```
x = bicgstabl(A,b)
x = bicgstabl(afun,b)
x = bicgstabl(A,b,tol)
x = bicgstabl(A,b,tol,maxit)
x = bicgstabl(A,b,tol,maxit,M)
x = bicgstabl(A,b,tol,maxit,M1,M2)
x = bicgstabl(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstabl(A,b,...)
[x,flag,relres] = bicgstabl(A,b,...)
[x,flag,relres,iter] = bicgstabl(A,b,...)
[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)
```

Description

`x = bicgstabl(A,b)` attempts to solve the system of linear equations $A*x=b$ for x . The n -by- n coefficient matrix A must be square and the right-hand side column vector b must have length n .

`x = bicgstabl(afun,b)` accepts a function handle `afun` instead of the matrix A . `afun(x)` accepts a vector input x and returns the matrix-vector product $A*x$. In all of the following syntaxes, you can replace A by `afun`.

`x = bicgstabl(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `bicgstabl` uses the default, $1e-6$.

`x = bicgstabl(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `bicgstabl` uses the default, $\min(N,20)$.

`x = bicgstabl(A,b,tol,maxit,M)` and `x = bicgstabl(A,b,tol,maxit,M1,M2)` use preconditioner M or $M=M1*M2$ and effectively solve the system $A*inv(M)*x = b$ for x . If M is `[]` then a preconditioner is not applied. M may be a function handle returning $M\backslash x$.

`x = bicgstabl(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]` then `bicgstabl` uses the default, an all zero vector.

`[x,flag] = bicgstabl(A,b,...)` also returns a convergence flag:

Flag	Convergence
0	bicgstabl converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	bicgstabl iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	bicgstabl stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during bicgstabl became too small or too large to continue computing.

`[x,flag,relres] = bicgstabl(A,b,...)` also returns the relative residual $\text{norm}(b-A*x)/\text{norm}(b)$. If `flag` is 0, $\text{relres} \leq \text{tol}$.

`[x,flag,relres,iter] = bicgstabl(A,b,...)` also returns the iteration number at which `x` was computed, where $0 \leq \text{iter} \leq \text{maxit}$. `iter` can be `k/4` where `k` is some integer, indicating convergence at a given quarter iteration.

`[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)` also returns a vector of the residual norms at each quarter iteration, including $\text{norm}(b-A*x_0)$.

Examples

Using bicgstabl with Inputs or with a Function

You can pass inputs directly to `bicgstabl`:

```
n = 21;
A = gallery('wilk',n);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M = diag([10:-1:1 1 1:10]);
x = bicgstabl(A,b,tol,maxit,M);
```

You can also use a matrix-vector product function:

```
function y = afun(x,n)
y = [0; x(1:n-1)] + [((n-1)/2:-1:0)';
(1:(n-1)/2)'] .* x + [x(2:n); 0];
```

and a preconditioner backsolve function:

```
function y = mfun(r,n)
y = r ./ [((n-1)/2:-1:1)';
1;
(1:(n-1)/2)'];
```

as inputs to `bicgstabl`:

```
x1 = bicgstabl(@(x)afun(x,n),b,tol,maxit,@(x)mfun(x,n));
```

Using bicgstabl with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12; maxit = 20;
```

Use `bicgstabl` to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = bicgstabl(A,b,tol,maxit);
```

`f10` is 1 because `bicgstabl` does not converge to the requested tolerance $1e-12$ within the requested 20 iterations. In fact, the behavior of `bicgstabl` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`)

is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicgstabl`.

```
semilogy(0:0.25:maxit,rv0/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = bicgstabl(A,b,tol,maxit,L,U);
```

`f11` is 0 because `bicgstabl` drives the relative residual to $1.0257e-015$ (the value of `rr1`). The relative residual is less than the prescribed tolerance of $1e-12$ at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of $1e-6$. The output `rv1(1)` is `norm(b)`, and the output `rv1(9)` is `norm(b-A*x2)` since `bicgstabl` uses quarter iterations.

You can follow the progress of `bicgstabl` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.25:it1,rv1/norm(b),'-o');  
set(gca,'XTick',0:0.25:it1);  
xlabel('Iteration number');  
ylabel('Relative residual');
```

bin2dec

Purpose Convert binary number string to decimal number

Syntax `bin2dec(binarystr)`

Description `bin2dec(binarystr)` interprets the binary string *binarystr* and returns the equivalent decimal number.

`bin2dec` ignores any space (' ') characters in the input string.

Examples Binary 010111 converts to decimal 23:

```
bin2dec('010111')
ans =
    23
```

Because space characters are ignored, this string yields the same result:

```
bin2dec(' 010 111 ')
ans =
    23
```

See Also `dec2bin`

Purpose Set FTP transfer type to binary

Syntax `binary(ftpobj)`

Description `binary(ftpobj)` sets the FTP download and upload mode to binary, which does not convert new line characters. Binary mode is the default for FTP objects. If you previously called the `ascii` method, use this method before transferring a nontext file, such as an executable or ZIP archive.

Input Arguments **ftpobj**
FTP object created by `ftp`.

Examples Connect to the MathWorks FTP server, and set the transfer mode to binary:

```
mw=ftp('ftp.mathworks.com');  
binary(mw)
```

See Also `ascii` | `ftp`

bitand

Purpose

Bit-wise AND

Syntax

```
intout = bitand(integ1,integ2)
intout = bitand(integ1,integ2,assumedtype)

objout = bitand(netobj1,netobj2)
```

Description

`intout = bitand(integ1,integ2)` returns the bit-wise AND of values `integ1` and `integ2`.

`intout = bitand(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitand(netobj1,netobj2)` returns the bit-wise AND of the .NET enumeration objects `netobj1` and `netobj2`.

Input Arguments

integ1, integ2 - Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 |
uint32 | uint64

assumedtype - Assumed data type of integ1 and integ2

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' |
'int16' | 'int8'

Assumed data type of `integ1` and `integ2`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

Data Types

`char`

`netobj1`, `netobj2` - Input values

`.NET` enumeration objects

Input values, specified as `.NET` enumeration objects. You must be running a version of Windows to use `.NET` enumeration objects as input arguments.

`bitand` is an instance method for MATLAB enumeration objects created from a `.NET` enumeration.

Output Arguments

`intout` - Bit-wise AND result

signed integer array | unsigned integer array | double array

Bit-wise AND result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

`objout` - Bit-wise AND result

`.NET` enumeration object

Bit-wise AND result, returned as a `.NET` enumeration objects.

Examples

Truth Table

Create a truth table for the logical AND operation.

bitand

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitand(A, B)
```

```
TTable =
```

```
    0    0
    0    1
```

bitand returns 1 only if both bit-wise inputs are 1.

Negative Values

Explore how bitand handles negative values

MATLAB encodes signed integers using two's complement. Thus, the bit-wise AND of 5 (11111010) and 6 (00000110) is 2 (00000010).

```
C = -5;
D = 6;
bitand(C,D,'int8')
```

```
ans =
```

```
    2
```

Related Examples

- “Creating .NET Enumeration Bit Flags”

Purpose	Bit-wise complement
Compatibility	bitcmp(A,N) will not accept N in a future release. Use bitcmp(A) or bitcmp(A,assumedtype) instead.
Syntax	<pre>cmp = bitcmp(A) cmp = bitcmp(A,assumedtype) cmp = bitcmp(A,N)</pre>
Description	<p>cmp = bitcmp(A) returns the bit-wise complement of A.</p> <p>cmp = bitcmp(A,assumedtype) assumes that A is of assumedtype.</p> <p>cmp = bitcmp(A,N) returns an N-bit complement of A. Elements of A cannot exceed 2^N-1.</p>
Input Arguments	<p>A - Input value signed integer array unsigned integer array double array</p> <p>Input value, specified as a signed integer array, unsigned integer array, or double array.</p> <ul style="list-style-type: none">• If A is a double array, and assumedtype is not specified, then MATLAB treats A as an unsigned 64-bit integer.• If assumedtype is specified, then all elements in A must have integer values within the range of assumedtype. <p>Data Types double int8 int16 int32 int64 uint8 uint16 uint32 uint64</p> <p>assumedtype - Assumed data type of A 'uint64' 'uint32' 'uint16' 'uint8' 'int64' 'int32' 'int16' 'int8'</p>

bitcmp

Assumed data type of A, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If A is a double array, then `assumedtype` can specify any valid integer type, but defaults to 'uint64'.
- If A is an integer type array, then `assumedtype` must specify that same integer type.

Data Types

char

N - number of returned bits

integer

Number of returned bits, specified as an integer. N cannot exceed the number of bits in the integer type of A.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 |
uint32 | uint64

Output Arguments

cmp - Bit-wise complement

signed integer array | unsigned integer array | double array

Bit-wise complement, returned as a signed integer array, unsigned integer array, or double array. `cmp` is the same size and type as A.

Examples

Complement of a Negative Integer

```
A = int8(-11);  
cmp = bitcmp(A)
```

```
cmp =
```

```
    10
```

You can see the complement operation when the numbers are shown in binary.

```
original = bitget(A,8:-1:1)
complement = bitget(bitcmp(A),8:-1:1)

original =

     1     1     1     1     0     1     0     1

complement =

     0     0     0     0     1     0     1     0
```

Complement of Unsigned Integers

```
cmp = bitcmp(64,'uint8')
maxint = intmax('uint8') - 64

cmp =

    191

maxint =

    191
```

The complement of an unsigned integer is equal to itself subtracted from the maximum integer of its data type.

bitget

Purpose

Get bit at specified position

Syntax

```
b = bitget(A,bit)
b = bitget(A,bit,assumedtype)
```

Description

`b = bitget(A,bit)` returns the bit value at position `bit` in integer array `A`.

`b = bitget(A,bit,assumedtype)` assumes that `A` is of `assumedtype`.

Input Arguments

A - Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If `A` is a double array, and `assumedtype` is not specified, then MATLAB treats `A` as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in `A` must have integer values within the range of `assumedtype`.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

bit - Bit position

integer | integer array

Bit position, specified as an integer or integer array. `bit` must be between 1 (the least-significant bit) and the number of bits in the integer class of `A`.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

assumedtype - Assumed data type of A

```
'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' |
'int16' | 'int8'
```

Assumed data type of A, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If A is a double array, then `assumedtype` can specify any valid integer type, but defaults to 'uint64'.
- If A is an integer type array, then `assumedtype` must specify that same integer type.

Data Types

char

Output Arguments

b - Bit value at bit

0 | 1

Bit value at `bit`, returned as 0 or 1. `b` is the same data type as A.

Examples

Maximum Integer

Find the difference in the binary representation between the maximum integer of signed and unsigned integers.

```
a1 = intmax('int8');
a2 = intmax('uint8');
b1 = bitget(a1,8:-1:1)
b2 = bitget(a2,8:-1:1)
```

b1 =

```
0  1  1  1  1  1  1  1
```

b2 =

```
1  1  1  1  1  1  1  1
```

The signed integers require a bit to accommodate negative integers.

Negative Numbers Using Two's Complement

Find the 8-bit representation of a negative number.

```
A = -29;  
b = bitget(A,8:-1:1,'int8')
```

b =

```
1 1 1 0 0 0 1 1
```

See Also

[bitand](#) | [bitcmp](#) | [bitor](#) | [bitshift](#) | [bitset](#) | [bitxor](#) | [intmax](#)

Purpose	Maximum double-precision floating-point integer
Compatibility	bitmax will be removed in a future release. Use <code>flintmax</code> instead.
Syntax	<code>bitmax</code>
Description	<code>bitmax</code> returns the maximum unsigned double-precision floating-point integer for your computer. It is the value when all bits are set, namely the value $2^{53} - 1$.

Note Instead of integer-valued double-precision variables, use unsigned integers for bit manipulations and replace `bitmax` with `intmax`.

Examples Display in different formats the largest floating point integer and the largest 32 bit unsigned integer:

```
format long e
bitmax
ans =
    9.007199254740991e+015
```

```
intmax('uint32')
ans =
    4294967295
```

```
format hex
bitmax
ans =
    433fffffffffffffff
```

```
intmax('uint32')
ans =
    ffffffff
```

bitmax

In the second bitmax statement, the last 13 hex digits of bitmax are f, corresponding to 52 1's (all 1's) in the mantissa of the binary representation. The first 3 hex digits correspond to the sign bit 0 and the 11 bit biased exponent 10000110011 in binary (1075 in decimal), and the actual exponent is $(1075 - 1023) = 52$. Thus the binary value of bitmax is $1.111\dots111 \times 2^{52}$ with 52 trailing 1's, or $2^{53} - 1$.

bitor

Purpose Bit-wise OR

Syntax

```
intout = bitor(integ1,integ2)
intout = bitor(integ1,integ2,assumedtype)

objout = bitor(netobj1,netobj2)
```

Description

`intout = bitor(integ1,integ2)` returns the bit-wise OR of `integ1` and `integ2`.

`intout = bitor(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitor(netobj1,netobj2)` returns the bit-wise OR of the .NET enumeration objects `netobj1` and `netobj2`.

Input Arguments

integ1, integ2 - Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

assumedtype - Assumed data type of integ1 and integ2

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of `integ1` and `integ2`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

Data Types

`char`

`netobj1`, `netobj2` - Input values

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

`bitor` is an instance method for MATLAB enumeration objects created from a .NET enumeration.

Output Arguments

`intout` - Bit-wise OR result

signed integer array | unsigned integer array | double array

Bit-wise OR result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

`objout` - Bit-wise OR result

.NET enumeration object

Bit-wise OR result, returned as a .NET enumeration objects.

Examples

Truth Table

Create a truth table for the logical OR operation.

bitor

```
A = uint8([0 1; 0 1]);  
B = uint8([0 0; 1 1]);  
TTable = bitor(A, B)
```

```
TTable =
```

```
    0    1  
    1    1
```

bitor returns 1 if either bit-wise input is 1.

Negative Values

Explore how bitor handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise OR of -5 (11111010) and 6 (00000110) is -1 (11111110).

```
C = -5;  
D = 6;  
bitor(C,D,'int8')
```

```
ans =
```

```
-1
```

Purpose	Set bit at specific location
Syntax	<pre>intout = bitset(A,bit) intout = bitset(A,bit,assumedtype) intout = bitset(A,bit,V) intout = bitset(A,bit,V,assumedtype)</pre>
Description	<p><code>intout = bitset(A,bit)</code> returns the value of <code>A</code> with position <code>bit</code> set to 1 (on).</p> <p><code>intout = bitset(A,bit,assumedtype)</code> assumes <code>A</code> is of type <code>assumedtype</code>.</p> <p><code>intout = bitset(A,bit,V)</code> returns <code>A</code> with position <code>bit</code> set to the value of <code>V</code>.</p> <ul style="list-style-type: none">• If <code>V</code> is zero, then the bit position <code>bit</code> is set to 0 (off).• If <code>V</code> is nonzero, then the bit position <code>bit</code> is set to 1 (on). <p><code>intout = bitset(A,bit,V,assumedtype)</code> assumes <code>A</code> is of type <code>assumedtype</code>.</p>
Input Arguments	<p>A - Input value signed integer array unsigned integer array double array</p> <p>Input value, specified as a signed integer array, unsigned integer array, or double array.</p> <ul style="list-style-type: none">• If <code>A</code> is a double array, and <code>assumedtype</code> is not specified, then MATLAB treats <code>A</code> as an unsigned 64-bit integer.• If <code>assumedtype</code> is specified, then all elements in <code>A</code> must have integer values within the range of <code>assumedtype</code>.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 |
uint32 | uint64

bit - Bit position

integer | integer array

Bit position, specified as an integer or integer array. `bit` must be between 1 (the least significant bit) and the number of bits in the integer class of `A`.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 |
uint32 | uint64

assumedtype - Assumed data type of A

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' |
'int16' | 'int8'

Assumed data type of `A`, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If `A` is a double array, then `assumedtype` can specify any valid integer type, but defaults to 'uint64'.
- If `A` is an integer type array, then `assumedtype` must specify that same integer type.

Data Types

char

V - bit value

scalar | numeric array

Bit value, specified as a scalar or a numeric array. If `V` and `bit` are arrays, they must be the same size.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 |
uint32 | uint64 | logical

Output Arguments

intout - Adjusted integer

signed integer array | unsigned integer array | double array

Adjusted integer, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same size and type as `A`.

Examples

Set Bits to On

Add powers of 2 onto a number.

```
A = 4;  
intout = bitset(A,4:6)
```

```
intout =  
  
      12      20      36
```

You can see that `bitset` sequentially turns on bits 4 through 6.

```
c = dec2bin(intout)
```

```
c =  
  
001100  
010100  
100100
```

Out of Range of Integer Type

MATLAB throws an error if you specify an integer outside the range of `assumedtype`.

```
intout = bitset(300,5,'int8')
```

```
Error using bitset  
Double inputs must have integer values in the range of ASSUMEDTYPE.
```

You can avoid this error by limiting your input to the range of the specified datatype.

Set Bits to Off

Repeatedly subtract powers of 2 from a number.

```
a = intmax('uint8')
for k = 0:7
    a = bitset(a, 8-k, 0);
    b(1,k+1) = a;
end
b
```

a =

255

b =

127 63 31 15 7 3 1 0

Set Multiple Bits

Set multiple bits to different values

```
bits = 2:6;
val = [1 0 0 1 1];
intout = bitset(0,bits,val,'int8')
```

intout =

2 0 0 16 32

Purpose	Shift bits specified number of places
Compatibility	<p><code>bitshift(A,k,N)</code> will not accept the argument <code>N</code> in a future release. Use <code>bitshift(A,k)</code> or <code>bitcmp(A,k,assumedtype)</code> instead.</p> <p><code>bitshift</code> no longer interprets double values as 53-bit unsigned integers by default, but as <code>uint64</code> values.</p>
Syntax	<pre>intout = bitshift(A,k) intout = bitshift(A,k,assumedtype) intout = bitshift(A,k,N)</pre>
Description	<p><code>intout = bitshift(A,k)</code> returns <code>A</code> shifted to the left by <code>k</code> bits, equivalent to multiplying by 2^k. Negative values of <code>k</code> correspond to shifting bits right or dividing by $2^{ k }$ and rounding to the nearest integer towards negative infinite. Any overflow bits are truncated.</p> <ul style="list-style-type: none">• If <code>A</code> is an array of signed integers, then <code>bitshift</code> returns the arithmetic shift results, preserving the signed bit when <code>k</code> is negative, and not preserving the signed bit when <code>k</code> is positive.• If <code>k</code> is positive, MATLAB shifts the bits to the left and inserts <code>k</code> 0-bits on the right.• If <code>k</code> is negative and <code>A</code> is nonnegative, then MATLAB shifts the bits to the right and inserts <code> k </code> 0-bits on the left.• If <code>k</code> is negative and <code>A</code> is negative, then MATLAB shifts the bits to the right and inserts <code> k </code> 1-bits on the left. <p><code>intout = bitshift(A,k,assumedtype)</code> assumes <code>A</code> is of type <code>assumedtype</code>.</p> <p><code>intout = bitshift(A,k,N)</code> truncates any bits that overflow <code>N</code> bits.</p>

bitshift

Input Arguments

A - Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If A is a double array, and `assumedtype` is not specified, then MATLAB treats A as an unsigned 64-bit integer.
- If `assumedtype` is specified, then all elements in A must have integer values within the range of `assumedtype`.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

k - Number of switched bits

integer | integer array

Number of switched bits, specified as an integer or integer array.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

assumedtype - Assumed data type of A

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of A, specified as 'uint64', 'uint32', 'uint16', 'uint8', 'int64', 'int32', 'int16', or 'int8'.

- If A is an integer type array, then `assumedtype` must specify that same integer type.
- If A is a double array, then `assumedtype` can specify any valid integer type.

Data Types

char

N - Number of bits kept

nonnegative integer | nonnegative integer array

Number of bits kept, specified as a nonnegative integer or integer array. N must be less than or equal to the number of bits in the unsigned integer class of A.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Output Arguments**intout - Shifted value**

signed integer array | unsigned integer array | double array

Shifted value, returned as signed integer array, unsigned integer array, or double array. `intout` is the same size and type as A.

Examples**Shifted 8-bit Integer**

Repeatedly shift the bits of an unsigned 8-bit value to the left until all the nonzero bits overflow.

```
a = intmax('uint8');
s1 = 'Initial uint8 value %5d is %08s in binary\n';
s2 = 'Shifted uint8 value %5d is %08s in binary\n';
fprintf(s1,a,dec2bin(a))
for i = 1:8
    a = bitshift(a,1);
    fprintf(s2,a,dec2bin(a))
end
```

```
Initial uint8 value    255 is 11111111 in binary
Shifted uint8 value   254 is 11111110 in binary
Shifted uint8 value   252 is 11111100 in binary
Shifted uint8 value   248 is 11111000 in binary
Shifted uint8 value   240 is 11110000 in binary
Shifted uint8 value   224 is 11100000 in binary
Shifted uint8 value   192 is 11000000 in binary
Shifted uint8 value   128 is 10000000 in binary
```

bitshift

Shifted uint8 value 0 is 00000000 in binary

Different Results for Different Integer Types

Find the shift for a number using different assumed integer types.

```
uintout = bitshift(6,5:7,'uint8')
intout = bitshift(6,5:7,'int8')
```

uintout =

```
192 128 0
```

intout =

```
-64 -128 0
```

[bitand](#) | [bitcmp](#) | [bitget](#) | [bitor](#) | [bitset](#) | [bitxor](#) | [intmax](#)

Purpose

Bit-wise XOR

Syntax

```
intout = bitxor(integ1,integ2)
intout = bitxor(integ1,integ2,assumedtype)

objout = bitxor(netobj1,netobj2)
```

Description

`intout = bitxor(integ1,integ2)` returns the bit-wise XOR of `integ1` and `integ2`.

`intout = bitxor(integ1,integ2,assumedtype)` assumes that `integ1` and `integ2` are of `assumedtype`.

`objout = bitxor(netobj1,netobj2)` returns the bit-wise XOR of the .NET enumeration objects `netobj1` and `netobj2`.

Input Arguments**integ1, integ2 - Input values**

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. `integ1` and `integ2` must be the same data type, or one must be a scalar double value.

- If `integ1` and `integ2` are double arrays, and `assumedtype` is not specified, then MATLAB treats `integ1` and `integ2` as unsigned 64-bit integers.
- If `assumedtype` is specified, then all elements in `integ1` and `integ2` must have integer values within the range of `assumedtype`.

Data Types

double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

assumedtype - Assumed data type of integ1 and integ2

'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'

Assumed data type of `integ1` and `integ2`, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If `integ1` and `integ2` are double arrays, then `assumedtype` can specify any valid integer type, but defaults to `'uint64'`.
- If `integ1` and `integ2` are integer type arrays, then `assumedtype` must specify that same integer type.

Data Types

`char`

`netobj1`, `netobj2` - Input values

`.NET` enumeration objects

Input values, specified as `.NET` enumeration objects. You must be running a version of Windows to use `.NET` enumeration objects as input arguments.

`bitxor` is an instance method for MATLAB enumeration objects created from a `.NET` enumeration.

Output Arguments

`intout` - Bit-wise XOR result

signed integer array | unsigned integer array | double array

Bit-wise XOR result, returned as a signed integer array, unsigned integer array, or double array. `intout` is the same data type and size as `integ1` and `integ2`.

- If either `integ1` or `integ2` is a scalar double, and the other is a non-double integer type, `intout` is the non-double integer type.

`objout` - Bit-wise XOR result

`.NET` enumeration object

Bit-wise XOR result, returned as a `.NET` enumeration objects.

Examples

Truth Table

Create a truth table for the logical XOR operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitxor(A, B)
```

```
TTable =

     0     1
     1     0
```

bitxor returns 0 if both bit-wise inputs are equal.

Negative Values

Explore how bitxor handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise XOR of -5 (11111010) and 6 (00000110) is -3 (11111100).

```
C = -5;
D = 6;
bitxor(C,D,'int8')
```

```
ans =

    -3
```

blanks

Purpose Create string of blank characters

Syntax `blanks(n)`

Description `blanks(n)` is a string of `n` blanks.

Examples `blanks` is useful with the `display` function. For example,

```
disp(['xxx' blanks(20) 'yyy'])
```

displays twenty blanks between the strings 'xxx' and 'yyy'.
`disp(blanks(n) ' ')` moves the cursor down `n` lines.

See Also `clc` | `format` | `home`

Purpose Construct block diagonal matrix from input arguments

Syntax `out = blkdiag(a,b,c,d,...)`

Description `out = blkdiag(a,b,c,d,...)`, where `a`, `b`, `c`, `d`, ... are matrices, outputs a block diagonal matrix of the form

$$\begin{bmatrix} a & 0 & 0 & 0 & 0 \\ 0 & b & 0 & 0 & 0 \\ 0 & 0 & c & 0 & 0 \\ 0 & 0 & 0 & d & 0 \\ 0 & 0 & 0 & 0 & \dots \end{bmatrix}$$

The input matrices do not have to be square, nor do they have to be of equal size.

See Also `diag` | `horzcat` | `vertcat`

box

Purpose Axes border

Syntax `box on`
`box off`
`box`
`box(axes_handle,...)`

Description `box on` displays the boundary of the current axes.
`box off` does not display the boundary of the current axes.
`box` toggles the visible state of the current axes boundary.
`box(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

Algorithms The `box` function sets the axes `Box` property to on or off.

See Also `axes | grid`

Purpose	Terminate execution of for or while loop
Syntax	<code>break</code>
Description	<p><code>break</code> terminates the execution of a for or while loop. Statements in the loop that appear after the <code>break</code> statement are not executed.</p> <p>In nested loops, <code>break</code> exits only from the loop in which it occurs. Control passes to the statement that follows the end of that loop.</p>
Tips	<code>break</code> is not defined outside a for or while loop. Use <code>return</code> in this context instead.
Examples	<p>The example below shows a while loop that reads the contents of the file <code>fft.m</code> into a MATLAB character array. A <code>break</code> statement is used to exit the while loop when the first empty line is encountered. The resulting character array contains the command line help for the <code>fft</code> program.</p> <pre>fid = fopen('fft.m','r'); s = ''; while ~feof(fid) line = fgetl(fid); if isempty(line) ~ischar(line) break end s = sprintf('%s%s\n', s, line); end disp(s); fclose(fid);</pre>
See Also	<code>for</code> <code>while</code> <code>end</code> <code>continue</code> <code>return</code>

brighten

Purpose Brighten or darken colormap

Syntax
`brighten(beta)`
`brighten(h,beta)`
`newmap = brighten(beta)`
`newmap = brighten(cmap,beta)`

Description `brighten(beta)` increases or decreases the color intensities in a colormap by replacing the current colormap with a brighter or darker colormap of essentially the same colors. The modified colormap is brighter if $0 < \text{beta} < 1$ and darker if $-1 < \text{beta} < 0$. `brighten(beta)`, followed by `brighten(-beta)`, where $\text{beta} < 1$, restores the original map.

`brighten(h,beta)` brightens all objects that are children of the figure having the handle `h`.

`newmap = brighten(beta)` returns a brighter or darker version of the current colormap without changing the display.

`newmap = brighten(cmap,beta)` returns a brighter or darker version of the colormap `cmap` without changing the display.

Examples

Brighten Colormap

Display a surface plot of membrane.

```
surf(membrane);
```

Brighten the colormap.

```
beta = .7;  
brighten(beta);
```

brighten

Algorithms

`brighten` raises values in the colormap to the power of gamma, where gamma is

$$\gamma = \begin{cases} 1 - \beta, & \beta > 0 \\ \frac{1}{1 + \beta}, & \beta \leq 0 \end{cases}$$

`brighten` has no effect on graphics objects defined with true color.

See Also `colormap` | `rgbplot`

How To

- “Altering Colormaps”

brush

Purpose Interactively mark, delete, modify, and save observations in graphs

Syntax

```
brush on
brush off
brush
brush color
brush(figure_handle,...)
brushobj = brush(figure_handle)
```

Description Data brushing is a mode for interacting with graphs in figure windows in which you can click data points or drag a selection rectangle around data points to highlight observations in a color of your choice. Highlighting takes different forms for different types of graphs, and brushing marks persist—even in other interactive modes—until removed by deselecting them.

`brush on` turns on interactive data brushing mode.

`brush off` turns brushing mode off, leaving any brushed observations still highlighted.

`brush` by itself toggles the state of the data brushing tool.

`brush color` sets the current color used for brushing graphics to the specified `ColorSpec`. Changing brush color affects subsequent brushing, but does not change the color of observations already brushed or the brush tool's state.

`brush(figure_handle,...)` applies the function to the specified figure handle.

`brushobj = brush(figure_handle)` returns a *brush mode object* for that figure, useful for controlling and customizing the figure's brushing state. The following properties of such objects can be modified using `get` and `set`:

Enable 'on' { 'off' }	Specifies whether this figure mode is currently enabled on the figure.
FigureHandle	The associated figure handle. This property supports get only.
Color	Specifies the color to be used for brushing.

brush cannot return a brush mode object at the same time you are calling it to set a brushing option.

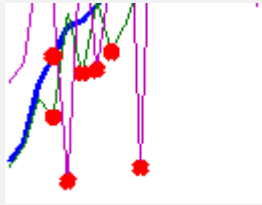

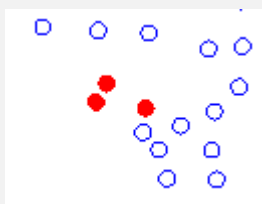

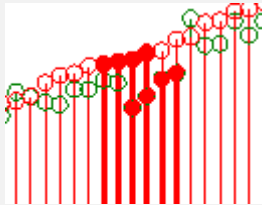

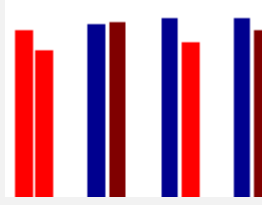

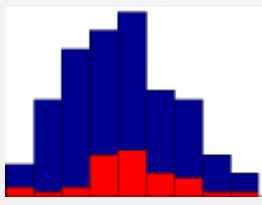

Tips

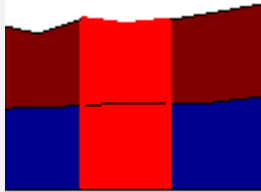

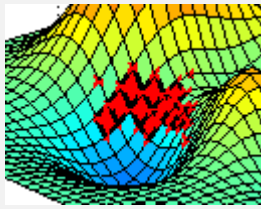

- “Types of Plots You Can Brush” on page 1-591
- “Plot Types You Cannot Brush” on page 1-593
- “Mode Exclusivity and Persistence” on page 1-594

- “Mouse Gestures for Data Brushing” on page 1-596
- “Brush Mode Callbacks” on page 1-597

Types of Plots You Can Brush

Data brushing places lines and patches on plots to create highlighting, marking different types of graphs as follows (brushing marks are shown in red):

brush

Graph Type	Brushing Annotation	Overlays?	Example
lineseries	Colored lines slightly wider than those in the lineseries with a marker distinct from those on the lineseries (filled circles if none) to identify brushed vertices. Only those line segments that connect brushed vertices are highlighted	Y	
scattergroup	Line with LineStyle 'none' and a marker with a color distinct from and slightly larger than the base scattergroup marker.	Y	
stemseries	The brushed stems and stem heads are shaded in the brushing color.	Y	
barseries	The interior of selected bars is filled in the brushing color.	N	
histogram	The bars to which brushed observations contribute are proportionately filled from the bottom up with the brushing color.	N	

Graph Type	Brushing Annotation	Overlays?	Example
areaseries	Patches filling the region between selected points and the x -axis in the brushing color.	N	
surfaceplot	Patches with edges slightly wider than the surfaceplot line width and with a marker distinct from that of the surfaceplot (X if none) to identify brushed vertices. Patches are plotted only when all four vertices that define them are brushed. The brushed observations are the set of marked vertices, not the patches.	N	

When using the linked plots feature, a graph can become brushed when you brush another graph that displays some of the same data, potentially brushing the same observations more than once. The overlaid brushing marks (whether lines or markers) are slightly wider than the brushing marks that they overlay; this makes multiply brushed observations visually distinct. The wider brushing marks are placed under the narrower ones, so that if they happen to have different colors, you can see all the colors. See the subsection “How Data Linking Affects Data Brushing” on page 1-595 for more information about brushing linked figures.

As the above table indicates, only lineseries, scatterseries, and stemseries brushing marks can be overlaid in this manner. Although you can brush them, you cannot overlay brushing marks on areaseries, barseries, histograms, or surfaceplots.

Plot Types You Cannot Brush

Currently, not all plot types enable data brushing. Graph functions that *do not* support brushing are:

- Line plots created with `line`
- Scatter plots created with `spy`
- Contour plots created with `contour`, `contourf`, or `contour3`
- Pie charts created with `pie` or `pie3`
- Radial graphs created with `polar`, `compass`, or `rose`
- Direction graphs created with `feather`, `quiver`, or `comet`
- Area and image plots created with `fill`, `image`, `imagesc`, or `pcolor`
- Bar graphs created with `pareto` or `errorbar`
- Functional plots created with `ezcontour` or `ezcontourf`
- 3-D plot types *other than* `plot3`, `stem3`, `scatter3`, `mesh`, `meshc`, `surf`, `surf1`, and `surfc`

You can use some of these functions to display base data that do not need to be brushable. For example, use `line` to plot mean y -values as horizontal lines that you do not need or want to brush.

Mode Exclusivity and Persistence

Data brushing mode is *exclusive*, like zoom, pan, data cursor, or plot edit mode. However, brush marks created in data brushing mode *persist* through all changes in mode. Brush marks that appear in other graphs while they are linked via `linkdata` also persist even when data linking is subsequently turned off. That is, severing connections to a graph's data sources does not remove brushing marks from it. The only ways to remove brushing marks are (in brushing mode):

- Brush an empty area in a brushed graph.
- Right-click and select **Clear all brushing** from the context menu.

Changing the brushing color for a figure does not recolor brushing marks on it until you brush it again. If you hold down the **Shift** key, all existing brush marks change to the new color. All brush marks that appear on linked plots in the same or different figure also change to the new color if the brushing action affects them. The behavior is the same whether you select a brushing color from the Brush Tool dropdown palette, set

it by calling `brush(colorspec)`, or by setting the `Color` property of a brush mode object (e.g., `set(brushobj, 'Color', colorspec)`).

How Data Linking Affects Data Brushing

When you use the Data Linking tool or call the `linkdata` function, brushing marks that you make on one plot appear on other plots that depict the same variable you are brushing—if those plots are also linked. This happens even if the affected plot is not in Brushing mode. That is, brushing marks appear on a linked plot *in any mode* when you brush another plot linked to it via a common variable or brush that variable in the Variables editor. Be aware that the following conditions apply, however:

- The graph type must support data brushing (see “Types of Plots You Can Brush” on page 1-591 and “Plot Types You Cannot Brush” on page 1-593)
- The graphed variable must not be complex; if you can plot a complex variable you can brush it, but such graphs do not respond when you brush the complex variable in another linked plot. For more information about linking complex variables, see Example 3 in the `linkdata` reference page.
- Observations that you brush display in the same color in all linked graphs. The color is the brush color you have selected in the window you are interacting with, and can differ from the brushing colors selected in the other affected figures. When you brush linked plots, the brushing color is associated with the variable(s) you brush

The last bullet implies that brush marks on an unlinked graph can change color when data linking is turned on for that figure. Brushing marks can, in fact, vanish and be replaced by marks in the same or different color when the plot enters a linked state. In the linked state, brushing is tied to variables (data sources), not just the graphics. If different observations for the same variable on a linked figure are brushed, those variables override the brushed graphics on the newly linked plot. In other words, the newly linked graph loses all its previous brush marks when it “joins the club” of common data sources.

Mouse Gestures for Data Brushing

You can brush graphs in several ways. The basic operation is to drag the mouse to highlight all observations within the rectangle you define. The following table lists data brushing gestures and their effects.

Action	Gesture	Result
Select data using a region of interest	ROI mouse drag	Region of interest (ROI) rectangle (or rectangular prism for 3-D axes) appears during the gesture and all brushable observations within the rectangle are highlighted. All other brushing marks in the axes are removed. The ROI rectangle disappears when the mouse button is released.
Select a single point	Single left-click on a graphic object that supports data brushing	Produces an equivalent result to ROI rectangle, brushing where the rectangle encloses only the single vertex on the graphical object closest to the mouse. All other brushing annotations in the figure are removed.
Add a point to the selection or remove a highlighted one	Single left-click on a graphic object that supports data brushing, with the Shift key down	Equivalent brushing by dragging an ROI rectangle that encloses only the single vertex on the graphic object closest to the mouse. All other brushed regions in the figure remain brushed.
Select all data associated with a graphic object	Double left-click on a graphic object that supports data brushing	All vertices for the graphic object are brushed.

Action	Gesture	Result
Add to or subtract from region of interest	Click or ROI drag with the Shift or Ctrl keys down	Region of interest grows; all unbrushed vertices within the rectangle become brushed and all brushed observations in it become unbrushed. All brushed vertices outside the ROI remain brushed.
Copy brushed data to Editor, Command Window, Variables editor, or Workspace Browser	Drag brushed data to another window or to a program/icon on the system desktop	Equivalent to copying brushed data and pasting into other window or an existing/new variable.

Brush Mode Callbacks

You can program the following callbacks for brush mode operations.

- **ActionPreCallback** <function_handle> — Function to execute before brushing

Use this callback to execute code when a brush operation begins. The function handle should reference a function with two implicit arguments:

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked
% event_obj    object containing struct of event data
```

The event data struct has the following field:

Axes	The handle of the axes that is being brushed
------	--

brush

- `ActionPostCallback` <function_handle> — Function to execute after brushing

Use this callback to execute code when a brush operation ends. The function handle should reference a function with two implicit arguments:

```
function myfunction(obj,event_obj)
% obj          handle to the figure that has been clicked
% event_obj    object containing struct of event data
%              (same as the event data of the
%              'ActionPreCallback' callback)
```

Examples

Example 1

On a scatterplot, drag out a rectangle to brush the graph:

```
x = rand(20,1);
y = rand(20,1);
scatter(x,y,80,'s')
brush on
```

Example 2

Brush observations from $-.2$ to $.2$ on a lineseries plot in dark red:

```
x = [-2*pi:.1:2*pi];  
y = sin(x);  
plot(x,y);  
h = brush;  
set(h, 'Color', [.6 .2 .1], 'Enable', 'on');
```

brush

How To

- “Marking Up Graphs with Data Brushing”

Purpose Apply element-by-element binary operation to two arrays with singleton expansion enabled

Syntax `C = bsxfun(fun,A,B)`

Description `C = bsxfun(fun,A,B)` applies the element-by-element binary operation specified by the function handle `fun` to arrays `A` and `B`, with singleton expansion enabled. `fun` can be one of the following built-in functions:

@plus	Plus
@minus	Minus
@times	Array multiply
@rdivide	Right array divide
@ldivide	Left array divide
@power	Array power
@max	Binary maximum
@min	Binary minimum
@rem	Remainder after division
@mod	Modulus after division
@atan2	Four-quadrant inverse tangent; result in radians
@atan2d	Four-quadrant inverse tangent; result in degrees
@hypot	Square root of sum of squares
@eq	Equal
@ne	Not equal
@lt	Less than
@le	Less than or equal to
@gt	Greater than

@ge	Greater than or equal to
@and	Element-wise logical AND
@or	Element-wise logical OR
@xor	Logical exclusive OR

`fun` can also be a handle to any binary element-wise function not listed above. A binary element-wise function of the form `C = fun(A,B)` accepts arrays `A` and `B` of arbitrary, but equal size and returns output of the same size. Each element in the output array `C` is the result of an operation on the corresponding elements of `A` and `B` only. `fun` must also support scalar expansion, such that if `A` or `B` is a scalar, `C` is the result of applying the scalar to every element in the other input array.

The corresponding dimensions of `A` and `B` must be equal to each other or equal to one. Whenever a dimension of `A` or `B` is singleton (equal to one), `bsxfun` virtually replicates the array along that dimension to match the other array. In the case where a dimension of `A` or `B` is singleton, and the corresponding dimension in the other array is zero, `bsxfun` virtually diminishes the singleton dimension to zero.

The size of the output array `C` is equal to:
`max(size(A),size(B)).*(size(A)>0 & size(B)>0)`.

Examples

Deviations from Mean

Use `bsxfun` to subtract the column mean from the corresponding column elements of a matrix, `A`.

```
A = [1 2 10; 1 4 20; 1 6 15] ;  
C = bsxfun(@minus, A, mean(A))
```

```
C =  
  
    0    -2    -5  
    0     0     5  
    0     2     0
```

Singleton Expansion with Custom Function

Call a custom-defined binary function with `bsxfun` by specifying a handle to the function.

```
fun = @(A,B) A.*sin(B);
A = 1:7;
B = pi*[0 1/4 1/3 1/2 2/3 3/4 1].';
C = bsxfun(fun,A,B)
```

C =

	0	0	0	0	0	0	0
	0.7071	1.4142	2.1213	2.8284	3.5355	4.2426	4.9497
	0.8660	1.7321	2.5981	3.4641	4.3301	5.1962	6.0622
	1.0000	2.0000	3.0000	4.0000	5.0000	6.0000	7.0000

builddocsearchdb

Purpose Build searchable documentation database

Syntax `builddocsearchdb(folder)`

Description `builddocsearchdb(folder)` builds a searchable database from HTML files in the specified folder. The `builddocsearchdb` function creates a subfolder named `helpsearch` to contain the database files. The database enables MATLAB to search for content within the HTML files, as long as the version of MATLAB is the same as the version used to create the database.

Input Arguments **folder - Full path to folder with HTML files**
`string`

Full path to a folder with HTML files, specified as a string.

To include a particular HTML document in the search database, the `builddocsearchdb` function requires that:

- The document has a title.
- The content is different from the title.

Example: `builddocsearchdb('c:\myfiles\html')`

Examples **Search Custom Help Files**

Build a search database for custom help files.

MATLAB includes a set of sample files to demonstrate how to create a custom toolbox and supporting documentation. This sample toolbox is called the *Upslope Area Toolbox*. The `upslope` folder includes a file named `info.xml`, which is required to display custom documentation, and a subfolder named `html`, which contains HTML documentation and supporting files.

Copy the sample files to a temporary folder, and add the copied files to the path.

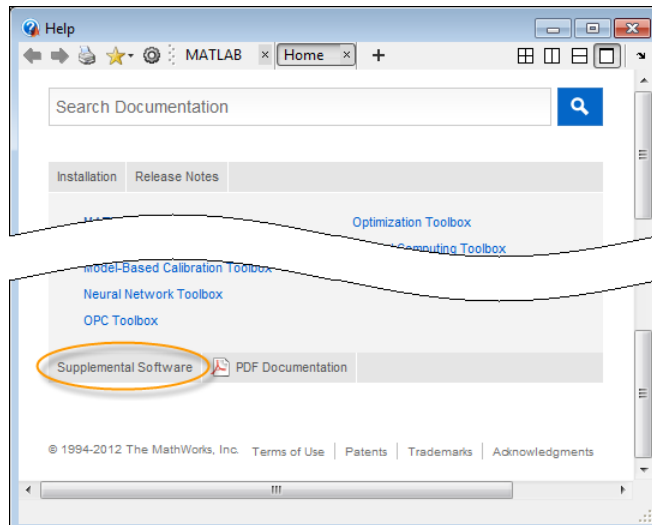

```
sample = fullfile(...
```

```
matlabroot,'help','techdoc','matlab_env',...  
    'examples','upslope');  
tmp = tempname;  
mkdir(tmp);  
copyfile(sample,tmp);  
addpath(tmp);
```

Create a search database.

```
folder = fullfile(tmp,'html');  
builddocsearchdb(folder)
```

Open the Supplemental Software documentation browser. There is a link to this browser at the bottom of the documentation home page.

Search the supplemental documentation for the term *tarboton*, which appears in several of the example help files. The search returns several results from the Upslope Area Toolbox.

builddocsearchdb

Remove the temporary example files.

```
rmpath(tmp)
rmdir(tmp, 's')
```

Concepts

- “Display Custom Documentation”

Purpose	Execute built-in function from overloaded method
Syntax	<code>builtin(function,x1,...,xn)</code> <code>[y1,...,yn] = builtin(function,x1,...,xn)</code>
Description	<code>builtin(function,x1,...,xn)</code> executes the built-in function with the input arguments <code>x1</code> through <code>xn</code> . Use <code>builtin</code> to execute the original built-in from within a method that overloads the function. To work properly, you must never overload <code>builtin</code> .

`[y1,...,yn] = builtin(function,x1,...,xn)` stores any output from function in `y1` through `yn`.

Input Arguments	function - Built-in function name string
	Valid built-in function name in the MATLAB path, specified as a string. function cannot be a function handle.
	x1,...,xn - Valid input arguments for function supported data types
	Valid input arguments for function, specified by supported data types.

Examples **Run an Overloaded Function within a Class Definition**

Execute the built-in functionality from within an overloaded method.

Create a simple class describing the speed of a particle and providing a `disp` method by pasting the following code into a file called `MyParticle.m`.

```
classdef MyParticle
    properties
        velocity;
    end
    methods
        function p = MyParticle(x,y,z)
```

builtin

```
        p.velocity.x = x;  
        p.velocity.y = y;  
        p.velocity.z = z;  
    end  
    function disp(p)  
        builtin('disp',p) %call builtin  
        if isscalar(p)  
            disp(' Velocity')  
            disp([' x: ',num2str(p.velocity.x)])  
            disp([' y: ',num2str(p.velocity.y)])  
            disp([' z: ',num2str(p.velocity.z)])  
        end  
    end  
end  
end
```

Create an instance MyParticle.

```
p = MyParticle(1,2,4)
```

```
p =
```

```
MyParticle
```

```
Properties:
```

```
velocity: [1x1 struct]
```

```
Methods
```

```
Velocity
```

```
x: 1
```

```
y: 2
```

```
z: 4
```

Definitions

built-in function

A built-in function is part of the MATLAB executable. MATLAB does not implement these functions in the MATLAB language. Although

most built-in functions have a `.m` file associated with them, this file only supplies documentation for the function.

You can use the syntax `which function` to check whether a function is built-in.

bvp4c

Purpose Solve boundary value problems for ordinary differential equations

Syntax

```
sol = bvp4c(odefun,bcfun,solinit)
sol = bvp4c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

Arguments

odefun	<p>A function handle that evaluates the differential equations $f(x,y)$. It can have the form</p> <pre>dydx = odefun(x,y) dydx = odefun(x,y,parameters)</pre> <p>For a scalar x and a column vector y, <code>odefun(x,y)</code> must return a column vector, <code>dydx</code>, representing $f(x,y)$. <code>parameters</code> is a vector of unknown parameters.</p>
bcfun	<p>A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a),y(b))$, <code>bcfun</code> can have the form</p> <pre>res = bcfun(ya,yb) res = bcfun(ya,yb,parameters)</pre> <p>where <code>ya</code> and <code>yb</code> are column vectors corresponding to $y(a)$ and $y(b)$. <code>parameters</code> is a vector of unknown parameters. The output <code>res</code> is a column vector.</p> <p>See “Multipoint Boundary Value Problems” on page 1-613 for a description of <code>bcfun</code> for multipoint boundary value problems.</p>
solinit	<p>A structure containing the initial guess for a solution. You create <code>solinit</code> using the function <code>bvpinit</code>. <code>solinit</code> has the following fields.</p>

	x	Ordered nodes of the initial mesh. Boundary conditions are imposed at $a = \text{solinit.x}(1)$ and $b = \text{solinit.x}(\text{end})$.
	y	Initial guess for the solution such that $\text{solinit.y}(:,i)$ is a guess for the solution at the node $\text{solinit.x}(i)$.
	parameters	Optional. A vector that provides an initial guess for unknown parameters.
	The structure can have any name, but the fields must be named x, y, and parameters. You can form solinit with the helper function <code>bvpinit</code> . See <code>bvpinit</code> for details.	
options	Optional integration argument. A structure you create using the <code>bvpset</code> function. See <code>bvpset</code> for details.	

Description

`sol = bvp4c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x,y)$$

on the interval $[a,b]$ subject to two-point boundary value conditions $bc(y(a),y(b)) = 0$.

`odefun` and `bcfun` are function handles. See the `function_handle` reference page for more information.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary.

`bvp4c` can also solve multipoint boundary value problems. See “Multipoint Boundary Value Problems” on page 1-613. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`. See the reference page for `bvpinit` for more information.

The `bvp4c` solver can also find unknown parameters p for problems of the form

$$y' = f(x, y, p)$$

$$0 = bc(y(a), y(b), p)$$

where p corresponds to parameters. You provide `bvp4c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp4c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp4c` produces a solution that is continuous on $[a, b]$ and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp4c` to evaluate the solution at specific points `xint` in the interval $[a, b]$.

```
sol = deval(sol, xint)
```

The structure `sol` returned by `bvp4c` has the following fields:

<code>sol.x</code>	Mesh selected by <code>bvp4c</code>
<code>sol.y</code>	Approximation to $y(x)$ at the mesh points of <code>sol.x</code>
<code>sol.yp</code>	Approximation to $y'(x)$ at the mesh points of <code>sol.x</code>
<code>sol.parameters</code>	Values returned by <code>bvp4c</code> for the unknown parameters, if any
<code>sol.solver</code>	' <code>bvp4c</code> '
<code>sol.stats</code>	Computational cost statistics (also displayed when the <code>stats</code> option is set with <code>bvpset</code>).

The structure `sol` can have any name, and `bvp4c` creates the fields `x`, `y`, `yp`, `parameters`, and `solver`.

`sol = bvp4c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

Singular Boundary Value Problems

`bvp4c` solves a class of singular boundary value problems, including problems with unknown parameters `p`, of the form

$$y' = S \cdot y/x + F(x,y,p)$$

$$0 = bc(y(0),y(b),p)$$

The interval is required to be $[0, b]$ with $b > 0$. Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix `S` as the value of the 'SingularTerm' option of `bvpset`, and `odefun` evaluates only $f(x,y,p)$. The boundary conditions must be consistent with the necessary condition $S \cdot y(0) = 0$ and the initial guess should satisfy this condition.

Multipoint Boundary Value Problems

`bvp4c` can solve multipoint boundary value problems where $a = a_0 < a_1 < a_2 < \dots < a_n = b$ are boundary points in the interval $[a,b]$. The points a_1, a_2, \dots, a_{n-1} represent interfaces that divide $[a,b]$ into regions. `bvp4c` enumerates the regions from left to right (from a to b), with indices starting from 1. In region k , $[a_{k-1}, a_k]$, `bvp4c` evaluates the derivative as

$$yp = \text{odefun}(x,y,k)$$

In the boundary conditions function

$$\text{bcfun}(yleft,yright)$$

`yleft(:,k)` is the solution at the left boundary of $[a_{k-1}, a_k]$. Similarly, `yright(:,k)` is the solution at the right boundary of region k . In particular,

```
yleft(:,1) = y(a)
```

and

```
yright(:,end) = y(b)
```

When you create an initial guess with

```
solinit = bvpinit(xinit,yinit),
```

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x,k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bvp4c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

Note The `bvp5c` function is used exactly like `bvp4c`, with the exception of the meaning of error tolerances between the two solvers. If $S(x)$ approximates the solution $y(x)$, `bvp4c` controls the residual $|S'(x) - f(x,S(x))|$. This controls indirectly the true error $|y(x) - S(x)|$. `bvp5c` controls the true error directly. `bvp5c` is more efficient than `bvp4c` for small error tolerances.

Examples

Using Initial Guess to Indicate Desired Solution

Boundary value problems can have multiple solutions. One purpose of the initial guess is to indicate which solution, among several, that you want.

The second-order differential equation

$$y'' + |y| = 0$$

has exactly two solutions that satisfy the boundary conditions

$$y(0) = 0,$$

$$y(4) = -2.$$

Before using `bvp4c` to solve the problem, you need to rewrite the differential equation as a system of two first-order ODEs,

$$y_1' = y_2,$$

$$y_2' = -|y_1|,$$

where $y_1 = y$ and $y_2 = y'$. This system has the required form

$$y' = f(x, y),$$

$$bc(y(a), y(b)) = 0.$$

The function, f , and the boundary conditions, bc , are coded in MATLAB as the functions `twoode` and `twobc`.

```
function dydx = twoode(x,y)
dydx = [ y(2); -abs(y(1)) ];
```

```
function res = twobc(ya,yb)
res = [ ya(1); yb(1) + 2 ];
```

Form a guess structure consisting of an initial mesh of five equally spaced points in $[0,4]$ and a guess of the constant values

$$y_1(x) = 1,$$

$$y_2(x) = 0.$$

```
solinit = bvpinit(linspace(0,4,5),[1 0]);
```

Solve the problem using `bvp4c`.

```
sol = bvp4c(@twoode,@twobc,solinit);
```

Evaluate the numerical solution at 100 equally spaced points and plot $y(x)$.

```
x = linspace(0,4);  
y = deval(sol,x);  
plot(x,y(1,:));
```

To obtain the other solution of this problem, use the initial guess

$$y_1(x) = -1,$$

$$y_2(x) = 0.$$

```
solinit = bvpinit(linspace(0,4,5),[-1 0]);  
sol = bvp4c(@twoode,@twobc,solinit);  
x = linspace(0,4);  
y = deval(sol,x);
```

```
plot(x,y(1,:));
```

Compute Fourth Eigenvalue of Mathieu's Equation

This boundary value problem involves an unknown parameter. The task is to compute the fourth ($q = 5$) eigenvalue λ of Mathieu's equation

$$y'' + (\lambda - 2q \cos 2x)y = 0.$$

Because the unknown parameter λ is present, this second-order differential equation is subject to *three* boundary conditions:

$$y'(0) = 0$$

$$y'(\pi) = 0$$

$$y(0) = 1$$

It is convenient to use local functions to place all the functions required by bvp4c in a single file.

```
function mat4bvp

lambda = 15;
solinit = bvpinit(linspace(0,pi,10),@mat4init,lambda);
sol = bvp4c(@mat4ode,@mat4bc,solinit);

fprintf('The fourth eigenvalue is approximately %7.3f.\n',...
        sol.parameters)

xint = linspace(0,pi);
Sxint = deval(sol,xint);
plot(xint,Sxint(1,:))
axis([0 pi -1 1.1])
title('Eigenfunction of Mathieu''s equation.')
xlabel('x')
ylabel('solution y')
% -----
function dydx = mat4ode(x,y,lambda)
q = 5;
dydx = [ y(2)
        -(lambda - 2*q*cos(2*x))*y(1) ];
% -----
function res = mat4bc(ya,yb,lambda)
res = [ ya(2)
        yb(2)
```

```
ya(1)-1 ];  
% -----  
function yinit = mat4init(x)  
yinit = [ cos(4*x)  
         -4*sin(4*x) ];
```

The differential equation (converted to a first-order system) and the boundary conditions are coded as local functions `mat4ode` and `mat4bc`, respectively. Because unknown parameters are present, these functions must accept three input arguments, even though some of the arguments are not used.

The guess structure `solinit` is formed with `bvpinit`. An initial guess for the solution is supplied in the form of a function `mat4init`. We chose $y = \cos 4x$ because it satisfies the boundary conditions and has the correct qualitative behavior (the correct number of sign changes). In the call to `bvpinit`, the third argument (`lambda = 15`) provides an initial guess for the unknown parameter λ .

After the problem is solved with `bvp4c`, the field `sol.parameters` returns the value $\lambda = 17.097$, and the plot shows the eigenfunction associated with this eigenvalue.

Algorithms

bvp4c is a finite difference code that implements the three-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a C^1 -continuous solution that is fourth-order accurate uniformly in $[a, b]$. Mesh selection and error control are based on the residual of the continuous solution.

bvp5c

Purpose Solve boundary value problems for ordinary differential equations

Syntax

```
sol = bvp5c(odefun,bcfun,solinit)
sol = bvp5c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

Arguments

odefun	A function handle that evaluates the differential equations $f(x,y)$. It can have the form $dydx = \text{odefun}(x,y)$ $dydx = \text{odefun}(x,y,\text{parameters})$ For a scalar x and a column vector y , $\text{odefun}(x,y)$ must return a column vector, $dydx$, representing $f(x,y)$. parameters is a vector of unknown parameters.	
bcfun	A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a),y(b))$, bcfun can have the form $\text{res} = \text{bcfun}(ya,yb)$ $\text{res} = \text{bcfun}(ya,yb,\text{parameters})$ where ya and yb are column vectors corresponding to $y(a)$ and $y(b)$. parameters is a vector of unknown parameters. The output res is a column vector.	
solinit	A structure containing the initial guess for a solution. You create solinit using the function bvpinit . solinit has the following fields.	
	x	Ordered nodes of the initial mesh. Boundary conditions are imposed at $a = \text{solinit}.x(1)$ and $b = \text{solinit}.x(\text{end})$.

	<code>y</code>	Initial guess for the solution such that <code>solinit.y(:,i)</code> is a guess for the solution at the node <code>solinit.x(i)</code> .
	<code>parameters</code>	Optional. A vector that provides an initial guess for unknown parameters.
		The structure can have any name, but the fields must be named <code>x</code> , <code>y</code> , and <code>parameters</code> . You can form <code>solinit</code> with the helper function <code>bvpinit</code> . See <code>bvpinit</code> for details.
<code>options</code>		Optional integration argument. A structure you create using the <code>bvpset</code> function. See <code>bvpset</code> for details.

Description

`sol = bvp5c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x,y)$$

on the interval `[a,b]` subject to two-point boundary value conditions

$$bc(y(a),y(b)) = 0$$

`odefun` and `bcfun` are function handles. See the `function_handle` reference page for more information.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`.

The `bvp5c` solver can also find unknown parameters p for problems of the form

$$y' = f(x,y,p)$$

$$0 = bc(y(a),y(b),p)$$

where p corresponds to parameters. You provide `bvp5c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp5c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp5c` produces a solution that is continuous on $[a,b]$ and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp5c` to evaluate the solution at specific points `xint` in the interval $[a,b]$.

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp5c` has the following fields:

<code>sol.x</code>	Mesh selected by <code>bvp5c</code>
<code>sol.y</code>	Approximation to $y(x)$ at the mesh points of <code>sol.x</code>
<code>sol.parameters</code>	Values returned by <code>bvp5c</code> for the unknown parameters, if any
<code>sol.solver</code>	' <code>bvp5c</code> '
<code>sol.stats</code>	Computational cost statistics (also displayed when the <code>stats</code> option is set with <code>bvpset</code>).

The structure `sol` can have any name, and `bvp5c` creates the fields `x`, `y`, `parameters`, and `solver`.

`sol = bvp5c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

Singular Boundary Value Problems

`bvp5c` solves a class of singular boundary value problems, including problems with unknown parameters p , of the form

$$y' = S \cdot y/x + f(x,y,p)$$

$$0 = bc(y(0),y(b),p)$$

The interval is required to be $[0, b]$ with $b > 0$. Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix S as the value of the 'SingularTerm' option of `bvpset`, and `odefun` evaluates only $f(x,y,p)$. The boundary conditions must be consistent with the necessary condition $S \cdot y(0) = 0$ and the initial guess should satisfy this condition.

Multipoint Boundary Value Problems

`bvp5c` can solve multipoint boundary value problems where $a = a_0 < a_1 < a_2 < \dots < a_n = b$ are boundary points in the interval $[a,b]$. The points a_1, a_2, \dots, a_{n-1} represent interfaces that divide $[a,b]$ into regions. `bvp5c` enumerates the regions from left to right (from a to b), with indices starting from 1. In region k , $[a_{k-1}, a_k]$, `bvp5c` evaluates the derivative as

$$yp = \text{odefun}(x,y,k)$$

In the boundary conditions function

$$\text{bcfun}(y_{\text{left}}, y_{\text{right}})$$

$y_{\text{left}}(:, k)$ is the solution at the left boundary of $[a_{k-1}, a_k]$. Similarly, $y_{\text{right}}(:, k)$ is the solution at the right boundary of region k . In particular,

$$y_{\text{left}}(:, 1) = y(a)$$

and

$$y_{\text{right}}(:, \text{end}) = y(b)$$

When you create an initial guess with

$$\text{solinit} = \text{bvpinit}(x_{\text{init}}, y_{\text{init}}),$$

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x, k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bvp5c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example of that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

Algorithms

`bvp5c` is a finite difference code that implements the four-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a C^1 -continuous solution that is fifth-order accurate uniformly in $[a, b]$. The formula is implemented as an implicit Runge-Kutta formula. `bvp5c` solves the algebraic equations directly; `bvp4c` uses analytical condensation. `bvp4c` handles unknown parameters directly; while `bvp5c` augments the system with trivial differential equations for unknown parameters.

References

[1] Shampine, L.F., M.W. Reichelt, and J. Kierzenka “Solving Boundary Value Problems for Ordinary Differential Equations in MATLAB with `bvp4c`” http://www.mathworks.com/bvp_tutorial. Note that this tutorial uses the `bvp4c` function, however in most cases the solvers can be used interchangeably.

@ | `bvp4c` | `bvpget` | `bvpinit` | `bvpset` | `bvpxtend` | `deval`

Purpose Extract properties from options structure created with `bvpset`

Syntax

```
val = bvpget(options,'name')  
val = bvpget(options,'name',default)
```

Description

`val = bvpget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = bvpget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = bvpget(options,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `options`.

See Also `bvp4c` | `bvp5c` | `bvpinit` | `bvpset` | `deval`

bvpinit

Purpose Form initial guess for BVP solvers

Syntax

```
solinit = bvpinit(x,yinit)
solinit = bvpinit(x,yinit,parameters)
solinit = bvpinit(sol,[anew bnew])
solinit = bvpinit(sol,[anew bnew],parameters)
```

Description `solinit = bvpinit(x,yinit)` forms the initial guess for a boundary value problem solver.

`x` is a vector that specifies an initial mesh. If you want to solve the BVP on $[a,b]$, then specify `x(1)` as a and `x(end)` as b . The solver adapts this mesh to the solution, so a guess like `xb=n linspace(a,b,10)` often suffices. However, in difficult cases, you should place mesh points where the solution changes rapidly. The entries of `x` must be in

- Increasing order if $a < b$
- Decreasing order if $a > b$

For two-point boundary value problems, the entries of `x` must be distinct. That is, if $a < b$, the entries must satisfy `x(1) < x(2) < ... < x(end)`. If $a > b$, the entries must satisfy `x(1) > x(2) > ... > x(end)`

For multipoint boundary value problem, you can specify the points in $[a,b]$ at which the boundary conditions apply, other than the endpoints a and b , by repeating their entries in `x`. For example, if you set

```
x = [0, 0.5, 1, 1, 1.5, 2];
```

the boundary conditions apply at three points: the endpoints 0 and 2, and the repeated entry 1. In general, repeated entries represent boundary points between regions in $[a,b]$. In the preceding example, the repeated entry 1 divides the interval $[0,2]$ into two regions: $[0,1]$ and $[1,2]$.

`yinit` is a guess for the solution. It can be either a vector, or a function:

- Vector – For each component of the solution, `bvpinit` replicates the corresponding element of the vector as a constant guess across

all mesh points. That is, `yinit(i)` is a constant guess for the *i*th component `yinit(i,:)` of the solution at all the mesh points in `x`.

- **Function** – For a given mesh point, the guess function must return a vector whose elements are guesses for the corresponding components of the solution. The function must be of the form

```
y = guess(x)
```

where `x` is a mesh point and `y` is a vector whose length is the same as the number of components in the solution. For example, if the guess function is a function, `bvpinit` calls

```
y(:,j) = guess(x(j))
```

at each mesh point.

For multipoint boundary value problems, the guess function must be of the form

```
y = guess(x, k)
```

where `y` an initial guess for the solution at `x` in region `k`. The function must accept the input argument `k`, which is provided for flexibility in writing the guess function. However, the function is not required to use `k`.

`solinit = bvpinit(x,yinit,parameters)` indicates that the boundary value problem involves unknown parameters. Use the vector `parameters` to provide a guess for all unknown parameters.

`solinit` is a structure with the following fields. The structure can have any name, but the fields must be named `x`, `y`, and `parameters`.

<code>x</code>	Ordered nodes of the initial mesh.
<code>y</code>	Initial guess for the solution with <code>solinit.y(:,i)</code> a guess for the solution at the node <code>solinit.x(i)</code> .
<code>parameters</code>	Optional. A vector that provides an initial guess for unknown parameters.

bvpinit

`solinit = bvpinit(sol,[anew bnew])` forms an initial guess on the interval `[anew bnew]` from a solution `sol` on an interval `[a,b]`. The new interval must be larger than the previous one, so either `anew <= a < b <= bnew` or `anew >= a > b >= bnew`. The solution `sol` is extrapolated to the new interval. If `sol` contains parameters, they are copied to `solinit`.

`solinit = bvpinit(sol,[anew bnew],parameters)` forms `solinit` as described above, but uses `parameters` as a guess for unknown parameters in `solinit`.

@ | [bvp4c](#) | [bvp5c](#) | [bvpget](#) | [bvpset](#) | [bvpxtend](#) | [deval](#)

Purpose

Create or alter options structure of boundary value problem

Syntax

```
options = bvpset('name1',value1,'name2',value2,...)
options = bvpset(olddopts,'name1',value1,...)
options = bvpset(olddopts,newopts)
bvpset
```

Description

`options = bvpset('name1',value1,'name2',value2,...)` creates a structure `options` that you can supply to the boundary value problem solver `bvp4c`, in which the named properties have the specified values. Any unspecified properties retain their default values. For all properties, it is sufficient to type only the leading characters that uniquely identify the property. `bvpset` ignores case for property names.

`options = bvpset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This overwrites any values in `olddopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = bvpset(olddopts,newopts)` combines an existing options structure `olddopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `olddopts`.

`bvpset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `bvpget` to query the options structure for the value of a specific property.

BVP Properties

`bvpset` enables you to specify properties for the boundary value problem solver `bvp4c`. There are several categories of properties that you can set:

- “Error Tolerance Properties” on page 1-632
- “Vectorization” on page 1-633
- “Analytical Partial Derivatives” on page 1-634
- “Singular BVPs” on page 1-635
- “Mesh Size Property” on page 1-636

- “Solution Statistic Property” on page 1-637

Error Tolerance Properties

Because `bvp4c` uses a collocation formula, the numerical solution is based on a mesh of points at which the collocation equations are satisfied. Mesh selection and error control are based on the residual of this solution, such that the computed solution $S(x)$ is the exact solution of a perturbed problem $S'(x) = f(x, S(x)) + res(x)$. On each subinterval of the mesh, a norm of the residual in the i th component of the solution, $res(i)$, is estimated and is required to be less than or equal to a tolerance. This tolerance is a function of the relative and absolute tolerances, `RelTol` and `AbsTol`, defined by the user.

$$\left| \left(res(i) / \max(abs(f(i)), AbsTol(i) / RelTol) \right) \right| \leq RelTol$$

The following table describes the error tolerance properties.

BVP Error Tolerance Properties

Property	Value	Description
<code>RelTol</code>	Positive scalar {1e-3}	<p>A relative error tolerance that applies to all components of the residual vector. It is a measure of the residual relative to the size of $f(x,y)$. The default, 1e-3, corresponds to 0.1% accuracy.</p> <p>The computed solution $S(x)$ is the exact solution of $S'(x) = F(x, S(x)) + res(x)$. On each subinterval of the mesh, the residual $res(x)$ satisfies</p> $\left \left(res(i) / \max(abs(F(i)), AbsTol(i) / RelTol) \right) \right \leq RelTol$
<code>AbsTol</code>	Positive scalar or vector {1e-6}	<p>Absolute error tolerances that apply to the corresponding components of the residual vector. <code>AbsTol(i)</code> is a threshold below which the values of the corresponding components are unimportant. If a scalar value is specified, it applies to all components.</p>

Vectorization

The following table describes the BVP vectorization property. Vectorization of the ODE function used by `bvp4c` differs from the vectorization used by the ODE solvers:

- For `bvp4c`, the ODE function must be vectorized with respect to the first argument as well as the second one, so that `F([x1 x2 ...], [y1 y2 ...])` returns `[F(x1,y1) F(x2,y2)...]`.
- `bvp4c` benefits from vectorization even when analytical Jacobians are provided. For stiff ODE solvers, vectorization is ignored when analytical Jacobians are used.

Vectorization Properties

Property	Value	Description
Vectorized	on {off}	<p>Set on to inform <code>bvp4c</code> that you have coded the ODE function <code>F</code> so that <code>F([x1 x2 ...], [y1 y2 ...])</code> returns <code>[F(x1,y1) F(x2,y2) ...]</code>. That is, your ODE function can pass to the solver a whole array of column vectors at once. This enables the solver to reduce the number of function evaluations and may significantly reduce solution time.</p> <p>With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. In the <code>shockbvp</code> example shown previously, the <code>shockODE</code> function has been vectorized using colon notation into the subscripts and by using the array multiplication <code>(.*)</code> operator.</p> <pre>function dydx = shockODE(x,y,e)</pre>

Vectorization Properties (Continued)

Property	Value	Description
		<pre> pix = pi*x; dydx = [y(2,:)... -x/e.*y(2,)-pi^2*cos(pix)- pix/e.*sin(pix)]; </pre>

Analytical Partial Derivatives

By default, the `bvp4c` solver approximates all partial derivatives with finite differences. `bvp4c` can be more efficient if you provide analytical partial derivatives $\partial f/\partial y$ of the differential equations, and analytical partial derivatives, $\partial bc/\partial ya$ and $\partial bc/\partial yb$, of the boundary conditions. If the problem involves unknown parameters, you must also provide partial derivatives, $\partial f/\partial p$ and $\partial bc/\partial p$, with respect to the parameters.

The following table describes the analytical partial derivatives properties.

BVP Analytical Partial Derivative Properties

Property	Value	Description
FJacobian	Function handle	A function handle that computes the analytical partial derivatives of $f(x,y)$. When solving $y' = f(x,y)$, set this property to <code>@fjac</code> if <code>dfdy = fjac(x,y)</code> evaluates the Jacobian $\partial f/\partial y$. If the problem involves unknown parameters p , <code>[dfdy,dfdp] = fjac(x,y,p)</code> must also return the partial derivative $\partial f/\partial p$. For problems with constant partial derivatives, set

BVP Analytical Partial Derivative Properties (Continued)

Property	Value	Description
		this property to the value of <code>dfdy</code> or to a cell array <code>{dfdy,dfdp}</code> .
BCJacobian	Function handle	A function handle that computes the analytical partial derivatives of $bc(ya,yb)$. For boundary conditions $bc(ya,yb)$, set this property to <code>@bcjac</code> if <code>[dbcodya,dbcodyb] = bcjac(ya,yb)</code> evaluates the partial derivatives $\partial bc/\partial ya$, and $\partial bc/\partial yb$. If the problem involves unknown parameters p , <code>[dbcodya,dbcodyb,dbcdp] = bcjac(ya,yb,p)</code> must also return the partial derivative $\partial bc/\partial p$. For problems with constant partial derivatives, set this property to a cell array <code>{dbcodya,dbcodyb}</code> or <code>{dbcodya,dbcodyb,dbcdp}</code> .

Singular BVPs

`bvp4c` can solve singular problems of the form

$$y' = S \frac{y}{x} + f(x,y,p)$$

posed on the interval $[0,b]$ where $b > 0$. For such problems, specify the constant matrix S as the value of `SingularTerm`. For equations of this form, `odefun` evaluates only the $f(x,y,p)$ term, where p represents unknown parameters, if any.

Singular BVP Property

Property	Value	Description
SingularTerm	Constant matrix	Singular term of singular BVPs. Set to the constant matrix S for equations of the form $y' = S \frac{y}{x} + f(x, y, p)$ posed on the interval $[0, b]$ where $b > 0$.

Mesh Size Property

bvp4c solves a system of algebraic equations to determine the numerical solution to a BVP at each of the mesh points. The size of the algebraic system depends on the number of differential equations (n) and the number of mesh points in the current mesh (N). When the allowed number of mesh points is exhausted, the computation stops, bvp4c displays a warning message and returns the solution it found so far. This solution does not satisfy the error tolerance, but it may provide an excellent initial guess for computations restarted with relaxed error tolerances or an increased value of N_{Max} .

The following table describes the mesh size property.

BVP Mesh Size Property

Property	Value	Description
NMax	positive integer {floor(1000/n)}	Maximum number of mesh points allowed when solving the BVP, where n is the number of differential equations in the problem. The default value of NMax limits the size of the algebraic system to about 1000 equations. For systems of a few differential equations, the default value of NMax should be sufficient to obtain an accurate solution.

Solution Statistic Property

The Stats property lets you view solution statistics.

The following table describes the solution statistics property.

BVP Solution Statistic Property

Property	Value	Description
Stats	on {off}	Specifies whether statistics about the computations are displayed. If the stats property is on, after solving the problem, bvp4c displays: <ul style="list-style-type: none"> • The number of points in the mesh • The maximum residual of the solution • The number of times it called the differential equation function odefun to evaluate $f(x,y)$

BVP Solution Statistic Property (Continued)

Property	Value	Description
		<ul style="list-style-type: none">The number of times it called the boundary condition function <code>bcfun</code> to evaluate $bc(y(a),y(b))$

Examples

To create an options structure that changes the relative error tolerance of `bvp4c` from the default value of $1e-3$ to $1e-4$, enter

```
options = bvpset('RelTol',1e-4);
```

To recover the value of 'RelTol' from `options`, enter

```
bvpget(options, 'RelTol')
```

```
ans =
```

```
1.0000e-004
```

See Also

`function_handle` | `bvp4c` | `bvp5c` | `bvpget` | `bvpinit` | `deval`

Purpose Form guess structure for extending boundary value solutions

Syntax

```
solinit = bvpxtend(sol,xnew,ynew)
solinit = bvpxtend(sol,xnew,extrap)
solinit = bvpxtend(sol,xnew)
solinit = bvpxtend(sol,xnew,ynew,pnew)
solinit = bvpxtend(sol,xnew,extrap,pnew)
```

Description `solinit = bvpxtend(sol,xnew,ynew)` uses solution `sol` computed on `[a,b]` to form a solution guess for the interval extended to `xnew`. The extension point `xnew` must be outside the interval `[a,b]`, but on either side. The vector `ynew` provides an initial guess for the solution at `xnew`.

`solinit = bvpxtend(sol,xnew,extrap)` forms the guess at `xnew` by extrapolating the solution `sol`. `extrap` is a string that determines the extrapolation method. `extrap` has three possible values:

- 'constant' — `ynew` is a value nearer to end point of solution in `sol`.
- 'linear' — `ynew` is a value at `xnew` of linear interpolant to the value and slope at the nearer end point of solution in `sol`.
- 'solution' — `ynew` is the value of (cubic) solution in `sol` at `xnew`.

The value of `extrap` is case-insensitive and only the leading, unique portion needs to be specified.

`solinit = bvpxtend(sol,xnew)` uses the extrapolating solution where `extrap` is 'constant'. If there are unknown parameters, values present in `sol` are used as the initial guess for parameters in `solinit`.

`solinit = bvpxtend(sol,xnew,ynew,pnew)` specifies a different guess `pnew`. `pnew` can be used with extrapolation, using the syntax `solinit = bvpxtend(sol,xnew,extrap,pnew)`. To modify parameters without changing the interval, use `[]` as place holder for `xnew` and `ynew`.

See Also `bvp4c` | `bvp5c` | `bvpinit`

calendar

Purpose Calendar for specified month

Syntax
c = calendar
c = calendar(d)
c = calendar(y, m)

Description c = calendar returns a 6-by-7 matrix containing a calendar for the current month. The calendar runs Sunday (first column) to Saturday.
c = calendar(d), where d is a serial date number or a date string, returns a calendar for the specified month.
c = calendar(y, m), where y and m are integers, returns a calendar for the specified month of the specified year.

Examples The command
calendar(1957,10)

reveals that the Space Age began on a Friday (on October 4, 1957, when Sputnik 1 was launched).

```
                Oct 1957
   S      M      Tu      W      Th      F      S
   0      0      1      2      3      4      5
   6      7      8      9      10     11     12
  13     14     15     16     17     18     19
  20     21     22     23     24     25     26
  27     28     29     30     31      0      0
   0      0      0      0      0      0      0
```

See Also datenum

Purpose	Call function in shared library
Syntax	<code>[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)</code>
Description	<code>[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)</code> calls function, <code>funcname</code> , in library, <code>libname</code> , passing input arguments, <code>arg1,...,argN</code> , and returns output values obtained from <code>funcname</code> in <code>x1,...,xN</code> .
Input Arguments	<p>libname - Name of shared library string</p> <p>Name of shared library, specified as a string. If you call <code>loadlibrary</code> using the <code>alias</code> option, then you must use the alias name for the <code>libname</code> argument.</p> <p>Data Types char</p> <p>funcname - Name of function in library string</p> <p>Name of function in library, specified as a string.</p> <p>Data Types char</p> <p>arg1,...,argN - Input arguments any type</p> <p>Input arguments, 1 through N, required by <code>funcname</code> (if any), specified by any type. The argument type is specified by the <code>funcname</code> argument list.</p>
Output Arguments	<p>x1,...,xN - Output arguments any type</p> <p>Output arguments, 1 through N, from <code>funcname</code> (if any), returned as any type. The argument type is specified by the <code>funcname</code> argument list.</p>

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

Examples

Call `addStructByRef` Function

Load the library.

```
if ~libisloaded('shrlibsample')
    addpath(fullfile(matlabroot,'extern','examples','shrlib'))
    loadlibrary('shrlibsample')
end
```

Display function signature.

```
libfunctionsview shrlibsample
```

```
[double, c_structPtr] addStructByRef(c_structPtr)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `struct`:

```
struct.p1 = 4; struct.p2 = 7.3; struct.p3 = -290;
```

Call the function.

```
[res,st] = calllib('shrlibsample','addStructByRef',struct);
```

Display the results.

```
res
```

```
res =
    -279
```

Cleanup.

```
unloadlibrary shrlibsample
```

callSoapService

Purpose Send SOAP message to endpoint

Syntax `response = callSoapService(endpoint,soapAction,message)`

Description `response = callSoapService(endpoint,soapAction,message)` sends message, a Java[®] document object model (DOM), to the soapAction service at endpoint. Create message using `createSoapMessage`, and extract results from response using `parseSoapResponse`.

Examples This example uses `callSoapService` in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

Note The example does not use an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

```
% Create the message:
message = createSoapMessage(...
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'},...
'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
'http://test/soap/services/LibraryCatalog',...
'urn:LibraryCatalog#getAuthor',...
message)
%
% Extract MATLAB data from the response
```

```
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

How To

- “Access Web Services Using MATLAB SOAP Functions”

Purpose Move camera position and target

Syntax

```
camdolly(dx,dy,dz)
camdolly(dx,dy,dz,'targetmode')
camdolly(dx,dy,dz,'targetmode','coordsys')
camdolly(axes_handle,...)
```

Description `camdolly(dx,dy,dz)` moves the camera position and the camera target by the specified amounts `dx`, `dy`, and `dz`.

`camdolly(dx,dy,dz,'targetmode')` uses the `targetmode` argument to determine how the camera moves:

- `movetarget` (default) — Move both the camera and the target.
- `fixtarget` — Move only the camera.

`camdolly(dx,dy,dz,'targetmode','coordsys')` uses the `coordsys` argument to determine how MATLAB interprets `dx`, `dy`, and `dz`:

- `camera` (default) — Move in the coordinate system of the camera. `dx` moves left/right, `dy` moves down/up, and `dz` moves along the viewing axis. MATLAB normalizes the units to the scene.

For example, setting `dx` to 1 moves the camera to the right, which pushes the scene to the left edge of the box formed by the axes position rectangle. A negative value moves the scene in the other direction. Setting `dz` to 0.5 moves the camera to a position halfway between the camera position and the camera target.

- `pixels` — Interpret `dx` and `dy` as pixel offsets and ignore `dz`.
- `data` — Interpret `dx`, `dy`, and `dz` as offsets in axes data coordinates.

`camdolly(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camdolly` operates on the current axes.

`camdolly` sets the axes `CameraPosition` and `CameraTarget` properties, which in turn sets the `CameraPositionMode` and `CameraTargetMode` properties to manual.

Examples

Move the camera along the x - and y -axes in a series of steps:

```
surf(peaks)
axis vis3d
t = 0:pi/20:2*pi;
dx = sin(t)/40;
dy = cos(t)/40;
for i = 1:length(t);
    camdolly(dx(i),dy(i),0)
    drawnow
end
```

How To

- “Camera Graphics Terminology”

cameratoolbar

Purpose Control camera toolbar programmatically

Syntax

```
cameratoolbar
cameratoolbar('NoReset')
cameratoolbar('SetMode',mode)
cameratoolbar('SetCoordSys',coordsys)
cameratoolbar('Show')
cameratoolbar('Hide')
cameratoolbar('Toggle')
cameratoolbar('ResetCameraAndSceneLight')
cameratoolbar('ResetCamera')
cameratoolbar('ResetSceneLight')
cameratoolbar('ResetTarget')
mode = cameratoolbar('GetMode')
paxis = cameratoolbar('GetCoordsys')
vis = cameratoolbar('GetVisible')
cameratoolbar(fig,...)
h = cameratoolbar
cameratoolbar('Close')
```

Description cameratoolbar creates a toolbar that enables interactive manipulation of the axes camera and light when you drag the mouse on the figure window. Several axes camera properties are set when the toolbar is initialized.

cameratoolbar('NoReset') creates the toolbar without setting any camera properties.

cameratoolbar('SetMode',mode) sets the toolbar mode (depressed button). mode can be 'orbit', 'orbitscenelight', 'pan', 'dollyhv', 'dollyfb', 'zoom', 'roll', 'nomode'. For descriptions of the various modes, see “Camera Toolbar”. You can also set these modes using the toolbar, by clicking the respective buttons.

cameratoolbar('SetCoordSys',coordsys) sets the principal axis of the camera motion. coordsys can be: 'x', 'y', 'z', 'none'.

cameratoolbar('Show') shows the toolbar on the current figure.

`cameratoolbar('Hide')` hides the toolbar on the current figure.

`cameratoolbar('Toggle')` toggles the visibility of the toolbar.

`cameratoolbar('ResetCameraAndSceneLight')` resets the current camera and scenelight.

`cameratoolbar('ResetCamera')` resets the current camera.

`cameratoolbar('ResetSceneLight')` resets the current scenelight.

`cameratoolbar('ResetTarget')` resets the current camera target.

`mode = cameratoolbar('GetMode')` returns the current mode.

`paxis = cameratoolbar('GetCoordsys')` returns the current principal axis.

`vis = cameratoolbar('GetVisible')` returns the visibility of the toolbar (1 if visible, 0 if not visible).

`cameratoolbar(fig, ...)` specifies the figure to operate on by passing the figure handle as the first argument.

`h = cameratoolbar` returns the handle to the toolbar.

`cameratoolbar('Close')` removes the toolbar from the current figure.

In general, the use of OpenGL hardware improves rendering performance.

Alternatives

Display the toolbar by selecting **Camera Toolbar** from the figure window's **View** menu.

How To

- “Camera Toolbar”

camlight

Purpose Create or move light object in camera coordinates

Syntax

```
camlight('headlight')
camlight('right')
camlight('left')
camlight
camlight(az,e1)
camlight(...,'style')
camlight(light_handle,...)
light_handle = camlight(...)
```

Description

`camlight('headlight')` creates a light at the camera position.

`camlight('right')` creates a light right and up from camera.

`camlight('left')` creates a light left and up from camera.

`camlight` with no arguments is the same as `camlight('right')`.

`camlight(az,e1)` creates a light at the specified azimuth (`az`) and elevation (`e1`) with respect to the camera position. The camera target is the center of rotation and `az` and `e1` are in degrees.

`camlight(...,'style')` defines the style argument using one of two values:

- `local` (default) — The light is a point source that radiates from the location in all directions.
- `infinite` — The light shines in parallel rays.

`camlight(light_handle,...)` uses the light specified in `light_handle`.

`light_handle = camlight(...)` returns the light object handle.

`camlight` sets the light object `Position` and `Style` properties. A light created with `camlight` does not track the camera. In order for the light to stay in a constant position relative to the camera, call `camlight` whenever you move the camera.

Examples

Create a light positioned to the left of the camera and then reposition the light each time the camera moves:

```
surf(peaks)
axis vis3d
h = camlight('left');
for i = 1:20;
    camorbit(10,0)
    camlight(h,'left')
    drawnow;
end
```

How To

- “Lighting Overview”

camlookat

Purpose Position camera to view object or group of objects

Syntax `camlookat(object_handles)`
`camlookat(axes_handle)`
`camlookat`

Description `camlookat(object_handles)` views the objects identified in the vector `object_handles`. The vector can contain the handles of axes children.

`camlookat(axes_handle)` views the objects that are children of the axes identified by `axes_handle`.

`camlookat` views the objects that are in the current axes by moving the camera position and camera target while preserving the relative view direction and camera view angle. The viewed object (or objects) roughly fill the axes position rectangle. To change the view, `camlookat` sets the axes `CameraPosition` and `CameraTarget` properties.

Examples Create three spheres at different locations and then progressively position the camera so that the scene composes around each sphere individually:

```
% Create three spheres using the sphere function:  
[x y z] = sphere;  
s1 = surf(x,y,z);  
hold on  
s2 = surf(x+3,y,z+3);  
s3 = surf(x,y,z+6);  
% Set the data aspect ratio using daspect:  
daspect([1 1 1])  
% Set the view:  
view(30,10)  
% Set the projection type using camproj:  
camproj perspective  
% Compose the scene around the current axes  
camlookat(gca)  
pause(2)  
% Compose the scene around sphere s1
```

```
camlookat(s1)
pause(2)
% Compose the scene around sphere s2
camlookat(s2)
pause(2)
% Compose the scene around sphere s3
camlookat(s3)
pause(2)
camlookat(gca)
```

How To

- “Camera Graphics Terminology”

camorbit

Purpose

Rotate camera position around camera target

Syntax

```
camorbit(dtheta,dphi)
camorbit(dtheta,dphi,'coordsys')
camorbit(dtheta,dphi,'coordsys','direction')
camorbit(axes_handle,...)
```

Description

`camorbit(dtheta,dphi)` rotates the camera position around the camera target by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`camorbit(dtheta,dphi,'coordsys')` rotates the camera position around the camera target, using the `coordsys` argument to determine the center of rotation. `coordsys` can take on two values:

- `data` (default) — Rotate the camera around an axis defined by the camera target and the `direction` (default is the positive `z` direction).
- `camera` — Rotate the camera about the point defined by the camera target.

`camorbit(dtheta,dphi,'coordsys','direction')` defines the axis of rotation for the `data` coordinate system using the `direction` argument in conjunction with the camera target. Specify `direction` as a three-element vector containing the `x`-, `y`-, and `z`-components of the direction or one of the characters, `x`, `y`, or `z`, to indicate `[1 0 0]`, `[0 1 0]`, or `[0 0 1]` respectively.

`camorbit(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camorbit` operates on the current axes.

The behavior of `camorbit` differs from the `rotate3d` function in that while the `rotate3d` tool modifies the `View` property of the axes, the `camorbit` function fixes the aspect ratio and modifies the `CameraTarget`, `CameraPosition` and `CameraUpVector` properties of the axes. See `Axes Properties` for more information.

Examples

Rotate the camera horizontally about a line defined by the camera target point and a direction that is parallel to the y -axis. Visualize this rotation as a cone formed with the camera target at the apex and the camera position forming the base:

```
surf(peaks)
axis vis3d
for i=1:36
    camorbit(10,0,'data',[0 1 0])
    drawnow
end
```

Rotate in the camera coordinate system to orbit the camera around the axes along a circle while keeping the center of a circle at the camera target:

```
surf(peaks)
axis vis3d
for i=1:36
    camorbit(10,0,'camera')
    drawnow
end
```

Alternatives

Enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

How To

- “Camera Graphics Terminology”

campan

Purpose Rotate camera target around camera position

Syntax

```
campan(dtheta,dphi)
campan(dtheta,dphi,coordsys)
campan(dtheta,dphi,coordsys,direction)
campan(axes_handle,...)
```

Description `campan(dtheta,dphi)` rotates the camera target of the current axes around the camera position by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`campan(dtheta,dphi,coordsys)` determine the center of rotation using the `coordsys` argument. It can take on two values:

- 'data' (default) — Rotate the camera target around an axis defined by the camera position and the `direction` (default is the positive `z` direction)
- 'camera' — Rotate the camera about the point defined by the camera target.

`campan(dtheta,dphi,coordsys,direction)` defines the axis of rotation for the data coordinate system using the `direction` argument with the camera position. Specify `direction` as a three-element vector containing the `x`-, `y`-, and `z`-components of the direction or one of the characters, 'x', 'y', or 'z', to indicate [1 0 0], [0 1 0], or [0 0 1] respectively.

`campan(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campan` operates on the current axes.

Examples Move the camera target to pan the object in a circular motion.

```
sphere;
axis vis3d
hPan = sin(-pi:1:pi);
vPan = cos(-pi:1:pi);
```

```
for k=1:length(hPan)
    campan(hPan(k),vPan(k))
    drawnow
    pause(.1)
end
```

How To

- “Camera Graphics Terminology”

campos

Purpose Set or query camera position

Syntax

```
campos
campos([camera_position])
campos('mode')
campos('auto')
campos('manual')
campos(axes_handle,...)
```

Description

`campos` returns the camera position in the current axes.

`campos([camera_position])` sets the position of the camera in the current axes to the specified value. Specify the position as a three-element vector containing the x -, y -, and z -coordinates of the desired location in the data units of the axes.

`campos('mode')` returns the value of the camera position mode, which can be either `auto` (the default) or `manual`.

`campos('auto')` sets the camera position mode to `auto`.

`campos('manual')` sets the camera position mode to `manual`.

`campos(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campos` operates on the current axes.

`campos` sets or queries values of the axes `CameraPosition` and `CameraPositionMode` properties. The camera position is the point in the Cartesian coordinate system of the axes from which you view the scene.

Examples Move the camera along the x -axis in a series of steps:

```
surf(peaks)
axis vis3d off
for x = -200:5:200
    campos([x,5,10])
    drawnow
end
```

How To

- “Camera Graphics Terminology”

camproj

Purpose Set or query projection type

Syntax
`camproj`
`camproj('projection_type')`
`camproj(axes_handle,...)`

Description `camproj` returns the projection type setting in the current axes. The projection type determines whether MATLAB 3-D views use a perspective or orthographic projection.

`camproj('projection_type')` sets the projection type in the current axes to the specified value. Possible values for *projection_type* are orthographic and perspective.

`camproj(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camproj` operates on the current axes.

`camproj` sets or queries values of the axes object `Projection` property.

Examples Compare the different `camproj` settings using `subplot`:

```
subplot(1,2,1); surf(membrane); camproj('perspective')
subplot(1,2,2); surf(membrane); camproj('orthographic')
```

How To

- “Camera Graphics Terminology”

camroll

Purpose Rotate camera about view axis

Syntax `camroll(dtheta)`
`camroll(axes_handle,dtheta)`

Description `camroll(dtheta)` rotates the camera around the camera viewing axis by the amounts specified in `dtheta` (in degrees). The viewing axis is the line passing through the camera position and the camera target.

`camroll(axes_handle,dtheta)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camroll` operates on the current axes.

`camroll` sets the axes `CameraUpVector` property and also sets the `CameraUpVectorMode` property to `manual`.

Examples Rotate the camera around the viewing axis:

```
surf(peaks)
axis vis3d
for i=1:36
    camroll(10)
    drawnow
end
```

See Also `axes` | `axis` | `camdolly` | `camorbit` | `camzoom` | `campan`

How To • “Camera Graphics Terminology”

Purpose Set or query location of camera target

Syntax

```
camtarget
camtarget([camera_target])
camtarget('mode')
camtarget('auto')
camtarget('manual')
camtarget('manual')
camtarget(axes_handle,...)
```

Description `camtarget` returns the location of the camera target in the current axes. The camera target is the location in the axes that the camera points to. The camera remains oriented toward this point regardless of its position.

`camtarget([camera_target])` sets the camera target in the current axes to the specified value. Specify the target as a three-element vector containing the x -, y -, and z -coordinates of the desired location in the data units of the axes.

`camtarget('mode')` returns the value of the camera target mode, which can be either `auto` (default) or `manual`.

`camtarget('auto')` sets the camera target mode to `auto`. When the camera target mode is `auto`, the camera target is the center of the axes plot box.

`camtarget('manual')` sets the camera target mode to `manual`.

`camtarget(axes_handle,...)` performs the set or query on the axes identified by `axes_handle`. When you do not specify an axes handle, `camtarget` operates on the current axes.

`camtarget` sets or queries values of the axes object `CameraTarget` and `CameraTargetMode` properties.

Examples Move the camera position and the camera target along the x -axis in a series of steps:

```
surf(peaks);
axis vis3d
```

camtarget

```
xp = linspace(-150,40,50);
xt = linspace(25,50,50);
for i=1:50
    campos([xp(i),25,5]);
    camtarget([xt(i),30,0])
    drawnow
end
```

How To

- “Camera Graphics Terminology”

Purpose Set or query camera up vector

Syntax

```
camup
camup([up_vector])
camup('mode')
camup('auto')
camup('manual')
camup(axes_handle,...)
```

Description `camup` returns the camera up vector setting in the current axes. The camera up vector specifies the direction that is oriented up in the scene.

`camup([up_vector])` sets the up vector in the current axes to the specified value. Specify the up vector as x , y , and z components.

`camup('mode')` returns the current value of the camera up vector mode, which can be either `auto` (default) or `manual`.

`camup('auto')` sets the camera up vector mode to `auto`. In `auto` mode, $[0\ 1\ 0]$ is the up vector of for 2-D views. This means the y -axis points up. For 3-D views, the up vector is $[0\ 0\ 1]$, meaning the z -axis points up.

`camup('manual')` sets the camera up vector mode to `manual`. In `manual` mode, the value of the camera up vector does not change unless you set it.

`camup(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camup` operates on the current axes.

Examples Set the x -axis to be the up axis:

```
surf(peaks)
camup([1 0 0]);
```

See Also

[axis](#) | [campos](#) | [camup](#) | [camtarg](#) | [Axes: CameraPosition](#) | [Axes: CameraTarget](#) | [Axes: CameraUpVector](#) | [Axes: CameraViewAngle](#) | [Axes: Projection](#)

How To

- “Camera Graphics Terminology”

Purpose Set or query camera view angle

Syntax

```
camva
camva(view_angle)
camva('mode')
camva('auto')
camva('manual')
camva(axes_handle,...)
```

Description `camva` returns the camera view angle setting in the current axes. The camera view angle determines the field of view of the camera. Larger angles produce a smaller view of the scene. Implement zooming by changing the camera view angle.

`camva(view_angle)` sets the view angle in the current axes to the specified value. Specify the view angle in degrees.

`camva('mode')` returns the current value of the camera view angle mode, which can be either `auto` (the default) or `manual`.

`camva('auto')` sets the camera view angle mode to `auto`.

`camva('manual')` sets the camera view angle mode to `manual`.

`camva(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camva` operates on the current axes.

Tips The `camva` function sets or queries values of the axes object `CameraViewAngle` and `CameraViewAngleMode` properties.

When the camera view angle mode is `auto`, the camera view angle adjusts so that the scene fills the available space in the window. If you move the camera to a different position, the camera view angle changes to maintain a view of the scene that fills the available area in the window.

Setting a camera view angle or setting the camera view angle to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes

to fit the window). This means setting the camera view angle to its current value,

```
camva(camva)
```

can cause a change in the way the graph looks. See axes for more information.

Examples

Create two pushbuttons, one that zooms in and another that zooms out:

```
% Set the range checking in the callback statements to keep
% the values for the camera view angle in the range greater
% than zero and less than 180.
uicontrol('Style','pushbutton',...
    'String','Zoom In',...
    'Position',[20 20 60 20],...
    'Callback','if camva <= 1;return;else;camva(camva-1);end');
uicontrol('Style','pushbutton',...
    'String','Zoom Out',...
    'Position',[100 20 60 20],...
    'Callback',...
    'if camva >= 179;return;else;camva(camva+1);end');
% Now create a graph to zoom in and out on:
surf(peaks);
```

TriRep.cartToBary

Purpose (Will be removed) Convert point coordinates from cartesian to barycentric

Note `cartToBary(TriRep)` will be removed in a future release. Use `cartesianToBarycentric(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax `B = cartToBary(TR, SI, XC)`

Description `B = cartToBary(TR, SI, XC)` returns the barycentric coordinates of each point in `XC` with respect to its associated simplex `SI`.

Input Arguments

`TR` Triangulation representation.

`SI` Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`.

`XC` Matrix that represents the Cartesian coordinates of the points to be converted. `XC` is of size `m-by-n`, where `m` is of `length(SI)`, the number of points to convert, and `n` is the dimension of the space where the triangulation resides.

Output Arguments

`B` Matrix of dimension `m-by-k` where `k` is the number of vertices per simplex.

Definitions A simplex is a triangle/tetrahedron or higher dimensional equivalent.

Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
```

```
y = [0 0 0 0 8 8 8 8]';  
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);  
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure  
subplot(1,2,1);  
triplot(dt); hold on;  
plot(cc(:,1), cc(:,2), '*r');  
hold off;  
axis equal;
```

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);  
y = [0 0 0 0 16 16 16 16]';  
tr = TriRep(tri,x,y)  
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);  
triplot(tr);  
hold on;  
plot(xc(:,1), xc(:,2), '*r');  
hold off;  
axis equal;
```

TriRep.cartToBary

| [triangulation](#)

Purpose Transform Cartesian coordinates to polar or cylindrical

Syntax `[THETA,RHO,Z] = cart2pol(X,Y,Z)`
`[THETA,RHO] = cart2pol(X,Y)`

Description `[THETA,RHO,Z] = cart2pol(X,Y,Z)` transforms three-dimensional Cartesian coordinates stored in corresponding elements of arrays X, Y, and Z, into cylindrical coordinates. THETA is a counterclockwise angular displacement in radians from the positive x-axis, RHO is the distance from the origin to a point in the x-y plane, and Z is the height above the x-y plane. Arrays X, Y, and Z must be the same size (or any can be scalar).

`[THETA,RHO] = cart2pol(X,Y)` transforms two-dimensional Cartesian coordinates stored in corresponding elements of arrays X and Y into polar coordinates.

Algorithms The mapping from two-dimensional Cartesian coordinates to polar coordinates, and from three-dimensional Cartesian coordinates to cylindrical coordinates is

Two-Dimensional Mapping
 $\text{theta} = \text{atan2}(y,x)$
 $\text{rho} = \sqrt{x.^2 + y.^2}$

Three-Dimensional Mapping
 $\text{theta} = \text{atan2}(y,x)$
 $\text{rho} = \sqrt{x.^2 + y.^2}$
 $Z = Z$

cart2pol

See Also

[cart2sph](#) | [pol2cart](#) | [sph2cart](#)

Purpose Transform Cartesian coordinates to spherical

Syntax `[azimuth,elevation,r] = cart2sph(X,Y,Z)`

Description `[azimuth,elevation,r] = cart2sph(X,Y,Z)` transforms Cartesian coordinates stored in corresponding elements of arrays X, Y, and Z into spherical coordinates. `azimuth` and `elevation` are angular displacements in radians. `azimuth` is the counterclockwise angle in the *x-y* plane measured from the positive *x*-axis. `elevation` is the elevation angle from the *x-y* plane. `r` is the distance from the origin to a point.

Arrays X, Y, and Z must be the same size (or any of them can be scalar).

Algorithms The mapping from three-dimensional Cartesian coordinates to spherical coordinates is

```
azimuth = atan2(y,x)
elevation = atan2(z,sqrt(x.^2 + y.^2))
r = sqrt(x.^2 + y.^2 + z.^2)
```

cart2sph

The notation for spherical coordinates is not standard. For the `cart2sph` function, `elevation` is measured from the x - y plane. Notice that if `elevation = 0`, the point is in the x - y plane. If `elevation = pi/2`, then the point is on the positive z -axis.

`cart2pol` | `pol2cart` | `sph2cart`

Purpose

Cast variable to different data type

Syntax

```
B = cast(A,newclass)
B = cast(A,'like',p)
```

Description

`B = cast(A,newclass)` converts `A` to class `newclass`, where `newclass` is the name of a built-in data type compatible with `A`. The `cast` function truncates any values in `A` that are too large to map into `newclass`.

`B = cast(A,'like',p)` converts `A` to the same data type and sparsity as the variable `p`. If `A` and `p` are both real, then `B` is also real. Otherwise, `B` is complex.

Examples**Convert Numeric Data Type**

Convert an `int8` value to `uint8`.

Define a scalar 8-bit integer.

```
a = int8(5);
```

Convert `a` to an unsigned 8-bit integer.

```
b = cast(a,'uint8');
class(b)
```

```
ans =
uint8
```

Match Data Type and Complex Nature of p

Define a single precision vector `p` that is complex valued.

```
p = single([1+i 2]);
```

Define a 2-by-3 matrix of ones.

```
A = ones(2,3);
```

Convert `A` to the same data type and complexity (real or complex) as `p`.

cast

```
B = cast(A, 'like', p)
```

```
B =
```

```
    1.0000 + 0.0000i    1.0000 + 0.0000i    1.0000 + 0.0000i  
    1.0000 + 0.0000i    1.0000 + 0.0000i    1.0000 + 0.0000i
```

Check the class of B.

```
class(B)
```

```
ans =
```

```
single
```

[class](#) | [typecast](#)

Concepts

- “Class Support for Array-Creation Functions”

Purpose

Concatenate arrays along specified dimension

Syntax

```
C = cat(dim, A, B)
C = cat(dim, A1, A2, A3, A4, ...)
```

Description

`C = cat(dim, A, B)` concatenates the arrays `A` and `B` along array the dimension specified by `dim`. The `dim` argument must be a real, positive, integer value.

`C = cat(dim, A1, A2, A3, A4, ...)` concatenates all the input arrays (`A1`, `A2`, `A3`, `A4`, and so on) along array dimension `dim`.

For nonempty arrays, `cat(2, A, B)` is the same as `[A, B]`, and `cat(1, A, B)` is the same as `[A; B]`.

If your input arrays are tables, `dim` must be either 1 or 2. `cat` then concatenates by calling `horzcat` or `vertcat` respectively.

Tips

When used with comma-separated list syntax, `cat(dim, C{:})` or `cat(dim, C.field)` is a convenient way to concatenate a cell or structure array containing numeric matrices into a single matrix.

You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”

Examples

Given

```
A =           B =
     1     2           5     6
     3     4           7     8
```

cat

concatenating along different dimensions produces

1	2
3	4
5	6
7	8

C = cat(1,A,B)

1	2	5	6
3	4	7	8

C = cat(2,A,B)

1	2
3	4

5	6
7	8

C = cat(3,A,B)

The commands

```
A = magic(3); B = pascal(3);  
C = cat(4, A, B);
```

produce a 3-by-3-by-1-by-2 array.

`vertcat` | `horzcat` | `strcat` | `char` | `num2cell` | `reshape` | `squeeze`
| `strjoin` | `shiftdim` | `special character`

Purpose

Create categorical array

Syntax

```
B = categorical(A)
B = categorical(A,valueSet)
B = categorical(A,valueSet,catnames)
B = categorical(A, __ ,Name,Value)
```

Description

`B = categorical(A)` creates a categorical array from the array, `A`. The categories of `B` are the sorted unique values from `A`.

For more information on creating and using categorical arrays, see “Categorical Arrays”.

`B = categorical(A,valueSet)` creates one category for each value in `valueSet`. The categories of `B` are in the same order as the values of `valueSet`.

You can use `valueSet` to include categories for values not present in `A`. Conversely, if `A` contains any values not present in `valueSet`, the corresponding elements of `B` are undefined.

`B = categorical(A,valueSet,catnames)` names the categories in `B` by matching the category values in `valueSet` with the names in `catnames`.

`B = categorical(A, __ ,Name,Value)` creates a categorical array with additional options specified by one or more `Name,Value` pair arguments. You can include any of the input arguments in previous syntaxes.

For example, you can specify that the categories have a mathematical ordering.

Input Arguments**A - Input array**

numeric array | logical array | categorical array | cell array of strings
| ...

Input array, specified as a numeric array, logical array, categorical array, or cell array of strings.

If **A** contains missing values, the corresponding element of **B** is `<undefined>`. Missing values are `NaN` for numeric arrays, the empty string (`' '`) for cell arrays of strings, and `<undefined>` for categorical arrays. **B** does not have a category for undefined values. To create an explicit category for missing or undefined values, you must include the desired category name in `catnames`, and `NaN`, the empty string, or `<undefined>` in `valueset`.

In addition to an array, **A** can be an object with the following class methods:

- `unique`
- `eq`

valueset - Values to define categories

`unique(A)` (default) | vector of unique values

Values to define categories, specified as a vector of unique values. The data type of `valueset` and the data type of **A** must be the same.

catnames - Category names

cell array of strings

Category names, specified as a cell array of strings. If you do not specify the `catnames` input argument, `categorical` uses the values in `valueset` as category names.

To merge multiple distinct values in **A** into a single category in **B**, include duplicate names corresponding to those values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Ordinal', true specifies that the categories have a mathematical ordering

'Ordinal' - Mathematical ordering indicator

false (default) | true | 0 | 1

Mathematical ordering indicator, specified as the comma-separated pair consisting of 'Ordinal' and either false, true, 0, or 1.

false `categorical` creates a categorical array that is not ordinal. This is the default behavior.

The categories of **B** have no mathematical ordering. Therefore, you can only compare the values in **B** for equality.

true `categorical` creates an ordinal categorical array.

The categories of **B** have a mathematical ordering, such that the first category specified is the smallest and the last category is the largest. You can compare the values in **B** using relational operators, such as less than and greater than, in addition to comparing the values for equality.

'Protected' - Category protection indicator

false | true | 0 | 1

Category protection indicator specified as the comma-separated pair consisting of 'Protected' and either false, true, 0, or 1. The categories of ordinal categorical arrays are always protected. The default value is true when you specify 'Ordinal', true and false otherwise.

false	When you assign new values to B, the categories update automatically. Therefore, you can combine (nonordinal) categorical arrays that have different categories. The categories can update accordingly to include the categories from both arrays.
true	When you assign new values to B, the values must belong to one of the existing categories. Therefore, you can only combine arrays that have the same categories. To add new categories to B, you must use the function <code>addcats</code> .

Examples

Create Categorical Array from Strings

Convert a cell array of strings to a categorical array.

Create a cell array of strings.

```
A = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

A =

```
    'r'    'b'    'g'  
    'g'    'r'    'b'  
    'b'    'r'    'g'
```

A is a 3-by-3 cell array containing three unique values.

Convert the cell array of strings, A, to a categorical array, B.

```
B = categorical(A)
```

B =

```
    r    b    g  
    g    r    b  
    b    r    g
```

The contents of B match the contents of A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
    'b'  
    'g'  
    'r'
```

The categories of B are the unique values from A in alphabetical order.

Create Categorical Array and Specify Possible Unique Values

Convert a cell array of strings, A, to a categorical array. Specify a list of categories that includes values that are not present in A.

Create a cell array of strings.

```
A = {'republican' 'democrat'; 'democrat' 'democrat'; 'democrat' 'republican'}
```

```
A =
```

```
    'republican'    'democrat'  
    'democrat'    'democrat'  
    'democrat'    'republican'
```

A is a 3-by-2 cell array containing two unique values.

Convert the cell array of strings, A, to a categorical array, B and include a category for independent.

```
valueset = {'democrat' 'republican' 'independent'}
```

```
B = categorical(A,valueset)
```

```
B =
```

```
    republican    democrat  
    democrat    democrat  
    democrat    republican
```

The contents of B match the contents of A.

Display the categories of B.

```
categories(B)

ans =

    'democrat'
    'republican'
    'independent'
```

The categories of B are in the same order as the values specified in `valueset`.

Create Categorical Array and Specify Category Names

Create a cell array of strings.

```
A = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

```
A =

    'r'    'b'    'g'
    'g'    'r'    'b'
    'b'    'r'    'g'
```

A is a 3-by-3 cell array containing three unique values.

Convert the cell array of strings, A, to a categorical array, B, and specify category names.

```
B = categorical(A,{'r' 'g' 'b'},{'red' 'green' 'blue'})
```

```
B =

    red    blue    green
    green  red    blue
```

```
         blue      red      green
```

B uses the specified category names for the contents from A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
    'red'  
    'green'  
    'blue'
```

The categories of B are in the order they were specified.

Create Categorical Array from Integers

Create a 2-by-3 numeric array.

```
A = gallery('integerdata',3,[2,3],3)
```

```
A =
```

```
     2     1     2  
     1     1     3
```

A contains the values 1, 2, and 3.

Convert the numeric array, A, to a categorical array. Use the values 1, 2, and 3 to define the categories car, bus, and bike, respectively.

```
valueset = 1:3;  
catnames = {'car' 'bus' 'bike'};
```

```
B = categorical(A,valueset,catnames)
```

```
B =
```

```
     bus     car     bus
```

```
car    car    bike
```

`categorical` maps the numeric values in `valueset` to the category names in `catnames`.

The 2-by-3 categorical array, `B`, is not ordinal. Therefore, you can only compare the values in `B` for equality. To compare the values in `B` using relational operators, such as less than and greater than, you must include the `'Ordinal'`, true name-value pair argument.

Create Ordinal Categorical Array from Integers

Create a 5-by-2 numeric array.

```
A = gallery('integerdata',3,[5,2],1)
```

```
A =
```

```
3    2
3    3
3    2
2    1
3    2
```

`A` contains the values 1, 2, and 3.

Convert the numeric array, `A`, to an ordinal categorical array where 1, 2, and 3 represent child, adult, and senior respectively.

```
valueset = [1:3];
catnames = {'child' 'adult' 'senior'};
```

```
B = categorical(A,valueset,catnames,'Ordinal',true)
```

```
B =
```

```
senior    adult
senior    senior
senior    adult
```

```
      adult      child  
      senior     adult
```

Since B is ordinal, the categories of B have a mathematical ordering, `child < adult < senior`.

`categories`

Concepts

- “Advantages of Using Categorical Arrays”

categories

Purpose Categories of categorical array

Syntax `C = categories(A)`

Description `C = categories(A)` returns a cell array of strings containing the categories of the categorical array, A.

Input Arguments **A - Categorical array**
vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

Examples **List Categories in Categorical Array**

Create a categorical array, A.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```
    plane    car    train    car    plane
```

A is a 1-by-5 categorical array.

Display the categories of A.

```
C = categories(A)
```

```
C =
```

```
    'car'  
    'plane'  
    'train'
```

Since you created A by specifying only an input array, the categories appear in alphabetical order.

List Categories in Ordinal Categorical Array

Create an ordinal categorical array.

```
A = categorical({'medium' 'large'; 'small' 'xlarge'; 'large' 'medium'},...
               {'small' 'medium' 'large' 'xlarge'},'Ordinal',true)
```

A =

```
      medium      large
      small      xlarge
      large      medium
```

A is a 3-by-2 ordinal categorical array.

Display the categories of A.

```
C = categories(A)
```

C =

```
'small'
'medium'
'large'
'xlarge'
```

The categories appear in the order in which you specified them. Since A is ordinal, the categories have the mathematical ordering `small < medium < large < xlarge`.

Tips

- C includes all categories in A, even if A does not contain any data from a category. To see the unique values in A, use `unique(A)`.
- The order of the categories listed in C is the same order used by functions, such as `summary` and `hist`. To change the order of the categories, use `reordercats`.

`categorical` | `unique` | `addcats` | `removecats` | `iscategory` | `mergecats` | `renamecats` | `reordercats` | `hist`

caxis

Purpose Color axis scaling

Syntax

```
caxis([cmin cmax])  
caxis auto  
caxis manual  
caxis(caxis)  
v = caxis  
caxis(axes_handle,...)
```

Description `caxis` controls the mapping of data values to the colormap. It affects any surfaces, patches, and images with indexed `CData` and `CDataMapping` set to `scaled`. It does not affect surfaces, patches, or images with `true color CData` or with `CDataMapping` set to `direct`.

`caxis([cmin cmax])` sets the color limits to specified minimum and maximum values. Data values less than `cmin` or greater than `cmax` map to `cmin` and `cmax`, respectively. Values between `cmin` and `cmax` linearly map to the current colormap.

`caxis auto` computes the color limits automatically using the minimum and maximum data values. This is the default behavior. Color values set to `Inf` map to the maximum color, and values set to `-Inf` map to the minimum color. Faces or edges with color values set to `NaN` are not drawn.

`caxis manual` and `caxis(caxis)` freeze the color axis scaling at the current limits. This enables subsequent plots to use the same limits when `hold` is on.

`v = caxis` returns a two-element row vector containing the `[cmin cmax]` currently in use.

`caxis(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

`caxis` changes the `CLim` and `CLimMode` properties of axes graphics objects.

Tips

How Color Axis Scaling Works

Surface, patch, and image graphics objects having indexed CData and CDataMapping set to scaled map CData values to colors in the figure colormap each time they render. CData values equal to or less than cmin map to the first color value in the colormap, and CData values equal to or greater than cmax map to the last color value in the colormap. The following linear transformation is performed on the intermediate values (referred to as C below) to map them to an entry in the colormap (whose length is m, and whose row index is referred to as index below).

```
index = fix((C-cmin)/(cmax-cmin)*m)+1;
%Clamp values outside the range [1 m]
index(index<1) = 1;
index(index>m) = m;
```

Examples

Change Color Axis Scaling

Define X, Y, and Z as data for a sphere and view the data as a surface. Define the colors for the surface, C.

```
[X,Y,Z] = sphere;
C = Z;
surf(X,Y,Z,C)
```

Values of C are in the range $[-1, 1]$. Values of C near -1 are assigned the lowest values in the colormap. Values of C near 1 are assigned the highest values in the colormap.

Map the top half of the surface to the highest value in the color table by setting the maximum color limit to 0 .

```
caxis([-1,0])
```

Reset the axis scaling back to its default range.

```
caxis auto
```

caxis

Return the values of the current color limits.

```
v = caxis
```

```
v =
```

```
    -1     1
```

Set Color Axis Scaling for Image Data

Load the cape file which contains the image data, X, and the colormap, map, for Cape Cod, Massachusetts.

```
load cape
```

Display the image with CDataMapping set to scaled, and use the map colormap.

```
figure  
image(X, 'CDataMapping', 'scaled')  
colormap(map)
```

The color limits span the range of the image data, which is 1 to 192. The blue color of the ocean is the first color in the colormap and is mapped to the lowest data value, 1. You can effectively move sea level by changing the lower color limit value using `caxis`.

Display the image data using four different color limit values.

```
load cape
```

```
figure
```

```
colormap(map)

subplot(2,2,1)
image(X,'CDataMapping','scaled')
title('caxis = [1 192]')

subplot(2,2,2)
image(X,'CDataMapping','scaled')
caxis([4,192]) % change caxis
title('caxis = [4 192]')

subplot(2,2,3)
image(X,'CDataMapping','scaled')
caxis([7,192]) % change caxis
title('caxis = [7 192]')

subplot(2,2,4)
image(X,'CDataMapping','scaled')
caxis([10,192]) % change caxis
title('caxis = [10 192]')
```

caxis

How To

- “Axes Color Limits — the CLim Property”

Purpose	Change current folder
Syntax	<pre>cd(newFolder) oldFolder = cd(newFolder) cd</pre>
Description	<p><code>cd(newFolder)</code> changes the current folder to <code>newFolder</code>.</p> <p><code>oldFolder = cd(newFolder)</code> returns the existing current folder as a string to <code>oldFolder</code>, and then changes the current folder to <code>newFolder</code>.</p> <p><code>cd</code> displays the current folder.</p>
Tips	<ul style="list-style-type: none">• When using the command syntax (<code>cd newfolder</code>), if the <code>newFolder</code> string contains spaces, enclose the string in single quotation marks.• On UNIX platforms, use the <code>~</code> (tilde) character to represent the user home directory.• If you use <code>cd</code> within a local function, the folder change persists after program control returns from the function. That is, the scope of the folder change is global.
Input Arguments	<p>newFolder</p> <p>A string specifying the folder to which you want to change the current folder. Valid values can be any one of the following:</p> <ul style="list-style-type: none">• A full or relative path.• <code>../</code>, which indicates one level up from the current folder.• Multiple strings of <code>../</code>, which indicates multiple levels up from the current folder.• <code>./</code>, which indicates a path relative to the current folder, although without the <code>./</code>, <code>cd</code> assumes that the path is relative to the current folder.

Output Arguments

oldFolder

A string specifying the current folder that was in place when you issued the `cd` command.

Definitions

The current folder is a reference location that MATLAB uses to find files. This folder is sometimes referred to as the *current directory*, *current working folder*, or *present working directory*.

Examples

Use `cd` with the `matlabroot` function to change the current folder to the `examples` directory for the currently running version of MATLAB:

```
cd(fullfile(matlabroot, '/help/techdoc/matlab_env/examples'))
```

On a Microsoft Windows platform, specify the full path to change the current folder from any location to the `examples` directory for MATLAB Version 7.11 (R2010b), assuming that version is installed on your C: drive:

```
cd('C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples')

% Change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples to
% C:/Program Files/MATLAB/R2010b/help/techdoc:

cd ../../

% Use a relative path to change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc back to
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples:

cd matlab_env/examples

% Change the current folder from its current location to a new
% location, but save its previous location. Later, change the
% current folder to the previous location.
```

```
% This returns
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples
% to oldFolder, and then changes the current folder to
% C:/Program Files:

oldFolder = cd('C:/Program Files')

% Display current folder:

pwd

% Change the current folder to the previous location:
cd(oldFolder)

pwd
```

On a UNIX platform, change the current folder to the examples directory for the currently running version of MATLAB, assuming it is installed in your home location:

```
cd('~ /help/techdoc/matlab_env/examples')
```

```

How To

- “Specify File Names”
- “Files and Folders that MATLAB Accesses”

DelaunayTri.convexHull

Purpose (Will be removed) Convex hull

Note `convexHull(DelaunayTri)` will be removed in a future release. Use `convexHull(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax
`K = convexHull(DT)`
`[K AV] = convexHull(DT)`

Description `K = convexHull(DT)` returns the indices into the array of points `DT.X` that correspond to the vertices of the convex hull.
`[K AV] = convexHull(DT)` returns the convex hull and the area or volume bounded by the convex hull.

Input Arguments

DT	Delaunay triangulation.
----	-------------------------

Output Arguments

K	If the points lie in 2-D space, K is a column vector of length <code>numf</code> . Otherwise K is a matrix of size <code>numf-by-ndim</code> , <code>numf</code> being the number of facets in the convex hull, and <code>ndim</code> the dimension of the space where the points reside.
AV	The area or volume of the convex hull.

Definitions The convex hull of a set of points `X` is the smallest convex region containing all of the points of `X`.

Examples

Example 1

Compute the convex hull of a set of random points located within a unit square in 2-D space.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
k = convexHull(dt)
plot(dt.X(:,1),dt.X(:,2), '.','markersize',10); hold on;
plot(dt.X(k,1),dt.X(k,2), 'r'); hold off;
```

Example 2

Compute the convex hull of a set of random points located within a unit cube in 3-D space, and the volume bounded by the convex hull.

DelaunayTri.convexHull

```
X = rand(25,3)
dt = DelaunayTri(X)
[ch v] = convexHull(dt)
trisurf(ch, dt.X(:,1),dt.X(:,2),dt.X(:,3), 'FaceColor', 'cyan')
```

Purpose	Change or view current folder on FTP server
Syntax	<code>cd(ftpobj, folder)</code> <code>cd(ftpobj)</code>
Description	<code>cd(ftpobj, folder)</code> changes the current folder on the FTP server. <code>cd(ftpobj)</code> displays the current folder on the server.
Input Arguments	ftpobj FTP object created by <code>ftp</code> . folder String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use <code>'..'</code> .
Examples	Connect to the MathWorks FTP server, change to the pub folder, and view its contents: <pre>mw=ftp('ftp.mathworks.com'); cd(mw, 'pub'); dir(mw)</pre>
See Also	<code>dir</code> <code>ftp</code>

cdf2rdf

Purpose Convert complex diagonal form to real block diagonal form

Syntax $[V,D] = \text{cdf2rdf}(V,D)$
 $[V,D] = \text{cdf2rdf}(V,D)$

Description If the eigensystem $[V,D] = \text{eig}(X)$ has complex eigenvalues appearing in complex-conjugate pairs, `cdf2rdf` transforms the system so D is in real diagonal form, with 2-by-2 real blocks along the diagonal replacing the complex pairs originally there. The eigenvectors are transformed so that

$$X = V*D/V$$

continues to hold. The individual columns of V are no longer eigenvectors, but each pair of vectors associated with a 2-by-2 block in D spans the corresponding invariant vectors.

Examples The matrix

$$X = \begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & -5 & 4 \end{bmatrix}$$

has a pair of complex eigenvalues.

$$[V,D] = \text{eig}(X)$$

$$V = \begin{bmatrix} 1.0000 & -0.0191 - 0.4002i & -0.0191 + 0.4002i \\ 0 & 0 - 0.6479i & 0 + 0.6479i \\ 0 & 0.6479 & 0.6479 \end{bmatrix}$$

$$D = \begin{bmatrix} 1.0000 & & \\ & 0 & \\ & & 0 \end{bmatrix}$$

$$\begin{array}{ccc} 0 & 4.0000 + 5.0000i & 0 \\ 0 & 0 & 4.0000 - 5.0000i \end{array}$$

Converting this to real block diagonal form produces

$$[V,D] = \text{cdf2rdf}(V,D)$$

V =

$$\begin{array}{ccc} 1.0000 & -0.0191 & -0.4002 \\ 0 & 0 & -0.6479 \\ 0 & 0.6479 & 0 \end{array}$$

D =

$$\begin{array}{ccc} 1.0000 & 0 & 0 \\ 0 & 4.0000 & 5.0000 \\ 0 & -5.0000 & 4.0000 \end{array}$$

Algorithms

The real diagonal form for the eigenvalues is obtained from the complex form using a specially constructed similarity transformation.

eig | rsf2csf

cdfepoch

Purpose Convert MATLAB formatted dates to CDF formatted dates

Syntax `E = cdfepoch(date)`

Description `E = cdfepoch(date)` converts the date, specified by `date`, into a `cdfepoch` object. `date` must be a valid date string, returned by `datestr`, or a serial date number, returned by `datenum`. `date` can also be a `cdfepoch` object.

When writing data to a CDF file using `cdfwrite`, use `cdfepoch` to convert MATLAB formatted dates to CDF formatted dates. The MATLAB `cdfepoch` object simulates the `CDFEPOCH` data type in CDF files.

To convert a `cdfepoch` object into a MATLAB serial date number, use the `todatenum` function.

Definitions The MATLAB serial date number calculates dates differently than CDF epochs.

A MATLAB serial date number represents the whole and fractional number of days from 1-Jan-0000 to a specific date. The year 0000 is merely a reference point and is not intended to be interpreted as a real year in time.

A CDF epoch is the number of milliseconds since 1-Jan-0000.

Examples Convert the current time in serial date number format into a CDF epoch object.

```
% NOW function returns current time as serial date number
dateobj = cdfepoch(now)
```

```
dateobj =
```

```
    cdfepoch object:
    11-Mar-2009 15:09:25
```

Convert the current time in date string format into a CDF epoch object.

```
% DATESTR function returns date as string
dateobj2 = cdfepoch(datestr(now))
```

```
dateobj2 =
```

```
    cdfepoch object:
    11-Mar-2009 15:09:25
```

Convert the CDF epoch object into a serial date number.

```
dateobj = cdfepoch(now);
mydatenum = todatenum(dateobj)
```

```
mydatenum =
```

```
    7.3384e+005
```

See Also

[datenum](#) | [datestr](#) | [todatenum](#) | [cdfinfo](#) | [cdfread](#)

cdfinfo

Purpose Information about Common Data Format (CDF) file

Syntax `info = cdfinfo(filename)`

Description `info = cdfinfo(filename)` returns information about the Common Data Format (CDF) file specified in the string `filename`.

Note Because `cdfinfo` creates temporary files, the current working directory must be writeable.

The following table lists the fields returned in the structure, `info`. The table lists the fields in the order that they appear in the structure.

Field	Description
Filename	Text string specifying the name of the file
FileModDate	Text string indicating the date the file was last modified
FileSize	Double scalar specifying the size of the file, in bytes
Format	Text string specifying the file format
FormatVersion	Text string specifying the version of the CDF library used to create the file
FileSettings	Structure array containing library settings used to create the file
Subfiles	Filenames containing the CDF file's data, if it is a multi-file format CDF

Field	Description	
Variables	N-by-6 cell array, where N is the number of variables, containing information about the variables in the file. The columns present the following information:	
	Column 1	Text string specifying name of variable
	Column 2	Double array specifying the dimensions of the variable, as returned by the <code>size</code> function
	Column 3	Double scalar specifying the number of records assigned for the variable
	Column 4	Text string specifying the data type of the variable, as stored in the CDF file
	Column 5	Text string specifying the record and dimension variance settings for the variable. The single T or F to the left of the slash designates whether values vary by record. The zero or more T or F letters to the right of the slash designate whether values vary at each dimension. Here are some examples. T/ (scalar variable) F/T (one-dimensional variable) T/TFF (three-dimensional variable)

Field	Description
GlobalAttributes	Structure array that contains one field for each global attribute. The name of each field corresponds to the name of an attribute. The data in each field, contained in a cell array, represents the entry values for that attribute.
VariableAttributes	Structure array that contains one field for each variable attribute. The name of each field corresponds to the name of an attribute. The data in each field is contained in a n -by-2 cell array, where n is the number of variables. The first column of this cell array contains the variable names associated with the entries. The second column contains the entry values.

Note Attribute names returned by `cdfinfo` might not match the names of the attributes in the CDF file exactly. Attribute names can contain characters that are illegal in MATLAB field names. `cdfinfo` removes illegal characters that appear at the beginning of attributes and replaces other illegal characters with underscores ('_'). When `cdfinfo` modifies an attribute name, it appends the attribute's internal number to the end of the field name. For example, the attribute name `Variable%Attribute` becomes `Variable_Attribute_013`.

Note To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

Examples

Get Information About CDF File

Get information about the sample file, `example.cdf`.

```

info = cdfinfo('example.cdf')

info =

    Filename: 'example.cdf'
    FileModDate: '13-May-2010 13:38:20'
    FileSize: 1310
    Format: 'CDF'
    FormatVersion: '2.7.0'
    FileSettings: [1x1 struct]
    Subfiles: {}
    Variables: {6x6 cell}
    GlobalAttributes: [1x1 struct]
    VariableAttributes: [1x1 struct]

```

View information about the variables in the file.

```
info.Variables
```

```
ans =
```

```
Columns 1 through 5
```

'Time'	[1x2 double]	[24]	'epoch'	'T/'
'Longitude'	[1x2 double]	[1]	'int8'	'F/FT'
'Latitude'	[1x2 double]	[1]	'int8'	'F/TF'
'Data'	[1x3 double]	[1]	'double'	'T/TTT'
'multidimensional'	[1x4 double]	[1]	'uint8'	'T/TTTT'

Purpose

Summary of Common Data Format (CDF) capabilities

Description

The MATLAB product provides both high-level and low-level access to Common Data Format (CDF) files. The high-level access functions make it easy to read data from a CDF file or write data from the workspace to a CDF file. The low-level interface provides you with more control over the import and export operations.

Note For information about MATLAB support for the Network Common Data Form (netCDF), which is a completely separate, incompatible format, see `netcdf`.

High-Level Functions

MATLAB includes functions that provide high-level access to CDF files:

- `cdfinfo`
- `cdfread`

In addition, MATLAB provides functions that convert time data to and from the CDF epoch data type: `cdfepoch` and `todatenum`.

Low-Level Functions

MATLAB provides direct access to dozens of functions in the CDF library. Using these functions, you can read and write data, create variables, attributes, and entries, and take advantage of other features of the CDF library. To use these functions, you must be familiar with the CDF C interface. Documentation about CDF, version 3.3.0, is available at the [CDF Web site](#).

The MATLAB functions correspond to functions in the CDF library new Standard Interface. In most cases, the syntax of a MATLAB function is similar to the syntax of the corresponding CDF library function. To use these functions, you must prefix the function name with the package name, `cdflib`. For example, to use the CDF library function to open an existing CDF file, you would use this syntax:

```
cdfid = cdflib.open('example.cdf');
```

The following tables list all of the functions in the MATLAB CDF library package, grouped by category.

Library Information

<code>cdflib</code>	Summary of Common Data Format (CDF) capabilities
<code>cdflib.getConstantNames</code>	Names of Common Data Format (CDF) library constants
<code>cdflib.getConstantValue</code>	Numeric value corresponding to Common Data Format (CDF) library constant
<code>cdflib.getFileBackward</code>	Return current backward compatibility mode setting
<code>cdflib.getLibraryCopyright</code>	Copyright notice of Common Data Format (CDF) library
<code>cdflib.getLibraryVersion</code>	Library version and release information
<code>cdflib.getValidate</code>	Library validation mode
<code>cdflib.setFileBackward</code>	Set backward compatibility mode
<code>cdflib.setValidate</code>	Specify library validation mode

File Operations

<code>cdflib.close</code>	Close Common Data Format (CDF) file
<code>cdflib.create</code>	Create Common Data Format (CDF) file
<code>cdflib.delete</code>	Delete existing Common Data Format (CDF) file
<code>cdflib.getCacheSize</code>	Number of cache buffers used
<code>cdflib.getChecksum</code>	Checksum mode

<code>cdflib.getCompression</code>	Compression settings
<code>cdflib.getCompressionCacheSize</code>	Number of compression cache buffers
<code>cdflib.getCopyright</code>	Copyright notice in Common Data Format (CDF) file
<code>cdflib.getFormat</code>	Format of Common Data Format (CDF) file
<code>cdflib.getMajority</code>	Majority of variables
<code>cdflib.getName</code>	Name of Common Data Format (CDF) file
<code>cdflib.getReadOnlyMode</code>	Read-only mode
<code>cdflib.getStageCacheSize</code>	Number of cache buffers for staging
<code>cdflib.getVersion</code>	Common Data Format (CDF) library version and release information
<code>cdflib.inquire</code>	Basic characteristics of Common Data Format (CDF) file
<code>cdflib.open</code>	Open existing Common Data Format (CDF) file
<code>cdflib.setCacheSize</code>	Specify number of dotCDF cache buffers
<code>cdflib.setChecksum</code>	Specify checksum mode
<code>cdflib.setCompression</code>	Specify compression settings
<code>cdflib.setCompressionCacheSize</code>	Specify number of compression cache buffers
<code>cdflib.setFormat</code>	Specify format of Common Data Format (CDF) file
<code>cdflib.setMajority</code>	Specify majority of variables

<code>cdflib.setReadOnlyMode</code>	Specify read-only mode
<code>cdflib.setStageCacheSize</code>	Specify number of staging cache buffers for Common Data Format (CDF) file

Variables

<code>cdflib.closeVar</code>	Close specified variable from multifile format Common Data Format (CDF) file
<code>cdflib.createVar</code>	Create new variable
<code>cdflib.deleteVar</code>	Delete variable
<code>cdflib.deleteVarRecords</code>	Delete range of records from variable
<code>cdflib.getVarAllocRecords</code>	Number of records allocated for variable
<code>cdflib.getVarBlockingFactor</code>	Blocking factor for variable
<code>cdflib.getVarCacheSize</code>	Number of multifile cache buffers
<code>cdflib.getVarCompression</code>	Information about compression used by variable
<code>cdflib.getVarData</code>	Single value from record in variable
<code>cdflib.getVarMaxAllocRecNum</code>	Maximum allocated record number for variable
<code>cdflib.getVarMaxWrittenRecNum</code>	Maximum written record number for variable
<code>cdflib.getVarName</code>	Variable name, given variable number
<code>cdflib.getVarNum</code>	Variable number, given variable name

<code>cdflib.getVarNumRecsWritten</code>	Number of records written to variable
<code>cdflib.getVarPadValue</code>	Pad value for variable
<code>cdflib.getVarRecordData</code>	Entire record for variable
<code>cdflib.getVarReservePercent</code>	Compression reserve percentage for variable
<code>cdflib.getVarsMaxWrittenRecNum</code>	Maximum written record number for CDF file
<code>cdflib.getVarSparseRecords</code>	Information about how variable handles sparse records
<code>cdflib.hyperGetVarData</code>	Read hyperslab of data from variable
<code>cdflib.hyperPutVarData</code>	Write hyperslab of data to variable
<code>cdflib.inquireVar</code>	Information about variable
<code>cdflib.putVarData</code>	Write single value to variable
<code>cdflib.putVarRecordData</code>	Write entire record to variable
<code>cdflib.renameVar</code>	Rename existing variable
<code>cdflib.setVarAllocBlockRecords</code>	Specify range of records to be allocated for variable
<code>cdflib.setVarBlockingFactor</code>	Specify blocking factor for variable
<code>cdflib.setVarCacheSize</code>	Specify number of multi-file cache buffers for variable
<code>cdflib.setVarCompression</code>	Specify compression settings used with variable
<code>cdflib.setVarInitialRecs</code>	Specify initial number of records written to variable

<code>cdflib.setVarPadValue</code>	Specify pad value used with variable
<code>cdflib.SetVarReservePercent</code>	Specify reserve percentage for variable
<code>cdflib.setVarsCacheSize</code>	Specify number of cache buffers used for all variables
<code>cdflib.setVarSparseRecords</code>	Specify how variable handles sparse records

Attributes

<code>cdflib.createAttr</code>	Create attribute
<code>cdflib.deleteAttr</code>	Delete attribute
<code>cdflib.deleteAttrEntry</code>	Delete attribute entry
<code>cdflib.deleteAttrgEntry</code>	Delete entry in global attribute
<code>cdflib.getAttrEntry</code>	Value of entry in attribute with variable scope
<code>cdflib.getAttrgEntry</code>	Value of entry in global attribute
<code>cdflib.getAttrMaxEntry</code>	Number of last entry for variable attribute
<code>cdflib.getAttrMaxgEntry</code>	Number of last entry for global attribute
<code>cdflib.getAttrName</code>	Name of attribute, given attribute number
<code>cdflib.getAttrNum</code>	Attribute number, given attribute name
<code>cdflib.getAttrScope</code>	Scope of attribute
<code>cdflib.getNumAttrEntries</code>	Number of entries for attribute with variable scope
<code>cdflib.getNumAttrgEntries</code>	Number of entries for attribute with global scope

<code>cdflib.getNumAttributes</code>	Number of attributes with variable scope
<code>cdflib.getNumgAttributes</code>	Number of attributes with global scope
<code>cdflib.inquireAttr</code>	Information about attribute
<code>cdflib.inquireAttrEntry</code>	Information about entry in attribute with variable scope
<code>cdflib.inquireAttrgEntry</code>	Information about entry in attribute with global scope
<code>cdflib.putAttrEntry</code>	Write value to entry in attribute with variable scope
<code>cdflib.putAttrgEntry</code>	Write value to entry in attribute with global scope
<code>cdflib.renameAttr</code>	Rename existing attribute

Utility Functions

<code>cdflib.computeEpoch</code>	Convert time value to CDF_EPOCH value
<code>cdflib.computeEpoch16</code>	Convert time value to CDF_EPOCH16 value
<code>cdflib.epoch16Breakdown</code>	Convert CDF_EPOCH16 value to time value
<code>cdflib.epochBreakdown</code>	Convert CDF_EPOCH value into time value

cdflib.close

Purpose	Close Common Data Format (CDF) file
Syntax	<code>cdflib.close(cdfId)</code>
Description	<p><code>cdflib.close(cdfId)</code> closes the specified CDF file. <code>cdfId</code> identifies the CDF file.</p> <p>You must close a CDF to guarantee that all modifications you made since opening the CDF are actually written to the file.</p>
Examples	<p>Open the example CDF file and then close it.</p> <pre>cdfid = cdflib.open('example.cdf'); cdflib.close(cdfid)</pre>
References	<p>This function corresponds to the CDF library C API routine <code>CDFcloseCDF</code>.</p> <p>To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF Web site.</p> <p>For copyright information, see the <code>cdfcopyright.txt</code> file.</p>
See Also	<code>cdflib.open</code> <code>cdflib.create</code>

- “Exporting to CDF Files”

Purpose Convert time value to CDF_EPOCH value

Syntax `epoch = cdflib.computeEpoch(timeval)`

Description `epoch = cdflib.computeEpoch(timeval)` converts the time value specified by `timeval` into a CDF_EPOCH value.

Input Arguments **timeval**

7-by-1 time vector. The following table describes the time components.

Component	Description
year	AD e.g. 1994
month	1 12
day	1 31
hour	0 23
minute	0 59
second	0 59
millisecond	0 999

Output Arguments **epoch**

MATLAB double representing a CDF_EPOCH time value.

Examples Convert a time value into a CDF_EPOCH value.

```
timeval = [1999 12 31 23 59 59 0];  
epoch = cdflib.computeEpoch(timeval);
```

References This function corresponds to the CDF library C API routine `computeEPOCH`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

cdflib.computeEpoch

Tutorials

- “Importing CDF Files”
- “Exporting to CDF Files”

Purpose Convert time value to CDF_EPOCH16 value

Syntax `epoch16 = cdflib.computeEpoch16(timeval)`

Description `epoch16 = cdflib.computeEpoch16(timeval)` converts the time value specified by `timeval` into a CDF_EPOCH16 value.

Input Arguments **timeval**

10-by-1 time vector. The following table describes the time components. To specify multiple time values, use additional columns.

Component	Description
year	AD e.g. 1994
month	1 12
day	1 31
hour	0 23
minute	0 59
second	0 59
millisecond	0 999
microsecond	0 999
nanosecond	0 999
picosecond	0 999

Output Arguments **epoch16**

CDF Epoch16 time value. If the input argument `timeval` has `m`-by-10 elements, the return value `epoch16` will have size 2-by-`m`

Examples Convert the time value into an CDF_EPOCH16 value:

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];
```

cdflib.computeEpoch16

```
epoch16 = cdflib.computeEpoch16(timeval);
```

References

Tutorials

- “Importing CDF Files”
- “Exporting to CDF Files”

Purpose	Create Common Data Format (CDF) file
Syntax	<code>cdfId = cdflib.create(filename)</code>
Description	<code>cdfId = cdflib.create(filename)</code> creates a new CDF file with the name specified by the text string <i>filename</i> . Returns the CDF file identifier <code>cdfId</code> .
Examples	<p>Create a CDF file. To run this example, you must have write permission in your current directory.</p> <pre>cdfId = cdflib.create('myfile.cdf'); % Clean up cdflib.delete(cdfId); clear cdfId</pre>
References	<p>This function corresponds to the CDF library C API routine <code>CDFcreateCDF</code>.</p> <p>To use this function, you must be familiar with the CDF C interface. cdflib.createAttr

Purpose Create attribute

Syntax `attrnum = cdflib.createAttr(cdfId,attrName,scope)`

Description `attrnum = cdflib.createAttr(cdfId,attrName,scope)` creates an attribute in a CDF file with the specified scope.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrName`

Text string that specifies the name you want to assign to the attribute.

`scope`

One of the following text strings, or its numeric equivalent, that specifies the scope of the attribute.

Text String	Description
'global_scope'	Attribute applies to the CDF as a whole.
'variable_scope'	Attribute applies only to the variable

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

Output Arguments

`attrNum`

Numeric value identifying the attribute. Attribute numbers are zero-based.

Examples

Create a CDF, and then create an attribute in the CDF. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute
attrNum = cdflib.createAttr(cdfid, 'Purpose', 'global_scope');

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFcreateAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

cdflib.createVar

Purpose Create new variable

Syntax `varnum = cdflib.createVar(cdfId, varname, datatype, numElements, dims, recVariance, dimVariance)`

Description `varnum = cdflib.createVar(cdfId, varname, datatype, numElements, dims, recVariance, dimVariance)` creates a new variable in the Common Data Format (CDF) file with the specified characteristics.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varname`

Text string that specifies the name you want to assign to the variable.

`datatype`

Data type of the variable. One of the following text strings, or its numeric equivalent, that specifies a valid CDF data type.

CDF Data Type	Description
CDF_BYTE	1-byte, signed integer
CDF_CHAR	1 byte, signed character data type that maps to the MATLAB char class
CDF_INT1	1-byte, signed integer
CDF_UCHAR	1 byte, unsigned character data type that maps to the MATLAB uint8 class
CDF_UINT1	1-byte, unsigned integer
CDF_INT2	2-byte, signed integer

CDF Data Type	Description
CDF_UINT2	2-byte, unsigned integer
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

numElements

Number of elements per datum. Value should be 1 for all data types, except CDF_CHAR and CDF_UCHAR.

dims

A vector of the dimensions extents; empty if there are no dimension extents.

recVariance

Specifies record variance: true or false.

dimVariance

A vector of logicals; empty if there are no dimensions.

Output Arguments**varNum**

The numeric identifier for the variable. Variable numbers are zero-based.

Examples

Create a CDF file and then create a variable named 'Time' in the CDF. The variable has no dimensions and varies across records. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no variables.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Retrieve info about the file again to verify variable was created.
% Note value of numVars field is now 1.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 1
    numvAttrs: 0
    numgAttrs: 0

% Clean up
cdflib.delete(cdfid);
```

```
clear cdfid
```

References

cdflib.delete

Purpose Delete existing Common Data Format (CDF) file

Syntax `cdflib.delete(cdfId)`

Description `cdflib.delete(cdfId)` deletes the existing CDF file specified by the identifier `cdfId`. If the CDF file is a multi-file format CDF, the `cdflib.delete` function also deletes the variable files (having file extensions of `.z0`, `.z1`, etc.).

Examples Create a CDF file, and then delete it. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('mytempfile.cdf');
```

```
% Verify that the file was created.  
ls *.cdf
```

```
mytempfile.cdf
```

```
% Delete the file.  
cdflib.delete(cdfId)
```

```
% Verify that the file no longer exists.  
ls *.cdf
```

References This function corresponds to the CDF library C API routine `CDFdeleteCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

Purpose Delete attribute

Syntax `cdflib.deleteAttr(cdfId,attrNum)`

Description `cdflib.deleteAttr(cdfId,attrNum)` deletes the specified attribute from the CDF file.

`cdfId` identifies the Common Data Format (CDF) file.`attrNum` is a numeric identifier that specifies the attribute. Attribute numbers are zero-based.

Examples Create a CDF file, and then create an attribute in the file. Then delete the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute.
attrNum = cdflib.createAttr(cdfId, 'Purpose', 'global_scope');

% Prove it exists.
anum = cdflib.getAttrNum(cdfid, 'Purpose')

anum =

    0

% Delete the attribute.
cdflib.deleteAttr(cdfid,attrNum);

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

cdflib.deleteAttrgEntry

Purpose Delete entry in global attribute

Syntax `cdflib.deleteAttrgEntry(cdfId,attrNum,entryNum)`

Description `cdflib.deleteAttrgEntry(cdfId,attrNum,entryNum)` deletes an entry from a global attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`
Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

`entryNum`
Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Examples Create a CDF and create a global attribute in the file. Write a value to an entry for the attribute and then delete the entry. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
    numvAttrs: 0
```

```
numgAttrs: 0

% Create an attribute with global scope in the file.
attrNum = cdflib.createAttr(cdfid,'my_global_attr','global_scope');

% Write a value to an entry for the attribute
cdflib.putAttrgEntry(cdfid,attrNum,0,'CDF_CHAR','My global attr');

% Get the value of the global attribute entry
value = cdflib.getAttrgEntry(cdfid,attrNum,0)

value =

My global attr

% Delete the entry
cdflib.deleteAttrgEntry(cdfid,attrNum,0);

% Now try to view the value of the entry
% Should return NO_SUCH_ENTRY failure.
value = cdflib.getAttrgEntry(cdfid,attrNum,0) % Should fail

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

cdflib.deleteVarRecords

Purpose Delete range of records from variable

Syntax `cdflib.deleteVarRecords(cdfId,varNum,startRec,endRec)`

Description `cdflib.deleteVarRecords(cdfId,varNum,startRec,endRec)` deletes a range of records from a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`
Numeric value that identifies the variable. Variable numbers are zero-based.

`startRec`
Numeric value that specifies the record at which to start deleting records. Record numbers are zero-based.

`endRec`
Numeric value that specifies the record at which to stop deleting records. Record numbers are zero-based.

Examples Make a writable copy of the example CDF, get the number of a variable in the CDF, and delete specific records in the variable. To run this example, you must be in a writable folder.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.cdf');
copyfile(srcFile,'myfile.cdf');
fileattrib('myfile.cdf','+w');
cdfid = cdflib.open('myfile.cdf');
varnum = cdflib.getVarNum(cdfid,'Temperature');
cdflib.deleteVarRecords(cdfid,varnum,1,2);
cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFdeletezVarRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

cdflib.epoch16Breakdown

Purpose Convert CDF_EPOCH16 value to time value

Syntax `timeVec = cdflib.epoch16Breakdown(epoch16Time)`

Description `timeVec = cdflib.epoch16Breakdown(epoch16Time)` convert a CDF_EPOCH16 value into a time vector. `timeVec` will have 10-by-*n* elements, where *n* is the number of CDF_EPOCH16 values.

The following table describes the time value components.

timeVec Element	Description	Valid Values
<code>timeVec(1,:)</code>	Year AD	e.g. 1994
<code>timeVec(2,:)</code>	Month	1 12
<code>timeVec(3,:)</code>	Day	1 31
<code>timeVec(4,:)</code>	Hour	0 23
<code>timeVec(5,:)</code>	Minute	0 59
<code>timeVec(6,:)</code>	Second	0 59
<code>timeVec(7,:)</code>	Millisecond	0 999
<code>timeVec(8,:)</code>	Microsecond	0 999
<code>timeVec(9,:)</code>	Nanosecond	0 999
<code>timeVec(10,:)</code>	Picosecond	0 999

Examples Convert CDF_EPOCH16 value into time value.

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];  
epoch16 = cdflib.computeEpoch16(timeval);
```

```
timevec = cdflib.epoch16Breakdown(epoch16)
```

```
timevec =
```

```
1999
```

cdflib.epochBreakdown

Purpose Convert CDF_EPOCH value into time value

Syntax `timeVec = cdflib.epochBreakdown(epochTime)`

Description `timeVec = cdflib.epochBreakdown(epochTime)` decomposes the CDF_EPOCH value, epochTime value into individual time components. timeVec will have 7-by-*n* elements, where *n* is the number of CDF_EPOCH values in epochTime.

The return value timeVec has the following elements:

timeVec Element	Description	Valid Values
timeVec(1,:)	Year AD	e.g. 1994
timeVec(2,:)	Month	1 12
timeVec(3,:)	Day	1 31
timeVec(4,:)	Hour	0 23
timeVec(5,:)	Minute	0 59
timeVec(6,:)	Second	0 59
timeVec(7,:)	Millisecond	0 999

Examples

Convert a CDF_EPOCH value into a time vector.

```
% First convert a time vector into a CDF_EPOCH value
timeval = [1999 12 31 23 59 59 0];
epoch = cdflib.computeEpoch(timeval);
```

```
% Convert the CDF_EPOCH value into a time vector
timevec = cdflib.epochBreakdown(epoch)
```

```
timevec =
    1999
         12
         31
```

cdflib.getAttrEntry

Purpose	Value of entry in attribute with variable scope
Syntax	<code>value = cdflib.getAttrEntry(cdfId,attrNum,entryNum)</code>
Description	<code>value = cdflib.getAttrEntry(cdfId,attrNum,entryNum)</code> returns the value of an attribute entry in a Common Data Format (CDF) file.
Input Arguments	<p><code>cdfId</code> Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p><code>attrNum</code> Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.</p> <p><code>entryNum</code> Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.</p>
Output Arguments	<p>Value Value of the entry.</p>
Examples	<p>Open the example CDF and get the value of an entry associated with an attribute with variable scope in the file.</p> <pre>cdfid = cdflib.open('example.cdf'); % The fourth attribute is of variable scope. attrscope = cdflib.getAttrScope(cdfid,3) attrscope = VARIABLE_SCOPE</pre>

```
% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrEntry(cdfid,3,0)

dtype =

cdf_char

numel =

    10

% Get the value of the entry for this attribute.
% Note that it's a character string, 10 characters in length
value = cdflib.getAttrEntry(cdfid,3,0)

value =

Time value

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

cdflib.getAttrMaxEntry

Purpose Number of last entry for variable attribute

Syntax `maxEntry = cdflib.getAttrMaxEntry(cdfId,attrNum)`

Description `maxEntry = cdflib.getAttrMaxEntry(cdfId,attrNum)` returns the number of the last entry for an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Output Arguments

maxEntry

Entry number of the last entry in the attribute. Entry numbers are zero-based.

Examples

Open the example CDF and get the number of the last entry associated with an attribute with variable scope in the file:

```
cdfid = cdflib.open('example.cdf');  
  
% The fourth attribute is of variable scope.  
attrscope = cdflib.getAttrScope(cdfid,3)  
  
attrscope =  
  
VARIABLE_SCOPE
```

```
% Get the number of the last entry for this attribute.
entrynum = cdflib.getAttrMaxEntry(cdfid,3)

entrynum =

    3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrMaxEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

cdflib.getAttrName

Purpose Name of attribute, given attribute number

Syntax `name = cdflib.getAttrName(cdfId,attrNum)`

Description `name = cdflib.getAttrName(cdfId,attrNum)` returns the name of an attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfid`
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`
Numeric value that identifies the attribute. Attribute numbers are zero-based.

Output Arguments

`name`
Text string specifying the name of the attribute.

Examples Open the example CDF and get name of an attribute.

```
cdfid = cdflib.open('example.cdf');

% Get name of the first attribute in the file.
attrName = cdflib.getAttrName(cdfid,0)

attrName =

SampleAttribute

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

cdflib.getAttrNum

Purpose	Attribute number, given attribute name
Syntax	<code>attrNum = cdflib.getAttrNum(cdfId,attrName)</code>
Description	<code>attrNum = cdflib.getAttrNum(cdfId,attrName)</code> returns the number of an attribute in a Common Data Format (CDF) file.
Input Arguments	<code>cdfId</code> Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code> . <code>attrName</code> Text string specifying the name of an attribute.
Output Arguments	<code>attrNum</code> Numeric value that identifies the attribute. Attribute numbers are zero-based.
Examples	Open the example CDF and get the attribute number associated with the <code>SampleAttribute</code> attribute. <pre>cdfid = cdflib.open('example.cdf'); attrNum = cdflib.getAttrNum(cdfid,'SampleAttribute') attrNum = 0 % Clean up cdflib.close(cdfid); clear cdfid</pre>

References

This function corresponds to the CDF library C API routine `CDFgetAttrNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getAttrScope

Purpose Scope of attribute

Syntax `scope = cdflib.getAttrScope(cdfId,attrNum)`

Description `scope = cdflib.getAttrScope(cdfId,attrNum)` returns the scope of an attribute in a Common Data Format (CDF) file.

Input Arguments

cdfid
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum
Numeric value that specifies the attribute. Attribute numbers are zero-based.

Output Arguments

scope
Either of the following text strings, or its numeric equivalent.

Text String	Description
'GLOBAL_SCOPE'	Attribute applies to the CDF as a whole.
'VARIABLE_SCOPE'	Attribute applies only to the variable.

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

Examples Open example CDF and get the scope of the first attribute in the file:

```
cdfid = cdflib.open('example.cdf');  
  
attrScope = cdflib.getAttrScope(cdfid,0)  
  
attrScope =
```

```
GLOBAL_SCOPE

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrScope`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getCacheSize

Purpose Number of cache buffers used

Syntax `numBuffers = cdflib.getCacheSize(cdfId)`

Description `numBuffers = cdflib.getCacheSize(cdfId)` returns the number of cache buffers used for the Common Data Format (CDF) file identified by `cdfId`. For a discussion of cache schemes, see the *CDF User's Guide*.

Examples Open the example CDF file and get the cache size:

```
cdfid = cdflib.open('example.cdf');  
  
numBuf = cdflib.getCacheSize(cdfid)  
  
numBuf =  
  
      300  
  
% Clean up  
cdflib.close(cdfid)  
clear cdfid
```

References This function corresponds to the CDF library C API routine `CDFgetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

Tutorials • “Importing CDF Files”
 • “Exporting to CDF Files”

Purpose Checksum mode

Syntax `mode = cdflib.getChecksum(cdfId)`

Description `mode = cdflib.getChecksum(cdfId)` returns the checksum mode of the Common Data Format (CDF) file.

Input Arguments **cdfid**
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments **mode**
Either of the following text strings or its numeric equivalent.

'MD5_CHECKSUM'	File uses MD5 checksum.
'NO_CHECKSUM'	File does not use a checksum.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples Open the example CDF file, and then get the checksum mode of the file:

```
cdfid = cdflib.open('example.cdf');  
  
checksummode = cdflib.getChecksum(cdfid)  
  
checksummode =  
  
NO_CHECKSUM  
  
% Clean up  
cdflib.close(cdfid);  
clear cdfid;
```

cdflib.getChecksum

References

This function corresponds to the CDF library C API routine `CDFgetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

Purpose	Compression settings
Syntax	<code>[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)</code>
Description	<code>[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)</code> returns information about the compression settings of a Common Data Format (CDF) file.
Input Arguments	cdfId Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code> .
Output Arguments	ctype Text string specifying compression type, such as <code>'HUFF_COMPRESSION'</code> . If the CDF does not use compression, the function returns the string <code>'NO_COMPRESSION'</code> . For a list of supported compression types, see <code>cdflib.setCompression</code> . cparms The value of the parameter associated with the type of compression. For example, for the <code>'RLE_COMPRESSION'</code> compression type, the parameter specifies the style of run-length encoding. For a list of parameters supported by each compression type, see <code>cdflib.setCompression</code> . cpercentage The rate of compression, expressed as a percentage.
Examples	Open the example CDF file and check the compression settings in the file. <pre>cdfId = cdflib.open('example.cdf'); [ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)</pre>

cdflib.getCompression

```
ctype =  
GZIP_COMPRESSION  
cparms =  
    7  
cper =  
    26  
  
% Clean up  
cdflib.close(cdfId)  
clear cdfId
```

cdflib.getConstantNames

Purpose Names of Common Data Format (CDF) library constants

Syntax `names = cdflib.getConstantNames()`

Description `names = cdflib.getConstantNames()` returns a cell array of text strings, where each text string is the name of a constant known to the Common Data Format (CDF) library.

Examples Get a list of the names of CDF library constants.

```
names = cdflib.getConstantNames()
```

```
names =  
  
    'AHUFF_COMPRESSION'  
    'ALPHAMVSD_ENCODING'  
    'ALPHAMVSG_ENCODING'  
    'ALPHAMVSI_ENCODING'  
    'ALPHAOSF1_ENCODING'  
    'CDF_BYTE'  
    'CDF_CHAR'  
    .  
    .  
    .

Purpose Numeric value corresponding to Common Data Format (CDF) library constant

Syntax `value = cdflib.getConstantValue(constantName)`

Description `value = cdflib.getConstantValue(constantName)` returns the numeric value of the CDF library constant specified by the text string *constantName*. To see a list of constant names, use `cdflib.getConstantNames`.

Examples View the list of CDF library constants and get the numeric value corresponding to one of the constants.

```
% Retrieve a list of library constants
names = cdflib.getConstantNames();

value = cdflib.getConstantValue(names{1})

value =

    3
```

cdflib.getCopyright

Purpose Copyright notice in Common Data Format (CDF) file

Syntax `copyright = cdflib.getCopyright(cdfId)`

Description `copyright = cdflib.getCopyright(cdfId)` returns the copyright notice in the CDF file identified by `cdfId`.

Examples Create a CDF file, and then get the copyright notice in the file. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');  
  
copyright = cdflib.getCopyright(cdfId)  
  
copyright =  
  
Common Data Format (CDF)  
(C) Copyright 1990-2009 NASA/GSFC  
Space Physics Data Facility  
NASA/Goddard Space Flight Center  
Greenbelt, Maryland 20771 USA  
(Internet -- CDFSUPPORT@LISTSERV.GSFC.NASA.GOV)  
  
% Clean up.  
cdflib.delete(cdfId)  
clear cdfId
```

References This function corresponds to the CDF library C API routine `CDFgetCopyright`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

cdflib.getFileBackward

Purpose Return current backward compatibility mode setting

Syntax `mode = cdflib.getFileBackward()`

Description `mode = cdflib.getFileBackward()` returns the backward compatibility mode.

Output Arguments **mode**
One of the following text strings:

BACKWARDFILEon	Backward compatibility mode is on.
BACKWARDFILEoff	Backward compatibility mode is off.

For more information about backward compatibility mode, see `cdflib.setFileBackward`.

Examples

```
mode = cdflib.getFileBackward  
  
mode =  
  
BACKWARDFILEoff
```

References This function corresponds to the CDF library C API routine `CDFgetFileBackward`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

See Also `cdflib.setFileBackward` | `cdflib.getConstantValue`

Tutorials

- “Importing CDF Files”
- “Exporting to CDF Files”

Purpose Format of Common Data Format (CDF) file

Syntax `format = cdflib.setFormat(cdfId)`

Description `format = cdflib.setFormat(cdfId)` returns the format of the CDF file.

Input Arguments **`cdfId`**
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments **`format`**
Either of the following text strings, or its numeric equivalent.

'SINGLE_FILE'	The CDF is stored in a single file.
'MULTI_FILE'	The CDF is made up of multiple files.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples Open the example CDF file and determine its file format:

```
cdfId = cdflib.open('example.cdf');  
  
format = cdflib.getFormat(cdfId)  
  
format =  
  
    'SINGLE_FILE'  
  
% Clean up.  
cdflib.close(cdfId)  
clear cdfId
```

cdflib.getFormat

cdflib.getLibraryVersion

Purpose	Library version and release information
Syntax	<code>[version,release,increment] = cdflib.getLibraryVersion()</code>
Description	<code>[version,release,increment] = cdflib.getLibraryVersion()</code> returns information about the Common Data Format (CDF) library.
Output Arguments	version Numeric value indicating the version number of the CDF library. release Numeric value indicating the release number of the CDF library. increment Numeric value indicating the increment number of the CDF library.
Examples	Get the version information of the CDF library: <pre>[version, release, increment] = cdflib.getLibraryVersion() version = 3 release = 3 increment = 0</pre>
References	This function corresponds to the CDF library C API routine <code>CDFgetLibraryVersion</code> .

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getMajority

Purpose Majority of variables

Syntax `majority = cdflib.getMajority(cdfId)`

Description `majority = cdflib.getMajority(cdfId)` returns the majority of variables in a Common Data Format (CDF) file.

Input Arguments **`cdfId`**
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments **`majority`**
Either of the following text strings, or its numeric equivalent.

'ROW_MAJOR'	C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default.
'COLUMN_MAJOR'	Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples Open the example CDF file, and then determine the majority of variables in the file:

```
cdfId = cdflib.open('example.cdf');  
  
majority = cdflib.getMajority(cdfId)  
  
majority =  
  
ROW_MAJOR
```

```
% Clean up
cdflib.close(cdfId)

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetMajority`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

cdflib.getName

Purpose Name of Common Data Format (CDF) file

Syntax `name = cdflib.getName(cdfId)`

Description `name = cdflib.getName(cdfId)` returns the name of the CDF file identified by `cdfId`.

Examples Open the example CDF file and get the name of the file. The path name returned for your installation will be different.

```
cdfId = cdflib.open('example.cdf');  
  
name = cdflib.getName(cdfId)  
  
name =  
  
yourinstallation\matlab\toolbox\matlab\demos\example  
  
% Clean up  
cdflib.close(cdfId)  
  
clear cdfId
```

References This function corresponds to the CDF library C API routine `CDFgetName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

Purpose Number of entries for attribute with variable scope

Syntax `nentries = cdflib.getNumAttrEntries(cdfId,attrNum)`

Description `nentries = cdflib.getNumAttrEntries(cdfId,attrNum)` returns the number of entries for the specified attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Examples Open the example CDF, find an attribute with variable scope, and determine how many entries are associated with the attribute:

```
cdfid = cdflib.open('example.cdf');

% Get the number of an attribute
% with variable scope
attrNum = cdflib.getAttrNum(cdfid,'Description');

% Check that scope of attribute is variable
attrScope = cdflib.getAttrScope(cdfid,attrNum)

VARIABLE_SCOPE

% Determine the number of entries for the attribute
attrEntries = cdflib.getNumAttrEntries(cdfid,attrNum)

attrEntries =

    4

% Clean up
cdflib.close(cdfid);
```

cdflib.getNumAttrEntries

References

This function corresponds to the CDF library C API routine `CDFgetNumAttrzEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

Purpose

Number of entries for attribute with global scope

Syntax

```
nentries = cdflib.getNumAttrgEntries(cdfId,attrNum)
```

Description

`nentries = cdflib.getNumAttrgEntries(cdfId,attrNum)` returns the number of entries written for the specified global attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

Examples

Open the example CDF and find out how many entries are associated with a global attribute in the file.

```
cdfid = cdflib.open('example.cdf');

% The first attribute is a global attribute.
attrgEntries = cdflib.getNumAttrgEntries(cdfid,0)

attrgEntries =

     3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetNumAttrgEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

Purpose Read-only mode

Syntax `mode = cdflib.getReadOnlyMode(cdfId)`

Description `mode = cdflib.getReadOnlyMode(cdfId)` returns the read-only mode of a Common Data Format (CDF) file.

Input Arguments **`cdfId`**
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments **`mode`**
Either of the following text strings or its numeric equivalent.

'READONLYon'	CDF is in read-only mode
'READONLYoff'	CDF can be modified.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples Open the example CDF file and determine its current read-only status:

```
cdfId = cdflib.open('example.cdf');  
  
mode = cdflib.getReadOnlyMode(cdfId)  
  
mode =  
  
READONLYoff  
  
% Clean up.  
cdflib.close(cdfId);  
clear cdfId
```

Purpose Library validation mode

Syntax `mode = cdflib.getValidate()`

Description `mode = cdflib.getValidate()` returns the validation mode of the Common Data Format (CDF) library.

Output Arguments **mode**
Either of the following text strings or its numeric equivalent.

'VALIDATEFILEon'	Validation mode is on. For information about validation mode, see <code>cdflib.setValidate</code> .
'VALIDATEFILEoff'	Validation mode is off.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples Determine the current validation mode of the CDF library.

```
mode = cdflib.getValidate()
```

```
mode =

Purpose

Number of multifile cache buffers

Syntax

```
numBuffers = cdflib.getVarCacheSize(cdfId,varNum)
```

Description

`numBuffers = cdflib.getVarCacheSize(cdfId,varNum)` returns the number of cache buffers used for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable identifiers are zero-based.

This function applies only to multifile format CDFs. For more information about caching, see the *CDF User's Guide*.

Examples

Create a multifile CDF and retrieve the number of buffers being used for a variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     1

% Clean up
```

cdflib.getVarCacheSize

```
cdflib.delete(cdfid);
```

```
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

Purpose	Information about compression used by variable
Syntax	<code>[ctype, cparams, percent] = cdflib.getVarCompression(cdfId, varNum)</code>
Description	<code>[ctype, cparams, percent] = cdflib.getVarCompression(cdfId, varNum)</code> returns information about the compression used for a variable in a Common Data Format (CDF) File.
Input Arguments	cdfid Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code> .
Output Arguments	ctype Text string identifying the type of compression. For a list of compression types, see <code>cdflib.setCompression</code> . cparams Any additional parameter required by the compression type. percent Numeric value indicating the level of compression, expressed as a percentage.
Examples	Open the example CDF file and check the compression settings of any variable. <pre>cdfid = cdflib.open('example.cdf'); % Check the compression setting of any variable in the file % The example checks the first variable (variable numbers are zero-based) [ctype params percent] = cdflib.getVarCompression(cdfid,0) ctype =</pre>

cdflib.getVarCompression

```
NO_COMPRESSION

params =

    []

percent =

    100

% Clean up
cdflib.close(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

Purpose	Single value from record in variable
Syntax	<pre>datum = cdflib.getVarData(cdfId,varNum,recNum,indices) datum = cdflib.getVarData(cdfId,varNum,recNum)</pre>
Description	<p><code>datum = cdflib.getVarData(cdfId,varNum,recNum,indices)</code> returns a single value from a variable in a Common Data Format (CDF) file.</p> <p><code>datum = cdflib.getVarData(cdfId,varNum,recNum)</code> returns a single value from a variable with no dimensions in a Common Data Format (CDF) file.</p>
Input Arguments	<p><code>cdfId</code> Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p><code>varNum</code> Numeric value identifying the variable containing the datum. Variable numbers are zero-based.</p> <p><code>recNum</code> Numeric value identifying the location of the datum in the variable. In CDF terminology, this is called the <i>record number</i>. Record numbers are zero-based.</p> <p><code>indices</code> Array of dimension indices within the record. Dimension indices are zero-based. If the variable has no dimensions, you can omit this parameter.</p>
Output Arguments	<p><code>datum</code> Value of the specified record.</p>

Examples

Open the example CDF file and retrieve data associated with a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine how many variables are in the file.
info = cdflib.inquire(cdfid);

info.numVars

ans =

    5

% Determine if the first variable has dimensions.
varinfo = cdflib.inquireVar(cdfid,0);
vardims = varinfo.dims
vardims =

    []

% Get data from variable, without specifying dimensions.
datum = cdflib.getVarData(cdfid, varnum, recnum)

datum =

    6.3146e+013

% Get dimensions of another variable in file.
varinfo = cdflib.inquireVar(cdfid,3);
vardims = varinfo.dims
vardims =

    [4 2 2]

% Retrieve the first datum in the record. Indices are zero-based.
datum = cdflib.getVarData(cdfid,3,0,[0 0 0])
```

```
info =  
  
    30  
  
% Clean up.  
cdflib.close(cdfid);  
clear cdfid
```

cdflib.getVarMaxAllocRecNum

Purpose Maximum allocated record number for variable

Syntax `maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)`

Description `maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)` returns the record number of the maximum allocated record for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

Examples Open example CDF and get the maximum allocated record number for a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine maximum record number for variable in file.
maxRecNum = cdflib.getVarMaxAllocRecNum(cdfid,0)

maxRecNum =

    63

% Clean up
cdflib.close(cdfid)

clear cdfid
```

References This function corresponds to the CDF library C API routine `CDFgetzVarMaxAllocRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

Syntax	<code>data = cdflib.getVarRecordData(cdfId,varNum,recNum)</code>
Description	<code>data = cdflib.getVarRecordData(cdfId,varNum,recNum)</code> returns the data in a record associated with a variable in a Common Data Format (CDF) file.
Input Arguments	<p>cdfId Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p>varNum Numeric value that identifies the variable in the CDF file. Variable numbers are zero-based.</p> <p>recNum Numeric value that identifies the record in the variable. Record numbers are zero-based.</p>
Output Arguments	<p>data Data in the record.</p>
Examples	<p>Open the example CDF, and then get the data associated with a record in a variable:</p> <pre>cdfid = cdflib.open('example.cdf'); % Get data in first record in first variable in file. recData = cdflib.getVarRecordData(cdfid,0,0) recData = 6.3146e+013</pre>

cdflib.getVarRecordData

```
% Clean up
cdflib.close(cdfid)

clear cdfid
```

Purpose	Compression reserve percentage for variable
Syntax	<code>percent = cdflib.getVarReservePercent(cdfId,varNum)</code>
Description	<code>percent = cdflib.getVarReservePercent(cdfId,varNum)</code> returns the compression reserve percentage for a variable in a Common Data Format (CDF) file. This operation only applies to compressed variables. <code>cdfId</code> identifies the CDF file. <code>varNum</code> is a numeric value that identifies the variable. Variable numbers are zero-based.
Definitions	reserve percentage Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space. By default, the reserve percent is 0 (no extra space is reserved). You can specify any percentage between 1 and 100 and values greater than 100. The value specifies the percentage of the uncompressed size of the variable.
Examples	Open the example CDF file, get the number of a compressed variable, and then determine the reserve percent for the variable. <pre>cdfid = cdflib.open('example.cdf'); varnum = cdflib.getVarNum(cdfid,'Temperature'); percent = cdflib.getVarReservePercent(cdfid,varnum); cdflib.close(cdfid);</pre>
References	This function corresponds to the CDF library C API routine <code>CDFgetzVarReservePercent</code> . To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF Web site .

Purpose Information about how variable handles sparse records

Syntax `stype = cdflib.getVarSparseRecords(cdfId,varNum)`

Description `stype = cdflib.getVarSparseRecords(cdfId,varNum)` returns information about how a variable in the Common Data Format (CDF) file handles sparse records.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value that identifies the variable. Variable numbers are zero-based.

Output Arguments

stype

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

Text String	Description
'NO_SPARSERECORDS'	No sparse records.
'PAD_SPARSERECORDS'	For sparse records, the library uses the variable's pad value when reading values from a missing record.
'PREV_SPARSERECORDS'	For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value.

cdflib.getVarSparseRecords

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Open the example CDF, and then get the sparse record type of a variable in the file:

```
cdfid = cdflib.open('example.cdf');  
  
stype = cdflib.getVarSparseRecords(cdfid,0)  
  
stype =  
  
NO_SPARSERECORDS  
  
%Clean up  
cdflib.close(cdfid);  
  
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarSparseRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

Purpose Common Data Format (CDF) library version and release information

Syntax [version,release,increment] = cdflib.getVersion(cdfId)

Description [version,release,increment] = cdflib.getVersion(cdfId) returns information about the version of the Common Data Format (CDF) library used to create a CDF file.

Input Arguments **cdfId**
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments **version**
Numeric value indicating the version number of the CDF library.

release
Numeric value indicating the release number of the CDF library.

increment
Numeric value indicating the increment number of the CDF library.

Examples Open the example CDF file, and then find out the version of the CDF library used to create it:

```
cdfId = cdflib.open('example.cdf');  
  
[version, release, increment] = cdflib.getVersion(cdfId)  
  
version =  
    2  
  
release =
```

cdflib.getVersion

```
7
increment =
8
% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDF.getVersion`.

Purpose	Read hyperslab of data from variable
Syntax	<pre>data = cdflib.hyperGetVarData(cdfId,varNum,recSpec,dimSpec) data = cdflib.hyperGetVarData(cdfId,varNum,recSpec)</pre>
Description	<p><code>data = cdflib.hyperGetVarData(cdfId,varNum,recSpec,dimSpec)</code> reads a hyperslab of data from a variable in the Common Data Format (CDF) file. Hyper access allows more than one value to be read from or written to a variable with a single call to the CDF library.</p> <p><code>data = cdflib.hyperGetVarData(cdfId,varNum,recSpec)</code> reads a hyperslab of data for a zero-dimensional variable in the Common Data Format (CDF) file.</p>
Input Arguments	<p>cdfId Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p>varNum Number identifying the variable containing the datum.</p> <p>recSpec Three-element array, [RSTART RCOUNT RSTRIDE], where RSTART, RCOUNT, and RSTRIDE are scalar values specifying the starting record, number of records to read, and the sampling interval or stride between records. Record numbers are zero-based.</p> <p>dimSpec Three-element cell array, {DSTART DCOUNT DSTRIDE}, where DSTART, DCOUNT, and DSTRIDE are <i>n</i>-element vectors that describe the start, number of values along each dimension, and sampling interval along each dimension. If the hyperslab has zero dimensions, you can omit this parameter. Dimension indices are zero-based.</p>

cdflib.hyperGetVarData

Examples

Open the example CDF file, and then get all the data associated with a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records allocated for the first variable in the
maxRecNum = cdflib.getVarMaxWrittenRecNum(cdfid,0);

% Retrieve all data in records for variable.
data = cdflib.hyperGetVarData(cdfid,0,[0 maxRecNum 1]);

% Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFHyperGetzVarData`.

`cdflib.hyperPutVarData`

Tutorials

- “Importing CDF Files”
- “Exporting to CDF Files”

Purpose	Write hyperslab of data to variable
Syntax	<code>cdflib.hyperPutVarData(cdfId, varNum, recSpec, dimSpec, data)</code>
Description	<code>cdflib.hyperPutVarData(cdfId, varNum, recSpec, dimSpec, data)</code> writes a hyperslab of data to a variable in a Common Data Format (CDF) file. Hyper access allows more than one value to be read from or written to a variable with a single call to the CDF library.
Input Arguments	<p><code>cdfId</code> Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p><code>varNum</code> Specifies the variable containing the datum.</p> <p><code>recSpec</code> Three-element array described by <code>[RSTART RCOUNT RSTRIDE]</code>, where <code>RSTART</code>, <code>RCOUNT</code>, and <code>RSTRIDE</code> are scalar values giving the start, number of records, and sampling interval (or stride) between records. Record indices are zero-based.</p> <p><code>dimSpec</code> Three-element cell array described by <code>{DSTART DCOUNT DSTRIDE}</code>, where <code>DSTART</code>, <code>DCOUNT</code>, and <code>DSTRIDE</code> are n-element vectors that describe the start, number of values along each dimension, and sampling interval along each dimension. If the hyperslab has zero dimensions, you can omit this parameter. Dimension indices are zero-based.</p> <p><code>data</code> Data to write to the variable.</p>
Examples	Create a CDF, create a variable, and then write a slab of data to the variable. To run this example, you must be in a writable folder.

cdflib.hyperPutVarData

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Grades', 'cdf_int1', 1, [], true, []);

% Write data to the variable
cdflib.hyperPutVarData(cdfid, varNum, 0, [], int8(98))

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

Tutorials

- “Importing CDF Files”
- “Exporting to CDF Files”

Purpose Basic characteristics of Common Data Format (CDF) file

Syntax `info = cdflib.inquire(cdfId)`

Description `info = cdflib.inquire(cdfId)` returns basic information about a Common Data Format (CDF) file.

Input Arguments **cdfId**
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments **info**
A structure containing the following fields:

Field	Description
encoding	Encoding of the variable data and attribute entry data
majority	Majority of the variable data
maxRec	Maximum record number written to a CDF variable
numVars	Number of CDF variables
numvAttrs	Number of attributes with variable scope
numgAttrs	Number of attributes with global scope

Examples Open the example CDF file, and then get basic information about the file:

```
cdflib = cdflib.open('example.cdf');

info = cdflib.inquire(cdfId)

info =
```

cdflib.inquire

```
encoding: 'IBMPC_ENCODING'  
majority: 'ROW_MAJOR'  
maxRec: 23  
numVars: 5  
numvAttrs: 1  
numgAttrs: 3
```

Purpose Information about attribute

Syntax `info = cdflib.inquireAttr(cdfId,attrNum)`

Description `info = cdflib.inquireAttr(cdfId,attrNum)` returns information about an attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`
Numeric value that identifies the attribute in the file. Attribute numbers are zero-based.

Output Arguments

`info`
Structure containing the following fields.

Field	Description
<code>name</code>	Attribute's name
<code>scope</code>	Either 'GLOBAL_SCOPE' or 'VARIABLE_SCOPE'
<code>maxgEntry</code>	The maximum entry number used for global attributes.
<code>maxEntry</code>	The maximum entry number used for attributes with variable scope.

Examples Open the example CDF, and then get information about the first attribute in the file.

```
cdfid = cdflib.open('example.cdf');
```

cdflib.inquireAttr

```
% Get information about an attribute
info = cdflib.inquireAttr(cdfid,0)

info =

         name: 'SampleAttribute'
         scope: 'GLOBAL_SCOPE'
    maxgEntry: 4
         maxEntry: -1

% Clean up
cdflib.close(cdfid);

clear cdfid
```

- “Exporting to CDF Files”

Purpose Information about variable

Syntax `info = cdflib.inquireVar(cdfId,varNum)`

Description `info = cdflib.inquireVar(cdfId,varNum)` returns information about a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`
Numeric value that identifies the variable. Variable numbers are zero-based.

Output Arguments

`info`
Structure containing the following fields.

Field	Description
<code>name</code>	Name of the variable
<code>datatype</code>	Data type
<code>numElements</code>	Number of elements of the datatype
<code>dims</code>	Sizes of the dimensions
<code>recVariance</code>	Record variance
<code>dimVariance</code>	Dimension variances

Record and dimension variances affect how the library physically stores variable data. For example, if a variable has a record variance of `VARY`, the library physically stores each record. If the record variance is `NOVARY`, the library only stores one record.

cdflib.inquireVar

Examples

Open the example CDF file and get information about a variable.

```
cdfid = cdflib.open('example.cdf');

% Determine if the file contains variables
info = cdflib.inquireVar(cdfid,1)

info =

         name: 'Longitude'
    datatype: 'cdf_int1'
numElements: 1
         dims: [2 2]
recVariance: 0
dimVariance: [1 0]
```

cdflib.putAttrEntry

Purpose Write value to entry in attribute with variable scope

Syntax `cdflib.putAttrEntry(cdfId, attrNum, entryNum, CDFDataType, entryVal)`

Description `cdflib.putAttrEntry(cdfId, attrNum, entryNum, CDFDataType, entryVal)` writes a value to an attribute entry in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Number identifying attribute. The attribute must have variable scope. Attribute numbers are zero-based.

entryNum

Number identifying entry. Entry numbers are zero-based.

CDFdatatype

One of the following text strings, or its numeric equivalent, that specify the data type of the attribute entry.

CDF Data Type	MATLAB Equivalent
CDF_BYTE	1-byte, signed integer
CDF_CHAR	1 byte, signed character data type that maps to the MATLAB <code>char</code> class
CDF_INT1	1-byte, signed integer.
CDF_UCHAR	1 byte, unsigned character data type that maps to the MATLAB <code>uint8</code> class
CDF_UINT1	1-byte, unsigned integer

CDF Data Type	MATLAB Equivalent
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer.
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

entryVal

Data to be written to attribute entry.

Examples

Create a CDF and create an attribute with variable scope in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
    numvAttrs: 0
```

cdflib.putAttrEntry

```
numgAttrs: 0

% Create an attribute of variable scope in the file.
attrNum = cdflib.createAttr(cdfid,'Another Attribute','variable_scope');

% Write a value to an entry for the attribute
cdflib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My Variable Attribute Test');

% Get the value of the global attribute entry
value = cdflib.getAttrEntry(cdfid,attrNum,0)

value =

My Variable Attribute Test

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

Purpose Write value to entry in attribute with global scope

Syntax `cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,entryVal)`

Description `cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,entryVal)` writes a value to a global attribute entry in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

attrNum

Number identifying attribute. Attribute numbers are zero-based. The attribute must have global scope.

entryNum

Number identifying entry. Entry numbers are zero-based.

CDFdatatype

One of the following text strings that specify the data type of the attribute entry, or its numeric equivalent.

CDF Data Type	MATLAB Equivalent
CDF_BYTE	1-byte, signed integer
CDF_CHAR	1 byte, signed character data type that maps to the MATLAB <code>char</code> class
CDF_INT1	1-byte, signed integer.
CDF_UCHAR	1 byte, unsigned character data type that maps to the MATLAB <code>uint8</code> class
CDF_UINT1	1-byte, unsigned integer

cdflib.putAttrgEntry

CDF Data Type	MATLAB Equivalent
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer.
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

entryVal

Data to be written to global attribute entry.

Examples

Create a CDF and create a global attribute in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

    encoding: 'IBMPC_ENCODING'
    majority: 'ROW_MAJOR'
    maxRec: -1
    numVars: 0
    numvAttrs: 0
```

```
numgAttrs: 0

% Create a global attribute in the file.
attrNum = cdflib.createAttr(cdfid, 'Purpose', 'global_scope');

% Write a value to an entry for the global attribute
cdflib.putAttrgEntry(cdfid, attrNum, 0, 'CDF_CHAR', 'My Test');

% Get the value of the global attribute entry
value = cdflib.getAttrgEntry(cdfid, attrNum, 0)

value =

My Test

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

cdflib.putVarData

Purpose Write single value to variable

Syntax `cdflib.putVarData(cdfId,varNum,recNum,indices,datum)`

Description `cdflib.putVarData(cdfId,varNum,recNum,indices,datum)` writes a single value to a variable in a Common Data File (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.

recNum

Numeric value that identifies the record to which you want to write the datum. Record numbers are zero-based.

dims

Dimension indices within the record. Dimension indices are zero-based.

datum

Data to be written to the variable.

Examples

Create a CDF, create a variable in the CDF and write data to the variable. To run this example, you must have write permission in the current folder.

```
cdfid = cdflib.create('your_file.cdf');  
  
% Create a variable in the file.  
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);
```

```
% Write some data to the variable
cdflib.putVarData(cdfid,varNum,0,[],int8(98))

% Read the value from the variable.
datum = cdflib.getVarData(cdfid,varNum,0)

datum =

    98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

cdflib.putVarRecordData

Purpose	Write entire record to variable
Syntax	<code>cdflib.putVarRecordData(cdfId,varNum,recNum,recordData)</code>
Description	<code>cdflib.putVarRecordData(cdfId,varNum,recNum,recordData)</code> writes data to a record in a variable in a Common Data Format (CDF) file.
Input Arguments	<p><code>cdfId</code> Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p><code>varNum</code> Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.</p> <p><code>recNum</code> Numeric value identifying the location of the datum in the variable. Record numbers are zero-based.</p> <p><code>recordData</code> Data to be written to the variable.</p>

Examples

Create a CDF, create a variable, and write an entire record of data to the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');  
  
% Create a variable in the file.  
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);  
  
% Write some data to the variable  
cdflib.putVarRecordData(cdfid,varNum,0,int8(98))
```

```
% Read the value from the variable.
datum = cdflib.getVarData(cdfid,varNum,0)

datum =

    98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFputzVarRecordData`.

cdflib.renameAttr

Purpose Rename existing attribute

Syntax `cdflib.renameAttr(cdfId,attrNum,newName)`

Description `cdflib.renameAttr(cdfId,attrNum,newName)` renames an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the attribute.

Examples Create a CDF, create an attribute in the CDF, and then rename the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create an attribute
attrNum = cdflib.createAttr(cdfid,'Purpose','global_scope');

% Rename the attribute
cdflib.renameAttr(cdfid, attrNum, 'NewPurpose');

% Check the name of the attribute
attrName = cdflib.getAttrName(cdfid,anum)

attrName =

NewPurpose

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References This function corresponds to the CDF library C API routine `CDFrenameAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

cdflib.renameVar

Purpose Rename existing variable

Syntax `cdflib.renameVar(cdfId,varNum,newName)`

Description `cdflib.renameVar(cdfId,varNum,newName)` renames a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the variable.

Examples Create a CDF, create a variable in the CDF, and then rename the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Get the name of the variable.
name = cdflib.getVarName(cdfid,varNum)

name =

Time

% Rename the variable
cdflib.renameVar(cdfid,varNum,'NewName');

% Check the new name.
name = cdflib.getVarName(cdfid,varNum)

name =

NewName

% Clean up
```

```
cdflib.delete(cdfid)
```

```
clear cdfid
```

cdflib.setCacheSize

Purpose Specify number of dotCDF cache buffers

Syntax `cdflib.setCacheSize(cdfId,numBuffers)`

Description `cdflib.setCacheSize(cdfId,numBuffers)` specifies the number of cache buffers the CDF library uses for an open dotCDF file. A *dotCDF* file is a file with the `.cdf` file extension.

`cdfId` identifies an open CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

For information about cache schemes, see the *CDF User's Guide*.

Examples Create a CDF file and set the cache size. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf');
```

```
% Get the default cache size  
numBuf = cdflib.getCacheSize(cdfid)
```

```
numBuf =
```

```
    300
```

```
% Specify a cache size  
cdflib.setCacheSize(cdfid,150)
```

```
% Check the cache size again  
numBuf = cdflib.getCacheSize(cdfid)
```

```
numBuf =
```

```
    150
```

```
% Clean up  
cdflib.delete(cdfId)  
clear cdfId
```

cdflib.setChecksum

Purpose Specify checksum mode

Syntax `cdflib.setChecksum(cdfId,mode)`

Description `cdflib.setChecksum(cdfId,mode)` specifies the checksum mode of a Common Data Format (CDF) file.

Input Arguments

`cdfId`
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`mode`

Either of the following text strings, or its numeric equivalent. To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

'MD5_CHECKSUM'	Sets file checksum to MD5 checksum.
'NO_CHECKSUM'	File does not use a checksum.

Examples Create a CDF file and set the checksum mode. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('mycdf.cdf');

% Check initial value of checksum.
mode = cdflib.getChecksum(cdfid)

NO_CHECKSUM

cdflib.setChecksum(cdfid,'MD5_CHECKSUM')

% Verify the setting
mode = cdflib.getChecksum(cdfid)

MD5_CHECKSUM
```

References

This function corresponds to the CDF library C API routine `CDFsetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

cdflib.setCompression

Purpose Specify compression settings

Syntax `cdflib.setCompression(cdfId, ctype, cparms)`

Description `cdflib.setCompression(cdfId, ctype, cparms)` specifies compression settings of a Common Data Format (CDF) file.

This function sets the compression for the CDF file itself, not that of any variables in the file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

ctype

One of the following text strings, or its numeric equivalent, specifying compression type.

Text String	Compression Type
'NO_COMPRESSION'	No compression
'RLE_COMPRESSION'	Run-length encoding compression
'HUFF_COMPRESSION'	Huffman compression
'AHUFF_COMPRESSION'	Adaptive Huffman compression
'GZIP_COMPRESSION'	GNU's zip compression

To get the numeric equivalent, use `cdflib.getConstantValue`.

cparms

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is 'GZIP_COMPRESSION'. For this compression type, use `cparms` to specify the level of compression as a numeric value between 1 and 9.

Examples

Create a CDF file and set the compression setting of the file. To run this example, your current folder must be writable.

```
cdfId = cdflib.create('your_file.cdf');

% Determine the file's default compression setting
[ctype, cparms, cpercent] = cdflib.getCompression(cdfId)

ctype =

NO_COMPRESSION

cparms =

[]

cpercent =

100

% Specify new compression setting
cdflib.setCompression(cdfId,'HUFF_COMPRESSION');

% Check the file's compression setting.
[ctype, cparms, cpercent] = cdflib.getCompression(cdfId)

ctype =

HUFF_COMPRESSION

cparms =

OPTIMAL_ENCODING_TREES

cpercent =
```

cdflib.setCompression

0

```
% Clean up  
cdflib.delete(cdfId)  
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

Tutorials

- “Importing CDF Files”
- “Exporting to CDF Files”

Purpose

Specify number of compression cache buffers

Syntax

```
cdflib.setCompressionCacheSize(cdfId,numBuffers)
```

Description

`cdflib.setCompressionCacheSize(cdfId,numBuffers)` specifies the number of cache buffers used for the compression scratch CDF file. For more information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` specifies the number of buffers.

Examples

Create a CDF file and specify the number of compression cache buffers used. To run this example you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the current number of compression cache buffers
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

    80

% Set a new value
cdflib.setCompressionCacheSize(cdfId,100)

% Check the new value
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

    100

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

cdflib.setCompressionCacheSize

References

This function corresponds to the CDF library C API routine `CDFsetCompressionCacheSize`.

Purpose Set backward compatibility mode

Syntax `cdflib.getFileBackward(mode)`

Description `cdflib.getFileBackward(mode)` sets the backward compatibility mode to the value specified by `mode`.

Tips

- Setting backward compatibility mode affects only your current MATLAB session, or until you call `cdflib.setFileBackward` again.

Input Arguments **mode**
One of the following text strings:

BACKWARDFILEon	Set backward compatibility mode on.
BACKWARDFILEoff	Set backward compatibility mode off.

Default: BACKWARDFILEoff

Definitions **backward compatibility mode**

When specified, ensures that any new CDF file created using CDF V3.0 (or later) will be readable by clients using version 2.7 of the CDF library. CDF 3.0 and later releases use a 64-bit file offset to allow for files greater than 2G bytes in size. CDF library versions released before CDF 3.0 use a 32-bit file offset.

Examples Set backward compatibility mode and then check the value.

```
cdflib.setFileBackward('BACKWARDFILEon');
```

```
mode = cdflib.getFileBackward
```

```
mode =
```

```
BACKWARDFILEon
```

cdflib.setFileBackward

Purpose Specify format of Common Data Format (CDF) file

Syntax `cdflib.setFormat(cdfId, format)`

Description `cdflib.setFormat(cdfId, format)` specifies the format of a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

format

Either of the following text strings, or its numeric equivalent.

'SINGLE_FILE'	The CDF consists of only one file. This is the default file format
'MULTI_FILE'	The CDF consists of one header file for control and attribute data and one additional file for each variable in the CDF.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Create a CDF file and specify its format. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('mycdffile.cdf');

% Specify multifile format.
cdflib.setFormat(cdfId, 'MULTI_FILE');

% Check format.
format = cdflib.getFormat(cdfId)

format =
```

cdflib.setFormat

MULTI_FILE

```
% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

Purpose Specify majority of variables

Syntax `cdflib.setMajority(cdfId,majority)`

Description `cdflib.setMajority(cdfId,majority)` specifies the majority of variables in a Common Data Format (CDF) file.

Input Arguments

`cdfId`
Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`majority`

Either of the following text strings, or its numeric equivalent.

'ROW_MAJOR'	C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default.
'COLUMN_MAJOR'	Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Create a CDF file and specify the majority used by variables in the file. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf')

% Specify the majority used by variables in the file
cdflib.setMajority(cdfId,'COLUMN_MAJOR');

% Check the majority value
majority = cdflib.getMajority(cdfId)
```

cdflib.setMajority

```
majority =  
  
COLUMN_MAJOR  
  
% Clean up  
cdflib.delete(cdfId)  
clear cdfId
```

References

Purpose

Specify read-only mode

Syntax

```
cdflib.setReadOnlyMode(cdfId,mode)
```

Description

`cdflib.setReadOnlyMode(cdfId,mode)` specifies the read-only mode of a Common Data Format (CDF) file.

After you open a CDF file, you can put the file into read-only mode to prevent accidental modification.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

mode

Either of the following text strings or its numeric equivalent.

'READONLYon'	CDF file is read-only
'READONLYoff'	CDF file is modifiable.

To get the numeric equivalent of these mode values, use `cdflib.getConstantValue`.

Examples

Open the example CDF file and set the file to read-only mode.

```
cdfId = cdflib.open('example.cdf');

% Set the file to READONLY mode
cdflib.setReadOnlyMode(cdfId,'READONLYon')

% Check read-only status of file again.
mode = cdflib.getReadOnlyMode(cdfId)

mode =

READONLYon
```

cdflib.setReadOnlyMode

```
% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetReadOnlyMode`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

Purpose Specify number of staging cache buffers for Common Data Format (CDF) file

Syntax `cdflib.setStageCacheSize(cdfId,numBuffers)`

Description `cdflib.setStageCacheSize(cdfId,numBuffers)` specifies the number of staging cache buffers for a Common Data Format (CDF) file. For information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

Examples Open the example CDF file and specify the number of cache buffers used.

```
cdfId = cdflib.open('example.cdf');

% Get current number of staging cache buffers
size = cdflib.getStageCacheSize(cdfId)

size =

    125

% Specify new cache size value.
cdflib.setStageCacheSize(cdfId, 200)

% Get size again.
size = cdflib.getStageCacheSize(cdfId)

size =

    200

% Clean up
cdflib.close(cdfId)
```

cdflib.setStageCacheSize

`clear cdfId`

References

- “Exporting to CDF Files”

Purpose Specify library validation mode

Syntax `cdflib.setValidate(mode)`

Description `cdflib.setValidate(mode)` specifies the validation mode of the Common Data Format (CDF) library. Specify the validation mode before opening any files.

Input Arguments

mode

Either of the following text strings, or its numeric equivalent:

'VALIDATEFILEon'	Turns validation mode on. With validation mode on, the library performs sanity checks on the data fields in the CDF file's internal data structures to make sure that the values are within valid ranges and consistent with the defined values/types/entries. This mode also ensures that variable and attribute associations within the file are valid. Note, however, that enabling this mode will, in most cases, slow down the file opening process, especially for large or very fragmented files.
'VALIDATEFILEoff'	Turns validation mode off.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples Set the validation mode of the CDF library.

```
cdflib.setValidate('VALIDATEFILEon');
```

References This function corresponds to the CDF library C API routine `CDFsetValidate`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

- “Exporting to CDF Files”

Purpose

Specify number of multi-file cache buffers for variable

Syntax

```
cdflib.setVarCacheSize(cdfId,varNum,numBuffers)
```

Description

`cdflib.setVarCacheSize(cdfId,varNum,numBuffers)` specifies the number of cache buffers the CDF library uses for a variable in a Common Data Format (CDF) file.

This function is only used with multifile format CDF files. It does not apply to single-file format CDFs. For more information about caching, see the *CDF User's Guide*.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

numBuffers

Numeric value identifying the number of cache buffers to use.

Examples

Create a multifile CDF, and then retrieve the number of buffers being used for a variable:

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
```

cdflib.setVarCacheSize

```
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

    1

% Increase the number of cache buffers used.
cdflib.setVarCacheSize(cdfid,varNum,5)

% Check the number of cache buffers used with the variable.
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

    5

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the [CDF Web site](#).

For copyright information, see the `cdfcopyright.txt` file.

cdflib.setVarCompression

Purpose Specify compression settings used with variable

Syntax `cdflib.setVarCompression(cdfId, varNum, ctype, cparams)`

Description `cdflib.setVarCompression(cdfId, varNum, ctype, cparams)` configures the compression setting for a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

ctype

One of the following text strings, or its numeric equivalent, specifying the compression type.

Text String	Compression Type
'NO_COMPRESSION'	No compression.
'RLE_COMPRESSION'	Run-length encoding compression
'HUFF_COMPRESSION'	Huffman compression
'AHUFF_COMPRESSION'	Adaptive Huffman compression
'GZIP_COMPRESSION'	GNU's zip compression

cparams

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is 'GZIP_COMPRESSION'. For this compression type,

you use `cparms` to specify the level of compression as a numeric value between 1 and 9.

Examples

Create a CDF, create a variable, and then set the compression used by the variable. To run this example, you must be in a folder with execute permission.

```
cdfid = cdflib.create('mycdf.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Specify the compression used by the variable.
cdflib.setVarCompression(cdfid,0,'GZIP_COMPRESSION',8)

% Check the compression setting of the variable
[ctype params percent] = cdflib.getVarCompression(cdfid,0)

ctype =

GZIP_COMPRESSION

params =

      8

percent =

      0

% Clean up
cdflib.delete(cdfid);
clear cdfid
```

References

Tutorials

- “Importing CDF Files”
- “Exporting to CDF Files”

Purpose

Specify initial number of records written to variable

Syntax

```
cdflib.setVarInitialRecs(cdfId,varNum,numrecs)
```

Description

`cdflib.setVarInitialRecs(cdfId,varNum,numrecs)` specifies the initial number of records to write to a variable in a Common Data Format (CDF) file.

Input Arguments**`cdfId`**

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable numbers are zero-based.

`numRecs`

Numeric value specifying the number of records to write.

Examples

Create a CDF, create a variable, and then specify the number of records to write for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Specify the number of records to write for the variable
cdflib.setVarInitialRecs(cdfid,varNum,100);

recsWritten = cdflib.getVarNumRecsWritten(cdfid,varNum)

recsWritten =
```

cdflib.setVarInitialRecs

100

```
% Clean up  
cdflib.delete(cdfid)
```

```
clear cdfid
```

References

Purpose	Specify pad value used with variable
Syntax	<code>cdflib.setVarPadValue(cdfId,varNum,padvalue)</code>
Description	<code>cdflib.setVarPadValue(cdfId,varNum,padvalue)</code> specifies the pad value used with a variable in a Common Data Format (CDF) file.
Input Arguments	<p>cdfId Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p>varNum Numeric value identifying a variable in the file. Variable numbers are zero-based.</p> <p>padValue Value to use a pad value for the variable. The data type of the pad value must match the data type of the variable.</p>
Examples	<p>Create a CDF, create a variable in the CDF, and then set the pad value used with the variable. To run this example, you must be in a writable folder.</p> <pre>cdfid = cdflib.create('your_file.cdf'); % Create a variable in the file. varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]); % Get the current pad value used with the variable padval = cdflib.getVarPadValue(cdfid,varNum) padval = 0</pre>

cdflib.setVarPadValue

```
% Change the pad value for the variable
cdflib.setVarPadValue(cdfid,varNum,int8(1));

% Check the new pad value.
padval = cdflib.getVarPadValue(cdfid,varNum)

padval =

     1

% Clean up
cdflib.delete(cdfid)

clear cdfid
```

Purpose	Specify reserve percentage for variable
Syntax	<code>cdflib.setVarReservePercent(cdfId,varNum,percent)</code>
Description	<code>cdflib.setVarReservePercent(cdfId,varNum,percent)</code> specifies the compression reserve percentage for a variable in a Common Data Format (CDF) file.
Input Arguments	<p>cdfId Identifier of a CDF file, returned by a call to <code>cdflib.create</code> or <code>cdflib.open</code>.</p> <p>varNum Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.</p> <p>percent Numeric value specifying the amount of extra space to allocate for a compressed variable, expressed as a percentage. You can specify values between 0 (no extra space is reserved) and 100, or values greater than 100. The value specifies the percentage of the uncompressed size of the variable. If you specify a fractional reserve percentages, the library rounds the value down.</p>
Definitions	<p>reserve percentage Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.</p>

cdflib.SetVarReservePercent

Examples

Create a CDF, create a variable, set the compression of the variable, and then set the reserve percent for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid, 'Time', 'cdf_int1', 1, [], true, []);

% Set the compression of the variable.
cdflib.setVarCompression(cdfid, varNum, 'GZIP_COMPRESSION', 8);

% Set the compression reserver percentage
cdflib.setVarReservePercent(cdfid, varNum, 80);

cdflib.close(cdfid);
```

- “Exporting to CDF Files”

Purpose

Specify how variable handles sparse records

Syntax

```
cdflib.getVarSparseRecords(cdfId, varNum, stype)
```

Description

`cdflib.getVarSparseRecords(cdfId, varNum, stype)` specifies the sparse records type of a variable in a Common Data Format (CDF) file.

Input Arguments

cdfId

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

varNum

Number that identifies the variable to be set. Variable numbers are zero-based.

stype

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

Text String	Description
'NO_SPARSERECORDS'	No sparse records
'PAD_SPARSERECORDS'	For sparse records, the library uses the variable's pad value when reading values from a missing record.
'PREV_SPARSERECORDS'	For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value.

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

cdflib.setVarSparseRecords

Examples

Open a multifile CDF and close a variable.

Create a CDF, create a variable, and set the sparse records type of the variable. To run this example you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Set the sparse records type of the variable
cdflib.setVarSparseRecords(cdfid,varNum,'PAD_SPARSERECORDS');

% Check the sparse records type of the variable
stype = cdflib.getVarSparseRecords(cdfid,varNum)

stype =

PAD_SPARSERECORDS

%Clean up
cdflib.delete(cdfid);

clear cdfid
```

Tutorials

- “Importing CDF Files”
- “Exporting to CDF Files”

Purpose

Read data from Common Data Format (CDF) file

Syntax

```
data = cdfread(filename)
data = cdfread(filename, param1, val1, param2, val2, ...)
[data, info] = cdfread(filename, ...)
```

Description

`data = cdfread(filename)` reads all the data from the Common Data Format (CDF) file specified in the string `filename`. CDF data sets typically contain a set of variables, of a specific data type, each with an associated set of records. The variable might represent time values with each record representing a specific time that an observation was recorded. `cdfread` returns all the data in a cell array where each column represents a variable and each row represents a record associated with a variable. If the variables have varying numbers of associated records, `cdfread` pads the rows to create a rectangular cell array, using pad values defined in the CDF file.

Note Because `cdfread` creates temporary files, the current working directory must be writeable.

`data = cdfread(filename, param1, val1, param2, val2, ...)` reads data from the file, where `param1`, `param2`, and so on, can be any of the parameters listed in the following table.

`[data, info] = cdfread(filename, ...)` returns details about the CDF file in the `info` structure.

Parameter	Value
'Records'	A vector specifying which records to read. Record numbers are zero-based. <code>cdfread</code> returns a cell array with the same number of rows as the number of records read and as many columns as there are variables.
'Variables'	A 1-by- n or n -by-1 cell array specifying the names of the variables to read from the file. n must be less than or equal to the total number of variables in the file. <code>cdfread</code> returns a cell array with the same number of columns as the number of variables read, and a row for each record read.
'Slices'	An m -by-3 array, where each row specifies where to start reading along a particular dimension of a variable, the skip interval to use on that dimension (every item, every other item, etc.), and the total number of values to read on that dimension. m must be less than or equal to the number of dimensions of the variable. If m is less than the total number of dimensions, <code>cdfread</code> reads every value from the unspecified dimensions ($[0 \ 1 \ n]$, where n is the total number of elements in the dimension. Note: Because the 'Slices' parameter describes how to process a single variable, it must be used in conjunction with the 'Variables' parameter.
'ConvertEpochToDatenum'	A Boolean value that determines whether <code>cdfread</code> automatically converts CDF epoch data types to MATLAB serial date numbers. If set to <code>false</code> (the default), <code>cdfread</code> wraps epoch values in MATLAB <code>cdfepoch</code> objects. Note: For better performance when reading large data sets, set this parameter to <code>true</code> .
'CombineRecords'	A Boolean value that determines how <code>cdfread</code> returns the CDF data sets read from the file. If set to <code>false</code> (the default), <code>cdfread</code> stores the data in an m -by- n cell array, where m is the number of records and n is the number

Parameter	Value
	<p>of variables requested. If set to <code>true</code>, <code>cdfread</code> combines all records for a particular variable into one cell in the output cell array. In this cell, <code>cdfread</code> stores scalar data as a column array. <code>cdfread</code> extends the dimensionality of nonscalar and string data. For example, instead of creating 1000 elements containing 20-by-30 arrays for each record, <code>cdfread</code> stores all the records in one cell as a 1000-by-20-by-30 array</p> <p>Note: If you use the 'Records' parameter to specify which records to read, you cannot use the 'CombineRecords' parameter.</p> <p>Note: When using the 'Variable' parameter to read one variable, if the 'CombineRecords' parameter is <code>true</code>, <code>cdfread</code> returns the data as an M-by-N numeric or character array; it does not put the data into a cell array.</p>

Note To improve performance when working with large data files, use the 'ConvertEpochToDatetime' and 'CombineRecords' options.

Note To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

Examples

Read all the data from a CDF file.

```
data = cdfread('example.cdf');
```

Read the data from the variable 'Time'.

```
data = cdfread('example.cdf', 'Variable', {'Time'});
```

Read the first value in the first dimension, the second value in the second dimension, the first and third values in the third dimension, and all values in the remaining dimension of the variable 'multidimensional'.

```
data = cdfread('example.cdf', ...  
             'Variable', {'multidimensional'}, ...  
             'Slices', [0 1 1; 1 1 1; 0 2 2]);
```

This is similar to reading the whole variable into data and then using matrix indexing, as in the following.

```
data{1}(1, 2, [1 3], :)
```

Collapse the records from a data set and convert CDF epoch data types to MATLAB serial date numbers.

```
data = cdfread('example.cdf', ...  
             'CombineRecords', true, ...  
             'ConvertEpochToDatenum', true);
```

How To

- “Importing CDF Files”

Purpose

Write data to Common Data Format (CDF) file

Note `cdfwrite` is not recommended. Use the `cdflib` low-level functions instead.

Syntax

```
cdfwrite(filename,variablelist)
cdfwrite(...,'PadValues',padvals)
cdfwrite(...,'GlobalAttributes',gattrib)
cdfwrite(...,'VariableAttributes',vattrib)
cdfwrite(...,'WriteMode',mode)
cdfwrite(...,'Format',format)
```

Description

`cdfwrite(filename,variablelist)` writes out a Common Data Format (CDF) file, specified in `filename`. The `filename` input is a string enclosed in single quotes. The `variablelist` argument is a cell array of ordered pairs, each of which comprises a CDF variable name (a string) and the corresponding CDF variable value. To write out multiple records for a variable, put the values in a cell array where each element in the cell array represents a record.

Note Because `cdfwrite` creates temporary files, both the destination directory for the file and the current working directory must be writeable.

`cdfwrite(...,'PadValues',padvals)` writes out pad values for given variable names. `padvals` is a cell array of ordered pairs, each of which comprises a variable name (a string) and a corresponding pad value. Pad values are the default values associated with the variable when an out-of-bounds record is accessed. Variable names that appear in `padvals` must appear in `variablelist`.

`cdfwrite(...,'GlobalAttributes',gattrib)` writes the structure `gattrib` as global metadata for the CDF file. Each field of the structure

is the name of a global attribute. The value of each field contains the value of the attribute. To write out multiple values for an attribute, put the values in a cell array where each element in the cell array represents a record.

Note To specify a global attribute name that is invalid in your MATLAB application, create a field called 'CDFAttributeRename' in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `GlobalAttributes` structure, and the corresponding name of the attribute to be written to the CDF file.

`cdfwrite(..., 'VariableAttributes', vattrib)` writes the structure `vattrib` as variable metadata for the CDF. Each field of the struct is the name of a variable attribute. The value of each field should be an M-by-2 cell array where M is the number of variables with attributes. The first element in the cell array should be the name of the variable and the second element should be the value of the attribute for that variable.

Note To specify a variable attribute name that is illegal in MATLAB, create a field called 'CDFAttributeRename' in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `VariableAttributes` struct, and the corresponding name of the attribute to be written to the CDF file. If you are specifying a variable attribute of a CDF variable that you are renaming, the name of the variable in the `VariableAttributes` structure must be the same as the renamed variable.

`cdfwrite(..., 'WriteMode', mode)`, where *mode* is either 'overwrite' or 'append', indicates whether or not the specified variables should be

appended to the CDF file if the file already exists. By default, `cdfwrite` overwrites existing variables and attributes.

`cdfwrite(..., 'Format', format)`, where *format* is either 'multifile' or 'singlefile', indicates whether or not the data is written out as a multifile CDF. In a multifile CDF, each variable is stored in a separate file with the name *.vN, where N is the number of the variable that is written out to the CDF. By default, `cdfwrite` writes out a single file CDF. When 'WriteMode' is set to 'Append', the 'Format' option is ignored, and the format of the preexisting CDF is used.

Examples

Write out a file 'example.cdf' containing a variable 'Longitude' with the value [0:360].

```
cdfwrite('example', {'Longitude', 0:360});
```

Write out a file 'example.cdf' containing variables 'Longitude' and 'Latitude' with the variable 'Latitude' having a pad value of 10 for all out-of-bounds records that are accessed.

```
cdfwrite('example', {'Longitude', 0:360, 'Latitude', 10:20}, ...  
        'PadValues', {'Latitude', 10});
```

Write out a file 'example.cdf', containing a variable 'Longitude' with the value [0:360], and with a variable attribute of 'validmin' with the value 10.

```
varAttribStruct.validmin = {'Longitude' [10]};  
cdfwrite('example', {'Longitude' 0:360}, 'VariableAttributes', ...  
        varAttribStruct);
```

ceil

Purpose Round toward positive infinity

Syntax `B = ceil(A)`

Description `B = ceil(A)` rounds the elements of `A` to the nearest integers greater than or equal to `A`. For complex `A`, the imaginary and real parts are rounded independently.

Examples `a = [-1.9, -0.2, 3.4, 5.6, 7, 2.4+3.6i]`

```
a =  
Columns 1 through 4  
-1.9000    -0.2000    3.4000    5.6000  
  
Columns 5 through 6  
7.0000    2.4000 + 3.6000i
```

```
ceil(a)
```

```
ans =  
Columns 1 through 4  
-1.0000    0    4.0000    6.0000  
  
Columns 5 through 6  
7.0000    3.0000 + 4.0000i
```

See Also `fix` | `floor` | `round`

Purpose	Create cell array
Syntax	<pre>C = cell(dim) C = cell(dim1,...,dimN) D = cell(obj)</pre>
Description	<p><code>C = cell(dim)</code> creates a cell array of empty matrices. If <code>dim</code> is a scalar, <code>C</code> is <code>dim</code>-by-<code>dim</code>. If <code>dim</code> is a vector, <code>C</code> is <code>dim(1)</code>-by-...-<code>dim(N)</code>, where <code>N</code> is the number of elements of <code>dim</code>.</p> <p><code>C = cell(dim1,...,dimN)</code> creates cell array <code>C</code>, where <code>C</code> is <code>dim1</code>-by-...-<code>dimN</code>.</p> <p><code>D = cell(obj)</code> converts a Java array or .NET array of <code>System.String</code> or <code>System.Object</code> into a MATLAB cell array.</p>
Tips	<p>Creating an empty array with the <code>cell</code> function, such as</p> <pre>C = cell(3,4,2);</pre> <p>is exactly equivalent to assigning an empty array to the last index of a new cell array:</p> <pre>C{3,4,2} = [];</pre>
Input Arguments	<p>dim</p> <p>Scalar integer or vector of integers that specifies the dimensions of cell array <code>C</code>.</p> <p>dim1,...,dimN</p> <p>Scalar integers that specify the dimensions of <code>C</code>.</p> <p>obj</p> <p>One of the following:</p> <ul style="list-style-type: none">• Java array or object• .NET array of type <code>System.String</code> or <code>System.Object</code>

Output Arguments

C

Cell array. Each cell contains an empty, 0-by-0 array of type double.

D

Cell array. Each cell contains a MATLAB type closest to the Java or .NET type. For more information, see:

- “Conversion of Java Return Types”
- “.NET Type to MATLAB Type Mapping”

Examples

Create an empty 3-by-4-by-2 cell array.

```
mycell = cell(3,4,2);
```

Create a cell array that is the same size as `mycell`, created in the previous example.

```
similar = cell(size(mycell));
```

Convert an array of `java.lang.String` objects into a MATLAB cell array.

```
strArray = java_array('java.lang.String', 3);  
strArray(1) = java.lang.String('one');  
strArray(2) = java.lang.String('two');  
strArray(3) = java.lang.String('three');
```

```
cellArray = cell(strArray)
```

This code returns

```
cellArray =  
    'one'  
    'two'
```

'three'

Create a cell array of folders in the c:\work folder, using the .NET Framework System.IO.Directory class :

```
myList = cell(System.IO.Directory.GetDirectories('c:\work'));  
celldisp(myList)
```

How To

- “Access Data in a Cell Array”

cell2mat

Purpose Convert cell array to numeric array

Syntax `A= cell2mat(C)`

Description `A= cell2mat(C)` converts cell array `C` with contents of the same data type into a single array, `A`.

Input Arguments

C

Cell array, where each cell contains the same type of data. The `cell2mat` function accepts numeric or character data within cells of `C`, but not structs, objects, or nested cells.

The contents of `C` must support concatenation into a hyperrectangle. Otherwise, the results are undefined. For example, the contents of cells in the same column must have the same number of columns, although they need not have the same number of rows.

Output Arguments

A

Array of the same type as the contents of the cells of `C`. The number of dimensions of `A` matches the highest number of dimensions of arrays within `C`.

Examples

Combine matrices in the four cells of cell array `c` into matrix `m`.

```
c = {[1], [2, 3, 4];  
     [5; 9], [6, 7, 8; 10, 11, 12]};
```

```
m = cell2mat(c)
```

`m` is a 3-by-4 matrix:

```
m =  
     1     2     3     4  
     5     6     7     8  
     9    10    11    12
```

See Also

[mat2cell](#) | [num2cell](#)

cell2struct

Purpose Convert cell array to structure array

Syntax `structArray = cell2struct(cellArray, fields, dim)`

Description `structArray = cell2struct(cellArray, fields, dim)` creates a structure array, `structArray`, from the information contained within cell array `cellArray`.

The `fields` argument specifies field names for the structure array. This argument is an array of strings or a cell array of strings.

The `dim` argument tells MATLAB which axis of the cell array to use in creating the structure array. Use a numeric double to specify `dim`.

To create a structure array with fields derived from `N` rows of a cell array, specify `N` field names in the `fields` argument, and the number 1 in the `dim` argument. To create a structure array with fields derived from `M` columns of a cell array, specify `M` field names in the `fields` argument and the number 2 in the `dim` argument.

The `structArray` output is a structure array with `N` fields, where `N` is equal to the number of fields in the `fields` input argument. The number of fields in the resulting structure must equal the number of cells along dimension `dim` that you want to convert.

Examples

Create the following table for use with the examples in this section. The table lists information about the employees of a small Engineering company. Reading the table by rows shows the names of employees by department. Reading the table by columns shows the number of years each employee has worked at the company.

	5 Years	10 Years	15 Years
Development	Lee, Reed, Hill	Dean, Frye	Lane, Fox, King
Sales	Howe, Burns	Kirby, Ford	Hall
Management	Price	Clark, Shea	Sims

	5 Years	10 Years	15 Years
Quality	Bates, Gray	Nash	Kay, Chase
Documentation	Lloyd, Young	Ryan, Hart, Roy	Marsh

Enter the following commands to create the initial cell array employees:

```
devel = {'Lee','Reed','Hill'}, {'Dean','Frye'}, ...  
        {'Lane','Fox','King'};   
sales = {'Howe','Burns'}, {'Kirby','Ford'}, {'Hall'};   
mgmt = {'Price'}, {'Clark','Shea'}, {'Sims'};   
qual = {'Bates','Gray'}, {'Nash'}, {'Kay','Chase'};   
docu = {'Lloyd','Young'}, {'Ryan','Hart','Roy'}, {'Marsh'};
```

```
employees = [devel; sales; mgmt; qual; docu]   
employees =
```

```
    {1x3 cell}    {1x2 cell}    {1x3 cell}   
    {1x2 cell}    {1x2 cell}    {1x1 cell}   
    {1x1 cell}    {1x2 cell}    {1x1 cell}   
    {1x2 cell}    {1x1 cell}    {1x2 cell}   
    {1x2 cell}    {1x3 cell}    {1x1 cell}
```

This is the resulting cell array:

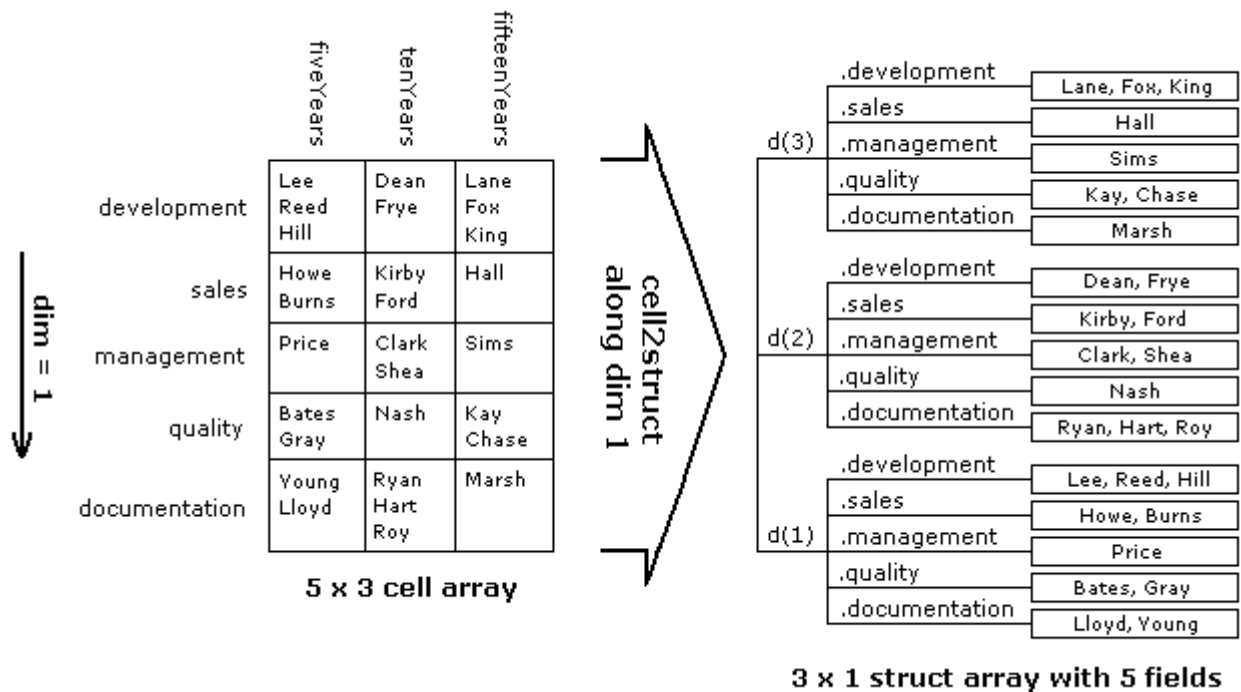

cell2struct

	fiveYears	tenYears	fifteenYears
development	Lee Reed Hill	Dean Frye	Lane Fox King
sales	Howe Burns	Kirby Ford	Hall
management	Price	Clark Shea	Sims
quality	Bates Gray	Nash	Kay Chase
documentation	Young Lloyd	Ryan Hart Roy	Marsh

5 x 3 cell array

Convert the cell array to a struct along dimension 1:

- 1 Convert the 5-by-3 cell array along its first dimension to construct a 3-by-1 struct array with 5 fields. Each of the rows along dimension 1 of the cell array becomes a field in the struct array:

Traversing the first (i.e., vertical) dimension, there are 5 rows with row headings that read as follows:

```
rowHeadings = {'development', 'sales', 'management', ...
               'quality', 'documentation'};
```

- Convert the cell array to a struct array, `depts`, in reference to this dimension:

```
depts = cell2struct(employees, rowHeadings, 1)
depts =
3x1 struct array with fields:
    development
    sales
```

```
management
quality
documentation
```

- 3** Use this row-oriented structure to find the names of the Development staff who have been with the company for up to 10 years:

```
depts(1:2).development
ans =
    'Lee'    'Reed'    'Hill'
ans =
    'Dean'   'Frye'
```

Convert the same cell array to a struct along dimension 2:

- 1** Convert the 5-by-3 cell array along its second dimension to construct a 5-by-1 struct array with 3 fields. Each of the columns along dimension 2 of the cell array becomes a field in the struct array:

	fiveYears	tenYears	fifteenYears	
development	Lee Reed Hill	Dean Frye	Lane Fox King	5 x 3 cell array
sales	Howe Burns	Kirby Ford	Hall	
management	Price	Clark Shea	Sims	
quality	Bates Gray	Nash	Kay Chase	
documentation	Young Lloyd	Ryan Hart Roy	Marsh	

5 x 1 struct array with 3 fields

y(5)	.fiveYears	Lloyd, Young
	.tenYears	Ryan, Hart, Roy
	.fifteenYears	Marsh
y(4)	.fiveYears	Bates, Gray
	.tenYears	Nash
y(3)	.fifteenYears	Kay, Chase
	.fiveYears	Lauer
	.tenYears	Clark, Shea
y(2)	.fifteenYears	Sims
	.fiveYears	Howe, Burns
y(1)	.tenYears	Kirby, Ford
	.fifteenYears	Hall
	.fiveYears	Lee, Reed, Hill
	.tenYears	Dean, Frye
	.fifteenYears	Lane, Fox, King

- 2** Traverse the cell array along the second (or horizontal) dimension. The column headings become fields of the resulting structure:

```
colHeadings = {'fiveYears' 'tenYears' 'fifteenYears'};

years = cell2struct(employees, colHeadings, 2)
years =
5x1 struct array with fields:
    fiveYears
    tenYears
    fifteenYears
```

- 3** Using the column-oriented structure, show how many employees from the Sales and Documentation departments have worked for the company for at least 5 years:

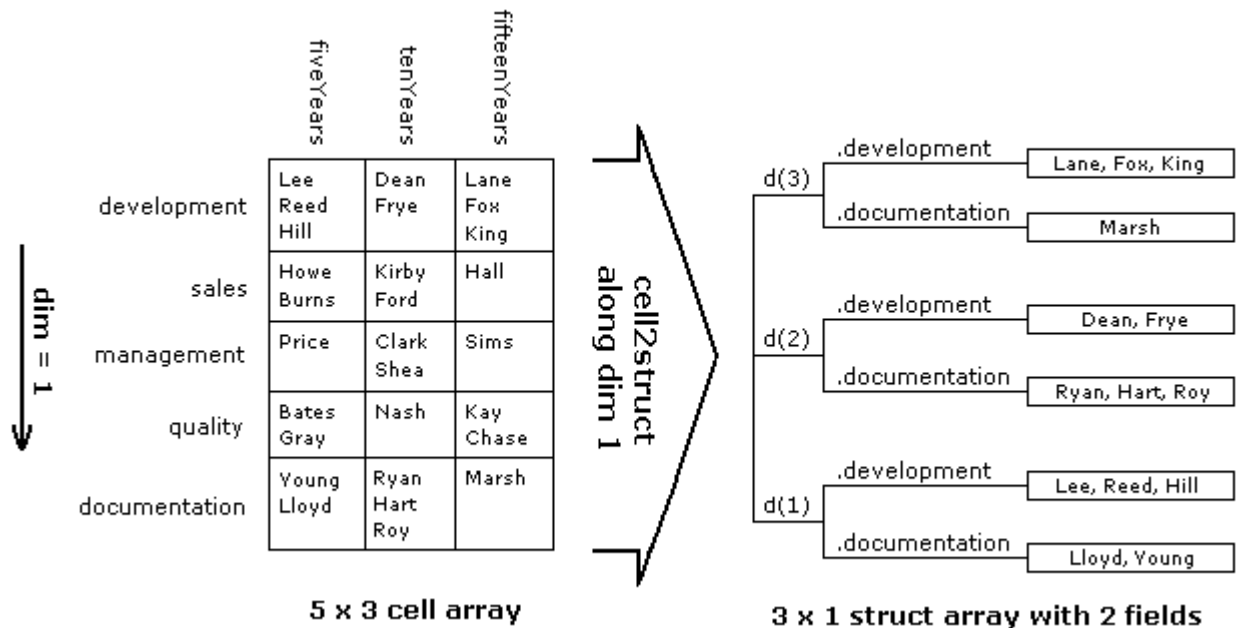

```
[~, sales_5years, ~, ~, docu_5years] = years.fiveYears
sales_5years =
    'Howe'    'Burns'
docu_5years =
    'Lloyd'   'Young'
```

Convert only part of the cell array to a struct:

- 1** Convert only the first and last rows of the cell array. This results in a 3-by-1 struct array with 2 fields:

```
rowHeadings = {'development', 'documentation'};

depts = cell2struct(employees([1,5],:), rowHeadings, 1)
depts =
3x1 struct array with fields:
    development
    documentation
```

- 2 Display those employees who belong to these departments for all three periods of time:

```

for k=1:3
    depts(k,:)
end

ans =
    development: {'Lee' 'Reed' 'Hill'}
    documentation: {'Lloyd' 'Young'}
ans =
    development: {'Dean' 'Frye'}
    documentation: {'Ryan' 'Hart' 'Roy'}
ans =
    development: {'Lane' 'Fox' 'King'}
  
```

| [isstruct](#) | [fieldnames](#)

How To

- [dynamic field names](#)

Purpose	Convert cell array to table
Syntax	<pre>T = cell2table(C) T = cell2table(C,Name,Value)</pre>
Description	<p><code>T = cell2table(C)</code> converts the contents of an <i>m</i>-by-<i>n</i> cell array, <i>C</i>, to an <i>m</i>-by-<i>n</i> table, <i>T</i>. Each variable in the table, <i>T</i>, is numeric, with a data type <code>double</code>, or a cell array of strings.</p> <p><code>cell2table</code> uses the input array name appended with the column number for the variable names in the table. If these names are not valid MATLAB identifiers, <code>cell2table</code> uses strings of the form <code>'Var1'</code>, ..., <code>'VarN'</code> where <i>N</i> is the number of columns in <i>C</i>.</p> <p><code>T = cell2table(C,Name,Value)</code> creates a table from a cell array, <i>C</i>, with additional options specified by one or more <i>Name,Value</i> pair arguments.</p> <p>For example, you can specify row names or variable names to include in the table.</p>
Input Arguments	<p>C - Input cell array 2-D cell array</p> <p>Input cell array, specified as a 2-D cell array.</p> <p>If the cell contents have compatible sizes and types, then <code>cell2table</code> vertically concatenates the contents of the cells in each column of <i>C</i> to create each variable in <i>T</i>. If the cell contents have different sizes or incompatible types, then the corresponding variable in the table, <i>T</i>, is a column of cells.</p> <p>Name-Value Pair Arguments</p> <p>Specify optional comma-separated pairs of <i>Name,Value</i> arguments. <i>Name</i> is the argument name and <i>Value</i> is the corresponding value. <i>Name</i> must appear inside single quotes (<code>' '</code>). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p>

Example: `RowNames', {'row1', 'row2', 'row3'}` uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

'RowNames' - Row names for T

`{}` (default) | cell array of nonempty, distinct strings

Row names for `T`, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows, `size(C,1)`.

'VariableNames' - Variable names for T

cell array of nonempty, distinct strings

Variable names for `T`, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables, `size(C,2)`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of `N` strings of the form `{'Var1' ... 'VarN'}`, where `N` is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

Output Arguments

T - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

Examples

Convert Cell Array to Table

Create a cell array containing strings and numeric data.

```
C = {5 'cereal' 110 'C+'; 12 'pizza' 140 'B'; ...  
    23 'salmon' 367 'A'; 2 'cookies' 160 'D'}
```

```
C =
```

```
[ 5]    'cereal'    [110]    'C+'
[12]    'pizza'    [140]    'B'
[23]    'salmon'   [367]    'A'
[ 2]    'cookies'  [160]    'D'
```

Convert the cell array, `C`, to a table and specify variable names.

```
T = cell2table(C,...
    'VariableNames',{'Age' 'FavoriteFood' 'Calories' 'NutritionGrade'})
```

T =

Age	FavoriteFood	Calories	NutritionGrade
5	'cereal'	110	'C+'
12	'pizza'	140	'B'
23	'salmon'	367	'A'
2	'cookies'	160	'D'

The variables `T.Age` and `T.Calories` are numeric while the variables `T.FavoriteFood` and `T.NutritionGrade` are cell arrays of strings.

Convert Column Headings to Variable Names

Convert a cell array to a table, and then include the first row from the cell array as variable names for the table.

Create a cell array where the first row contains strings to identify column headings.

```
Patients = {'Gender' 'Age' 'Height' 'Weight' 'Smoker';...
    'M' 38 71 176 true;...
    'M' 43 69 163 false;...
    'M' 38 64 131 false;...
    'F' 38 64 131 false;...
    'F' 40 67 133 false;...
    'F' 49 64 119 false}
```

cell2table

```
Patients =
```

```
    'Gender'    'Age'    'Height'    'Weight'    'Smoker'
    'M'         [ 38]    [  71]    [  176]    [    1]
    'M'         [ 43]    [  69]    [  163]    [    0]
    'M'         [ 38]    [  64]    [  131]    [    0]
    'F'         [ 38]    [  64]    [  131]    [    0]
    'F'         [ 40]    [  67]    [  133]    [    0]
    'F'         [ 49]    [  64]    [  119]    [    0]
```

Exclude the columns headings and convert the contents of the cell array to a table.

```
C = Patients(2:end,:);
T = cell2table(C)
```

```
T =
```

C1	C2	C3	C4	C5
'M'	38	71	176	true
'M'	43	69	163	false
'M'	38	64	131	false
'F'	38	64	131	false
'F'	40	67	133	false
'F'	49	64	119	false

The table, T, has variable names C1, ..., C5.

Change the variable names by setting the table property, T.Properties.VariableNames, to the first row of the cell array.

```
T.Properties.VariableNames = Patients(1,:)
```

```
T =
```

Gender	Age	Height	Weight	Smoker
--------	-----	--------	--------	--------

'M'	38	71	176	true
'M'	43	69	163	false
'M'	38	64	131	false
'F'	38	64	131	false
'F'	40	67	133	false
'F'	49	64	119	false

Related Examples

- “Access Data in a Table”

celldisp

Purpose Display cell array contents

Syntax `celldisp(C)`
`celldisp(C, name)`

Description `celldisp(C)` recursively displays the contents of a cell array. `celldisp(C, name)` uses the string *name* for the display instead of the name of the first input (or ans).

Examples Use `celldisp` to display the contents of a 2-by-3 cell array:

```
C = {[1 2] 'Tony' 3+4i; [1 2;3 4] -5 'abc'};  
celldisp(C)
```

```
C{1,1} =  
    1    2
```

```
C{2,1} =  
    1    2  
    3    4
```

```
C{1,2} =  
Tony
```

```
C{2,2} =  
-5
```

```
C{1,3} =  
3.0000+ 4.0000i
```

```
C{2,3} =  
abc
```

See Also `cellplot`

How To

- “Export Cell Array to Text File”

Purpose

Apply function to each cell in cell array

Syntax

```
[A1,...,Am] = cellfun(func,C1,...,Cn)
[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)
```

Description

`[A1,...,Am] = cellfun(func,C1,...,Cn)` calls the function specified by function handle `func` and passes elements from cell arrays `C1,...,Cn`, where `n` is the number of inputs to function `func`. Output arrays `A1,...,Am`, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The `i`th iteration corresponds to the syntax `[A1(i),...,Am(i)] = func(C{i},...,Cn{i})`. The `cellfun` function does not perform the calls to function `func` in a specific order.

`[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

Input Arguments**func**

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

Backward Compatibility

`cellfun` accepts function name strings for function `func`, rather than a function handle, for these function names: `isempty`, `islogical`, `isreal`, `length`, `ndims`, `prodofsize`, `size`, `isclass`. Enclose the function name in single quotes.

If you specify a function name string rather than a function handle:

- `cellfun` does not call any overloaded versions of the function.

- The `size` and `isclass` functions require additional inputs to the `cellfun` function:

`A = cellfun('size', C, k)` returns the size along the `k`th dimension of each element of `C`.

`A = cellfun('isclass', C, classname)` returns logical 1 (true) for each element of `C` that matches the `classname` string. This syntax returns logical 0 (false) for objects that are a subclass of `classname`.

C1,...,Cn

Cell arrays that contain the `n` inputs required for function `func`. Each cell array must have the same dimensions.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'UniformOutput'

Logical value, as follows:

- | | |
|------------------------|--|
| <code>true</code> (1) | Indicates that for all inputs, each output from function <code>func</code> is a cell array or a scalar value that is always of the same type and size. The <code>cellfun</code> function combines the outputs in arrays <code>A1, ..., Am</code> , where <code>m</code> is the number of function outputs. Each output array is of the same type as the individual function outputs. |
| <code>false</code> (0) | Requests that the <code>cellfun</code> function combine the outputs into cell arrays <code>A1, ..., Am</code> . The outputs of function <code>func</code> can be of any size or type. |

Default: `true`

'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

Output Arguments**A1,...,Am**

Arrays that collect the m outputs from function `func`. Each array A is the same size as each of the inputs C_1, \dots, C_n .

Function `func` can return output arguments of different classes. However, if `UniformOutput` is true (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

Examples

Compute the mean of each vector in cell array `C`.

```
C = {1:10, [2; 4; 6], []};
```

```
averages = cellfun(@mean, C)
```

This code returns

```
averages =  
    5.5000    4.0000    NaN
```

Compute the size of each array in C, created in the previous example.

```
[nrows, ncols] = cellfun(@size, C)
```

This code returns

```
nrows =  
     1     3     0  
ncols =  
    10     1     0
```

Create a cell array that contains strings, and abbreviate those strings to the first three characters. Because the output strings are nonscalar, set `UniformOutput` to `false`.

```
days = {'Monday', 'Tuesday', 'Wednesday', 'Thursday', 'Friday'};  
abbrev = cellfun(@(x) x(1:3), days, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
abbrev =  
    'Mon'    'Tue'    'Wed'    'Thu'    'Fri'
```

Compute the covariance between arrays in two cell arrays C and D. Because the covariance output is nonscalar, set `UniformOutput` to `false`.

```
c1 = rand(5,1); c2 = rand(10,1); c3 = rand(15,1);  
d1 = rand(5,1); d2 = rand(10,1); d3 = rand(15,1);
```

```
C = {c1, c2, c3};
D = {d1, d2, d3};

covCD = cellfun(@cov, C, D, 'UniformOutput', false)
```

This code returns

```
covCD =
    [2x2 double]    [2x2 double]    [2x2 double]
```

Define and call a custom error handling function.

```
function result = errorfun(S, varargin)
    warning(S.identifier, S.message);
    result = NaN;
end

A = {rand(3)};
B = {rand(5)};
AgtB = cellfun(@(x,y) x > y, A, B, 'ErrorHandler', @errorfun, ...
    'UniformOutput', false)
```

cellplot

Purpose Graphically display structure of cell array

Syntax
`cellplot(c)`
`cellplot(c, 'legend')`
`handles = cellplot(c)`

Description `cellplot(c)` displays a figure window that graphically represents the contents of `c`. Filled rectangles represent elements of vectors and arrays, while scalars and short text strings are displayed as text.

`cellplot(c, 'legend')` places a colorbar next to the plot labelled to identify the data types in `c`.

`handles = cellplot(c)` displays a figure window and returns a vector of surface handles.

Limitations The `cellplot` function can display only two-dimensional cell arrays.

Examples Consider a 2-by-2 cell array containing a matrix, a vector, and two text strings:

```
c{1,1} = '2-by-2';  
c{1,2} = 'eigenvalues of eye(2)';  
c{2,1} = eye(2);  
c{2,2} = eig(eye(2));
```

The command `cellplot(c)` produces

**See Also**`celldisp`**How To**

- “Export Cell Array to Text File”

cellstr

Purpose Create cell array of strings from character array

Syntax `c = cellstr(S)`

Description `c = cellstr(S)` places each row of the character array `S` into separate cells of `c`. Any trailing spaces in the rows of `S` are removed.

Use the `char` function to convert back to a string matrix.

Examples Given the string matrix

```
S = ['abc '; 'defg'; 'hi  ']
```

```
S =  
    abc  
    defg  
    hi
```

```
whos S  
  Name      Size      Bytes  Class  
  S          3x4          24   char array
```

The following command returns a 3-by-1 cell array.

```
c = cellstr(S)
```

```
c =  
    'abc'  
    'defg'  
    'hi'
```

```
whos c  
  Name      Size      Bytes  Class  
  c          3x1          198   cell array
```

See Also `iscellstr` | `strings` | `char` | `isstrprop` | `strsplit`

Purpose

Conjugate gradients squared method

Syntax

```
x = cgs(A,b)
cgs(A,b,tol)
cgs(A,b,tol,maxit)
cgs(A,b,tol,maxit,M)
cgs(A,b,tol,maxit,M1,M2)
cgs(A,b,tol,maxit,M1,M2,x0)
[x,flag] = cgs(A,b,...)
[x,flag,relres] = cgs(A,b,...)
[x,flag,relres,iter] = cgs(A,b,...)
[x,flag,relres,iter,resvec] = cgs(A,b,...)
```

Description

`x = cgs(A,b)` attempts to solve the system of linear equations $A*x = b$ for x . The n -by- n coefficient matrix A must be square and should be large and sparse. The column vector b must have length n . You can specify A as a function handle, `afun`, such that `afun(x)` returns $A*x$.

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `cgs` converges, a message to that effect is displayed. If `cgs` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual $\text{norm}(b-A*x) / \text{norm}(b)$ and the iteration number at which the method stopped or failed.

`cgs(A,b,tol)` specifies the tolerance of the method, `tol`. If `tol` is `[]`, then `cgs` uses the default, $1e-6$.

`cgs(A,b,tol,maxit)` specifies the maximum number of iterations, `maxit`. If `maxit` is `[]` then `cgs` uses the default, $\min(n,20)$.

`cgs(A,b,tol,maxit,M)` and `cgs(A,b,tol,maxit,M1,M2)` use the preconditioner M or $M = M1*M2$ and effectively solve the system $\text{inv}(M)*A*x = \text{inv}(M)*b$ for x . If M is `[]` then `cgs` applies no preconditioner. M can be a function handle `mfun` such that `mfun(x)` returns $M \setminus x$.

`cgs(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess `x0`. If `x0` is `[]`, then `cgs` uses the default, an all-zero vector.

`[x,flag] = cgs(A,b,...)` returns a solution `x` and a flag that describes the convergence of `cgs`.

Flag	Convergence
0	<code>cgs</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>cgs</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>cgs</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>cgs</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = cgs(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is 0, then `relres <= tol`.

`[x,flag,relres,iter] = cgs(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = cgs(A,b,...)` also returns a vector of the residual norms at each iteration, including `norm(b-A*x0)`.

Examples

Using `cgs` with a Matrix Input

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12; maxit = 15;
M1 = diag([10:-1:1 1 1:10]);
x = cgs(A,b,tol,maxit,M1);
```

displays the message

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

Using cgs with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner $M1$ with a handle to a backsolve function `mfun`. The example is contained in the file `run_cgs` that

- Calls `cgs` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_cgs` are available to `afun` and `mfun`.

The following shows the code for `run_cgs`:

```
function x1 = run_cgs
n = 21;
b = afun(ones(n,1));
tol = 1e-12; maxit = 15;
x1 = cgs(@afun,b,tol,maxit,@mfun);

    function y = afun(x)
        y = [0; x(1:n-1)] + ...
            [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
            [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_cgs
```

MATLAB software returns

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

Using cgs with a Preconditioner.

This example demonstrates the use of a preconditioner.

Load west0479, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define **b** so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12; maxit = 20;
```

Use **cgs** to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = cgs(A,b,tol,maxit);
```

f10 is 1 because **cgs** does not converge to the requested tolerance $1e-12$ within the requested 20 iterations. In fact, the behavior of **cgs** is so poor that the initial guess ($x_0 = \text{zeros}(\text{size}(A,2),1)$) is the best solution and is returned as indicated by $it_0 = 0$. MATLAB stores the residual history in **rv0**.

Plot the behavior of **cgs**.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since A is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the 'udiag' option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));  
[x1,f11,rr1,it1,rv1] = cgs(A,b,tol,maxit,L,U);
```

f11 is 0 because cgs drives the relative residual to $4.3851e-014$ (the value of rr1). The relative residual is less than the prescribed tolerance of $1e-12$ at the third iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of $1e-6$. The output rv1(1) is norm(b) and the output rv1(14) is norm(b-A*x2).

You can follow the progress of cgs by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');  
xlabel('Iteration number');  
ylabel('Relative residual');
```

Purpose Convert to character array (string)

Syntax

```
S = char(X)
S = char(C)
S = char(T1,T2,...,TN)
```

Description `S = char(X)` converts array `X` of nonnegative integer codes into a character array. Valid codes range from 0 to 65535, where codes 0 through 127 correspond to 7-bit ASCII characters. The characters that MATLAB can process (other than 7-bit ASCII characters) depend upon your current locale setting. To convert characters into a numeric array, use the `double` function.

`S = char(C)`, when `C` is a cell array of strings, places each element of `C` into the rows of the character array `s`. Use `cellstr` to convert back.

`S = char(T1,T2,...,TN)` forms the character array `S` containing the text strings `T1`, `T2`, ..., `TN` as rows, automatically padding each string with blanks to form a valid matrix. Each text parameter, `Ti`, can itself be a character array. This allows the creation of arbitrarily large character arrays. Empty strings are significant.

Examples **Convert Integers to Characters**

Create a 3-by-32 array of the printable ASCII characters.

```
asc = char(reshape(32:127,32,3)')
```

```
asc =
```

```
! "#$%&'()*+,-./0123456789:;<=>?
@ABCDEFGHIJKLMNopqrstuvwxyz[\]^_
`abcdefghijklmnopqrstuvwxyz{|}~
```

Tutorials

- “How the MATLAB Process Uses Locale Settings”

Purpose	Check MATLAB code files for possible problems
Alternatives	For information on using the graphical user interface for checking code, see “Check Code for Errors and Warnings”.
Syntax	<pre>checkcode('filename') checkcode('filename', '-config=settings.txt') checkcode('filename', '-config=factory') inform=checkcode('filename', '-struct') msg=checkcode('filename', '-string') [inform, filepaths]=checkcode('filename') inform=checkcode('filename', '-id') inform=checkcode('filename', '-fullpath') inform=checkcode('filename', '-notok') checkcode('filename', '-cyc') checkcode('filename', '-codegen') checkcode('filename', '-eml')</pre>

Description `checkcode('filename')` displays messages, sometimes referred to as Code Analyzer messages, about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `checkcode(F1,F2,F3,...)`, where each input is a character array, MATLAB software displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `checkcode` messages is subject to some change between versions.

`checkcode('filename', '-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

Note If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

checkcode

For information about creating a `settings.txt` file, see “Save and Reuse Code Analyzer Message Settings”. If you specify an invalid file, `checkcode` returns a message indicating that it cannot open or read the file you specified. In that case, `checkcode` uses the factory default settings.

`checkcode('filename', '-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=checkcode('filename', '-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
<code>message</code>	Message describing the suspicious construct that code analysis caught.
<code>line</code>	Vector of file line numbers to which the message refers.
<code>column</code>	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=checkcode('filename', '-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as input, `msg` contains a string where each file’s information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the `-struct` or `-string` argument and you specify an output argument, the default behavior is `-struct`. If you omit the argument

and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepath]=checkcode('filename')` additionally returns `filepath`, the absolute paths to the file names, in the same order as you specified them.

`inform=checkcode('filename','-id')` requests the message ID, where ID is a string of the form ABC... When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=checkcode('filename','-fullpath')` assumes that the input file names are absolute paths, so that `checkcode` does not try to locate them.

`inform=checkcode('filename','-notok')` runs `checkcode` for all lines in `filename`, even those lines that end with the `checkcode` suppression directive, `%#ok`.

`checkcode('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`checkcode('filename','-codegen')` enables code generation messages for display in the Command Window.

`checkcode('filename','-em1')` `-em1` is not recommended. Use `-codegen` instead.

Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in `matlabroot/help/techdoc/matlab_env/examples`. If you want to run

the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

Running checkcode on a File with No Options

To run `checkcode` on the example file, `lengthofline.m`, run

```
checkcode('lengthofline')
```

MATLAB displays the Code Analyzer messages for `lengthofline.m` in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more info.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

Running checkcode with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=checkcode('lengthofline', '-id')
```

MATLAB returns

```
inform =
```

```
19x1 struct array with fields:
```

```
    message  
     line  
   column  
     id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =
```

```
    message: 'The value assigned here to variable 'nohandle' might never be used.'  
         line: 22  
    column: [1 9]  
         id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.NASGU is the ID for the message 'The value assigned here to variable 'nohandle' might never be used.'.

Displaying McCabe Complexity with checkcode

To display the McCabe complexity of a MATLAB code file, run checkcode with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
checkcode lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the Code Analyzer messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more in
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

How To

- For information on the suppression directive, `%#ok`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages”.

Purpose

Check files into source control system (UNIX platforms)

Syntax

```
checkin('filename', 'comments', 'comment_text')
checkin({'filename1', 'filename2'}, 'comments', 'comment_text')
checkin('filename', 'comments',
'comment_text', 'option', 'value')
```

Description

`checkin('filename', 'comments', 'comment_text')` checks in the file named `filename` to the source control system. Use the full path for `filename` and include the file extension. You must save the file before checking it in, but the file can be open or closed. The `comment_text` is a MATLAB string containing checkin comments for the source control system. You must supply **comments** and `comment_text`.

`checkin({'filename1', 'filename2'}, 'comments', 'comment_text')` checks in the files `filename1` through `filename` to the source control system. Use the full paths for the files and include file extensions. Comments apply to all files checked in.

`checkin('filename', 'comments', 'comment_text', 'option', 'value')` provides additional checkin options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1', 'filename2', ...}`. Options apply to all file names. The *option* and *value* arguments are shown in the following table.

option Argument	value Argument	Purpose
'force'	'on'	filename is checked in even if the file has not changed since it was checked out.
'force'	'off' (default)	filename is not checked in if there were no changes since checkout.

checkin

option Argument	value Argument	Purpose
'lock'	'on'	filename is checked in with comments, and is automatically checked out.
'lock'	'off' (default)	filename is checked in with comments but does not remain checked out.

Examples

Check In a File

Check the file `/myserver/myfiles/clock.m` into the source control system, with the comment `Adjustment for leapyear`:

```
checkin('/myserver/myfiles/clock.m','comments',...  
'Adjustment for leapyear')
```

Check In Multiple Files

Check two files into the source control system, using the same comment for each:

```
checkin({'/myserver/myfiles/clock.m', ...  
'/myserver/myfiles/calendar.m'}, 'comments', ...  
'Adjustment for leapyear')
```

Check In a File and Keep It Checked Out

Check the file `/myserver/myfiles/clock.m` into the source control system and keep the file checked out:

```
checkin('/myserver/myfiles/clock.m','comments',...  
'Adjustment for leapyear','lock','on')
```

See Also

`checkout` | `cmopts` | `undocheckout` | `verctrl`

How To

- “Check In Files (UNIX Platforms)”

Purpose Check files out of source control system (UNIX platforms)

Syntax

```
checkout('filename')
checkout({'filename1','filename2', ...})
checkout('filename','option','value',...)
```

Description `checkout('filename')` checks out the file named `filename` from the source control system. Use the full path for `filename` and include the file extension. The file can be open or closed when you use `checkout`.

`checkout({'filename1','filename2', ...})` checks out the files named `filename1` through `filename2` from the source control system. Use the full paths for the files and include the file extensions.

`checkout('filename','option','value',...)` provides additional `checkout` options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1','filename2', ...}`. Options apply to all file names. The *option* and *value* arguments are shown in the following table.

option Argument	value Argument	Purpose
'force'	'on'	The checkout is forced, even if you already have the file checked out. This is effectively an <code>undocheckout</code> followed by a <code>checkout</code> .
'force'	'off' (default)	Prevents you from checking out the file if you already have it checked out.

checkout

option Argument	value Argument	Purpose
'lock'	'on' (default)	The checkout gets the file, allows you to write to it, and locks the file so that access to the file for others is read only.
'lock'	'off'	The checkout gets a read-only version of the file, allowing another user to check out the file for updating. You do not have to check the file in after checking it out with this option.
'revision'	'version_num'	Checks out the specified revision of the file.

If you end the MATLAB session, the file remains checked out. You can check in the file from within the MATLAB desktop during a later session, or directly from your source control system.

Examples

Check Out a File

Check out the file `/myserver/myfiles/clock.m` from the source control system:

```
checkout('/myserver/myfiles/clock.m')
```

Check Out Multiple Files

Check out `/matlab/myfiles/clock.m` and `/matlab/myfiles/calendar.m` from the source control system:

```
checkout({'/myserver/myfiles/clock.m', ...
```

```
'/myserver/myfiles/calendar.m'})
```

Force a Checkout, Even If File Is Already Checked Out

Check out `/matlab/myfiles/clock.m` even if `clock.m` is already checked out to you:

```
checkout('/myserver/myfiles/clock.m', 'force', 'on')
```

Check Out Specified Revision of File

Check out revision 1.1 of `clock.m`:

```
checkout('/matlab/myfiles/clock.m', 'revision', '1.1')
```

`checkin` | `cmopts` | `undocheckout` | `customverctrl` | `verctrl`

How To

- “Check Out Files (UNIX Platforms)”

Purpose Cholesky factorization

Syntax

```
R = chol(A)
L = chol(A, 'lower')
R = chol(A, 'upper')
[R,p] = chol(A)
[L,p] = chol(A, 'lower')
[R,p] = chol(A, 'upper')
[R,p,S] = chol(A)
[R,p,s] = chol(A, 'vector')
[L,p,s] = chol(A, 'lower', 'vector')
[R,p,s] = chol(A, 'upper', 'vector')
```

Description $R = \text{chol}(A)$ produces an upper triangular matrix R from the diagonal and upper triangle of matrix A , satisfying the equation $R' * R = A$. The `chol` function assumes that A is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the upper triangle as the lower triangle. Matrix A must be positive definite.

$L = \text{chol}(A, 'lower')$ produces a lower triangular matrix L from the diagonal and lower triangle of matrix A , satisfying the equation $L * L' = A$. The `chol` function assumes that A is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the lower triangle as the upper triangle. When A is sparse, this syntax of `chol` is typically faster. Matrix A must be positive definite. $R = \text{chol}(A, 'upper')$ is the same as $R = \text{chol}(A)$.

$[R,p] = \text{chol}(A)$ for positive definite A , produces an upper triangular matrix R from the diagonal and upper triangle of matrix A , satisfying the equation $R' * R = A$ and p is zero. If A is not positive definite, then p is a positive integer and MATLAB does not generate an error. When A is full, R is an upper triangular matrix of order $q = p - 1$ such that $R' * R = A(1:q, 1:q)$. When A is sparse, R is an upper triangular matrix of size q -by- n so that the L-shaped region of the first q rows and first q columns of $R' * R$ agree with those of A .

$[L,p] = \text{chol}(A, 'lower')$ for positive definite A , produces a lower triangular matrix L from the diagonal and lower triangle of matrix A ,

satisfying the equation $L*L' = A$ and p is zero. If A is not positive definite, then p is a positive integer and MATLAB does not generate an error. When A is full, L is a lower triangular matrix of order $q = p - 1$ such that $L*L' = A(1:q, 1:q)$. When A is sparse, L is a lower triangular matrix of size q -by- n so that the L-shaped region of the first q rows and first q columns of $L*L'$ agree with those of A . $[R, p] = chol(A, 'upper')$ is the same as $[R, p] = chol(A)$.

The following three-output syntaxes require sparse input A .

$[R, p, S] = chol(A)$, when A is sparse, returns a permutation matrix S . Note that the reordering S may differ from that obtained from `amd` since `chol` will slightly change the ordering for increased performance. When $p=0$, R is an upper triangular matrix such that $R'*R = S'*A*S$. When p is not zero, R is an upper triangular matrix of size q -by- n so that the L-shaped region of the first q rows and first q columns of $R'*R$ agree with those of $S'*A*S$. The factor of $S'*A*S$ tends to be sparser than the factor of A .

$[R, p, s] = chol(A, 'vector')$, when A is sparse, returns the permutation information as a vector s such that $A(s, s) = R'*R$, when $p=0$. You can use the 'matrix' option in place of 'vector' to obtain the default behavior.

$[L, p, s] = chol(A, 'lower', 'vector')$, when A is sparse, uses only the diagonal and the lower triangle of A and returns a lower triangular matrix L and a permutation vector s such that $A(s, s) = L*L'$, when $p=0$. As above, you can use the 'matrix' option in place of 'vector' to obtain a permutation matrix. $[R, p, s] = chol(A, 'upper', 'vector')$ is the same as $[R, p, s] = chol(A, 'vector')$.

Note Using `chol` is preferable to using `eig` for determining positive definiteness.

Examples

Example 1

The gallery function provides several symmetric, positive, definite matrices.

```
A=gallery('moler',5)
```

```
A =
```

```
    1   -1   -1   -1   -1
   -1    2    0    0    0
   -1    0    3    1    1
   -1    0    1    4    2
   -1    0    1    2    5
```

```
C=chol(A)
```

```
ans =
```

```
    1   -1   -1   -1   -1
    0    1   -1   -1   -1
    0    0    1   -1   -1
    0    0    0    1   -1
    0    0    0    0    1
```

```
isequal(C'*C,A)
```

```
ans =
```

```
    1
```

For sparse input matrices, chol returns the Cholesky factor.

```
N = 100;
A = gallery('poisson', N);
```

N represents the number of grid points in one direction of a square N-by-N grid. Therefore, A is N^2 by N^2 .

```
L = chol(A, 'lower');
D = norm(A - L*L', 'fro');
```

The value of D will vary somewhat among different versions of MATLAB but will be on order of 10^{-14} .

Example 2

The binomial coefficients arranged in a symmetric array create a positive definite matrix.

```
n = 5;
X = pascal(n)
X =
    1    1    1    1    1
    1    2    3    4    5
    1    3    6   10   15
    1    4   10   20   35
    1    5   15   35   70
```

This matrix is interesting because its Cholesky factor consists of the same coefficients, arranged in an upper triangular matrix.

```
R = chol(X)
R =
    1    1    1    1    1
    0    1    2    3    4
    0    0    1    3    6
    0    0    0    1    4
    0    0    0    0    1
```

Destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element.

```
X(n,n) = X(n,n) - 1
X =
    1    1    1    1    1
    1    2    3    4    5
```

chol

```
1   3   6  10  15
1   4  10  20  35
1   5  15  35  69
```

Now an attempt to find the Cholesky factorization of X fails.

```
chol(X)
Error using chol
Matrix must be positive definite.
```

See Also

[ichol](#) | [cholupdate](#)

Purpose Rank 1 update to Cholesky factorization

Syntax

```
R1 = cholupdate(R,x)
R1 = cholupdate(R,x,'+')
R1 = cholupdate(R,x,'-')
[R1,p] = cholupdate(R,x,'-')
```

Description

`R1 = cholupdate(R,x)` where `R = chol(A)` is the original Cholesky factorization of `A`, returns the upper triangular Cholesky factor of $A + x*x'$, where `x` is a column vector of appropriate length. `cholupdate` uses only the diagonal and upper triangle of `R`. The lower triangle of `R` is ignored.

`R1 = cholupdate(R,x,'+')` is the same as `R1 = cholupdate(R,x)`.

`R1 = cholupdate(R,x,'-')` returns the Cholesky factor of $A - x*x'$. An error message reports when `R` is not a valid Cholesky factor or when the downdated matrix is not positive definite and so does not have a Cholesky factorization.

`[R1,p] = cholupdate(R,x,'-')` will not return an error message. If `p` is 0, `R1` is the Cholesky factor of $A - x*x'$. If `p` is greater than 0, `R1` is the Cholesky factor of the original `A`. If `p` is 1, `cholupdate` failed because the downdated matrix is not positive definite. If `p` is 2, `cholupdate` failed because the upper triangle of `R` was not a valid Cholesky factor.

Tips `cholupdate` works only for full matrices.

Examples

```
A = pascal(4)
A =

     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    20

R = chol(A)
R =
```

cholupdate

```
      1      1      1      1
      0      1      2      3
      0      0      1      3
      0      0      0      1
x = [0 0 0 1]';
```

This is called a rank one update to A since $\text{rank}(x*x')$ is 1:

```
A + x*x'
ans =
```

```
      1      1      1      1
      1      2      3      4
      1      3      6     10
      1      4     10     21
```

Instead of computing the Cholesky factor with $R1 = \text{chol}(A + x*x')$, we can use cholupdate:

```
R1 = cholupdate(R,x)
R1 =
```

```
  1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    1.4142
```

Next destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element of A. The downdated matrix is:

```
A - x*x'
ans =
```

```
      1      1      1      1
      1      2      3      4
```

```

1     3     6    10
1     4    10    19

```

Compare chol with cholupdate:

```

R1 = chol(A-x*x')
Error using chol
Matrix must be positive definite.
R1 = cholupdate(R,x,'-')
Error using cholupdate
Downdated matrix must be positive definite.

```

However, subtracting 0.5 from the last element of A produces a positive definite matrix, and we can use cholupdate to compute its Cholesky factor:

```

x = [0 0 0 1/sqrt(2)]';
R1 = cholupdate(R,x,'-')
R1 =
    1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    0.7071

```

Algorithms

cholupdate uses the algorithms from the LINPACK subroutines ZCHUD and ZCHDD. cholupdate is useful since computing the new Cholesky factor from scratch is an $O(N^3)$ algorithm, while simply updating the existing factor in this way is an $O(N^2)$ algorithm.

circshift

Purpose Shift array circularly

Compatibility The default behavior of `circshift(A,K)`, where `K` is a scalar, will change in a future release. The new default behavior will be to operate along the first array dimension of `A` whose size does not equal 1. Use `circshift(A,[K 0])` to retain current behavior.

Syntax
`Y = circshift(A,K)`
`Y = circshift(A,K,dim)`

Description `Y = circshift(A,K)` circularly shifts the elements in array `A` by `K` positions. Specify `K` as an integer to shift the rows of `A`, or as a vector of integers to specify the shift amount in each dimension.

`Y = circshift(A,K,dim)` circularly shifts the values in array `A` by `K` positions along dimension `dim`. Inputs `K` and `dim` must be scalars.

Input Arguments

A - Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64 | logical | char | struct | table
| cell

Complex Number Support: Yes

K - Shift amount

integer scalar | vector of integers

Shift amount, specified as an integer scalar or vector of integers. If the shift amount is larger than the length of the corresponding dimension in `A`, then the shift circularly wraps to the beginning of that dimension. For example, shifting a 3-element vector by +3 positions will bring its elements back to their original positions.

- If you specify `K` as an integer and do not specify `dim`, then `circshift` shifts the rows of `A` down (positive integer) or up (negative integer).
- If you specify `K` as a vector of integers, each element specifies the shift amount for the N th dimension in `A`. If the N th element in `K` is positive, then the values of `A` are shifted towards the end (positive integer) or beginning (negative integer) of the N th dimension.

dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is `dim = 1`. If you specify `dim`, then `K` must be an integer scalar. Specify `dim = 1` to exchange rows, `dim = 2` to exchange columns, and so on.

Examples**Shift Column Vector Elements**

Create a numeric column vector.

```
A = (1:10)'
```

```
A =
```

```
1
2
3
4
5
6
7
8
9
10
```

Use `circshift` to shift the elements by three positions.

```
Y = circshift(A,3)
```

circshift

```
Y =  
  
     8  
     9  
    10  
     1  
     2  
     3  
     4  
     5  
     6  
     7
```

The result, Y, has the same elements as A but they are in a different order.

Move Characters in Array

Create an array of characters.

```
A = 'racecar'
```

```
A =
```

```
racecar
```

Use `circshift` to shift the characters by three positions in the second dimension.

```
Y = circshift(A,3,2)
```

```
Y =
```

```
carrace
```

The characters are in a different order in Y.

Move Matrix Elements

Create a numeric array with a cluster of ones in the top left.

```
A = [1 1 0 0; 1 1 0 0; 0 0 0 0; 0 0 0 0]
```

```
A =
```

```

     1     1     0     0
     1     1     0     0
     0     0     0     0
     0     0     0     0

```

Use `circshift` to shift the elements of `A` by one position in each dimension.

```
Y = circshift(A,[1 1])
```

```
Y =
```

```

     0     0     0     0
     0     1     1     0
     0     1     1     0
     0     0     0     0

```

The cluster of ones is now in the center of the matrix.

To move the cluster back to its original position, use `circshift` on `Y` with negative shift values.

```
X = circshift(Y,[-1 -1])
```

```
X =
```

```

     1     1     0     0
     1     1     0     0
     0     0     0     0
     0     0     0     0

```

The matrix `X` is equivalent to `A`.

TriRep.circumcenters

Purpose (Will be removed) Circumcenters of specified simplices

Note `circumcenters(TriRep)` will be removed in a future release. Use `circumcenter(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax
`CC = circumcenters(TR, SI)`
`[CC RCC] = circumcenters(TR, SI)`

Description `CC = circumcenters(TR, SI)` returns the coordinates of the circumcenter of each specified simplex `SI`. `CC` is an `m`-by-`n` matrix, where `m` is of length `length(SI)`, the number of specified simplices, and `n` is the dimension of the space where the triangulation resides.

`[CC RCC] = circumcenters(TR, SI)` returns the circumcenters and the corresponding radii of the circumscribed circles or spheres.

Input Arguments

<code>TR</code>	Triangulation object.
<code>SI</code>	Column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If <code>SI</code> is not specified the circumcenter information for the entire triangulation is returned, where the circumcenter associated with simplex <code>i</code> is the <code>i</code> 'th row of <code>CC</code> .

Output Arguments

CC	m-by-n matrix. m is the number of specified simplices and n is the dimension of the space where the triangulation resides. Each row <code>CC(i,:)</code> represents the coordinates of the circumcenter of simplex <code>SI(i)</code> .
RCC	Vector of length <code>length(SI)</code> , the number of specified simplices containing radii of the circumscribed circles or spheres.

Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

Examples

Example 1

Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y)
```

Compute the circumcenters.

```
cc = circumcenters(trep);
triplot(trep);
axis([-50 350 -50 350]);
axis equal;
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
```

The circumcenters represent points on the medial axis of the polygon.

Example 2

Query a 3-D triangulation created with `DelaunayTri`. Compute the circumcenters of the first five tetrahedra.

```
X = rand(10,3);  
dt = DelaunayTri(X);  
cc = circumcenters(dt, [1:5]')
```

Purpose	Clear current axes
Syntax	<pre>cla cla reset cla(ax) cla(ax, 'reset')</pre>
Description	<p>cla deletes from the current axes all graphics objects whose handles are not hidden (i.e., their <code>HandleVisibility</code> property is set to <code>on</code>).</p> <p>cla reset deletes from the current axes all graphics objects regardless of the setting of their <code>HandleVisibility</code> property and resets all axes properties, except <code>Position</code> and <code>Units</code>, to their default values.</p> <p>cla(ax) or cla(ax, 'reset') clears the single axes with handle ax.</p>
Tips	<p>The cla command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the <code>HandleVisibility</code> setting of callback. This means that when issued from within a callback routine, cla deletes only those objects whose <code>HandleVisibility</code> property is set to <code>on</code>.</p>
See Also	<code>clf</code> <code>hold</code> <code>newplot</code> <code>reset</code>

clabel

Purpose Contour plot elevation labels

Syntax

```
clabel(C)
clabel(C,h)
clabel(C,v)
clabel(C,h,v)
clabel( __ ,Name,Value)

clabel(C,'manual')
clabel(C,h,'manual')

text_handles = clabel( __ )
```

Description `clabel(C)` labels all contours displayed in the current contour plot. Labels are upright and displayed with '+' symbols. `clabel` randomly selects label positions.

`clabel(C,h)` rotates the labels and inserts them in the contour lines. This syntax inserts only those labels that fit within the contour, depending on the size of the contour.

`clabel(C,v)` labels only the contour levels specified by the vector, `v`.

`clabel(C,h,v)` labels only the contour levels specified by vector `v`, rotates the labels, and inserts them in the contour lines.

`clabel(__ ,Name,Value)` specifies the text object properties and the 'LabelSpacing' contourgroup property, using one or more `Name,Value` pair arguments, in addition to any of the input arguments in previous syntaxes.

`clabel(C,'manual')` places contour labels at locations you select with a mouse. Click the mouse or press the space bar to label the contour

closest to the center of the crosshair. Press the **Return** key while the cursor is within the figure window to terminate labeling.

`clabel(C,h,'manual')` places contour labels at locations you select with a mouse. Press the **Return** key while the cursor is within the figure window to terminate labeling. The labels are rotated and inserted in the contour lines.

`text_handles = clabel(__)` additionally returns an array containing the handles of the text objects created, using any of the input arguments in the previous syntaxes. If you call `clabel` without the `h` argument, `text_handles` also contains the handles of line objects used to create the '+' symbols.

Input Arguments

C - Contour matrix

2-by-n matrix

Contour matrix containing the data that defines the contour lines. `C` is returned by the `contour`, `contour3`, or `contourf` function.

h - Handle to the contourgroup object

value returned by contour functions

Handle to the `contourgroup` object specified as the value returned by the `contour`, `contour3`, or `contourf` function.

v - Contour level values

vector

Contour level values, specified as a row or column vector of individual values.

Example: `[0,10,20]`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can

specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','Rotation',45` adds red labels to a contour plot, where each label is rotated 45 degrees.

In addition to the following, you can specify other text object properties using `Name,Value` pair arguments. See [Text Properties](#).

'Color' - Text color

`[0 0 0]` (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`.

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
<code>[1 1 0]</code>	y	yellow
<code>[1 0 1]</code>	m	magenta
<code>[0 1 1]</code>	c	cyan
<code>[1 0 0]</code>	r	red
<code>[0 1 0]</code>	g	green
<code>[0 0 1]</code>	b	blue
<code>[1 1 1]</code>	w	white
<code>[0 0 0]</code>	k	black

Example: `'Color',[0 1 0]`

Example: `'Color','green'`

'FontName' - Font name

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

Example: 'FontName', 'Courier'

'FontSize' - Font size

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

Example: 'FontSize', 12.5

'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize

accordingly. points, inches, centimeters, and pixels are absolute units. 1 point = $\frac{1}{72}$ inch

Note When setting both the `FontSize` and the `FontUnits`, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`. For example, to set the font size to 0.3 inches, call `'FontUnits','inches','FontSize',0.3` in the argument list.

'FontWeight' - Weight of text characters

`'normal'` (default) | `'bold'` | `'light'` | `'demi'`

Weight of text characters, specified as the comma-separated pair consisting of `'FontWeight'` and one of the following strings:

- `'normal'`
- `'bold'`
- `'light'`
- `'demi'`

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to `'bold'` or `'demi'` causes MATLAB to use a bold font.

Example: `'FontWeight','bold'`

'LabelSpacing' - Spacing between labels

144 (default) | scalar

Spacing between labels on each contour line, specified as the comma-separated pair consisting of `'LabelSpacing'` and a scalar. Specify the label spacing in points, where 1 point = $\frac{1}{72}$ inch.

Example: `'LabelSpacing',72`

'Rotation' - Text orientation

0 (default) | scalar

Text orientation, specified as the comma-separated pair consisting of 'Rotation' and a scalar. Specify values of rotation in degrees. Positive values result in counterclockwise rotation.

Example: 'Rotation',45

Output Arguments

text_handles - Handles of text objects

handle

Handles of the text objects that `clabel` creates. The `UserData` properties of the text objects contain the contour values displayed.

If you call `clabel` without the `h` argument, `text_handles` also contains the handles of line objects used to create the '+' symbols.

Examples

Label Contour Plot with Vertical Text and '+' Symbols

Generate a contour plot and obtain the contour matrix, `C`.

```
[x,y,z] = peaks;  
figure  
C = contour(x,y,z);
```

clabel

Label the contour plot.

```
clabel(C)
```

Label Contour Plot with Rotated Text Inserted in Contour Lines

Generate a contour plot and obtain the contour matrix, C , and the handle to the contourgroup object, h .

```
[x,y,z] = peaks;  
figure  
[C,h] = contour(x,y,z);
```

clabel

Label the contour plot.

```
clabel(C,h);
```

Label Specific Contour Levels

Label only the contours with contour levels 2 or 6.

```
[x,y,z] = peaks;
figure
[C,h] = contour(x,y,z);
v = [2,6];
clabel(C,h,v)
```

Set Label Spacing

Set the label spacing to 72 points (1 inch).

```
[x,y,z] = peaks;  
figure  
[C,h] = contour(x,y,z);  
clabel(C,h,'LabelSpacing',72)
```

Label Contour Plot and Set Text Properties

Use `Name`, `Value` arguments to set the font size, font color, and text orientation of the labels.

```
[x,y,z] = peaks;  
figure  
[C,h] = contour(x,y,z);  
clabel(C,h,'FontSize',15,'Color','r','Rotation',0)
```

'FontSize',15,'Color','r' adds 15-point red labels to the contour plot. 'Rotation',0 makes the text upright.

Label Contour Plot and Return Object Handles

Label a contour plot and return the handles of the objects created.

```
[x,y,z] = peaks;  
figure  
[C,h] = contour(x,y,z);  
text_handles = clabel(C,h);
```

MATLAB® returns an array containing the handles of the text objects created.

Set the color of the labels to blue, using the handle to the text objects.

```
set(text_handles, 'Color', 'blue')
```

clabel

Purpose

Determine class of object

Syntax

```
ClassName = class(object)
obj = class(s, 'class_name')
obj = class(s, 'class_name', parent1, parent2, ...)
obj = class(struct([]), 'class_name', parent1, parent2, ...)
obj_struct = class(struct_array, 'class_name', parent_array)
```

Description

ClassName = `class(object)` returns a string specifying the class of object. See “Fundamental MATLAB Classes” for more information on MATLAB classes.

Note Before MATLAB 7.6 (classes defined without a `classdef` statement), class constructors called the `class` function to create the object. The following `class` function syntaxes apply only within classes defined before Version 7.6.

`obj = class(s, 'class_name')` creates an array of class *class_name* objects using the struct *s* as a pattern to determine the size of *obj*.

`obj = class(s, 'class_name', parent1, parent2, ...)` inherits the methods and fields of the parent objects *parent1*, *parent2*, and so on. The size of the parent objects must match the size of *s* or be a scalar (1-by-1), in which case, MATLAB performs scalar expansion.

`obj = class(struct([]), 'class_name', parent1, parent2, ...)` constructs object containing only fields that it inherits from the parent objects. All parents must have the same, nonzero size, which determines the size of the returned object *obj*.

`obj_struct = class(struct_array, 'class_name', parent_array)` maps every element of the *parent_array* to a corresponding element in the *struct_array* to produce the output array of objects, *obj_struct*.

All arrays must be of the same size. If either the *struct_array* or the *parent_array* is of size 1-by-1, then MATLAB performs scalar expansion to match the array sizes.

class

To create an object array of size 0-by-0, set the size of the `struct_array` and `parent_array` to 0-by-0.

Examples

Return the class of Java object `obj`:

```
import java.lang.*;
obj = String('mystring');
class(obj)
```

```
ans =
```

```
java.lang.String
```

Return class of any MATLAB variable:

```
h = @sin;
class(h)
```

```
ans =
```

```
function_handle
```

Tutorials

- “Class Syntax Fundamentals”

Purpose Class definition keywords

Syntax

```
classdef classname
    properties
        PropName
    end
    methods
        methodName
    end
    events
        EventName
    end
    enumeration
        EnumName (arg)
    end
end
```

Description `classdef classname` begins the class definition and an `end` keyword terminates the `classdef` block. Only blank lines and comments can precede `classdef`. Enter a class definition in a file having the same name as the class, with a filename extension of `.m`. Class definition files can be in folders on the MATLAB path or in `@` folders whose parent folder is on the MATLAB path. See “Class Files” for more information. See “Classdef Block” and “Class Definition” for more information on classes.

`properties` begins a property definition block, an `end` keyword terminates the `properties` block. Class definitions can contain multiple property definition blocks, each specifying different attribute settings that apply to the properties in that particular block. See “Defining Properties” for more information.

Note Properties cannot have the same name as the class.

classdef

`methods` begins a methods definition block, an `end` keyword terminates the `methods` block. This block contains functions that implement class methods. Class definitions can contain multiple method blocks, each specifying different attribute settings that apply to the methods in that particular block. It is possible to define method functions in separate files. See “How to Use Methods” for more information.

`events` begins an events definition block, an `end` keyword terminates the `events` block. This block contains event names defined by the class. Class definitions can contain multiple event blocks, each specifying different attribute settings that apply to the events in that particular block. See “Events and Listeners — Syntax and Techniques” for more information.

`enumeration` begins an enumeration definition block, an `end` keyword terminates the `enumeration` block. See “Enumerations” for more information.

`properties`, `methods`, `events`, and `enumeration` are also the names of MATLAB functions used to query the respective class members for a given object or class name.

To see the attributes of all class components in a popup window, click this link: [Attribute Tables](#)

Examples

Use these keywords to define classes.

```
classdef (Attributes) class_name
    properties (Attributes)
        PropertyName
    end
    methods (Attributes)
        function obj = methodName(obj, arg2, ...)
            ...
        end
    end
    events (Attributes)
        EventName
end
```

```
enumeration  
    EnumName  
end  
end
```

See Also properties | methods | events

Tutorials • “Class Syntax Fundamentals”

clc

Purpose Clear Command Window

Syntax `clc`

Description `clc` clears all input and output from the Command Window display, giving you a “clean screen.”

After using `clc`, you cannot use the scroll bar to see the history of functions, but you still can use the up arrow key, ↑, to recall statements from the command history.

Examples Use `clc` in a MATLAB code file to always display output in the same starting position on the screen.

See Also `clear` | `clf` | `close` | `home`

Purpose	Remove items from workspace, freeing up system memory
Syntax	<pre>clear clear name1 ... nameN clear -regex expr1 ... exprN clear ItemType</pre>
Description	<p><code>clear</code> removes all variables from the current workspace, releasing them from system memory.</p> <p><code>clear name1 ... nameN</code> removes the variables, scripts, functions, or MEX-functions <code>name1 ... nameN</code> from memory.</p> <ul style="list-style-type: none">• If <code>name</code> is a function name, then <code>clear name</code> reinitializes any persistent variables in the function.• If function name is locked by <code>mlock</code>, then it remains in memory.• If variable name is global, then <code>clear</code> removes it from the current workspace, but it remains in the global workspace. <p><code>clear -regex expr1 ... exprN</code> clears all variables that match any of the regular expressions listed. This option only clears variables.</p> <p><code>clear ItemType</code> clears the types of items indicated by <code>ItemType</code>, such as all, functions, or classes.</p>
Input Arguments	<p>name1 ... nameN - Names of variables, scripts, functions, or MEX-functions to clear</p> <p>string</p> <p>Names of variables, scripts, functions, or MEX-functions to clear, specified as strings.</p> <p>Use a partial path to distinguish between different overloaded versions of a function. For example, <code>clear polynom/display</code> clears only the</p>

clear

display method for polynom objects, leaving any other implementations in memory.

expr1 ... exprN - Regular expressions matching names of variables to clear

string

Regular expressions matching names of variables to clear, specified as strings.

ItemType - Type of items to clear

all | classes | functions | global | import | java | mex | variables

Type of items to clear, specified as one of the following strings. Click the linked strings below for additional information.

Value of ItemType	Items Cleared								
	Variables in scope	Scripts and functions	Class definitions	Persistent variables	Debugger breakpoints	MEX functions	Global variables	Imports	Java classes on the dynamic path
all	✓	✓		✓	✓	✓	✓	From command prompt only	
classes	✓	✓	✓	✓	✓	✓	✓		
functions		✓		✓	✓	✓			
global							✓		
import								✓	
java	✓	✓		✓	✓	✓	✓		✓

Value of ItemType	Items Cleared							
	Variables in scope	Scripts and function definitions	Class definitions	Persistent variables	Debug breakpoints	MEX Global variables	Imports	Java classes on the dynamic path
mex						✓		
variables								

The following applies to clearing types of items.

all:

- `clear all` also removes the import list when issued from the command prompt.

classes:

- `clear classes` issues a warning and does not clear a class of objects if any of those objects still exists after the workspace is cleared. For example, objects can still exist in persistent variables of functions or figure windows.
- `clear classes` does not clear a class if its file is locked using the `mlock` command. No warning is issued in this case.
- Call `clear classes` whenever you change a class definition.

global:

- `clear global` removes all global variables in the base and global workspaces. If called from a function, `clear global` also removes all global variables in the function workspace.
- Use `clear global name1 ... nameN` to clear the global variables with the specified names.
- Use `clear global regexp expr1 ... exprN` to clear all global variables that match any of the regular expressions listed.

clear

import:

- Call `clear import` only from the command prompt. Calling `clear import` in a function returns an error.

java:

- `clear java` issues a warning and does not remove the Java class definition if any Java objects exist outside the workspace (for example, in user data or persistent variables in a locked code file).
- Issue a `clear java` command after modifying any files on the dynamic Java path.

mex:

- `clear mex` does not clear locked MEX functions or functions that are currently in use.

If the name of a variable is a value of `ItemType`, then calling `clear` followed by that name deletes the variable with that name. `clear` does not interpret the name as a keyword in this context. For example, if the workspace contains variables `a`, `all`, `b`, and `ball`, `clear all` removes the variable `all` only.

Tips

- The `clear` function can remove variables that you specify. To remove all but some specified variables, use `clearvars` instead.
- You can clear the handle of a figure or graphics object, but the object itself is not removed. Use `delete` to remove objects. Deleting an object does not delete the variable (if any) used for storing its handle.
- The `clear` function does not clear Simulink® models. Use `bdclose` instead.
- On UNIX systems, `clear` does not affect the amount of memory allocated to the MATLAB process.

Examples

Clear a Single Variable

Define two variables `a` and `b`, and then clear `a`.

```
a = 1;
b = 2;
clear a
whos
```

Name	Size	Bytes	Class	Attributes
b	1x1	8	double	

Only variable `b` remains in the workspace.

Clear Specific Variables by Name

Using regular expressions, clear those variables with names that begin with `Mon`, `Tue`, or `Wed`.

```
clear -regexp ^Mon ^Tue ^Wed;
```

Clear List of Variables

Create a cell array, `varlist`, that contains the names of variables to clear. Then, clear those variables.

```
varlist = {'v1', 'v2', 'time'};
clear(varlist{:})
```

Clear All Compiled Scripts, Functions, and MEX-functions

```
clear functions
```

If a function is locked, it will not be cleared from memory.

- “Modifying and Reloading Classes”
- “The Java Class Path”
- “Regular Expressions”

clearvars

Purpose Clear variables from memory

Syntax

```
clearvars
clearvars variables
clearvars -except keepVariables
clearvars variables -except keepVariables

clearvars -global ____
```

Description `clearvars` removes all variables from the currently active workspace.

`clearvars variables` removes the variables specified by `variables`. If any of the variables are global, `clearvars` removes these variables from the current workspace only, leaving them accessible to any functions that declare them as global.

`clearvars -except keepVariables` removes all variables, except for those specified by `keepVariables`. Use this syntax to keep specific variables and remove all others.

`clearvars variables -except keepVariables` removes the variables specified by `variables`, and does not remove the variables specified by `keepVariables`. This syntax allows you to use a combination of variable names, wild card characters, or regular expressions to specify variables to remove or keep.

`clearvars -global ____` removes the specified global variables from the workspace, including those made global within functions, using any of the input arguments in the preceding syntaxes. The `-global` flag must be first in the argument list.

Input Arguments

variables - Names of variables to remove

strings

Names of variables to remove, specified as one or more strings in one of the following forms.

Form of Variables Input	Variables to Remove
<i>var1 ... varN</i>	Named variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>clearvars A*</code> clears all variables in the workspace with names that start with A.
<code>-regexp</code> <i>expr1 ... exprN</i>	Variables with names that match the regular expressions, specified as strings. For example, <code>clearvars -regexp ^Mon ^Tues</code> clears only the variables in the workspace with names that begin with Mon or Tues.

keepVariables - Names of variables to keep

strings

Names of variables to keep, specified as one or more strings in one of the following forms.

clearvars

Form of Variables Input	Variables to Keep
<code>var1 ... varN</code>	Named variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>clearvars -except A*</code> clears all variables in the workspace, except those with names that start with A.
<code>-regexp expr1 ... exprN</code>	Variables with names that match the regular expressions, specified as strings. For example, <code>clearvars -except -regexp ^Mon ^Tues</code> clears all the variables in the workspace, except those with names that begin with Mon or Tues.

Examples

Clear Named Variables

Define three variables, a, b, and c. Then, clear a and c.

```
a = 1;  
b = 2;  
c = 3;  
clearvars a c  
whos
```

```
      Name      Size      Bytes  Class  Attributes  
  
      b          1x1           8  double
```

Only variable b remains in the workspace.

Clear All Variables Except Specified

Remove all variables from the workspace except for the variables C and D.

```
clearvars -except C D
```

Clear Variables Using Regular Expressions and Name Variables to Exclude

Clear variables with names that start with `b` and are followed by 3 digits, except for the variable `b106`.

```
clearvars -regexp ^b\d{3}$ -except b106
```

Name Variables to Clear and Preserve Variables Using Regular Expressions

Clear variables with names that start with `a` and do not end with `a`.

```
clearvars a* -except -regexp a$
```

Clear Global Variables Except Specified

Clear all global variables, except those with names that start with `x`.

```
clearvars -global -except x*
```

Clear List of Variables

Clear a list of variables used for intermediate calculations.

Create two variables in the workspace.

```
cashOnHand = 20;  
cost = 12.99;
```

Store a list of the names of all the variables currently in the workspace.

```
initialVars = who;
```

Specify or calculate additional variables, `taxRate` and `tax`.

```
taxRate = 0.0625;  
tax = round(100*cost*taxRate)/100;
```

Update the initial variables, `cost` and `cashOnHand`.

clearvars

```
cost = cost + tax;  
cashOnHand = cashOnHand - cost;
```

Clear all variables except the initial variables, using the function form of `clearvars`. When using the function form of a syntax, enclose input strings in single quotes, and separate them with commas.

```
clearvars('-except',initialVars{:})
```

`clearvars` clears the variables, `initialVars`, `taxRate`, and `tax`.

Concepts

- “What Is the MATLAB Workspace?”
- “Regular Expressions”
- “Command vs. Function Syntax”

Purpose Remove serial port object from MATLAB workspace

Syntax `clear obj`

Description `clear obj` removes `obj` from the MATLAB workspace, where `obj` is a serial port object or an array of serial port objects.

Tips If `obj` is connected to the device and it is cleared from the workspace, then `obj` remains connected to the device. You can restore `obj` to the workspace with the `instrfind` function. A serial port object connected to the device has a `Status` property value of `open`.

To disconnect `obj` from the device, use the `fclose` function. To remove `obj` from memory, use the `delete` function. You should remove invalid serial port objects from the workspace with `clear`.

Examples This example creates the serial port object `s` on a Windows platform, copies `s` to a new variable `scopy`, and clears `s` from the MATLAB workspace. `s` is then restored to the workspace with `instrfind` and is shown to be identical to `scopy`.

```
s = serial('COM1');
scopy = s;
clear s
s = instrfind;
isequal(scopy,s)
ans =
     1
```

See Also `delete` | `fclose` | `instrfind` | `isvalid` | `Status`

clf

Purpose Clear current figure window

Syntax

```
clf
clf('reset')
clf(fig)
clf(fig, 'reset')
figure_handle = clf(...)
```

Description

clf deletes from the current figure all graphics objects whose handles are not hidden (i.e., their `HandleVisibility` property is set to `on`).

clf('reset') deletes from the current figure all graphics objects regardless of the setting of their `HandleVisibility` property and resets all figure properties except `Position`, `Units`, `PaperPosition`, and `PaperUnits` to their default values.

clf(fig) or clf(fig, 'reset') clears the single figure with handle fig.

figure_handle = clf(...) returns the handle of the figure. This is useful when the figure `IntegerHandle` property is `off` because the noninteger handle becomes invalid when the reset option is used (i.e., `IntegerHandle` is reset to `on`, which is the default).

Tips

The clf command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the `HandleVisibility` setting of callback. This means that when issued from within a callback routine, clf deletes only those objects whose `HandleVisibility` property is set to `on`.

Alternatives

Use **Clear Figure** from the figure window's **Edit** menu to clear the contents of a figure. You can also create a *desktop shortcut* to clear the current figure with one mouse click. See “Create Shortcuts to Rerun Commands”.

See Also cla | clc | hold | reset

Purpose Copy and paste strings to and from system clipboard

Syntax

```
clipboard('copy', data)
str = clipboard('paste')
data = clipboard('pastespecial')
```

Description `clipboard('copy', data)` sets the clipboard contents to *data*. If *data* is not a character array, the clipboard uses `mat2str` to convert *data* to a string.

`str = clipboard('paste')` returns the current contents of the clipboard as a string or, if MATLAB cannot convert the current clipboard contents to a string, as an empty string (' ').

`data = clipboard('pastespecial')` returns the current contents of the clipboard as an array by using `uiimport`.

Definitions The `clipboard` function requires Oracle® Java software.

See Also `load` | `mat2str` | `uiimport`

clock

Purpose Current date and time as date vector

Syntax `c = clock`

Description `c = clock` returns a six-element date vector containing the current date and time in decimal form:

“[year month day hour minute seconds]”

Examples **Round clock Output to Integer Display**

Use `clock` to return the current date and time.

```
format shortg
c = clock
```

```
c =
```

```
2014          1          17          15          46          37.37
```

The sixth element of the date vector output (seconds) is accurate to several digits beyond the decimal point.

Use the `fix` function to round to integer display format.

```
fix(c)
```

```
ans =
```

```
2014          1          17          15          46          37
```

Tips

- To time the duration of an event, use the `timeit` or `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on

the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.

See Also

`date` | `now` | `tic` | `toc` | `cputime` | `etime` | `fix` | `timeit`

close

Purpose Remove specified figure

Syntax

```
close
close(h)
close name
close all
close all hidden
close all force
status = close(...)
```

Description `close` deletes the current figure or the specified figure(s). It optionally returns the status of the close operation.

`close` deletes the current figure (equivalent to `close(gcf)`).

`close(h)` deletes the figure identified by `h`. If `h` is a vector or matrix, `close` deletes all figures identified by `h`.

`close name` deletes the figure with the specified name.

`close all` deletes all figures whose handles are not hidden.

`close all hidden` deletes all figures including those with hidden handles.

`close all force` deletes all figures, including GUIs for which `CloseRequestFcn` has been altered to not close the window.

`status = close(...)` returns 1 if the specified windows have been deleted and 0 otherwise.

Algorithms The `close` function works by evaluating the specified figure's `CloseRequestFcn` property with the statement

```
eval(get(h, 'CloseRequestFcn'))
```

The default `CloseRequestFcn`, `closereq`, deletes the current figure using `delete(get(0, 'CurrentFigure'))`. If you specify multiple figure handles, `close` executes each figure's `CloseRequestFcn` in turn. If an error that terminates the execution of a `CloseRequestFcn` occurs, the

figure is not deleted. Note that using your computer's window manager (i.e., the **Close** menu item) also calls the figure's `CloseRequestFcn`.

If a figure's handle is hidden (i.e., the figure's `HandleVisibility` property is set to `callback` or `off` and the root `ShowHiddenHandles` property is set to `on`), you must specify the `hidden` option when trying to access a figure using the `all` option.

To delete all figures unconditionally, use the statements

```
set(0, 'ShowHiddenHandles', 'on')
delete(get(0, 'Children'))
```

The figure `CloseRequestFcn` allows you to either delay or abort the closing of a figure once the `close` function has been issued. For example, you can display a dialog box to see if the user really wants to delete the figure or save and clean up before closing.

When coding a `CloseRequestFcn` callback, make sure that it does not call `close`, because this sets up a recursion that results in a MATLAB warning. Instead, the callback should destroy the figure with `delete`. The `delete` function does not execute the figure's `CloseRequestFcn`; it simply deletes the specified figure.

`delete` | `figure` | `gcf` | `Figure: HandleVisibility` | `Root: ShowHiddenHandles`

Tiff.close

Purpose Close Tiff object

Syntax `tiffobj.close()`

Description `tiffobj.close()` closes a Tiff object.

Examples **Close Tiff Object**

Open a Tiff object and then close it.

```
t = Tiff('example.tif', 'r');  
t.close();
```

References This method corresponds to the `TIFFClose` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

Tutorials

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

Purpose Close Audio/Video Interleaved (AVI) file

Syntax `aviobj = close(aviobj)`

Description `aviobj = close(aviobj)` finishes writing and closes the AVI file associated with `aviobj`, which is an AVI file object created using the `avifile` function.

To close all open AVI files, use the `clear mex` command.

See Also `avifile` | `addframe (avifile)` | `movie2avi`

FTP.close

Purpose Close connection to FTP server

Syntax `close(ftpobj)`

Description `close(ftpobj)` closes the connection to the FTP server.

- Tips**
- If you do not run `close` at the end of your session, the connection either times out automatically or terminates when you exit MATLAB.
 - After calling `close`, calling any other FTP method on the same object automatically reopens the connection.
 - `close` does not return any output to indicate success or failure.

Input Arguments

ftpobj
FTP object created by `ftp`.

Examples Connect to the MathWorks FTP server, and then disconnect:

```
mw=ftp('ftp.mathworks.com');  
close(mw)
```

See Also `ftp`

Purpose	Close file after writing video data
Syntax	<code>close(writerObj)</code>
Description	<code>close(writerObj)</code> closes the file associated with object <code>writerObj</code> . The object remains in the workspace. If you call the <code>open</code> method after closing, <code>open</code> discards any existing contents of the file.
Input Arguments	writerObj VideoWriter object created by the <code>VideoWriter</code> function.
Examples	AVI File from Animation Write a sequence of frames to a compressed AVI file, <code>peaks.avi</code> . Prepare the new file. <pre>writerObj = VideoWriter('peaks.avi'); open(writerObj);</pre> Generate initial data and set axes and figure properties. <pre>Z = peaks; surf(Z); axis tight set(gca, 'nextplot', 'replacechildren'); set(gcf, 'Renderer', 'zbuffer');</pre> Setting the <code>Renderer</code> property to <code>zbuffer</code> or <code>Painters</code> works around limitations of <code>getframe</code> with the OpenGL® renderer on some Windows systems. Create a set of frames and write each frame to the file. <pre>for k = 1:20 surf(sin(2*pi*k/20)*Z,Z) frame = getframe; writeVideo(writerObj,frame);</pre>

VideoWriter.close

```
end  
close(writerObj);
```

- “Source Control Interface on UNIX Platforms”

cmpermute

Purpose Rearrange colors in colormap

Syntax `[Y,newmap] = cmpermute(X,map)`
`[Y,newmap] = cmpermute(X,map,index)`

Description `[Y,newmap] = cmpermute(X,map)` randomly reorders the colors in `map` to produce a new colormap, `newmap`. The `cmpermute` function also modifies the values in `X` to maintain correspondence between the indices and the colormap, and returns the result in `Y`. The image `Y` and associated colormap, `newmap`, produce the same image as `X` and `map`.

`[Y,newmap] = cmpermute(X,map,index)` uses an ordering matrix (such as the second output of `sort`) to define the order of colors in the new colormap.

Class Support The input image `X` can be of class `uint8` or `double`. `Y` is returned as an array of the same class as `X`.

Examples Randomly Reorder Colormap and Display Image

Load the `clown` data set to get image `X` and its associated colormap, `map`. Display the image.

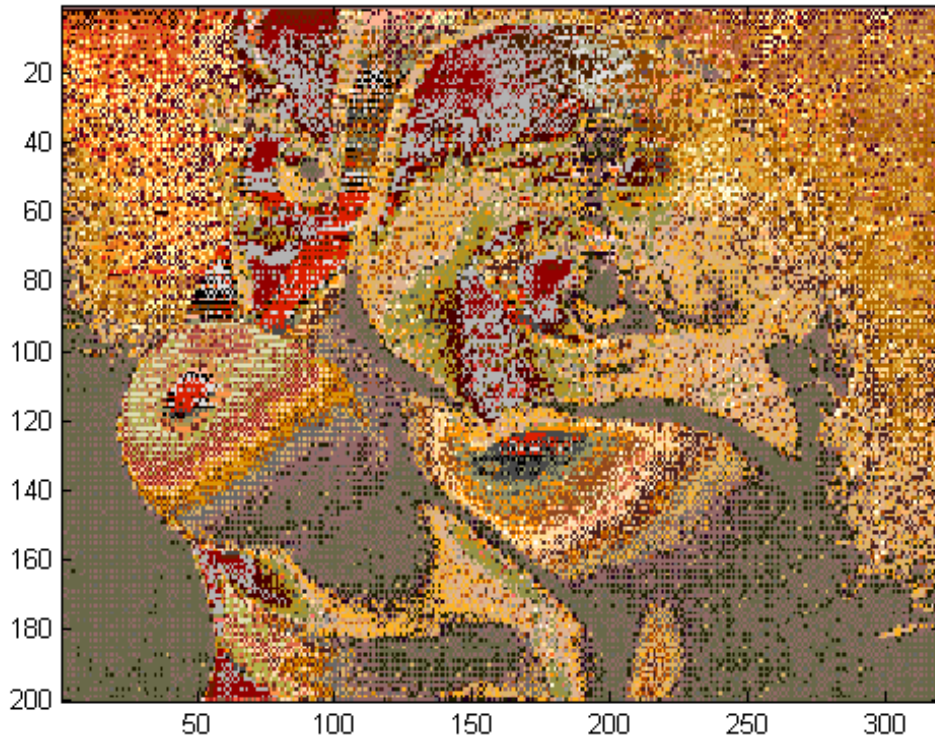

```
load clown
figure;
image(X);
colormap(map)
```

Randomly reorder the colormap to get the new colormap, newmap.
Display image X with the new colormap.

```
[Y, newmap] = cmpermute(X,map);  
colormap(newmap)
```

cmpermute

See Also [randperm](#) | [sort](#)

Purpose Eliminate duplicate colors in colormap; convert grayscale or truecolor image to indexed image

Syntax

```
[Y,newmap] = cmunique(X,map)
[Y,newmap] = cmunique(RGB)
[Y,newmap] = cmunique(I)
```

Description [Y,newmap] = cmunique(X,map) returns the indexed image Y and associated colormap, newmap, that produce the same image as (X,map) but with the smallest possible colormap. The cmunique function removes duplicate rows from the colormap and adjusts the indices in the image matrix accordingly.

[Y,newmap] = cmunique(RGB) converts the truecolor image RGB to the indexed image Y and its associated colormap, newmap. The return value newmap is the smallest possible colormap for the image, containing one entry for each unique color in RGB.

Note newmap might be very large, because the number of entries can be as many as the number of pixels in RGB.

[Y,newmap] = cmunique(I) converts the grayscale image I to an indexed image Y and its associated colormap, newmap. The return value, newmap, is the smallest possible colormap for the image, containing one entry for each unique intensity level in I.

Class Support The input image can be of class uint8, uint16, or double. The class of the output image Y is uint8 if the length of newmap is less than or equal to 256. If the length of newmap is greater than 256, Y is of class double.

Examples **Eliminate Duplicate Entries in Colormap**

Use the magic function to define X as a 4-by-4 array that uses every value in the range between 1 and 16.

cmunique

```
X = magic(4);
```

Use the `gray` function to create an eight-entry colormap. Then, concatenate the two eight-entry colormaps to create a colormap with 16 entries, `map`. In `map`, entries 9 through 16 are duplicates of entries 1 through 8.

```
map = [gray(8); gray(8)];  
size(map)
```

```
ans =
```

```
16    3
```

Use `cmunique` to eliminate duplicate entries in the colormap.

```
[Y, newmap] = cmunique(X, map);  
size(newmap)
```

```
ans =
```

```
8    3
```

`cmunique` adjusts the values in the original image `X` so that `Y` and `newmap` produce the same image as `X` and `map`.

```
figure  
image(X)  
colormap(map)  
title('X and map')
```

```
figure  
image(Y)
```

```
colormap(newmap)  
title('Y and newmap')
```

See Also `rgb2ind`

Purpose Column approximate minimum degree permutation

Syntax `p = colamd(S)`

Description `p = colamd(S)` returns the column approximate minimum degree permutation vector for the sparse matrix `S`. For a non-symmetric matrix `S`, `S(:,p)` tends to have sparser LU factors than `S`. The Cholesky factorization of `S(:,p)' * S(:,p)` also tends to be sparser than that of `S'*S`.

`knobs` is a two-element vector. If `S` is `m`-by-`n`, then rows with more than `(knobs(1))*n` entries are ignored. Columns with more than `(knobs(2))*m` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs(1) = knobs(2) = spparms('wh_frac')`.

`stats` is an optional vector that provides data about the ordering and the validity of the matrix `S`.

<code>stats(1)</code>	Number of dense or empty rows ignored by <code>colamd</code>
<code>stats(2)</code>	Number of dense or empty columns ignored by <code>colamd</code>
<code>stats(3)</code>	Number of garbage collections performed on the internal data structure used by <code>colamd</code> (roughly of size $2.2*\text{nnz}(S) + 4*m + 7*n$ integers)
<code>stats(4)</code>	0 if the matrix is valid, or 1 if invalid
<code>stats(5)</code>	Rightmost column index that is unsorted or contains duplicate entries, or 0 if no such column exists

<code>stats(6)</code>	Last seen duplicate or out-of-order row index in the column index given by <code>stats(5)</code> , or 0 if no such row index exists
<code>stats(7)</code>	Number of duplicate and out-of-order row indices

Although MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `colamd`. For this reason, `colamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `colamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `colamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `colamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

The ordering is followed by a column elimination tree post-ordering.

Examples

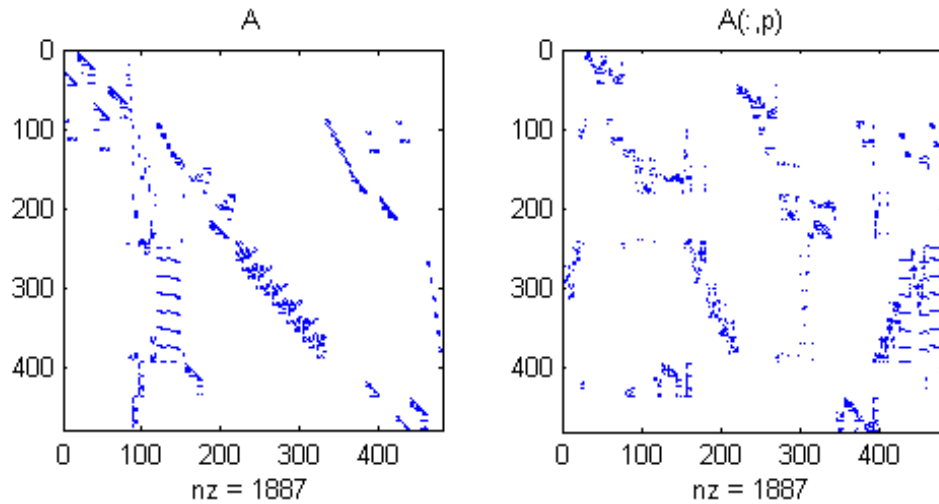

Compare Sparse Matrix and LU Factorization

The Harwell-Boeing collection of sparse matrices and the MATLAB® demos directory include a test matrix `west0479`. It is a matrix of order 479 resulting from a model due to Westerberg of an eight-stage chemical distillation column. The spy plot shows evidence of the eight stages. The `colamd` ordering scrambles this structure.

```
load west0479
A = west0479;
p = colamd(A);

figure();
subplot(1,2,1), spy(A,4), title('A')
```

```
subplot(1,2,2), spy(A(:,p),4), title('A(:,p)')
```

Comparing the spy plot of the LU factorization of the original matrix with that of the reordered matrix shows that minimum degree reduces the time and storage requirements by better than a factor of 2.8. The nonzero counts are 15918 and 5920, respectively.

```
figure();
subplot(1,2,1), spy(lu(A),4), title('lu(A)')
subplot(1,2,2), spy(lu(A(:,p)),4), title('lu(A(:,p))')
```

colorbar(cbar_handle,'option')
```

Description The colorbar function displays the current colormap in the current figure and resizes the current axes to accommodate the colorbar.

colorbar adds a new vertical colorbar on the right side of the current axes. If a colorbar exists in that location, colorbar replaces it with a new one. If a colorbar exists at a nondefault location, it is retained along with the new colorbar.

colorbar('off'), colorbar('hide'), and colorbar('delete') delete all colorbars associated with the current axes.

colorbar(...,'peer',axes_handle) creates a colorbar associated with the axes axes_handle instead of the current axes.

colorbar(...,'location') adds a colorbar in the specified orientation with respect to the axes. If a colorbar exists at the location specified, it is replaced. Any colorbars not occupying the specified location are retained. Possible values for *location* are

North	Inside plot box near top
South	Inside bottom
East	Inside right
West	Inside left

colorbar

NorthOutside	Outside plot box near top
SouthOutside	Outside bottom
EastOutside	Outside right
WestOutside	Outside left

Using one of the `...Outside` values for *location* ensures that the colorbar does not overlap the plot, whereas overlaps can occur when you specify any of the other four values.

`colorbar(..., 'PropertyName', propertyvalue)` specifies property names and values for the axes object used to create the colorbar. See *Axes Properties* for a description of the properties you can set. The *location* property applies only to colorbars and legends, not to axes.

`cbar_axes = colorbar(...)` returns a handle to a new colorbar object, which is a child of the current figure. If a colorbar exists, a new one is still created.

`colorbar('option')` specifies options for colorbar visibility. *'option'* is one of `'off'`, `'hide'` or `'delete'`. All of the options delete the colorbar in the current axes.

`colorbar(cbar_handle, 'option')` specifies options for colorbar visibility. *'option'* is one of `'off'`, `'hide'` or `'delete'`. All of the options delete the colorbar specified by the `cbar_handle`.

You can use `colorbar` with 2-D and 3-D plots.

Tips

To obtain the handle to an existing colorbar, use the command

```
cbar_handle = findobj(figure_handle, 'tag', 'Colorbar')
```

where `figure_handle` is the handle of the figure containing the colorbar you want to modify. If the figure contains more than one colorbar, `cbar_handle` is returned as a vector, and you must choose which of the handles to specify to `colorbar`.

Examples

Display a colorbar beside the axes and use descriptive text strings as y -tick labels. Labels repeat cyclically when the number of y -ticks is greater than the number of labels, and not all labels will appear if there are fewer y -ticks than labels you have specified. Also note that when colorbars are horizontal, their ticks and labels are governed by the `XTick` property rather than the `YTick` property.

```
surf(peaks(30))
colorbar('YTickLabel',...
        {'Freezing','Cold','Cool','Neutral',...
         'Warm','Hot','Burning','Nuclear'})
```

colorbar

Display a horizontal colorbar beneath the axes of a filled contour plot:

```
contourf(peaks(60))  
colormap cool  
colorbar('location','southoutside')
```

Alternatives

Add a colorbar to a plot with the colorbar tool  on the figure toolbar, or use **Insert > Colorbar** from the figure menu. Use the Property Editor to modify the position, font and other properties of a legend.

colorbar

`colormap`

Purpose	Set default property values to display different color schemes
Syntax	<pre>colordef white colordef black colordef none colordef(fig,color_option) h = colordef('new',color_option)</pre>
Description	<p>colordef enables you to select either a white or black background for graphics display. It sets axis lines and labels so that they contrast with the background color.</p> <p>colordef white sets the axis background color to white, the axis lines and labels to black, and the figure background color to light gray.</p> <p>colordef black sets the axis background color to black, the axis lines and labels to white, and the figure background color to dark gray.</p> <p>colordef none sets the figure coloring to that used by MATLAB Version 4. The most noticeable difference is that the axis background is set to 'none', making the axis background and figure background colors the same. The figure background color is set to black.</p> <p>colordef(fig,color_option) sets the color scheme of the figure identified by the handle fig to one of the color options 'white', 'black', or 'none'. When you use this syntax to apply colordef to an existing figure, the figure must have no graphic content. If it does, you should first clear it (via clf) before using this form of the command.</p> <p>h = colordef('new',color_option) returns the handle to a new figure created with the specified color options (i.e., 'white', 'black', or 'none'). This form of the command is useful for creating GUIs when you may want to control the default environment. The figure is created with 'visible','off' to prevent flashing.</p>
Tips	colordef affects only subsequently drawn figures, not those currently on the display. This is because colordef works by setting default property values (on the root or figure level). You can list the currently set default values on the root level with the statement

colordef

```
get(0, 'Default')
```

You can remove all default values using the `reset` command:

```
reset(0)
```

See the `get` and `reset` references pages for more information.

See Also

`whitebg` | `clf`

Purpose Set and get current colormap

Syntax

```
colormap(map)
colormap('default')
cmap = colormap
colormap(ax, ...)
```

Description A colormap is an m -by-3 matrix of real numbers between 0.0 and 1.0. Each row is an RGB vector that defines one color. The k th row of the colormap defines the k th color, where $\text{map}(k, :) = [r(k) \ g(k) \ b(k)]$ specifies the intensity of red, green, and blue.

`colormap(map)` sets the colormap to the matrix `map`. If any values in `map` are outside the interval `[0 1]`, you receive the error `Colormap must have values in [0,1]`.

`colormap('default')` sets the current colormap to the default colormap.

`cmap = colormap` retrieves the current colormap. The values returned are in the interval `[0 1]`.

`colormap(ax, ...)` uses the figure corresponding to axes `ax` instead of the current figure.

Specifying Colormaps

Files in the `color` folder generate a number of colormaps. Each file accepts the colormap size as an argument. For example,

```
colormap(hsv(128))
```

creates an `hsv` colormap with 128 colors. If you do not specify a size, a colormap the same size as the current colormap is created.

Supported Colormaps

The built-in MATLAB colormaps are illustrated and described below. In addition to specifying built-in colormaps programmatically, you can use the **Colormap** menu in the **Figure Properties** pane of the Plot Tools GUI to select one interactively.

colormap

The named built-in colormaps are the following:

- autumn varies smoothly from red, through orange, to yellow.
- bone is a grayscale colormap with a higher value for the blue component. This colormap is useful for adding an “electronic” look to grayscale images.
- colorcube contains as many regularly spaced colors in RGB color space as possible, while attempting to provide more steps of gray, pure red, pure green, and pure blue.
- cool consists of colors that are shades of cyan and magenta. It varies smoothly from cyan to magenta.
- copper varies smoothly from black to bright copper.
- flag consists of the colors red, white, blue, and black. This colormap completely changes color with each index increment.
- gray returns a linear grayscale colormap.

- `hot` varies smoothly from black through shades of red, orange, and yellow, to white.
- `hsv` varies the hue component of the hue-saturation-value color model. The colors begin with red, pass through yellow, green, cyan, blue, magenta, and return to red. The colormap is particularly appropriate for displaying periodic functions. `hsv(m)` is the same as `hsv2rgb([h ones(m,2)])` where `h` is the linear ramp, $h = (0:m-1)/m$.
- `jet` ranges from blue to red, and passes through the colors cyan, yellow, and orange. It is a variation of the `hsv` colormap. The `jet` colormap is associated with an astrophysical fluid jet simulation from the National Center for Supercomputer Applications. See “Examples” on page 1-1045.
- `lines` produces a colormap of colors specified by the axes `ColorOrder` property and a shade of gray.
- `pink` contains pastel shades of pink. The pink colormap provides sepia tone colorization of grayscale photographs.
- `prism` repeats the six colors red, orange, yellow, green, blue, and violet.
- `spring` consists of colors that are shades of magenta and yellow.
- `summer` consists of colors that are shades of green and yellow.
- `white` is an all white monochrome colormap.
- `winter` consists of colors that are shades of blue and green.

Examples

Use Summer Colormap

Create a surface plot of the peaks function.

```
figure;  
surf(peaks);
```

colormap

Change the colormap to the summer colormap.

```
colormap(summer)
```

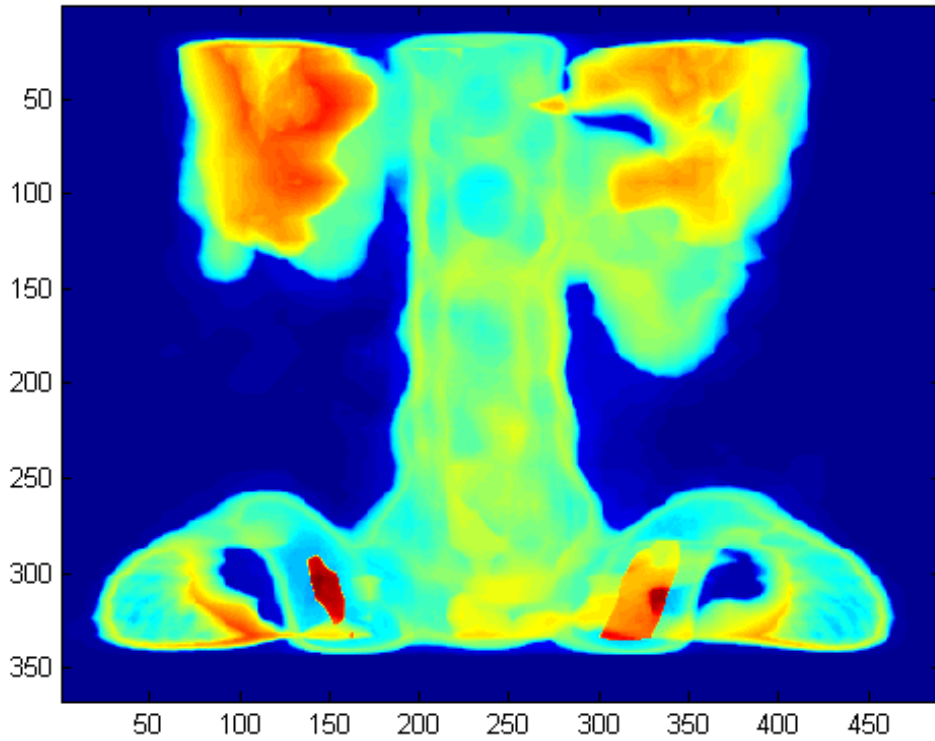

Use Bone Colormap

Load the spine data set to get array `X`. Use the `image` function to display the data in `X`.

```
load spine  
image(X)
```

colormap

Change the colormap to the bone colormap.

```
colormap(bone)
```

Algorithms

Each figure has its own `colormap` property. `colormap` is a function that sets and gets this property.

Alternatives

Select a built-in colormap with the Property Editor. To modify the current colormap, use the Colormap Editor, accessible from **Edit > Colormap** on the figure menu.

colormap

How To

- “Coloring Mesh and Surface Plots”

Purpose Open colormap editor

Syntax colormapeditor

Description colormapeditor displays the current figure's colormap as a strip of rectangular cells in the colormap editor. Node pointers are colored cells below the colormap strip that indicate points in the colormap where the rate of the variation of R, G, and B values changes. You can also work in the HSV colorspace by setting the **Interpolating Colorspace** selector to HSV.

You can also start the colormap editor by selecting **Colormap** from the **Edit** menu.

Node Pointer Operations

You can select and move node pointers to change a range of colors in the colormap. The color of a node pointer remains constant as you move it, but the colormap changes by linearly interpolating the RGB values between nodes.

Change the color at a node by double-clicking the node pointer. A color picker box appears, from which you can select a new color. After you select a new color at a node, the colors between nodes are reinterpolated.

You can select a different color map using the **Standard Colormaps** submenu of the GUI **Tools** menu. The Plotting Tools Property Editor has a dropdown menu that also lets you select from standard colormaps, but does not help you to modify a colormap.

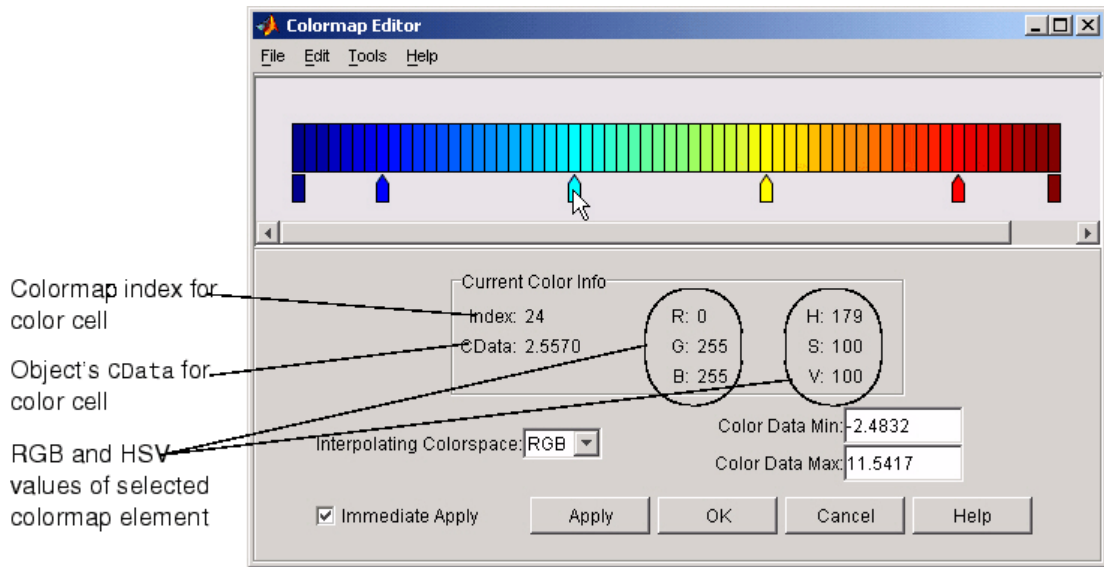

Operation	How to Perform
Select a built-in colormap	Tools > Standard Colormaps
Add a node	Click below the corresponding cell in the colormap strip.
Select a node	Left-click the node.

Operation	How to Perform
Select multiple nodes	Adjacent: left-click first node, Shift+click the last node. Nonadjacent: left-click first node, Ctrl+click subsequent nodes.
Move a node	Select and drag with the mouse or select and use the left and right arrow keys.
Move multiple nodes	Select multiple nodes and use the left and right arrow keys to move nodes as a group. Movement stops when one of the selected nodes hits an unselected node or an end node.
Delete a node	Select the node and then press the Delete key, or select Delete from the Edit menu, or type Ctrl+x .
Delete multiple nodes	Select the nodes and then press the Delete key, or select Delete from the Edit menu, or type Ctrl+x .
Display color picker for a node	Double-click the node pointer.

Current Color Info

When you put the mouse over a color cell or node pointer, the colormap editor displays the following information about that colormap element:

- The element's index in the colormap
- The value from the graphics object color data that is mapped to the node's color (i.e., data from the `CData` property of any image, patch, or surface objects in the figure)
- The color's RGB and HSV color value

Interpolating Colorspace

The colorspace determines what values are used to calculate the colors of cells between nodes. For example, in the RGB colorspace, internode colors are calculated by linearly interpolating the red, green, and blue intensity values from one node to the next. Switching to the HSV colorspace causes the colormap editor to recalculate the colors between nodes using the hue, saturation, and value components of the color definition.

Note that when you switch from one colorspace to another, the color editor preserves the number, color, and location of the node pointers, which can cause the colormap to change.

Interpolating in HSV. Since hue is conceptually mapped about a color circle, the interpolation between hue values can be ambiguous. To minimize this ambiguity, the interpolation uses the shortest distance around the circle. For example, interpolating between two nodes, one with hue of 2 (slightly orange red) and another with a hue of 356 (slightly magenta red), does not result in hues 3,4,5...353,354,355 (orange/red-yellow-green-cyan-blue-magenta/red). Taking the shortest distance around the circle gives 357,358,1,2 (orange/red-red-magenta/red).

Color Data Min and Max

The **Color Data Min** and **Color Data Max** text fields enable you to specify values for the axes **CLim** property. These values change the mapping of object color data (the **CData** property of images, patches, and surfaces) to the colormap. See “Axes Color Limits — the **CLim** Property” for discussion and examples of how to use this property.

Examples

This example modifies a default MATLAB colormap so that ranges of data values are displayed in specific ranges of color. The graph is a slice plane illustrating a cross section of fluid flow through a jet nozzle. See the [slice](#) reference page for more information on this type of graph.

Example Objectives

The objectives are as follows:

- Regions of flow from left to right (positive data) are mapped to colors from yellow through orange to dark red. Yellow is slowest and dark red is the fastest moving fluid.
- Regions that have a speed close to zero are colored green.
- Regions where the fluid is actually moving right to left (negative data) are shades of blue (darker blue is faster).

The following picture shows the desired coloring of the slice plane. The colorbar shows the data to color mapping.

Running the Example

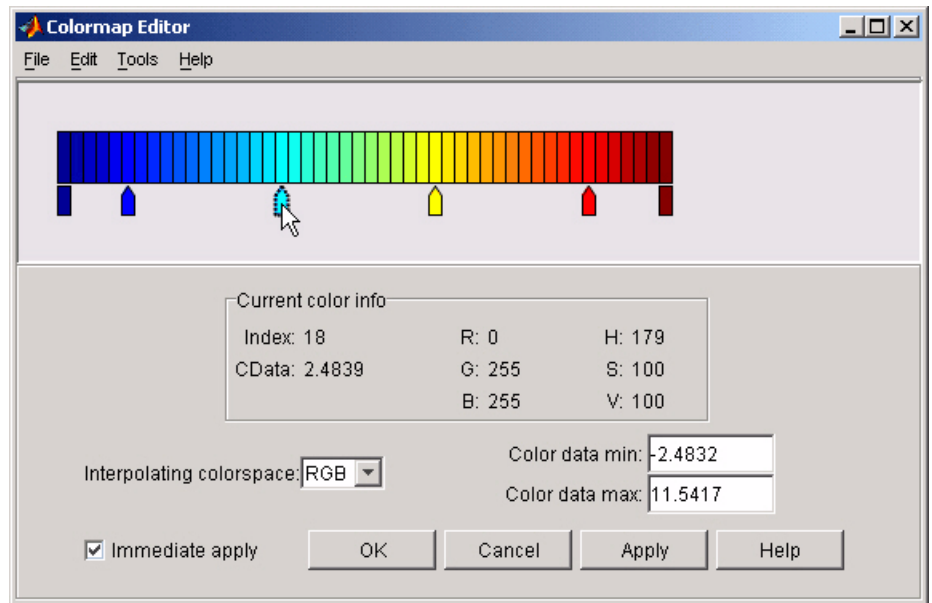

Note If you are viewing this documentation in the MATLAB help browser, you can display the graph used in this example by running this file from the MATLAB editor (select **Run** from the **Debug** menu).

Initially, the default colormap (`jet`) colored the slice plane, as illustrated in the following picture. Note that this example uses a colormap that is 48 elements to display wider bands of color (the default is 64 elements).

colormapeditor

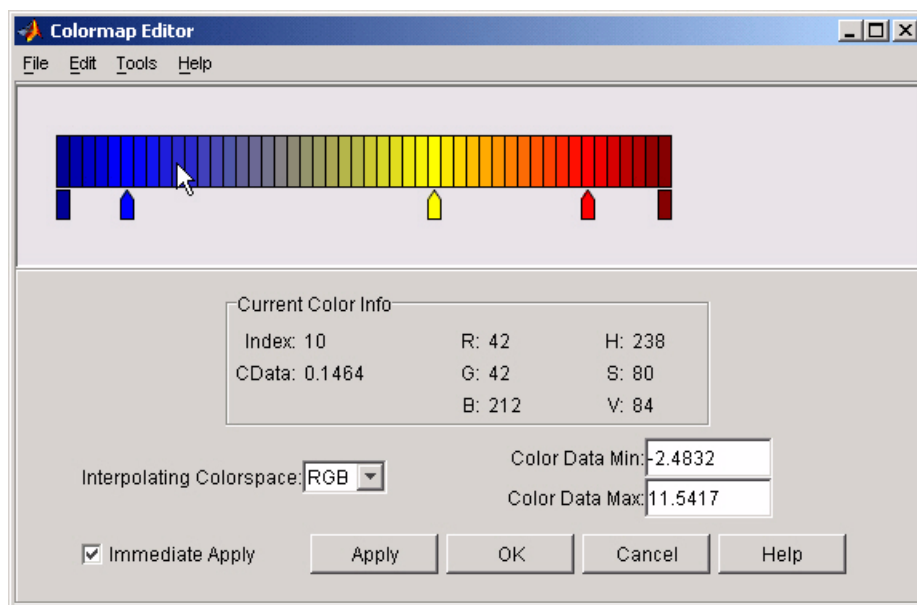

- 1 Start the colormap editor using the `colormapeditor` command. The color map editor displays the current figure's colormap, as shown in the following picture.

- 2 Since we want the regions of left-to-right flow (positive speed) to range from yellow to dark red, we can delete the cyan node pointer. To do this, first select it by clicking with the left mouse button and press **Delete**. The colormap now looks like this.

colormapeditor

The **Immediate Apply** box is checked, so the graph displays the results of the changes made to the colormap.

- 3** We want the fluid speed values around zero to stand out, so we need to find the color cell where the negative-to-positive transition occurs. Dragging the cursor over the color strip enables you to read the data values in the **Current Color Info** panel.

In this case, cell 10 is the first positive value, so we click below that cell and create a node pointer. Double-clicking the node pointer displays the color picker. Set the color of this node to green.

colormapeditor

The graph continues to update to the modified colormap.

- 4 In the current state, the colormap colors are interpolated from the green node to the yellowish node about 20 cells away. We actually want only the single cell that is centered around zero to be colored green. To limit the color green to one cell, move the blue and yellow node pointers next to the green pointer.

colormapeditor

- 5 Before making further adjustments to the colormap, we need to move the green cell so that it is centered around zero. Use the colorbar to locate the green cell.

Note that green cell is not centered around zero.

To recenter the green cell around zero, select the blue, green, and yellow node pointers (left-click blue, **Shift+click** yellow) and move them as a group using the left arrow key. Watch the colorbar in the figure window to see when the green color is centered around zero.

colormapeditor

The slice plane now has the desired range of colors for negative, zero, and positive data.

Green cell is now centered around zero.

- 6 Increase the orange-red coloring in the slice by moving the red node pointer toward the yellow node.

colormapeditor

- 7 Darken the endpoints to bring out more detail in the extremes of the data. Double-click the end nodes to display the color picker. Set the red endpoint to the RGB value [50 0 0] and set the blue endpoint to the RGB value [0 0 50].

The slice plane coloring now matches the example objectives.

Saving the Modified Colormap

You can save the modified colormap using the `colormap` function or the figure `Colormap` property.

After you have applied your changes, save the current figure colormap in a variable:

```
mycmap = get(fig,'Colormap');
```

To use this colormap in another figure, set that figure's `Colormap` property:

```
set(new_fig,'Colormap',mycmap)
```

To save your modified colormap in a MAT-file, use the `save` command to save the `mycmap` workspace variable:

```
save('MyColormaps','mycmap')
```

To use your saved colormap in another MATLAB session, load the variable into the workspace and assign the colormap to the figure:

colormapeditor

```
load('MyColormaps','mycmap')  
set(fig,'Colormap',mycmap)
```

How To

- “Colormaps”

ColorSpec (Color Specification)

Purpose Color specification

Description ColorSpec is not a function; it refers to the three ways in which you specify color for MATLAB graphics:

- RGB triple
- Short name
- Long name

The short names and long names are MATLAB strings that specify one of eight predefined colors. The RGB triple is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color; the intensities must be in the range [0 1]. The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

Tips The eight predefined colors and any colors you specify as RGB values are not part of a figure's colormap, nor are they affected by changes to the figure's colormap. They are referred to as *fixed* colors, as opposed to *colormap* colors.

Some high-level functions (for example, `scatter`) accept a colorspec as an input argument and use it to set the CData of graphic objects they create. When using such functions, take care not to specify a colorspec

ColorSpec (Color Specification)

in a property/value pair that sets `CData`; values for `CData` are always `n`-length vectors or `n`-by-3 matrices, where `n` is the length of `XData` and `YData`, never strings.

Examples

To change the background color of a figure to green, specify the color with a short name, a long name, or an RGB triple. These statements generate equivalent results:

```
whitebg('g')
whitebg('green')
whitebg([0 1 0]);
```

You can use `ColorSpec` anywhere you need to define a color. For example, this statement changes the figure background color to pink:

```
set(gcf, 'Color', [1,0.4,0.6])
```

`bar` | `bar3` | `colordef` | `colormap` | `fill` | `fill3` | `whitebg` | `uicolor`

Purpose	Sparse column permutation based on nonzero count
Syntax	<code>j = colperm(S)</code>
Description	<p><code>j = colperm(S)</code> generates a permutation vector <code>j</code> such that the columns of <code>S(:, j)</code> are ordered according to increasing count of nonzero entries. This is sometimes useful as a preordering for LU factorization; in this case use <code>lu(S(:, j))</code>.</p> <p>If <code>S</code> is symmetric, then <code>j = colperm(S)</code> generates a permutation <code>j</code> so that both the rows and columns of <code>S(j, j)</code> are ordered according to increasing count of nonzero entries. If <code>S</code> is positive definite, this is sometimes useful as a preordering for Cholesky factorization; in this case use <code>chol(S(j, j))</code>.</p>
Algorithms	The algorithm involves a sort on the counts of nonzeros in each column.
Examples	<p>The n-by-n <i>arrowhead</i> matrix</p> <pre>A = [ones(1, n); ones(n-1, 1) speye(n-1, n-1)]</pre> <p>has a full first row and column. Its LU factorization, <code>lu(A)</code>, is almost completely full. The statement</p> <pre>j = colperm(A)</pre> <p>returns <code>j = [2:n 1]</code>. So <code>A(j, j)</code> sends the full row and column to the bottom and the rear, and <code>lu(A(j, j))</code> has the same nonzero structure as <code>A</code> itself.</p> <p>On the other hand, the Bucky ball example,</p> <pre>B = bucky</pre> <p>has exactly three nonzero elements in each row and column, so <code>j = colperm(B)</code> is the identity permutation and is no help at all for reducing fill-in with subsequent factorizations.</p>

colperm

Purpose Convenience function for static .NET System.Delegate Combine method

Syntax `result = Combine(delegateA,delegateB)`

Description `result = Combine(delegateA,delegateB)` combines two delegates into a new delegate.

Input Arguments

delegateA
.NET System.Delegate object. The first delegate in the new delegate.

delegateB
.NET System.Delegate object. The last delegate in the new delegate.

Output Arguments

result
.NET System.Delegate object. A new delegate that delegates to the input delegate delegateA, then delegateB

Alternatives Use the static Combine method of the System.Delegate class.

See Also [Remove](#) | [RemoveAll](#)

How To

- “Combine and Remove .NET Delegates”

comet

Purpose 2-D comet plot

Syntax `comet(y)`
`comet(x,y)`
`comet(x,y,p)`
`comet(axes_handle,...)`

Description `comet(y)` displays a comet graph of the vector y . A comet graph is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet(x,y)` displays a comet graph of vector y versus vector x .

`comet(x,y,p)` specifies a comet body of length $p \cdot \text{length}(y)$. p defaults to 0.1.

`comet(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

Examples Create a simple comet graph:

```
t = 0:.01:2*pi;  
x = cos(2*t).*(cos(t).^2);  
y = sin(2*t).*(sin(t).^2);  
comet(x,y);
```

**See Also**

comet3

comet3

Purpose

3-D comet plot

Syntax

```
comet3(z)
comet3(x,y,z)
comet3(x,y,z,p)
comet3(axes_handle,...)
```

Description

A comet plot is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet3(z)` displays a 3-D comet graph of the vector `z`.

`comet3(x,y,z)` displays a comet graph of the curve through the points `[x(i),y(i),z(i)]`.

`comet3(x,y,z,p)` specifies a comet body of length `p*length(y)`. `p` must be between 0 and 1.

`comet3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

Tips

The trace left by `comet3` is created by using an `EraseMode` of `none`, which means you cannot print the graph (you get only the comet head), and it disappears if you cause a redraw (for example, by resizing the window).

Examples

Create a 3-D comet graph.

```
t = -10*pi:pi/250:10*pi;
comet3((cos(2*t).^2).*sin(t),(sin(2*t).^2).*cos(t),t);
```

`comet`

Purpose Open Command History window, or select it if already open

Syntax `commandhistory`

Description `commandhistory` opens the MATLAB Command History window when it is closed, and selects the Command History window when it is open. The Command History window presents a log of the statements most recently run in the Command Window.

See Also `diary` | `prefdir` | `startup`

How To

- “Command History”

commandwindow

Purpose Open Command Window, or select it if already open

Syntax `commandwindow`

Description `commandwindow` opens the MATLAB Command Window when it is closed, and selects the Command Window when it is open.

Tips To determine the number of columns and rows that display in the Command Window, given its current size, use

```
matlab.desktop.commandwindow.size
```

The number of columns is based on the width of the Command Window. With the matrix display width preference set to 80 columns, the number of columns is always 80.

- “Set Command Window Preferences”

Purpose	Companion matrix
Syntax	<code>A = compan(u)</code>
Description	<code>A = compan(u)</code> returns the corresponding companion matrix whose first row is <code>-u(2:n)/u(1)</code> , where <code>u</code> is a vector of polynomial coefficients. The eigenvalues of <code>compan(u)</code> are the roots of the polynomial.
Examples	<p>The polynomial $(x - 1)(x - 2)(x + 3) = x^3 - 7x + 6$ has a companion matrix given by</p> <pre>u = [1 0 -7 6] A = compan(u) A = 0 7 -6 1 0 0 0 1 0</pre> <p>The eigenvalues are the polynomial roots:</p> <pre>eig(compan(u)) ans = -3.0000 2.0000 1.0000</pre> <p>This is also <code>roots(u)</code>.</p>
See Also	<code>eig</code> <code>poly</code> <code>polyval</code> <code>roots</code>

Purpose

Plot arrows emanating from origin

Syntax

```
compass(U,V)
compass(Z)
compass(...,LineStyle)
compass(axes_handle,...)
h = compass(...)
```

Description

A compass graph displays the vectors with components (U,V) as arrows emanating from the origin. U , V , and Z are in Cartesian coordinates and plotted on a circular grid.

`compass(U,V)` displays a compass graph having n arrows, where n is the number of elements in U or V . The location of the base of each arrow is the origin. The location of the tip of each arrow is a point relative to the base and determined by $[U(i),V(i)]$.

`compass(Z)` displays a compass graph having n arrows, where n is the number of elements in Z . The location of the base of each arrow is the origin. The location of the tip of each arrow is relative to the base as determined by the real and imaginary components of Z . This syntax is equivalent to `compass(real(Z),imag(Z))`.

`compass(...,LineStyle)` draws a compass graph using the line type, marker symbol, and color specified by `LineStyle`.

`compass(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = compass(...)` returns handles to line objects.

Examples

Create Compass Graph

Create a compass graph of the eigenvalues of a random matrix.

```
rng(0,'twister') % initialize random number generator
```

```
M = randn(20,20);  
Z = eig(M);
```

```
figure  
compass(Z)
```

[feather](#) | [polar](#) | [LineSpec](#) | [quiver](#) | [rose](#)

complex

Purpose Create complex array

Syntax
`z = complex(a,b)`
`z = complex(x)`

Description `z = complex(a,b)` creates a complex output, `z`, from two real inputs, such that $z = a + bi$.

The `complex` function provides a useful substitute for expressions, such as $a + 1i*b$ or $a + 1j*b$, when

- `a` and `b` are not `double` or `single`
- `b` is all zeros

`z = complex(x)` returns the complex equivalent of `x`, such that `isreal(z)` returns logical 0 (`false`).

- If `x` is real, then `z` is $x + 0i$.
- If `x` is complex, then `z` is identical to `x`.

Input Arguments

a - Real component

scalar | vector | matrix | multidimensional array

Real component, specified as a scalar, vector, matrix, or multidimensional array.

The size of `a` must match the size of `b`, unless one is a scalar. If either `a` or `b` is a scalar, MATLAB expands the scalar to match the size of the other input.

`a` and `b` must be the same data type with the following exceptions:

- `single` can combine with `double`.
- `scalar double` can combine with an integer data type.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64

b - Imaginary component

scalar | vector | matrix | multidimensional array

Imaginary component, specified as a scalar, vector, matrix, or multidimensional array.

The size of **b** must match the size of **a**, unless one is a scalar. If either **a** or **b** is a scalar, MATLAB expands the scalar to match the size of the other input.

a and **b** must be the same data type with the following exceptions:

- single can combine with double.
- scalar double can combine with an integer data type.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64

x - Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64

Complex Number Support: Yes

Output Arguments**z - Complex array**

scalar | vector | matrix | multidimensional array

Complex array, returned as a scalar, vector, matrix, or multidimensional array.

The size of **z** is the same as the input arguments.

The following describes the data type of `z`, when `a` and `b` have different data types.

- If either `a` or `b` is `single`, then `z` is `single`.
- If either `a` or `b` is an integer data type, then `z` is the same integer data type.

Examples

Complex Scalar from Two Real Scalars

Use the `complex` function to create the complex scalar, $3 + 4i$.

```
z = complex(3,4)
```

```
z =
```

```
3.0000 + 4.0000i
```

Complex Vector from Two Complex Vectors

Create a complex `uint8` vector from two real `uint8` vectors.

```
a = uint8([1;2;3;4]);
```

```
b = uint8([2;2;7;7]);
```

```
z = complex(a,b)
```

```
z =
```

```
1 + 2i
```

```
2 + 2i
```

```
3 + 7i
```

```
4 + 7i
```

The size of `z`, 4-by-1, is the same as the size of the input arguments.

Complex Scalar from One Real Scalar

Create a complex scalar with zero imaginary part.

```
z = complex(12)
```

`z =`

```
12.0000 + 0.0000i
```

Verify that `z` is complex.

```
isreal(z)
```

`ans =`

```
0
```

Tips

- If `b` contains only zeros, then `z` is complex and the value of all its imaginary components is 0. In contrast, the addition `a + 0i` returns a strictly real result.

Concepts

- “Complex Numbers”

Tiff.computeStrip

Purpose Index number of strip containing specified coordinate

Syntax
`stripNumber = tiffobj.computeStrip(row)`
`stripNumber = tiffobj.computeStrip(row,plane)`

Description `stripNumber = tiffobj.computeStrip(row)` returns the index number of the strip containing the given row. The value of row must be one-based.

`stripNumber = tiffobj.computeStrip(row,plane)` returns the index number of the strip containing the given row in the specified plane, if the value of the PlanarConfiguration tag is `Tiff.PlanarConfiguration.Separate`. The values of row and plane must be one-based.

`computeStrip` clamps out-of-range coordinate values to the bounds of the image.

Examples Determine Index Number of Strip

Determine the index number of the strip containing a row in the second image of a file.

Create a Tiff object associated with the example file, `example.tif`, and make the second image the current directory.

```
t = Tiff('example.tif','r');  
t.setDirectory(2);
```

Get the number of rows in the image. Then, get the index of the strip containing the middle row.

```
numRows = t.getTag('ImageLength');  
stripNumber = t.computeStrip(numRows/2)
```

```
stripNumber =
```

4

Close the Tiff object.

```
t.close();
```

References

This method corresponds to the TIFFComputeStrip function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

Tiff.computeTile

Purpose Index number of tile containing specified coordinates

Syntax

```
tileNumber = tiffobj.computeTile([row col])  
tileNumber = tiffobj.computeTile([row col],plane)
```

Description

`tileNumber = tiffobj.computeTile([row col])` returns the index number of the tile containing the pixel specified by the one-based indices, `row` and `col`.

`tileNumber = tiffobj.computeTile([row col],plane)` returns the index number of the tile containing the pixel specified by the indices in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`. The `row`, `column`, and `plane` coordinate values are one-based.

`computeTile` clamps out-of-range coordinate values to the bounds of the image.

Examples **Get Index Number of Tile Containing Last Pixel**

Open a Tiff object and get the dimensions of the image to calculate coordinates.

```
t = Tiff('example.tif','r');  
numRows = t.getTag('ImageLength');  
numCols = t.getTag('ImageWidth');
```

Get the ID number of the tile containing the coordinates.

```
tileNum = t.computeTile([numRows numCols])
```

```
tileNum =
```

```
    110
```

Close the Tiff object.

```
t.close();
```

References

This method corresponds to the `TIFFComputeTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

computer

Purpose Information about computer on which MATLAB software is running

Syntax

```
str = computer
archstr = computer('arch')
[str,maxsize] = computer
[str,maxsize, endian] = computer
```

Description `str = computer` returns the string `str` with the computer type on which MATLAB is running.

`archstr = computer('arch')` returns the string `archstr` which is used by the mex command `-arch` switch.

`[str,maxsize] = computer` returns the integer `maxsize`, the maximum number of elements allowed in an array with this version of MATLAB.

`[str,maxsize, endian] = computer` returns either 'L' for little-endian byte ordering or 'B' for big-endian byte ordering.

Platform	Word Size	archstr	maxsize	endian	ispc	isunix	ismac	
Microsoft Windows	32-bit	PCWIN	win32	2 ³¹ - 1	L	1	0	0
	64-bit	PCWIN64	win64	2 ⁴⁸ - 1	L	1	0	0
Linux	64-bit	GLNXA64	glnxa64	2 ⁴⁸ - 1	L	0	1	0
Apple Macintosh	64-bit	MACI64	maci64	2 ⁴⁸ - 1	L	0	1	1

Tips In some cases, both 32-bit and 64-bit versions of MATLAB can run on the same platform. In this case, the value returned by `computer` reflects which of these are running. For example, if you run a 32-bit version of MATLAB on a Windows x64 platform, `computer` returns `PCWIN`, indicating that the 32-bit version is running. You can get this

information and the value of `archstr` from the **Help** menu, as described in “Information About your Installation”.

See Also

`getenv` | `setenv` | `ispc` | `isunix` | `ismac`

cond

Purpose Condition number with respect to inversion

Syntax
`c = cond(X)`
`c = cond(X,p)`

Description The *condition number* of a matrix measures the sensitivity of the solution of a system of linear equations to errors in the data. It gives an indication of the accuracy of the results from matrix inversion and the linear equation solution. Values of `cond(X)` and `cond(X,p)` near 1 indicate a well-conditioned matrix.

`c = cond(X)` returns the 2-norm condition number, the ratio of the largest singular value of X to the smallest.

`c = cond(X,p)` returns the matrix condition number in p -norm:

$\text{norm}(X,p) * \text{norm}(\text{inv}(X),p)$

If p is...	Then <code>cond(X,p)</code> returns the...
1	1-norm condition number
2	2-norm condition number
'fro'	Frobenius norm condition number
inf	Infinity norm condition number

Algorithms The algorithm for `cond` (when $p = 2$) uses the singular value decomposition, `svd`. When the input matrix is sparse, `cond` ignores any specified p value and calls `condest`.

See Also `condeig` | `condest` | `norm` | `normest` | `rank` | `rcond` | `svd`

Purpose Condition number with respect to eigenvalues

Syntax `c = condeig(A)`
`[V,D,s] = condeig(A)`

Description `c = condeig(A)` returns a vector of condition numbers for the eigenvalues of A. These condition numbers are the reciprocals of the cosines of the angles between the left and right eigenvectors.

`[V,D,s] = condeig(A)` is equivalent to

```
[V,D] = eig(A);  
s = condeig(A);
```

Large condition numbers imply that A is near a matrix with multiple eigenvalues.

See Also `balance` | `cond` | `eig`

condest

Purpose 1-norm condition number estimate

Syntax
`c = condest(A)`
`c = condest(A,t)`
`[c,v] = condest(A)`

Description `c = condest(A)` computes a lower bound `c` for the 1-norm condition number of a square matrix `A`.
`c = condest(A,t)` changes `t`, a positive integer parameter equal to the number of columns in an underlying iteration matrix. Increasing the number of columns usually gives a better condition estimate but increases the cost. The default is `t = 2`, which almost always gives an estimate correct to within a factor 2.

`[c,v] = condest(A)` also computes a vector `v` which is an approximate null vector if `c` is large. `v` satisfies $\text{norm}(A*v,1) = \text{norm}(A,1)*\text{norm}(v,1)/c$.

Note `condest` invokes `rand`. If repeatable results are required then use `rng` to set the random number generator to its startup settings before using `condest`.

`rng('default')`

Tips This function is particularly useful for sparse matrices.

Algorithms `condest` is based on the 1-norm condition estimator of Hager [1] and a block-oriented generalization of Hager's estimator given by Higham and Tisseur [2]. The heart of the algorithm involves an iterative search to

estimate $\|A^{-1}\|_1$ without computing A^{-1} . This is posed as the convex but nondifferentiable optimization problem $\max \|A^{-1}\mathbf{x}\|_1$ subject to $\|\mathbf{x}\|_1 = 1$

cond | norm | normest

Purpose Plot velocity vectors as cones in 3-D vector field

Syntax

```
coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)
coneplot(U,V,W,Cx,Cy,Cz)
coneplot(...,s)
coneplot(...,color)
coneplot(...,'quiver')
coneplot(...,'method')
coneplot(X,Y,Z,U,V,W,'nointerp')
coneplot(axes_handle,...)
h = coneplot(...)
```

Description `coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)` plots velocity vectors as cones pointing in the direction of the velocity vector and having a length proportional to the magnitude of the velocity vector. `X, Y, Z` define the coordinates for the vector field. `U, V, W` define the vector field. These arrays must be the same size, monotonic, and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). `Cx, Cy, Cz` define the location of the cones in the vector field. The section “Specifying Starting Points for Stream Plots” in *Visualization Techniques* provides more information on defining starting points.

`coneplot(U,V,W,Cx,Cy,Cz)` (omitting the `X, Y, and Z` arguments) assumes `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p]=size(U)`.

`coneplot(...,s)` automatically scales the cones to fit the graph and then stretches them by the scale factor `s`. If you do not specify a value for `s`, `coneplot` uses a value of 1. Use `s = 0` to plot the cones without automatic scaling.

`coneplot(...,color)` interpolates the array `color` onto the vector field and then colors the cones according to the interpolated values. The size of the `color` array must be the same size as the `U, V, W` arrays. This option works only with cones (that is, not with the `quiver` option).

`coneplot(...,'quiver')` draws arrows instead of cones (see `quiver3` for an illustration of a quiver plot).

`coneplot(..., 'method')` specifies the interpolation method to use. *method* can be `linear`, `cubic`, or `nearest`. `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`coneplot(X, Y, Z, U, V, W, 'nointerp')` does not interpolate the positions of the cones into the volume. The cones are drawn at positions defined by `X`, `Y`, `Z` and are oriented according to `U`, `V`, `W`. Arrays `X`, `Y`, `Z`, `U`, `V`, `W` must all be the same size.

`coneplot(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = coneplot(...)` returns the handle to the patch object used to draw the cones. You can use the `set` command to change the properties of the cones.

`coneplot` automatically scales the cones to fit the graph, while keeping them in proportion to the respective velocity vectors.

Examples

Plot the velocity vector cones for vector volume data representing the motion of air through a rectangular region of space:

Load the data. The `winds` data set contains six 3-D arrays: `u`, `v`, and `w` specify the vector components at each of the coordinates specified in `x`, `y`, and `z`. The coordinates define a lattice grid structure where the data is sampled within the volume. `load wind`.

```
load wind
```

Now establish the range of the data to place the slice planes and to specify where you want the cone plots (`min`, `max`):

```
xmin = min(x(:));  
xmax = max(x(:));  
ymin = min(y(:));  
ymax = max(y(:));  
zmin = min(z(:));
```

Use `daspect` to set the data aspect ratio of the axes before calling `coneplot`.

```
daspect([2,2,1])
```

Decide where in data space you want to plot cones. This example selects the full range of x and y in eight steps and the range 3 to 15 in four steps in z using `linspace` and `meshgrid`.

```
xrange = linspace(xmin,xmax,8);  
yrange = linspace(ymin,ymax,8);  
zrange = 3:4:15;  
[cx cy cz] = meshgrid(xrange,yrange,zrange);
```

Draw the cones, setting the scale factor to 5 to make the cones larger than the default size:

```
hcones = coneplot(x,y,z,u,v,w,cx,cy,cz,5);
```

Use the `jet` colormap:

```
colormap jet
```

Set the coloring of each cone using `FaceColor` and `EdgeColor`:

```
set(hcones,'FaceColor','red','EdgeColor','none')
```

Calculate the magnitude of the vector field (which represents wind speed) to generate scalar data for the `slice` command:

```
hold on  
wind_speed = sqrt(u.^2 + v.^2 + w.^2);
```

Create slice planes along the x -axis at $xmin$ and $xmax$, along the y -axis at $ymax$, and along the z -axis at $zmin$:

```
hsurfaces = slice(x,y,z,wind_speed,[xmin,xmax],ymax,zmin);
```

Specify interpolated face color so the slice coloring indicates wind speed, and do not draw edges (`hold`, `slice`, `FaceColor`, `EdgeColor`):

```
set(hsurfaces,'FaceColor','interp','EdgeColor','none')  
hold off
```

Use the `axis` command to set the axis limits equal to the range of the data. `axis tight`. Orient the view to azimuth = 30 and elevation = 40. (`rotate3d` is a useful command for selecting the best view.)

```
view(30,40);axis off
```

Select perspective projection to provide a more realistic looking volume using `camproj`:

```
camproj perspective;
```

Zoom in on the scene a little to make the plot as large as possible using `camzoom`:

```
camzoom(1.5)
```

The light source affects both the slice planes (surfaces) and the cone plots (patches). However, you can set the lighting characteristics of each independently.

Add a light source to the right of the camera and use Gouraud lighting to give the cones and slice planes a smooth, three-dimensional appearance using `camlight` and `lighting`:

```
camlight right; lighting gouraud
```

Increase the value of the `AmbientStrength` property for each slice plane to improve the visibility of the dark blue colors:

```
set(hsurfaces,'AmbientStrength',0.6)
```

Increase the value of the `DiffuseStrength` property of the cones to brighten particularly those cones not showing specular reflections:

```
set(hcones,'DiffuseStrength',0.8)
```

coneplot

Tutorials

- “Overview of Volume Visualization”

Purpose Complex conjugate

Syntax `ZC = conj(Z)`

Description `ZC = conj(Z)` returns the complex conjugate of the elements of Z.

Algorithms If Z is a complex array:

`conj(Z) = real(Z) - i*imag(Z)`

See Also *i* | *j* | `imag` | `real`

continue

Purpose Pass control to next iteration of `for` or `while` loop

Syntax `continue`

Description `continue` temporarily interrupts the execution of a program loop, skipping any remaining statements in the body of the loop for the current pass. The `continue` statement does not cause an immediate exit from the loop as a `break` or `return` statement would do, but instead continues within the loop for as long as the stated `for` or `while` condition holds true.

A `continue` statement in a *nested* loop behaves in the same manner. Execution resumes at the `for` or `while` statement of the loop in which the `continue` statement was encountered, and reenters the loop if the stated condition evaluates to `true`.

Examples Count the number of lines of code in the file `magic.m`, skipping all blank lines and comments.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) || strncmp(line,'% ',1) || ~ischar(line)
        continue
    end
    count = count + 1;
end
fprintf('%d lines\n',count);
fclose(fid);
```

See Also `for` | `while` | `end` | `break` | `return`

Purpose Contour plot of matrix

Syntax

```
contour(Z)
contour(Z,n)
contour(Z,v)
contour(X,Y,Z)
contour(X,Y,Z,n)
contour(X,Y,Z,v)
contour(...,LineStyle)
contour(axes_handle,...)
[C,h] = contour(...)
```

Description A contour plot displays isolines of matrix Z . Label the contour lines using `clabel`.

`contour(Z)` draws a contour plot of matrix Z , where Z is interpreted as heights with respect to the x - y plane. Z must be at least a 2-by-2 matrix that contains at least two different values. The number of contour lines and the values of the contour lines are chosen automatically based on the minimum and maximum values of Z . The ranges of the x - and y -axis are $[1:n]$ and $[1:m]$, where $[m,n] = \text{size}(Z)$.

`contour(Z,n)` draws a contour plot of matrix Z with n contour levels where n is a scalar.

`contour(Z,v)` draws a contour plot of matrix Z with contour lines at the data values specified in the monotonically increasing vector v . The number of contour levels is equal to `length(v)`. Specifying the vector v sets the `LevelListMode` to manual to allow user control over contour levels. To display a single contour line at a particular value, define v as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level i , use `contour(Z,[i i])`.

`contour(X,Y,Z)`, `contour(X,Y,Z,n)`, and `contour(X,Y,Z,v)` draw contour plots of Z using X and Y to determine the x - and y -axis limits.

- If X and Y are vectors, then the length of X must equal the number of columns in Z and the length of Y must equal the number of rows in Z .
- If X and Y are matrices, then their sizes must equal the size of Z .

If X or Y is irregularly spaced, then `contour` calculates contours using a regularly spaced contour grid, and then transforms the data to X or Y .

`contour(...,LineStyle)` draws the contours using the line type and color specified by `LineStyle`. `contour` ignores marker symbols.

`contour(axes_handle,...)` plots into axes `axes_handle` instead of `gca`.

`[C,h] = contour(...)` returns a contour matrix, C , that contains the data that defines the contour lines, and a handle, h , to a `contourgroup` object. The `clabel` function uses contour matrix C to label the contour lines. `ContourMatrix` is also a read-only `contourgroup` property that you can obtain from the returned handle.

Use contour object properties to control the contour plot appearance.

Tips

- The contour function cannot determine if there are discontinuities in the input data. You can add NaN values to the data to prevent drawing the contour lines in those regions.

Examples

Create Contour Plot

Use the `meshgrid` function to generate matrices X and Y . Create a third matrix, Z , and plot its contours.

```
x = linspace(-2*pi,2*pi);
y = linspace(0,4*pi);
[X,Y] = meshgrid(x,y);
Z = sin(X)+cos(Y);
```

```
figure
contour(X,Y,Z)
```

Specify Number of Contour Lines

Store the data from the peaks function in matrices X, Y, and Z. Plot 20 contours of the data in Z.

```
[X,Y,Z] = peaks;  
figure  
contour(X,Y,Z,20)
```

contour

Display Contour Labels

Set up matrices X, Y, and Z. Create a contour plot and display the contour labels by setting the ShowText property to on.

```
x = -2:0.2:2;  
y = -2:0.2:3;  
[X,Y] = meshgrid(x,y);  
Z = X.*exp(-X.^2-Y.^2);
```

```
figure  
contour(X,Y,Z,'ShowText','on')
```

Display Single Contour Line

Create a contour plot of the peaks function and display only one contour level at $Z = 1$.

```
x = -3:0.125:3;  
y = -3:0.125:3;
```

contour

```
[X,Y] = meshgrid(x,y);  
Z = peaks(X,Y);  
v = [1,1];
```

```
figure  
contour(X,Y,Z,v);
```

[properties](#) | [text](#) [properties](#)

How To

- “Label Contour Plot Levels”
- “Highlight Specific Contour Levels”

contour3

Purpose 3-D contour plot

Syntax

```
contour3(Z)
contour3(Z,n)
contour3(Z,v)
contour3(X,Y,Z)
contour3(X,Y,Z,n)
contour3(X,Y,Z,v)
contour3(...,LineStyle)
contour3(axes_handle,...)
[C,h] = contour3(...)
```

Description contour3 creates a 3-D contour plot of a surface defined on a rectangular grid.

contour3(Z) draws a contour plot of matrix Z in a 3-D view. Z is interpreted as heights with respect to the x-y plane. Z must be at least a 2-by-2 matrix that contains at least two different values. The number of contour levels and the values of contour levels are chosen automatically based on the minimum and maximum values of Z. The ranges of the x- and y-axis are [1:n] and [1:m], where [m,n] = size(Z).

contour3(Z,n) draws a contour plot of matrix Z with n contour levels in a 3-D view.

contour3(Z,v) draws a contour plot of matrix Z with contour lines at the values specified in vector v. The number of contour levels is equal to length(v). Specifying the vector v sets the LevelListMode to manual to allow user control over contour levels. To display a single contour line at a particular value, define v as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level i, use contour3(Z,[i i]).

contour3(X,Y,Z), contour3(X,Y,Z,n), and contour3(X,Y,Z,v) draw contour plots of Z using X and Y to determine the x- and y-axis limits.

- If X and Y are vectors, then the length of X must equal the number of columns in Z and the length of Y must equal the number of rows in Z .
- If X and Y are matrices, then their sizes must equal the size of Z .

If X or Y is irregularly spaced, then `contour3` calculates contours using a regularly spaced contour grid, and then transforms the data to X or Y .

`contour3(...,LineStyle)` draws the contour lines using the line type and color specified by `LineStyle`. `contour3` ignores marker symbols.

`contour3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`[C,h] = contour3(...)` returns a contour matrix, C , that contains the data that defines the contour lines, and a handle, h , to an array of handles to graphics objects. The `clabel` function uses contour matrix C to label the contour lines. The graphic objects that `contour3` creates are patch objects, or if you specify a `LineStyle` argument, line objects.

Tips

If you do not specify `LineStyle`, the functions `colormap` and `caxis` control the color.

Label the contour lines using `clabel`.

`contour3(...)` works the same as `contour(...)` with these exceptions:

- The contours are drawn at their corresponding Z level.
- Multiple patch or line objects are created instead of a `contourgroup`.
- Calling `contour3` with trailing property-value pairs is not allowed.

Examples

Create 3-D Contour Plot

Set up matrices X and Y using the `meshgrid` function. Plot 30 contours of matrix Z .

```
x = -2:0.25:2;
[X,Y] = meshgrid(x);
Z = X.*exp(-X.^2-Y.^2);
```

contour3

`contour3(X,Y,Z,30)`

See Also

`contour` | `contourc` | `contourf` | `meshc` | `meshgrid` | `surfc` | `contourgroup` properties

Purpose

Low-level contour plot computation

Syntax

```
C = contourc(Z)
C = contourc(Z,n)
C = contourc(Z,v)
C = contourc(x,y,Z)
C = contourc(x,y,Z,n)
C = contourc(x,y,Z,v)
```

Description

`contourc` calculates the contour matrix `C` used by `contour`, `contour3`, and `contourf`. The values in `Z` determine the heights of the contour lines with respect to a plane. The contour calculations use a regularly spaced grid determined by the dimensions of `Z`.

`C = contourc(Z)` computes the contour matrix from data in matrix `Z`, where `Z` must be at least a 2-by-2 matrix. The contours are isolines in the units of `Z`. The number of contour lines and the corresponding values of the contour lines are chosen automatically.

`C = contourc(Z,n)` computes contours of matrix `Z` with `n` contour levels.

`C = contourc(Z,v)` computes contours of matrix `Z` with contour lines at the values specified in vector `v`. The length of `v` determines the number of contour levels. To compute a single contour of level `i`, use `contourc(Z,[i i])`.

`C = contourc(x,y,Z)`, `C = contourc(x,y,Z,n)`, and `C = contourc(x,y,Z,v)` compute contours of `Z` using vectors `x` and `y` to determine the x - and y -axis limits. `x` and `y` must be monotonically increasing.

Tips

`C` is a two-row matrix specifying all the contour lines. Each contour line defined in matrix `C` begins with a column that contains the value of the contour (specified by `v` and used by `clabel`), and the number of (x,y) vertices in the contour line. The remaining columns contain the data for the (x,y) pairs.

```
C = [value1 xdata(1) xdata(2) ...
```

contourc

```
xdata(dim1) value2 xdata(1) xdata(2) ... xdata(dim2)...  
dim1 ydata(1) ydata(2) ...  
ydata(dim1) dim2 ydata(1) ydata(2) ...  
ydata(dim2)];
```

Specifying irregularly spaced *x* and *y* vectors is not the same as contouring irregularly spaced data. If *x* or *y* is irregularly spaced, `contourc` calculates contours using a regularly spaced contour grid, then transforms the data to *x* or *y*.

`clabel` | `contour` | `contour3` | `contourf`

How To

- “The Contouring Algorithm”

Purpose Filled 2-D contour plot

Syntax

```
contourf(Z)
contourf(Z,n)
contourf(Z,v)
contourf(X,Y,Z)
contourf(X,Y,Z,n)
contourf(X,Y,Z,v)
contourf(...,LineStyle)
contourf(axes_handle,...)
contour(axes_handle,...)
[C,h] = contourf(...)
```

Description A filled contour plot displays isolines calculated from matrix *Z* and fills the areas between the isolines using constant colors corresponding to the current figure's colormap.

`contourf(Z)` draws a filled contour plot of matrix *Z*, where *Z* is interpreted as heights with respect to the *x-y* plane. *Z* must be at least a 2-by-2 matrix that contains at least two different values. The number of contour lines and the values of the contour lines are chosen automatically based on the minimum and maximum values of *Z*. The ranges of the *x*- and *y*-axis are `[1:n]` and `[1:m]`, where `[m,n] = size(Z)`.

`contourf(Z,n)` draws a filled contour plot of matrix *Z* with *n* contour levels.

`contourf(Z,v)` draws a filled contour plot of matrix *Z* with contour lines at the data values specified in the monotonically increasing vector *v*. Specifying the vector *v* sets the `LevelListMode` to manual to allow user control over contour levels. To display a single contour line at a particular value, define *v* as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level *i*, use `contourf(Z,[i i])`.

`contourf(X,Y,Z)`, `contourf(X,Y,Z,n)`, and `contourf(X,Y,Z,v)` draw filled contour plots of Z using X and Y to determine the x - and y -axis limits.

- If X and Y are vectors, then the length of X must equal the number of columns in Z and the length of Y must equal the number of rows in Z .
- If X and Y are matrices, then their sizes must equal the size of Z .

If X or Y is irregularly spaced, then `contourf` calculates contours using a regularly spaced contour grid, and then transforms the data to X or Y .

`contourf(...,LineStyle)` draws the contour lines using the line type and color specified by `LineStyle`. `contourf` ignores marker symbols.

`contourf(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`contour(axes_handle,...)` plots into axes `axes_handle` instead of `gca`.

`[C,h] = contourf(...)` returns a contour matrix, `C`, that contains the data that defines the contour lines, and a handle, `h`, to a `ContourGroup` object containing the filled contours. The `clabel` function uses contour matrix `C` to label the contour lines. `ContourMatrix` is also a read-only `ContourGroup` property that you can obtain from the returned handle.

Tips

Label the contour lines using `clabel`.

NaNs in the Z -data leave white holes with black borders in the contour plot.

Examples

Create Filled Contour Plot

Use the `peaks` function to define z as a 20-by-20 matrix. Create a filled contour plot of z with 10 contour lines.

```
Z = peaks(20);  
contourf(Z,10);
```

[properties](#)

How To

- “Change Fill Colors for Contour Plot”

Contourgroup Properties

Purpose Define contourgroup properties

Modifying Properties You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default properties for contourgroup objects. See “Plot Objects” for more information on contourgroup objects.

Contourgroup Property Descriptions This section provides a description of properties. Curly braces { } enclose default values.

Annotation

`hg.Annotation` object (read-only)

Control the display of contourgroup objects in legends. Specifies whether this contourgroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the contourgroup object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
<code>on</code>	Include the contourgroup object in a legend as one entry, but not its children objects
<code>off</code>	Do not include the contourgroup or its children in a legend (default)
<code>children</code>	Include only the children of the contourgroup as separate entries in the legend

Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');  
hLegendEntry = get(hAnnotation, 'LegendInformation');  
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

Using the IconDisplayStyle Property

See “Control Legend Content” for more information and examples.

BeingDeleted

`on` | `{off}` (read-only)

This object is being deleted. Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

BusyAction

`cancel` | `{queue}`

Callback queuing

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

Contourgroup Properties

running callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`
string | function handle

Button press callback function. Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

For information on the syntax of callback functions, see `Function Handle Callbacks`.

Children

array of graphics object handles

Children of the contourgroup object. An array containing the handles of all line objects parented to the contourgroup object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

Clipping

{on} | off

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

ContourMatrix

2-by-n matrix (read-only)

Two-row matrix specifying all contour lines. Each contour line defined in the `ContourMatrix` begins with a column that contains the value of the contour (specified by the `LevelList` property and is used by `clabel`), and the number of (x,y) vertices in the contour line. The remaining columns contain the data for the (x,y) pairs.

For example:

```
C = [value1 xdata(1) xdata(2)...  
     value2 xdata(1) xdata(2)...;  
     dim1 ydata(1) ydata(2)...
```

Contourgroup Properties

```
dim2 ydata(1) ydata(2)...]
```

That is:

```
C = [C(1) C(2)...C(I)...C(N)]
```

where N is the number of contour levels, and:

```
C(i) = [ level(i) x(1) x(2)...x( numel(i));  
        numel(i) y(1) y(2)...y( numel(i))];
```

For further information, see `contour` and “The Contouring Algorithm”.

CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback function executed during object creation. Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where @*CallbackFcn* is a function handle that references the callback function and *graphicfcn* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

Callback executed during object deletion. Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

See the `BeingDeleted` property for related information.

DisplayName

string

String used by legend. The `legend` function uses the `DisplayName` property to label the contourgroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.

Contourgroup Properties

- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

EraseMode

{normal} | none | xor | background

Erase mode. Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object’s color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes

Color property is none. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes Color property. Set the figure background color with the figure Color property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the EraseMode of all objects is normal. This means graphics objects created with EraseMode set to none, xor, or background can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the getframe command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Fill

{off} | on

Color spaces between contour lines.

- on — Default when using contourf or ezcontourf.
- off — Default when using contour or ezcontour.

By default, contour draws only the contour lines of the surface. If you set Fill to on, contour colors the regions in between the contour lines according to the Z-value of the region and changes the contour lines to black.

HandleVisibility

{on} | callback | off

Contourgroup Properties

Control access to object's handle. Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility`

settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

HitTest

{on} | off

Selectable by mouse click. Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the contour plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

HitTestArea

on | {off}

Select the object by clicking lines or area of extent. Select plot objects by:

- Clicking contour lines(default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the contour lines (excluding the baseline) to select the object. When `HitTestArea`

Contourgroup Properties

is on, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the contour lines).

Interruptible
off | {on}

Callback routine interruption

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
 - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
 - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

Note MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LabelSpacing`

distance in points (default = 144)

Spacing between labels on each contour line. When you display contour line labels using either the `ShowText` property or the `clabel` command, the labels are spaced 144 points (2 inches) apart on each line. You can specify the spacing by setting the `LabelSpacing` property to a value in points. If the length of an individual contour line is less than the specified value, MATLAB displays only one contour label on that line.

`LevelList`

vector of `ZData`-values

Values at which contour lines are drawn. When the `LevelListMode` property is `auto`, the contour function automatically chooses contour values that span the range of values in `ZData` (the input argument `Z`). You can set this property to the values at which you want contour lines drawn.

To specify the contour interval (space between contour lines) use the `LevelStep` property.

Contourgroup Properties

LevelListMode
{auto} | manual

User-specified or autogenerated LevelList values. By default, the contour function automatically generates the values at which contours are drawn. If you set this property to `manual`, contour does not change the values in `LevelList` as you change the values of `ZData`.

LevelStep
scalar

Spacing of contour lines. The contour function draws contour lines at regular intervals determined by the value of `LevelStep`. When the `LevelStepMode` property is `auto`, contour determines the contour interval automatically based on the `ZData`.

LevelStepMode
{auto} | manual

User-specified or autogenerated LevelStep values. By default, the contour function automatically determines a value for the `LevelStep` property. If you set this property to `manual`, contour does not change the value of `LevelStep` as you change the values of `ZData`.

LineColor
{auto} | ColorSpec | none

Color of the contour lines. This property determines how MATLAB colors the contour lines.

- `auto` — Each contour line is a single color determined by its contour value, the figure colormap, and the color axis (`caxis`).
- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is `[0 0 0]` (black). See `ColorSpec` for more information on specifying color.

- none — No contour lines are drawn.

LineStyle

{-} | -- | : | -. | none

Line style of contourgroup object.

Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

LineWidth

size in points

Width of linear objects and edges of filled areas. Specify in points. 1 point = $1/72$ inch. The default is 0.5 points.

Parent

handle of parent axes, hggroup, or hgtransform

Parent of object. Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

Selected

on | {off}

Object selection state. When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this

Contourgroup Properties

property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

SelectionHighlight
{on} | off

Object highlighted when selected.

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

ShowText
on | {off}

Display labels on contour lines. When you set this property to on, MATLAB displays text labels on each contour line indicating the contour value. See also `LevelList`, `clabel`, and the example “Display Contour Labels” on page 1-1106.

Tag
string

User-specified object label. Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object’s handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

TextList
vector

Contour values to label. This property contains the contour values where text labels are placed. By default, these values are the same as those contained in the `LevelList` property, which define where the contour lines are drawn. Note that there must be an equivalent contour line to display a text label.

For example, the following statements create and label a contour plot:

```
[c,h]=contour(peaks);  
clabel(c,h)
```

You can get the `LevelList` property to see the contour line values:

```
get(h,'LevelList')
```

Suppose you want to view the contour value 4.375 instead of the value of 4 that the contour function used. To do this, you need to set both the `LevelList` and `TextList` properties:

```
set(h,'LevelList',[-6 -4 -2 0 2 4.375 6 8],...  
    'TextList',[-6 -4 -2 0 2 4.375 6 8])
```

TextListMode
{auto} | manual

User-specified or auto TextList values. When this property is `auto`, MATLAB sets the `TextList` property equal to the values of the `LevelList` property (i.e., a text label for each contour line). When this property is `manual`, MATLAB does not set the values of the `TextList` property. Note that specifying values for the `TextList` property causes the `TextListMode` property to be set to `manual`.

Contourgroup Properties

TextStep
scalar

Determines which contour line have numeric labels. The contour function labels contour lines at regular intervals which are determined by the value of the TextStep property. When the TextStepMode property is auto, contour labels every contour line when the ShowText property is on.

TextStepMode
{auto} | manual

User-specified or autogenerated TextStep values. By default, the contour function automatically determines a value for the TextStep property. If you set this property to manual, contour does not change the value of TextStep as you change the values of ZData.

Type
string (read-only)

Type of graphics object. String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For contourgroup objects, Type is 'hggroup'. This statement finds all the hggroup objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

UIContextMenu
handle of uicontextmenu object

Associate context menu with object. Handle of a uicontextmenu object created in the object's parent figure. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

UserData

array

User-specified data. Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

Visible

{on} | off

Visibility of object and its children.

- **on** — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

XData

vector | matrix

x-axis values for graph. The *x*-axis values for graphs are specified by the `X` input argument. If `XData` is a vector, `length(XData)` must equal `length(YData)` and must be monotonic. If `XData` is a matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use `XData` to define meaningful coordinates for an underlying surface whose topography is being mapped.

XDataMode

{auto} | manual

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the `X` input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

Contourgroup Properties

If you set `XDataMode` to `auto` after having specified `XData`, MATLAB resets the *x*-axis ticks to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`

MATLAB variable, as a string

Link XData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`

scalar | vector | matrix

Y-axis limits. This property determines the *y*-axis limits used in the contour plot. If you do not specify a `Y` argument, the `contour` function calculates *y*-axis limits based on the size of the input argument `Z`.

`YData` can be either a matrix equal in size to `ZData` or a vector equal in length to the number of columns in `ZData`.

Use `YData` to define meaningful coordinates for the underlying surface whose topography is being mapped.

`YDataMode`
{auto} | manual

Use automatic or user-specified y-axis values. In auto mode (the default) the contour function automatically determines the *y*-axis limits. If you set this property to manual, specify a value for `YData`, or specify a *Y* argument, then contour sets this property to manual and does not change the axis limits.

If you set `YDataMode` to auto after having specified `YData`, MATLAB resets the *y*-axis ticks to the row indices of the `ZData`, overwriting any previous values for `YData`.

`YDataSource`
MATLAB variable, as a string

Link YData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Contourgroup Properties

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

ZData

matrix

Contour data. This property contains the data from which the contour lines are generated (specified as the input argument `Z`). `ZData` must be at least a 2-by-2 matrix. The number of contour levels and the values of the contour levels are chosen automatically based on the minimum and maximum values of `ZData`. The limits of the x - and y -axis are `[1:n]` and `[1:m]`, where `[m,n] = size(ZData)`.

ZDataSource

MATLAB variable, as a string

Link ZData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

How To

- “Core Graphics Objects”
- “Setting Default Property Values”

contourslice

Purpose Draw contours in volume slice planes

Syntax

```
contourslice(X,Y,Z,V,Sx,Sy,Sz)
contourslice(X,Y,Z,V,Xi,Yi,Zi)
contourslice(V,Sx,Sy,Sz)
contourslice(V,Xi,Yi,Zi)
contourslice(...,n)
contourslice(...,cvals)
contourslice(...,[cv cv])
contourslice(...,'method')
contourslice(axes_handle,...)
h = contourslice(...)
```

Description `contourslice(X,Y,Z,V,Sx,Sy,Sz)` draws contours in the x -, y -, and z -axis aligned planes at the points in the vectors Sx , Sy , Sz . The arrays X , Y , and Z define the coordinates for the volume V and must be monotonic and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). The color at each contour is determined by the volume V , which must be an m -by- n -by- p volume array.

`contourslice(X,Y,Z,V,Xi,Yi,Zi)` draws contours through the volume V along the surface defined by the 2-D arrays Xi , Yi , Zi . The surface should lie within the bounds of the volume.

`contourslice(V,Sx,Sy,Sz)` and `contourslice(V,Xi,Yi,Zi)` (omitting the X , Y , and Z arguments) assume $[X,Y,Z] = \text{meshgrid}(1:n,1:m,1:p)$, where $[m,n,p] = \text{size}(v)$.

`contourslice(...,n)` draws n contour lines per plane, overriding the automatic value.

`contourslice(...,cvals)` draws `length(cval)` contour lines per plane at the values specified in vector `cvals`.

`contourslice(...,[cv cv])` computes a single contour per plane at the level `cv`.

`contourslice(..., 'method')` specifies the interpolation method to use. *method* can be `linear`, `cubic`, or `nearest`. `nearest` is the default except when the contours are being drawn along the surface defined by X_i, Y_i, Z_i , in which case `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`contourslice(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = contourslice(...)` returns a vector of handles to patch objects that are used to implement the contour lines.

Examples

Contour Slices of Fluid Flow

Store the matrices X, Y, Z , and V from the flow data set.

```
[X,Y,Z,V] = flow;
```

Create nine contour plots in the y - z plane, no plots in the x - z plane, and one plot in the x - y plane by specifying S_x as a vector of nine elements, S_y as an empty vector, and S_z as a scalar.

```
Sx = 1:9;  
Sy = [];  
Sz = 0;
```

Draw 10 contour lines between -8 and 2 by specifying `cvals` as a 10-element vector of linearly spaced values between -8 and 2.

```
cvals = linspace(-8,2,10);
```

Create the contour slice plots and set the axis limits. Set the data aspect ratio, change the camera position, and display the black box outline.

```
figure  
contourslice(X,Y,Z,V,Sx,Sy,Sz,cvals);  
  
axis([0,10,-3,3,-3,3]);  
daspect([1,1,1]);
```

contourslice

```
campos([0, -20, 7]);  
box on
```

Contour Slices Along Spherical Surface

Set up matrices X, Y, and Z using the meshgrid function.

```
x = -2:0.2:2;  
y = -2:0.25:2;  
z = -2:0.16:2;
```

```
[X,Y,Z] = meshgrid(x,y,z);
```

Use X, Y, and Z to define V as a matrix of volume data.

```
V = X.*exp(-X.^2-Y.^2-Z.^2);
```

Return matrices Xi, Yi, and Zi from the sphere function.

```
[Xi,Yi,Zi] = sphere;
```

Draw contours through the volume V along the surface defined by Xi, Yi, and Zi. Change the plot view to a 3-D view.

```
contourslice(X,Y,Z,V,Xi,Yi,Zi)  
view(3)
```

contourslice

Purpose

Summary of classes in MATLAB Constraints Interface

Description

Constraints specify business rules against which to qualify a calculated value. Use constraints in conjunction with the `matlab.unittest.qualifications` qualification methods `assertThat`, `assumeThat`, `fatalAssertThat`, or `verifyThat`. Constraints determine whether or not a calculated (actual) value satisfies the constraint. Constraints also provide diagnostics. The `matlab.unittest.constraints` package consists of the following classes.

- “Constraint Implementations” on page 1-1145
- “Actual Value Proxies” on page 1-1148
- “Tolerances” on page 1-1148
- “Comparators” on page 1-1148

Constraint Implementations

Fundamental Constraint-Related Interfaces

`matlab.unittest.constraints.BooleanConstraint` Interface class for boolean combinations of constraints

`matlab.unittest.constraints.Constraint` Fundamental interface class for comparisons

General Purpose

`matlab.unittest.constraints.EventuallySatisfies` Constraint for value to asynchronously satisfy constraint

`matlab.unittest.constraints.HasField` Constraint specifying structure containing particular field

`matlab.unittest.constraints.IsAnything` Constraint specifying any value

`matlab.unittest.constraints.IsEqualTo` General constraint to compare for equality

`matlab.unittest.constraints.IsFalse` Constraint specifying false value

matlab.unittest.constraints.IsSameHandleAs **Constraint** specifying handle instance same as another

matlab.unittest.constraints.IsTrue **Constraint** specifying true value

matlab.unittest.constraints>ReturnsConstraint **Constraint** specifying function handle that returns true

Errors and Warnings

matlab.unittest.constraints.IssuesNoWarnings **Constraint** specifying function that issues no warnings

matlab.unittest.constraints.IssuesWarning **Constraint** specifying function that issues expected warning profile

matlab.unittest.constraints.Throws **Constraint** specifying function handle that throws MException

Inequalities

matlab.unittest.constraints.IsGreaterThan **Constraint** specifying value greater than another value

matlab.unittest.constraints.IsGreaterThanOrEqualTo **Constraint** specifying value greater than or equal to another value

matlab.unittest.constraints.IsLessThan **Constraint** specifying value less than another value

matlab.unittest.constraints.IsLessThanOrEqualTo **Constraint** specifying value less than or equal to another value

Array Size

matlab.unittest.constraints.HasElementCount **Constraint** specifying expected number of elements

matlab.unittest.constraints.HasLength **Constraint** specifying expected length of array

matlab.unittest.constraints.HasSizeConstraint specifying expected size of array

matlab.unittest.constraints.IsEmptyConstraint specifying empty value

Type

matlab.unittest.constraints.IsInstanceOfConstraint specifying inclusion in given class hierarchy

matlab.unittest.constraints.IsOfClassConstraint specifying class type

Strings

matlab.unittest.constraints.ContainsSubstringConstraint specifying string containing substring

matlab.unittest.constraints.EndsWithSubstringConstraint specifying string ending with substring

matlab.unittest.constraints.IsSubStringOfConstraint specifying substring of another string

matlab.unittest.constraints.MatchesConstraint specifying string matches regular expression

matlab.unittest.constraints.StartsWithSubstringConstraint specifying string starting with substring

Finiteness

matlab.unittest.constraints.HasInfConstraint specifying array containing any infinite value

matlab.unittest.constraints.HasNaNConstraint specifying array containing NaN value

matlab.unittest.constraints.IsFiniteConstraint specifying finite value

Numeric Attributes

matlab.unittest.constraints.IsReal Constraint specifying real valued array

matlab.unittest.constraints.IsSparse Constraint specifying sparse array

Actual Value Proxies

matlab.unittest.constraints.AnyCellTest If any element of cell array meets constraint

matlab.unittest.constraints.AnyElementTest If any element of array meets constraint

matlab.unittest.constraints.EveryCellTest If all elements of cell array meet constraint

matlab.unittest.constraints.EveryElementTest If all elements of array meet constraint

Tolerances

matlab.unittest.constraints.AbsoluteTolerance Absolute numeric tolerance

matlab.unittest.constraints.RelativeTolerance Relative numeric tolerance

matlab.unittest.constraints.Tolerance Abstract interface class for tolerances

Comparators

matlab.unittest.constraints.CellComparator Comparator for cell arrays

matlab.unittest.constraints.LogicalComparator Comparator for two logical values

matlab.unittest.constraints.NumericComparator Comparator for numeric data types

matlab.unittest.constraints.ObjectComparator for MATLAB or Java objects

matlab.unittest.constraints.PublicPropertyComparator for public properties of MATLAB objects

matlab.unittest.constraints.StringComparator for two strings

matlab.unittest.constraints.StructComparator for MATLAB structure arrays

matlab.unittest.constraints.AbsoluteTolerance

Superclasses Tolerance

Purpose Absolute numeric tolerance

Description This numeric Tolerance assesses the magnitude of the difference between actual and expected values. For the tolerance to be satisfied, `abs(expVal - actVal) <= absTol` must be true.

Construction `AbsoluteTolerance(tolVals)` creates an absolute tolerance object that assesses the magnitude of the difference between the actual and expected values.

The data types of the inputs to the `AbsoluteTolerance` constructor determine the data types to which the tolerance is applied.

For example, `AbsoluteTolerance(10*eps)` constructs an `AbsoluteTolerance` for comparing double-precision numeric arrays while `AbsoluteTolerance(int8(2))` constructs an `AbsoluteTolerance` for comparing numeric arrays of type `int8`. If the actual and expected values being compared contain more than one numeric data type, the tolerance only applies to the data types specified by the values passed into the constructor.

Different tolerance values can be specified for different data types by passing multiple tolerance values to the constructor. For example, `AbsoluteTolerance(10*eps, 10*eps('single'), int8(1))` constructs an `AbsoluteTolerance` that would apply the following absolute tolerances.

- `10*eps` applies an absolute tolerance of `10*eps` for double-precision numeric arrays.
- `10*eps('single')` applies an absolute tolerance of `10*eps` for single-precision numeric arrays.
- `int8(1)` applies an absolute tolerance of 1 for numeric arrays of type `int8`.

You can specify more than one tolerance for a particular data type by combining tolerances with the & and | operators. To combine two tolerances, the sizes of the tolerance values for each data type must be compatible.

Input Arguments

tolVals

Numeric tolerances, specified as a cell array of numeric arrays. Each input argument contains the tolerance specification for a particular data type. Each numeric array can be a scalar or array with the same number of dimensions as the actual and expected values.

Properties

Values

Numeric tolerances, specified by the tolVals input argument.

Methods

and	Form logical element-wise conjunction of tolerances
or	Form logical element-wise disjunction of tolerances

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test with Absolute Tolerance

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.AbsoluteTolerance;
```

```
testCase = TestCase.forInteractiveUse;
```

matlab.unittest.constraints.AbsoluteTolerance

Assert that the difference between and actual value, 4.1, and an expected value, 4.5, is less than 0.5.

```
testCase.assertThat(4.1, IsEqualTo(4.5, ...  
    'Within', AbsoluteTolerance(0.5)));
```

Interactive assertion passed.

Specify Absolute Tolerance for Different Data Types

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.AbsoluteTolerance;
```

```
testCase = TestCase.forInteractiveUse;
```

Create the following actual and expected cell arrays.

```
act = {'abc', 123, single(106), int8([1, 2, 3])};  
exp = {'abc', 122, single(105), int8([2, 4, 6])};
```

Test whether the arrays satisfy the `AbsoluteTolerance` constraint within a value of 2.

```
testCase.verifyThat(act, IsEqualTo(exp, ...  
    'Within', AbsoluteTolerance(2)));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
    Path to failure: <Value>{3}
```

```
    --> The values are not equal using "isequaln".
```

```
    --> The tolerance does not support single values so it was not used.
```

```
Actual Value:
    106
Expected Value:
    105
```

```
Actual cell:
    'abc'    [123]    [106]    [1x3 int8]
Expected cell:
    'abc'    [122]    [105]    [1x3 int8]
```

The test fails because the tolerance is only applied to the double data type.

Create a tolerance object that specifies different tolerances for different data types.

```
tolObj = AbsoluteTolerance(2, single(3), int8([2, 3, 5]));
```

A tolerance of 2 is applied to double valued data. A tolerance of 3 is applied to single valued data. A tolerance of [2 3 5] is applied to corresponding array elements of int8 valued data.

Verify that the expected and actual values satisfy the `AbsoluteTolerance` constraint.

```
testCase.verifyThat(act, IsEqualTo(exp, 'Within', tolObj));
```

```
Interactive verification passed.
```

Combine Absolute and Relative Tolerances

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
```

matlab.unittest.constraints.AbsoluteTolerance

```
testCase = TestCase.forInteractiveUse;
```

Define an actual value approximation for pi.

```
act = 3.14;
```

Construct a tolerance object to test that difference between the actual and expected values is within 0.001 and within 0.25%.

```
tolObj = AbsoluteTolerance(0.001) & RelativeTolerance(0.0025);
```

Verify that the actual value is within the tolerance of the expected value of pi.

```
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
    --> The values are not equal using "isequaln".
```

```
    --> AndTolerance failed.
```

```
        --> AbsoluteTolerance failed.
```

```
            --> The value was not within absolute tolerance.
```

```
                Tolerance Value:
```

```
                    1.0000000000000000e-03
```

```
            --> RelativeTolerance passed.
```

```
Actual Value:
```

```
    3.1400000000000000
```

```
Expected Value:
```

```
    3.141592653589793
```

The actual value does not satisfy the `AbsoluteTolerance` constraint.

Construct a constraint that is satisfied if the values are within 0.001 or 0.25%, and retest the actual value.

```
tolObj = AbsoluteTolerance(0.001) | RelativeTolerance(0.0025);  
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj));
```

Interactive verification passed.

Combine Absolute and Relative Tolerances to Test Small and Large Values

Typically when testing equality of values, an absolute (floor) tolerance dominates when the values are near zero, and a relative tolerance dominates for larger values.

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.AbsoluteTolerance;  
import matlab.unittest.constraints.RelativeTolerance;
```

```
testCase = TestCase.forInteractiveUse;
```

Define two structures containing electromagnetic properties of a vacuum. One structure, `approxVacuumProps`, contains approximate values for the permeability and speed of light in a vacuum.

```
approxVacuumProps.Permeability = 1.2566e-06; % Approximate  
approxVacuumProps.Permittivity = 8.854187817*10^-12;  
approxVacuumProps.LightSpeed = 2.9979e+08; % Approximate
```

```
baselineVacuumProps.Permeability = 4*pi*10^-7;  
baselineVacuumProps.Permittivity = 8.854187817*10^-12;  
baselineVacuumProps.LightSpeed = 1/sqrt(...  
    baselineVacuumProps.Permeability*baselineVacuumProps.Permittivity);
```

Test that the relative difference between the approximate and baseline values is within `eps*1e11`.

matlab.unittest.constraints.AbsoluteTolerance

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
    'Within', RelativeTolerance(eps*1e11)));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

IsEqualTo failed.

--> NumericComparator failed.

Path to failure: <Value>.Permeability

--> The values are not equal using "isequaln".

--> RelativeTolerance failed.

--> The value was not within relative tolerance.

Tolerance Value:

2.220446049250313e-05

Actual Value:

1.2566000000000000e-06

Expected Value:

1.256637061435917e-06

Actual struct:

Permeability: 1.2566000000000000e-06

Permittivity: 8.854187816999999e-12

LightSpeed: 299790000

Expected struct:

Permeability: 1.256637061435917e-06

Permittivity: 8.854187816999999e-12

LightSpeed: 2.997924580105029e+08

The test fails because the relative difference in the permeabilities is not within the tolerance. The difference between the two values is small, but the numbers are close to zero, so the difference relative to their size isn't small enough to satisfy the tolerance.

matlab.unittest.constraints.AbsoluteTolerance

Construct a tolerance object to test that the absolute difference between the approximate and baseline values is within $1e-4$.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps,
    'Within', AbsoluteTolerance(1e-4)));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

IsEqualTo failed.

```
--> NumericComparator failed.
```

```
    Path to failure: <Value>.LightSpeed
```

```
    --> The values are not equal using "isequaln".
```

```
    --> AbsoluteTolerance failed.
```

```
        --> The value was not within absolute tolerance.
```

```
            Tolerance Value:
```

```
                1.0000000000000000e-04
```

```
            Actual Value:
```

```
                299790000
```

```
            Expected Value:
```

```
                2.997924580105029e+08
```

```
Actual struct:
```

```
    Permeability: 1.2566000000000000e-06
```

```
    Permittivity: 8.8541878169999999e-12
```

```
    LightSpeed: 299790000
```

```
Expected struct:
```

```
    Permeability: 1.256637061435917e-06
```

```
    Permittivity: 8.8541878169999999e-12
```

```
    LightSpeed: 2.997924580105029e+08
```

matlab.unittest.constraints.AbsoluteTolerance

The test fails because the absolute difference in the speed of light is not within the tolerance. The difference between the two values is small relative to their size, but too large to satisfy the tolerance.

Construct a logical disjunction of tolerance objects to test that the absolute difference between the approximate and baseline values is within $1e-4$ or the relative difference is within $\text{eps} \cdot 1e11$. This tolerance is used so permeability values, which are close to zero, satisfy the absolute (floor) tolerance, and speed of light values, which are large, satisfy the relative tolerance.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...  
    'Within', RelativeTolerance(eps*1e11)| AbsoluteTolerance(1e-4)));
```

```
Interactive verification passed.
```

[matlab.unittest.constraints.RelativeTolerance](#) |
[matlab.unittest.constraints.IsEqualTo](#)

Concepts

matlab.unittest.constraints.AbsoluteTolerance.and

Purpose Form logical element-wise conjunction of tolerances

Syntax `outTo1Obj = and(to1Obj1, to1Obj2)`

Description `outTo1Obj = and(to1Obj1, to1Obj2)` forms the logical element-wise conjunction of tolerances and returns a single tolerance, `outTo1Obj`. This is a means to specify that every element of the actual value should be equal to the expected value to within the tolerance specified by both `to1Obj1` and `to1Obj2`. A qualification failure occurs when either `to1Obj1` or `to1Obj2` is not satisfied for one or more elements of the comparison values.

Typically, the `and` method is not called directly, but the `and` operator, `&`, is used to denote the conjunction of any two tolerance objects.

Input Arguments **to1Obj**
Tolerance instance

Examples **Form Logical and of Tolerances**

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;

% Create a TestCase for interactive use
testCase = TestCase.forInteractiveUse;

% Passing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(2) & RelativeTolerance(0.02)));
testCase.verifyThat([101, 105], IsEqualTo([100, 100], 'Within', ...
    AbsoluteTolerance([2, 10]) & RelativeTolerance([0.02, 0.1])));

% Failing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
```

matlab.unittest.constraints.AbsoluteTolerance.and

```
        AbsoluteTolerance(2) & RelativeTolerance(0.02));  
testCase.verifyThat([101, 105], IsEqualTo([100, 100], 'Within', ...  
        AbsoluteTolerance(2) & RelativeTolerance(0.02));
```

See Also or

Purpose Form logical element-wise disjunction of tolerances

Syntax `outTo1Obj = or(tolObj1,tolObj2)`

Description `outTo1Obj = or(tolObj1,tolObj2)` forms the logical element-wise disjunction of tolerances and returns a single tolerance, `outTo1Obj`. This is a means to specify that every element of the actual value should be equal to the expected value to within the tolerance specified by either `tolObj1` or `tolObj2`. A qualification failure occurs when both `tolObj1` and `tolObj2` are not satisfied for one or more elements of the comparison values.

Forming the logical disjunction of tolerances is particularly useful when relative tolerance is used in general, but absolute tolerance is used when values are small.

Typically, the `or` method is not called directly, but the `or` operator, `|`, is used to denote the disjunction of any two tolerance objects.

Input Arguments

tolObj
Tolerance instance

Examples

Form Logical or of Tolerances

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
```

```
% Create a TestCase for interactive use
testCase = TestCase.forInteractiveUse;
```

```
% Simple passing qualification
testCase.verifyThat(105, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(3) | RelativeTolerance(0.1)));
```

```
% The following qualification passes because the or
```

```
% operation is performed element-wise between the
% actual and expected values being compared:
testCase.verifyThat([8, 104], IsEqualTo([10, 100], 'Within', ...
    AbsoluteTolerance(3) | RelativeTolerance(0.05)));
% Note that the following would fail:
testCase.verifyThat([8, 104], ...
    IsEqualTo([10, 100], 'Within', AbsoluteTolerance(3)) | ...
    IsEqualTo([10, 100], 'Within', RelativeTolerance(0.05)));

% Failing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(0.5) | RelativeTolerance(0)));
testCase.verifyThat([101, 101], IsEqualTo([100, 100], 'Within', ...
    AbsoluteTolerance([2, 0.5]) | RelativeTolerance([0.02, 0.001])));
```

Purpose	Test if any element of cell array meets constraint
Description	<p>The AnyCellOf class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of a cell array, which ensures that a passing result occurs if at least one element of the cell array satisfies the constraint.</p> <p>It is intended that you use this class through <code>matlab.unittest</code> qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.</p>
Construction	<p><code>AnyCellOf(actVal)</code> creates a proxy instance that tests if any element of a provided cell array, <code>actVal</code>, meets a constraint. The test passes if at least one element individually satisfies the constraint.</p>
	Input Arguments
	actVal Actual value to test against constraint
Properties	ActualValue Actual value to test against constraint. Set this property through the constructor via the <code>actVal</code> input argument.
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
Examples	Test That Any Cell Satisfies Constraint Create a test case for interactive testing. <pre>import matlab.unittest.TestCase import matlab.unittest.constraints.AnyCellOf;</pre>

matlab.unittest.constraints.AnyCellOf

```
testCase = TestCase.forInteractiveUse;
```

Test that at least one cell of actVal is finite.

```
import matlab.unittest.constraints.IsFinite;
actVal = {NaN, Inf, 5};
testCase.verifyThat(AnyCellOf(actVal), IsFinite);
```

Interactive verification passed.

Test that at least one cell of the actual value contains five elements.

```
import matlab.unittest.constraints.HasElementCount
testCase.verifyThat(AnyCellOf({42, [11 38], 1:5}), HasElementCount(5));
```

Interactive verification passed.

Test that at least one cell of the actual value matches the string 'tea' regardless of case.

```
import matlab.unittest.constraints.Matches
testCase.verifyThat(AnyCellOf({'Coffee', 'Tea', 'Water'}), ...
    Matches('tea', 'IgnoringCase', true));
```

Interactive verification passed.

Test that at least one cell of the actual value is less than zero.

```
import matlab.unittest.constraints.IsLessThan;
testCase.verifyThat(AnyCellOf({1, 5}), IsLessThan(0));
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
```

All cells failed. The first cell failed because:

```
--> IsLessThan failed.
```

```
    --> The value must be less than the maximum value.
```

```
Actual Value:
    1
Maximum Value (Exclusive):
    0
```

```
Actual Value Cell Array:
    [1]    [5]
```

Neither actual value element is less than zero.

Test that neither cell of the actual value is empty.

```
import matlab.unittest.constraints.IsEmpty
testCase.verifyThat(AnyCellOf({inputParser.empty, ''}), ~IsEmpty)
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
```

All cells failed. The first cell failed because:

```
--> Negated IsEmpty failed.
    --> The value must not be empty.
    --> The value has a size of [0 0].
```

```
Actual Value:
    0x0 inputParser array with properties:
```

```
    FunctionName
    CaseSensitive
    KeepUnmatched
    PartialMatching
    StructExpand
    Parameters
    Results
    Unmatched
    UsingDefaults
```

matlab.unittest.constraints.AnyCellOf

```
Actual Value Cell Array:  
[] ''
```

Both actual value elements are empty.

Concepts

Purpose

Test if any element of array meets constraint

Description

The `AnyElementOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of an array, which ensures that a passing result occurs when at least one element of the array satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

Construction

`AnyElementOf(actVal)` creates a proxy instance that tests if any element of a provided array, `actVal`, meets a constraint. The test passes if at least one element individually satisfies the constraint.

Tips

- `AnyElementOf` checks if any element in the provided array satisfies an associated constraint. However, there are some constraints, such as `HasNaN` and `HasInf`, that natively validate if any of the elements satisfy a condition. In these situations, use of `AnyElementOf` is unnecessary and impedes qualification performance.

Input Arguments

`actVal`

Actual value to test against constraint

Properties

`ActualValue`

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

Examples

Test That Any Element Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.AnyElementOf;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that at least one element of actVal is finite.

```
import matlab.unittest.constraints.IsFinite;
actVal = [NaN, Inf, 5];
testCase.verifyThat(AnyElementOf(actVal), IsFinite);
```

```
Interactive verification passed.
```

Test that at least one element of the actual value is complex.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(AnyElementOf([1+0i 4i]), ~IsReal);
```

```
Interactive verification passed.
```

Test that at least one element of the actual value array is less than zero.

```
import matlab.unittest.constraints.IsLessThan;
testCase.verifyThat(AnyElementOf([1 5]), IsLessThan(0));
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
```

```
-----
All elements failed. The first element failed because:
```

```
--> IsLessThan failed.
```

```
    --> The value must be less than the maximum value.
```

```
Actual Value:
```

```
1
Maximum Value (Exclusive):
0
```

```
Actual Value Array:
1    5
```

Neither actual value element is less than zero.

Concepts

matlab.unittest.constraints.BooleanConstraint

Superclasses Constraint

Purpose Interface class for boolean combinations of constraints

Description The BooleanConstraint interface class provides an interface for boolean combinations of Constraints. Any constraint that derives from BooleanConstraint can be combined and negated using the and (&), or (|), and not (~) operators.

Classes that derive from the BooleanConstraint interface class must implement everything required by the standard Constraint interface. When a given constraint is negated, the diagnostics must be written in a different form than for a standard (non-negated) failure. Therefore, classes deriving from the BooleanConstraint class must implement a method to provide a Diagnostic object for the negated case, in addition to the non-negated case.

In exchange for meeting these requirements, all BooleanConstraint implementations inherit the appropriate MATLAB overloads for and, or, and not so that they can be combined with other BooleanConstraints objects or negated.

Methods

and	Form logical conjunction of constraints
getNegativeDiagnosticFor	Produce negated diagnostic for value
not	Form logical negation of constraint
or	Form logical disjunction of constraints

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create Boolean HasSameSizeAs Constraint

Create a custom constraint that determines if a given value is the same size as an expected value.

In a file in your working folder, create a file `HasSameSizeAs.m`. The constructor accepts a value to compare to the actual size. This value is stored within the `ValueWithExpectedSize` property. It is recommended that `BooleanConstraint` implementations be immutable, so set the property `SetAccess=immutable`.

```
classdef HasSameSizeAs < matlab.unittest.constraints.BooleanConstraint
    properties(SetAccess=immutable)
        ValueWithExpectedSize
    end

    methods
        function constraint = HasSameSizeAs(value)
            constraint.ValueWithExpectedSize = value;
        end
    end
end
```

Include these methods in the `methods` block in `HasSameSizeAs.m`. Since the `BooleanConstraint` class is a subclass of `Constraint`, classes that derive from it must implement the `satisfiedBy` and `getDiagnosticFor` methods. For more information about these methods, see `matlab.unittest.constraints.Constraint`.

```
    methods
        function bool = satisfiedBy(constraint, actual)
            bool = isequal(size(actual), size(constraint.ValueWithExpectedSize));
        end
        function diag = getDiagnosticFor(constraint, actual)
            import matlab.unittest.diagnostics.StringDiagnostic;

            if constraint.satisfiedBy(actual)
```

matlab.unittest.constraints.BooleanConstraint

```
        diag = StringDiagnostic('HasSameSizeAs passed.');
```

```
    else
```

```
        diag = StringDiagnostic(sprintf(...
```

```
            'HasSameSizeAs failed.\nActual Size: [%s]\nExpectedSi
```

```
            int2str(size(actual)), int2str(size(constraint.ValueW
```

```
        end
```

```
    end
```

```
end
```

Include the `getNegativeDiagnosticFor` method in the `a` methods block with protected access in `HasSameSizeAs.m`. Classes that derive from `BooleanConstraint` must implement the `getNegativeDiagnosticFor` method. This method must provide a `Diagnostic` object that is expressed in the negative sense of the constraint.

```
    methods(Access=protected)
```

```
        function diag = getNegativeDiagnosticFor(constraint, actual)
```

```
            import matlab.unittest.diagnostics.StringDiagnostic;
```

```
            if constraint.satisfiedBy(actual)
```

```
                diag = StringDiagnostic(sprintf(...
```

```
                    ['Negated HasSameSizeAs failed.\nSize [%s] of ' ...
```

```
                    'Actual Value and Expected Value were the same ' ...
```

```
                    'but should not have been.'], int2str(size(actual)))
```

```
            else
```

```
                diag = StringDiagnostic('Negated HasSameSizeAs passed.');
```

```
            end
```

```
        end
```

```
    end
```

In exchange for implementing the required methods, the constraint inherits the appropriate `and`, `or`, and `not` overloads so it can be combined with other `BooleanConstraint` objects or negated.

HasSameSizeAs Class Definition Summary

```
classdef HasSameSizeAs < matlab.unittest.constraints.BooleanConstraint
```

```
    properties(SetAccess=immutable)
```

matlab.unittest.constraints.BooleanConstraint

```
        ValueWithExpectedSize
    end
    methods
        function constraint = HasSameSizeAs(value)
            constraint.ValueWithExpectedSize = value;
        end
        function bool = satisfiedBy(constraint, actual)
            bool = isequal(size(actual), size(constraint.ValueWithExpectedSize));
        end
        function diag = getDiagnosticFor(constraint, actual)
            import matlab.unittest.diagnostics.StringDiagnostic;

            if constraint.satisfiedBy(actual)
                diag = StringDiagnostic('HasSameSizeAs passed.');
            else
                diag = StringDiagnostic(sprintf(...
                    'HasSameSizeAs failed.\nActual Size: [%s]\nExpected Size: [%s]',
                    int2str(size(actual)), ...
                    int2str(size(constraint.ValueWithExpectedSize))));
            end
        end
    end
    methods(Access=protected)
        function diag = getNegativeDiagnosticFor(constraint, actual)
            import matlab.unittest.diagnostics.StringDiagnostic;
            if constraint.satisfiedBy(actual)
                diag = StringDiagnostic(sprintf(...
                    ['Negated HasSameSizeAs failed.\nSize [%s] of ' .
                    'Actual Value and Expected Value were the same ' .
                    'but should not have been.'], int2str(size(actual), 1, 2)));
            else
                diag = StringDiagnostic('Negated HasSameSizeAs passed.');
            end
        end
    end
end
end
```

matlab.unittest.constraints.BooleanConstraint

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasLength;
```

```
testCase = TestCase.forInteractiveUse;
```

Test a passing case.

```
testCase.verifyThat(zeros(5), HasLength(5) | ~HasSameSizeAs(repmat(1,5)))
```

```
Interactive verification passed.
```

The test passes because one of the or conditions, `HasLength(5)`, is true.

Test a failing case.

```
testCase.verifyThat(zeros(5), HasLength(5) & ~HasSameSizeAs(repmat(1,5)))
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
```

```
AndConstraint failed.
```

```
--> + [First Condition]:
```

```
    |   HasLength passed.
```

```
--> AND
```

```
    + [Second Condition]:
```

```
    |   Negated HasSameSizeAs failed.
```

```
    |   Size [5  5] of Actual Value and Expected Value were the same but
```

```
    -+-----
```

The test fails because one of the and conditions, `~HasSameSizeAs(repmat(1,5))`, is false.

Diagnostic | `matlab.unittest.constraints`

Concepts

matlab.unittest.constraints.BooleanConstraint.and

Purpose Form logical conjunction of constraints

Syntax `outConstObj = and(constObj1, constObj2)`

Description `outConstObj = and(constObj1, constObj2)` forms the logical conjunction of combinable constraints. The `and` method returns a constraint, `outConstObj`, that is the boolean conjunction of `constObj1` and `constObj2`. If `constObj1` and `constObj2` are not satisfied by the actual value provided, the comparison results in a qualification failure.

Typically, the `and` method is not called directly, but the `and` operator, `&`, is used to denote the conjunction of any two combinable constraints.

Input Arguments

constObj
BooleanConstraint instance

Examples Implement and method

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.ContainsSubstring;
import matlab.unittest.constraints.HasElementCount;
import matlab.unittest.constraints.HasSize;
import matlab.unittest.constraints.IsEmpty;
import matlab.unittest.constraints.IsInstanceOf;
import matlab.unittest.constraints.IsGreaterThan;
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
import matlab.unittest.constraints.IsOfClass;
import matlab.unittest.constraints.IsReal;

% Create a TestCase for interactive use
testCase = TestCase.forInteractiveUse;

% Passing qualifications
testCase.verifyThat(3, IsReal & IsGreaterThanOrEqualTo(3));
testCase.verifyThat('Some char', IsOfClass(?char) & ~IsEmpty);
testCase.verifyThat([1 2 3; 4 5 6], HasLength(3) & HasElementCount(6));
```

```
% Failing qualifications
testCase.verifyThat(3+i, IsGreaterThan(4), & IsReal);
testCase.verifyThat({1, 2}, IsInstanceOf(?cell) & HasSize([1 2]));
testCase.verifyThat('', ContainsSubstring('string') & IsEmpty);
```

or | not |

matlab.unittest.constraints.BooleanConstraint.getNegativeDiagnosticFor

Purpose Produce negated diagnostic for value

Syntax `diag = getNegativeDiagnosticFor(constObj, actVal)`

Description `diag = getNegativeDiagnosticFor(constObj, actVal)` produces a negated diagnostic for a value. The `getNegativeDiagnosticFor` method analyzes the provided value, `actVal`, against the constraint, `constObj`, and produces a `matlab.unittest.diagnostics.Diagnostic` object, `diag`, which corresponds to the negation of the constraint, `constObj`. This method is a protected method.

The diagnostics that this method produces are expressed in the negative sense of the constraint. For example, a hypothetical `IsTasty` constraint, when negated, should express that the actual value was "tasty", when it should not have been, and it should describe the details on why it was found to be tasty.

Like the `getDiagnosticFor` method of `Constraint`, the `getNegativeDiagnosticFor` is only called upon failures, and thus can afford a more detailed analysis than the `satisfiedBy` method.

Input Arguments

constObj
BooleanConstraint instance

actVal
Value for comparison

Examples **Implement getNegativeDiagnosticFor method**

```
function diag = getNegativeDiagnosticFor(constraint, actual)
% getNegativeDiagnosticFor - produce a diagnostic when the constraint is
%
% This method is called by the testing framework when the constraint has
% been met but should not have been met because it was negated in a
% boolean expression. It should produce a Diagnostic result that
% describes the failure in the correct terms which express the
% requirement that the constraint actually should not have been met.
```

matlab.unittest.constraints.BooleanConstraint.getNegative

```
import matlab.unittest.diagnostics.StringDiagnostic;

if constraint.satisfiedBy(actual)
    % Create the negative diagnostic. This will show information such
    % constraint class name and display the raw actual and expected va
    % Using the DiagnosticSense.NegativeDiagnostic enumeration also
    % produces language more appropriate for the negated case.
    diag = StringDiagnostic(sprintf(...
        'Negated HasSameSizeAs failed.\nSize [%s] of Actual Value and
        int2str(size(actual))));
else
    % Produce a passing diagnostic, with language appropriate for the
    diag = StringDiagnostic('Negated HasSameSizeAs passed. ');
end %if

end %function
```

See Also

[getDiagnosticFor](#) | [satisfiedBy](#) | [Diagnostic](#) | [not](#)

matlab.unittest.constraints.BooleanConstraint.not

Purpose Form logical negation of constraint

Syntax `negConstObj = not(constObj)`

Description `negConstObj = not(constObj)` forms the logical negation of a negatable constraint. The `not` method returns a constraint, `negConstObj`, that is the boolean complement of the constraint object, `constObj`. This is a means to specify that the constraint should not be satisfied by the actual value provided, and that a qualification failure should be produced when the constraint is satisfied.

Typically, the `not` method is not called directly, but the tilde operator, `~`, is used to denote the negation of any given negatable constraint. Upon encountering a failure, the `getNegativeDiagnosticFor` method provides the resulting constraint diagnostics.

Input Arguments

constObj
BooleanConstraint instance

Examples Implement not method

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.HasNaN;
import matlab.unittest.constraints.IsEmpty;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.IsInstanceOf;
import matlab.unittest.constraints.IsReal;
import matlab.unittest.constraints.IsOfClass;

% Create a TestCase for interactive use
testCase = TestCase.forInteractiveUse;

% Passing qualifications
testCase.verifyThat(3, ~IsEqualTo(4));
testCase.verifyThat('Some char', ~IsInstanceOf(?double));
testCase.verifyThat(3, ~HasNaN);
```

```
% Failing qualifications
testCase.verifyThat(3, ~IsReal);
testCase.verifyThat('Some char', ~IsOfClass('char'));
testCase.verifyThat([], ~IsEmpty);
```

See Also

[getNegativeDiagnosticFor](#) |
[matlab.unittest.constraints.BooleanConstraint](#) | [and](#) | [or](#)

matlab.unittest.constraints.BooleanConstraint.or

Purpose Form logical disjunction of constraints

Syntax `outConstObj = or(constObj1, constObj2)`

Description `outConstObj = or(constObj1, constObj2)` forms the logical disjunction of combinable constraints. The `or` method returns a constraint, `outConstObj`, that is the boolean disjunction of `constObj1` and `constObj2`. The comparison only results in a qualification failure if both `constObj1` and `constObj2` are not satisfied by the provided actual value.

Typically, the `or` method is not called directly, but the `or` operator, `|`, is used to denote the disjunction of any two combinable constraints.

Input Arguments

constObj
BooleanConstraint instance

Examples **Implement or method**

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.HasInf;
import matlab.unittest.constraints.HasNaN;
import matlab.unittest.constraints.EndsWithSubstring;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.IsGreaterThan;
import matlab.unittest.constraints.IsLessThan;
import matlab.unittest.constraints.IsOfClass;
import matlab.unittest.constraints.IsReal;
import matlab.unittest.constraints.StartsWithSubstring;

% Create a TestCase for interactive use
testCase = TestCase.forInteractiveUse;

% Passing qualifications
testCase.verifyThat([3 NaN 5], HasNaN | HasInf);
testCase.verifyThat(5, IsEqualTo(5) | IsLessThan(0));
```

```
testCase.verifyThat(-3, IsEqualTo(5) | IsLessThan(0));

% Failing qualifications
testCase.verifyThat(3+i, IsGreaterThan(4), | IsReal);
testCase.verifyThat(true, IsOfClass(?char) | IsOfClass(?cell));
testCase.verifyThat('Some long string', StartsWithSubstring('long') |
```

matlab.unittest.constraints.CellComparator

Purpose	Comparator for cell arrays
Description	The CellComparator compares cell arrays.
Construction	<p>CellComparator creates a comparator for cell arrays.</p> <p>CellComparator(compObj) indicates a comparator, compObj, that defines the comparator used to compare values contained in the cell array. By default, a cell comparator only supports empty cell arrays.</p> <p>CellComparator(__,Name,Value) provides a comparator with additional options specified by one or more Name,Value pair arguments. Name must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.</p>
Input Arguments	<p>compObj Comparator object</p> <p>Name-Value Pair Arguments</p> <p>Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.</p> <p>'IgnoringCase'</p> <p>Indicator whether the comparator is insensitive to case, specified as false or true (logical 0 or 1). When it is false, the comparator is sensitive to case. The comparator only utilizes this name-value pair if the contents being compared are strings.</p> <p>Default: false</p> <p>'IgnoringWhitespace'</p>

Indicator whether the comparator is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace. Whitespace characters are space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator only utilizes this name-value pair if the contents being compared are strings.

Default: `false`

'Recursively'

Indicator of whether comparator operates recursively, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types the cell comparator supports are fully supported in recursion. For example:

```
comp1 = CellComparator(StringComparator)
comp2 = CellComparator(StringComparator, 'Recursively', true)
```

Both `comp1` and `comp2` support a cell arrays of strings. However, only `comp2` supports cell arrays that recursively contain either cell arrays or strings as their elements.

Default: `false`

'Within'

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. The comparator only utilizes this name-value pair if the contents being compared are a numeric type.

Default: (empty)

matlab.unittest.constraints.CellComparator

Properties

IgnoreCase

Indicator whether the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'.

IgnoreWhitespace

Indicator whether the comparator is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'.

Recursive

Indicator of whether comparator operates recursively, specified in the name-value pair argument, 'Recursively'.

Tolerance

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Compare Cell Arrays

Create a test case for interactive testing.

```
import matlab.unittest.constraints.CellComparator;
import matlab.unittest.constraints.StringComparator;
import matlab.unittest.constraints.IsEqualTo;
```

```
testCase = matlab.unittest.TestCase;
```

Use a `CellComparator` to test that two cell arrays are equal to each other.

```
actual = {'abc', 'def'};
expected = {'abc', 'def'};
testCase.verifyThat(actual, IsEqualTo(expected, ...
```

```
'Using', CellComparator(StringComparator)));
```

Interactive verification passed.

By default, the `CellComparator` only supports comparison empty cell arrays, it is necessary to pass it a `StringComparator`.

Change the actual value and compare it to the expected value. For the constraint to be satisfied, it is necessary that you construct the constraint to ignore case and whitespace.

```
actual = {'ABC', 'D E F'};
testCase.verifyThat(actual, IsEqualTo(expected, 'Using', ...
    CellComparator(StringComparator, ...
    'IgnoringWhitespace', true, 'IgnoringCase', true)));
```

Interactive verification passed.

Test nested cell arrays of strings by constructing the comparator to operate recursively.

```
actual = {'abc', {'def', 'ghi'}};
expected = {'abc', {'def', 'ghi'}};

testCase.verifyThat(actual, IsEqualTo(expected, 'Using', ...
    CellComparator(StringComparator, 'Recursively', true)));
```

Interactive verification passed.

Concepts

matlab.unittest.constraints.Constraint

Purpose Fundamental interface class for comparisons

Description The Constraint interface class is the means by which `matlab.unittest.constraints` encode comparison logic and the corresponding diagnostic information. Every comparison that conditionally can produce a failure inherits from the Constraint interface class.

Classes deriving from the Constraint interface class must provide a means to determine if a given value satisfies the constraint. To do this, implement the `satisfiedBy` method, which includes the definition of the underlying comparison logic. Classes deriving from the Constraint class also must provide a diagnostic for any given actual value. The testing framework uses the diagnostic when it encounters a qualification failure. To do this, implement the `getDiagnosticFor` method.

In exchange for meeting these requirements, all Constraint implementations are easily used with all qualification types through the `verifyThat`, `assertThat`, `assumeThat`, or `fatalAssertThat` methods. The qualifications use the comparison and diagnostic knowledge contained within the constraints. Also, the constraints can be used in situations where a test failure is not wanted, but the testing framework needs to reuse the comparison logic. For example, a constraint implementation may want to use the logic defined inside of another constraint. Since the constraint can interact with the other constraint directly, it can use the logic without the potential of causing a qualification failure.

Methods

<code>getDiagnosticFor</code>	Produce diagnostic for compared value
<code>satisfiedBy</code>	Determine whether value satisfies constraint

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create HasSameSizeAs Constraint

Create a custom constraint that determines if a given value is the same size as an expected value.

In a file in your working folder, create a `HasSameSizeAs.m`. The constructor accepts a value to compare to the actual size. This value is stored within the `ValueWithExpectedSize` property. Since, it is recommended that `Constraint` implementations are immutable, set the property `SetAccess=immutable`.

```
classdef HasSameSizeAs < matlab.unittest.constraints.Constraint

    properties(SetAccess=immutable)
        ValueWithExpectedSize
    end

    methods
        function constraint = HasSameSizeAs(value)
            constraint.ValueWithExpectedSize = value;
        end
    end
end
```

Classes that derive from `Constraint` must implement the `satisfiedBy` method. This method must contain the comparison logic and return a boolean value.

Include the `satisfiedBy` method in the `methods` block in `HasSameSizeAs.m`.

```
function bool = satisfiedBy(constraint, actual)
    bool = isequal(size(actual), size(constraint.ValueWithExp
end
```

This method returns true if the actual size and expected size are equal.

Classes deriving from `Constraint` must implement the `getDiagnosticFor` method. This method must evaluate the actual

matlab.unittest.constraints.Constraint

value against the constraint and provide a Diagnostic object. In this example, `getDiagnosticFor` returns a `StringDiagnostic`. Include the `getDiagnosticFor` method in the methods block in `HasSameSizeAs.m`.

```
function diag = getDiagnosticFor(constraint, actual)
    import matlab.unittest.diagnostics.StringDiagnostic;

    if constraint.satisfiedBy(actual)
        diag = StringDiagnostic('HasSameSizeAs passed.');
```

```
    else
        diag = StringDiagnostic(sprintf(...
            'HasSameSizeAs failed.\nActual Size: [%s]\nExpectedSi
            int2str(size(actual)), int2str(size(constraint.ValueW
    end
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase

testCase = TestCase.forInteractiveUse;

Test a passing case.

testCase.verifyThat(zeros(5), HasSameSizeAs(repmat(1,5)));

Interactive verification passed.

Test a failing case.

testCase.verifyThat(zeros(5), HasSameSizeAs(ones(1,5)));

Interactive verification failed.

-----
Framework Diagnostic:
-----
HasSameSizeAs failed.
Actual Size: [5 5]
```

ExpectedSize: [1 5]

Concepts

matlab.unittest.constraints.Constraint.getDiagnosticFor

Purpose Produce diagnostic for compared value

Syntax `diag = getDiagnosticFor(constObj,actVal)`

Description `diag = getDiagnosticFor(constObj,actVal)` produces a diagnostic, `diag`, for a compared value, `actVal`. When creating a custom constraint, the class author must implement the `getDiagnosticFor` method so that it analyzes the value, `actVal`, against the constraint, `constObj`, and instantiates and returns a `matlab.unittest.diagnostics.Diagnostic` object.

Typically, the testing framework calls this method when it encounters a qualification failure. Therefore, the constraint author can afford to undertake a more detailed analysis in the `getDiagnosticFor` method than the `satisfiedBy` method.

Input Arguments

actVal
Value for comparison

constObj
Constraint instance

Output Arguments

diag
Diagnostic instance

Examples See example for `matlab.unittest.constraints.Constraint`.

See Also `satisfiedBy` | `Diagnostic` | `ConstraintDiagnostic`

matlab.unittest.constraints.Constraint.satisfiedBy

Purpose Determine whether value satisfies constraint

Syntax `TF = satisfiedBy(constObj, actVal)`

Description `TF = satisfiedBy(constObj, actVal)` determines whether a value, `actVal`, satisfies a constraint, `constObj`. The `satisfiedBy` method is used to determine qualification success or failure. It returns `true` or `false` (logical 0 or 1). When creating a custom constraint, a class author must place comparison logic in this method.

Since the most common usage is for the passing case, the constraint author should optimize for speed in that case. It is only in the failing case that more expensive detailed analysis is helpful.

Input Arguments

actVal

Value to evaluate against the constraint

constObj

Constraint instance

Examples See example for `matlab.unittest.constraints.Constraint`.

See Also `getDiagnosticFor`

matlab.unittest.constraints.ContainsSubstring

Superclasses BooleanConstraint

Purpose Constraint specifying string containing substring

Construction ContainsSubstring(substring) creates a constraint that specifies a string containing a substring, `substring`. The constraint is satisfied only if the actual value contains an expected string.

ContainsSubstring(substring,Name,Value) provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

substring

Text that must be contained within the actual value, specified as a string. `substring` can include newline characters.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

IgnoringCase

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

Default: `false`

IgnoringWhitespace

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

Default: false

Properties

IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'. This property applies at all levels of recursion, such as nested structures.

IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'. This property applies at all levels of recursion, such as nested structures.

Substring

String that must be included in the actual value, specified in the input argument, substring.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Contains Specified Substring

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.ContainsSubstring;
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test the actVal contains the substring 'One'.

```
testCase.verifyThat(actVal, ContainsSubstring('One'));
```

matlab.unittest.constraints.ContainsSubstring

Interactive verification passed.

Test the actVal contains the substring 'long'.

```
testCase.verifyThat(actVal, ContainsSubstring('long'));
```

Interactive verification failed.

Framework Diagnostic:

ContainsSubstring failed.

--> The string must contain the substring.

Actual String:

 This Is One Long String

Expected Substring:

 long

By default, the `ContainsSubstring` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat(actVal, ContainsSubstring('long',...  
    'IgnoringCase', true));
```

Interactive verification passed.

Test actVal contains the substring 'thisisone'. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, ContainsSubstring('thisisone', ...  
    'IgnoringCase', true, 'IgnoringWhitespace', true));
```

Interactive verification passed.

Assert that actVal does not contain the substring 'longer'.

```
testCase.assertThat(actVal, ~ContainsSubstring('longer',...
```

```
'IgnoringCase', true));
```

```
Interactive verification passed.
```

Concepts

matlab.unittest.constraints.EndsWithSubstring

Superclasses BooleanConstraint

Purpose Constraint specifying string ending with substring

Construction `EndsWithSubstring(suffix)` creates a constraint specifying a string ending with a substring. The constraint is satisfied only if the actual value ends with an expected string, `suffix`.

`EndsWithSubstring(suffix,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

suffix

Text that occurs at the end of the actual value, specified as a string. `suffix` can include newline characters.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

IgnoringCase

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

Default: `false`

IgnoringWhitespace

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

Default: false

Properties

IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'. This property applies at all levels of recursion, such as nested structures.

IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'. This property applies at all levels of recursion, such as nested structures.

Suffix

Text that occurs at the end of the actual value, specified in the input argument, `suffix`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Ends with Specified Substring

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EndsWithSubstring;
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test the `actVal` ends with the substring 'String'.

```
testCase.verifyThat(actVal, EndsWithSubstring('String'));
```

matlab.unittest.constraints.EndsWithSubstring

Interactive verification passed.

Test the actVal ends with the substring 'InG'.

```
testCase.verifyThat(actVal, EndsWithSubstring('InG'));
```

Interactive verification failed.

Framework Diagnostic:

EndsWithSubstring failed.

--> The string has an incorrect suffix.

Actual String:

 This Is One Long String

Expected Suffix:

 InG

By default, the `EndsWithSubstring` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat(actVal, EndsWithSubstring('InG',...  
    'IgnoringCase', true));
```

Interactive verification passed

Test the actVal ends with the substring 'longstring'. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, EndsWithSubstring('longstring', ...  
    'IgnoringCase', true, 'IgnoringWhitespace', true));
```

Interactive verification passed.

Assert that actVal does not end with the substring 'long'.

```
testCase.assertThat(actVal, ~EndsWithSubstring('long'));
```

Interactive verification passed.

[ContainsSubstring](#) | [IsSubstringOf](#) | [StartsWithSubstring](#) | [Matches](#)

Concepts

matlab.unittest.constraints.Eventually

Superclasses Constraint

Purpose Poll for value to asynchronously satisfy constraint

Construction `outConstObj = Eventually(constObj)` creates a constraint, `outConstObj`, that polls for an actual value function handle to asynchronously satisfy the constraint specified in the `constObj` constraint. It is not satisfied if evaluation of the function handle does not produce a value that satisfies the constraint within 20 seconds. The testing framework invokes the `drawnow` function while the `Eventually` constraint waits for specified function to satisfy the constraint.

`outConstObj = Eventually(constObj, 'WithTimeoutOf', timeOutVal)` creates a constraint that polls for the constraint to be satisfied within the timer period specified in `timeOutVal`.

Input Arguments

constObj

Constraint instance

timeOutVal

Maximum time to wait for passing behavior, specified in seconds

Default: 20 seconds

Properties **TimeOut**

Maximum time to wait for passing behavior, specified by the `timeOutVal` input argument

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Verify Test Passes Eventually

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.Eventually
import matlab.unittest.constraints.IsGreaterThan
import matlab.unittest.constraints.IsLessThan
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that, within the timeout period, a call to `toc` results in a value greater than 10 (seconds). The `Eventually` constraint repeatedly calls `toc` until either the constraint is satisfied or the elapsed time exceeds the timeout period. Repeated calls to `toc` result in the elapsed time since the last call to `tic`.

```
tic;
testCase.verifyThat(@toc, Eventually(IsGreaterThan(10)));
```

```
Interactive verification passed.
```

The verification may take as long as 10 seconds for `toc` to reach a passing value. If you issue the call to `tic` and wait more than 10 seconds before issuing the `verifyThat` command, the verification returns immediately since `toc` already returns a value greater than 10.

Verify that, within the timeout period, `toc` does not return a negative value.

```
testCase.verifyThat(@toc, Eventually(IsLessThan(0)));
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
```

```
Eventually failed.
```

```
--> The function did not pass after 20 seconds.
```

matlab.unittest.constraints.Eventually

```
--> IsLessThan failed.  
--> The value must be less than the maximum value.
```

```
Actual Value:  
    20.286452356691139  
Maximum Value (Exclusive):  
    0
```

```
Evaluated Function:  
    @toc
```

This failure is expected since elapsed time is not going to be less than zero. However, `Eventually` polls `toc` for the duration of the timeout period.

Adjust the timeout period so `Eventually` polls for 5 seconds.

```
tic;  
testCase.verifyThat(@toc, Eventually(IsGreaterThan(10), ...  
    'WithTimeoutOf', 5));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
Eventually failed.  
--> The function did not pass after 5 seconds.  
--> IsGreaterThan failed.  
--> The value must be greater than the minimum value.
```

```
Actual Value:  
    5.076293030150061  
Minimum Value (Exclusive):  
    10
```

```
Evaluated Function:  
    @toc
```

If you didn't wait more than 5 seconds between calls to `tic` and `verifyThat`, the test fails because the elapsed time is not greater than 10 seconds within the modified timeout period.

Concepts

matlab.unittest.constraints.EveryCellOf

Purpose Test if all elements of cell array meet constraint

Description The `EveryCellOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of a cell array, which ensures that a passing result occurs when every element of the cell array satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

Construction `EveryCellOf(actVal)` creates a proxy instance that tests if every element of a provided cell array, `actVal`, meets a constraint. The test passes if all elements satisfy the constraint.

Tips

- `EveryCellOf` checks if every element in the provided cell array satisfies an associated constraint. However, there are some constraints, a prominent one being `IsEqualTo`, that natively validate if all elements in cell arrays satisfy a condition. In these situations, use of `EveryCellOf` is unnecessary and impedes qualification performance.

Input Arguments

`actVal`

Actual value to test against constraint

Properties

`ActualValue`

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Every Cell Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EveryCellOf;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that every cell of `actVal` contains the substring 'ain'.

```
import matlab.unittest.constraints.ContainsSubstring
actVal = {'Rain', 'Main', 'Plain'};
testCase.verifyThat(EveryCellOf(actVal), ContainsSubstring('ain'));
```

```
Interactive verification passed.
```

Test that every cell of the actual value array has two elements.

```
import matlab.unittest.constraints.HasElementCount
testCase.verifyThat(EveryCellOf({'hello', 'world'}, {11 38})), HasElementCount(2));
```

```
Interactive verification passed.
```

Test that every cell of the actual value array is empty.

```
import matlab.unittest.constraints.IsEmpty
testCase.verifyThat(EveryCellOf({inputParser.empty, ''}), IsEmpty)
```

```
Interactive verification passed.
```

Test that every cell of the actual value array is finite.

```
import matlab.unittest.constraints.IsFinite;
testCase.verifyThat(EveryCellOf({NaN, Inf, 5}), IsFinite);
```

matlab.unittest.constraints.EveryCellOf

Interactive verification failed.

Framework Diagnostic:

At least one cell failed.

Failing indices:

1 2

The first failing cell failed because:

--> IsFinite failed.

--> The value must be finite.

Actual Value:

NaN

Actual Value Cell Array:

[NaN] [Inf] [5]

Only the third element has a finite value.

Test that every cell of the actual value array is real.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(EveryCellOf({1 4i}), IsReal);
```

Interactive verification failed.

Framework Diagnostic:

At least one cell failed.

Failing indices:

2

The first failing cell failed because:

--> IsReal failed.

--> The value must be real.

Actual Value:

```
0.0000000000000000 + 4.000000000000000i
```

Actual Value Cell Array:

```
[1] [0.0000000000000000 + 4.000000000000000i]
```

The second element has an imaginary value.

Concepts

matlab.unittest.constraints.EveryElementOf

Purpose Test if all elements of array meet constraint

Description The `EveryElementOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of an array, which ensures that a passing result occurs when every element of the array that satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

Construction `EveryElementOf(actVal)` creates a proxy instance that tests if every element of a provided array, `actVal`, meets a constraint. The test passes if all elements satisfy the constraint.

Tips

- `EveryElementOf` checks if every element in the provided array satisfies an associated constraint. However, there are some constraints, such as `IsEqualTo` and `IsGreaterThan`, `IsLessThan`, that natively validate if all elements in the array satisfy a condition. In these situations, use of `EveryElementOf` is unnecessary and impedes qualification performance.

Input Arguments

`actVal`

Actual value to test against constraint

Properties

`ActualValue`

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Every Element Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EveryElementOf;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that every element of `actVal` is less than 55.

```
import matlab.unittest.constraints.IsLessThan;
actVal = [1 1 2 3 5 8 13 21 34];
testCase.verifyThat(EveryElementOf(actVal), IsLessThan(55));
```

```
Interactive verification passed.
```

Test that every element of the actual value array is complex.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(EveryElementOf([1+2i 4i]), ~IsReal);
```

```
Interactive verification passed.
```

Test that every element of the actual value array is less than zero.

```
import matlab.unittest.constraints.IsLessThan;
testCase.verifyThat(EveryElementOf([1 -5]), IsLessThan(0));
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
At least one element failed.
```

matlab.unittest.constraints.EveryElementOf

```
Failing indices:
    1
The first failing element failed because:
--> IsLessThan failed.
    --> The value must be less than the maximum value.

Actual Value:
    1
Maximum Value (Exclusive):
    0

Actual Value Array:
    1    -5
```

Only the second element is less than zero.

Test that every element of the actual value array has a NaN value.

```
import matlab.unittest.constraints.HasNaN;
testCase.verifyThat(EveryElementOf([NaN 0/0 5]), HasNaN);
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
```

At least one element failed.

```
Failing indices:
    3
The first failing element failed because:
--> HasNaN failed.
    --> The value must be NaN.
```

```
Actual Value:
    5
```

```
Actual Value Array:
```

```
NaN NaN 5
```

Only the third element has a NaN value.

Concepts

matlab.unittest.constraints.HasElementCount

Superclasses BooleanConstraint

Purpose Constraint specifying expected number of elements

Construction HasElementCount(countVal) provides a constraint that specifies an expected number of elements. The constraint is satisfied if the actual value array has the same number of elements specified as by countVal.

Input Arguments

countVal

Number of elements a value must have to satisfy the constraint.

Properties **Count**

Number of elements a value must have to satisfy the constraint. Set this property through the constructor via the countVal input argument.

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test for Expected Number of Elements**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasElementCount;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify a scalar has an element count of one.

```
testCase.verifyThat(3, HasElementCount(1));
```

```
Interactive verification passed.
```

Test the element count of the vector.

```
testCase.assertThat([42 7 13], HasElementCount(3));
```

Interactive assertion passed.

Test the element count of the matrix.

```
testCase.assertThat([1 2 3; 4 5 6], HasElementCount(5));
```

Interactive assertion failed.

```
-----  
Framework Diagnostic:  
-----  
HasElementCount failed.  
--> The value did not have the correct number of elements.
```

```
    Actual Number of Elements:
```

```
        6
```

```
    Expected Number of Elements:
```

```
        5
```

```
Actual Value:
```

```
    1     2     3  
    4     5     6
```

```
Assertion failed.
```

The matrix has six elements.

Test that a square identity matrix has the correct number of elements.

```
n = 7;  
testCase.assumeThat(eye(n), HasElementCount(n^2));
```

Interactive assumption passed.

Verify the element count of a cell array of strings.

matlab.unittest.constraints.HasElementCount

```
testCase.verifyThat({'aString', 'anotherString'}, HasElementCount(2));
```

```
Interactive verification passed.
```

Test the element count of a structure.

```
s.Field1 = 1;  
s.Field2 = 2;  
testCase.verifyThat(s, HasElementCount(2));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
HasElementCount failed.
```

```
--> The value did not have the correct number of elements.
```

```
Actual Number of Elements:
```

```
1
```

```
Expected Number of Elements:
```

```
2
```

```
Actual Value:
```

```
Field1: 1
```

```
Field2: 2
```

The structure has two fields, but it only has one element.

```
testCase.verifyThat(s, HasElementCount(1));
```

```
Interactive verification passed.
```

Concepts

Superclasses BooleanConstraint

Purpose Constraint specifying structure containing particular field

Construction HasField(fieldname) provides a constraint specifying structure containing particular field, fieldname. The constraint is satisfied if the actual value is a structure and that structure contains a field named fieldname.

Input Arguments

fieldname

Name of the field that a structure must contain to satisfy the constraint, specified as a string.

Properties **Field**

Name of the field that a structure must contain to satisfy the constraint. Set this property through the constructor via the fieldname input argument.

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Structure Has Particular Field**

Create at TestCase for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.HasField;
```

```
testCase = TestCase.forInteractiveUse;
```

Define the following structure, S, with two fields.

```
S = struct('Tag', 123, 'Serial', 345);
```

matlab.unittest.constraints.HasField

Verify that the structure has a 'Tag' field.

```
testCase.verifyThat(S, HasField('Tag'));
```

Interactive verification passed.

Verify that the structure has a 'tag' field.

```
testCase.verifyThat(S, HasField('tag'));
```

Interactive verification failed.

Framework Diagnostic:

HasField failed.

--> The value did not have the expected field.

Actual Fieldnames:

 'Tag'

 'Serial'

Expected Fieldname:

 'tag'

Actual Value:

 Tag: 123

 Serial: 345

The verification fails because the field name comparison is case sensitive.

Verify that the structure has a 'Tag' field.

```
testCase.verifyThat(S, HasField('Tag'));
```

Interactive verification passed.

Verify that the structure has both a 'Tag' and a 'Serial' field.

```
testCase.verifyThat(S, HasField('Tag') & HasField('Serial'));
```

```
Interactive verification passed.
```

Verify that the structure does not have a 'Name' field.

```
testCase.verifyThat(S, ~HasField('Name'));
```

```
Interactive verification passed.
```

Concepts

matlab.unittest.constraints.HasInf

Superclasses BooleanConstraint

Purpose Constraint specifying array containing any infinite value

Construction HasInf creates a constraint that is able to determine if any value of an actual value array is an infinite value. This constraint is satisfied only if the actual value array contains at least one infinite value.

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Array Contains Infinite Value**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasInf;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the value Inf satisfies the constraint.

```
testCase.verifyThat(Inf, HasInf);
```

```
Interactive verification passed.
```

Assert that an array contains an infinite value.

```
testCase.assertThat([0 1 1 2 3 5 8 13], HasInf);
```

```
Interactive assertion failed.
```

```
-----
Framework Diagnostic:
-----
```

```
HasInf failed.
```

```
--> At least one element must be Inf or -Inf.
```

```
Actual Value:  
      0      1      1      2      3      5      8     13  
Assertion failed.
```

The array does not contain any infinite values.

Verify that an array contains an infinite value.

```
testCase.verifyThat([-Inf 5 NaN], HasInf);
```

```
Interactive verification passed.
```

Assert that a complex number that is infinite in the imaginary part satisfies the constraint.

```
testCase.assertThat(42+Inf*1i, HasInf);
```

```
Interactive verification passed.
```

Verify that an array does not contain any infinite values.

```
testCase.verifyThat([NaN -7+NaN*1i], ~HasInf);
```

```
Interactive verification passed.
```

Negating the `HasInf` constraint does not ensure the value is finite, only that it does not contain any infinite values.

See Also

`IsFinite` | `HasNaN` | `isinf`

Concepts

matlab.unittest.constraints.HasLength

Superclasses BooleanConstraint

Purpose Constraint specifying expected length of array

Construction HasLength(lengthVal) provides a constraint that specifies an expected length of an array. The constraint is satisfied if the largest dimension length of the actual value array has the same number of elements specified as by lengthVal.

Input Arguments

lengthVal

Length a value must have to satisfy the constraint.

Properties **Count**

Length a value must have to satisfy the constraint. Set this property through the constructor via the lengthVal input argument.

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test for Expected Array Length**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasLength;
```

```
testCase = TestCase.forInteractiveUse;
```

Assert that a 2x5x3 array has an expected length.

```
testCase.assertThat(rand(2, 5, 3), HasLength(5));
```

```
Interactive assertion passed.
```

Verify that a cell array of strings has an expected length.

```
testCase.verifyThat({'SomeString', 'SomeOtherString'}, HasLength(2));
```

```
Interactive verification passed.
```

Verify that an identity matrix has an expected length.

```
testCase.verifyThat(eye(2), HasLength(4));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----  
HasLength failed.  
--> The array has an incorrect length.
```

```
Actual Length:  
      2  
Expected Length:  
      4
```

```
Actual Array:  
      1      0  
      0      1
```

The matrix has a length of 2.

See Also Concepts

[IsEmpty](#) | [HasElementCount](#) | [HasSize](#) | [length](#)

matlab.unittest.constraints.HasNaN

Superclasses BooleanConstraint

Purpose Constraint specifying array containing NaN value

Construction HasNaN creates a constraint that is able to determine if any value of an actual value array is NaN. This constraint is satisfied only if the actual value array contains at least one NaN value.

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Array Contains NaN Value**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasNaN;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the value NaN satisfies the constraint.

```
testCase.verifyThat(NaN, HasNaN);
```

```
Interactive verification passed.
```

Assert that an array contains a NaN value.

```
testCase.assertThat([0 1 1 2 3 5 8 13], HasNaN);
```

```
Interactive assertion failed.
```

```
-----
Framework Diagnostic:
```

```
-----
HasNaN failed.
```

```
--> At least one element must be NaN.
```

```
Actual Value:
      0      1      1      2      3      5      8     13
Assertion failed.
```

The array does not contain a NaN value.

Verify that an array contains a NaN value.

```
testCase.verifyThat([-Inf 5 NaN], HasNaN);
```

```
Interactive verification passed.
```

Assert that a complex number satisfies the constraint.

```
testCase.assertThat(42+NaN*1i, HasNaN);
```

```
Interactive assertion passed.
```

Verify that an array does not contain any NaN values.

```
testCase.verifyThat([Inf -7+Inf*1i], ~HasNaN);
```

```
Interactive verification passed.
```

Negating the `HasNaN` constraint does not ensure the value is finite, only that it does not contain any NaN values.

Concepts

matlab.unittest.constraints.HasSize

Superclasses BooleanConstraint

Purpose Constraint specifying expected size of array

Construction `HasSize(sizeVal)` provides a constraint that specifies an expected size of an array. The constraint is satisfied if the actual value array size is equal to the size specified by `sizeVal`.

Input Arguments

sizeVal

Size a value must have to satisfy the constraint.

Properties

Count

Size a value must have to satisfy the constraint. Set this property through the constructor via the `sizeVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test for Expected Array Size

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasSize;
```

```
testCase = TestCase.forInteractiveUse;
```

Assert that a 2x5x3 array has an expected size.

```
testCase.assertThat(rand(2, 5, 3), HasSize([2 5 3]));
```

```
Interactive assertion passed.
```

Verify that a cell array of strings has an expected size.

```
testCase.verifyThat({'SomeString', 'SomeOtherString'}, HasSize([1 2]))
```

Interactive verification passed.

Verify that an identity matrix has an expected size.

```
testCase.verifyThat(eye(2), HasSize([4 1]));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

HasSize failed.

--> The value had an incorrect size.

Actual Size:

2 2

Expected Size:

4 1

Actual Value:

1 0

0 1

The matrix has a size of 2x2.

Concepts

matlab.unittest.constraints.IsAnything

Superclasses	Constraint
Purpose	Constraint specifying any value
Construction	<code>IsAnything</code> provides a constraint specifying any value. The constraint is satisfied by any value. It is the default constraint for selectors that do not require an input argument.
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
Examples	<p>Instantiate IsAnything Object</p> <p>Create a test case for interactive testing.</p> <pre>import matlab.unittest.TestCase; import matlab.unittest.constraints.IsAnything; testCase = TestCase.forInteractiveUse;</pre> <p>Verify that the following values satisfy the <code>IsAnything</code> constraint: <code>NaN</code>, an <code>inputParser</code> object, a numeric array, and a complex number.</p> <pre>testCase.verifyThat(NaN, IsAnything); testCase.verifyThat(inputParser, IsAnything); testCase.verifyThat(1:10, IsAnything); testCase.verifyThat(-Inf+5j, IsAnything);</pre> <pre>Interactive verification passed. Interactive verification passed. Interactive verification passed. Interactive verification passed.</pre> <p>Test that empty cells, arrays, and strings satisfy the <code>IsAnything</code> constraint.</p> <pre>testCase.verifyThat({}, IsAnything); testCase.verifyThat([], IsAnything);</pre>

```
testCase.verifyThat('', IsAnything);
```

```
Interactive verification passed.  
Interactive verification passed.  
Interactive verification passed.
```

The constraint is satisfied even though the data are empty.

`matlab.unittest.selectors`

Concepts

matlab.unittest.constraints.IsEmpty

Superclasses	BooleanConstraint
Purpose	Constraint specifying empty value
Construction	IsEmpty provides a constraint that specifies an empty value. The constraint is satisfied if the actual value array is empty.
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Is Empty**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEmpty;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that an empty string satisfies the IsEmpty constraint.

```
testCase.verifyThat('', IsEmpty);
```

```
Interactive verification passed.
```

Assert that a vector is not empty.

```
testCase.assertThat([13 42], ~IsEmpty);
```

```
Interactive verification passed.
```

Verify that a matrix with a dimension of length zero is empty.

```
testCase.verifyThat(rand(2, 5, 0, 3), IsEmpty);
```

```
Interactive verification passed.
```

Assert that an empty object satisfies the IsEmpty constraint.

```
testCase.assertThat(MException.empty, IsEmpty);
```

Interactive assertion passed.

Verify that a cell array containing an empty numeric array is empty.

```
testCase.verifyThat({[]}, IsEmpty);
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

IsEmpty failed.

--> The value must be empty.

--> The value has a size of [1 1].

Actual Value:

```
{[]}
```

The cell array is not empty, even though the only thing it contains is an empty array.

Concepts

matlab.unittest.constraints.IsFalse

Superclasses	Constraint
Purpose	Constraint specifying false value
Construction	IsFalse provides a constraint specifying a false value. This constraint is satisfied only by a scalar logical with a value of false.
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
Examples	Test Actual Value Is False

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsFalse;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that false satisfies the IsFalse constraint.

```
testCase.verifyThat(false, IsFalse);
```

```
Interactive verification passed.
```

Test that the IsFalse constraint is not satisfied by true.

```
testCase.verifyThat(true, IsFalse);
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
```

```
IsFalse failed.
```

```
--> The value must evaluate to "false".
```

Actual Value:

1

The test fails because true returns logical(1).

Test that the IsFalse constraint is not satisfied by the double 0.

```
testCase.verifyThat(0, IsFalse);
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

IsFalse failed.

--> The value must be logical. It is of type "double".

Actual Value:

0

The IsFalse constraint is satisfied only by logical(0).

Test that the IsFalse constraint is not satisfied by a logical array of zeros.

```
testCase.verifyThat([false false false], IsFalse);
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

IsFalse failed.

--> The value must be scalar. It has a size of [1 3].

Actual Value:

0 0 0

matlab.unittest.constraints.IsFalse

The `IsFalse` constraint is only satisfied if the value is scalar and `logical(0)`.

See Also `IsTrue`

Concepts

Superclasses BooleanConstraint

Purpose Constraint specifying finite value

Construction IsFinite creates a constraint that is able to determine if all values of an actual value array are finite. This constraint is satisfied only if the actual value array does not contain any infinite or NaN values.

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Array Contains Only Finite Values**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsFinite;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the value 17 satisfies the constraint.

```
testCase.verifyThat(17, IsFinite);
```

```
Interactive verification passed.
```

Assert that an array is completely finite.

```
testCase.assertThat([0 1 1 2 3 5 8 13], IsFinite);
```

```
Interactive assertion passed.
```

Verify that an array is completely finite.

```
testCase.verifyThat([-Inf 5 NaN], IsFinite);
```

```
Interactive verification failed.
```

matlab.unittest.constraints.IsFinite

```
-----  
Framework Diagnostic:  
-----  
IsFinite failed.  
--> All elements must be finite-valued.  
    Failing indices:  
           1     3  
  
Actual Value:  
      -Inf     5   NaN
```

The array contains an infinite value.

Test if a complex number that is infinite in the imaginary part satisfies the constraint.

```
testCase.assertThat(42+Inf*1i, IsFinite);
```

```
Interactive assertion failed.
```

```
-----  
Framework Diagnostic:  
-----  
IsFinite failed.  
--> The value must be finite.  
  
Actual Value:  
      42.000000000000000 +          Infi  
Assertion failed.
```

Verify that an array does not contain all finite values.

```
testCase.verifyThat([NaN -7+NaN*1i], ~IsFinite);
```

```
Interactive verification passed.
```

Concepts

matlab.unittest.constraints.IsGreaterThan

Superclasses Constraint

Purpose Constraint specifying value greater than another value

Construction `IsGreaterThan(floorVal)` creates a constraint specifying that an actual value is greater than another value. The constraint is satisfied if the actual value array is greater than the specified floor value, `floorVal`. The actual value is greater than `floorVal` only if the result of the expression `actual > floorVal` is nonempty and all values are true.

Input Arguments

floorVal

Largest value that fails the constraint.

Properties **FloorValue**

Largest value that fails the constraint. Set this property through the constructor via the `floorVal` input argument.

Methods

<code>and</code>	Form logical conjunction of constraints
<code>or</code>	Form logical disjunction of constraints

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Is Greater Than Provided Floor Value**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsGreaterThan;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value is greater than two.

```
actVal = 3;  
testCase.verifyThat(actVal, IsGreaterThan(2));
```

Interactive verification passed.

Test that the actual value is greater than three.

```
testCase.verifyThat(actVal, IsGreaterThan(3));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----  
IsGreaterThan failed.  
--> The value must be greater than the minimum value.
```

```
Actual Value:  
    3  
Minimum Value (Exclusive):  
    3
```

The actual value is equal to, not greater than, three.

Test that each element in the actual value array is greater than four.

```
actVal = [5 6 7];  
testCase.verifyThat(actVal, IsGreaterThan(4));
```

Interactive verification passed.

Test that each element in the actual value matrix is greater than four.

```
actVal = [1 2 3; 4 5 6];
```

matlab.unittest.constraints.IsGreaterThan

```
testCase.verifyThat(actVal, IsGreaterThan(4));
```

```
testCase.verifyThat(actVal, IsGreaterThan(4));  
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
IsGreaterThan failed.  
--> Each element must be greater than the minimum value.
```

```
    Failing Indices:  
           1     2     3     5
```

```
Actual Value:  
           1     2     3  
           4     5     6  
Minimum Value (Exclusive):  
           4
```

The matrix contains four elements with a value less than or equal to four.

Test that the actual value, 5, is greater than every element in an array.

```
testCase.verifyThat(5, IsGreaterThan([1 2 3]));
```

```
Interactive verification passed.
```

Test that elements in the actual value array are greater than the corresponding floor values.

```
testCase.verifyThat([5 -3 2], IsGreaterThan([4 -9 0]));
```

```
Interactive verification passed.
```

Repeat the test, this time negating the first actual value element.

```
testCase.verifyThat([-5 -3 2], IsGreaterThan([4 -9 0]));
```

Interactive verification failed.

Framework Diagnostic:

IsGreaterThan failed.

--> Each element must be greater than each corresponding element of the

Failing Indices:

1

Actual Value:

-5 -3 2

Minimum Value (Exclusive):

4 -9 0

The negated element is less than four.

Concepts

matlab.unittest.constraints.IsGreaterThanOrEqualTo

Superclasses Constraint

Purpose Constraint specifying value greater than or equal to another value

Construction `IsGreaterThanOrEqualTo(floorVal)` creates a constraint specifying that an actual value is greater than or equal to another value. The constraint is satisfied if the actual value array is greater than or equal to the specified floor value, `floorVal`. The actual value is greater than or equal to `floorVal` only if the result of the expression `actual >= floorVal` is nonempty and all values are true.

Input Arguments

floorVal

Minimum value to satisfy the constraint.

Properties **FloorValue**

Minimum value to satisfy the constraint. Set this property through the constructor via the `floorVal` input argument.

Methods

<code>and</code>	Form logical conjunction of constraints
<code>or</code>	Form logical disjunction of constraints

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Is Greater Than or Equal to Provided Floor Value**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
```

matlab.unittest.constraints.IsGreaterThanOrEqualTo

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value is greater than or equal to two.

```
actVal = 3;  
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(2));
```

Test that the actual value is greater than or equal to three.

```
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(3));
```

Interactive verification passed.

Test that each element in the actual value array is greater than or equal to four.

```
actVal = [5 6 7];  
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(4));
```

Interactive verification passed.

Test that each element in the actual value matrix is greater than or equal to four.

```
actVal = [1 2 3; 4 5 6];  
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(4));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

IsGreaterThanOrEqualTo failed.

--> Each element must be greater than or equal to the minimum value.

Failing Indices:

```
1      3      5
```

matlab.unittest.constraints.IsGreaterThanOrEqualTo

```
Actual Value:
      1      2      3
      4      5      6
Minimum Value (Inclusive):
      4
```

The matrix contains three elements that are greater than or equal to four.

Test that the actual value, 5, is greater than or equal to every element in an array.

```
testCase.verifyThat(5, IsGreaterThanOrEqualTo([1 2 3 5]));
```

Interactive verification passed.

Test that elements in the actual value array are greater than or equal to the corresponding floor values.

```
testCase.verifyThat([5 -3 0], IsGreaterThanOrEqualTo([4 -9 0]));
```

Interactive verification passed.

Repeat the test, this time negating the first actual value element.

```
testCase.verifyThat([-5 -3 0], IsGreaterThanOrEqualTo([4 -9 0]));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

IsGreaterThanOrEqualTo failed.

--> Each element must be greater than or equal to each corresponding element

Failing Indices:

1

```
Actual Value:
    -5    -3     0
Minimum Value (Inclusive):
     4    -9     0
```

The negated element is less than or equal to four.

Concepts

matlab.unittest.constraints.IsEqualTo

Superclasses BooleanConstraint

Purpose General constraint to compare for equality

Description The IsEqualTo class creates a constraint that compares data for equality. The type of comparison it uses is governed by the data type of the expected value. First, the testing framework checks if the expected value is an object. This check is performed first because it is possible for the object to have overridden methods that are used in subsequent checks (e.g. `islogical`). The following list categorizes and describes the various tests.

Data Type	Equality Comparison Method
MATLAB & Java Objects	If the expected value is a MATLAB or Java object, the IsEqualTo constraint calls the <code>isequal</code> method on the expected value object. If <code>isequal</code> returns <code>false</code> and a supported tolerance is specified, the constraint checks the actual and expected values for equivalent class, size, and sparsity. If these checks fail, the constraint is not satisfied. If these checks pass, the constraint uses the tolerance in the comparison.
Logicals	If the expected value is a <code>logical</code> , the constraint checks the actual and expected values for equivalent sparsity. If the sparsity matches, the constraint compares the values with the <code>isequal</code> method. Otherwise, the constraint is not satisfied.
Numerics	If the expected value is <code>numeric</code> , the constraint checks the actual and expected values for equivalent class, size, and sparsity. If the all these checks match, the constraint uses the <code>isequaln</code> method for comparison. If <code>isequaln</code> returns <code>true</code> , the constraint is satisfied. If the complexity does not match or <code>isequaln</code> returns <code>false</code> , and a supported tolerance is supplied, the constraint uses the tolerance in the comparison. Otherwise, the constraint is not satisfied.

Data Type	Equality Comparison Method
Strings	If the expected value is a string, the constraint uses the <code>strcmp</code> function to check the actual and expected values for equality. However, if the <code>IgnoreCase</code> property is true, the strings are compared using <code>strcmpi</code> . If the <code>IgnoreWhitespace</code> is true, all whitespace characters are removed from the actual and expected strings before passing them to <code>strcmp</code> or <code>strcmpi</code> .
Structures	If the expected value is a struct, the constraint compares the field count of the actual and expected values. If not equal, the constraint is not satisfied. Otherwise, each field of the expected value struct must exist on the actual value struct. If any field names are different, the constraint is not satisfied. Then, the constraint recursively compares the fields in a depth first examination. The recursion continues until a fundamental data type is encountered (i.e. logical, numeric, string, or object), and then the values are compared as described above.
Cell Arrays	If the expected value is a cell array, the constraint checks the actual and expected values for size equality. If they are not equal in size, the constraint is not satisfied. Otherwise, each element of the array is recursively compared in a manner identical to fields in a structure, described above.

Construction

`IsEqualTo(expVal)` provides a general constraint to compare for equality.

`IsEqualTo(expVal,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

expVal

The expected value that will be compared to the actual value.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

IgnoringCase

Indicator if the constraint is insensitive to case, specified as **false** or **true** (logical 0 or 1)

Default: false

IgnoringWhitespace

Indicator if the constraint is insensitive to whitespace, specified as **false** or **true** (logical 0 or 1)

Default: false

Using

Particular comparator to use for constraint construction, specified as a `matlab.unittest.constraints.Comparator` object

Default: (empty)

Within

Tolerance to use in constraint construction, specified as a `matlab.unittest.constraints.Tolerance` object

Default: (empty)

Properties

Comparator

Specific comparator used in construction of the constraint, specified as a `matlab.unittest.constraints.Comparator` object in the name-value pair argument, 'Using'.

Expected

The expected value that will be compared to the actual value specified in the `expVal` input argument.

IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'. This property applies at all levels of recursion, such as nested structures.

IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'. This property applies at all levels of recursion, such as nested structures.

Tolerance

Specific tolerance used in construction of the constraint, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'. This property applies at all levels of recursion, such as nested structures.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test Numerics for Equality

Create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase;
```

matlab.unittest.constraints.IsEqualTo

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that an actual value of 5 is equal to the expected value.

```
expVal = 5;
testCase.verifyThat(expVal, IsEqualTo(5));
```

```
Interactive verification passed.
```

Assume that the actual value is 4.95. Verify that the difference between the actual value and expected value is less than 0.09.

```
testCase.verifyThat(expVal, IsEqualTo(4.95, 'Within', AbsoluteTolerance(0.09)));
```

```
Interactive verification passed.
```

Assume that the actual value is 4.9. Verify that the difference between the actual and expected value is less than 1%.

```
testCase.verifyThat(expVal, IsEqualTo(4.9, 'Within', RelativeTolerance(0.01)));
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
    --> The values are not equal using "isequaln".
```

```
    --> RelativeTolerance failed.
```

```
        --> The value was not within relative tolerance.
```

```
            Tolerance Value:
```

```
                0.0100000000000000
```

```
Actual Value:
      5
Expected Value:
4.900000000000000
```

The two values differ by more than 1%.

Test Floating Point Calculation with Tolerance

Create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that $0.1 \cdot 3 = 0.3$.

```
act = 0.1*3;
exp = 0.3;
testCase.verifyThat(act, IsEqualTo(exp))
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
```

IsEqualTo failed.

--> NumericComparator failed.

--> The values are not equal using "isequaln".

```
Actual Value:
0.300000000000000
Expected Value:
0.300000000000000
```

This test fails due to round off error in floating point arithmetic.

matlab.unittest.constraints.IsEqualTo

Perform the comparison of floating point numbers using a tolerance.
Test that $0.1 * 3 = 0.3$ within a relative tolerance of $2 * \text{eps}$.

```
testCase.verifyThat(act, IsEqualTo(exp, ...  
    'Within', RelativeTolerance(2*eps)));
```

Interactive verification passed.

Test Strings for Equality

Create a TestCase for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that two strings are equal.

```
expVal = 'Hello';  
testCase.verifyThat(expVal, IsEqualTo('Hello'));
```

Interactive verification passed.

Change the case of the actual string and test for equality.

```
testCase.verifyThat(expVal, IsEqualTo('hello'));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

```
IsEqualTo failed.
```

```
--> StringComparator failed.
```

```
    --> The strings are not equal
```

```
Actual String:
```

```
    Hello
```

```
Expected String:  
    hello
```

Ignore case and test again.

```
testCase.verifyThat(expVal, IsEqualTo('hello', 'IgnoringCase', true));
```

```
Interactive verification passed.
```

Ignore whitespace and test two strings.

```
expVal = 'a bc';  
testCase.verifyThat(expVal, IsEqualTo('abc', 'IgnoringWhitespace', true));  
testCase.verifyThat(expVal, IsEqualTo('ab c', 'IgnoringWhitespace', true));
```

```
Interactive verification passed.  
Interactive verification passed.
```

Test Objects for Equality Using Comparator

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.RelativeTolerance;  
import matlab.unittest.constraints.PublicPropertyComparator;
```

```
testCase = TestCase.forInteractiveUse;
```

Define actual and expected timeseries objects. Perturb one of the actual data points by 1%.

```
expected = timeseries(1:10);  
actual = expected;  
actual.Data(7) = 1.01*actual.Data(7);
```

Test that the actual and expected values are equal within a relative tolerance of 2%.

```
testCase.verifyThat(actual, IsEqualTo(expected, ...
```

matlab.unittest.constraints.IsEqualTo

```
'Within', RelativeTolerance(.02)));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
IsEqualTo failed.
```

```
--> ObjectComparator failed.
```

```
--> The objects are not equal using "isequal".
```

```
--> The tolerance does not support timeseries values so it was not used.
```

```
Actual Object:
```

```
timeseries
```

```
Common Properties:
```

```
    Name: 'unnamed'
```

```
    Time: [10x1 double]
```

```
    TimeInfo: [1x1 tsdata.timemetadadata]
```

```
    Data: [1x1x10 double]
```

```
    DataInfo: [1x1 tsdata.datametadadata]
```

```
More properties, Methods
```

```
Expected Object:
```

```
timeseries
```

```
Common Properties:
```

```
    Name: 'unnamed'
```

```
    Time: [10x1 double]
```

```
    TimeInfo: [1x1 tsdata.timemetadadata]
```

```
    Data: [1x1x10 double]
```

```
    DataInfo: [1x1 tsdata.datametadadata]
```

```
More properties, Methods
```

Use the `PublicPropertyComparator` in the construction of the constraint.

```
testCase.verifyThat(actual, IsEqualTo(expected,...  
    'Within', RelativeTolerance(.02),...  
    'Using', PublicPropertyComparator.supportingAllValues));
```

```
Interactive verification passed.
```

The test passes because the `PublicPropertyComparator` compares each public property individually instead of comparing the object all at once. In the former test, the `ObjectComparator` is used on the `timeseries` object, and therefore relies on the `isequal` method of the `timeseries` class. Due to the perturbation in the actual `timeseries`, `isequal` returns `false`. The comparator does not apply the tolerance because the double-valued tolerance cannot apply directly to the `timeseries` object. In the latter test, the comparator applies the tolerance to each public property that contains double-valued data.

Concepts

matlab.unittest.constraints.IsInstanceOf

Superclasses BooleanConstraint

Purpose Constraint specifying inclusion in given class hierarchy

Construction `IsInstanceOf(class)` provides a constraint specifying inclusion in a given class hierarchy. The constraint is satisfied if the actual value instance passes the “isa” relationship with `class` .

Input Arguments

class

Class name that the actual value must derive from or be an instance of to satisfy the constraint, specified as a fully qualified class name string or a `meta.class` instance.

Properties

Class

Class name that the actual value must derive from or be an instance of to satisfy the constraint. Set this property through the constructor via the `class` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Instance of Specified Class

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsInstanceOf;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the actual value, 5, is an instance of the double class.

```
testCase.verifyThat(5, IsInstanceOf('double'));
```

Interactive verification passed.

Repeat the test using an instance of `meta.class` instead of a string.

```
testCase.verifyThat(5, IsInstanceOf(?double));
```

Interactive verification passed.

Assert that zero is an instance of the logical class.

```
testCase.assertThat(0, IsInstanceOf('logical'));
```

Interactive assertion failed.

```
-----  
Framework Diagnostic:  
-----
```

```
IsInstanceOf failed.
```

```
--> The value must be an instance of the expected type.
```

```
    Actual Class:  
        double  
    Expected Type:  
        logical
```

```
Actual Value:
```

```
    0
```

```
Assertion failed.
```

Verify that `@sin` is a function handle.

```
testCase.verifyThat(@sin, IsInstanceOf(?function_handle));
```

Interactive verification passed.

Verify that `name` is an instance of the char class.

```
name = 42;
```

```
testCase.verifyThat(name, IsInstanceOf('char'));
```

matlab.unittest.constraints.IsInstanceOf

```
Interactive verification failed.

-----
Framework Diagnostic:
-----
IsInstanceOf failed.
--> The value must be an instance of the expected type.

    Actual Class:
           double
    Expected Type:
           char

Actual Value:
           42
```

Test That Derived Class Is Instance of Specified Class

In a file in your working folder, create a class, `DerivedExample`, that inherits from the `handle` class.

```
classdef DerivedExample < handle
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsInstanceOf;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that an instance of the `DerivedExample` class is an instance of a `handle`.

```
exObj = DerivedExample;
testCase.verifyThat(exObj, IsInstanceOf(?handle));
```

```
Interactive verification passed.
```

Even though `exObj` is not an instance of the `handle` class, the verification passes because it derives from the `handle` class.

Concepts

matlab.unittest.constraints.IsLessThan

Superclasses Constraint

Purpose Constraint specifying value less than another value

Construction `IsLessThan(ceilVal)` creates a constraint specifying that an actual value less is than another value. The constraint is satisfied if the actual value array is less than the specified ceiling value, `ceilVal`. The actual value is less than `ceilVal` only if the result of the expression `actual < ceilVal` is nonempty and all values are true.

Input Arguments

ceilVal

Smallest value that fails the constraint.

Properties **CeilingValue**

Smallest value that fails the constraint. Set this property through the constructor via the `ceilVal` input argument.

Methods

<code>and</code>	Form logical conjunction of constraints
<code>or</code>	Form logical disjunction of constraints

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Is Less Than Provided Ceiling Value**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsLessThan;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value is less than four.

```
actVal = 3;  
testCase.verifyThat(actVal, IsLessThan(4));
```

Interactive verification passed.

Test that the actual value is less than three.

```
testCase.verifyThat(actVal, IsLessThan(3));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:

Concepts

matlab.unittest.constraints.IsLessThanOrEqualTo

Superclasses Constraint

Purpose Constraint specifying value less than or equal to another value

Construction `IsLessThanOrEqualTo(ceilVal)` creates a constraint specifying that an actual value is less than or equal to another value. The constraint is satisfied if the actual value array is less than or equal to the specified ceiling value, `ceilVal`. The actual value is less than or equal to `ceilVal` only if the result of the expression `actual <= ceilVal` is nonempty and all values are true.

Input Arguments

ceilVal

Maximum value to satisfy the constraint.

Properties **CeilingValue**

Maximum value to satisfy the constraint. Set this property through the constructor via the `ceilVal` input argument.

Methods

<code>and</code>	Form logical conjunction of constraints
<code>or</code>	Form logical disjunction of constraints

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Is Less Than or Equal to Provided Ceiling Value**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
```

matlab.unittest.constraints.IsLessThanOrEqualTo

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
```

```
testCase = TestCase.forInteractiveUse;

Concepts

matlab.unittest.constraints.IsOfClass

Superclasses BooleanConstraint

Purpose Constraint specifying class type

Construction `IsOfClass(class)` provides a constraint specifying the class type. The constraint is satisfied if the actual value is the same class as `class`. The constraint is not satisfied if the actual value derives from `class`.

Input Arguments

class

Class name that must be matched by the actual value to satisfy the constraint, specified as a fully qualified class name string or a `meta.class` instance.

Properties

Class

Class name that must be matched by the actual value to satisfy the constraint. Set this property through the constructor via the `class` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Class Is Specified Class

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsOfClass;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the actual value, 5, is a double.

```
testCase.verifyThat(5, IsOfClass('double'));
```

Interactive verification passed.

Repeat the test using an instance of `meta.class` instead of a string.

```
testCase.verifyThat(5, IsOfClass(?double));
```

Interactive verification passed.

Assert that zero is an instance of the logical class.

```
testCase.assertThat(0, IsOfClass('logical'));
```

Interactive assertion failed.

```
-----  
Framework Diagnostic:  
-----  
IsOfClass failed.  
--> The value's class is incorrect.
```

```
    Actual Class:  
        double  
    Expected Class:  
        logical
```

```
Actual Value:  
    0  
Assertion failed.
```

Verify that `@sin` is a function handle.

```
testCase.verifyThat(@sin, IsOfClass(?function_handle));
```

Interactive verification passed.

Verify that `name` is an instance of the char class.

```
name = 42;  
testCase.verifyThat(name, IsOfClass('char'));
```

matlab.unittest.constraints.IsOfClass

```
Interactive verification failed.  
  
-----  
Framework Diagnostic:  
-----  
IsOfClass failed.  
--> The value's class is incorrect.
```

```
    Actual Class:  
        double  
    Expected Class:  
        char
```

```
Actual Value:  
    42
```

Test That Derived Class Is Instance of Specified Class

In a file in your working folder, create a class, `DerivedExample`, that inherits from the `handle` class.

```
classdef DerivedExample < handle  
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase  
import matlab.unittest.constraints.IsOfClass;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that an instance of the `DerivedExample` class is an instance of a `handle`.

```
exObj = DerivedExample;  
testCase.verifyThat(exObj, IsOfClass(?handle));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----  
IsOfClass failed.  
--> The value's class is incorrect.  
  
    Actual Class:  
        DerivedExample  
    Expected Class:  
        handle  
  
Actual Value:  
    DerivedExample with no properties.
```

Even though `exObj` derives from the `handle` class, it is not an instance of the `handle` class.

Verify that an instance of the `DerivedExample` class is an instance of a `DerivedExample`.

```
testCase.verifyThat(exObj, IsOfClass(?DerivedExample));
```

```
Interactive verification passed.
```

Concepts

matlab.unittest.constraints.IsReal

Superclasses	BooleanConstraint
Purpose	Constraint specifying real valued array
Construction	IsReal provides a constraint specifying a real valued array. This constraint is satisfied only if the actual value contains only real values.
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Array Is Real Valued**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsReal;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the values 5 and 5+0i are real.

```
testCase.verifyThat(5, IsReal);
testCase.verifyThat(5+0i, IsReal);
```

```
Interactive verification passed.
Interactive verification passed.
```

Test if the imaginary number is real.

```
testCase.verifyThat(sqrt(-1), IsReal);
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
IsReal failed.
--> The value must be real.
```

```
Actual Value:  
0.0000000000000000 + 1.0000000000000000i
```

The actual value is imaginary.

Assert that an array contains only real values.

```
testCase.assertThat([0 1 1 2 3 5 8 13], IsReal);
```

```
Interactive assertion passed.
```

Test that the array, `arr`, is real.

```
arr = [NaN -Inf];  
testCase.verifyThat(arr, IsReal);
```

```
Interactive verification passed.
```

Multiply the array by a complex number and test that the values are not real.

```
testCase.verifyThat(42i*arr, ~IsReal);
```

```
Interactive verification passed.
```

Concepts

matlab.unittest.constraints.IsSameHandleAs

Superclasses	BooleanConstraint
Purpose	Constraint specifying handle instance same as another
Construction	<p>IsSameHandle(h) provides a constraint specifying a handle instance or group of instances is same as another.</p> <p>The constraint is satisfied only if each element of the actual value is the same instance as each corresponding element of h.</p>
Input Arguments	<p>h</p> <p>handle object or array of handle objects. The actual value array passed to the qualification must be the same size as h.</p>
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test Handles for Equality

In a file in your working folder, create the following handle class for interactive testing.

```
classdef ExampleHandle < handle
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsSameHandleAs;

testCase = TestCase.forInteractiveUse;
```

Instantiate two handles.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Verify that the handle, h1, is the same as h1.

```
testCase.verifyThat(h1, IsSameHandleAs(h1));
```

Interactive verification passed.

Test that h1 is the same handle instance as h2.

```
testCase.verifyThat(h1, IsSameHandleAs(h2));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----  
IsSameHandleAs failed.  
--> Values do not refer to the same handle.
```

Actual Value:

ExampleHandle with no properties.

Expected Handle Object:

ExampleHandle with no properties.

Test that two arrays of handles are the same instances.

```
expArr = [h1 h2 h1];
```

```
actArr = [h1 h2 h1];
```

```
testCase.verifyThat(expArr, IsSameHandleAs(actArr));
```

Interactive verification passed.

The arrays satisfy the constraint even though the elements within a particular array are not the same instance as each other.

Verify that the constraint is not satisfied if it expects a single handle and the actual value is an array of the same instances.

```
testCase.verifyThat([h1 h1], IsSameHandleAs(h1));
```

matlab.unittest.constraints.IsSameHandleAs

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
IsSameHandleAs failed.  
--> Sizes do not match.  
    Actual Value Size           : [1  2]  
    Expected Handle Object Size : [1  1]
```

```
Actual Value:  
    1x2 ExampleHandle array with no properties.  
Expected Handle Object:  
    ExampleHandle with no properties.
```

Similarly, the constraint is not satisfied a single handle instance if it expects an array of handles.

```
testCase.verifyThat(h2, IsSameHandleAs([h2 h2]));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
IsSameHandleAs failed.  
--> Sizes do not match.  
    Actual Value Size           : [1  1]  
    Expected Handle Object Size : [1  2]
```

```
Actual Value:  
    ExampleHandle with no properties.  
Expected Handle Object:  
    1x2 ExampleHandle array with no properties.
```

Concepts

matlab.unittest.constraints.IsSparse

Superclasses BooleanConstraint

Purpose Constraint specifying sparse array

Construction IsSparse creates a constraint specifying a sparse array. This constraint is satisfied only when the actual value is sparse.

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Test That Actual Value Array Is Sparse**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsSparse;
```

```
testCase = TestCase.forInteractiveUse;
```

Create an identity matrix, and test if it is sparse.

```
F = eye(7);
testCase.verifyThat(F, IsSparse);
```

```
testCase.verifyThat(F, IsSparse);
Interactive verification failed.
```

```
-----
Framework Diagnostic:
```

```
-----
IsSparse failed.
--> The value must be sparse.
```

Actual Value:

```
    1    0    0    0    0    0    0
    0    1    0    0    0    0    0
    0    0    1    0    0    0    0
```

```
0  0  0  1  0  0  0
0  0  0  0  1  0  0
0  0  0  0  0  1  0
0  0  0  0  0  0  1
```

The matrix, F, is a full matrix.

Convert F to a sparse matrix and retest for sparsity.

```
S = sparse(F);
testCase.verifyThat(S, IsSparse);
```

Interactive verification passed.

`issparse`

Concepts

matlab.unittest.constraints.IsSubstringOf

Superclasses BooleanConstraint

Purpose Constraint specifying substring of another string

Construction `IsSubstringOf(superstring)` creates a constraint specifying a substring of another string. The constraint is satisfied only if the actual value is contained within an expected string, `superstring`.

`IsSubstringOf(superstring,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

superstring

Text that contains the actual value, specified as a string. `superstring` can include newline characters.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

IgnoringCase

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

Default: `false`

IgnoringWhitespace

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

Default: false

Properties

IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'. This property applies at all levels of recursion, such as nested structures.

IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'. This property applies at all levels of recursion, such as nested structures.

Superstring

String that includes the actual value, specified in the input argument, `superstring`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Substring of Specified String

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsSubstringOf;
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
S = 'This Is One Long String';
```

Test that the actual value string, 'One', is contained in S.

```
testCase.verifyThat('One', IsSubstringOf(S));
```

matlab.unittest.constraints.IsSubstringOf

Interactive verification passed.

Test that the actual value string, 'long', is contained in S.

```
testCase.verifyThat('long', IsSubstringOf(S));
```

Interactive verification failed.

Framework Diagnostic:

IsSubstringOf failed.

--> The string must be found within the superstring.

Actual String:

long

Expected Superstring:

This Is One Long String

By default, the `IsSubstringOf` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat('long', IsSubstringOf(S, ...  
    'IgnoringCase', true));
```

Interactive verification passed.

Test that the actual value string, 'thisisone', is contained in S. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat('thisisone', IsSubstringOf(S, ...  
    'IgnoringCase', true, 'IgnoringWhitespace', true));
```

Interactive verification passed.

Assert that the actual value string, 'longer', is not contained in S.

```
testCase.assertThat('Longer', ~IsSubstringOf(S));
```

Interactive assertion passed.

Concepts

matlab.unittest.constraints.IssuesNoWarnings

Superclasses Constraint

Purpose Constraint specifying function that issues no warnings

Construction `outConstObj = IssuesNoWarnings` creates a constraint, `outConstObj`, specifying a function that issues no warnings when the testing framework invokes it. The constraint is satisfied if no warnings are issued when the testing framework invokes the function.

`outConstObj = IssuesNoWarnings('WhenNargoutIs', numOutputs)` creates a constraint that can determine if the actual value is a function handle that issues no warnings when the testing framework invokes it with a particular number of output arguments, `numOutputs`.

Input Arguments

numOutputs

Number of outputs the constraint requests when invoking the function handle, specified as a non-negative, real, scalar integer.

Default: 0

Properties **FunctionOutputs**

Output arguments produced at invocation of the supplied function handle, specified as a cell array. This property provides access to output arguments. It is read only and the testing framework sets it when it invokes the function handle. The number of outputs is determined by the `Nargout` property.

Nargout

Number of output arguments the instance uses when executing functions. Set this property through the constructor via the `numOutputs` input argument.

Copy Semantics Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate IssuesNoWarnings Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IssuesNoWarnings;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that a call to true does not result in any warning.

```
testCase.verifyThat(@true, IssuesNoWarnings);
```

```
Interactive verification passed.
```

Verify that a call to size with an empty array does not result in any warning. Examine the output arguments.

```
issuesNoWarningsConstraint = IssuesNoWarnings('WhenNargoutIs', 2);
testCase.verifyThat(@( ) size([]), issuesNoWarningsConstraint);
[actualOut1, actualOut2] = issuesNoWarningsConstraint.FunctionOutputs;
```

```
Interactive verification passed.
```

Verify that the constraint is not satisfied if the actual value is not a function handle.

```
testCase.verifyThat(5, IssuesNoWarnings);
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:

Concepts

matlab.unittest.constraints.IssuesWarnings

Superclasses Constraint

Purpose Constraint specifying function that issues expected warning profile

Description The IssuesWarnings class creates a constraint that issues an expected warning profile. The constraint is satisfied only if the actual value is a function handle that issues a specific set of warnings. You specify warnings using warning identifiers.

By default, the constraint only confirms that when the testing framework invokes the function handle, MATLAB issues the specified set of warnings. It ignores the number of times the warnings are issued, in what order they are issued, and whether or not any unspecified warnings are issued. However, you can set parameters to respect the order, the count, and the warning set. Alternatively, you can specify the exact warning profile for comparison.

Construction `outConstObj = IssuesWarnings(warnArr)` creates a constraint, `outConstObj`, specifying a function that issues expected warnings, `warnArr`.

`outConstObj = IssuesWarnings(expVal,Name,Value)` creates a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (`'`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

warnArr

Warning identifiers expected when the testing framework invokes the function handle, specified as a cell array of warning identifiers. If `warnArr` is empty, the constructor throws an `MException`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Exactly

Indicator if the value is a function handle that must issue a warning profile that is an exact match, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance relies on specification of other parameters and default instance behavior to determine the strictness of its comparison. When set to `true`, the instance requires the warning profile to be exactly the same as the specified warning profile.

Default: `false`

RespectingCount

Indicator whether to respect element counts, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance is insensitive to the number of occurrences of members and ignores their frequency. When set to `true`, the instance is sensitive to the total number of set members. This means that, in addition to ensuring that all of the specified warnings are issued, this instance is not satisfied if the number of times that a particular warning issues differs from the number of times that warning is specified in `warnArr`.

Default: `false`

RespectingOrder

Indicator whether to respect the order of elements, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance is insensitive to the order of the set members. When set to `true`, the instance is sensitive to the order of the set members. This means that this instance is not satisfied if the order of the

matlab.unittest.constraints.IssuesWarnings

issued warnings differs from the order the warnings are specified in `warnArr`.

The order of a given set of warnings is determined by trimming the warning profiles to a profile with no repeated adjacent warnings. For example, the warning profile `{id:A, id:A, id:B, id:C, id:C, id:C, id:A, id:A, id:A}` is trimmed to `{id:A, id:B, id:C, id:A}`.

When this constraint respects order, the order of the warnings that are issued and expected must match the order of the expected warning profile. Warnings issued that are not listed in `warnArr` are ignored when determining order.

Default: `false`

RespectingSet

Indicator whether to respect set elements, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the instance ignores additional set members. When set to `true`, the instance is sensitive to additional set members. This means that, in addition to ensuring that all of the specified warnings are issued, this instance is not satisfied if any extra, unspecified warnings are issued.

Default: `false`

WhenNargoutIs

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

Default: `0`

Properties

Exact

Indicator of whether the constraint performs exact comparisons. Set this property through the constructor via the name-value pair argument, 'Exactly'.

ExpectedWarnings

Expected warning identifiers. Set this read-only property through the constructor via the warnArr input argument.

FunctionOutputs

Output arguments produced at invocation of the supplied function handle, specified as a cell array. This property provides access to output arguments. It is read only and the testing framework sets it when it invokes the function handle. The number of outputs is determined by the Nargout property.

Nargout

Number of output arguments the instance uses when it executes functions. Set this property through the constructor via the name-value pair argument, 'WhenNargoutIs'.

RespectCount

Indicator if the constraint respects the element counts, specified through the constructor via the name-value pair argument, 'RespectingCount'.

RespectOrder

Indicator if the constraint respects the order of elements, specified through the constructor via the name-value pair argument, 'RespectingOrder'.

RespectSet

Indicator if the constraint respects set elements, specified through the constructor via the name-value pair argument, 'RespectingSet'.

matlab.unittest.constraints.IssuesWarnings

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate IssuesWarnings Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IssuesWarnings;
```

```
testCase = TestCase.forInteractiveUse;
```

Create a helper anonymous function for use in this example. Create several warning identifiers.

```
issueWarnings = @(idCell) cellfun(@(id) warning(id,'Message'), idCell);
firstID = 'first:id';
secondID = 'second:id';
thirdID = 'third:id';
```

Verify that the helper function issues a particular warning.

```
testCase.verifyThat(@( ) issueWarnings({firstID}),...
    IssuesWarnings({firstID}));
```

```
Interactive verification passed.
```

Verify the function issues a warning ignoring count, warning set, and order.

```
testCase.verifyThat(@( ) issueWarnings({firstID, thirdID, secondID,...
    firstID}), IssuesWarnings({secondID, firstID}));
```

```
Interactive verification passed.
```

Verify the function issues a warning while respecting the warning set.

```
testCase.verifyThat(@( ) issueWarnings({firstID, thirdID, secondID,...
    firstID}), IssuesWarnings({firstID, secondID, thirdID}, ...
```

```
'RespectingSet', true));
```

Interactive verification passed.

Verify the function issues a warning while respecting the warning count.

```
testCase.verifyThat(@( ) issueWarnings({secondID, firstID, thirdID,...  
    secondID}), IssuesWarnings({firstID, secondID, secondID}, ...  
    'RespectingCount', true));
```

Interactive verification passed.

Verify the function issues a warning while respecting the warning order.

```
testCase.verifyThat(@( ) issueWarnings({firstID, secondID, secondID,..  
    thirdID}), IssuesWarnings({firstID, secondID}, 'RespectingOrder',
```

Interactive verification passed.

Verify the function issues an exact match to the expected warning profile.

```
testCase.verifyThat(@( ) issueWarnings({firstID, secondID, secondID,..  
    thirdID}), IssuesWarnings({firstID, secondID, secondID, thirdID},  
    'Exactly', true));
```

Interactive verification passed.

Verify that the constraint is not satisfied if the actual value is not a function handle.

```
testCase.verifyThat(5, IssuesWarnings({firstID}));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:
```

```
-----  
IssuesWarnings failed.
```

matlab.unittest.constraints.IssuesWarnings

--> The value must be an instance of the expected type.

```
Actual Class:
    double
Expected Type:
    function_handle
```

```
Actual Value:
    5
```

Verify that the constraint is not satisfied if the function does not issue a warning.

```
testCase.verifyThat(@rand, IssuesWarnings({firstID}));
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
```

IssuesWarnings failed.

--> The function handle did not issue a correct warning profile.

The expected warning profile ignores:

```
Set
Count
Order
```

--> The function handle did not issue any warnings.

```
Expected Warning Profile:
    first:id
```

```
Evaluated Function:
    @rand
```

Verify that the constraint is not satisfied if the function issues a non-specified warning identifier.

```
testCase.verifyThat(@( ) issueWarnings({firstID}), IssuesWarnings({secondID}));
```

matlab.unittest.constraints.IssuesWarnings

Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
```

```
IssuesWarnings failed.
```

```
--> The function handle did not issue a correct warning profile.
    The expected warning profile must match exactly.
```

```
--> The function handle did not issue the exact warning profile ex
```

```
Actual Warning Profile:
```

```
    first:id
    first:id
    second:id
    first:id
```

```
Expected Warning Profile:
```

```
    first:id
    second:id
    first:id
    first:id
```

```
Evaluated Function:
```

matlab.unittest.constraints.IssuesWarnings

```
@()issueWarnings({firstID,firstID,secondID,firstID})
```

Test whether the warning array is the same as the expected array when respecting set, order and count.

```
testCase.verifyThat(actVal, IssuesWarnings(warnArr,...  
    'RespectingSet',true, 'RespectingOrder',true, 'RespectingCount',true));
```

```
Interactive verification passed.
```

In this example, a constraint that specifies a warning profile that respects set, order and count is not the same as one that specifies an exact warning profile.

Concepts

- “Message Identifiers”

Superclasses	Constraint
Purpose	Constraint specifying true value
Construction	IsTrue provides a constraint specifying a true value. This constraint is satisfied only by a scalar logical with a value of true.
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
Tips	<ul style="list-style-type: none">• For faster test execution, use <code>verifyTrue</code>, <code>assertTrue</code>, <code>assumeTrue</code>, or <code>fatalAssertTrue</code> instead of <code>IsTrue</code>.• To display custom comparisons in the form of a function handle, use <code>ReturnsTrue</code> instead of <code>IsTrue</code>.

Examples **Test Actual Value Is True**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsTrue;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that true satisfies the `IsTrue` constraint.

```
testCase.verifyThat(true, IsTrue);
```

```
Interactive verification passed.
```

Test that the `IsTrue` constraint is not satisfied by false.

```
testCase.verifyThat(false, IsTrue);
```

```
Interactive verification failed.
```

```
-----
```

matlab.unittest.constraints.IsTrue

```
Framework Diagnostic:
-----
.IsTrue failed.
--> The value must evaluate to "true".
```

```
Actual Value:
      0
```

The test fails because `false` returns `logical(0)`.

Test that the `IsTrue` constraint is not satisfied by the double 1.

```
testCase.verifyThat(1, IsTrue);
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
.IsTrue failed.
--> The value must be logical. It is of type "double".
```

```
Actual Value:
      1
```

The `IsTrue` constraint is satisfied only by `logical(1)`.

Test that the `IsTrue` constraint is not satisfied by a logical array of ones.

```
testCase.verifyThat([true true true], IsTrue);
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
.IsTrue failed.
--> The value must be scalar. It has a size of [1 3].
```

Actual Value:

```
1    1    1
```

The `IsTrue` constraint is satisfied only if the value is scalar and `logical(1)`.

[IsFalse](#) | [ReturnsTrue](#)

Concepts

matlab.unittest.constraints.LogicalComparator

Purpose Comparator for two logical values

Construction LogicalComparator creates a comparator for two logical values. The comparator is satisfied if the actual and expected values have the same sparsity and the logical values are equivalent.

Copy Semantics Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples **Compare Logical Values**

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.LogicalComparator;
import matlab.unittest.constraints.IsEqualTo;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the value of true.

```
testCase.assertThat(true, IsEqualTo(true, ...
    'Using', LogicalComparator));
```

```
Interactive assertion passed.
```

Test an array of true values.

```
testCase.assertThat([true true true], IsEqualTo(true, ...
    'Using', LogicalComparator));
```

```
Interactive assertion failed.
```

```
-----
Framework Diagnostic:
-----
IsEqualTo failed.
--> LogicalComparator failed.
```

```
--> The logical values are not equal
```

```
Actual Logical Value:  
      1      1      1  
Expected Logical Value:  
      1  
Assertion failed.
```

The actual value must be a scalar logical to satisfy the constraint.

Compare the value of 1 to true.

```
testCase.verifyThat(1, IsEqualTo(true, 'Using', LogicalComparator));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----  
IsEqualTo failed.  
--> LogicalComparator failed.  
    --> The logical values are not equal
```

```
Actual Logical Value:  
      1  
Expected Logical Value:  
      1
```

Compare the value of false to true.

```
testCase.assertThat(false, IsEqualTo(true, 'Using', LogicalComparator));
```

```
Interactive assertion failed.
```

```
-----  
Framework Diagnostic:  
-----  
IsEqualTo failed.
```

matlab.unittest.constraints.LogicalComparator

```
--> LogicalComparator failed.  
    --> The logical values are not equal  
  
Actual Logical Value:  
    0  
Expected Logical Value:  
    1  
Assertion failed.
```

Concepts

Superclasses	BooleanConstraint
Purpose	Constraint specifying string matches regular expression
Construction	<p><code>Matches(expr)</code> creates a constraint that specifies that a string matches a regular expression. The constraint is satisfied only if the actual value matches the given regular expression, <code>expr</code>.</p> <p><code>Matches(expr, 'IgnoringCase', caseInsensitive)</code> creates a constraint indicating whether to ignore case difference.</p>
	Input Arguments
	expr Regular expression that the actual value must match to satisfy the constraint, specified as a string. <code>expr</code> can include newline characters.
	caseInsensitive Indicator if the constraint is insensitive to case, specified as <code>false</code> or <code>true</code> (logical 0 or 1) Default: <code>false</code>
Properties	Expression Regular expression that the actual value must match, specified in the input argument, <code>expr</code> .
	IgnoreCase Indicator if the constraint is insensitive to case, specified in the input argument, <code>ignoreCase</code> . This property applies at all levels of recursion, such as nested structures.
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Matches Regular Expression

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.Matches;
```

```
testCase = TestCase.forInteractiveUse;
```

Test that the actual value string, 'Epsilon Eridani', matches 'eps'.

```
testCase.verifyThat('Epsilon Eridani', Matches('^eps'));
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
```

```
Matches failed.
```

```
--> The string did not match the regular expression.
```

```
Actual String:
```

```
    Epsilon Eridani
```

```
Regular Expression:
```

```
    ^eps
```

To satisfy the constraint, configure it to be case insensitive.

```
testCase.verifyThat('Epsilon Eridani', Matches('^eps', ...
    'IgnoringCase', true));
```

```
Interactive verification passed.
```

Define the regular expression that the actual value must match.

```
expr = 'Some[Ss]?tring';
```

The [Ss]? contained in the regular expression indicates that either 'S' or 's' matches at that location 0 or 1 times.

Test that the actual values, 'SomeString' and 'Somestring', satisfy the constraint.

```
testCase.verifyThat('SomeString', Matches(expr));
testCase.verifyThat('Somestring', Matches(expr));
```

```
Interactive verification passed.
Interactive verification passed.
```

Test that the actual value 'Somestring' satisfies the constraint.

```
testCase.verifyThat('Somestring', Matches(expr));
```

```
Interactive verification passed.
```

Test that the actual value 'somestring' satisfies the constraint.

```
testCase.verifyThat('somestring', Matches(expr));
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
Matches failed.
--> The string did not match the regular expression.

Actual String:
    somestring
Regular Expression:
    Some[Ss]?tring
```

Concepts

- “Regular Expressions”

matlab.unittest.constraints.NumericComparator

Purpose	Comparator for numeric data types
Construction	<p><code>NumericComparator</code> creates a comparator for numeric data types. The comparator is satisfied if inputs are of the same class with equivalent size, complexity, and sparsity and the built-in <code>isequaln</code> function returns true.</p> <p><code>NumericComparator('Within', tolObj)</code> creates a comparator using a specified tolerance. In this case, <code>NumericComparator</code> first checks for equivalent class, size, and sparsity of the actual and expected values. If these checks fail, the comparator is not satisfied. If these checks pass and the <code>isequaln</code> or complexity check fails, <code>NumericComparator</code> delegates comparison to the supplied tolerance, <code>tolObj</code>.</p>
Input Arguments	<p>tolObj</p> <p>matlab.unittest.constraints.Tolerance instance</p>
Properties	<p>Tolerance</p> <p>Specific tolerance used in construction of the comparator, specified as a <code>Tolerance</code> object in the <code>tolObj</code> input argument.</p>
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
Examples	<p>Compare Numeric Values</p> <p>Create a test case for interactive testing.</p> <pre>import matlab.unittest.TestCase; import matlab.unittest.constraints.NumericComparator; import matlab.unittest.constraints.IsEqualTo; testCase = TestCase.forInteractiveUse;</pre> <p>Test 1.618 is equal to 1.618 using a numeric comparator.</p>

```
testCase.verifyThat(1.618, IsEqualTo(1.618,...  
    'Using', NumericComparator));
```

Interactive verification passed.

Verify that $(1+\sqrt{5})/2$ is equal to 1.618.

```
testCase.verifyThat((1+sqrt(5))/2, IsEqualTo(1.618, ...  
    'Using', NumericComparator));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----  
IsEqualTo failed.  
--> NumericComparator failed.  
    --> The values are not equal using "isequaln".
```

```
Actual Value:  
    1.618033988749895  
Expected Value:  
    1.618000000000000
```

Retest using a relative tolerance of 0.25%.

```
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase.verifyThat((1+sqrt(5))/2, IsEqualTo(1.618, ...  
    'Using', NumericComparator('Within', RelativeTolerance(0.0025))));
```

Interactive verification passed.

Concepts

matlab.unittest.constraints.ObjectComparator

Purpose	Comparator for MATLAB or Java objects
Construction	<p>ObjectComparator creates a comparator for MATLAB or Java objects. The comparator is satisfied if the built-in <code>isequal</code> function returns <code>true</code>.</p> <p>ObjectComparator('Within',tolObj) creates a comparator using a specified tolerance. In this case, ObjectComparator first checks that a call to <code>isequal</code> returns <code>true</code>. If the check fails, the ObjectComparator then checks for equivalent class, size, and sparsity of the actual and expected values. If these checks pass, ObjectComparator delegates comparison to the supplied tolerance, <code>tolObj</code>. This value of this tolerance must be of the same class as the actual and expected values.</p>
Input Arguments	<p>tolObj</p> <p>Tolerance instance</p>
Properties	<p>Tolerance</p> <p>Specific tolerance used in construction of the comparator, specified as a <code>matlab.unittest.constraints.Tolerance</code> object in the <code>tolObj</code> input argument.</p>
Copy Semantics	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.
Examples	<p>Compare MATLAB Objects</p> <p>In a file, <code>MyInt.m</code>, in your working folder, create a subclass of <code>int8</code>.</p> <pre>classdef MyInt < int8 methods function i = MyInt(value) i@int8(value); end end end</pre>

matlab.unittest.constraints.ObjectComparator

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.ObjectComparator;
import matlab.unittest.constraints.IsEqualTo;

testCase = TestCase.forInteractiveUse;
```

Use an `ObjectComparator` to test that two instances of `MyInt` are equal to each other.

```
testCase.verifyThat(MyInt(10), ...
    IsEqualTo(MyInt(10), 'Using', ObjectComparator));
```

```
Interactive verification passed.
```

Test that the equality of two instances of `MyInt` constructed with different input values.

```
testCase.verifyThat(MyInt(11), ...
    IsEqualTo(MyInt(10), 'Using', ObjectComparator));
```

```
Interactive verification failed.
```

```
-----
Framework Diagnostic:
-----
IsEqualTo failed.
--> ObjectComparator failed.
    --> The objects are not equal using "isequal".
```

```
Actual Object:
    MyInt:

        int8 data:
            11
Expected Object:
    MyInt:
```

matlab.unittest.constraints.ObjectComparator

```
int8 data:  
10
```

One instance of `MyInt` has a value of 11, and the other has a value of 10.

Repeat the test and specify values must be equal within an absolute tolerance of 1.

```
import matlab.unittest.constraints.AbsoluteTolerance;  
  
testCase.verifyThat(MyInt(11), IsEqualTo(MyInt(10), ...  
    'Using', ObjectComparator('Within', AbsoluteTolerance(MyInt(1))))));
```

```
Interactive verification passed.
```

Concepts

matlab.unittest.constraints.PublicPropertyComparator

Purpose	Comparator for public properties of MATLAB objects
Description	<p>The <code>PublicPropertyComparator</code> compares public properties of MATLAB objects.</p> <p>The <code>PublicPropertyComparator</code> supports MATLAB objects or arrays of objects and recursively compares data structures contained in the public properties. The <code>PublicPropertyComparator</code> is different from the <code>isequal</code> function because it only examines the public properties of the objects.</p>
Construction	<p><code>PublicPropertyComparator</code> creates a comparator for public properties of MATLAB objects. This comparator only supports objects with no public properties.</p> <p><code>PublicPropertyComparator(compObj)</code> indicates a comparator, <code>compObj</code>, that defines the comparator used to compare public properties. This comparator only supports in recursion the data types supported by <code>compObj</code>.</p> <p><code>PublicPropertyComparator(___, Name, Value)</code> provides a comparator with additional options specified by one or more <code>Name, Value</code> pair arguments. You can specify several name-value pair arguments in any order as <code>Name1, Value1, ..., NameN, ValueN</code>. You can use this syntax with any of the input arguments of the previous syntaxes.</p> <p><code>PublicPropertyComparator.supportingAllValues</code> creates a comparator for public properties of MATLAB objects that supports any value in recursion. <code>supportingAllValues</code> is a <code>Static</code> method of the <code>PublicPropertyComparator</code> class.</p> <p>You typically pass this comparator to another constraint, such as <code>IsEqualTo</code>. You can use the <code>Name, Value</code> pairs of the <code>IsEqualTo</code> constraint in combination with a comparator constructed with the <code>PublicPropertyComparator.supportingAllValues</code> syntax.</p>

Input Arguments

compObj

Comparator object

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

'IgnoringCase'

Indicator if the comparator is insensitive to case, specified as **false** or **true** (logical 0 or 1). When it is **false**, the comparator is sensitive to case. The comparator only uses this name-value pair if the contents being compared consists of strings.

Default: **false**

'IgnoringWhitespace'

Indicator if the comparator is insensitive to whitespace, specified as **false** or **true** (logical 0 or 1). When it is **false**, the comparator is sensitive to whitespace. Whitespace characters are space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator only uses this name-value pair if the contents being compared consists of strings.

Default: **false**

'Recursively'

Indicator of whether comparator operates recursively, specified as **false** or **true** (logical 0 or 1). When this value is **false**, the comparator does not operate recursively on its data.

When the value is **true**, the data types the public property comparator supports are fully supported in recursion.

Default: false

'Within'

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. The comparator only uses this name-value pair if the contents being compared consists of numeric types.

Default: (empty)

Properties

IgnoreCase

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'.

IgnoreWhitespace

Indicator if the comparator is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'.

Recursive

Indicator of whether comparator operates recursively, specified in the name-value pair argument, 'Recursively'.

Tolerance

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate PublicPropertyComparator Object

In a file, `Employee.m`, in your working folder, construct the following class.

```
classdef Employee
```

matlab.unittest.constraints.PublicPropertyComparator

```
        properties (SetAccess=immutable)
            Name;
        end
        properties (Access=private)
            Location;
        end
        methods
            function obj = Employee(name,location)
                obj.Name = name;
                obj.Location = location;
            end
        end
    end
end
```

At the command prompt, create two instances of the Employee class.

```
e1 = Employee('sam','Building A');
e2 = Employee('Sam','Building B');
```

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.PublicPropertyComparator;
import matlab.unittest.constraints.StringComparator;
```

```
testCase = TestCase.forInteractiveUse;
```

Construct a comparator and verify that e1 and e2 are equal.

```
compObj = PublicPropertyComparator;
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', compObj));
```

```
Error using matlab.unittest.constraints.ComparatorList/throwUnsupportedType
No comparator in list supports the char below:
    Sam
List contains the following comparators:
    <empty>
```

matlab.unittest.constraints.PublicPropertyComparator

```
Error in matlab.unittest.constraints.ComparatorList/getAndPrepareComparatorFor (line 10)
    list.throwUnsupportedType(expVal);

Error in matlab.unittest.constraints.ComparatorList/satisfiedBy (line 15)
    comp = list.getAndPrepareComparatorFor(expVal);

Error in matlab.unittest.internal.constraints.FieldComparator/findFirstDifferingField (line 10)
    bool = comp.satisfiedBy(actField, expField);

Error in matlab.unittest.internal.constraints.FieldComparator/fieldsHaveSameClass (line 10)
    bool = comparator.findFirstDifferingField(actVal, expVal);

Error in matlab.unittest.internal.constraints.FieldComparator/satisfiedBy (line 10)
    bool = haveSameClass(actVal, expVal) && ...

Error in matlab.unittest.constraints.IsEqualTo/satisfiedBy (line 165)
    bool = comp.supports(actual) && comp.satisfiedBy(actual, constraint);

Error in matlab.unittest.internal.qualifications.QualificationDelegate/satisfiedBy (line 10)
    result = constraint.satisfiedBy(actual);

Error in matlab.unittest.qualifications.Verifiable/verifyThat (line 20)
    qualifyThat(verifyable.VerificationDelegate, actual, constraint);
```

The test fails because, by default, the `PublicPropertyComparator` does not support strings.

Construct a comparator that supports strings. Specify that the comparison is not case-sensitive.

```
compObj = PublicPropertyComparator(StringComparator, 'IgnoringCase', true);
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', compObj));
```

Interactive verification passed.

matlab.unittest.constraints.PublicPropertyComparator

Note that the test passes even though `e1.Location` and `e2.Location` are not the same. Since `Location` is a private property, the comparator does not compare its contents.

Instantiate PublicPropertyComparator Object to Support All Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.PublicPropertyComparator;
```

```
testCase = TestCase.forInteractiveUse;
```

Test a passing case.

```
m1 = MException('Msg:ID','MsgText');
m2 = MException('Msg:ID','MsgText');
testCase.verifyThat(m1, IsEqualTo(m2, 'Using', ...
    PublicPropertyComparator.supportingAllValues));
```

Interactive verification passed.

Test a failing case.

```
m1 = MException('Msg:ID','MsgText');
m2 = MException('Msg:ID','msgtext');
testCase.verifyThat(m1, IsEqualTo(m2, 'Using', ...
    PublicPropertyComparator.supportingAllValues));
```

Interactive verification failed.

```
-----
Framework Diagnostic:
-----
IsEqualTo failed.
--> StringComparator failed.
    Path to failure: <Value>.message
```

matlab.unittest.constraints.PublicPropertyComparator

```
--> The strings are not equal

Actual String:
  MsgText
Expected String:
  msgtext

Actual MException:
  MException with properties:

    identifier: 'Msg:ID'
    message: 'MsgText'
    cause: {}
    stack: [0x1 struct]
Expected MException:
  MException with properties:

    identifier: 'Msg:ID'
    message: 'msgtext'
    cause: {}
    stack: [0x1 struct]
```

Test a case that passes when the comparator ignores differences in case.

```
m1 = MException('Msg:ID','MsgText');
m2 = MException('Msg:ID','msgtext');
testCase.verifyThat(m1, IsEqualTo(m2, 'IgnoringCase', true,...
    'Using', PublicPropertyComparator.supportingAllValues));
```

Interactive verification passed.

Instantiate PublicPropertyComparator Object with Tolerance

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
```

matlab.unittest.constraints.PublicPropertyComparator

```
import matlab.unittest.constraints.PublicPropertyComparator;
```

```
testCase = TestCase.forInteractiveUse;
```

Define actual and expected timeseries objects. Perturb one of the actual data points by 1%.

```
expected = timeseries(1:10);  
actual = expected;  
actual.Data(7) = 1.01*actual.Data(7);
```

Test that the actual and expected values are equal within a relative tolerance of 2%.

```
testCase.verifyThat(actual, IsEqualTo(expected,...  
    'Within', RelativeTolerance(.02)));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
IsEqualTo failed.
```

```
--> ObjectComparator failed.
```

```
    --> The objects are not equal using "isequal".
```

```
    --> The tolerance does not support timeseries values so it was not used.
```

```
Actual Object:
```

```
    timeseries
```

```
Common Properties:
```

```
    Name: 'unnamed'
```

```
    Time: [10x1 double]
```

```
    TimeInfo: [1x1 tsdata.timemetadata]
```

```
    Data: [1x1x10 double]
```

```
    DataInfo: [1x1 tsdata.datametadata]
```

```
More properties, Methods
```

```
Expected Object:  
timeseries
```

```
Common Properties:
```

```
    Name: 'unnamed'  
    Time: [10x1 double]  
    TimeInfo: [1x1 tsdata.timemetadata]  
    Data: [1x1x10 double]  
    DataInfo: [1x1 tsdata.datametadata]
```

```
More properties, Methods
```

Use the `PublicPropertyComparator` in the construction of the constraint.

```
testCase.verifyThat(actual, IsEqualTo(expected,...  
    'Within', RelativeTolerance(.02),...  
    'Using', PublicPropertyComparator.supportingAllValues));
```

```
Interactive verification passed.
```

The test passes because the `PublicPropertyComparator` compares each public property individually instead of comparing the object all at once. In the former test, the `ObjectComparator` is used on the `timeseries` object, and therefore relies on the `isequal` method of the `timeseries` class. Due to the perturbation in the actual `timeseries`, `isequal` returns `false`. The comparator does not apply the tolerance because the double-valued tolerance cannot apply directly to the `timeseries` object. In the latter test, the comparator applies the tolerance to each public property that contains double-valued data.

Concepts

matlab.unittest.constraints.RelativeTolerance

Superclasses Tolerance

Purpose Relative numeric tolerance

Description This numeric Tolerance assesses the magnitude of the difference between actual and expected values, relative to the expected value. For the tolerance to be satisfied, `abs(expVal - actVal) <= relTol.*abs(expVal)` must be true.

Construction `RelativeTolerance(tolVals)` creates a relative tolerance object that assesses the magnitude of the difference between actual and expected values, relative to the expected value.

The data types of the inputs to the `RelativeTolerance` constructor determine the data types to which the tolerance is applied.

For example, `RelativeTolerance(10*eps)` constructs a `RelativeTolerance` for comparing double-precision numeric arrays while `RelativeTolerance(int8(2))` constructs a `RelativeTolerance` for comparing numeric arrays of type `int8`. If the actual and expected values being compared contain more than one numeric data type, the tolerance only applies to the data types specified by the values passed into the constructor.

You can specify different tolerance values for different data types by passing multiple tolerance values to the constructor. For example, `RelativeTolerance(10*eps, 10*eps('single'), int8(1))` constructs an `RelativeTolerance` that would apply the following absolute tolerances.

- `10*eps` applies a relative tolerance of `10*eps` for double-precision numeric arrays.
- `10*eps('single')` applies a relative tolerance of `10*eps` for single-precision numeric arrays.
- `int8(1)` applies a relative tolerance of 1 for numeric arrays of type `int8`.

More than one tolerance can be specified for a particular data type by combining tolerances with the & and | operators. In order to combine two tolerances, the sizes of the tolerance values for each data type must be compatible.

Input Arguments

tolVals

Numeric tolerances, specified as a cell array of numeric arrays. Each input argument contains the tolerance specification for a particular data type. Each numeric array can be a scalar or array with the same number of dimensions as the actual and expected values.

Properties

Values

Numeric tolerances, specified by the tolVals input argument.

Methods

and	Form logical element-wise conjunction of tolerances
or	Form logical element-wise disjunction of tolerances

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test with Relative Tolerance

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.RelativeTolerance;
```

matlab.unittest.constraints.RelativeTolerance

```
testCase = TestCase.forInteractiveUse;
```

Assert that the difference between and actual value, 4.1, and an expected value, 4.5, is less than 10%.

```
testCase.assertThat(4.1, IsEqualTo(4.5, ...  
    'Within', RelativeTolerance(0.1)));
```

Interactive assertion passed.

Specify Relative Tolerance for Different Data Types

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.RelativeTolerance;
```

```
testCase = TestCase.forInteractiveUse;
```

Create the following actual and expected cell arrays.

```
act = {'abc', 123, single(106)};  
exp = {'abc', 122, single(105)};
```

Test that the arrays satisfy the RelativeTolerance constraint within 2%.

```
testCase.verifyThat(act, IsEqualTo(exp, ...  
    'Within', RelativeTolerance(0.02)));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

matlab.unittest.constraints.RelativeTolerance

```
Path to failure: <Value>{3}
--> The values are not equal using "isequaln".
--> The tolerance does not support single values so it was not used.
```

```
Actual Value:
    106
Expected Value:
    105
```

```
Actual cell:
    'abc'    [123]    [106]
Expected cell:
    'abc'    [122]    [105]
```

The test fails because the tolerance is only applied to the double data type.

Create a tolerance object that specifies different tolerances for different data types.

```
tolObj = RelativeTolerance(0.02, single(0.02));
```

A tolerance of 2% is applied to double and single valued data.

Verify that the expected and actual values satisfy the `RelativeTolerance` constraint.

```
testCase.verifyThat(act, IsEqualTo(exp, 'Within', tolObj));
```

```
Interactive verification passed.
```

Combine Relative and Absolute Tolerances

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
```

matlab.unittest.constraints.RelativeTolerance

```
testCase = TestCase.forInteractiveUse;
```

Define an actual value approximation for pi.

```
act = 3.14;
```

Construct a tolerance object to test that difference between the actual and expected values is within 0.001 and within 0.25%.

```
tolObj = AbsoluteTolerance(0.001) & RelativeTolerance(0.0025);
```

Verify that the actual value is within the tolerance of the expected value of pi.

```
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
    --> The values are not equal using "isequaln".
```

```
    --> AndTolerance failed.
```

```
        --> AbsoluteTolerance failed.
```

```
            --> The value was not within absolute tolerance.
```

```
                Tolerance Value:
```

```
                    1.0000000000000000e-03
```

```
            --> RelativeTolerance passed.
```

```
Actual Value:
```

```
    3.1400000000000000
```

```
Expected Value:
```

```
    3.141592653589793
```

The actual value does not satisfy the AbsoluteTolerance constraint.

Construct a constraint that is satisfied if the values are within 0.001 or 0.25%, and retest the actual value.

```
tolObj = AbsoluteTolerance(0.001) | RelativeTolerance(0.0025);  
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj));
```

Interactive verification passed.

Combine Absolute and Relative Tolerances to Test Small and Large Values

Typically when testing equality of values, an absolute (floor) tolerance dominates when the values are near zero, and a relative tolerance dominates for larger values.

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.AbsoluteTolerance;  
import matlab.unittest.constraints.RelativeTolerance;
```

```
testCase = TestCase.forInteractiveUse;
```

Define two structures containing electromagnetic properties of a vacuum. One structure, `approxVacuumProps`, contains approximate values for the permeability and speed of light in a vacuum.

```
approxVacuumProps.Permeability = 1.2566e-06; % Approximate  
approxVacuumProps.Permittivity = 8.854187817*10^-12;  
approxVacuumProps.LightSpeed = 2.9979e+08; % Approximate
```

```
baselineVacuumProps.Permeability = 4*pi*10^-7;  
baselineVacuumProps.Permittivity = 8.854187817*10^-12;  
baselineVacuumProps.LightSpeed = 1/sqrt(...  
    baselineVacuumProps.Permeability*baselineVacuumProps.Permittivity);
```

matlab.unittest.constraints.RelativeTolerance

Test that the relative difference between the approximate and baseline values is within $\text{eps} \times 1e11$.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
    'Within', RelativeTolerance(eps*1e11)));
```

Interactive verification failed.

Framework Diagnostic:

IsEqualTo failed.

--> NumericComparator failed.

Path to failure: <Value>.Permeability

--> The values are not equal using "isequaln".

--> RelativeTolerance failed.

--> The value was not within relative tolerance.

Tolerance Value:

2.220446049250313e-05

Actual Value:

1.2566000000000000e-06

Expected Value:

1.256637061435917e-06

Actual struct:

Permeability: 1.2566000000000000e-06

Permittivity: 8.854187816999999e-12

LightSpeed: 299790000

Expected struct:

Permeability: 1.256637061435917e-06

Permittivity: 8.854187816999999e-12

LightSpeed: 2.997924580105029e+08

The test fails because the relative difference in the permeabilities is not within the tolerance. The difference between the two values is small,

but the numbers are close to zero, so the difference relative to their size isn't small enough to satisfy the tolerance.

Construct a tolerance object to test that the absolute difference between the approximate and baseline values is within $1e-4$.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, 'Within', AbsoluteTolerance(1e-4)));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----  
IsEqualTo failed.  
--> NumericComparator failed.  
    Path to failure: <Value>.LightSpeed  
    --> The values are not equal using "isequaln".  
    --> AbsoluteTolerance failed.  
        --> The value was not within absolute tolerance.
```

```
    Tolerance Value:  
                1.0000000000000000e-04
```

```
    Actual Value:  
                299790000  
    Expected Value:  
                2.997924580105029e+08
```

```
Actual struct:  
    Permeability: 1.2566000000000000e-06  
    Permittivity: 8.854187816999999e-12  
    LightSpeed: 299790000  
Expected struct:  
    Permeability: 1.256637061435917e-06  
    Permittivity: 8.854187816999999e-12  
    LightSpeed: 2.997924580105029e+08
```

matlab.unittest.constraints.RelativeTolerance

The test fails because the absolute difference in the speed of light is not within the tolerance. The difference between the two values is small relative to their size, but too large to satisfy the tolerance.

Construct a logical disjunction of tolerance objects to test that the absolute difference between the approximate and baseline values is within $1e-4$ or the relative difference is within $\text{eps} \cdot 1e11$. This tolerance is used so permeability values, which are close to zero, satisfy the absolute (floor) tolerance, and speed of light values, which are large, satisfy the relative tolerance.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...  
    'Within', RelativeTolerance(eps*1e11)| AbsoluteTolerance(1e-4)));
```

```
Interactive verification passed.
```

[matlab.unittest.constraints.AbsoluteTolerance](#) |
[matlab.unittest.constraints.IsEqualTo](#)

Concepts

matlab.unittest.constraints.RelativeTolerance.and

Purpose Form logical element-wise conjunction of tolerances

Syntax `outTo1Obj = and(to1Obj1, to1Obj2)`

Description `outTo1Obj = and(to1Obj1, to1Obj2)` forms the logical element-wise conjunction of tolerances and returns a single tolerance, `outTo1Obj`. This is a means to specify that every element of the actual value should be equal to the expected value to within the tolerance specified by both `to1Obj1` and `to1Obj2`. A qualification failure occurs when either `to1Obj1` or `to1Obj2` is not satisfied for one or more elements of the comparison values.

Typically, the `and` method is not called directly, but the `and` operator, `&`, is used to denote the conjunction of any two tolerance objects.

Input Arguments

to1Obj
Tolerance instance

Examples Form Logical and of Tolerances

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;

% Create a TestCase for interactive use
testCase = TestCase.forInteractiveUse;

% Passing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(2) & RelativeTolerance(0.02)));
testCase.verifyThat([101, 105], IsEqualTo([100, 100], 'Within', ...
    AbsoluteTolerance([2, 10]) & RelativeTolerance([0.02, 0.1])));

% Failing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
```

matlab.unittest.constraints.RelativeTolerance.and

```
AbsoluteTolerance(2) & RelativeTolerance(0.02));  
testCase.verifyThat([101, 105], IsEqualTo([100, 100], 'Within', ...  
    AbsoluteTolerance(2) & RelativeTolerance(0.02));
```

See Also or

Purpose Form logical element-wise disjunction of tolerances

Syntax `outTo1Obj = or(tolObj1,tolObj2)`

Description `outTo1Obj = or(tolObj1,tolObj2)` forms the logical element-wise disjunction of tolerances and returns a single tolerance, `outTo1Obj`. This is a means to specify that every element of the actual value should be equal to the expected value to within the tolerance specified by either `tolObj1` or `tolObj2`. A qualification failure occurs when both `tolObj1` and `tolObj2` are not satisfied for one or more elements of the comparison values.

Forming the logical disjunction of tolerances is particularly useful when relative tolerance is used in general, but absolute tolerance is used when values are small.

Typically, the `or` method is not called directly, but the `or` operator, `|`, is used to denote the disjunction of any two tolerance objects.

Input Arguments

tolObj
Tolerance instance

Examples

Form Logical or of Tolerances

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
```

```
% Create a TestCase for interactive use
testCase = TestCase.forInteractiveUse;
```

```
% Simple passing qualification
testCase.verifyThat(105, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(3) | RelativeTolerance(0.1)));
```

```
% The following qualification passes because the or
```

```
% operation is performed element-wise between the
% actual and expected values being compared:
testCase.verifyThat([8, 104], IsEqualTo([10, 100], 'Within', ...
    AbsoluteTolerance(3) | RelativeTolerance(0.05)));
% Note that the following would fail:
testCase.verifyThat([8, 104], ...
    IsEqualTo([10, 100], 'Within', AbsoluteTolerance(3)) | ...
    IsEqualTo([10, 100], 'Within', RelativeTolerance(0.05)));

% Failing qualifications
testCase.verifyThat(101, IsEqualTo(100, 'Within', ...
    AbsoluteTolerance(0.5) | RelativeTolerance(0)));
testCase.verifyThat([101, 101], IsEqualTo([100, 100], 'Within', ...
    AbsoluteTolerance([2, 0.5]) | RelativeTolerance([0.02, 0.001])));

--> The function handle should have returned a scalar. The return value
```

```
--> Returned value:
```

```
    1    1
```

```
Actual Function Handle:  
    @()strcmp('a',{'a','a'})
```

The constraint is not satisfied because the call to strcmp results a logical array, not a logical scalar.

Concepts

matlab.unittest.constraints.StartsWithSubstring

Superclasses BooleanConstraint

Purpose Constraint specifying string starting with substring

Construction `StartsWithSubstring(prefix)` creates a constraint specifying a string starting with a substring. The constraint is satisfied only if the actual value starts with an expected string, `prefix`.

`StartsWithSubstring(prefix,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

prefix

Text at the start of the actual value, specified as a string. `prefix` can include newline characters.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

IgnoringCase

Indicator if the constraint is insensitive to case, specified as `false` or `true` (logical 0 or 1)

Default: `false`

IgnoringWhitespace

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1)

Default: false

Properties

IgnoreCase

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, 'IgnoringCase'. This property applies at all levels of recursion, such as nested structures.

IgnoreWhitespace

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'. This property applies at all levels of recursion, such as nested structures.

Prefix

Text at the start of the actual value, specified in the input argument, `prefix`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Starts with Specified Substring

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.StartsWithSubstring;
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test that `actVal` starts with the substring 'This'.

```
testCase.verifyThat(actVal, StartsWithSubstring('This'));
```

matlab.unittest.constraints.StartsWithSubstring

Interactive verification passed.

Test that actVal starts with the substring 'this is'.

```
testCase.verifyThat(actVal, StartsWithSubstring('this is'));
```

Interactive verification failed.

Framework Diagnostic:

StartsWithSubstring failed.

--> The string has an incorrect prefix.

Actual String:

 This Is One Long String

Expected Prefix:

 this is

By default, the StartsWithSubstring constraint is case sensitive.

Repeat the test, this time ignoring case.

```
testCase.verifyThat(actVal, StartsWithSubstring('this is', ...  
    'IgnoringCase', true));
```

Interactive verification passed.

Test that actVal starts with the substring 'thisisone'. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, StartsWithSubstring('thisisone', ...  
    'IgnoringCase', true, 'IgnoringWhitespace', true));
```

Interactive verification passed.

Assert that actVal does not start with the substring 'long'.

```
testCase.assertThat(actVal, ~StartsWithSubstring('Long'));
```

Interactive assertion passed.

Concepts

matlab.unittest.constraints.StringComparator

Purpose

Comparator for two strings

Construction

`StringComparator` creates a comparator for two strings. The comparator is satisfied if the two strings are equal.

`StringComparator(,Name,Value)` creates a comparator with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'IgnoringCase'

Indicator if the comparator is insensitive to case, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to case.

Default: `false`

'IgnoringWhitespace'

Indicator if the comparator is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace. Whitespace characters are space, form feed, new line, carriage return, horizontal tab, and vertical tab.

Default: `false`

Properties

IgnoreCase

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoreCase'.

IgnoreWhitespace

Indicator if the comparator is insensitive to whitespace, specified in the name-value pair argument, 'IgnoreWhitespace'.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Compare Cell Arrays

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.StringComparator;
import matlab.unittest.constraints.IsEqualTo;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that the actual and expected strings are equal using a string comparator.

```
expected = 'coffee';
actual = 'coffee';
testCase.verifyThat(actual, IsEqualTo(expected, ...
    'Using', StringComparator));
```

```
Interactive verification passed.
```

Change the actual string and repeat the comparison.

```
expected = 'coF Fee';
testCase.verifyThat(actual, IsEqualTo(expected, ...
    'Using', StringComparator));
```

```
Interactive verification failed.
```

matlab.unittest.constraints.StringComparator

```
-----  
Framework Diagnostic:  
-----  
IsEqualTo failed.  
--> StringComparator failed.  
    --> The strings are not equal
```

```
Actual String:  
    coffee  
Expected String:  
    coF Fee
```

For the test to pass, construct a comparator that ignores case and whitespace.

```
testCase.verifyThat(actual, IsEqualTo(expected, ...  
    'Using', StringComparator('IgnoringCase', true, ...  
    'IgnoringWhitespace', true)));
```

```
Interactive verification passed.
```

Concepts

Purpose

Comparator for MATLAB structure arrays

Construction

`StructComparator` creates a comparator for MATLAB structure arrays.

`StructComparator(compObj)` indicates a comparator, `compObj`, that defines the comparator used to compare values contained in the structure. By default, a `StructComparator` only supports empty structure arrays.

`StructComparator(__,Name,Value)` provides a comparator with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`compObj`

Comparator object

A comparator is passed into the `StructComparator` to provide support for data types during recursion. By default, the `StructComparator` only supports empty structure arrays.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'IgnoringCase'

Indicator if the comparator is insensitive to case, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to case. The comparator only uses this name-value pair if the contents being compared are strings.

Default: `false`

'IgnoringWhitespace'

Indicator if the comparator is insensitive to whitespace, specified as `false` or `true` (logical 0 or 1). When it is `false`, the comparator is sensitive to whitespace. Whitespace characters are space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator only uses this name-value pair if the contents being compared are strings.

Default: `false`

'Recursively'

Indicator of whether comparator operates recursively, specified as `false` or `true` (logical 0 or 1). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types the `StructComparator` supports are fully supported in recursion. For example:

```
comp1 = StructComparator(NumericComparator);  
comp2 = StructComparator(NumericComparator, 'Recursively', true);
```

Both `comp1` and `comp2` support structures that contain numeric values as their fields. However, only `comp2` supports a structures that recursively contain either structures or numeric values as their fields.

Default: `false`

'Within'

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. This name-value pair is applicable to contents that are a numeric type.

Default: (empty)

Properties

IgnoreCase

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, 'IgnoreCase'.

IgnoreWhitespace

Indicator if the comparator is insensitive to whitespace, specified in the name-value pair argument, 'IgnoringWhitespace'.

Recursive

Indicator of whether comparator operates recursively, specified in the name-value pair argument, 'Recursively'.

Tolerance

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, 'Within'.

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

Examples

Compare Numeric Structures

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.StructComparator;
import matlab.unittest.constraints.NumericComparator;
```

```
testCase = TestCase.forInteractiveUse;
```

Create two equal structures.

```
s1 = struct('id',7,'score',7.3);
s2 = s1;
```

matlab.unittest.constraints.StructComparator

Test that the structures are equal. By default, the `StructComparator` only supports empty structures, so you need to configure the comparator with a `NumericComparator`.

```
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...  
    StructComparator(NumericComparator)));
```

Interactive verification passed.

Change the score of `s2` and compare the structures again.

```
s2.score = 7.6;  
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...  
    StructComparator(NumericComparator)));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----  
IsEqualTo failed.  
--> NumericComparator failed.  
    Path to failure: <Value>.score  
    --> The values are not equal using "isequaln".  
  
    Actual Value:  
        7.300000000000000  
    Expected Value:  
        7.600000000000000  
  
Actual struct:  
    id: 7  
    score: 7.300000000000000  
Expected struct:  
    id: 7  
    score: 7.600000000000000
```

Specify an absolute tolerance for the comparison.

```
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...  
    StructComparator(NumericComparator, 'Within', ...  
    AbsoluteTolerance(0.5))));
```

Interactive verification passed.

Compare Character Structures

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;  
import matlab.unittest.constraints.IsEqualTo;  
import matlab.unittest.constraints.StructComparator;  
import matlab.unittest.constraints.StringComparator;
```

```
testCase = TestCase.forInteractiveUse;
```

Create two structures. One of the fields is a nested structure.

```
e1 = struct('name', struct('first','sam','last','smith'), ...  
    'location','Building A');  
e2 = e1;
```

Verify that the two structures are equal. Since the struct contains a nested struct, configure the constraint to operate recursively.

```
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...  
    StructComparator(StringComparator, 'Recursively', true)));
```

Interactive verification passed.

Change the first name field of the e2 structure and repeat the comparison.

```
e2.name.first = ' SAM';  
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...  
    StructComparator(StringComparator, 'Recursively', true)));
```

Interactive verification failed.

matlab.unittest.constraints.StructComparator

```
-----  
Framework Diagnostic:  
-----  
IsEqualTo failed.  
--> StringComparator failed.  
    Path to failure: <Value>.name.first  
    --> The strings are not equal
```

```
    Actual String:  
        sam  
    Expected String:  
        SAM
```

```
Actual struct:  
    name: [1x1 struct]  
    location: 'Building A'  
Expected struct:  
    name: [1x1 struct]  
    location: 'Building A'
```

Configure the comparator to ignore case and whitespace.

```
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...  
    StructComparator(StringComparator, 'Recursively', true, ...  
    'IgnoringCase', true, 'IgnoringWhitespace', true)));
```

Interactive verification passed.

Concepts

Superclasses	Constraint
Purpose	Constraint specifying function handle that throws MException
Description	<p>The Throws class creates a constraint that is satisfied only if the actual value is a function handle that throws a specific exception.</p> <p>If the function throws an MException and the constraint's ExpectedException property is an error identifier, a qualification failure occurs if the actual MException thrown has a different identifier. Alternately, if the ExpectedException property is a meta.class, the constraint is not satisfied if the actual MException thrown does not derive from the ExpectedException.</p>

Construction `outConstObj = Throws(excep)` provides a constraint, `outConstObj`, specifying a function handle that throws a particular MException, `excep`.

`outConstObj = Throws(excep,Name,Value)` provides a constraint with additional options specified by one or more `Name,Value` pair arguments. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

excep

Error identifier or `meta.class` representing the specific type of expected exception. The Throws constructor throws an MException if `excep` is a `meta.class` but does not derive from MException.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can

matlab.unittest.constraints.Throws

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

CausedBy

Expected causes, specified as a cell array of strings and/or `meta.class` instances.

The testing results in a qualification failure if any causes specified in `CausedBy` are not found within the cause tree.

Default: `{}`

WhenNargoutIs

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

Default: `0`

Properties

ExpectedException

Expected `MException` identifier or class. Set this read only property through the constructor via the `except` input argument.

Nargout

Number of output arguments the instance uses when executing functions. Set this property through the constructor via the name-value pair argument, `'WhenNargoutIs'`.

RequiredCauses

Expected causes for the function handle throwing an `MException`. Set this property through the constructor via the name-value pair argument, `'CausedBy'`.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate Throws Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.Throws;
```

```
testCase = TestCase.forInteractiveUse;
```

Verify that a function throws a specified error id.

```
testCase.verifyThat(@() error('SOME:error:id', 'Error!'), ...
    Throws('SOME:error:id'));
```

```
Interactive verification passed.
```

Verify that a function throws a specified exception class.

```
testCase.verifyThat(@() error('SOME:error:id', 'Error!'), ...
    Throws(?MException));
```

```
Interactive verification passed.
```

Verify that a function, when called with a specified number of outputs, throws a specified error.

```
testCase.verifyThat(@() disp('hi'), Throws('MATLAB:maxlhs', ...
    'WhenNargoutIs', 1));
```

```
Interactive verification passed.
```

Check causes by identifier.

```
me = MException('TOP:error:id', 'TopLevelError!');
causeBy = MException('causedBy:someOtherError:id', 'CausedByError!');
me = me.addCause(causeBy);
testCase.verifyThat(@() me.throw, Throws('TOP:error:id', 'CausedBy', ...
    {'causedBy:someOtherError:id'}));
```

matlab.unittest.constraints.Throws

Interactive verification passed.

Check causes by class.

```
me = MException('TOP:error:id','TopLevelError!');
causeBy = MException('causedBy:someOtherError:id','CausedByError!');
me = me.addCause(causeBy);
testCase.verifyThat(@() me.throw, Throws('TOP:error:id','CausedBy', ...
    {?MException}));
```

Interactive verification passed.

Verify that the constraint is not satisfied if the actual value is not a function handle.

```
testCase.fatalAssertThat(5, Throws('some:id'));
```

Interactive fatal assertion failed.

```
-----
Framework Diagnostic:
-----
```

Throws failed.

--> The value must be an instance of the expected type.

```
Actual Class:
    double
Expected Type:
    function_handle
```

Actual Value:

5

Fatal assertion failed.

Verify that the constraint is not satisfied if the function does not throw an exception.

```
testCase.assumeThat(@rand, Throws(?MException));
```

Interactive assumption failed.

Framework Diagnostic:

Throws failed.

--> The function did not throw any exception.

Expected Exception Type:
MException

Evaluated Function:
@rand

Assumption failed.

Verify that the constraint is not satisfied if the function issues a non-specified error identifier.

```
testCase.verifyThat(@() error('SOME:id'), Throws('OTHER:id'));
```

Interactive verification failed.

Framework Diagnostic:

Throws failed.

--> The function threw an exception with the wrong identifier.

Actual Identifier:
MATLAB:error:missingMessageArgument
Expected Identifier:
OTHER:id

Evaluated Function:
@()error('SOME:id')

Verify that the constraint is not satisfied if the function throws an exception and the cause does not match the specified identifier.

matlab.unittest.constraints.Throws

```
testCase.verifyThat(@() error('TOP:error:id','TopLevelError!'), ...
    Throws('TOP:error:id','CausedBy',{'causedBy:someOtherError:id'}));
```

Interactive verification failed.

```
-----  
Framework Diagnostic:  
-----
```

Throws failed.

--> The following causes were not found in the exception tree:

--> Identifier:

causedBy:someOtherError:id

Evaluated Function:

```
@()error('TOP:error:id','TopLevelError!')
```

Concepts

- “Message Identifiers”

Purpose

Abstract interface class for tolerances

Description

Tolerances define a notion of fuzzy equality for a set of data types and can be plugged in to the `IsEqualTo` constraint through the `'Within'` name-value pair argument.

Classes that derive from the `Tolerance` interface class must provide a tolerance definition. Implement this via the `satisfiedBy` method. Classes that derive from the `Tolerance` class also must provide a diagnostic for two compared values. The testing framework uses the diagnostic when the compared values are outside of the allowable tolerance. Implement this via the `getDiagnosticFor` method. Finally, classes that derive from the `Tolerance` class must provide a means to determine which data types the tolerance supports. Define the supported data types by implementing the `supports` method.

Methods

<code>getDiagnosticFor</code>	Produce diagnostic for two values specified to be within tolerance
<code>satisfiedBy</code>	Determine whether two values are within tolerance
<code>supports</code>	Determine whether tolerance supports specified data type

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

Examples

Create Custom Tolerance Class

Determine if two DNA sequences have a Hamming distance within a specified tolerance. For two DNA sequences (strings) of the same length, the Hamming distance is the number of positions in which the nucleotides (letters) of one sequence differ from the other.

In a file, `DNA.m`, in your working folder, create a simple class for a DNA sequence.

matlab.unittest.constraints.Tolerance

```
classdef DNA
    properties(SetAccess=immutable)
        Sequence
    end

    methods
        function dna = DNA(sequence)
            validLetters = ...
                sequence == 'A' | ...
                sequence == 'C' | ...
                sequence == 'T' | ...
                sequence == 'G';

            if ~all(validLetters(:))
                error('Sequence contained a letter not found in DNA.');
            end
            dna.Sequence = sequence;
        end
    end
end
```

In a file in your working folder, create a tolerance class so that you can test that DNA sequences are within a specified Hamming distance. The constructor requires a `Value` property that defines the maximum Hamming distance.

```
classdef HammingDistance < matlab.unittest.constraints.Tolerance
    properties
        Value
    end

    methods
        function tolerance = HammingDistance(value)
            tolerance.Value = value;
        end
    end
end
```

Tolerance classes must implement a `supports` method. In a `methods` block with the `HammingDistance` class definition, include the following method so that the tolerance supports DNA objects.

```
methods
    function tf = supports(~, value)
        tf = isa(value, 'DNA');
    end
end
```

Tolerance classes must implement a `satisfiedBy` method. The testing framework uses this method to determine if two values are within the tolerance. In a `methods` block with the `HammingDistance` class definition, include the following method that returns true or false.

```
methods
    function tf = satisfiedBy(tolerance, actual, expected)
        if ~isSameSize(actual.Sequence, expected.Sequence)
            tf = false;
            return
        end
        tf = hammingDistance(actual.Sequence, expected.Sequence) <
    end
end
```

In the `HammingDistance.m` file, define the following helper functions outside of the `classdef` block. The `isSameSize` function returns true if two DNA sequences are the same size, and the `hammingDistance` function returns the Hamming distance between two sequences.

```
function tf = isSameSize(str1, str2)
tf = isequal(size(str1), size(str2));
end
```

```
function distance = hammingDistance(str1, str2)
distance = nnz(str1 ~= str2);
end
```

matlab.unittest.constraints.Tolerance

Tolerance classes must implement a `getDiagnosticFor` method. The function returns a `Diagnostic` object with information about the comparison. In a methods block with the `HammingDistance` class definition, include the following method that returns a `StringDiagnostic`.

```
methods
    function diag = getDiagnosticFor(tolerance, actual, expected)
        import matlab.unittest.diagnostics.StringDiagnostic;

        if ~isSameSize(actual.Sequence, expected.Sequence)
            str = 'The DNA sequences must be the same length.';
        else
            str = sprintf('%s%d.\n%s%d.', ...
                'The DNA sequences have a Hamming distance of ', ...
                hammingDistance(actual.Sequence, expected.Sequence),
                'The allowable distance is ', ...
                tolerance.Value);
        end
        diag = StringDiagnostic(str);
    end
end
```

HammingDistance Class Definition Summary

```
classdef HammingDistance < matlab.unittest.constraints.Tolerance
    properties
        Value
    end

    methods
        function tolerance = HammingDistance(value)
            tolerance.Value = value;
        end

        function tf = supports(~, value)
            tf = isa(value, 'DNA');
        end
    end
end
```

```
function tf = satisfiedBy(tolerance, actual, expected)
    if ~isSameSize(actual.Sequence, expected.Sequence)
        tf = false;
        return
    end
    tf = hammingDistance(actual.Sequence, expected.Sequence) <
end

function diag = getDiagnosticFor(tolerance, actual, expected)
    import matlab.unittest.diagnostics.StringDiagnostic;

    if ~isSameSize(actual.Sequence, expected.Sequence)
        str = 'The DNA sequences must be the same length.';
    else
        str = sprintf('%s%d.\n%s%d.', ...
            'The DNA sequences have a Hamming distance of ',
            hammingDistance(actual.Sequence, expected.Sequence),
            'The allowable distance is ', ...
            tolerance.Value);
    end
    diag = StringDiagnostic(str);
end
end

function tf = isSameSize(str1, str2)
    tf = isequal(size(str1), size(str2));
end

function distance = hammingDistance(str1, str2)
    distance = nnz(str1 ~= str2);
end
```

At the command prompt, create a TestCase for interactive testing.

```
import matlab.unittest.TestCase;
```

matlab.unittest.constraints.Tolerance

```
import matlab.unittest.constraints.IsEqualTo;
```

```
testCase = TestCase.forInteractiveUse;
```

Create two DNA objects.

```
sampleA = DNA('ACCTGAGTA');
```

```
sampleB = DNA('ACCACAGTA');
```

Verify that the DNA sequences are equal to each other.

```
testCase.verifyThat(sampleA, IsEqualTo(sampleB));
```

```
Interactive verification failed.
```

```
-----  
Framework Diagnostic:  
-----
```

```

```

The sequences are not equal to each other within a tolerance of 1. The testing framework displays additional diagnostics from the `getDiagnosticFor` method.

Verify that the DNA sequences are equal to each other, within a Hamming distance of 2.

```
testCase.verifyThat(sampleA, IsEqualTo(sampleB,...  
    'Within', HammingDistance(2)));
```

```
Interactive verification passed.
```

Concepts

matlab.unittest.constraints.Tolerance.getDiagnosticFor

Purpose Produce diagnostic for two values specified to be within tolerance

Syntax `diag = getDiagnosticFor(tolObj,actVal,expVal)`

Description `diag = getDiagnosticFor(tolObj,actVal,expVal)` produces a diagnostic, `diag`, for a value, `actVal`, evaluated against another value, `expVal`, within the tolerance defined by `tolObj`. When creating a custom tolerance, the class author must implement the `getDiagnosticFor` method so that it analyzes the two values, `actVal` and `expVal`, against the tolerance, `tolObj`, and instantiates and returns a `matlab.unittest.diagnostics.Diagnostic` object.

Typically, this diagnostic is used when the `getDiagnosticFor` method of `IsEqualTo` is invoked, and the result is incorporated into the diagnostic output of the `IsEqualTo` constraint.

Input Arguments

actVal

Value to determine if is within tolerance of `expVal`

tolObj

Tolerance instance

expVal

Expected value

See Also

`supports` | `satisfiedBy` | `Diagnostic` | `ConstraintDiagnostic`

matlab.unittest.constraints.Tolerance.satisfiedBy

Purpose Determine whether two values are within tolerance

Syntax `TF = satisfiedBy(tolObj,actVal,expVal)`

Description `TF = satisfiedBy(tolObj,actVal,expVal)` determines whether two values, `actVal` and `expVal`, are within the tolerance defined by `tolObj`. The `satisfiedBy` method is used to determine whether the tolerance is met. It returns `true` or `false` (logical 0 or 1). When creating a custom tolerance, a class author uses this method to contain the tolerance definition.

Input Arguments

actVal

Value to determine if is within tolerance of `expVal`

tolObj

Tolerance instance

expVal

Expected value

See Also `getDiagnosticFor` | `supports`

matlab.unittest.constraints.Tolerance.supports

Purpose	Determine whether tolerance supports specified data type
Syntax	<code>TF = supports(tolObj,typeVal)</code>
Description	<p><code>TF = supports(tolObj,typeVal)</code> determines whether the tolerance supports a specific data type. It returns <code>true</code> or <code>false</code> (logical 0 or 1).</p> <p>The <code>supports</code> method provides the ability for a tolerance author to specify support for data types. Generally, the method operates by examining the type of <code>typeVal</code> to determine whether it is supported.</p>
Input Arguments	<p>tolObj Tolerance instance</p> <p>typeVal Value used to determine tolerance support</p>
See Also	<code>getDiagnosticFor</code> <code>satisfiedBy</code>

Purpose Grayscale colormap for contrast enhancement

Syntax
`cmap = contrast(X)`
`cmap = contrast(X,m)`

Description The `contrast` function enhances the contrast of an image. It creates a new gray colormap, `cmap`, that has an approximately equal intensity distribution. All three elements in each row are identical.

`cmap = contrast(X)` returns a gray colormap that is the same length as the current colormap. If there are NaN or Inf elements in `X` the length of the colormap increases.

`cmap = contrast(X,m)` returns an `m`-by-3 gray colormap.

Examples **Display Image with Gray Colormap**

Load `clown` to get image `X` and its associated colormap, `map`. Display the image produced by `X` and `map`.

```
load clown
figure
image(X)
colormap(map)
```

contrast

Use `contrast` to return a gray colormap that is the same length as the current colormap, `map`. Display the image with the new colormap, `cmap`.

```
cmap = contrast(X);  
colormap(cmap)
```

See Also `brighten` | `colormap` | `image`

conv

Purpose Convolution and polynomial multiplication

Syntax
`w = conv(u,v)`
`w = conv(..., 'shape')`

Description `w = conv(u,v)` convolves vectors `u` and `v`. Algebraically, convolution is the same operation as multiplying the polynomials whose coefficients are the elements of `u` and `v`.

`w = conv(..., 'shape')` returns a subsection of the convolution, as specified by the `shape` parameter:

<code>full</code>	Returns the full convolution (default).
<code>same</code>	Returns the central part of the convolution of the same size as <code>u</code> .
<code>valid</code>	Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, <code>length(w)</code> is <code>max(length(u)-max(0,length(v)-1),0)</code> .

Definitions Let $m = \text{length}(u)$ and $n = \text{length}(v)$. Then w is the vector of length $m+n-1$ whose k th element is

$$w(k) = \sum_j u(j)v(k-j+1)$$

The sum is over all the values of j which lead to legal subscripts for $u(j)$ and $v(k+1-j)$, specifically $j = \max(1, k+1-n) : \min(k, m)$. When $m = n$, this gives

$$\begin{aligned}w(1) &= u(1)*v(1) \\w(2) &= u(1)*v(2)+u(2)*v(1) \\w(3) &= u(1)*v(3)+u(2)*v(2)+u(3)*v(1) \\&\dots \\w(n) &= u(1)*v(n)+u(2)*v(n-1)+ \dots +u(n)*v(1) \\&\dots\end{aligned}$$

$$w(2*n-1) = u(n)*v(n)$$

`conv2` | `convn` | `deconv` | `filter` | `convmtx` | `xcorr`

conv2

Purpose 2-D convolution

Syntax
`C = conv2(A,B)`
`C = conv2(h1,h2,A)`
`C = conv2(...,shape)`

Description `C = conv2(A,B)` computes the two-dimensional convolution of matrices *A* and *B*. If one of these matrices describes a two-dimensional finite impulse response (FIR) filter, the other matrix is filtered in two dimensions. The size of *C* is determined as follows: if `[ma,na] = size(A)`, `[mb,nb] = size(B)`, and `[mc,nc] = size(C)`, then `mc = max([ma+mb-1,ma,mb])` and `nc = max([na+nb-1,na,nb])`.

`C = conv2(h1,h2,A)` first convolves *A* with the vector *h1* along the rows and then with the vector *h2* along the columns. The size of *C* is determined as follows: if `n1 = length(h1)` and `n2 = length(h2)`, then `mc = max([ma+n1-1,ma,n1])` and `nc = max([na+n2-1,na,n2])`.

`C = conv2(...,shape)` returns a subsection of the two-dimensional convolution, as specified by the *shape* parameter:

'full'	Returns the full two-dimensional convolution (default).
'same'	Returns the central part of the convolution of the same size as <i>A</i> .
'valid'	Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, <code>size(C) = max([ma-max(0,mb-1),na-max(0,nb-1)],0)</code> .

Note All numeric inputs to `conv2` must be of type `double` or `single`.

Algorithms `conv2` uses a straightforward formal implementation of the two-dimensional convolution equation in spatial form. If *a* and *b* are

functions of two discrete variables, n_1 and n_2 , then the formula for the two-dimensional convolution of a and b is

$$c(n_1, n_2) = \sum_{k_1=-\infty}^{\infty} \sum_{k_2=-\infty}^{\infty} a(k_1, k_2) b(n_1 - k_1, n_2 - k_2)$$

In practice however, `conv2` computes the convolution for finite intervals.

Note that matrix indices in MATLAB software always start at 1 rather than 0. Therefore, matrix elements $A(1, 1)$, $B(1, 1)$, and $C(1, 1)$ correspond to mathematical quantities $a(0, 0)$, $b(0, 0)$, and $c(0, 0)$.

Examples

Shape for Subsection of 2-D Convolution

For the 'same' case, `conv2` returns the central part of the convolution. If there are an odd number of rows or columns, the "center" leaves one more at the beginning than the end.

This example first computes the convolution of A using the default ('full') shape, then computes the convolution using the 'same' shape. Note that the array returned using 'same' corresponds to the red highlighted elements of the array returned using the default shape.

```
A = rand(3);
B = rand(4);
C = conv2(A,B) % C is 6-by-6
```

```
C =
    0.1838    0.2374    0.9727    1.2644    0.7890    0.3750
    0.6929    1.2019    1.5499    2.1733    1.3325    0.3096
    0.5627    1.5150    2.3576    3.1553    2.5373    1.0602
    0.9986    2.3811    3.4302    3.5128    2.4489    0.8462
    0.3089    1.1419    1.8229    2.1561    1.6364    0.6841
    0.3287    0.9347    1.6464    1.7928    1.2422    0.5423
```

```
Cs = conv2(A,B,'same') % Cs is the same size as A: 3-by-3
Cs =
    2.3576    3.1553    2.5373
```

```
3.4302  3.5128  2.4489
1.8229  2.1561  1.6364
```

Extract Edges from Raised Pedestal

In image processing, the Sobel edge finding operation is a two-dimensional convolution of an input array with the special matrix:

```
s = [1 2 1; 0 0 0; -1 -2 -1];
```

These commands extract the horizontal edges from a raised pedestal.

```
A = zeros(10);
A(3:7,3:7) = ones(5);
H = conv2(A,s);
figure, mesh(H)
```

Transposing the filter s extracts the vertical edges of A .

```
V = conv2(A,s');  
figure, mesh(V)
```

This figure combines both horizontal and vertical edges.

```
figure  
mesh(sqrt(H.^2 + V.^2))
```

convhull

Purpose Convex hull

Note Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `convhull`.

Syntax

```
K = convhull(X,Y)
K = convhull(X,Y,Z)
K = convhull(X)
K = convhull(...,'simplify', logicalvar)
[K,V] = convhull(...)
```

Definitions `convhull` returns the convex hull of a set of points in 2-D or 3-D space.

Description

`K = convhull(X,Y)` returns the 2-D convex hull of the points (X,Y), where X and Y are column vectors. The convex hull K is expressed in terms of a vector of point indices arranged in a counterclockwise cycle around the hull.

`K = convhull(X,Y,Z)` returns the 3-D convex hull of the points (X,Y,Z), where X, Y, and Z are column vectors. K is a triangulation representing the boundary of the convex hull. K is of size `mtri-by-3`, where `mtri` is the number of triangular facets. That is, each row of K is a triangle defined in terms of the point indices.

`K = convhull(X)` returns the 2-D or 3-D convex hull of the points X. This variant supports the definition of points in matrix format. X is of size `mpts-by-ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, $2 \leq \text{ndim} \leq 3$. The output facets are equivalent to those generated by the 2-input or 3-input calling syntax.

`K = convhull(...,'simplify', logicalvar)` provides the option of removing vertices that do not contribute to the area/volume of the convex hull, the default is false. Setting 'simplify' to true returns the topology in a more concise form.

`[K,V] = convhull(...)` returns the convex hull `K` and the corresponding area/volume `V` bounded by `K`.

Visualization Use `plot` to plot the output of `convhull` in 2-D. Use `trisurf` or `trimesh` to plot the output of `convhull` in 3-D.

Examples **Plot 2-D Convex Hull**

```
xx = -1:.05:1; yy = abs(sqrt(xx));  
[x,y] = pol2cart(xx,yy);  
k = convhull(x,y);  
plot(x(k),y(k),'r-',x,y,'b+')
```

convhull

| [voronoi](#)

Purpose	N-D convex hull
Syntax	<pre>K = convhulln(X) K = convhulln(X, options) [K, v] = convhulln(...)</pre>
Description	<p><code>K = convhulln(X)</code> returns the indices <code>K</code> of the points in <code>X</code> that comprise the facets of the convex hull of <code>X</code>. <code>X</code> is an <code>m</code>-by-<code>n</code> array representing <code>m</code> points in <code>N</code>-dimensional space. If the convex hull has <code>p</code> facets then <code>K</code> is <code>p</code>-by-<code>n</code>.</p> <p><code>convhulln</code> uses <code>Qhull</code>.</p> <p><code>K = convhulln(X, options)</code> specifies a cell array of strings <code>options</code> to be used as options in <code>Qhull</code>. The default options are:</p> <ul style="list-style-type: none"> • <code>{'Qt'}</code> for 2-, 3-, and 4-dimensional input • <code>{'Qt', 'Qx'}</code> for 5-dimensional input and higher. <p>If <code>options</code> is <code>[]</code>, the default options are used. If <code>options</code> is <code>{''}</code>, no options are used, not even the default. For more information on <code>Qhull</code> and its options, see http://www.qhull.org/.</p> <p><code>[K, v] = convhulln(...)</code> also returns the volume <code>v</code> of the convex hull.</p>
Visualization	<p>Plotting the output of <code>convhulln</code> depends on the value of <code>n</code>:</p> <ul style="list-style-type: none"> • For <code>n = 2</code>, use <code>plot</code> as you would for <code>convhull</code>. • For <code>n = 3</code>, you can use <code>trisurf</code> to plot the output. The calling sequence is <pre>K = convhulln(X); trisurf(K,X(:,1),X(:,2),X(:,3))</pre> • You cannot plot <code>convhulln</code> output for <code>n > 3</code>.
Examples	The following example illustrates the options input for <code>convhulln</code> . The following commands

convhulln

```
X = [0 0; 0 1e-10; 0 0; 1 1];  
K = convhulln(X)
```

return a warning.

```
Warning: qhull precision warning:  
The initial hull is narrow  
(cosine of min. angle is 0.9999999999999998).  
A coplanar point may lead to a wide facet.  
Options 'QbB' (scale to unit box) or 'Qbb'  
(scale last coordinate) may remove this warning.  
Use 'Pp' to skip this warning.
```

To suppress the warning, use the option 'Pp'. The following command passes the option 'Pp', along with the default 'Qt', to convhulln.

```
K = convhulln(X,{'Qt','Pp'})
```

```
K =
```

```
   1   4  
   1   2  
   4   2
```

Algorithms

convhulln is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>. For copyright information, see <http://www.qhull.org/COPYING.txt>.

matlab.mixin.CustomDisplay

Purpose Display customization interface class

Description This class provides an interface for customizing the MATLAB display of objects. Derive your class from `matlab.mixin.CustomDisplay` to add the custom display functionality to your class.

`matlab.mixin.CustomDisplay` implements three public sealed methods. `disp` and `display` provide a simple object display. The `details` method provides a standard formal display of object information.

For customizing object display, `matlab.mixin.CustomDisplay` defines a number of protected methods that you can override in your subclass. By overriding specific methods, you can customize specific aspects of the object display.

Methods

<code>convertDimensionsToString</code>	Return array dimensions as string
<code>details</code>	Fully detailed formal object display
<code>disp</code>	Simple informal object display
<code>display</code>	Print variable name and display object
<code>displayEmptyObject</code>	Display for empty object arrays
<code>displayNonScalarObject</code>	Display format for non-scalar objects
<code>displayPropertyGroups</code>	Display titles and property groups as defined
<code>displayScalarHandleToDeletedObject</code>	Display format for deleted scalar handles
<code>displayScalarObject</code>	Display format for scalar objects
<code>getClassNameForHeader</code>	Return class name for display

<code>getDeletedHandleText</code>	Returns text for handle to deleted object display
<code>getDetailedFooter</code>	Returns default detailed footer for object display
<code>getDetailedHeader</code>	Returns default detailed header for object display
<code>getFooter</code>	Build and return display footer text
<code>getHandleText</code>	Return string 'handle' with link to documentation
<code>getHeader</code>	Build and return display header text
<code>getPropertyGroups</code>	Construct array of property groups
<code>getSimpleHeader</code>	Return simple header for object display

Attributes

Abstract	This class defines an interface that subclasses inherit. You cannot instantiate this class.
HandleCompatible	You can use this class to derive both handle and value classes.

See Also `matlab.mixin.util.PropertyGroup`

matlab.mixin.CustomDisplay.convertDimensionsToString

Purpose	Return array dimensions as string								
Syntax	<pre>dimstr = matlab.mixin.CustomDisplay.convertDimensionsToString(obj)</pre>								
Description	<pre>dimstr = matlab.mixin.CustomDisplay.convertDimensionsToString(obj)</pre> converts a size vector into a properly formatted string of dimensions for the nonscalar header.								
Input Arguments	obj MATLAB object								
Output Arguments	dimstr String representing the object's dimensions as determined by calling <code>size</code> .								
Attributes	<table><tr><td>Static</td><td>true</td></tr><tr><td>Access</td><td>Protected</td></tr><tr><td>Sealed</td><td>true</td></tr><tr><td>Hidden</td><td>true</td></tr></table> <p>To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.</p>	Static	true	Access	Protected	Sealed	true	Hidden	true
Static	true								
Access	Protected								
Sealed	true								
Hidden	true								
See Also	<code>matlab.mixin.CustomDisplay.getHeader</code>								
Related Examples	<ul style="list-style-type: none">“Custom Display Interface”								

Purpose Fully detailed formal object display

Syntax `details(obj)`

Description `details(obj)` displays the detailed state of `obj`. The detailed display is not affected by customizations made to classes derived from `matlab.mixin.CustomDisplay`.

Attributes

Access = public	You can call <code>details</code> on any object that is a class derived from <code>matlab.mixin.CustomDisplay</code> .
Sealed	You cannot override the <code>details</code> method in your subclass of <code>matlab.mixin.CustomDisplay</code> .

Input Arguments

obj

Instance of a class derived from `matlab.mixin.CustomDisplay`.

Default: none

Examples

Suppose `EmployeeInfo` is a subclass of `matlab.mixin.CustomDisplay`

```
details(e1)
```

`EmployeeInfo handle` with properties:

```
Name: 'Bill Tork'  
JobTitle: 'Software Engineer'  
Department: 'Product Development'  
Salary: 1000  
Password: 'bill123'
```

[Methods, Events, Superclasses](#)

matlab.mixin.CustomDisplay.details

See Also

disp | display

Related Examples

- “Custom Display Interface”

Purpose Simple informal object display

Syntax `disp(obj)`

Description `disp(obj)` displays the contents of `obj` in one of four simple formats, based on the state of `obj`.

- Handle to deleted object
- Empty object array
- Scalar
- Nonscalar

To customize a display format, override one or more of the four handler methods.

Input Arguments

obj

Object of a class derived from `matlab.mixin.CustomDisplay`

Attributes

Access	public
Sealed	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`disp` | `details` |
`matlab.mixin.CustomDisplay.displayScalarObject` |
`matlab.mixin.CustomDisplay.displayNonScalarObject` |
`matlab.mixin.CustomDisplay.displayEmptyObject` |
`matlab.mixin.CustomDisplay.displayScalarHandleToDeletedObject`

Related Examples

- “Custom Display Interface”

matlab.mixin.CustomDisplay.display

Purpose Print variable name and display object

Syntax `display(obj)`

Description `display(obj)` prints the name of input argument `obj` as it appears in the workspace of the caller. If there is no assignment to a variable, `display` uses, `ans`. `display` then calls the `disp` method to print the object.

Input Arguments

obj
Object array of a class derived from `matlab.mixin.CustomDisplay`

Attributes

Access	public
Sealed	true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

See Also `disp` | [details](#)

Related Examples

- “Custom Display Interface”

matlab.mixin.CustomDisplay.displayEmptyObject

Purpose Display for empty object arrays

Syntax `displayEmptyObject(obj)`

Description `displayEmptyObject(obj)` is called by `disp` when the object, `obj`, is empty. An object array is empty if one or more of its dimensions are zero. An empty object array is never scalar.

The default display of an empty object consists of a header and a list of property names. The header consists of the object's dimensions and the properties are shown in the order defined in the class definition. `displayEmptyObject` shows only those properties with `public GetAccess` and `Hidden` set to `false`.

Override this method to customize the appearance of an empty object array.

Input Arguments **obj**
Object of a class derived from `matlab.mixin.CustomDisplay`

Attributes
Access protected

To learn about attributes of methods, see [Method Attributes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

See Also `matlab.mixin.CustomDisplay.displayScalarObject` |
`matlab.mixin.CustomDisplay.displayNonScalarObject` |
`matlab.mixin.CustomDisplay.displayScalarHandleToDeletedObject`

Related Examples

- “Custom Display Interface”

matlab.mixin.CustomDisplay.displayNonScalarObject

Purpose Display format for non-scalar objects

Syntax `displayNonScalarObject(obj)`

Description `displayNonScalarObject(obj)` is called by the `disp` method when the object, `obj`, is nonscalar (`prod(size(obj)) > 1`)

The default display of a nonscalar object array consists of a header and a list of property names. The header consists of the object's dimensions and the properties are shown in the order defined in the class definition. `displayNonScalarObject` shows only those properties with public `GetAccess` and `Hidden` set to `false`.

Override this method to customize the display a nonscalar object array.

Input Arguments

obj
Object array of a class derived from `matlab.mixin.CustomDisplay`

Attributes

Access	protected

matlab.mixin.CustomDisplay.displayScalarHandleToDeletedOb

Purpose Display format for deleted scalar handles

Syntax `displayScalarHandleToDeletedObject(obj)`

Description `displayScalarHandleToDeletedObject(obj)` is called by the `disp` method when `obj` is:

- An instance of a handle class
- Scalar
- A handle to a deleted object

That is, the following expression is true.

```
isa(obj, 'handle') && isscalar(obj) && ~isvalid(obj)
```

Override this method to customize the appearance of your object's display when it is deleted.

Input Arguments

obj

Object of a class derived from `matlab.mixin.CustomDisplay`

Attributes

Access

protected

To learn about attributes of methods, see [Method Attributes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

Related Examples

- “Custom Display Interface”

matlab.mixin.CustomDisplay.displayScalarObject

Purpose Display format for scalar objects

Syntax `displayScalarObject(obj)`

Description `displayScalarObject(obj)` is called by the `disp` method when the object, `obj`, is scalar (`prod(size(obj)) == 1`).

The default display of a scalar object consists of a header and a list of properties and their values. Properties are shown in the order they are defined in the class definition. `displayScalarObject` shows only those properties with `public GetAccess` and `Hidden` set to `false`.

Override this method to customize the display of a scalar object.

Input Arguments

obj
Object of a class derived from `matlab.mixin.CustomDisplay`

Attributes

Access protected

To learn about attributes of methods, see [Method Attributes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

Related Examples

- “Custom Display Interface”

matlab.mixin.CustomDisplay.getClassNameForHeader

Purpose Return class name for display

Syntax `name = matlab.mixin.CustomDisplay.getClassNameForHeader(obj)`

Description `name = matlab.mixin.CustomDisplay.getClassNameForHeader(obj)` returns the class name of `obj`. If the display supports hypertext links, the text is linked to the help for the class of `obj`.

Use this method when building a custom display that includes the class name, but differs from the default header.

Input Arguments **obj**
MATLAB object

Output Arguments **name**
The simple class name, linked to the help for the class if the display supports hypertext links

Attributes	Static	true
	Access	Protected

matlab.mixin.CustomDisplay.getDeletedHandleText

Purpose Returns text for handle to deleted object display

Syntax `handleText = matlab.mixin.CustomDisplay.getDeletedHandleText`

Description `handleText = matlab.mixin.CustomDisplay.getDeletedHandleText` returns the text:

`'handle to deleted'`

The text is linked to the documentation on deleted handle objects.

Output Arguments **handleText**
String 'handle to deleted', linked if the display supports hypertext links

matlab.mixin.CustomDisplay.getDetailedFooter

Purpose Returns default detailed footer for object display

Syntax `headerText = matlab.mixin.CustomDisplay.getDetailedFooter(obj)`

Description `headerText = matlab.mixin.CustomDisplay.getDetailedFooter(obj)` returns the string containing:

[Methods](#), [Events](#), [Superclass](#)

Each link executes the respective command on `obj`.

Input Arguments **obj**
MATLAB object

Output Arguments **headerText**
String containing the linked phrase 'Methods, Events, Superclasses' or the empty string if the display does not support hypertext links

Related Examples

- “Custom Display Interface”

matlab.mixin.CustomDisplay.getPropertyGroups

Purpose Construct array of property groups

Syntax `groups = getPropertyGroups(obj)`

Description `groups = getPropertyGroups(obj)` returns an array of `matlab.mixin.util.PropertyGroup` objects. MATLAB displays property groups separated by blank spaces.

Each default display state handler method calls this method once. The default implementation returns the properties in one group. These properties must have public `GetAccess` and not be defined as `Hidden`. If the object is scalar, MATLAB includes dynamic properties.

Override this method to construct one or more customized groups of properties to display.

Each group object array has the following fields:

- **Title** — String used as the header for the property group or an empty string if no title is used.
- **PropertyList** — The property list can be either:
 - A 1-by-1 struct of property name-property value pairs
 - A cell array of string property names.

Use the struct of name-value pairs if the object is scalar and you want to assign custom property values. Otherwise, use a cell array of string property names. If the object is scalar MATLAB adds the property values retrieved from the object.

Input Arguments **obj**
Object array of a class derived from `matlab.mixin.CustomDisplay`

Output Arguments **groups**
1xN array of `matlab.mixin.util.PropertyGroup` objects, where N is the number of groups

matlab.mixin.CustomDisplay.getPropertyGroups

Examples

Custom Property Group

Customize the values returned by some properties.

Write a `getPropertyGroups` method.

```
methods (Access = protected)
    function propgrp = getPropertyGroups(obj)
        if ~isscalar(obj)
            propgrp = getPropertyGroups@matlab.mixin.CustomDisplay(obj);
        else
            pd(1:length(obj.Password)) = '*';
            propList = struct('Department',obj.Department,...
                'JobTitle',obj.JobTitle,...
                'Name',obj.Name,...
                'Salary','Not available',...
                'Password',pd);
            propgrp = matlab.mixin.util.PropertyGroup(propList);
        end
    end
end
```

Add function to class definition.

Purpose

Superclass providing copy functionality for handle objects

Description

The `matlab.mixin.Copyable` class is an abstract handle class that provides a copy method for copying handle objects. The copy method makes a shallow copy of the object (that is, it shallow copies all non-dependent properties from the source to the destination object). In making a shallow copy, MATLAB does not call copy recursively on any handles contained in property values.

Subclass `matlab.mixin.Copyable` when you want to define handles classes that inherit a copy method. The copy method:

- Copies data without calling class constructors or property set functions and therefore produces no side effects.
- Enables subclasses to customize the copy behavior

Customizing Subclass Copy Behavior

The copy method provides the public, non-overrideable interface to copy behavior. `copy` takes an array of objects as input and returns an array of the same shape and dimensions.

`copyElement` is a protected method that the copy method uses to perform the copy operation on each object in the input array. `copyElement` is not `Sealed` so you can override it in your subclass to customize the behavior of the inherited copy method.

Implementing a Selective Deep Copy

This example overrides the `copyElement` method in a subclass of `matlab.mixin.Copyable` to implement a deep copy of a specific class of handle objects.

Consider the following classes:

- `ContainsHandles` — subclass of `matlab.mixin.Copyable` that contains handle objects in two properties
- `DeepCp` — subclass of `matlab.mixin.Copyable`
- `ShallowCp` — subclass of `handle`

matlab.mixin.Copyable

Here are the simplified class definitions:

```
classdef ContainsHandles < matlab.mixin.Copyable
    properties
        Prop1
        Prop2
        DeepObj    % Contains a DeepCp object
        ShallowObj % Contains a ShallowCp object
    end
    methods
        function obj = ContainsHandles(val1, val2, deepobj, shallowobj)
            if nargin > 0
                obj.Prop1 = val1;
                obj.Prop2 = val2;
                obj.DeepObj = deepobj;
                obj.ShallowObj = shallowobj;
            end
        end
    end
    methods(Access = protected)
        % Override copyElement method:
        function cpObj = copyElement(obj)
            % Make a shallow copy of all four properties
            cpObj = copyElement@matlab.mixin.Copyable(obj);
            % Make a deep copy of the DeepCp object
            cpObj.DeepObj = copy(obj.DeepObj);
        end
    end
end
```

The DeepCp class derives from matlab.mixin.Copyable:

```
classdef DeepCp < matlab.mixin.Copyable
    properties
        DpProp
    end
    methods
        function obj = DeepCp(val)
```

```
        ...
        end
    end
end
```

The handle class `ShallowCp` does not derive from `matlab.mixin.Copyable` and, therefore, has no copy method:

```
classdef ShallowCp < handle
    properties
        ShProp
    end
    methods
        function obj = ShallowCp(val)
            ...
        end
    end
end
```

Create a `ContainsHandles` object, which contains the two handle objects in its `DpProp` and `ShProp` properties:

```
>> sc = ShallowCp(7);
>> dc = DeepCp(7);
>> a = ContainsHandles(4,5,dc,sc);
>> a.DeepObj
ans =
```

DeepCp with properties:

```
    DpProp: 7
>> a.ShallowObj.ShProp
ans =
```

ShallowCp with properties:

```
    ShProp: 7
```

matlab.mixin.Copyable

Make a copy of the `ContainsHandles` object:

```
>> b = copy(a);
```

The returned copy `b` contains a shallow copy of object `sc`, and a deep copy of object `dc`. That is, the `dc` object passed to `ContainsHandles` constructor is now a new, independent objects as a result of the copy operation. You can now change the `dc` object without affecting the copy. This is not the case for the shallow copied object, `sc`:

```
% Change the property values of the handle objects:
```

```
>> sc.ShProp = 5;
```

```
>> dc.DpProp = 5;
```

```
% Note that the deep copied object is not affected:
```

```
>> b.DeepObj
```

```
ans =
```

```
    DeepCp with properties:
```

```
        DpProp: 7
```

```
% The shallow copied object is still referencing the same data:
```

```
>> b.ShallowObj
```

```
ans =
```

```
    ShallowCp with properties:
```

```
        ShProp: 5
```

Overriding Copy Behavior in Hierarchies

The `copyElement` method in a superclass cannot access the private data in a subclass.

If you override `copyElement` in a subclass of `matlab.mixin.Copyable`, and then use this subclass as a superclass, you need to override `copyElement` in all subclasses that contain private properties. The

override of `copyElement` in subclasses should call the `copyElement` in the respective superclass, as in the previous example.

The following simplified code demonstrates this approach:

```
classdef SuperClass < matlab.mixin.Copyable
    properties(Access = private)
        super_prop
    end
    methods
        ...

        function cpObj = copyElement(obj)
            ...
            cpObj = copyElement@matlab.mixin.Copyable(obj);
            ...
        end
    end
end

classdef SubClass1 < SuperClass
    properties(Access=private)
        sub_prop1
    end
    methods
        function cpObj = copyElement(obj)
            % Copy super_prop
            cpObj = copyElement@SuperClass(obj);
            % Copy sub_prop1 in subclass
            % Assignment can introduce side effects
            cpObj.sub_prop1 = obj.sub_prop1;
        end
    end
end
```

The override of `copyElement` in `SubClass1` copies the private subclass property because the superclass cannot access private data in the subclass.

Note The assignment of `sub_prop1` in the override of `copyElement` in `SubClass1` calls the property set method, if one exists, possibly introducing side effects to the copy operation.

Copy Behaviors for Specific Inputs

Given a call to the `matlab.mixin.Copyable` `copy` method of the form:

```
B = copy(A);
```

Under the following conditions, produces the described results:

- A has dynamic properties — `copy` does not copy dynamic properties. You can implement dynamic-property copying in the subclass if needed.
- A has no non-Dependent properties — `copy` creates a new object with no property values without calling the class constructor to avoid introducing side effects.
- A contains deleted handles — `copy` creates deleted handles of the same class in the output array.
- A has attached listeners — `copy` does not copy listeners.
- A contains objects of enumeration classes — Enumeration classes cannot subclass `matlab.mixin.Copyable`.
- A `delete` method calls `copy` — `copy` creates a legitimate copy, obeying all the behaviors that apply in any other usage.

Note You cannot derive an enumeration class from `matlab.mixin.Copyable` because the number of instances you can create are limited to the ones defined inside the enumeration block. See “Working with Enumerations” for more information about enumeration classes.

Methods

`copy` Copy array of handle objects

Definitions

Deep Copy

Copy each property value and assign it to the new (copied) property. Recursively copy property values that reference handle objects to copy all of the underlying data.

Shallow Copy

Copy each property value and assign it to the new (copied) property. If a property value is a handle, copy the handle but not the underlying data.

Attributes

`ConstructOnLoad` true

To learn about attributes of classes, see Class Attributes in the MATLAB Object-Oriented Programming documentation.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

See Also

`handle`

How To

- Class Attributes

matlab.mixin.Copyable.copy

Purpose Copy array of handle objects

Syntax `B = copy(A)`

Description `B = copy(A)` copies each element in the array of handles `A` to the new array of handles `B`.

The copy method performs a copy according to the following rules:

- The copy method does not copy Dependent properties
- MATLAB does not call the copy method recursively on any handles contained in property values
- MATLAB does not call the class constructor or property set methods during the copy operation.
- `B` has the same number of elements and same size as `A`.
- `B` is the same class as `A`.
- If `A` is empty, `B` is also empty.
- If `A` is heterogeneous, `B` is also heterogeneous.
- If `A` contains deleted handle objects, copy creates deleted handles of the same class in `B`.
- Dynamic properties and listeners associated with objects in `A` are not copied to objects in `B`.
- You can call `copy` inside your class `delete` method.

Input Arguments **A**
Handle object array

Output Arguments **B**
Handle object array containing copies of the objects in `A`.

Attributes

Sealed true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

[matlab.mixin.Copyable](#) | [handle](#) | [copyElement](#)

copyfile

Purpose

Copy file or folder

Syntax

```
copyfile('source','destination')
copyfile('source','destination','f')
[status] = copyfile(___)
[status, message] = copyfile(___)
[status,message,messageid] = copyfile(___)
```

Description

`copyfile('source','destination')` copies the file or folder named `source` to the file or folder `destination`. The values for `source` and `destination` are 1 x n strings. Use full path names or path names relative to the current folder. To copy multiple files or folders, use one or more wildcard characters (*) after the last file separator in `source`. You cannot use a wildcard character in `destination`.

`copyfile('source','destination','f')` copies `source` to `destination`, even when `destination` is not writable. The state of the read-write attribute for `destination` does not change. You can use `f` with any syntax for `copyfile`.

`[status] = copyfile(___)` reports the outcome as a logical scalar, `status`. The value is 1 for success and 0 for failure.

`[status, message] = copyfile(___)` returns any warning or error message as a string to `message`. When `copyfile` succeeds, `message` is an empty string.

`[status,message,messageid] = copyfile(___)` returns any warning or error identifier as a string to `messageId`. When `copyfile` succeeds, `messageId` is an empty string.

Tips

- The timestamp for `destination` is the same as the timestamp for `source`.
- When `source` is a folder, `destination` must be a folder.
 - When `source` is a folder and `destination` does not exist, `copyfile` creates `destination` and copies the contents of `source` into `destination`.

- When source is a folder and destination is an existing folder, copyfile copies the contents of source into destination.
- When source is multiple files and destination does not exist, copyfile creates destination.

Examples

Copy File to Another Folder

Copy myFun.m from the current folder to d:/work/Projects/.

```
copyfile('myFun.m', 'd:/work/Projects/')
```

Copy File to Its Current Folder

Copy myFun.m in the current folder, assigning it the name myFun2.m.

```
copyfile('myFun.m', 'myFun2.m')
```

Copy Files and Folders to a New Folder Using Wildcards

Copy files and subfolders whose names begin with my, from the Projects subfolder within the current folder to the folder newProjects, which is at the same level as the current folder:

```
copyfile('Projects/my*', '../newProjects/')
```

Copy Files to a New, Nonexistent Folder

Copy the contents of the Projects subfolder within the current folder to the I:/work/newProjects folder, where newProjects does not exist.

```
copyfile('Projects', 'I:/work/newProjects')
```

Copy File that Overwrites a Read-Only File

Copy the contents of myFun.m from the current folder to d:/work/restricted/myFun2.m, where myFun2.m is read-only.

```
[status,message,messageId]=copyfile('myFun.m', ...  
'd:/work/restricted/myFun2.m','f')
```

```
status =  
1
```

copyfile

```
message =  
    ''
```

```
messageId =  
    ''
```

The status of 1 and empty `message` and `messageId` strings confirm the copy was successful.

| `movefile` | `rmdir`

How To

- “Specify File Names”
- “Manage Files and Folders”

Purpose Copy graphics objects and their descendants

Syntax `new_handle = copyobj(h,p)`

Description `copyobj` creates copies of graphics objects. The copies are identical to the original objects except the copies have different values for their Parent property and a new handle. The new parent must be appropriate for the copied object (e.g., you can copy a line object only to another axes object).

`new_handle = copyobj(h,p)` copies one or more graphics objects identified by `h` and returns the handle of the new object or a vector of handles to new objects. The new graphics objects are children of the graphics objects specified by `p`.

Tips `h` and `p` can be scalars or vectors. When both are vectors, they must be the same length, and the output argument, `new_handle`, is a vector of the same length. In this case, `new_handle(i)` is a copy of `h(i)` with its Parent property set to `p(i)`.

When `h` is a scalar and `p` is a vector, `h` is copied once to each of the parents in `p`. Each `new_handle(i)` is a copy of `h` with its Parent property set to `p(i)`, and `length(new_handle)` equals `length(p)`.

When `h` is a vector and `p` is a scalar, each `new_handle(i)` is a copy of `h(i)` with its Parent property set to `p`. The length of `new_handle` equals `length(h)`.

When programming a GUI, do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

Examples Copy a surface to a new axes within a different figure.

```
h = surf(peaks);  
colormap hot  
figure    % Create a new figure
```

```
axes      % Create an axes object in the figure
new_handle = copyobj(h,gca);
colormap hot
view(3)
grid on
```

Note that while the surface is copied, the `colormap` (figure property), `view`, and `grid` (axes properties) are not copied.

Purpose

Correlation coefficients

Syntax

```
R = corrcoef(X)
R = corrcoef(x,y)
[R,P]=corrcoef(...)
[R,P,RLO,RUP]=corrcoef(...)
[...]=corrcoef(...,'param1',val1,'param2',val2,...)
```

Description

`R = corrcoef(X)` returns a matrix `R` of correlation coefficients calculated from an input matrix `X` whose rows are observations and whose columns are variables. The matrix `R = corrcoef(X)` is related to the covariance matrix `C = cov(X)` by

$$R(i,j) = \frac{C(i,j)}{\sqrt{C(i,i)C(j,j)}}.$$

`corrcoef(X)` is the zeroth lag of the normalized covariance function, that is, the zeroth lag of `xcov(x, 'coeff')` packed into a square array.

`R = corrcoef(x,y)` where `x` and `y` are column vectors is the same as `corrcoef([x y])`. If `x` and `y` are not column vectors, `corrcoef` converts them to column vectors. For example, in this case `R=corrcoef(x,y)` is equivalent to `R=corrcoef([x(:) y(:)])`.

`[R,P]=corrcoef(...)` also returns `P`, a matrix of p-values for testing the hypothesis of no correlation. Each p-value is the probability of getting a correlation as large as the observed value by random chance, when the true correlation is zero. If `P(i,j)` is small, say less than 0.05, then the correlation `R(i,j)` is significant.

`[R,P,RLO,RUP]=corrcoef(...)` also returns matrices `RLO` and `RUP`, of the same size as `R`, containing lower and upper bounds for a 95% confidence interval for each coefficient.

`[...]=corrcoef(...,'param1',val1,'param2',val2,...)` specifies additional parameters and their values. Valid parameters are the following.

'alpha' A number between 0 and 1 to specify a confidence level of $100*(1 - \alpha)\%$. Default is 0.05 for 95% confidence intervals.

'rows' Either 'all' (default) to use all rows, 'complete' to use rows with no NaN values, or 'pairwise' to compute $R(i, j)$ using rows with no NaN values in either column i or j .

The p-value is computed by transforming the correlation to create a t statistic having $n-2$ degrees of freedom, where n is the number of rows of X . The confidence bounds are based on an asymptotic normal distribution of $0.5*\log((1+R)/(1-R))$, with an approximate variance equal to $1/(n-3)$. These bounds are accurate for large samples when X has a multivariate normal distribution. The 'pairwise' option can produce an R matrix that is not positive definite.

Examples

Generate random data having correlation between column 4 and the other columns.

```
x = randn(30,4);        % Uncorrelated data
x(:,4) = sum(x,2);     % Introduce correlation.
[r,p] = corrcoef(x)    % Compute sample correlation and p-values.
[i,j] = find(p<0.05); % Find significant correlations.
[i,j]                 % Display their (row,col) indices.
```

```
r =
    1.0000    -0.3566     0.1929     0.3457
   -0.3566     1.0000    -0.1429     0.4461
    0.1929    -0.1429     1.0000     0.5183

[cov](#) | [mean](#) | [median](#) | [std](#) | [var](#) | [xcorr](#) | [xcov](#)

Purpose Cosine of argument in radians

Syntax `Y = cos(X)`

Description `Y = cos(X)` returns the cosine for each element of `X`. The `cos` function operates element-wise on arrays. The function accepts both real and complex inputs. For purely real values or imaginary values of `X`, `cos` returns real values in the interval `[-1,1]`. For complex values of `X`, `cos` returns complex values. All angles are in radians.

Input Arguments **X - Input angle in radians**
scalar value | vector | matrix | N-D array

Input angle in radians, specified as a real-valued or complex-valued scalar, vector, matrix or N-D array. The `cos` operation is element-wise when `X` is non-scalar.

Data Types

single | double

Complex Number Support: Yes

Output Arguments **Y - Cosine of input angle**
scalar value | vector | matrix | N-D array

Cosine of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

Examples **Plot Cosine Function**

Plot the cosine function over the domain $-\pi \leq x \leq \pi$.

```
x = -pi:0.01:pi;  
plot(x,cos(x)), grid on
```

Cosine of Vector of Complex Angles

Calculate the cosine of the complex angles in vector x .

$$x = [-i \pi + i \pi/2 \quad -1 + i 4];$$

$$y = \cos(x)$$

$$y =$$

$$1.5431 + 0.0000i \quad -2.5092 - 0.0000i \quad 14.7547 + 22.9637i$$

Definitions**Cosine Function**

The cosine of an angle, α , defined with reference to a right angled triangle is

$$\text{cosine}(\alpha) = \frac{\text{adjacent side}}{\text{hypotenuse}} = \frac{b}{h}.$$

The cosine of a complex angle, α , is

$$\text{cosine}(\alpha) = \frac{e^{i\alpha} + e^{-i\alpha}}{2}.$$

cosd

Purpose	Cosine of argument in degrees
Syntax	$Y = \text{cosd}(X)$
Description	$Y = \text{cosd}(X)$ returns the cosine of the elements of X , which are expressed in degrees.
Input Arguments	X - Angle in degrees scalar value vector matrix N-D array Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The <code>cosd</code> operation is element-wise when X is nonscalar. Data Types single double Complex Number Support: Yes
Output Arguments	Y - Cosine of angle scalar value vector matrix N-D array Cosine of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .
Examples	Cosine of 90 degrees compared to cosine of $\pi/2$ radians <code>cosd(90)</code> <code>ans =</code> 0 <code>cos(pi/2)</code> <code>ans =</code> 6.1232e-17

Cosine of complex angles specified in degrees

Create an array of three complex angles and compute the cosine.

```
z = [180+i 45+2i 10+3i];  
y = cosd(z)
```

```
y =
```

```
-1.0002          0.7075 - 0.0247i    0.9862 - 0.0091i
```

[cos](#) | [acos](#) | [acosd](#)

cosh

Purpose Hyperbolic cosine

Syntax $Y = \cosh(X)$

Description The cosh function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.
 $Y = \cosh(X)$ returns the hyperbolic cosine for each element of X .

Examples **Graph of Hyperbolic Cosine**

Graph the hyperbolic cosine function over the domain $-5 \leq x \leq 5$.

```
x = -5:0.01:5;  
plot(x,cosh(x)), grid on
```

Hyperbolic Cosine

The hyperbolic cosine of z is

$$\cosh(z) = \frac{e^z + e^{-z}}{2}.$$

See Also

[acosh](#) | [cos](#) | [sinh](#) | [tanh](#)

cot

Purpose Cotangent of angle in radians

Syntax $Y = \cot(X)$

Description $Y = \cot(X)$ returns the cotangent of elements of X . The \cot function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of X in the interval $[-\text{Inf}, \text{Inf}]$, \cot returns real values in the interval $[-\text{Inf}, \text{Inf}]$. For complex values of X , \cot returns complex values. All angles are in radians.

Input Arguments **X - Input angle in radians**
scalar value | vector | matrix | N-D array

Input angle in radians, specified as real-valued or complex-valued scalar, vector, matrix or N-D array. The \cot operation is element-wise when X is non-scalar.

Data Types

single | double

Complex Number Support: Yes

Output Arguments **Y - Cotangent of input angle**
scalar value | vector | matrix | N-D array

Cotangent of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

Examples **Plot Cotangent Function**

Plot the cotangent function over the domain $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;  
x2 = 0.01:0.01:pi-0.01;  
plot(x1,cot(x1),x2,cot(x2)), grid on
```

Cotangent of Vector of Complex Angles

Calculate the cotangent of the complex angles in vector x.

```
x = [-i pi+i*pi/2 -1+i*4];
y = cot(x)
```

y =

$$0.0000 + 1.3130i \quad -0.0000 - 1.0903i \quad -0.0006 - 0.9997i$$

Definitions Cotangent Function

The cotangent of an angle, α , defined with reference to a right angled triangle is

$$\text{cotangent}(\alpha) = \frac{1}{\text{tangent}(\alpha)} = \frac{\text{adjacent side}}{\text{opposite side}} = \frac{b}{a}.$$

The cotangent of a complex angle α is

$$\cotangent(\alpha) = \frac{i(e^{i\alpha} + e^{-i\alpha})}{(e^{i\alpha} - e^{-i\alpha})}.$$

See Also

cotd | coth | acot | acotd | acoth

cotd

Purpose Cotangent of argument in degrees

Syntax $Y = \text{cotd}(X)$

Description $Y = \text{cotd}(X)$ returns the cotangent of the elements of X , which are expressed in degrees.

Input Arguments **X - Angle in degrees**
scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cotd` operation is element-wise when X is nonscalar.

Data Types
single | double
Complex Number Support: Yes

Output Arguments **Y - Cotangent of angle**
scalar value | vector | matrix | N-D array

Cotangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X .

Examples **Cotangent of angles approaching 90 and 180 degrees**

Create a vector of input angles consisting of 90° and the next smaller and larger double precision numbers. Then compute the cotangent.

```
x1 = [90-eps(90) 90 90+eps(90)];  
y1 = cotd(x1)
```

```
y1 =
```

```
1.0e-15 *
```

```
0.2480      0      -0.2480
```

`cotd` returns zero when the input angle is exactly 90° . Evaluation at the next smaller double-precision angle returns a slightly positive result. Likewise, the cotangent is slightly negative when the input angle is the next double-precision number larger than 90° .

The behavior is similar for input angles near 180° .

```
x2 = [180-eps(180) 180 180+eps(180)];  
y2 = cotd(x2)
```

```
y2 =
```

```
1.0e+15 *  
-2.0159      Inf      2.0159
```

Cotangent of complex angle, specified in degrees

```
x = 35+5i;  
y = cotd(x)
```

```
y =
```

```
1.3958 - 0.2606i
```

coth

Purpose Hyperbolic cotangent

Syntax $Y = \text{coth}(X)$

Description The coth function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians. $Y = \text{coth}(X)$ returns the hyperbolic cotangent for each element of X .

Examples **Graph of Hyperbolic Cotangent**

Plot the hyperbolic cotangent over the domain $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;  
x2 = 0.01:0.01:pi-0.01;  
plot(x1,coth(x1),x2,coth(x2)), grid on
```

Definitions Hyperbolic Cotangent

The hyperbolic cotangent of z is

$$\coth(z) = \frac{1}{\tanh(z)}.$$

See Also `acoth` | `cot` | `sinh` | `cosh` | `tanh`

countcats

Purpose Count occurrences of categorical array elements by category

Syntax
`B = countcats(A)`
`B = countcats(A,dim)`

Description `B = countcats(A)` returns the number of elements in each category of the categorical array, A.

- If A is a vector, then `countcats` returns the number of elements in each category.
- If A is a matrix, then `countcats` treats the columns of A as vectors and returns the category counts for each column of A.
- If A is a multidimensional array, then `countcats` acts along the first array dimension whose size does not equal 1.

`B = countcats(A,dim)` returns the category counts along dimension `dim`.

For example, you can return the category counts of each row in a categorical array using `countcats(A,2)`.

Input Arguments

A - Categorical array
vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

dim - Dimension to operate along
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional categorical array, A.

If `dim = 1`, then `countcats(A,1)` returns the category counts for each column of A.

If $\text{dim} = 2$, then `countcats(A,2)` returns the category counts of each row of A.

If dim is greater than $\text{ndims}(A)$, then `countcats(A)` returns an array the same size as A for each category. `countcats` returns 1 for elements in the corresponding category and 0 otherwise.

Examples

Category Counts of Categorical Vector

Create a 1-by-5 categorical vector.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```
    plane    car    train    car    plane
```

A has three categories, car, plane, and train.

countcats

Find the number of elements in each category of A.

```
B = countcats(A)
```

```
B =
```

```
     2     2     1
```

The first element in B corresponds to the first category of A, which is `car`. The second element in B corresponds to the second category of A, which is `plane`. The third element of B corresponds to the third category of A, which is `train`.

Since A is a row vector, `countcats` returns a row vector.

Category Counts of Each Column in Array

Create a 3-by-2 categorical array, A, from a numeric array.

```
valueset = 1:3;
```

```
catnames = {'red' 'green' 'blue'};
```

```
A = categorical([1 3; 2 1; 3 1],valueset,catnames)
```

```
A =
```

```
     red     blue  
     green    red  
     blue     red
```

A has three categories, `red`, `green`, and `blue`.

Find the category counts of each column in A.

```
B = countcats(A)
```

```
B =
```

```
     1     2  
     1     0
```

```

1      1

```

The first row of B corresponds to the first category of A. The value, red, occurs once in the first column of A and twice in the second column.

The second row of B corresponds to the second category of A. The value, green, occurs once in the first column of A, and it does not occur in the second column.

The third row of B corresponds to the third category of A. The value, blue, occurs once in the first column of A and once in the second column.

Category Counts of Each Row in Array

Create a 3-by-2 categorical array, A, from a numeric array.

```

valueset = 1:3;
catnames = {'red' 'green' 'blue'};

```

```

A = categorical([1 3; 2 1; 3 1],valueset,catnames)

```

```

A =

```

```

      red      blue
      green    red
      blue     red

```

A has three categories, red, green, and blue.

Find the category counts of A along the second dimension.

```

B = countcats(A,2)

```

```

B =

```

```

1      0      1
1      1      0
1      0      1

```

The first column of **B** corresponds to the first category of **A**. The value, **red**, occurs once in the first row of **A**, once in the second row, and once in the third row.

The second column of **B** corresponds to the second category of **A**. The value, **green**, occurs in only one element. It occurs in the second row of **A**.

The third column of **B** corresponds to the third category of **A**. The value, **blue**, occurs once in the first row of **A** and once in the third row.

Category Counts of Array Containing Undefined Elements

Create a 6-by-1 categorical array, **A**, from a numeric array.

```
valueset = 1:3;
catnames = {'red' 'green' 'blue'};

A = categorical([1;3;2;1;3;1],valueset,catnames)
```

```
A =

    red
    blue
    green
    red
    blue
    red
```

Remove the blue category.

```
A = removecats(A, 'blue')
```

```
A =

    red
<undefined>
    green
    red
<undefined>
```

```
red
```

A has two categories, red and green. Elements of A that were from the blue category are now undefined.

Find the number of elements in each category of A.

```
B = countcats(A)
```

```
B =
```

```
    3  
    1
```

The first element in B corresponds to the first category of A. The value, red, occurs three times in A.

The second element in B corresponds to the second category of A. The value, green, occurs once in A.

countcats does not return any information on undefined elements.

Use the summary function to view the number of undefined elements in addition to the number of elements in each category of A.

```
summary(A)
```

```
    red            3  
   green           1  
  <undefined>     2
```

Tips

- To find the number of undefined elements in a categorical array, A, you must use `summary` or `isundefined`.

See Also

`iscategory` | `ismember` | `summary` | `isundefined` | `categories`

Purpose Covariance matrix

Syntax
`C = cov(x)`
`C = cov(x,y)`
`C = cov(x,1)`
`C = cov(x,y,1)`

Description `C = cov(x)`, if `x` is a vector, returns the variance of `x`. For matrix input `X`, where each row is an observation, and each column is a variable, `cov(X)` is the covariance matrix. `diag(cov(X))` is a vector of variances for each column, and `sqrt(diag(cov(X)))` is a vector of standard deviations. `cov(X,Y)`, where `X` and `Y` are matrices with the same number of elements, is equivalent to `cov([X(:) Y(:)])`.

`C = cov(x)` or `C = cov(x,y)` normalizes by $N - 1$, if $N > 1$, where N is the number of observations. This makes `cov(X)` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For $N = 1$, `cov` normalizes by N .

`C = cov(x,1)` or `C = cov(x,y,1)` normalizes by N and produces the second moment matrix of the observations about their mean. `cov(X,Y,0)` is the same as `cov(X,Y)` and `cov(X,0)` is the same as `cov(X)`.

Tips `cov` removes the mean from each column before calculating the result.

The *covariance* between two random variables is:

$$\text{cov}(x_1, x_2) = E[(x_1 - \mu_1)(x_2 - \mu_2)]$$

where E is the mathematical expectation and $\mu_i = E x_i$.

Examples Consider `A = [-1 1 2 ; -2 3 1 ; 4 0 3]`. To obtain a vector of variances for each column of `A`:

```
v = diag(cov(A))'  
v =  
    10.3333     2.3333     1.0000
```

Compare vector v with covariance matrix C of A :

$C = \text{cov}(A)$

$C =$

10.3333	-4.1667	3.0000
-4.1667	2.3333	-1.5000
3.0000	-1.5000	1.0000

The diagonal elements $C(i, i)$ represent the variances for the columns of A . The off-diagonal elements $C(i, j)$ represent the covariances of columns i and j .

See Also

[corrcoef](#) | [mean](#) | [median](#) | [std](#) | [var](#) | [xcorr](#) | [xcov](#)

cplxpair

Purpose Sort complex numbers into complex conjugate pairs

Syntax

```
B = cplxpair(A)
B = cplxpair(A,tol)
B = cplxpair(A,[],dim)
B = cplxpair(A,tol,dim)
```

Description `B = cplxpair(A)` sorts the elements along different dimensions of a complex array, grouping together complex conjugate pairs.

The conjugate pairs are ordered by increasing real part. Within a pair, the element with negative imaginary part comes first. The purely real values are returned following all the complex pairs. The complex conjugate pairs are forced to be exact complex conjugates. A default tolerance of $100 \cdot \text{eps}$ relative to $\text{abs}(A(i))$ determines which numbers are real and which elements are paired complex conjugates.

If `A` is a vector, `cplxpair(A)` returns `A` with complex conjugate pairs grouped together.

If `A` is a matrix, `cplxpair(A)` returns `A` with its columns sorted and complex conjugates paired.

If `A` is a multidimensional array, `cplxpair(A)` treats the values along the first non-singleton dimension as vectors, returning an array of sorted elements.

`B = cplxpair(A,tol)` overrides the default tolerance.

`B = cplxpair(A,[],dim)` sorts `A` along the dimension specified by scalar `dim`.

`B = cplxpair(A,tol,dim)` sorts `A` along the specified dimension and overrides the default tolerance.

Diagnostics If there are an odd number of complex numbers, or if the complex numbers cannot be grouped into complex conjugate pairs within the tolerance, `cplxpair` generates the error message

Complex numbers can't be paired.

Purpose	Elapsed CPU time
Syntax	<code>cputime</code>
Description	<code>cputime</code> returns the total CPU time (in seconds) used by your MATLAB application from the time it was started. This number can overflow the internal representation and wrap around.
Tips	Although it is possible to measure performance using the <code>cputime</code> function, it is recommended that you use the <code>timeit</code> or <code>tic</code> and <code>toc</code> functions for this purpose exclusively. See Using tic and toc Versus the cputime Function in the MATLAB Programming Fundamentals documentation for more information.
Examples	<p>The following code returns the CPU time used to run <code>surf(peaks(40))</code>.</p> <pre>t = cputime; surf(peaks(40)); e = cputime-t e = 0.4667</pre>
See Also	<code>clock</code> <code>etime</code> <code>tic</code> <code>timeit</code> <code>toc</code>

RandStream.create

Purpose Create random number streams

Class RandStream

Syntax

```
[s1,s2,...] = RandStream.create('gentype','NumStreams',n)
s = RandStream.create('gentype')
[ ... ] = RandStream.create('gentype', Name, Value,...)
```

Description

[s1,s2,...] = RandStream.create('gentype','NumStreams',n) creates n random number streams that use the uniform pseudorandom number generator algorithm specified by **gentype**. The streams are independent in a pseudorandom sense. The streams are not necessarily independent from streams created at other times. `RandStream.list` returns all possible values for **gentype** or see “Choosing a Random Number Generator” in the MATLAB Mathematics documentation for details on generator algorithms.

Note Multiple streams are not supported by all generator types. Use either the multiplicative lagged Fibonacci generator (`m1fg6331_64`) or the combined multiple recursive generator (`mrq32k3a`) to create multiple streams.

`s = RandStream.create('gentype')` creates a single random stream. The `RandStream` constructor is a more concise alternative when you need to create a single stream.

`[...] = RandStream.create('gentype', Name, Value,...)` allows you to specify optional Name, Value pairs to control creation of the stream. The parameters are:

NumStreams	Total number of streams of this type that will be created across sessions or labs. Default is 1.
StreamIndices	Stream indices that should be created in this call. Default is 1:N, where N is the value given with the 'NumStreams' parameter.
Seed	Nonnegative scalar integer with which to initialize all streams. Default is 0. Seeds must be an integer between 0 and $2^{32} - 1$ or 'shuffle' to create a seed based on the current time.
NormalTransform	Transformation algorithm used by <code>randn(S, ...)</code> to generate normal pseudorandom values. Options are 'Ziggurat', 'Polar', or 'Inversion'.
CellOutput	Logical flag indicating whether or not to return the stream objects as elements of a cell array. Default is false.

Typically, you call `RandStream.create` once to create multiple independent streams in a single pass. Alternatively, you can create each stream from separate calls to `RandStream.create`, but you must specify the appropriate values for `gentype`, 'NumStreams', 'Seed', and 'StreamIndices' to ensure their independence:

- Specify the same set of values for `gentype`, 'NumStreams', and 'Seed' in each case.
- Specify a different value for 'StreamIndices' that is between 1 and the 'NumStreams' value in each case.

RandStream.create

Examples

Create three independent streams.

```
[s1,s2,s3] = RandStream.create('mrg32k3a','NumStreams',3);  
r1 = rand(s1,100000,1);  
r2 = rand(s2,100000,1);  
r3 = rand(s3,100000,1);  
corrcoef([r1,r2,r3])
```

Create one stream from a set of three independent streams and designate it as the global stream.

```
s2 = RandStream.create('mrg32k3a','NumStreams',3,'StreamIndices',2);  
RandStream.setGlobalStream(s2);
```

Purpose Create MATLAB class based on WSDL document

Syntax `createClassFromWsd1(source)`

Description `createClassFromWsd1(source)` creates a MATLAB class, `servicename`, based on a service name defined in `source`. The `source` argument is a string that specifies a URL, full path, or relative path to a Web Services Description Language (WSDL) document located on a server. `createClassFromWsd1` creates a class folder, `@servicename`, in the current folder. The class folder contains a method file for each Web service operation, and the display method (`display.m`) and constructor (`servicename.m`) for the class.

Examples Get the methods from the `myWebService` WSDL document, which specifies two methods. The example does not use an actual WSDL document; therefore, you cannot run it. The example only illustrates how to use the function.

Create the class:

```
createClassFromWsd1('pathto_myWebService')
```

MATLAB creates the following in the current folder:

```
@myWebService  
@myWebService/method1.m  
@myWebService/method2.m  
@myWebService/display.m  
@myWebService/myWebService.m
```

Retrieve a student name, given the WSDL document for `TestScoreWebService`, at <http://examplestandardtests.com/scoreswebservice?WSDL>. The example does not use an actual WSDL document; therefore, you cannot run it. The example only illustrates how to use the function.

```
url = 'http://examplestandardtests.com/scoreswebservice?WSDL';
```

createClassFromWsd1

```
createClassFromWsd1(url);  
obj = TestScoreWebService;  
% Show the methods  
methods(obj)  
% Retrieve the first student name  
students = StudentNames(obj);  
students.StudentInfo(1)
```

MATLAB returns

```
StudentNameLast: 'Benjamin'  
StudentNameFirst: 'Ali'
```

Display the endpoint and WSDL document location:

```
display('TestScoreWebService')
```

MATLAB returns

```
endpoint: 'http://examplestandardtests.com/scoreswebservice'  
wsdl: 'http://examplestandardtests.com/scoreswebservice?WSDL'
```

How To

- “Access Web Services That Use WSDL Documents”
- “Specify Proxy Server Settings for Connecting to the Internet”

Purpose	Create copy of inputParser object (to be removed)
Compatibility	The createCopy method will be removed in a future release. Use copy instead.
Syntax	<code>pNew = createCopy(p)</code>
Description	<code>pNew = createCopy(p)</code> creates a copy of inputParser object <code>p</code> .
Tips	<ul style="list-style-type: none">Using <code>createCopy</code> is not the same as copying by assignment, such as <code>pNew = p</code>, which creates a new handle to the same object <code>p</code>.
Input Arguments	<p>p</p> <p>Object of class <code>inputParser</code>.</p>
Output Arguments	<p>pNew</p> <p><code>inputParser</code> object with the same properties as object <code>p</code>.</p>
Examples	<p>Copy Input Parser Scheme</p> <p>Create a copy of an existing <code>inputParser</code> object, and add an optional input to the copy.</p> <pre>p = inputParser; default = 0; addRequired(p, 'first'); addOptional(p, 'second', default); pNew = createCopy(p); addOptional(pNew, 'third', default);</pre> <p>Object <code>p</code> has two inputs in the scheme, <code>first</code> and <code>second</code>. Object <code>pNew</code> has an additional input, <code>third</code>.</p> <p>Parse each object.</p>

inputParser.createCopy

```
input1 = 1; input2 = 2; input3 = 3;

parse(p,input1);
p.Results

ans =
    first: 1
    second: 0

parse(pNew,input1,input2,input3);
pNew.Results

ans =
    first: 1
    second: 2
    third: 3
```

Purpose Create SOAP message to send to server

Syntax `message = createSoapMessage(namespace,method,values,names,types,style)`

Description `message = createSoapMessage(namespace,method,values,names,types,style)` creates a SOAP message based on the values you provide for the arguments. `message` is a Java document object model (DOM). To send message to the Web service, use it with `callSoapService`.

Argument	Description
<code>namespace</code>	Location of the Web service in the form of a valid Uniform Resource Identifier (URI).
<code>method</code>	Name of the Web service operation you want to run.
<code>values</code>	Cell array of input you need to provide for the method.
<code>names</code>	Cell array of parameters for method.
<code>types</code>	Cell array defining the XML data types for <code>values</code> . Specifying <code>style</code> is optional; when you do not include the argument, MATLAB uses unspecified.
<code>style</code>	Style for structuring the SOAP message, either ' document ' or ' rpc '. Specifying <code>style</code> is optional; when you do not include the argument, MATLAB uses rpc . Use a style supported by the service you specified in <code>namespace</code> .

Examples This example uses `createSoapMessage` in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

createSoapMessage

Note The example is not based on an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

```
% Create the message:
message = createSoapMessage(...
    'urn:LibraryCatalog',...
    'getAuthor',...
    {'In the Fall'},...
    {'nameToLookUp'},...
    {'{http://www.w3.org/2001/XMLSchema}string'},...
    'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
    'http://test/soap/services/LibraryCatalog',...
    'urn:LibraryCatalog#getAuthor',...
    message)
%
% Extract MATLAB data from the response
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

How To

- “Access Web Services Using MATLAB SOAP Functions”

Purpose

Cross product

Syntax

```
C = cross(A,B)
C = cross(A,B,dim)
```

Description

`C = cross(A,B)` returns the cross product of A and B.

- If A and B are vectors, then they must have a length of 3.
- If A and B are matrices or multidimensional arrays, then they must have the same size. In this case, the `CROSS` function treats A and B as collections of three-element vectors. The function calculates the cross product of corresponding vectors along the first array dimension whose size equals 3.

`C = cross(A,B,dim)` evaluates the cross product of arrays A and B along dimension, `dim`. A and B must have the same size, and both `size(A,dim)` and `size(B,dim)` must be 3. The `dim` input is a positive integer scalar.

Input Arguments**A,B - Input arrays**

numeric arrays

Input arrays, specified as numeric arrays.

Data Types

single | double

Complex Number Support: Yes

dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. The size of dimension `dim` must be 3. If no value is specified, the default is the first array dimension whose size equals 3.

Consider two 2-D input arrays, A and B:

CROSS

- `cross(A,B,1)` treats the columns of A and B as vectors and returns the cross products of corresponding columns.
- `cross(A,B,2)` treats the rows of A and B as vectors and returns the cross products of corresponding rows.

`cross` returns an error if `dim` is greater than `ndims(A)`.

Examples

Cross Product of Vectors

Create two 3-D vectors.

```
A = [4 -2 1];
```

```
B = [1 -1 3];
```

Find the cross product of A and B.

```
C = cross(A,B)
```

```
C =
```

```
-5  -11  -2
```

The result, C, is a vector that is perpendicular to both A and B.

Use dot products to verify that C is perpendicular to A and B.

```
dot(C,A)==0 & dot(C,B)==0
```

```
ans =
```

1

The result is logical 1 (true).

Cross Product of Matrices

Create two matrices containing random integers.

```
rng(0)
```

```
A = randi(15,3,5)
```

```
B = randi(25,3,5)
```

```
A =
```

```
    13    14     5    15    15
    14    10     9     3     8
     2     2    15    15    13
```

```
B =
```

```
     4    20     1    17    10
    11    24    22    19    17
    23    17    24    19     5
```

Find the cross product of A and B.

```
C = cross(A,B)
```

```
C =
```

```
    300    122   -114   -228   -181
   -291   -198   -105    -30    55
     87    136    101    234    175
```

The result, C, contains five independent cross products between the columns of A and B. For example, $C(:, 1)$ is equal to the cross product of $A(:, 1)$ with $B(:, 1)$.

Cross Product of Multidimensional Arrays

Create two 3-by-3-by-3 multidimensional arrays of random integers.

```
rng(0)
A = randi(10,3,3,3);
B = randi(25,3,3,3);
```

Find the cross product of A and B, treating the rows as vectors.

```
C = cross(A,B,2)
```

```
C(:,:,1) =
```

```
   -34    12    62
    15    72  -109
   -49     8     9
```

```
C(:,:,2) =
```

```
   198  -164  -170
    45     0   -18
   -55   190  -116
```

```
C(:,:,3) =
```

```
  -109   -45   131
     1   -74    82
    -6   101  -121
```

The result is a collection of row vectors. For example, $C(1, :, 1)$ is equal to the cross product of $A(1, :, 1)$ with $B(1, :, 1)$.

Find the cross product of A and B along the third dimension (`dim = 3`).

```
D = cross(A,B,3)
```

$$D(:, :, 1) =$$

$$\begin{array}{ccc} -14 & 179 & -106 \\ -56 & -4 & -75 \\ 2 & -37 & 10 \end{array}$$

$$D(:, :, 2) =$$

$$\begin{array}{ccc} -37 & -162 & -37 \\ 50 & -124 & -78 \\ 1 & 63 & 118 \end{array}$$

$$D(:, :, 3) =$$

$$\begin{array}{ccc} 62 & -170 & 56 \\ 46 & 72 & 105 \\ -2 & -53 & -160 \end{array}$$

The result is a collection of vectors oriented in the third dimension. For example, $C(1, 1, :)$ is equal to the cross product of $A(1, 1, :)$ with $B(1, 1, :)$.

Definitions

Cross Product

The cross product between two 3-D vectors produces a new vector that is perpendicular to both.

Consider the two vectors

$$\begin{aligned} A &= a_1 \hat{i} + a_2 \hat{j} + a_3 \hat{k}, \\ B &= b_1 \hat{i} + b_2 \hat{j} + b_3 \hat{k}. \end{aligned}$$

In terms of a matrix determinant involving the basis vectors \hat{i} , \hat{j} , and \hat{k} , the cross product of A and B is

$$C = A \times B = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}$$
$$= (a_2b_3 - a_3b_2)\hat{i} + (a_3b_1 - a_1b_3)\hat{j} + (a_1b_2 - a_2b_1)\hat{k}.$$

Geometrically, $A \times B$ is perpendicular to both A and B . The magnitude of the cross product, $\|A \times B\|$, is equal to the area of the parallelogram formed using A and B as sides. This area is related to the magnitudes of A and B as well as the angle between the vectors by

$$\|A \times B\| = \|A\|\|B\|\sin \alpha.$$

Thus, if A and B are parallel, then the cross product is zero.

Purpose	Cosecant of input angle in radians
Syntax	$Y = \text{csc}(X)$
Description	$Y = \text{csc}(X)$ returns the cosecant of the elements of X . The <code>csc</code> function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of X in the interval $[-\text{Inf}, \text{Inf}]$, <code>csc</code> returns real values in the interval $[-\text{Inf}, -1]$ and $[1, \text{Inf}]$. For complex values of X , <code>csc</code> returns complex values. All angles are in radians.
Input Arguments	X - Input angle in radians scalar value vector matrix N-D array Input angle in radians, specified as a real-valued or complex-valued scalar, vector, matrix or N-D array. The <code>csc</code> operation is element-wise when X is non-scalar. Data Types single double Complex Number Support: Yes
Output Arguments	Y - Cosecant of input angle scalar value vector matrix N-D array Cosecant of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.
Examples	Plot Cosecant Function Plot the cosecant function over the domain $-\pi < x < 0$ and $0 < x < \pi$ as shown. <pre>x1 = -pi+0.01:0.01:-0.01; x2 = 0.01:0.01:pi-0.01; plot(x1,csc(x1),x2,csc(x2)), grid on</pre>

Cosecant of Vector of Complex Angles

Calculate the cosecant of the complex angles in vector x.

```
x = [-i pi+i*pi/2 -1+i*4];
y = csc(x)
```

y =

$$0.0000 + 0.8509i \quad 0.0000 + 0.4345i \quad -0.0308 - 0.0198i$$

Definitions

Cosecant Function

The cosecant of an angle, α , defined with reference to a right angled triangle is

$$\operatorname{cosecant}(\alpha) = \frac{1}{\sin(\alpha)} = \frac{\text{hypotenuse}}{\text{opposite side}} = \frac{h}{a}.$$

The cosecant of a complex angle, α , is

$$\operatorname{cosecant}(\alpha) = \frac{2i}{e^{i\alpha} - e^{-i\alpha}}.$$

Purpose Hyperbolic cosecant

Syntax $Y = \operatorname{csch}(x)$

Description The `csch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians. $Y = \operatorname{csch}(x)$ returns the hyperbolic cosecant for each element of x .

Examples **Graph of Hyperbolic Cosecant**

Plot the hyperbolic cosecant over the domain $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;  
x2 = 0.01:0.01:pi-0.01;  
plot(x1,csch(x1),x2,csch(x2)), grid on
```

Definitions **Hyperbolic Cosecant**

The hyperbolic cosecant of z is

$$\text{csch}(z) = \frac{1}{\sinh(z)}.$$

See Also [acsch](#) | [csc](#) | [sinh](#) | [cosh](#)

Purpose Read comma-separated value file

Syntax

```
M = csvread(filename)
M = csvread(filename,row,col)
M = csvread(filename,row,col, csvRange)
```

Description M = csvread(filename) reads a comma-separated value formatted file, filename. The file can only contain numeric values.

M = csvread(filename,row,col) reads data from the file starting at the specified row and column. The row and column arguments are zero based, so that row = 0 and col = 0 specify the first value in the file.

M = csvread(filename,row,col, csvRange) reads only the range specified by csvRange.

Input Arguments

filename - Name of file to read

string

Name of the file to read, specified as a string.

Example: 'myFile.dat'

Data Types

char

row - Row of first value to read

0 (default) | positive integer

Row of the first value to read, specified as a positive integer. row is zero based, so that row = 0 specifies the first row of data.

Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

col - Column of first value to read

0 (default) | positive integer

Column of the first value to read, specified as a positive integer. `col` is zero based, so that `col = 0` specifies the first column of data.

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

csvRange - Range of data to read

4-element vector | string

Range of the data to read, specified as a 4-element vector or a string.

- If `csvRange` is a 4-element vector, then it must have the form `[R1,C1,R2,C2]`, where `(R1,C1)` is the upper left corner of the data to be read and `(R2,C2)` is the lower right corner. The range is zero based, so that `R1 = 0` specifies the first row of data, and `C1 = 0` specifies the first column of data.
- If `csvRange` is a string, then it should be specified using spreadsheet notation, as in `csvRange = 'A1..B7'`.

Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

Output Arguments

M - Numeric data

matrix

Numeric data, returned as a matrix of double values.

Examples

Read File Containing Comma-Separated Values

Create a file, `csvlist.dat`, that contains these comma-separated values.

```
02, 04, 06, 08
03, 06, 09, 12
05, 10, 15, 20
07, 14, 21, 28
```

Read the entire file.

```
filename = 'csvlist.dat';
M = csvread(filename)
```

M =

```

     2     4     6     8
     3     6     9    12
     5    10    15    20
     7    14    21    28
```

csvread returns the numeric data in M.

Read Data Starting at Specific Row and Column

Read data from the file, csvlist.dat, of the previous example, starting at zero-based row 2, column 0.

```
M = csvread('csvlist.dat',2,0)
```

M =

```

     5    10    15    20
     7    14    21    28
```

Read a Specific Range of Data

Read a specific range of data from the file, csvlist.dat, of the first example.

Read the matrix bounded by zero-based (1,0) and (2,2).

```
M = csvread('csvlist.dat',1,0,[1,0,2,2])
```

M =

```

     3     6     9
     5    10    15
```

csvread

Algorithms

csvread fills empty delimited fields with zero. When csvread reads data files with lines that end with a nonspace delimiter, such as a semicolon, it returns a matrix, M, that has an additional last column of zeros.

csvread imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type. The table shows valid forms for a complex number.

Form	Example
-<real>-<imag>i j	5.7-3.1i
-<imag>i j	-7j

Embedded white-space in a complex number is invalid and is regarded as a field delimiter.

csvwrite | dlmread | textscan | readtable | uiimport

Purpose Complex conjugate transpose

Syntax
 $b = a'$
 $b = \text{ctranspose}(a)$

Description
 $b = a'$ computes the complex conjugate transpose of matrix a and returns the result in b .
 $b = \text{ctranspose}(a)$ is called for the syntax a' (complex conjugate transpose) when a is an object.

See Also transpose

csvwrite

Purpose Write comma-separated value file

Syntax `csvwrite(filename,M)`
`csvwrite(filename,M,row,col)`

Description `csvwrite(filename,M)` writes matrix `M` into `filename` as comma-separated values. The `filename` input is a string enclosed in single quotes.

`csvwrite(filename,M,row,col)` writes matrix `M` into `filename` starting at the specified row and column offset. The row and column arguments are zero based, so that `row=0` and `C=0` specify the first value in the file.

- Tips**
- `csvwrite` terminates each line with a line feed character and no carriage return.
 - `csvwrite` writes a maximum of five significant digits. If you need greater precision, use `dlmwrite` with a precision argument.
 - `csvwrite` does not accept cell arrays for the input matrix `M`. To export a cell array that contains only numeric data, use `cell2mat` to convert the cell array to a numeric matrix before calling `csvwrite`. To export cell arrays with mixed alphabetic and numeric data, where each cell contains a single element, you can create an Excel spreadsheet (if your system has Excel installed) using `xlswrite`. For all other cases, you must use low-level export functions to write your data. For more information, see “Export Cell Array to Text File” in the MATLAB Data Import and Export documentation.

Examples The following example creates a comma-separated value file from the matrix `m`.

```
m = [3 6 9 12 15; 5 10 15 20 25; ...  
     7 14 21 28 35; 11 22 33 44 55];  
  
csvwrite('csvlist.dat',m)  
type csvlist.dat
```

```
3,6,9,12,15  
5,10,15,20,25  
7,14,21,28,35  
11,22,33,44,55
```

The next example writes the matrix to the file, starting at a column offset of 2.

```
csvwrite('csvlist.dat',m,0,2)  
type csvlist.dat
```

```
,,3,6,9,12,15  
,,5,10,15,20,25  
,,7,14,21,28,35  
,,11,22,33,44,55
```

[csvread](#) | [dlmwrite](#) | [xlswrite](#) | [writetable](#) | [uiimport](#)

cumprod

Purpose Cumulative product

Syntax
B = cumprod(A)
B = cumprod(A,dim)

Description B = cumprod(A) returns an array the same size as the array A containing the cumulative product.

- If A is a vector, then cumprod(A) returns a vector containing the cumulative product of the elements of A.
- If A is a matrix, then cumprod(A) returns a matrix containing the cumulative products for each column of A.
- If A is a multidimensional array, then cumprod(A) acts along the first nonsingleton dimension.

B = cumprod(A,dim) returns the cumulative product along dimension dim. For example, if A is a matrix, then cumprod(A,2) returns the cumulative product of each row.

Input Arguments

A - Input array
vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types
double | single | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64 | logical

Complex Number Support: Yes

dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A.

- `cumprod(A,1)` works along the rows of `A` and returns the cumulative product of each column.
- `cumprod(A,2)` works along the columns of `A` and returns the cumulative product of each row.

`cumprod` returns `A` if `dim` is greater than `ndims(A)`.

Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

B - Cumulative product array

`vector` | `matrix` | `multidimensional array`

Cumulative product array, returned as a vector, matrix, or multidimensional array of the same size as the input array `A`.

The class of `B` is the same as the class of `A` except if `A` is `logical`, in which case `B` is `double`.

Definitions

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If `X` is a 1-by-`n` row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-`n` empty array, then the second dimension is the first nonsingleton dimension of `X`.

- If X is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of X .

Examples

Cumulative Product of Vector

Find the cumulative product of the integers from 1 to 5.

```
A = [1:5];  
B = cumprod(A)
```

B =

```
     1     2     6    24   120
```

$B(2)$ is the product of $A(1)$ and $A(2)$, while $B(5)$ is the product of elements $A(1)$ through $A(5)$.

Cumulative Product of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

A =

```
     1     4     7  
     2     5     8  
     3     6     9
```

Find the cumulative product of the columns of A .

```
B = cumprod(A)
```

B =

```
     1     4     7  
     2    20    56  
     6   120   504
```

B(5) is the product of A(4) and A(5), while B(9) is the product of A(7) , A(8), and A(9).

Cumulative Product of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]
```

```
A =
```

```
     1     3     5
     2     4     6
```

Find the cumulative product of the rows of A.

```
B = cumprod(A,2)
```

```
B =
```

```
     1     3    15
     2     8    48
```

B(3) is the product of A(1) and A(3), while B(5) is the product of A(1), A(3), and A(5) .

Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

```
A =
```

```
     1     0     1
     1     1     0
```

Find the cumulative product of the rows of A.

cumprod

```
B = cumprod(A,2)
```

```
B =
```

```
    1    0    0
    1    1    0
```

The output is double.

```
class(B)
```

```
ans =
```

```
double
```

```

Purpose	Cumulative sum
Syntax	<pre>B = cumsum(A) B = cumsum(A,dim)</pre>
Description	<p><code>B = cumsum(A)</code> returns an array of the same size as the array <code>A</code> containing the cumulative sum.</p> <ul style="list-style-type: none">• If <code>A</code> is a vector, then <code>cumsum(A)</code> returns a vector containing the cumulative sum of the elements of <code>A</code>.• If <code>A</code> is a matrix, then <code>cumsum(A)</code> returns a matrix containing the cumulative sums for each column of <code>A</code>.• If <code>A</code> is a multidimensional array, then <code>cumsum(A)</code> acts along the first nonsingleton dimension. <p><code>B = cumsum(A,dim)</code> returns the cumulative sum of the elements along dimension <code>dim</code>. For example, if <code>A</code> is a matrix, then <code>cumsum(A,2)</code> returns the cumulative sum of each row.</p>
Input Arguments	<p>A - Input array vector matrix multidimensional array</p> <p>Input array, specified as a vector, matrix, or multidimensional array.</p> <p>Data Types double single int8 int16 int32 int64 uint8 uint16 uint32 uint64 logical</p> <p>Complex Number Support: Yes</p> <p>dim - Dimension to operate along positive integer scalar</p> <p>Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.</p> <p>Consider a two-dimensional input array, <code>A</code>:</p>

cumsum

- `cumsum(A,1)` works along the rows of A and returns the cumulative sum of each column.
- `cumsum(A,2)` works along the columns of A and returns the cumulative sum of each row.

`cumsum` returns A if `dim` is greater than `ndims(A)`.

Data Types

`double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

B - Cumulative sum array

`vector` | `matrix` | `multidimensional array`

Cumulative sum array, returned as a vector, matrix, or multidimensional array of the same size as the input array A.

The class of B is the same as the class of A except if A is `logical`, in which case B is `double`.

Definitions

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If X is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of X.
- If X is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of X.

- If X is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of X .

Examples

Cumulative Sum of Vector

Find the cumulative sum of the integers from 1 to 5.

```
A = [1:5];
B = cumsum(A)
```

B =

```
     1     3     6    10    15
```

$B(2)$ is the sum of $A(1)$ and $A(2)$, while $B(5)$ is the sum of elements $A(1)$ through $A(5)$.

Cumulative Sum of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

A =

```
     1     4     7
     2     5     8
     3     6     9
```

Find the cumulative sum of the columns of A .

```
B = cumsum(A)
```

B =

```
     1     4     7
     3     9    15
     6    15    24
```

B(5) is the sum of A(4) and A(5), while B(9) is the sum of A(7) , A(8), and A(9).

Cumulative Sum of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]
```

A =

```
     1     3     5
     2     4     6
```

Find the cumulative sum of the rows of A.

```
B = cumsum(A,2)
```

B =

```
     1     4     9
     2     6    12
```

B(3) is the sum of A(1) and A(3), while B(5) is the sum of A(1), A(3), and A(5) .

Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

A =

```
     1     0     1
     1     1     0
```

Find the cumulative sum of the rows of A.

```
B = cumsum(A,2)
```

```
B =
```

```
    1    1    2
    1    2    2
```

The output is double.

```
class(B)
```

```
ans =
```

```
double
```

cumtrapz

Purpose Cumulative trapezoidal numerical integration

Syntax
`Z = cumtrapz(Y)`
`Z = cumtrapz(X,Y)`
`Z = cumtrapz(___,dim)`

Description `Z = cumtrapz(Y)` computes an approximation of the cumulative integral of `Y` via the trapezoidal method with unit spacing. To compute the integral with other than unit spacing, multiply `Z` by the spacing increment. Input `Y` can be complex.

For vectors, `cumtrapz(Y)` is a vector containing the cumulative integral of `Y`.

For matrices, `cumtrapz(Y)` is a matrix the same size as `Y` with the cumulative integral over each column.

For multidimensional arrays, `cumtrapz(Y)` works across the first nonsingleton dimension.

`Z = cumtrapz(X,Y)` computes the cumulative integral of `Y` with respect to `X` using trapezoidal integration. `X` and `Y` must be vectors of the same length, or `X` must be a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`. `cumtrapz` operates across this dimension. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `cumtrapz(X,Y)` operates across this dimension.

`Z = cumtrapz(___,dim)` integrates across the dimension of `Y` specified by scalar `dim`, using any of the input arguments in the previous syntaxes. The length of `X` must be the same as `size(Y,dim)`.

Examples

Example 1

```
Y = [0 1 2; 3 4 5];
```

```
cumtrapz(Y,1)  
ans =  
0      0      0
```

```
        1.5000    2.5000    3.5000
cumtrapz(Y,2)
ans =
0      0.5000    2.0000
      0      3.5000    8.0000
```

Example 2

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);

ct = cumtrapz(z,1./z);
ct(end)
ans =
    0.0000 + 3.1411i
```

curl

Purpose Compute curl and angular velocity of vector field

Syntax

```
[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)
[curlx,curly,curlz,cav] = curl(U,V,W)
[curlz,cav]= curl(X,Y,U,V)
[curlz,cav]= curl(U,V)
[curlx,curly,curlz] = curl(...), [curlx,curly] = curl(...)
cav = curl(...)
```

Description [curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W) computes the curl (curlx, curly, curlz) and angular velocity (cav) perpendicular to the flow (in radians per time unit) of a 3-D vector field U, V, W.

The arrays X, Y, and Z, which define the coordinates for U, V, and W, must be monotonic, but do not need to be uniformly spaced. X, Y, and Z must have the same number of elements, as if produced by `meshgrid`.

[curlx,curly,curlz,cav] = curl(U,V,W) assumes X, Y, and Z are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where [m,n,p] = size(U).

[curlz,cav]= curl(X,Y,U,V) computes the curl z-component and the angular velocity perpendicular to z (in radians per time unit) of a 2-D vector field U, and V.

The arrays X and Y, which define the coordinates for U and V, must be monotonic, but do not need to be uniformly spaced. X and Y must have the same number of elements, as if produced by `meshgrid`.

[curlz,cav]= curl(U,V) assumes X and Y are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where [m,n] = size(U).

```
[curlx,curly,curlz] = curl(...), [curlx,curly] = curl(...)  
returns only the curl.
```

```
cav = curl(...) returns only the curl angular velocity.
```

Examples

This example uses colored slice planes to display the curl angular velocity at specified locations in the vector field.

```
figure  
load wind  
cav = curl(x,y,z,u,v,w);  
h = slice(x,y,z,cav,[90 134],59,0);  
shading interp  
daspect([1 1 1]);  
axis tight  
colormap hot(16)  
camlight  
set([h(1),h(2)], 'ambientstrength', .6)
```

curl

This example views the curl angular velocity in one plane of the volume and plots the velocity vectors (quiver) in the same plane.

```
load wind
k = 4;
x = x(:,:,k); y = y(:,:,k); u = u(:,:,k); v = v(:,:,k);
cav = curl(x,y,u,v);
pcolor(x,y,cav); shading interp
hold on;
quiver(x,y,u,v,'y')
hold off
colormap copper
```

How To

- “Displaying Curl with Stream Ribbons”

Purpose Index of current IFD

Syntax `dirNum = tiffobj.currentDirectory()`

Description `dirNum = tiffobj.currentDirectory()` returns the index of the current image file directory (IFD). Index values are one-based. Use this index value with the `setDirectory` member function.

Examples **Determine Current IFD**

Open a Tiff object and determine which IFD is the current IFD.

```
t = Tiff('example.tif', 'r');  
dnum = t.currentDirectory()
```

```
dnum =
```

```
1
```

Close the Tiff object.

```
t.close();
```

References This method corresponds to the `TIFFCurrentDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

customverctrl

Purpose Allow custom source control system (UNIX platforms)

Syntax `customverctrl`

Description `customverctrl` function is for customers who want to integrate a source control system that is not supported for use with MATLAB software. When using this function, conform to the structure of one of the supported version control systems, for example, RCS. For examples, see the files `clearcase.m`, `cvs.m`, `pvcs.m`, and `rsc.m` in `matlabroot\toolbox\matlab\verctrl`.

See Also `checkin` | `checkout` | `cmopts` | `undocheckout` | `verctrl`

Purpose

Generate cylinder

**Syntax**

```
[X,Y,Z] = cylinder
[X,Y,Z] = cylinder(r)
[X,Y,Z] = cylinder(r,n)
cylinder(axes_handle,...)
cylinder(...)
```

Description

`cylinder` generates x -, y -, and z -coordinates of a unit cylinder. You can draw the cylindrical object using `surf` or `mesh`, or draw it immediately by not providing output arguments.

`[X,Y,Z] = cylinder` returns the x -, y -, and z -coordinates of a cylinder with a radius equal to 1. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r)` returns the x -, y -, and z -coordinates of a cylinder using r to define a profile curve. `cylinder` treats each element in r as a radius at equally spaced heights along the unit height of the cylinder. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r,n)` returns the x -, y -, and z -coordinates of a cylinder based on the profile curve defined by vector r . The cylinder has n equally spaced points around its circumference.

`cylinder(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`cylinder(...)`, with no output arguments, plots the cylinder using `surf`.

cylinder

Tips

`cylinder` treats its first argument as a profile curve. The resulting surface graphics object is generated by rotating the curve about the x -axis, and then aligning it with the z -axis.

Examples

Create a cylinder with randomly colored faces.

```
cylinder  
axis square  
h = findobj('Type','surface');  
set(h,'CData',rand(size(get(h,'CData'))))
```

Generate a cylinder defined by the profile function $2+\sin(t)$.

```
t = 0:pi/10:2*pi;
```

```
[X,Y,Z] = cylinder(2+cos(t));  
surf(X,Y,Z)  
axis square
```

See Also

[sphere](#) | [surf](#)

daqread

Purpose Read Data Acquisition Toolbox (.daq) file

Syntax

```
data = daqread('filename')
[data, time] = daqread(...)
[data, time, abstime] = daqread(...)
[data, time, abstime, events] = daqread(...)
[data, time, abstime, events, daqinfo] = daqread(...)
data = daqread(..., 'Param1', Val1, ...)
daqinfo = daqread('filename', 'info')
```

Description `data = daqread('filename')` reads all the data from the Data Acquisition Toolbox™ (.daq) file specified by `filename`. `daqread` returns `data`, an m -by- n data matrix, where m is the number of samples and n is the number of channels. If `data` includes data from multiple triggers, the data from each trigger is separated by a NaN. If you set the `OutputFormat` property to `tscollection`, `daqread` returns a time series collection object. See below for more information.

`[data, time] = daqread(...)` returns `time/value` pairs. `time` is an m -by-1 vector, the same length as `data`, that contains the relative time for each sample. Relative time is measured with respect to the first trigger that occurs.

`[data, time, abstime] = daqread(...)` returns the absolute time of the first trigger. `abstime` is returned as a clock vector.

`[data, time, abstime, events] = daqread(...)` returns a log of events. `events` is a structure containing event information. If you specify either the `Samples`, `Time`, or `Triggers` parameters (see below), the events structure contains only the specified events.

`[data, time, abstime, events, daqinfo] = daqread(...)` returns a structure, `daqinfo`, that contains two fields: `ObjInfo` and `HwInfo`. `ObjInfo` is a structure containing property name/property value pairs and `HwInfo` is a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

`data = daqread(..., 'Param1', Val1, ...)` specifies the amount of data returned and the format of the data, using the following parameters.

Parameter	Description
Samples	Specify the sample range.
Time	Specify the relative time range.
Triggers	Specify the trigger range.
Channels	Specify the channel range. Channel names can be specified as a cell array.
DataFormat	Specify the data format as doubles (default) or native.
TimeFormat	Specify the time format as vector (default) or matrix.
OutputFormat	Specify the output format as matrix (the default) or <code>tscollection</code> . When you specify <code>tscollection</code> , <code>daqread</code> only returns data.

The `Samples`, `Time`, and `Triggers` properties are mutually exclusive; that is, either `Samples`, `Triggers` or `Time` can be defined at once.

`daqinfo = daqread('filename', 'info')` returns metadata from the file in the `daqinfo` structure, without incurring the overhead of reading the data from the file as well. The `daqinfo` structure contains two fields:

`daqinfo.ObjInfo`

a structure containing parameter/value pairs for the data acquisition object used to create the file, `filename`. Note: The `UserData` property value is not restored.

`daqinfo.HwInfo`

a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

Tips

More About .daq Files

- The format used by `daqread` to return data, relative time, absolute time, and event information is identical to the format used by the `getdata` function that is part of Data Acquisition Toolbox. For more information, see the Data Acquisition Toolbox documentation.
- If data from multiple triggers is read, then the size of the resulting data array is increased by the number of triggers issued because each trigger is separated by a NaN.
- `ObjInfo.EventLog` always contains the entire event log regardless of the value specified by `Samples`, `Time`, or `Triggers`.
- The `UserData` property value is not restored when you return device object (`ObjInfo`) information.
- When reading a `.daq` file, the `daqread` function does not return property values that were specified as a cell array.
- Data Acquisition Toolbox (`.daq`) files are created by specifying a value for the `LogFileName` property (or accepting the default value), and configuring the `LoggingMode` property to `Disk` or `Disk&Memory`.

More About Time Series Collection Object Returned

When `OutputFormat` is set to `tscollection`, `daqread` returns a time series collection object. This times series collection object contains an absolute time series object for each channel in the file. The following describes how `daqread` sets some of the properties of the times series collection object and the time series objects.

- The `time` property of the time series collection object is set to the value of the `InitialTriggerTime` property specified in the file.
- The `name` property of each time series object is set to the value of the `Name` property of a channel in the file. If this name cannot be used as a time series object name, `daqread` sets the name to `'Channel'` with the `HwChannel` property of the channel appended.
- The value of the `Units` property of the time series object depends on the value of the `DataFormat` parameter. If the `DataFormat` parameter

is set to 'double', `daqread` sets the `DataInfo` property of each time series object in the collection to the value of the `Units` property of the corresponding channel in the file. If the `DataFormat` parameter is set to 'native', `daqread` sets the `Units` property to 'native'. See the Data Acquisition Toolbox documentation for more information on these properties.

- Each time series object will have `tsdata.event` objects attached corresponding to the log of events associated with the channel.

If `daqread` returns data from multiple triggers, the data from each trigger is separated by a NaN in the time series data. This increases the length of data and time vectors in the time series object by the number of triggers.

Examples

Use Data Acquisition Toolbox to acquire data. The analog input object, `ai`, acquires one second of data for four channels, and saves the data to the output file `data.daq`.

```
ai = analoginput('nidaq','Dev1');
chans = addchannel(ai,0:3);
set(ai,'SampleRate',1000)
ActualRate = get(ai,'SampleRate');
set(ai,'SamplesPerTrigger', ActualRate)
set(ai,'LoggingMode','Disk&Memory')
set(ai,'LogFileName','data.daq')
start(ai)
```

After the data has been collected and saved to a disk file, you can retrieve the data and other acquisition-related information using `daqread`. To read all the sample-time pairs from `data.daq`:

```
[data,time] = daqread('data.daq');
```

To read samples 500 to 1000 for all channels from `data.daq`:

```
data = daqread('data.daq','Samples',[500 1000]);
```

daqread

To read only samples 1000 to 2000 of channel indices 2, 4 and 7 in native format from the file, `data.daq`:

```
data = daqread('data.daq', 'Samples', [1000 2000],...  
              'Channels', [2 4 7], 'DataFormat', 'native');
```

To read only the data which represents the first and second triggers on all channels from the file, `data.daq`:

```
[data, time] = daqread('data.daq', 'Triggers', [1 2]);
```

To obtain the channel property information from `data.daq`:

```
daqinfo = daqread('data.daq', 'info');  
chaninfo = daqinfo.ObjInfo.Channel;
```

To obtain a list of event types and event data contained by `data.daq`:

```
daqinfo = daqread('data.daq', 'info');  
events = daqinfo.ObjInfo.EventLog;  
event_type = {events.Type};  
event_data = {events.Data};
```

To read all the data from the file `data.daq` and return it as a time series collection object:

```
data = daqread('data.daq', 'OutputFormat', 'tscollection');
```

Purpose	Set or query axes data aspect ratio
Syntax	<pre>daspect daspect([aspect_ratio]) daspect('mode') daspect('auto') daspect('manual') daspect(axes_handle,...)</pre>
Description	<p>The data aspect ratio determines the relative scaling of the data units along the x-, y-, and z-axes.</p> <p><code>daspect</code> with no arguments returns the data aspect ratio of the current axes.</p> <p><code>daspect([aspect_ratio])</code> sets the data aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the x-, y-, and z-axis scaling (e.g., <code>[1 1 3]</code> means one unit in x is equal in length to one unit in y and three units in z).</p> <p><code>daspect('mode')</code> returns the current value of the data aspect ratio mode, which can be either <code>auto</code> (the default) or <code>manual</code>. See Tips.</p> <p><code>daspect('auto')</code> sets the data aspect ratio mode to <code>auto</code>.</p> <p><code>daspect('manual')</code> sets the data aspect ratio mode to <code>manual</code>.</p> <p><code>daspect(axes_handle,...)</code> performs the set or query on the axes identified by the first argument, <code>axes_handle</code>. When you do not specify an axes handle, <code>daspect</code> operates on the current axes.</p>
Tips	<p><code>daspect</code> sets or queries values of the axes object <code>DataAspectRatio</code> and <code>DataAspectRatioMode</code> properties.</p> <p>When the data aspect ratio mode is <code>auto</code>, the data aspect ratio adjusts so that each axis spans the space available in the figure window. If you are displaying a representation of a real-life object, you should set the data aspect ratio to <code>[1 1 1]</code> to produce the correct proportions.</p>

Setting a value for data aspect ratio or setting the data aspect ratio mode to manual disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the data aspect ratio to a value, including its current value,

```
daspect(daspect)
```

can cause a change in the way the graphs look. See the Stretch-to-Fill section of the axes description for more information.

Examples

Equal Scaling Along Each Axis

Plot the function $z = xe^{(-x^2-y^2)}$ over the range $-2 \leq x \leq 2$ and $-2 \leq y \leq 2$.

```
[x,y] = meshgrid(-2:.2:2);  
z = x.*exp(-x.^2 - y.^2);
```

```
figure  
surf(x,y,z)
```

Query the data aspect ratio to show the axis scaling.

```
daspect
```

```
ans =
```

```
    4    4    1
```

daspect

Use equal scaling along each axis by setting the data aspect ratio to `[1,1,1]`.

```
daspect([1,1,1])
```

datacursormode

Purpose Enable, disable, and manage interactive data cursor mode

Syntax

```
datacursormode on
datacursormode off
datacursormode
datacursormode toggle
datacursormode(figure_handle)
dcm_obj = datacursormode(figure_handle)
```

Description

`datacursormode on` enables data cursor mode on the current figure.

`datacursormode off` disables data cursor mode on the current figure.

`datacursormode` or `datacursormode toggle` toggles data cursor mode in the current figure.

`datacursormode(figure_handle)` enables or disables data cursor mode on the specified figure.

`dcm_obj = datacursormode(figure_handle)` returns the data cursor mode object for the figure. The object enables you to customize the data cursor. For more information on data cursor mode objects, see “Output Arguments” on page 1-1511. You cannot change the state of data cursor mode in a call to `datacursormode` that returns a mode object.

A *data cursor* is a small black square with a white border that you interactively position on a graph in data cursor mode. When you click a graphic object such as a line on a graph, a *data tip* appears. Data tips are small text boxes or windows that float within an axes that display data values at data cursor locations. The default style is a text box. Data tips list *x*-, *y*- and (where appropriate) *z*-values for one data point at a time. See “Examples” on page 1-1515 for an illustration of these two styles.

- Tips**
- Most types of graphs and 3-D plots support data cursor mode, but several do not (pareto, for example).
 - Polar plots support data tips, but display Cartesian rather than polar coordinates on them.

- Histograms created with `hist display` specialized data tips that itemize the observation counts, lower and upper limits and center point for histogram bins.
- You place data tips only by clicking data objects on graphs. You cannot place them programmatically (by executing code to position a data cursor).
- When `DisplayStyle` is `datatip`, you can place multiple data tips on a graph. When `DisplayStyle` is `window`, it reports only the most recent data tip.
- `datacursormode off` exits data cursor mode but does not remove displayed data tips. However, if the `DisplayStyle` is `window`, the data tip window goes away.

Input Arguments

figure_handle

Optional handle of figure window

Default: The current figure

state

`'`, `'toggle'`, `'on'`, or `'off'`

Default: `'toggle'`

Output Arguments

dcm_obj

Use the object returned by `datacursormode` to control aspects of data cursor behavior. You can use the `set` and `get` commands to set and query object property values. You can customize how data cursor mode presents information by coding callback functions for these objects.

Parameter Name/Value Pairs for Data Cursor Mode Objects

The following parameters apply to objects returned by calls to `datacursormode`, not to the function itself.

'DisplayStyle'

datatip | window

Determines how the data cursor displays.

- `datatip` displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select.
- `window` displays data cursor information for the data point you interactively select in a floating window within the figure.

Default: `datatip`

'Enable'

on | off

Specifies whether data cursor mode is currently enabled for the figure.

Default: `off`

'Figure'

handle

Handle of the figure associated with the data cursor mode object.

'SnapToDataVertex'

on | off

Specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position.

Default: `on`

'UpdateFcn'

function handle

Reference to a function that formats the text appearing in the data cursor. You can supply your own function to customize data tip display. Your function must include at least two arguments. The first argument is unused, and can be a variable name or tilde (~). The second argument passes the data cursor event object to your update function. The event object encapsulates the state of the data cursor. The following function definition illustrates the update function:

```
function output_txt = myfunction(~,event_obj)
% ~           Currently not used (empty)
% event_obj  Object containing event data structure
% output_txt Data cursor text (string or cell array
%            of strings)
```

event_obj is an object that has the following properties.

Target	Handle of the object the data cursor is referencing (the object which you click, for example, a line or a bar from a series)
Position	An array specifying the x, y (and z for 3-D graphs) coordinates of the cursor

You can query these properties within your function. For example,

```
pos = get(event_obj, 'Position');
```

returns the coordinates of the cursor. Another way of accessing that data is to obtain the struct and query its Position field:

```
eventdata = get(event_obj);
pos = eventdata.Position;
```

You can also obtain the position directly from the object:

```
pos = event_obj.Position;
```

You can redefine the data cursor UpdateFcn at run time. For example:

```
set(dcm_obj, 'UpdateFcn', @myupdatefcn)
```

applies the function `myupdatefcn` to the current data tip or tips. When you set an update function in this way, the function must be on the MATLAB path. If instead you select the data cursor mode context menu item **Select text update function**, you can interactively select a function that is not on the path.

Do not redefine figure window callbacks, such as `ButtonDownFcn`, `KeyPressFcn`, or `CloseRequestFcn` while in data cursor mode. If you attempt to change any *figure* callbacks when you are in an interactive mode, you receive a warning and the attempt fails. MATLAB interactive modes are:

- brush
- datacursormode
- pan
- rotate3d
- zoom

This restriction does not apply to changing the figure `WindowButtonMotionFcn` callback or `uicontrol` callbacks.

Querying Data Cursor Mode

Use the `getCursorInfo` function to query the data cursor mode object (`dcm_obj` in the update function syntax) to obtain information about the data cursor. For example,

```
info_struct = getCursorInfo(dcm_obj);
```

returns a vector of structures, one for each data cursor on the graph. Each structure has the following fields.

Target	The handle of the graphics object containing the data point
Position	An array specifying the x , y , (and z) coordinates of the cursor

Line and lineseries objects have an additional field.

DataIndex	A scalar index into the data arrays that correspond to the nearest data point. The value is the same for each array.
-----------	--

See “Output Arguments” on page 1-1511 for more details on data cursor mode objects.

Examples

This example creates a plot and enables data cursor mode from the command line.

```
surf(peaks)
datacursormode on
% Click mouse on surface to display data cursor
```

Selecting a point on the surface opens a data tip displaying its x -, y -, and z -coordinates.

datacursormode

You change the data tip display style to be a window instead of a text box using the **Tools > Options > Display cursor in window**, or use the context menu **Display Style > Window inside figure** to view the data tip in a floating window that you can move around inside the axes.

You can position multiple text box data tips on the same graph, the window style of data tip displays only one value at a time. For more information on interacting with data cursors, including point selection options and exporting data tips to the workspace, see “Data Cursor — Displaying Data Values Interactively”.

This example enables data cursor mode on the current figure and sets data cursor mode options. The following statements

- Create a graph
- Toggle data cursor mode to on
- Obtain the data cursor mode object, specify data tip options, and get the handle of the line the data tip occupies:

```
fig = figure;
z = peaks;
plot(z(:,30:35))
```

datacursormode

```
dcm_obj = datacursormode(fig);  
set(dcm_obj, 'DisplayStyle', 'datatip', ...  
    'SnapToDataVertex', 'off', 'Enable', 'on')  
  
disp('Click line to display a data tip, then press Return.')  
% Wait while the user does this.  
pause  
  
c_info = getCursorInfo(dcm_obj);  
% Make selected line wider  
set(c_info.Target, 'LineWidth', 2)
```

This example shows you how to customize the text that the data cursor displays. For example, you can replace the text displayed in the data tip and data window (x: and y:) with Time: and Amplitude: by creating a simple update function.

Save the following functions in your current directory or any writable directory on the MATLAB path before running them. As they are functions, you cannot highlight them and then evaluate the selection to make them work.

Save this code as `doc_datacursormode.m`:

```
function doc_datacursormode
% Plots graph and sets up a custom data tip update function
fig = figure;
a = -16; t = 0:60;
plot(t,sin(a*t))
dcm_obj = datacursormode(fig);
set(dcm_obj, 'UpdateFcn', @myupdatefcn)
```

Save the following code as `myupdatefcn.m` on the MATLAB path:

```
function txt = myupdatefcn(empty,event_obj)
% Customizes text of data tips

pos = get(event_obj, 'Position');
txt = {['Time: ', num2str(pos(1))], ...
      ['Amplitude: ', num2str(pos(2))]};
```

To set up and use the update function, type:

```
doc_datacursormode
```

When you place a data tip using this update function, it looks like the one in the following figure.

Alternatives

Use the Data Cursor tool  to label x , y , and z values on graphs and surfaces. You can control how data tips display by right-clicking and selecting items from the context menu.

datacursormode

Tutorials

- “Data Cursor — Displaying Data Values Interactively”

How To

- “Example — Visually Exploring Demographic Statistics”
- “Data Cursors with Histograms”

Purpose Produce short description of input variable

Syntax `datatipinfo(var)`

Description `datatipinfo(var)` displays a short description of a variable, similar to what is displayed in a `datatip` in the MATLAB debugger.

Examples Get `datatip` information for a 5-by-5 matrix:

```
A = rand(5);
```

```
datatipinfo(A)
```

```
A: 5x5 double =  
    0.4445    0.3567    0.7458    0.0767    0.4400  
    0.7962    0.6575    0.3918    0.8289    0.9746  
    0.5641    0.9808    0.0265    0.4838    0.6722  
    0.9099    0.9653    0.2508    0.4859    0.4054  
    0.2857    0.5198    0.7383    0.9301    0.9604
```

Get `datatip` information for a 50-by-50 matrix. For this larger matrix, `datatipinfo` displays just the size and data type:

```
A = rand(50);
```

```
datatipinfo(A)
```

```
A: 50x50 double
```

Also for multidimensional matrices, `datatipinfo` displays just the size and data type:

```
A = rand(5);
```

```
A(:,:,2) = A(:,:,1);
```

```
datatipinfo(A)
```

```
A: 5x5x2 double
```

date

Purpose Current date string

Syntax `str = date`

Description `str = date` returns a string containing the date in dd-mmm-yyyy format.

See Also `clock` | `datestr` | `datenum` | `now`

Purpose

Convert date and time to serial date number

Syntax

```
DateNumber = datenum(DateString)
DateNumber = datenum(DateString,formatIn)
DateNumber = datenum(DateString,PivotYear)
DateNumber = datenum(DateString,formatIn,PivotYear)
```

```
DateNumber = datenum(DateVector)
DateNumber = datenum(Y,M,D)
DateNumber = datenum(Y,M,D,H,MN,S)
```

Description

`DateNumber = datenum(DateString)` converts date strings to serial date numbers. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`DateNumber = datenum(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateNumber = datenum(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateNumber = datenum(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

`DateNumber = datenum(DateVector)` converts date vectors to serial date numbers, and returns a column vector of `m` date numbers, where `m` is the total number of date vectors in `DateVector`.

`DateNumber = datetime(Y,M,D)` returns the serial date numbers for corresponding elements of the Y, M, and D (year, month, day) arrays. The arrays must be of the same size (or any can be a scalar). You can also specify the input arguments as a date vector, [Y,M,D].

`DateNumber = datetime(Y,M,D,H,MN,S)` additionally returns the serial date numbers for corresponding elements of the H, MN, and S (hour, minute, and second) arrays. The arrays must be of the same size (or any can be a scalar). You can also specify the input arguments as a date vector, [Y,M,D,H,MN,S].

Input Arguments

DateVector - Date vectors

matrix

Date vectors, specified as an *m*-by-6 or *m*-by-3 matrix containing *m* full or partial date vectors, respectively. A full date vector has six elements, specifying year, month, day, hour, minute, and second, in that order. A partial date vector has three elements, specifying year, month, and day, in that order. Each element of `DateVector` should be a positive or negative integer value with the exception of the seconds element, which can be fractional. If an element falls outside the conventional range, MATLAB adjusts both that date vector element and the previous element. For example, if the minutes element is 70, MATLAB adjusts the hours element by 1 and sets the minutes element to 10. If the minutes element is -15, then MATLAB decreases the hours element by 1 and sets the minutes element to 45. Month values are an exception. MATLAB sets month values less than 1 to 1.

Example: [2003,10,24,12,45,07]

Data Types

double

DateString - Date strings

string | character array | 1-D cell array of strings

Date strings, specified as a character array where each row corresponds to one date string, or as a one dimensional cell array of strings. All of the date strings must have the same format.

Example: '24 Oct-2003 12:45:07'

Example: ['19-Sep-2013'; '20-Sep-2013'; '21-Sep-2013']

Example: {'15-Oct-2010' '20-Nov-2012'}

If the date string format is known, you should also specify `formatIn`. If you do not specify `formatIn`, `DateString` must be in one of the following formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years

default to the current year. MATLAB considers two-character date string years (e.g., '79') to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (mm), the month value must not be greater than 12.
- However, for the format 'mm/dd/yy', if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, MATLAB considers the date string to be in 'yy/mm/dd' format.

formatIn - Format of the input date string

string

Format of the input date string, specified as a string of symbolic identifiers.

Example: 'dddd, mmm dd, yyyy'

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

Symbolic Identifier	Description	Example
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12

Symbolic Identifier	Description	Example
m	Month using capitalized first letter	M, D
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20
d	Day using capitalized first letter	M, T
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The formatIn string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use 'yy-mmm-dd-m' because it has two month identifiers. The one exception to this is that you can combine one instance of dd with one instance of any of the other day identifiers. For example, 'dddd mmm dd yyyy' is a valid input.
- When you use AM or PM, the HH field is also required.
- You only can use QQ alone or with a year specifier.

PivotYear - Start year of 100-year date range

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If `formatIn` contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: 2000

Data Types

double

Y,M,D - Year, month, and day arrays

scalar | vector | matrix | array

Year, month, and day arrays specified as a scalar, vector, matrix or array. These must be the same size, or any one can be a scalar. Y,M,D should be integer values.

If Y,M,D are all scalars or all column vectors, you can specify the input arguments as a date vector, [Y,M,D].

Example: 2003,10,24

Data Types

double

Y,M,D,H,MN,S - Year, month, day, hour, minute and second arrays

scalar | vector | matrix | array

Year, month, day, hour, minute and second arrays specified as a scalar, vector, matrix or array. These must be the same size, or any one can be a scalar. `datenum` does not accept milliseconds as a separate input, but as a fractional part of the seconds input, S. Y,M,D,H,MN should be integer values.

If Y,M,D,H,MN,S are all scalars or all column vectors, you can specify the input arguments as a date vector[Y,M,D,H,MN,S].

Example: 2003,10,24,12,45,07.451

Data Types

double

Output Arguments**DateNumber - Serial date numbers**

scalar | vector

Serial date numbers, returned as a column vector of length m , where m is the total number of input date vectors or date strings.

Tips

- To create arbitrarily shaped output, use `thedatenum(Y,M,D)` and `datenum(Y,M,D,H,MN,S)` syntaxes. The `datenum(DateVector)` syntax creates only a column vector of date numbers.

```
datenum(2013,[1 3; 2 4],ones(2,2))
```

```
ans =
```

```
    735235    735294
    735266    735325
```

Examples**Convert Date String to Date Number**

```
DateString = '19-May-2001';
formatIn = 'dd-mmm-yyyy';
datenum(DateString,formatIn)
```

```
ans =
```

```
    730990
```

`datenum` returns a date number for the date string with the format 'dd-mmm-yyyy'.

Convert Multiple Date Strings to Date Numbers

Pass multiple date strings in a cell array. All input date strings must use the same format.

datenum

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};  
formatIn = 'mm/dd/yyyy';  
datenum(DateString,formatIn)
```

```
ans =
```

```
733301  
729159  
734471
```

Convert Date String to Date Number Using Pivot Year

Convert a date string to a serial date number using the default pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy')
```

```
n =
```

```
736858
```

The corresponding date string to this date number is 12-Jun-2017.

Convert the same date string to a serial date number using 1400 as the pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy',1400)
```

```
n =
```

```
517712
```

The corresponding date string to this date number is 12-Jun-1417.

Convert Date Vector to Date Number

```
datenum([2009,4,2,11,7,18])
```

```
ans =
```

```
7.3387e+05
```

Convert Year, Month, and Day to Date Number

Convert a date specified by year, month and day values to a serial date number.

```
n = datenum(2001,12,19)
```

```
n =
```

```
731204
```

[datestr](#) | [datevec](#)

Concepts

- “Represent Dates and Times in MATLAB”
- “Carryover in Date Vectors and Strings”

datestr

Purpose Convert date and time to string format

Syntax

```
DateString = datestr(DateVector)
DateString = datestr(DateNumber)

DateString = datestr(___,formatOut)

DateString = datestr(DateStringIn)
DateString = datestr(DateStringIn,formatOut,PivotYear)

DateString = datestr(___, 'local')
```

Description `DateString = datestr(DateVector)` converts date vectors to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date vectors in `DateVector`. `datestr` returns date strings in the default date string format `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second). By default, if `HH:MM:SS = 00:00:00` then the date string returned has the format `dd-mmm-yyyy`.

`DateString = datestr(DateNumber)` converts serial date numbers to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date numbers in `DateNumber`.

`DateString = datestr(___,formatOut)` specifies the format of the output date strings using `formatOut`. You can use `formatOut` with any of the input arguments in the above syntaxes.

`DateString = datestr(DateStringIn)` converts `DateStringIn` to date strings in the default date string format `dd-mmm-yyyy HH:MM:SS`. All date strings in `DateStringIn` must have the same format.

`DateString = datestr(DateStringIn,formatOut,PivotYear)` converts `DateStringIn` to `DateString`, in the format specified by `formatOut`, and using optional `PivotYear` to interpret date strings that specify the year as two characters.

`DateString = datestr(___, 'local')` returns the date string in the language of the current locale. This is the language you select by means of your computer's operating system. If you leave `local` out of the argument list, `datestr` returns the date string in the default language, which is US English. Use `local` with any of the previous syntaxes. The `local` argument must be last in the argument sequence.

Input Arguments

DateVector - Date vectors

matrix

Date vectors, specified as an `m`-by-6 matrix, where `m` is the number of full (six-element) date vectors. Each element of `DateVector` should be a positive or negative integer value with the exception of the seconds element, which can be fractional. If an element falls outside the conventional range, MATLAB adjusts both that date vector element and the previous element. For example, if the minutes element is 70, MATLAB adjusts the hours element by 1 and sets the minutes element to 10. If the minutes element is -15, then MATLAB decreases the hours element by 1 and sets the minutes element to 45. Month values are an exception. MATLAB sets month values less than 1 to 1.

Example: `[2003,10,24,12,45,07]`

Data Types

double

DateNumber - Serial date numbers

scalar | vector | matrix | array

Serial date numbers, specified as a scalar, vector, matrix, or array of positive double-precision numbers.

Example: `731878`

Data Types

double

formatOut - Format of the date string output

-1 (default) | string | integer

datestr

Format of the date string output, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format. If you do not specify `formatOut`, `datestr` returns a date string in the default date string format `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second). By default, if `HH:MM:SS = 00:00:00` then the date string returned has the format `dd-mmm-yyyy`.

The following table shows symbolic identifiers you can use to construct the `formatOut` string. You can include characters such as a hyphen, space, or colon to separate the fields.

Symbolic Identifier	Description	Example
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12
m	Month using capitalized first letter	M, D
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20
d	Day using capitalized first letter	M, T

Symbolic Identifier	Description	Example
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The formatOut string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use 'yy-mmm-dd-m' because it has two month identifiers. The one exception to this is that you can combine one instance of dd with one instance of any of the other day identifiers. For example, 'dddd mmm dd yyyy' is a valid input.
- When you use AM or PM, the HH field is also required.
- You only can use QQ alone or with a year specifier.

The following table lists predefined MATLAB date formats.

Numeric Identifier	Date String Format	Example
-1 (default)	'dd-mmm-yyyy HH:MM:SS' or 'dd-mmm-yyyy' if 'HH:MM:SS' = 00:00:00	01-Mar-2000 15:45:17 or 01-Mar-2000
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000

datestr

Numeric Identifier	Date String Format	Example
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd,yyyy'	Mar.01,2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01

Numeric Identifier	Date String Format	Example
26	'yyyymmdd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000
29	'yyyy-mm-dd' (ISO 8601)	2000-03-01
30	'yyyymmddTHHMMSS' (ISO 8601)	20000301T154517
31	'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17

DateStringIn - Date strings to convert

string | cell array

Date strings to convert, specified as a single string or a cell array of strings, where each row corresponds to one date string.

MATLAB considers two-character date string years (for example, '79') to fall within the 100-year range centered around the current year.

All date strings must have the same date format, and they must be in one of the following MATLAB date formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000

Date String Format	Example
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Note When converting from one date string format to another, you should first pass the strings to the `datenum` function, so that you can specify the format of the input date strings. This ensures that the format of the input date strings is correctly interpreted. For example, see “Convert Date String from Custom Format” on page 1-1541.

PivotYear - Start year of 100-year date range

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If `formatIn` contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: 2000

Data Types

double

Output Arguments

DateString - Date strings

string | two-dimensional character array

Date strings, returned as a character array with *m* rows, where *m* is the total number of input date vectors, serial date numbers, or date strings. The default output date string format is `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second) unless the hours, minutes and seconds are all 0 in which case `HH:MM:SS` is suppressed.

Tips

- To convert a date string not in a predefined MATLAB date format, first convert the date string to a date number, using either `datenum` or `datevec`.

Examples

Convert Date Vector to Date String

```
DateVector = [2009,4,2,11,7,18];
```

```
datestr(DateVector)
```

```
ans =
```

```
02-Apr-2009 11:07:18
```

`datestr` returns a date string in the default date string format.

Convert Date and Time to Specific Format

Format the current date in the `mm/dd/yy` format.

You can specify this format using a string of symbolic identifiers.

```
formatOut = 'mm/dd/yy';  
datestr(now,formatOut)
```

```
ans =
```

datestr

```
01/17/14
```

Alternatively, you can specify this format using a numeric identifier.

```
formatOut = 2;  
datestr(now,formatOut)
```

```
ans =
```

```
01/17/14
```

You can reformat the date and time, and also show milliseconds.

```
dt = datestr(now,'mmm dd, yyyy HH:MM:SS.FFF AM')
```

```
dt =
```

```
January 17, 2014 3:51:01.740 PM
```

Convert 12-Hour Time String to 24-Hour Equivalent

Convert the 12-hour time 05:32 p.m. to its 24-hour equivalent.

```
datestr('05:32 PM','HH:MM')
```

```
ans =
```

```
17:32
```

Convert the 24-hour time 05:32 to its 12-hour equivalent.

```
datestr('05:32','HH:MM PM')
```

```
ans =
```

```
5:32 AM
```

The use of AM or PM in the `formatOut` string does not influence which characters actually become part of the date string; they only determine whether or not to include them in the date string. MATLAB® selects AM or PM based on the time entered.

Convert Date String from Custom Format

Call `datenum` inside of `datestr` to specify the format of the input date string.

```
formatOut = 'dd mmm yyyy';  
datestr(datenum('16-04-55','dd-mm-yy',1900),formatOut)
```

```
ans =
```

```
16 Apr 1955
```

Convert Multiple Date Strings

Convert more than one date string input by passing the multiple date strings in a cell array.

All input date strings must use the same format. For example, the following command passes three dates that all use the `mm/dd/yyyy` format.

```
datestr(datenum({'09/16/2007';'05/14/1996';'11/29/2010'}), ...  
        'mm/dd/yyyy')
```

```
ans =
```

```
16-Sep-2007  
14-May-1996  
29-Nov-2010
```

`datestr` returns a character array of converted date strings in the default date string format.

Convert Date String with Values Outside Normal Range

Call `datenum` inside of `datestr` to return the expected value, because the date below uses a value outside its normal range (`month=13`).

```
datestr(datenum('13/24/88','mm/dd/yy'))
```

```
ans =
```

```
24-Jan-1989
```

Use a Pivot Year

Change the pivot year to change the year range.

Use a pivot year of 1900.

```
DateStringIn = '4/16/55';  
formatOut = 1;  
PivotYear = 1900;  
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =
```

```
16-Apr-1955
```

For the same date string, use a pivot year of 2000.

```
PivotYear = 2000;  
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =
```

```
16-Apr-2055
```

Return Date String in Local Language

Convert a date number to a date string in the language of the current locale.

Use the `local` argument in a French locale.

```
DateNumber = 725935;  
formatOut = 'mmm-dd-yyyy';  
str = datestr(DateNumber,formatOut,'local')
```

```
str =  
Juillet-17-1987
```

You can make the same call without specifying `'local'`.

```
str = datestr(DateNumber,formatOut)
```

```
str =  
July-17-1987
```

In this case, the output defaults to the English language.

datestr

Purpose

Date formatted tick labels

Syntax

```
datetick(tickaxis)  
datetick(tickaxis,dateFormat)
```

```
datetick( __ , 'keeplimits')
```

```
datetick( __ , 'keepticks')
```

```
datetick(axes_handle, __ )
```

Description

`datetick(tickaxis)` labels the tick lines of the axis specified by `tickaxis` using dates, replacing the default numeric labels. `datetick` selects a label format based on the minimum and maximum limits of the specified axis. The axis data values should be serial date numbers, as returned by the `datenum` function.

`datetick(tickaxis,dateFormat)` formats the labels according to the string `dateFormat`.

`datetick(__ , 'keeplimits')` changes the tick labels to date-based labels while preserving the axis limits. Append `'keeplimits'` to any of the previous syntaxes.

`datetick(__ , 'keepticks')` changes the tick labels to date-based labels while preserving their locations. Append `'keepticks'` to any of the previous syntaxes.

`datetick(axes_handle, __)` labels the tick lines of an axis on the axes specified by `axes_handle`. The `axes_handle` argument can precede any of the input argument combinations in the previous syntaxes.

datetick

Input Arguments

tickaxis - Axis to label

'x' (default) | 'y' | 'z'

Axis to label with dates, specified as 'x', 'y', or 'z'.

dateFormat - Format of tick line labels

string | integer

Format of the tick line labels, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format.

The following table shows symbolic identifiers you can use to construct the `dateFormat` string. You can include characters such as a hyphen, space, or colon to separate the fields. For example, to display the day of the month followed by the three-letter abbreviation of the day of the week in parentheses, use `dateFormat = 'dd (ddd)'`.

Symbolic Identifier	Description	Example
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12
m	Month using capitalized first letter	M, D
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20

Symbolic Identifier	Description	Example
d	Day using capitalized first letter	M, T
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The following table lists predefined MATLAB date formats.

Numeric Identifier	Date String Format	Example
-1 (default)	'dd-mmm-yyyy HH:MM:SS' or 'dd-mmm-yyyy' if 'HH:MM:SS' = 00:00:00	01-Mar-2000 15:45:17 or 01-Mar-2000
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01

Numeric Identifier	Date String Format	Example
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd,yyyy'	Mar.01,2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmyyyy'	Mar2000
29	'yyyy-mm-dd' (ISO 8601)	2000-03-01

Numeric Identifier	Date String Format	Example
30	'yyymmddTHMMSS' (ISO 8601)	20000301T154517
31	'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17

Examples

Label x-Axis Ticks with 2-digit Years

Graph population data for the 20th Century taken from the 1990 US census and label x -axis ticks with 2-digit years.

Create time data by decade.

```
t = (1900:10:1990)';
```

Enter total population counts for the USA.

```
p = [75.995 91.972 105.711 123.203 131.669 ...  
150.697 179.323 203.212 226.505 249.633]';
```

Convert years to serial date numbers using the `datenum` function, and then plot the data.

```
figure  
plot(datenum(t,1,1),p)  
grid on
```

datetick

Replace *x*-axis ticks with 2-digit years. The numeric identifier 11 corresponds to the predefined MATLAB® date format 'yy'.

```
dateFormat = 11;  
datetick('x',dateFormat)
```

Label x-Axis Ticks with Hours of the Day

Plot traffic count data against date ticks for hours of the day showing AM and PM.

Get traffic count data.

```
load count.dat
```

Create arrays for an arbitrary date, for example, April 18, 1995.

```
n = length(count);  
year = 1990 * ones(1,n);  
month = 4 * ones(1,n);  
day = 18 * ones(1,n);
```

Create arrays for each of 24 hours.

```
hour = 1:n;  
minutes = zeros(1,n);
```

Get the serial date numbers for the date arrays.

```
xdate = datenum(year,month,day,hour,minutes,minutes);
```

Plot the traffic data against the serial date numbers.

```
figure  
plot(xdate,count)
```

Label the tick lines of the graph's x-axis with the hours of the day.

```
datetick('x','HHPM')
```

Label x-Axis and Preserve Axis Limits

Select a starting date.

```
startDate = datenum('02-01-1962');
```

Select an ending date.

```
endDate = datenum('11-15-2012');
```

Create a variable, `xdata`, that corresponds to the number of years between the start and end dates.

```
xData = linspace(startDate, endDate, 50);
```

Plot random data.

```
figure  
plot(xData, rand(1, 50))
```

datetick

Label the x -axis with 4-digit years, preserving the x -axis limits by using the 'keeplimits' option.

```
datetick('x','yyyy','keeplimits')
```

Add Month Labels to Plot and Preserve Number of Ticks

Select a starting date.

```
startDate = datenum('01-01-2009');
```

Select an ending date.

```
endDate = datenum('12-31-2009');
```

Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate,endDate,12);
```

Plot random data.

```
figure  
plot(xData,rand(1,12))
```

datetick

Set the number of XTicks to the number of points in xData.

```
set(gca, 'XTick', xData)
```

Label the *x*-axis with month names, preserving the total number of ticks by using the 'keepticks' option.

```
datetick('x','mmm','keepticks')
```

Create Multiple Plots Within Figure and Label Axis with Month Names

Select a starting date and an ending date.

```
startDate = datenum('01-01-2009');  
endDate = datenum('12-31-2009');
```

Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate,endDate,12);
```

Plot random data.

```
figure  
s(1)=subplot(2,1,1);  
plot(xData,rand(1,12))  
s(2) = subplot(2,1,2);  
plot(xData,rand(1,12))
```

datetick

Set the number of `XTicks` to the number of points in `xData`. Label the `x`-axis of each subplot with month names, referring to each subplot using its axes handle. Preserve the total number of ticks by using the `'keepticks'` option.

```
set(s,'XTick',xData)
for i = 1:2
    datetick(s(i),'x','mmm','keepticks')
end
```

Algorithms

`datetick` calls the `datestr` function to convert date numbers to date strings.

Tips

- To change the tick spacing and locations, set the appropriate axes property (i.e., `XTick`, `YTick`, or `ZTick`) before calling `datetick`.
- Calling `datetick` sets the `TickMode` of the specified axis to `'manual'`. This means that after zooming, panning or otherwise changing axis limits, you should call `datetick` again to update the ticks and labels.

`XTick` | `YTick` | `ZTick` | `datenum` | `datestr`

datevec

Purpose Convert date and time to vector of components

Syntax `DateVector = datevec(DateNumber)`

`DateVector = datevec(DateString)`

`DateVector = datevec(DateString,formatIn)`

`DateVector = datevec(DateString,PivotYear)`

`DateVector = datevec(DateString,formatIn,PivotYear)`

`[Y, M, D, H, MN, S] = datevec(___)`

Description

`DateVector = datevec(DateNumber)` converts one or more date numbers to date vectors. `datevec` returns an *m*-by-6 matrix containing *m* date vectors, where *m* is the total number of date numbers in `DateNumber`.

`DateVector = datevec(DateString)` converts date strings to date vectors. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateVector = datevec(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

[Y, M, D, H, MN, S] = datevec(___) returns the components of the date vector as individual variables Y, M, D, H, MN, and S (year, month, day, hour, minutes and seconds). datevec returns milliseconds as a fractional part of the seconds (S) output.

Input Arguments

DateNumber - Serial date number

scalar | vector | multidimensional array

Serial date number, specified as a scalar, vector, or multidimensional array of positive double-precision numbers.

Example: 731878

Data Types

double

DateString - Date strings

string | character array | 1-D cell array of strings

Date strings, specified as a character array where each row corresponds to one date string, or as a one dimensional cell array of strings. All of the date strings must have the same format.

Example: '24 Oct-2003 12:45:07'

Example: ['19-Sep-2013'; '20-Sep-2013'; '21-Sep-2013']

Example: {'15-Oct-2010' '20-Nov-2012'}

If the date string format is known, you should also specify formatIn. If you do not specify formatIn, DateString must be in one of the following formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00

Date String Format	Example
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. MATLAB considers two-character date string years (e.g., '79') to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (mm), the month value must not be greater than 12.
- However, for the format 'mm/dd/yy', if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, MATLAB considers the date string to be in 'yy/mm/dd' format.

formatIn - Format of the input date string

string

Format of the input date string, specified as a string of symbolic identifiers.

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

Symbolic Identifier	Description	Example
yyyy	Year in full	1990, 2002
yy	Year in two digits	90, 02
QQ	Quarter year using letter Q and one digit	Q1
mmmm	Month using full name	March, December
mmm	Month using first three letters	Mar, Dec
mm	Month in two digits	03, 12
m	Month using capitalized first letter	M, D
dddd	Day using full name	Monday, Tuesday
ddd	Day using first three letters	Mon, Tue
dd	Day in two digits	05, 20
d	Day using capitalized first letter	M, T
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59

Symbolic Identifier	Description	Example
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The formatIn string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use 'yy-mmm-dd-m' because it has two month identifiers. The one exception to this is that you can combine one instance of dd with one instance of any of the other day identifiers. For example, 'dddd mmm dd yyyy' is a valid input.
- When you use AM or PM, the HH field is also required.
- datevec does not accept formats that include 'QQ'

PivotYear - Start year of 100-year date range

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If formatIn contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: 2000

Data Types

double

Output Arguments

DateVector - Date vectors

vector | matrix

Date vectors, returned as an m-by-6 matrix, where each row corresponds to one date vector, and m is the total number of input date numbers or date strings.

[Y, M, D, H, MN, S] - Components of the date vector

scalar

Components of the date vector (year, month, day, hour, minute, and second), returned as individual scalar variables. Milliseconds are a fractional part of the seconds output.

Examples**Convert Date Number to Date Vector**

```
format short g
```

```
n = 733779.651;  
datevec(n)
```

```
ans =
```

```
      2009           1           6           15           37
```

Convert Date String to Date Vector

```
DateString = '28.03.2005';  
formatIn = 'dd.mm.yyyy';  
datevec(DateString,formatIn)
```

```
ans =
```

```
      2005           3           28           0           0
```

datevec returns a date vector for the date string with the format 'dd.mm.yyyy'.

Convert Multiple Date Strings to Date Vectors

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};  
formatIn = 'mm/dd/yyyy';  
datevec(DateString,formatIn)
```

```
ans =
```

```
    2007         9        16         0         0         0  
    1996         5        14         0         0         0  
    2010        11        29         0         0         0
```

Convert Date with Milliseconds to Date Vector

```
datevec('11:21:02.647','HH:MM:SS.FFF')
```

```
ans =
```

```
1.0e+03 *  
    2.0140    0.0010    0.0010    0.0110    0.0210    0.0026
```

In the output date vector, milliseconds are a fractional part of the seconds field. The date string '11:21:02.647' does not contain enough information to convert to a full date vector. The days default to 1, months default to January, and years default to the current year.

Convert Date String to Date Vector Using Pivot Year

Convert a date string to a date vector using the default pivot year.

```
DateString = '12-jun-17';  
formatIn = 'dd-mmm-yy';  
DateVector = datevec(DateString,formatIn)
```

```
DateVector =  
  
          2017          6          12          0          0
```

Convert the same date string to a date vector using 1800 as the pivot year.

```
DateVector = datevec(DateString,formatIn,1800)
```

```
DateVector =  
  
          1817          6          12          0          0
```

Assign Elements of Returned Date Vector

Convert a date string to a date vector and return the components of the date vector.

```
[y, m, d, h, mn, s] = datevec('01.02.12','dd.mm.yy')
```

```
y =  
  
          2012
```

```
m =  
  
          2
```

datevec

d =

1

h =

0

mn =

0

s =

0

Limitations

- When computing date vectors, MATLAB sets month values less than 1 to 1. Day values, D, less than 1 are set to the last day of the previous month minus $|D|$. However, if $0 \leq \text{DateNumber} < 1$, then `datevec(DateNumber)` returns a date vector of the form `[0 0 0 H MN S]`, where H, MN, and S are hours, minutes, and seconds, respectively.

Tips

- The vectorized calling syntax can offer significant performance improvement for large arrays.

`datenum` | `datestr`

Concepts

- “Represent Dates and Times in MATLAB”
- “Carryover in Date Vectors and Strings”

Purpose Clear breakpoints

Syntax

```
dbclear all
dbclear in file ...
dbclear in file ... -completenames
dbclear if error ...
dbclear if warning ...
dbclear if naninf
dbclear if infnan
```

Description `dbclear all` removes all breakpoints in all MATLAB code files, as well as breakpoints set for errors, caught errors, caught error identifiers, warnings, warning identifiers, and `naninf/infnan`.

`dbclear in file ...` and `dbclear in file ... -completenames` formats are listed here:

Format	Action
<code>dbclear in file</code>	Removes all breakpoints in <code>file</code> . <code>file</code> must be the name of a MATLAB program file, and can include a MATLAB partial path.
<code>dbclear in file -completenames</code>	If the command includes the <code>-completenames</code> option, then <code>file</code> need not be on the path, as long as it is a fully qualified file name. (On Microsoft Windows platforms, this is a file name that begins with <code>\\</code> or with a drive letter followed by a colon. On UNIX platforms, this is a file name that begins with <code>/</code> or <code>~</code> .) <code>file</code> can include a <code>></code> to specify the path to a particular local function or to a nested function within a code file.
<code>dbclear in file at lineno</code>	Removes the breakpoint set at line number <code>lineno</code> in <code>file</code> .
<code>dbclear in file at lineno@</code>	Removes the breakpoint set in the anonymous function at line number <code>lineno</code> in <code>file</code> .

dbclear

Format	Action
<code>dbclear in file at lineno@n</code>	Removes the breakpoint set in the nth anonymous function at line number <code>lineno</code> in <code>file</code> .
<code>dbclear in file at locfun</code>	Removes all breakpoints in local function <code>locfun</code> in <code>file</code> .

`dbclear if error ...` formats are listed here:

Format	Action
<code>dbclear if error</code>	Removes the breakpoints set using the <code>dbstop if error</code> and <code>dbstop if error</code> identifier statements.
<code>dbclear if error identifier</code>	Removes the breakpoint set using <code>dbstop if error</code> identifier for the specified identifier. Running this produces an error if <code>dbstop if error</code> or <code>dbstop if error all</code> is set.
<code>dbclear if caught error</code>	Removes the breakpoints set using the <code>dbstop if caught error</code> and <code>dbstop if caught error</code> identifier statements.
<code>dbclear if caught error identifier</code>	Removes the breakpoints set using the <code>dbstop if caught error</code> identifier statement for the specified identifier. Running this produces an error if <code>dbstop if caught error</code> or <code>dbstop if caught error all</code> is set.

`dbclear if warning ...` formats are listed here:

<code>dbclear if warning</code>	Removes the breakpoints set using the <code>dbstop if warning</code> and <code>dbstop if warning</code> identifier statements.
<code>dbclear if warning identifier</code>	Removes the breakpoint set using <code>dbstop if warning</code> identifier for the specified identifier. Running this produces an error if <code>dbstop if warning</code> or <code>dbstop if warning all</code> is set.

`dbclear if naninf` removes the breakpoint set by `dbstop if naninf` or `dbstop if infnan`.

`dbclear if infnan` removes the breakpoint set by `dbstop if infnan` or `dbstop if naninf`.

Tips

The **at** and **in** keywords are optional.

In the syntax, `file` can be a MATLAB program file, or the path to a function within a file. For example

```
dbclear in foo>myfun
```

clears the breakpoint at the `myfun` function in the file `foo.m`.

dbcont

Purpose Resume execution

Syntax dbcont

Description dbcont resumes execution of a MATLAB code file from a breakpoint. Execution continues until another breakpoint is encountered, a pause condition is met, an error occurs, or MATLAB software returns to the base workspace prompt.

Note If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

dblquad

Purpose

Numerically evaluate double integral over rectangle

dblquad will be removed in a future release. Use `integral2` instead.

Syntax

```
q = dblquad(fun,xmin,xmax,ymin,ymax)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)
```

Description

`q = dblquad(fun,xmin,xmax,ymin,ymax)` calls the `quad` function to evaluate the double integral $\text{fun}(x,y)$ over the rectangle $x_{\min} \leq x \leq x_{\max}$, $y_{\min} \leq y \leq y_{\max}$. The input argument, `fun`, is a function handle that accepts a vector `x`, a scalar `y`, and returns a vector of integrand values.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol)` uses a tolerance `tol` instead of the default, which is `1.0e-6`.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quad1` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quad1`.

Examples

Pass function handle `@integrnd` to `dblquad`:

```
Q = dblquad(@integrnd,pi,2*pi,0,pi);
```

where the function `integrnd.m` is:

```
function z = integrnd(x, y)
z = y*sin(x)+x*cos(y);
```

Pass anonymous function handle `F` to `dblquad`:

```
F = @(x,y)y*sin(x)+x*cos(y);
Q = dblquad(F,pi,2*pi,0,pi);
```

The `integrnd` function integrates $y \sin(x) + x \cos(y)$ over the square $\pi \leq x \leq 2\pi$, $0 \leq y \leq \pi$. Note that the integrand can be evaluated with a vector x and a scalar y .

Nonsquare regions can be handled by setting the integrand to zero outside of the region. For example, the volume of a hemisphere is:

```
dblquad(@(x,y) sqrt(max(1-(x.^2+y.^2),0)), -1, 1, -1, 1)
```

or

```
dblquad(@(x,y) sqrt(1-(x.^2+y.^2)).*(x.^2+y.^2<=1), -1, 1, -1, 1)
```

How To

- “Anonymous Functions”

dbmex

Purpose Enable MEX-file debugging (on UNIX platforms)

Syntax
dbmex **on**
dbmex **off**
dbmex **stop**

Description dbmex **on** enables MEX-file debugging for UNIX platforms.

To use this option, first start the MATLAB software from a debugger by typing `matlab -Ddebugger`, where `debugger` is the name of the debugger program. You must invoke `dbmex on` before calling your MEX-file. If you have already loaded the MEX-file, remove it from memory using the `clear` function.

dbmex **off** disables MEX-file debugging.

dbmex **stop** returns to the debugger prompt.

Tips For more information about debugging MEX-files, see “Debug C/C++ Language MEX-Files”.

See Also `dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbstop` | `dbtype` | `dbup`

Purpose Quit debug mode

Syntax dbquit
dbquit('all')
dbquit all

Description dbquit terminates debug mode. The Command Window then displays the standard prompt (>>). The file being processed is *not* completed and no results are returned. All breakpoints remain in effect, unless your file contains (and MATLAB has processed) one or more of the following commands: clear all, clear function, clear classes.

If you debug file1 and step into file2, running dbquit terminates debugging for both files. However, if you debug file3 and also debug file4, running dbquit terminates debugging for file4, but file3 remains in debug mode until you run dbquit again.

dbquit('all') or the command form, dbquit all, ends debugging for all files at once.

Examples This example illustrates the use of dbquit relative to dbquit('all'). Set breakpoints in and run file1 and file2:

```
>> dbstop in file1
>> dbstop in file2
>> file1
K>> file2
K>> dbstack
```

MATLAB software returns

```
K>> dbstack
   In file1 at 11
   In file2 at 22
```

If you use the dbquit syntax

```
K>> dbquit
```

dbquit

MATLAB ends debugging for `file2` but `file1` is still in debug mode as shown here

```
K>> dbstack
      in file1 at 11
```

Run `dbquit` again to exit debug mode for `file1`.

Alternatively, `dbquit('all')` ends debugging for both files at once:

```
K>> dbstack
      In file1 at 11
      In file2 at 22
dbquit('all')
dbstack
```

returns no result.

Related Examples

- “Correct Problems and End Debugging”

Purpose Function call stack

Syntax

```
dbstack
dbstack(n)
dbstack(' -completenames' )
[ST,I] = dbstack(...)
```

Description dbstack displays the line numbers and file names of the function calls that led to the current breakpoint, listed in the order in which they were executed. The display lists the line number of the most recently executed function call (at which the current breakpoint occurred) first, followed by its calling function, which is followed by its calling function, and so on. This continues until the topmost MATLAB function is reached. Each line number is a hyperlink you can click to go directly to that line in the Editor. The notation `functionname>localfunctionname` is used to describe the location of the local function.

dbstack(n) omits the first n frames from the display. This is useful when issuing a dbstack from within an error handler, for example.

dbstack(' -completenames') outputs the “complete name“ (the absolute file name and the entire sequence of functions that nests the function in the stack frame) of each function in the stack.

Either none, one, or both n and ' -completenames ' can appear. If both appear, the order is irrelevant.

[ST,I] = dbstack(...) returns the stack trace information in an m-by-1 structure, ST, with the fields:

file	The file in which the function appears. This field is the empty string if there is no file.
name	Function name within the file.
line	Function line number.

The current workspace index is returned in I.

If you step past the end of a file, `dbstack` returns a negative line number value to identify that special case. For example, if the last line to be executed is line 15, then the `dbstack` line number is 15 before you execute that line and -15 afterwards.

Tips

In addition to using `dbstack` while debugging, you can also use `dbstack` within a MATLAB code file outside the context of debugging. In this case, to get and analyze information about the current file stack. For example, to get the name of the calling file, use `dbstack` with an output argument within the file being called. For example:

```
st=dbstack;
```

Examples

This example shows the information returned when you issue `dbstack` while debugging a MATLAB code file:

```
dbstack
```

```
In /usr/local/matlab/toolbox/matlab/cond.m at line 13  
In test1.m at line 2  
In test.m at line 3
```

This example shows the information returned when you issue `dbstack` while debugging `lengthofline.m` to get the complete name of the file, the function name, and line number in which the function appears:

```
[ST,I] = dbstack('-completenames')  
ST =  
    file: 'I:\MATLABfiles\mymfiles\lengthofline.m'  
    name: 'lengthofline'  
    line: 28  
I =  
    1
```

**Related
Examples**

- “Examine Values”

dbstatus

Purpose List all breakpoints

Syntax

```
dbstatus
dbstatus file
dbstatus('-completenames')
s = dbstatus(...)
```

Description `dbstatus` lists all the breakpoints in effect including errors, caught errors, warnings, and `naninfs`.

`dbstatus file` displays a list of the line numbers for which breakpoints are set in the specified file, where `file` is a MATLAB code file function name or a MATLAB relative partial path. Each line number is a hyperlink you can click to go directly to that line in the Editor.

`dbstatus('-completenames')` displays, for each breakpoint, the absolute file name and the sequence of functions that nest the function containing the breakpoint.

`s = dbstatus(...)` returns breakpoint information in an `m`-by-1 structure with the fields listed in the following table. Use this syntax to save breakpoint status and restore it at a later time using `dbstop(s)`—see `dbstop` for an example.

<code>name</code>	Function name.
<code>file</code>	Full path for file containing breakpoints.
<code>line</code>	Vector of breakpoint line numbers.
<code>anonymous</code>	Vector of integers representing the anonymous functions in the <code>line</code> field. For example, 2 means the second anonymous function in that line. A value of 0 means the breakpoint is at the start of the line, not in an anonymous function.
<code>expression</code>	Cell vector of breakpoint conditional expression strings corresponding to lines in the <code>line</code> field.

cond	Condition string ('error', 'caught error', 'warning', or 'naninf').
identifier	When cond is 'error', 'caught error', or 'warning', a cell vector of MATLAB message identifier strings for which the particular cond state is set.

Use `dbstatus class/function`, `dbstatus private/function`, or `dbstatus class/private/function` to determine the status for methods, private functions, or private methods (for a class named `class`).

In all forms you can further qualify the function name with a local function name, as in `dbstatus function>localfunction`.

Tips

In the syntax, `file` can be a file, or the path to a function within a file. For example

```
Breakpoint for foo>myfun is on line 9
```

means there is a breakpoint at the `myfun` local function, which is line 9 in the file `foo.m`.

dbstep

Purpose Execute one or more lines from current breakpoint

Syntax
dbstep
dbstep *nlines*
dbstep **in**
dbstep **out**

Description This function allows you to debug a MATLAB code file by following its execution from the current breakpoint. At a breakpoint, the `dbstep` function steps through execution of the current file one line at a time or at the rate specified by *nlines*.

`dbstep` executes the next executable line of the current file. `dbstep` steps over the current line, skipping any breakpoints set in functions called by that line.

`dbstep nlines` executes the specified number of executable lines.

`dbstep in` steps to the next executable line. If that line contains a call to another MATLAB code file function, execution will step to the first executable line of the called function. If there is no call to a MATLAB code file on that line, `dbstep in` is the same as `dbstep`.

`dbstep out` runs the rest of the function and stops just after leaving the function.

For all forms, MATLAB software also stops execution at any breakpoint it encounters.

Note If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

**Related
Examples**

- “Step Through a File”

dbstop

Purpose

Set breakpoints for debugging

Syntax

```
dbstop in file
dbstop in file at location
dbstop in file if expression
dbstop in file at location if expression
dbstop if condition
dbstop(s)
```

Description

`dbstop in file` sets a breakpoint at the first executable line in `file`. When you run `file`, MATLAB enters debug mode and pauses execution at the first executable line.

`dbstop in file at location` sets a breakpoint at the specified location. MATLAB execution pauses immediately before that location, unless the location is an anonymous function. If the location is an anonymous function, then execution pauses just after the breakpoint.

`dbstop in file if expression` sets a breakpoint at the first executable line of the file. Execution pauses only if `expression` evaluates to 1 (true).

`dbstop in file at location if expression` sets a breakpoint at the specified location. Execution pauses at or just before that location only if the `expression` evaluates to true.

`dbstop if condition` pauses execution at the line that meets the specified condition.

`dbstop(s)` restores breakpoints you previously saved to `s`. The files containing the saved breakpoints must be on the search path or in the current folder. MATLAB assigns breakpoints by line number; therefore, the lines in the file must be the same as when you saved the breakpoints, or the results are unpredictable.

Tips

- Use `dbcont` or `dbstep` to resume execution after a breakpoint pauses execution. Use `dbquit` to exit debug mode.

- If you debug a file that MATLAB uses when running and debugging files, and that file is not a MATLAB code file, then some debugging features do not operate as expected. For instance, typing `help functionname` at the debug (`K>>`) prompt will not return help.
- MATLAB can become unresponsive when it stops at a breakpoint while displaying a modal dialog box or figure created by your program. Use **Ctrl+C** to exit debug mode and return to the MATLAB prompt (`>>`).
- If MATLAB pauses and displays a hyperlinked line number in the Command Window, click the hyperlink, The file opens in the Editor at the line where MATLAB paused execution. For an example of such a link, see the image in “Stop at File That Is Not a MATLAB Code File” on page 1-1596
- You can set breakpoints only at executable lines in saved files that are in the current folder or in folders on the search path.
- `dbstop if warning` has no effect when you disable warnings using `warning off all`. Similarly, `dbstop if warning identifier` has no effect when you disable warnings for the specified message identifier. See `warning` for more information about `off`, `all`, and `warning off identifier`

Input Arguments

file

File specification, typically for a MATLAB function, specified as a string. The file specification can include a partial path, but must be in a folder on the search path, or in the current folder.

If the command includes the `-completenames` option, then the file need not be on the search path, as long as the file specification is a “fully qualified name” on page 1-1593. In addition, `filespec` can include a filemarker (`>`) to specify the path to a particular local function or to a nested function within the file.

If `file` is not a MATLAB code file (for instance, it is a built-in or MDL-file), then MATLAB issues a warning. MATLAB cannot stop *in* the file, so it pauses before executing the file.

location

Location in `file` where you want to set a breakpoint, specified as one of the following:

- `lineno`

Line number in `file` specified as a string. The default is 1.

- `lineno@n`

`n`th anonymous function on line number, `lineno`, specified as a string. The default value of `n` is 1.

- `subfun`

Name of a local function in `file`, specified as a string.

expression

Code that evaluates (as if by `eval`) to a scalar logical value of 1 or 0, (true or false, respectively).

condition

Condition that causes execution to pause when that condition evaluates to true. Specify `condition` as one of the following:

- `error`— Run-time error that occurs outside a `try/catch` block. You cannot resume execution after an uncaught run-time error.

If you want execution to pause only if a specific error occurs, specify the message id. For example:

- `dbstop if error` stops execution at the first run-time error that occurs outside a `try/catch` block.
- `dbstop if error MATLAB:ls:InputsMustBeStrings` pauses execution at the first run-time error outside a `try/catch` block that has a message ID of `MATLAB:ls:InputsMustBeStrings`.

- `caught error` — Run-time error that occurs within the `try` portion of a `try/catch` block. If you want execution to stop only if a specific

error occurs, specify the message id. See the error condition for an example of specifying a message id.

- **warning**— Run-time warning occurs. If you want execution to pause only if a specific warning occurs, specify the message id. See the error condition for an example of specifying a message id.

This condition has no effect if you disabled warnings with the `warning off all` command or if you disabled warnings for the specified id. For more information about disabling warnings, see `warning`.

- **naninf and infnan**

The code returns an infinite value (`Inf`) or a value that is not a number (`NaN`) as a result of an operator, function call, or scalar assignment. The `naninf` and `infnan` conditions have identical effects.

s

Breakpoints previously saved to a structure using `s=dbstatus`.

Definitions

fully qualified name

- On Microsoft Windows platforms, a file name that begins with two back slashes (`\\`) or with a drive letter followed by a colon (`:`).
- On UNIX platforms, a file name that begins with a slash (`/`) or a tilde (`~`).

Examples

Stop at First Executable Line

This example shows how to set a breakpoint and pause execution at the first executable line in `buggy.m`.

- 1** Create a file, `buggy.m`, which contains these statements.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

- 2** Issue the `dbstop` command.

```
dbstop in buggy
```

- 3 Run buggy.

```
buggy(2:5)
```

MATLAB displays the line where it pauses and enters debug mode.

```
2 n = length(x);  
K>>
```

- 4 Advance to the next line in the file.

```
dbstep
```

- 5 Examine the value of n in the Variable Editor.

```
openvar('n')
```

- 6 Quit debug mode.

```
dbquit
```

Stop if Error

This example shows how to set a breakpoint and pause execution if a run-time error occurs.

- 1 Create a file, `buggy.m`, which contains these statements.

```
function z = buggy(x)  
n = length(x);  
z = (1:n)./x;
```

- 2 Issue these statements in the Command Window:

```
dbstop if error  
buggy(magic(3))
```

Because `buggy.m` works on vectors only, the input in step 2 results in a run-time error. MATLAB goes into debug mode, paused at line 3 in `buggy.m`.

```
Error using ./  
Matrix dimensions must agree.
```

```
Error in buggy at 3  
z = (1:n)./x;  
3   z = (1:n)./x;
```

3 Quit debug mode.

```
dbquit
```

Stop if InfNaN

This example shows how to set a breakpoint and pause execution if the code returns a NaN value.

1 Create a file, `buggy.m`, containing these statements.

```
function z = buggy(x)  
n = length(x);  
z = (1:n)./x;
```

2 Issue these commands.

```
dbstop if naninf  
buggy(0:2)
```

If any of the elements of the input, `x`, is zero, a division by zero occurs in `buggy.m`. Therefore, MATLAB returns the following message.

```
NaN/Inf breakpoint hit for buggy on line 3.
```

MATLAB is in debug mode, paused at line 3.

Stop at Function in File

This example shows how to set a breakpoint in the `collatzall` program file at the first executable line in the `collatzplot_new` function.

- 1 Copy `collatzall.m` from the MATLAB examples folder to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...  
'examples','collatzall.m'),'.','f')
```

- 2 Open `collatzall.m` in the Editor.

```
open collatzall.m
```

- 3 Set the breakpoint.

```
dbstop in collatzall>collatzplot_new
```

Stop at File That Is Not a MATLAB Code File

This example shows how to set a breakpoint at the built-in function `clear` when you run `myfile.m`.

- 1 Create a file, `myfile.m`, in the Editor, containing these statements.

```
function myfile(x)  
n = length(x);  
if n < 10  
    disp('length is less than 10')  
else  
    disp('length is 10 or greater')  
end  
clear  
disp('Value of n is cleared')
```

- 2 Issue these commands to set the breakpoint.

```
x = [1 2 3 4 5 6 7 8 9 10]
```

```
dbstop in clear; myfile(x)
```

MATLAB issues a warning, and pauses before the call to the `clear` function. The warning appears as shown in this image.

```
Warning: MATLAB debugger can only stop in MATLAB code files, and
"m_interpreter>clear" is not a MATLAB code file.
      Instead, the debugger will stop at the point right before
      "m_interpreter>clear" is called.
length is 10 or greater
8      clear
K>> |
```

Restore Saved Breakpoints

This example shows how to save, and then restore, saved breakpoints.

- 1 Copy `collatzall.m` from the MATLAB examples folder to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc','matlab_env', ...
    'examples','collatzall.m'),'.','f')
```

- 2 Open `collatzall.m` in the Editor.

```
open collatzall.m
```

- 3 Set breakpoints from the Command Window.

```
dbstop at 12 in collatzall
dbstop if error
```

- 4 Run `dbstatus`.

```
dbstatus
```

MATLAB describes the breakpoints you set.

dbstop

Breakpoint for `collatzall>collatzplot_new` is on line 12.
Stop if error.

- 5 Save the breakpoints to the structure, `s`, and then save `s` to the MAT-file, `myfilebrkpnts`.

```
s=dbstatus('-completenames');  
save myfilebrkpnts s
```

Using `s=dbstatus('-completenames')` saves absolute paths and the breakpoint function nesting sequence.

- 6 Clear all breakpoints.

```
dbclean collatzall
```

- 7 Restore the breakpoints by loading the MAT-file.

```
load myfilebrkpnts  
dbstop(s)
```

The file (or files) containing the breakpoints must be on the search path or in the current folder.

- 8 Verify the breakpoints.

```
dbstatus collatzall
```

dbup

Purpose Shift current workspace to workspace of caller, while in debug mode

Syntax dbup

Description This function allows you to examine the calling MATLAB code file to determine what caused the arguments to be passed to the called function.

dbup changes the current workspace context, while the user is in the debug mode, to the workspace of the calling file.

Multiple dbup functions change the workspace context to each previous calling file on the stack until the base workspace context is reached. (It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.)

Tips If you receive an error message such as the following, it means that the parent workspace is under construction so that the value of x is unavailable:

```
??? Reference to a called function result under construction x

Concepts

- “Problems Viewing Variable Values from the Parent Workspace”

Purpose

Solve delay differential equations (DDEs) with constant delays

Syntax

```
sol = dde23(ddefun,lags,history,tspan)
sol = dde23(ddefun,lags,history,tspan,options)
```

Arguments

ddefun

Function handle that evaluates the right side of the differential equations

$y'(t) = f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$. The function must have the form

```
dydt = ddefun(t,y,Z)
```

where t corresponds to the current t , y is a column vector that approximates $y(t)$, and $Z(:, j)$ approximates $y(t - \tau_j)$ for delay $\tau_j = \text{lags}(j)$. The output is a column vector

corresponding to $f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$.

lags

Vector of constant, positive delays τ_1, \dots, τ_k .

history

Specify history in one of three ways:

- A function of t such that $y = \text{history}(t)$ returns the solution $y(t)$ for $t \leq t_0$ as a column vector
- A constant column vector, if $y(t)$ is constant
- The solution `sol` from a previous integration, if this call continues that integration

<code>tspan</code>	Interval of integration from <code>t0=tspan(1)</code> to <code>tf=tspan(end)</code> with <code>t0 < tf</code> .
<code>options</code>	Optional integration argument. A structure you create using the <code>dde23set</code> function. See <code>dde23set</code> for details.

Description

`sol = dde23(ddefun, lags, history, tspan)` integrates the system of DDEs

$$y'(t) = f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$$

on the interval $[t_0, t_f]$, where τ_1, \dots, τ_k are constant, positive delays and t_0, t_f . The input argument, `ddefun`, is a function handle.

“Parameterizing Functions” explains how to provide additional parameters to the function `ddefun`, if necessary.

`dde23` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0, tf]`.

```
yint = deval(sol, tint)
```

The structure `sol` returned by `dde23` has the following fields.

<code>sol.x</code>	Mesh selected by <code>dde23</code>
<code>sol.y</code>	Approximation to $y(x)$ at the mesh points in <code>sol.x</code> .
<code>sol.yp</code>	Approximation to $y'(x)$ at the mesh points in <code>sol.x</code>
<code>sol.solver</code>	Solver name, 'dde23'

`sol = dde23(ddefun, lags, history, tspan, options)` solves as above with default integration properties replaced by values in `options`, an argument created with `dde23set`. See `dde23set` and “Types of DDEs” in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance 'RelTol' ($1e-3$ by default) and vector of absolute error tolerances 'AbsTol' (all components are $1e-6$ by default).

Use the 'Jumps' option to solve problems with discontinuities in the history or solution. Set this option to a vector that contains the locations of discontinuities in the solution prior to t_0 (the history) or in coefficients of the equations at known values of t after t_0 .

Use the 'Events' option to specify a function that dde23 calls to find where functions $g(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$ vanish. This function must be of the form

```
[value, isterminal, direction] = events(t, y, Z)
```

and contain an event function for each event to be tested. For the k th event function in events:

- `value(k)` is the value of the k th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and 0 otherwise.
- `direction(k) = 0` if you want dde23 to compute all zeros of this event function, +1 if only zeros where the event function increases, and -1 if only zeros where the event function decreases.

If you specify the 'Events' option and events are detected, the output structure `sol` also includes fields:

<code>sol.xe</code>	Row vector of locations of all events, i.e., times when an event function vanished
<code>sol.ye</code>	Matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>
<code>sol.ie</code>	Vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code>

Examples

This example solves a DDE on the interval $[0, 5]$ with lags 1 and 0.2. The function `ddex1de` computes the delay differential equations, and `ddex1hist` computes the history for $t \leq 0$.

Note The file, `ddex1.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex1` at the command line. To run it, type `ddex1` at the command line.

```
sol = dde23(@ddex1de,[1, 0.2],@ddex1hist,[0, 5]);
```

This code evaluates the solution at 100 equally spaced points in the interval $[0, 5]$, then plots the result.

```
tint = linspace(0,5);  
yint = deval(sol,tint);  
plot(tint,yint);
```

`ddex1` shows how you can code this problem using local functions. For more examples see `ddex2`.

Algorithms

`dde23` tracks discontinuities and integrates with the explicit Runge-Kutta (2,3) pair and interpolant of `ode23`. It uses iteration to take steps longer than the lags.

See Also

`ddesd` | `ddensd` | `ddeget` | `ddeset` | `deval` | `function_handle`

Purpose Extract properties from delay differential equations options structure

Syntax

```
val = ddeget(options,'name')  
val = ddeget(options,'name',default)
```

Description `val = ddeget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = ddeget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = ddeget(opts,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `opts`.

See Also `dde23` | `ddesd` | `ddensd` | `ddeset`

ddensd

Purpose

Solve delay differential equations (DDEs) of neutral type

Syntax

```
sol = ddensd(ddefun,dely,delyp,history,tspan)
sol = ddensd(ddefun,dely,delyp,history,tspan,options)
```

Description

`sol = ddensd(ddefun,dely,delyp,history,tspan)` integrates a system of delay differential equations of neutral type, that has the form

$$y'(t) = f(t, y(t), y(dy_1), \dots, y(dy_p), y'(dyp_1), \dots, y'(dyp_q)) \quad (1-1)$$

where

- t is the independent variable representing time.
- dy_i is any of p solution delays.
- dyp_j is any of q derivative delays.

`sol = ddensd(ddefun,dely,delyp,history,tspan,options)` replaces default integration parameters with those specified in `options`, a structure created with the `ddeSet` function.

Input Arguments

ddefun - Derivative function

function handle

Derivative function, specified as a function handle whose syntax is `yp = ddefun(t,y,ydel,ypdel)`. The arguments for `ddefun` are described in the table below.

ddefun Argument	Description
<code>t</code>	A scalar value representing the current value of time, t .
<code>y</code>	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is n -by-1, where n is the number of equations in the system you want to solve.

ddefun Argument	Description
ydel	A matrix whose columns, <code>ydel(:, i)</code> , represent $y(dy_i)$. The size of this matrix is n-by-p, where n is the number of equations in the system you want to solve, and p is the number of $y(dy)$ terms in Equation 1-1.
ypdel	A matrix whose columns, <code>ypdel(:, j)</code> represent $y'(dyp_j)$. The size of this matrix is n-by-q, where n is the number of equations in the system you want to solve, and q is the number of $y'(dyp)$ terms in Equation 1-1.
yp	The result returned by <code>ddefun</code> . It is an n-by-1 vector whose elements represent the right side of Equation 1-1.

dely - Solution delays

function handle | vector

Solution delays, specified as a function handle, which returns dy_1, \dots, dy_p in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If you specify `dely` as a function handle, the syntax must be `dy = dely(t, y)`. The arguments for this function are described in the table below.

dely Argument	Description
t	A scalar value representing the current value of time, t .
y	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is n-by-1, where n is the number of equations in the system you want to solve.
dy	A vector returned by the dely function whose values are the solution delays, dy_i , in Equation 1-1. The size of this vector is p-by-1, where p is the number of solution delays in the equation. Each element must be less than or equal to t .

If you want to specify constant solution delays having the form $dy_i = t - \tau_i$, then **dely** must be a vector, where $\text{dely}(i) = \tau_i$. Each value in this vector must be greater than or equal to zero.

If dy is not present in the problem, set **dely** to `[]`.

Data Types

function_handle | single | double

delyp - Derivative delays

function_handle | vector

Derivative delays, specified as a function handle, which returns $dy_{p_1}, \dots, dy_{p_q}$ in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If **delyp** is a function handle, its syntax must be `dyp = delyp(t,y)`. The arguments for this function are described in the table below.

delyp Argument	Description
t	A scalar value representing the current value of time, t .
y	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is n-by-1, where n is the number of equations in the system you want to solve.
dyp	A vector returned by the <code>delyp</code> function whose values are the derivative delays, dyp_j , in Equation 1-1. The size of this vector must be q-by-1, where q is the number of solution delays, dyp_j , in the equation. Each element of <code>dyp</code> must be less than t . There is one exception to this restriction: if you are solving an initial value DDE, the value of <code>dyp</code> can equal t at $t = t_0$. For more information, see “Initial Value Neutral Delay Differential Equations” on page 1-1611.

If you want specify constant derivative delays having the form $dyp_j = t - \tau_j$, then `delyp` must be a vector, where `delyp(j) = τ_j` . Each value in this vector must be greater than zero. An exception to this restriction occurs when you solve initial value problems for DDEs of neutral type. In such cases, a value in `delyp` can equal zero at $t = t_0$. See “Initial Value Neutral Delay Differential Equations” on page 1-1611 for more information.

If `dyp` is not present in the problem, set `delyp` to `[]`.

Data Types

function_handle | single | double

history - Solution history

function handle | column vector | structure (sol, from previous integration) | 1-by-2 cell array

Solution history, specified as a function handle, column vector, `sol` structure (from a previous integration), or a cell array. This is the solution at $t \leq t_0$.

- If the history varies with time, specify the solution history as a function handle whose syntax is `y = history(t)`. This function returns an n -by-1 vector that approximates the solution, $y(t)$, for $t \leq t_0$. The length of this vector, n , is the number of equations in the system you want to solve.
- If $y(t)$ is constant, you can specify `history` as an n -by-1 vector of the constant values.
- If you are calling `ddensd` to continue a previous integration to t_0 , you can specify `history` as the output, `sol`, from the previous integration.
- If you are solving an initial value DDE, specify `history` as a cell array, `{y0, yp0}`. The first element, `y0`, is a column vector of initial values, $y(t_0)$. The second element, `yp0`, is a column vector whose elements are the initial derivatives, $y'(t_0)$. These vectors must be consistent, meaning that they satisfy Equation 1-1 at t_0 . See “Initial Value Neutral Delay Differential Equations” on page 1-1611 for more information.

Data Types

`function_handle` | `single` | `double` | `struct` | `cell`

`tspan` - Interval of integration

1-by-2 vector

Interval of integration, specified as the vector `[t0 tf]`. The first element, `t0`, is the initial value of t . The second element, `tf`, is the final value of t . The value of `t0` must be less than `tf`.

Data Types

`single` | `double`

`options` - Optional integration parameters

structure returned by `ddeset`

Optional integration parameters, specified as a structure created and returned by the `ddeset` function. Some commonly used properties are: 'RelTol', 'AbsTol', and 'Events'. See the `ddeset` reference page for more information about specifying options.

Output Arguments

sol - Solution

structure

Solution, returned as a structure containing the following fields.

<code>sol.x</code>	Mesh selected by <code>ddensd</code> .
<code>sol.y</code>	An approximation to $y(t)$ at the mesh points.
<code>sol.yp</code>	An approximation to $y'(t)$ at the mesh points.
<code>sol.solver</code>	A string identifying the solver, 'ddensd'.

You can pass `sol` to the `deval` function to evaluate the solution at specific points. For example, `y = deval(sol, 0.5*(sol.x(1) + sol.x(end)))` evaluates the solution at the midpoint of the interval of integration.

Definitions

Initial Value Neutral Delay Differential Equations

An initial value DDE has $dy_i \geq t_0$ and $dyp_j \geq t_0$, for all i and j . At $t = t_0$, all delayed terms reduce to $y(dy_i) = y(t_0)$ and $y'(dyp_j) = y'(t_0)$:

$$y'(t_0) = f(t_0, y(t_0), y(t_0), \dots, y(t_0), y'(t_0), \dots, y'(t_0)) \tag{1-2}$$

For $t > t_0$, all derivative delays must satisfy $dyp < t$.

When you solve initial value neutral DDEs, you must supply $y'(t_0)$ to `ddensd`. To do this, specify `history` as a cell array `{Y0, YP0}`. Here, `Y0` is the column vector of initial values, $y(t_0)$, and `YP0` is a column vector of initial derivatives, $y'(t_0)$. These vectors must be consistent, meaning that they satisfy Equation 1-2 at t_0 .

Examples

Neutral DDE with Two Delays

Solve the following neutral DDE, presented by Paul, for $0 \leq t \leq \pi$:

$$y'(t) = 1 + y(t) - 2y(t/2)^2 - y'(t - \pi)$$

with history: $y(t) = \cos(t)$ for $t \leq 0$.

Create a new program file in the editor. This file will contain a main function and four local functions.

Define the first-order DDE as a local function.

```
function yp = ddefun(t,y,ydel,ypdel)
    yp = 1 + y - 2*ydel^2 - ypdel;
end
```

Define the solution delay as a local function.

```
function dy = dely(t,y)
    dy = t/2;
end
```

Define the derivative delay as a local function.

```
function dyp = delyp(t,y)
    dyp = t-pi;
end
```

Define the solution history as a local function.

```
function y = history(t)
    y = cos(t);
end
```

Define the interval of integration and solve the DDE using the `ddensd` function. Add this code to the main function.

```
tspan = [0 pi];
sol = ddensd(@ddefun,@dely,@delyp,@history,tspan);
```

Evaluate the solution at 100 equally spaced points between 0 and π .
Add this code to the main function.

```
tn = linspace(0,pi);  
yn = deval(sol,tn);
```

Plot the results. Add this code to the main function.

```
plot(tn,yn);  
xlim([0 pi]);  
ylim([-1.2 1.2]);  
xlabel('time t');  
ylabel('solution y');
```

Run your program to calculate the solution and display the plot.

The file, `ddex4.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex4` at the command line.

Algorithms

For information about the algorithm used in this solver, see Shampine [2].

deval | ddeset | ddesd | dde23 | function_handle

ddestd

Purpose Solve delay differential equations (DDEs) with general delays

Syntax
`sol = ddestd(ddefun,delays,history,tspan)`
`sol = ddestd(ddefun,delays,history,tspan,options)`

Arguments

ddefun Function handle that evaluates the right side of the differential equations $y'(t) = f(t,y(t),y(d(1)),\dots,y(d(k)))$. The function must have the form

`dydt = ddefun(t,y,Z)`

where t corresponds to the current t , y is a column vector that approximates $y(t)$, and $Z(:,j)$ approximates $y(d(j))$ for delay $d(j)$ given as component j of `delays(t,y)`. The output is a column vector corresponding to $f(t,y(t),y(d(1)),\dots,y(d(k)))$.

delays Function handle that returns a column vector of delays $d(j)$. The delays can depend on both t and $y(t)$. `ddestd` imposes the requirement that $d(j) \leq t$ by using $\min(d(j),t)$.

If all the delay functions have the form $d(j) = t - \tau_j$, you can set the argument `delays` to a constant vector `delays(j) = τ_j` . With delay functions of this form, `ddestd` is used exactly like `dde23`.

history	Specify history in one of three ways: <ul style="list-style-type: none"> • A function of t such that $y = \text{history}(t)$ returns the solution $y(t)$ for $t \leq t_0$ as a column vector • A constant column vector, if $y(t)$ is constant • The solution <code>sol</code> from a previous integration, if this call continues that integration
tspan	Interval of integration from <code>t0=tspan(1)</code> to <code>tf=tspan(end)</code> with <code>t0 < tf</code> .
options	Optional integration argument. A structure you create using the <code>ddeset</code> function. See <code>ddeset</code> for details.

Description

`sol = ddesd(ddefun,delays,history,tspan)` integrates the system of DDEs

$$y'(t) = f(t, y(t), y(d(1)), \dots, y(d(k)))$$

on the interval $[t_0, t_f]$, where delays $d(j)$ can depend on both t and $y(t)$, and $t_0 < t_f$. Inputs `ddefun` and `delays` are function handles. See the `function_handle` reference page for more information.

“Parameterizing Functions” explains how to provide additional parameters to the functions `ddefun`, `delays`, and `history`, if necessary.

`ddesd` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

`yint = deval(sol,tint)`

The structure `sol` returned by `ddesd` has the following fields.

<code>sol.x</code>	Mesh selected by <code>ddesd</code>
<code>sol.y</code>	Approximation to $y(x)$ at the mesh points in <code>sol.x</code> .
<code>sol.yp</code>	Approximation to $y'(x)$ at the mesh points in <code>sol.x</code>
<code>sol.solver</code>	Solver name, 'ddesd'

`sol = ddesd(ddefun,delays,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and “Types of DDEs” in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance 'RelTol' ($1e-3$ by default) and vector of absolute error tolerances 'AbsTol' (all components are $1e-6$ by default).

Use the 'Events' option to specify a function that `ddesd` calls to find where functions $g(t,y(t),y(d(1)),\dots,y(d(k)))$ vanish. This function must be of the form

```
[value,isterminal,direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the k th event function in `events`:

- `value(k)` is the value of the k th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and 0 otherwise.
- `direction(k) = 0` if you want `ddesd` to compute all zeros of this event function, +1 if only zeros where the event function increases, and -1 if only zeros where the event function decreases.

If you specify the 'Events' option and events are detected, the output structure `sol` also includes fields:

<code>sol.xe</code>	Row vector of locations of all events, i.e., times when an event function vanished
<code>sol.ye</code>	Matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>
<code>sol.ie</code>	Vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code>

Examples

The equation

```
sol = ddesd(@ddex1de,@ddex1delays,@ddex1hist,[0,5]);
```

solves a DDE on the interval $[0,5]$ with delays specified by the function `ddex1delays` and differential equations computed by `ddex1de`. The history is evaluated for $t \leq 0$ by the function `ddex1hist`. The solution is evaluated at 100 equally spaced points in $[0,5]$:

```
tint = linspace(0,5);
yint = deval(sol,tint);
```

and plotted with

```
plot(tint,yint);
```

This problem involves constant delays. The delay function has the form

```
function d = ddex1delays(t,y)
%DDEX1DELAYS Delays for using with DDEX1DE.
d = [ t - 1
      t - 0.2];
```

The problem can also be solved with the syntax corresponding to constant delays

```
delays = [1, 0.2];
sol = ddesd(@ddex1de,delays,@ddex1hist,[0, 5]);
```

or using `dde23`:

ddesd

```
sol = dde23(@ddex1de,delays,@ddex1hist,[0, 5]);
```

For more examples of solving delay differential equations see `ddex2` and `ddex3`.

See Also

`dde23` | `ddeget` | `ddensd` | `ddeset` | `deval` | `function_handle`

Purpose Create or alter delay differential equations options structure

Syntax

```
options = ddeset('name1',value1,'name2',value2,...)
options = ddeset(olddopts,'name1',value1,...)
options = ddeset(olddopts,newopts)
ddeset
```

Description `options = ddeset('name1',value1,'name2',value2,...)` creates an integrator options structure `options` in which the named properties have the specified values. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify the property. `ddeset` ignores case for property names.

`options = ddeset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This overwrites any values in `olddopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = ddeset(olddopts,newopts)` combines an existing options structure `olddopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `olddopts`.

`ddeset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `ddeget` to query the options structure for the value of a specific property.

DDE Properties

The following sections describe the properties that you can set using `ddeset`. There are several categories of properties:

- Error control
- Solver output
- Step size
- Event location
- Discontinuities

Error Control Properties

At each step, the DDE solvers estimate an error e . The `dde23` function estimates the local truncation error, and the other solvers estimate the residual. In either case, this error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

$$|e(i)| * \max(\text{RelTol} * \text{abs}(y(i)), \text{AbsTol}(i))$$

For routine problems, the solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over “long” intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For the absolute error tolerance, the scaling of the solution components is important: if $|y|$ is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in y . You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component $y(i)$ when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in $y(i)$ so that you can accurately compute more interesting components.

The following table describes the error control properties.

DDE Error Control Properties

Property	Value	Description
RelTol	Positive scalar {1e-3}	<p>A relative error tolerance that applies to all components of the solution vector y. It is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components except those smaller than thresholds $AbsTol(i)$. The default, 1e-3, corresponds to 0.1% accuracy.</p> <p>The estimated error in each integration step satisfies $e(i) \leq \max(RelTol * abs(y(i)), AbsTol(i))$.</p>
AbsTol	Positive scalar or vector {1e-6}	<p>Absolute error tolerances that apply to the individual components of the solution vector. $AbsTol(i)$ is a threshold below which the value of the ith solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero. Even if you are not interested in a component $y(i)$ when it is small, you may have to specify $AbsTol(i)$ small enough to get some correct digits in $y(i)$ so that you can accurately compute more interesting components.</p> <p>If $AbsTol$ is a vector, the length of $AbsTol$ must be the same as the length of the solution vector y. If $AbsTol$ is a scalar, the value applies to all components of y.</p>
NormControl	on {off}	<p>Control error relative to norm of solution. Set this property on to request that the solvers control the error in each integration step with $norm(e) \leq \max(RelTol * norm(y), AbsTol)$. By default, the solvers use a more stringent component-wise error control.</p>

Solver Output Properties

You can use the solver output properties to control the output that the solvers generate.

DDE Solver Output Properties

Property	Value	Description
OutputFcn	Function handle {@odeplot}	<p>The output function is a function that the solver calls after every successful integration step. To specify an output function, set 'OutputFcn' to a function handle. For example,</p> <pre>options = ddeset('OutputFcn',... @myfun)</pre> <p>sets 'OutputFcn' to @myfun, a handle to the function myfun. See the function_handle reference page for more information.</p> <p>The output function must be of the form</p> <pre>status = myfun(t,y,flag)</pre> <p>“Parameterizing Functions” explains how to provide additional parameters to myfun, if necessary.</p> <p>The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:</p> <ul style="list-style-type: none"> • <code>init</code> — The solver calls <code>myfun(tspan,y0,'init')</code> before beginning the integration to allow the output function to initialize. <code>tspan</code> is the input argument to the solvers. <code>y0</code> is the initial value of the solution, either from <code>history(t0)</code> or specified in the <code>initialY</code> option. • <code>{none}</code> — The solver calls <code>status = myfun(t,y)</code> after each integration step on which output is requested. <code>t</code> contains points where output was

DDE Solver Output Properties (Continued)

Property	Value	Description
		<p>generated during the step, and <i>y</i> is the numerical solution at the points in <i>t</i>. If <i>t</i> is a vector, the <i>ith</i> column of <i>y</i> corresponds to the <i>ith</i> element of <i>t</i>.</p> <p><i>myfun</i> must return a status output value of 0 or 1. If <code>literal > status</code>, the solver halts integration. You can use this mechanism, for instance, to implement a Stop button.</p> <ul style="list-style-type: none"> • done — The solver calls <code>myfun([], [], 'done')</code> when integration is complete to allow the output function to perform any cleanup chores. <p>You can use these general purpose output functions or you can edit them to create your own. Type <code>help functionname</code> at the command line for more information.</p> <ul style="list-style-type: none"> • odeplot – time series plotting (default when you call the solver with no output argument and you have not specified an output function) • odephas2 – two-dimensional phase plane plotting • odephas3 – three-dimensional phase plane plotting • odeprint – print solution as the solver computes it
OutputSel	Vector of indices	<p>Vector of indices specifying which components of the solution vector the solvers pass to the output function. For example, if you want to use the <code>odeplot</code> output function, but you want to plot only the first and third components of the solution, you can do this using</p> <pre>options = ddeaset... ('OutputFcn',@odeplot,...</pre>

DDE Solver Output Properties (Continued)

Property	Value	Description
		'OutputSel',[1 3]); By default, the solver passes all components of the solution to the output function.
Stats	on {off}	Specifies whether the solver should display statistics about its computations. By default, Stats is off . If it is on , after solving the problem the solver displays: <ul style="list-style-type: none"> • The number of successful steps • The number of failed attempts • The number of times the DDE function was called

Step Size Properties

The step size properties let you specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step size properties.

DDE Step Size Properties

Property	Value	Description
InitialStep	Positive scalar	Suggested initial step size. InitialStep sets an upper bound on the magnitude of the first step size the solver tries. If you do not set InitialStep , the solver bases the initial step size on the slope of the solution at the initial time <code>tspan(1)</code> . The initial step size is limited by the shortest delay. If the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know

DDE Step Size Properties (Continued)

Property	Value	Description
		this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable <code>InitialStep</code> .
MaxStep	Positive scalar {0.1* abs(t0-tf)}	Upper bound on solver step size. If the differential equation has periodic coefficients or solutions, it may be a good idea to set MaxStep to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do <i>not</i> reduce MaxStep: <ul style="list-style-type: none"> • When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance <code>RelTol</code>, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector <code>AbsTol</code>. (See “Error Control Properties” on page 1-1622 for a description of the error tolerance properties.) • To make sure that the solver doesn’t step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances <code>RelTol</code> and <code>AbsTol</code>. Use MaxStep as a last resort.

Event Location Property

In some DDE problems, the times of specific events are important. While solving a problem, the solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the Events property.

DDE Events Property

String	Value	Description
Events	Function handle	<p>A function handle that includes one or more event functions. For <code>dde23</code> and <code>ddesd</code>, this function has the following syntax:</p> <pre>[value, isterminal, direction] = events(t, y, YDEL)</pre> <p>For <code>ddensd</code>, the syntax is:</p> <pre>[value, isterminal, direction] = events(t, y, YDEL, YPDEL)</pre> <p>The output arguments, <code>value</code>, <code>isterminal</code>, and <code>direction</code>, are vectors for which the <code>ith</code> element corresponds to the <code>ith</code> event function:</p> <ul style="list-style-type: none">• <code>value(i)</code> is the value of the <code>ith</code> event function.• <code>isterminal(i) = 1</code> if you want the integration to terminate at a zero of this event function, and <code>0</code> otherwise.• <code>direction(i) = 0</code> if you want the solver to locate all zeros (the default), <code>+1</code> if only zeros where the event function is increasing, and <code>-1</code> if only zeros where the event function is decreasing. <p>If you specify an events function and events are detected, the solver returns three additional fields in the solution structure <code>sol</code>:</p> <ul style="list-style-type: none">• <code>sol.xe</code> is a row vector of times at which events occur.• <code>sol.ye</code> is a matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>.• <code>sol.ie</code> is a vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code>.

DDE Events Property (Continued)

String	Value	Description
		For examples that use an event function while solving ordinary differential equation problems, see “Event Location” (<code>ballode</code>) and “Advanced Event Location” (<code>orbitode</code>), in the MATLAB Mathematics documentation.

Discontinuity Properties

The solver functions can solve problems with discontinuities in the history or in the coefficients of the equations. The following properties enable you to provide these solvers with a different initial value, and, for `dde23`, locations of known discontinuities. For more information, see “Discontinuities in DDEs”.

The following table describes the discontinuity properties.

DDE Discontinuity Properties

String	Value	Description
<code>Jumps</code>	Vector	Location of discontinuities. Points t where the history or solution may have a jump discontinuity in a low-order derivative. This applies only to the <code>dde23</code> solver.
<code>InitialY</code>	Vector	Initial value of solution. By default the initial value of the solution is the value returned by <code>history</code> at the initial point. Supply a different initial value as the value of the <code>InitialY</code> property.

Examples

To create an options structure that changes the relative error tolerance of the solver from the default value of $1e-3$ to $1e-4$, enter

```
options = ddeset('RelTol',1e-4);
```

ddeset

To recover the value of 'RelTol' from options, enter

```
ddeget(options,'RelTol')
```

```
ans =
```

```
1.0000e-004
```

Purpose Distribute inputs to outputs

Note Beginning with MATLAB Version 7.0 software, you can access the contents of cell arrays and structure fields without using the `deal` function. See Example 3, below.

Syntax

```
[Y1, Y2, Y3, ...] = deal(X)
[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)
[S.field] = deal(X)
[X{:}] = deal(A.field)
[Y1, Y2, Y3, ...] = deal(X{:})
[Y1, Y2, Y3, ...] = deal(S.field)
```

Description

`[Y1, Y2, Y3, ...] = deal(X)` copies the single input to all the requested outputs. It is the same as `Y1 = X, Y2 = X, Y3 = X, ...`

`[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)` is the same as `Y1 = X1; Y2 = X2; Y3 = X3; ...`

Tips

`deal` is most useful when used with cell arrays and structures via comma-separated list expansion. Here are some useful constructions:

`[S.field] = deal(X)` sets all the fields with the name `field` in the structure array `S` to the value `X`. If `S` doesn't exist, use `[S(1:m).field] = deal(X)`.

`[X{:}] = deal(A.field)` copies the values of the field with name `field` to the cell array `X`. If `X` doesn't exist, use `[X{1:m}] = deal(A.field)`.

`[Y1, Y2, Y3, ...] = deal(X{:})` copies the contents of the cell array `X` to the separate variables `Y1, Y2, Y3, ...`

`[Y1, Y2, Y3, ...] = deal(S.field)` copies the contents of the fields with the name `field` to separate variables `Y1, Y2, Y3, ...`

Examples

Example 1 – Assign Data From a Cell Array

Use `deal` to copy the contents of a 4-element cell array into four separate output variables.

```
C = {rand(3) ones(3,1) eye(3) zeros(3,1)};
[a,b,c,d] = deal(C{:})
```

```
a =
    0.9501    0.4860    0.4565
    0.2311    0.8913    0.0185
    0.6068    0.7621    0.8214
```

```
b =
     1
     1
     1
```

```
c =
     1     0     0
     0     1     0
     0     0     1
```

```
d =
     0
     0
     0
```

Example 2 – Assign Data From Structure Fields

Use `deal` to obtain the contents of all the name fields in a structure array:

```
A.name = 'Pat'; A.number = 176554;
A(2).name = 'Tony'; A(2).number = 901325;
[name1,name2] = deal(A(:).name)
```

```
name1 =
    Pat
```

```
name2 =  
    Tony
```

Example 3 – Doing the Same Without deal

Beginning with MATLAB Version 7.0 software, you can, in most cases, access the contents of cell arrays and structure fields without using the `deal` function. The two commands shown below perform the same operation as those used in the previous two examples, except that these commands do not require `deal`.

```
[a,b,c,d] = C{:}  
[name1,name2] = A(:).name
```

```

deblank

Purpose Strip trailing blanks from end of string

Syntax `str = deblank(str)`
`c = deblank(c)`

Description `str = deblank(str)` removes all trailing whitespace and null characters from the end of character string `str`. A whitespace is any character for which the `isspace` function returns logical 1 (`true`).

`c = deblank(c)` when `c` is a cell array of strings, applies `deblank` to each element of `c`.

The `deblank` function is useful for cleaning up the rows of a character array.

Examples

Example 1 – Removing Trailing Blanks From a String

Compose a string `str` that contains space, tab, and null characters:

```
NL = char(0);    TAB = char(9);  
str = [NL 32 TAB NL 'AB' 32 NL 'CD' NL 32 TAB NL 32];
```

Display all characters of the string between `|` symbols:

```
['|' str '|']  
ans =  
    |    AB  CD    |
```

Remove trailing whitespace and null characters, and redisplay the string:

```
newstr = deblank(str);  
  
['|' newstr '|']  
ans =  
    |    AB  CD|
```

Example 2- Removing Trailing Blanks From a Cell Array of Strings

Create a 2-by-2 cell array in which each cell contains a word with trailing blanks:

```
A{1,1} = 'MATLAB   ' ;  
A{1,2} = 'SIMULINK   ' ;  
A{2,1} = 'Toolboxes   ' ;  
A{2,2} = 'MathWorks   ' ;  
A =  
    'MATLAB   '      'SIMULINK   '  
    'Toolboxes   '  'MathWorks   '
```

Remove the trailing blanks and redisplay the cell array:

```
A = deblank(A);  
  
A  
A =  
    'MATLAB'      'SIMULINK'  
    'Toolboxes'  'MathWorks'
```

[strjust](#) | [strtrim](#)

dec2base

Purpose Convert decimal to base N number in string

Syntax `str = dec2base(d, base)`
`str = dec2base(d, base, n)`

Description `str = dec2base(d, base)` converts the nonnegative integer `d` to the specified base. `d` must be a nonnegative integer smaller than 2^{52} , and `base` must be an integer between 2 and 36. The returned argument `str` is a string.

`str = dec2base(d, base, n)` produces a representation with at least `n` digits.

Examples The expression `dec2base(23, 2)` converts 23_{10} to base 2, returning the string `'10111'`.

See Also `base2dec`

Purpose Convert decimal to binary number in string

Syntax `str = dec2bin(d)`
`str = dec2bin(d,n)`

Description returns the
`str = dec2bin(d)` binary representation of `d` as a string. `d` must be a nonnegative integer smaller than 2^{52} .
`str = dec2bin(d,n)` produces a binary representation with at least `n` bits.
The output of `dec2bin` is independent of the endian settings of the computer you are using.

Examples Decimal 23 converts to binary 010111:

```
dec2bin(23)
ans =
    10111
```

See Also [bin2dec](#) | [dec2hex](#)

dec2hex

Purpose Convert decimal to hexadecimal number in string

Syntax `str = dec2hex(d)`
`str = dec2hex(d, n)`

Description `str = dec2hex(d)` converts the decimal integer `d` to its hexadecimal representation stored in a MATLAB string. `d` must be a nonnegative integer smaller than 2^{52} . MATLAB converts noninteger inputs, such as those of class `double` or `char`, to their integer equivalents before converting to hexadecimal.

`str = dec2hex(d, n)` produces a hexadecimal representation with at least `n` digits.

Examples To convert decimal 1023 to hexadecimal,

```
dec2hex(1023)
ans =
    3FF
```

```
dec2hex(1023, 6)
ans =
0003FF
```

Convert 2-by-5 array `A` to hexadecimal:

```
A = [3487,    125,  8997,  1433,  189; ...
      771,  84832,   118,  9366,  212];
```

<code>A(:)</code>	<code>dec2hex(A)</code>
<code>ans =</code>	<code>ans =</code>
3487	00D9F
771	00303
125	0007D
84832	14B60
8997	02325
118	00076
1433	00599

9366	02496
189	000BD
212	000D4

See Also

[dec2bin](#) | [format](#) | [hex2dec](#) | [hex2num](#)

decic

Purpose

Compute consistent initial conditions for ode15i

Syntax

```
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,options)
[y0mod,yp0mod,resnrm] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0...)
```

Description

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)` uses the inputs `y0` and `yp0` as initial guesses for an iteration to find output values that satisfy the requirement $f(t0, y0mod, yp0mod) = 0$, i.e., `y0mod` and `yp0mod` are consistent initial conditions. `odefun` is a function handle. The function `decic` changes as few components of the guesses as possible. You can specify that `decic` holds certain components fixed by setting `fixed_y0(i) = 1` if no change is permitted in the guess for `y0(i)` and 0 otherwise. `decic` interprets `fixed_y0 = []` as allowing changes in all entries. `fixed_yp0` is handled similarly.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

You cannot fix more than `length(y0)` components. Depending on the problem, it may not be possible to fix this many. It also may not be possible to fix certain components of `y0` or `yp0`. It is recommended that you fix no more components than necessary.

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,options)` computes as above with default tolerances for consistent initial conditions, `AbsTol` and `RelTol`, replaced by the values in `options`, a structure you create with the `odeset` function.

`[y0mod,yp0mod,resnrm] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0...)` returns the norm of `odefun(t0,y0mod,yp0mod)` as `resnrm`. If the norm seems unduly large, use `options` to decrease `RelTol` ($1e-3$ by default).

Examples

The files, `ihb1dae.m` and `iburgersode.m`, provide examples which use `decic` to solve implicit ODEs.

ode15i | odeget | odeset | function_handle

deconv

Purpose Deconvolution and polynomial division

Syntax $[q,r] = \text{deconv}(v,u)$

Description $[q,r] = \text{deconv}(v,u)$ deconvolves vector u out of vector v , using long division. The quotient is returned in vector q and the remainder in vector r such that $v = \text{conv}(u,q)+r$.

If u and v are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials, and deconvolution is polynomial division. The result of dividing v by u is quotient q and remainder r .

Examples

If

```
u = [1 2 3 4]
v = [10 20 30]
```

the convolution is

```
c = conv(u,v)
c =
    10    40   100   160   170   120
```

Use deconvolution to recover u :

```
[q,r] = deconv(c,u)
q =
    10    20    30
r =
    0     0     0     0     0     0
```

This gives a quotient equal to v and a zero remainder.

Algorithms `deconv` uses the `filter` primitive.

See Also `conv` | `residue`

Purpose	Discrete Laplacian
Syntax	<code>L = del2(U)</code> <code>L = del2(U,h)</code> <code>L = del2(U,h1,...,hN)</code>
Description	<p><code>L = del2(U)</code> returns a discrete approximation of Laplace's differential operator applied to <code>U</code> using the default spacing, <code>h = 1</code>, between all points.</p> <p><code>L = del2(U,h)</code> specifies a uniform, scalar spacing, <code>h</code>, between points in all dimensions of <code>U</code>.</p> <p><code>L = del2(U,h1,...,hN)</code> specifies the spacing, <code>h1,...,hN</code>, between points in each corresponding dimension of <code>U</code>. For each dimension, specify the spacing as a scalar or a vector of coordinates. The number of spacing inputs must equal the number of dimensions in <code>U</code>.</p>
Input Arguments	<p>U - Input array vector matrix multidimensional array Input array, specified as a vector, matrix, or multidimensional array.</p> <p>Data Types single double Complex Number Support: Yes</p> <p>h - Spacing in all dimensions 1 (default) scalar Spacing in all dimensions, specified as 1 (default), or a scalar.</p> <p>Data Types single double Complex Number Support: Yes</p> <p>h1,...,hN - Spacing in each dimension</p>

scalars | vectors

Spacing in each dimension, specified as scalars or vectors. The number of spacing inputs must be equal to the number of dimensions in U . Each spacing input defines the spacing between points in the corresponding dimension of U :

- Use a scalar to specify a uniform spacing.
- Use a vector to specify a nonuniform spacing. The coordinate vector gives the position of each point and must have the same number of elements as the corresponding dimension of U (a one-to-one match of coordinates and points).

Data Types

single | double

Complex Number Support: Yes

Output Arguments

L - Discrete Laplacian approximation

vector | matrix | multidimensional array

Discrete Laplacian approximation, returned as a vector, matrix, or multidimensional array. L is the same size as the input, U .

Examples

Second Derivative of Vector

Calculate the acceleration of an object from a vector of position data.

Create a vector of position data.

```
p = [1 3 6 10 16 18 29];
```

To find the acceleration of the object, use `de12` to calculate the second numerical derivative of p . Use the default spacing $h = 1$ between data points.

```
L = 4*de12(p)
```

```
L =
```

```
1 1 1 2 -4 9 22
```

Each value of L is an approximation of the instantaneous acceleration at that point.

Second Derivative of Cosine Vector

Calculate the discrete 1-D Laplacian of a cosine vector.

Define the domain of the function.

```
x = linspace(-2*pi,2*pi);
```

This produces 100 evenly spaced points in the range $-2\pi \leq x \leq 2\pi$.

Create a vector of cosine values in this domain.

```
U = cos(x);
```

Calculate the Laplacian of U using `del2`. Use the domain vector x to define the 1-D coordinate of each point in U .

```
L = 4*del2(U,x);
```

Analytically, the Laplacian of this function is equal to $\Delta U = -\cos(x)$.

Plot the results.

```
plot(x,U,x,L);legend('U(x)', 'L(x)', 'Location', 'Best')
```

The graph of U and L agrees with the analytic result for the Laplacian.

Laplacian of Multivariate Function

Calculate and plot the discrete Laplacian of a multivariate function.

Define the x and y domain of the function.

```
[x,y] = meshgrid(-5:0.25:5, -5:0.25:5);
```

Define the function $U(x, y) = \frac{1}{3}(x^4 + y^4)$ over this domain.

```
U = 1/3.*(x.^4+y.^4);
```

Calculate the Laplacian of this function using `del2`. The spacing between the points in `U` is equal in all directions, so you can specify a single spacing input, `h`.

```
h = 0.25;  
L = 4*del2(U,h);
```

Analytically, the Laplacian of this function is equal to $\Delta U(x,y) = 4x^2 + 4y^2$.

Plot the discrete Laplacian, `L`.

```
figure;hold on;grid on;  
title('Plot of  $\Delta U(x,y) = 4x^2+4y^2$ ','Interpreter','latex')  
xlabel('x'); ylabel('y'); zlabel('z');  
surf(x,y,L);  
view(35,14)
```

The graph of L agrees with the analytic result for the Laplacian.

Laplacian of Natural Logarithm Function

Calculate the discrete Laplacian of a natural logarithm function.

Define the x and y domain of the function on a grid of real numbers.

```
[x,y] = meshgrid(-5:5, -5:0.5:5);
```

Define the function $U(x,y) = \frac{1}{2} \log(x^2y)$ over this domain.

```
U = 0.5*log(x.^2.*y);
```

The logarithm is complex-valued when the argument y is negative.

Use `del2` to calculate the discrete Laplacian of this function. Specify the spacing between grid points in each direction.

```
hx = 1;  
hy = 0.5;  
L = 4*del2(U,hx,hy);
```

Analytically, the Laplacian is equal to $\Delta U(x,y) = -\left(\frac{1}{x^2} + \frac{1}{2y^2}\right)$. This function is not defined on the lines $x = 0$ or $y = 0$.

Plot the real parts of U and L on the same graph.

```
figure;hold on;grid on;  
title('Plot of U(x,y) and  $\Delta U(x,y)$ ','Interpreter','latex')  
xlabel('x'); ylabel('y'); zlabel('z');  
surf(x,y,real(L)); surf(x,y,real(U));  
view(41,58)
```

The top surface is U and the bottom surface is L .

Definitions

Laplace's differential operator

If a matrix U is a function $U(x,y)$ that is evaluated at the points of a square grid, then $4*\text{del2}(U)$ is a finite difference approximation of Laplace's differential operator applied to U ,

$$L = \frac{\Delta U}{4} = \frac{1}{4} \left(\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} \right).$$

For functions of more variables, $U(x,y,z,\dots)$, the discrete Laplacian `del2(U)` calculates second-derivatives in each dimension,

$$L = \frac{\Delta U}{2N} = \frac{1}{2N} \left(\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + \frac{\partial^2 U}{\partial z^2} + \dots \right),$$

where N is the number of dimensions in U and $N \geq 2$.

Algorithms

If the input U is a matrix, the interior points of L are found by taking the difference between a point in U and the average of its four neighbors:

$$L_{ij} = \sum_i \sum_j \left[\frac{(u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1})}{4} - u_{i,j} \right].$$

Then, `del2` calculates the values on the edges of L by linearly extrapolating the second differences from the interior. This formula is extended for multidimensional U .

`diff` | `gradient`

DelaunayTri

Superclasses TriRep

Purpose (Will be removed) Delaunay triangulation in 2-D and 3-D

Note DelaunayTri will be removed in a future release. Use delaunayTriangulation instead.

Description DelaunayTri creates a Delaunay triangulation object from a set of points. You can incrementally modify the triangulation by adding or removing points. In 2-D triangulations you can impose edge constraints. You can perform topological and geometric queries, and compute the Voronoi diagram and convex hull.

Definitions The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

Construction DelaunayTri (Will be removed) Construct Delaunay triangulation

Methods

convexHull	(Will be removed) Convex hull
inOutStatus	(Will be removed) Status of triangles in 2-D constrained Delaunay triangulation

incenters	(Will be removed) Incenters of specified simplices
isEdge	(Will be removed) Test if vertices are joined by edge
neighbors	(Will be removed) Simplex neighbor information

DelaunayTri

size	(Will be removed) Size of triangulation matrix
vertexAttachments	(Will be removed) Return simplices attached to specified vertices

Properties

Constraints	<p>Constraints is a numc-by-2 matrix that defines the constrained edge data in the triangulation, where numc is the number of constrained edges. Each constrained edge is defined in terms of its endpoint indices into X.</p> <p>The constraints can be specified when the triangulation is constructed or can be imposed afterwards by directly editing the constraints data.</p> <p>This feature is only supported for 2-D triangulations.</p>
X	<p>The dimension of X is mpts-by-ndim, where mpts is the number of points and ndim is the dimension of the space where the points reside. If column vectors of x,y or x,y,z coordinates are used to construct the triangulation, the data is consolidated into a single matrix X.</p>
Triangulation	<p>Triangulation is a matrix representing the set of simplices (triangles or tetrahedra etc.) that make up the triangulation. The matrix is of size mtri-by-nv, where mtri is the number of simplices and nv is the number of vertices per simplex. The triangulation is represented by standard simplex-vertex format; each row specifies a simplex defined by indices into X, where X is the array of point coordinates.</p>

Instance Hierarchy

DelaunayTri is a subclass of TriRep.

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

DelaunayTri

Purpose (Will be removed) Construct Delaunay triangulation

Note DelaunayTri will be removed in a future release. Use delaunayTriangulation instead.

Syntax

```
DT = DelaunayTri()  
DT = DelaunayTri(X)  
DT = DelaunayTri(x,y)  
DT = DelaunayTri(x,y,z)  
DT = DelaunayTri(..., C)
```

Description

DT = DelaunayTri() creates an empty Delaunay triangulation.

DT = DelaunayTri(X), DT = DelaunayTri(x,y) and DT = DelaunayTri(x,y,z) create a Delaunay triangulation from a set of points. The points can be specified as an mpts-by-ndim matrix X, where mpts is the number of points and ndim is the dimension of the space where the points reside, where ndim is 2 or 3. Alternatively, the points can be specified as column vectors (x,y) or (x,y,z) for 2-D and 3-D input.

DT = DelaunayTri(..., C) creates a constrained Delaunay triangulation. The edge constraints C are defined by an numc-by-2 matrix, numc being the number of constrained edges. Each row of C defines a constrained edge in terms of its endpoint indices into the point set X. This feature is only supported for 2-D triangulations.

Definitions

The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

Examples

Compute the Delaunay triangulation of twenty random points located within a unit square.

```
x = rand(20,1);
```

```
y = rand(20,1);  
dt = DelaunayTri(x,y)  
triplot(dt);
```

For more examples, type `help demoDelaunayTri` at the MATLAB command-line prompt.

delaunay

Purpose Delaunay triangulation

Note Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `delaunay`.

Syntax

```
TRI = delaunay(X,Y)
TRI = delaunay(X,Y,Z)
TRI = delaunay(X)
```

Definitions `delaunay` creates a Delaunay triangulation of a set of points in 2-D or 3-D space. A 2-D Delaunay triangulation ensures that the circumcircle associated with each triangle contains no other point in its interior. This definition extends naturally to higher dimensions.

Description `TRI = delaunay(X,Y)` creates a 2-D Delaunay triangulation of the points (X,Y) , where X and Y are column-vectors. `TRI` is a matrix representing the set of triangles that make up the triangulation. The matrix is of size `mtri-by-3`, where `mtri` is the number of triangles. Each row of `TRI` specifies a triangle defined by indices with respect to the points.

`TRI = delaunay(X,Y,Z)` creates a 3-D Delaunay triangulation of the points (X,Y,Z) , where X , Y , and Z are column-vectors. `TRI` is a matrix

representing the set of tetrahedra that make up the triangulation. The matrix is of size `mtri-by-4`, where `mtri` is the number of tetrahedra. Each row of `TRI` specifies a tetrahedron defined by indices with respect to the points.

`TRI = delaunay(X)` creates a 2-D or 3-D Delaunay triangulation from the point coordinates `X`. This variant supports the definition of points in matrix format. `X` is of size `mpts-by-ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, $2 \leq \text{ndim} \leq 3$. The output triangulation is equivalent to that of the dedicated functions supporting the 2-input or 3-input calling syntax.

`delaunay` produces an isolated triangulation, useful for applications like plotting surfaces via the `trisurf` function. If you wish to query the triangulation; for example, to perform nearest neighbor, point location, or topology queries, use `delaunayTriangulation` instead.

Visualization

Use one of these functions to plot the output of `delaunay`:

- | | |
|----------------------|--|
| <code>triplot</code> | Displays the triangles defined in the <code>m-by-3</code> matrix <code>TRI</code> . |
| <code>trisurf</code> | Displays each triangle defined in the <code>m-by-3</code> matrix <code>TRI</code> as a surface in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example |

```
trisurf(TRI,x,y,zeros(size(x)))
```

delaunay

`trimesh` Displays each triangle defined in the m-by-3 matrix TRI as a mesh in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example,

```
trimesh(TRI,x,y,zeros(size(x)))
```

produces almost the same result as `triplot`, except in 3-D space.

`tetramesh` Plots a triangulation composed of tetrahedra.

Examples

Plot Delaunay Triangulation

Plot the Delaunay triangulation of a large dataset.

```
load seamount
tri = delaunay(x,y);
trisurf(tri,x,y,z);
```

delaunayn

Purpose N-D Delaunay triangulation

Syntax `T = delaunayn(X)`
`T = delaunayn(X, options)`

Description `T = delaunayn(X)` computes a set of simplices such that no data points of `X` are contained in any circumspheres of the simplices. The set of simplices forms the Delaunay triangulation. `X` is an `m`-by-`n` array representing `m` points in `n`-dimensional space. `T` is a `numt`-by-`(n+1)` array where each row contains the indices into `X` of the vertices of the corresponding simplex.

`T = delaunayn(X, options)` specifies a cell array of strings options. The default options are:

- `{'Qt', 'Qbb', 'Qc'}` for 2- and 3-dimensional input
- `{'Qt', 'Qbb', 'Qc', 'Qx'}` for 4 and higher-dimensional input

If options is `[]`, the default options used. If options is `{''}`, no options are used, not even the default.

Visualization Plotting the output of `delaunayn` depends of the value of `n`:

- For `n = 2`, use `triplot`, `trisurf`, or `trimesh` as you would for `delaunay`.
- For `n = 3`, use `tetramesh`.

For more control over the color of the facets, use `patch` to plot the output.

- You cannot plot `delaunayn` output for `n > 3`.

Examples **3-D Delaunay Triangulation**

This example generates an `n`-dimensional Delaunay triangulation, where `n = 3`.

```
d = [-1 1];  
[x,y,z] = meshgrid(d,d,d); % A cube
```

```
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
X = [x(:) y(:) z(:)];
Tes = delaunayn(X)
```

Tes =

4	3	9	1
4	9	2	1
7	9	3	1
7	5	9	1
7	9	4	3
7	8	4	9
6	2	9	1
6	9	5	1
6	4	9	2
6	4	8	9
6	9	7	5
6	8	7	9

You can use `tetramesh` to visualize the tetrahedrons that form the corresponding simplex. `camorbit` rotates the camera position to provide a meaningful view of the figure.

```
tetramesh(Tes,X);camorbit(20,0)
```

del aunayn

Superclasses triangulation

Purpose Delaunay triangulation in 2-D and 3-D

Description Use the `delaunayTriangulation` class to create a 2-D or 3-D triangulation from a set of points. When your points are in 2-D, you can specify edge constraints .

You can perform a variety of topological and geometric queries on a `delaunayTriangulation`, including any triangulation query. For example, locate a facet that contains a specific point, find the vertices of the convex hull, or compute the Voronoi Diagram.

Construction `DT = delaunayTriangulation(P)` creates a Delaunay triangulation from the points in `P`. Matrix `P` has 2 or 3 columns, depending on whether your points are in 2-D or 3-D space.

`DT = delaunayTriangulation(P,C)` specifies the edge constraints in matrix `C`. In this case, `P` specifies points in 2-D. Each row of `C` defines the start and end vertex IDs of a constrained edge.

`DT = delaunayTriangulation(x,y)` creates a 2-D Delaunay triangulation from the point coordinates in the column vectors, `x` and `y`.

`DT = delaunayTriangulation(x,y,C)` specifies the edge constraints in matrix `C`.

`DT = delaunayTriangulation(x,y,z)` creates a 3-D Delaunay triangulation from the point coordinates in the column vectors, `x`, `y`, and `z`.

`DT = delaunayTriangulation()` creates an empty Delaunay triangulation.

Input Arguments

P

del aunayTriangulation

Input points, specified as a matrix whose columns are the x , y , (and possibly z) coordinates of the triangulation points. The row numbers of P are the vertex IDs in the triangulation.

x

x -coordinates vector, specified as a column vector containing the x -coordinates of the triangulation points.

y

y -coordinates vector, specified as a column vector containing the y -coordinates of the triangulation points.

z

z -coordinates vector, specified as a column vector containing the z -coordinates of the triangulation points.

C

Vertex IDs of constrained edges, specified as a 2-column matrix. Each row of C corresponds to a constrained edge and contains two IDs:

- $C(j, 1)$ is the ID of the vertex at the start of an edge.
- $C(j, 2)$ is the ID of the vertex at end of the edge.

You can specify edge constraints for 2-D triangulations only.

Properties

Points

Points in the triangulation, represented as a matrix containing the following information:

- Each row in $DT.Points$ contains the coordinates of a vertex.
- Each row number of $DT.Points$ is a vertex ID.

ConnectivityList

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `DT.ConnectivityList` is a “Triangle or Tetrahedron ID” on page 1-1669.
- Each element is a vertex ID.

Constraints

Constrained edges, represented as a two-column matrix of vertex IDs. Each row of `DT.Constraints` corresponds to a constrained edge and contains two IDs:

- `DT.Constraints(j,1)` is the ID of the vertex at the start of an edge.
- `DT.Constraints(j,2)` is the ID of the vertex at end of the edge.

`DT.Constraints` is an empty matrix when the triangulation has no constrained edges.

Methods

<code>convexHull</code>	Convex hull
<code>isInterior</code>	Test if triangle is in interior of 2-D constrained Delaunay triangulation
<code>nearestNeighbor</code>	Vertex closest to specified location
<code>pointLocation</code>	Triangle or tetrahedron containing specified location
<code>voronoiDiagram</code>	Voronoi diagram

deLaunayTriangulation

Inherited Methods

barycentricToCartesian	Converts point coordinates from barycentric to Cartesian
cartesianToBarycentric	Converts point coordinates from Cartesian to barycentric
circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
neighbors	Neighbors to specified triangle or tetrahedron
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex
vertexNormal	Triangulation vertex normal

Definitions

Delaunay Triangulation

In a 2-D Delaunay triangulation, the circumcircle associated with each triangle does not contain any points in its interior. Similarly, a 3-D Delaunay triangulation does not have any points in the interior of the circumsphere associated with each tetrahedron. This definition extends to N-D, although `delaunayTriangulation` supports only 2-D and 3-D.

Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

Triangle or Tetrahedron ID

A row number of the matrix, `DT.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

Examples

2-D Delaunay Triangulation

Create a 2-D `delaunayTriangulation` for 30 random points.

```
P = gallery('uniformdata',[30 2],0);  
DT = delaunayTriangulation(P)
```

```
DT =
```

```
delaunayTriangulation with properties:
```

```
    Points: [30x2 double]  
ConnectivityList: [50x3 double]  
    Constraints: []
```

Plot the triangulation.

delaunayTriangulation

```
figure  
triplot(DT)
```

3-D Delaunay Triangulation

Create a 3-D delaunayTriangulation for 30 random points.

```
x = gallery('uniformdata',[30 1],0);  
y = gallery('uniformdata',[30 1],1);  
z = gallery('uniformdata',[30 1],2);
```

```
DT = delaunayTriangulation(x,y,z)
```

```
DT =
```

```
delaunayTriangulation with properties:
```

```
    Points: [30x3 double]  
ConnectivityList: [111x4 double]  
    Constraints: []
```

Plot the triangulation at 30% opacity with a light blue face color.

```
faceColor = [0.6875 0.8750 0.8984];  
figure  
tetramesh(DT, 'FaceColor', faceColor, 'FaceAlpha', 0.3);
```

Purpose	Convex hull
Syntax	$K = \text{convexHull}(DT)$ $[K,v] = \text{convexHull}(DT)$
Description	$K = \text{convexHull}(DT)$ returns the vertices of the convex hull. $[K,v] = \text{convexHull}(DT)$ also returns the area or volume bounded by the convex hull.
Input Arguments	DT A Delaunay triangulation, see <code>delaunayTriangulation</code> .
Output Arguments	K Convex hull vertices, returned as a matrix of vertex IDs. The shape of K depends on whether your triangulation is 2-D or 3-D: <ul style="list-style-type: none">• When DT is 2-D, K is a column vector containing the sequence of vertex IDs around the convex hull.• When DT is 3-D, K is a triangulation connectivity list containing the triangles on the convex hull.
	v Area or volume bounded by the convex hull, returned as a scalar value.
Definitions	Vertex ID A row number of the matrix, <code>DT.Points</code> . Use this ID to refer a specific vertex in the triangulation.
Examples	Convex Hull in 2-D Space Create a Delaunay triangulation from a set of random points.

delaunayTriangulation.convexHull

```
x = gallery('uniformdata',[10,1],0);  
y = gallery('uniformdata',[10,1],1);  
DT = delaunayTriangulation(x,y);
```

Calculate the convex hull.

```
k = convexHull(DT)
```

```
k =
```

```
1  
3  
2  
8  
9  
1
```

Plot the points and highlight the convex hull in red.

```
plot(DT.Points(:,1),DT.Points(:,2), '.','markersize',10);  
hold on;  
plot(DT.Points(k,1),DT.Points(k,2), 'r');  
hold off;
```

Convex Hull in 3-D Space

Use `convexHull` to calculate the convex hull of a set of random points within a unit cube.

Create a Delaunay triangulation from a set of random points.

```
P = gallery('uniformdata',[25,3],1);  
DT = delaunayTriangulation(P);
```

del aunayTriangulation.convexHull

Calculate the convex hull and the volume bounded by the convex hull.

```
[K,v] = convexHull(DT);
```

Examine the volume.

```
v
```

```
v =
```

```
0.3561
```

Plot the convex hull.

```
trisurf(K,DT.Points(:,1),DT.Points(:,2),DT.Points(:,3),...  
        'FaceColor','cyan')
```

See Also

delaunayTriangulation.isInterior

Purpose Test if triangle is in interior of 2-D constrained Delaunay triangulation

Syntax `tf = isInterior(DT)`

Description `tf = isInterior(DT)` returns an array of logical values that indicate whether the triangles in a constrained Delaunay triangulation are inside the bounded geometric domain. A triangle, `DT.ConnectivityList(j, :)`, is classified as inside the domain when `tf(j)` is true. Otherwise, the triangle is outside the domain.

Input Arguments **DT**
A 2-D `delaunayTriangulation` that has a set of constrained edges that define a bounded geometric domain.

Output Arguments **tf**
Logical values, returned as a column vector. Element `tf(j)` is true when the triangle whose ID is `j` is inside the domain of `DT`.

Definitions **Triangle ID**
A row number of the matrix, `DT.ConnectivityList`. You use this ID to refer a specific triangle.

Examples **Find and Plot Triangles within a Boundary**

Create a geometric domain whose shape is a square frame.

```
outerprofile = [-5 -5; -3 -5; -1 -5; 1 -5;  
               3 -5; 5 -5; 5 -3; 5 -1;  
               5 1; 5 3; 5 5; 3 5;  
               1 5; -1 5; -3 5; -5 5;  
               -5 3; -5 1; -5 -1; -5 -3];
```

```
innerprofile = outerprofile.*0.5;  
profile = [outerprofile; innerprofile];
```

Define the edge constraints.

```
outercons = [(1:19)' (2:20)'; 20 1;];  
innercons = [(21:39)' (22:40)'; 40 21];  
C = [outercons; innercons];
```

Create the constrained Delaunay triangulation.

```
DT = delaunayTriangulation(profile,C);
```

Plot the triangulation.

```
subplot(1,2,1);  
triplot(DT);
```

```
% Highlight the inner square in red.
```

```
hold on;  
plot(DT.Points(innercons',1),DT.Points(innercons',2),...  
      '-r','LineWidth',2);
```

```
% Highlight the outer square in red and resize the |x| and |y| axes to  
% the plot square.
```

```
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...  
      '-r','LineWidth', 2);  
axis equal;
```

```
% Plot only the triangles that lie inside of the domain.
```

```
hold off;  
subplot(1,2,2);  
inside = isInterior(DT);  
triplot(DT.ConnectivityList(inside, :),DT.Points(:,1),DT.Points(:,2));
```

```
% Highlight the inner and outer squares in red.
```

```
hold on;  
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...  
      '-r','LineWidth', 2);  
plot(DT.Points(innercons',1),DT.Points(innercons',2), ...  
      '-r','LineWidth', 2);
```

delunayTriangulation.isInterior

```
axis equal;  
hold off;
```

See Also [triangulation](#)

delaunayTriangulation.nearestNeighbor

Purpose

Vertex closest to specified location

Syntax

```
vi = nearestNeighbor(DT,QP)
vi = nearestNeighbor(DT,qx,qy)
vi = nearestNeighbor(DT,qx,qy,qz)
[vi,d] = nearestNeighbor( ___ )
```

Description

`vi = nearestNeighbor(DT,QP)` returns the IDs of the vertices closest to the query points in `QP`. Each row in matrix `QP` contains the x , y , (and possibly z) coordinates of a query point.

`vi = nearestNeighbor(DT,qx,qy)` specifies the x and y coordinates of the query points in 2-D as separate column vectors.

`vi = nearestNeighbor(DT,qx,qy,qz)` specifies the x , y , and z coordinates of the query points in 3-D as separate column vectors.

`[vi,d] = nearestNeighbor(___)` also returns the Euclidean distance between each query point and its nearest neighbor. You can specify both output arguments with any of the previous syntaxes.

`nearestNeighbor` does not support constrained Delaunay triangulations.

Input Arguments

DT

A Delaunay triangulation, see `delaunayTriangulation`.

QP

Query points, specified as a matrix whose columns are the x , y , (and possibly z) coordinates of the points to query.

qx

Query x -coordinates, specified as a column vector containing the x -coordinates of the points to query.

qy

Query y -coordinates, specified as a column vector containing the y -coordinates of the points to query.

delaunayTriangulation.nearestNeighbor

Output Arguments

qz

Query z -coordinates, specified as a column vector containing the z -coordinates of the points to query.

vi

Vertex IDs of nearest neighbor, returned as a column vector. $vi(j)$ is the “Vertex ID” on page 1-1682 of the nearest neighbor to the query point $QP(j)$.

d

Distance to nearest neighbor, returned as a column vector the same length as vi . Each value in d is the Euclidean distance between a query point and its nearest neighbor.

Definitions

Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Nearest Neighbors of Query Points in 2-D

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);  
y = gallery('uniformdata',[20 1],1);  
DT = delaunayTriangulation(x,y);
```

Define two query points.

```
QP = [0.25 0.25; 0.5 0.5];
```

Find the nearest neighbors to the query points and the distances between them.

```
[vi,d] = nearestNeighbor(DT,QP);
```

Examine the vertex IDs of the nearest neighbors.

```
vi
```

```
vi =
```

```
    10  
     4
```

Examine the coordinates of the nearest neighbors.

```
DT.Points(vi,:)
```

```
ans =
```

```
    0.4447    0.3759  
    0.4860    0.5982
```

Examine the Euclidean distance between each query point and its nearest neighbor.

```
d
```

```
d =
```

```
    0.2319  
    0.0992
```

[triangulation](#) | [pointLocation](#)

delaunayTriangulation.pointLocation

Purpose Triangle or tetrahedron containing specified location

Syntax

```
ti = pointLocation(DT,QP)
ti = pointLocation(DT,qx,qy)
ti = pointLocation(DT,qx,qy,qz)
[ti,B] = pointLocation( __ )
```

Description

`ti = pointLocation(DT,QP)` returns the enclosing triangles or tetrahedra for each query point in `QP`. Each row in matrix `QP` contains the x , y , (and possibly z) coordinates of a query point.

`ti = pointLocation(DT,qx,qy)` specifies the x and y coordinates of the query points in 2-D as separate column vectors.

`ti = pointLocation(DT,qx,qy,qz)` specifies the x , y , z coordinates of the query points in 3-D as separate column vectors.

`[ti,B] = pointLocation(__)` also returns the barycentric coordinates of each query point with respect to its enclosing triangle or tetrahedron. You can specify both output arguments with any of the previous syntaxes.

Input Arguments

DT

A Delaunay triangulation, see `delaunayTriangulation`.

QP

Query points, specified as a matrix whose columns are the x , y , (and possibly z) coordinates of the points to query.

qx

Query x -coordinates, specified as a column vector containing the x -coordinates of the points to query.

qy

Query y -coordinates, specified as a column vector containing the y -coordinates of the points to query.

qz

Query z -coordinates, specified as a column vector containing the z -coordinates of the points to query.

Output Arguments

ti

IDs of enclosing triangles or tetrahedra, returned as a column vector. Each element in **ti** is the ID of a triangle or tetrahedron that encloses a query point. **ti(k)** encloses the k th query point.

pointLocation returns NaN values for any points outside the convex hull.

B

Barycentric coordinates, returned as matrix. The values at **B(j, :)** are the barycentric coordinates of the j th query point with respect to **ti(j)**.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, **DT.ConnectivityList**. Use this ID to refer a specific triangle or tetrahedron.

Examples

Find Enclosing Triangles in 2-D

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);  
y = gallery('uniformdata',[20 1],1);  
DT = delaunayTriangulation(x,y);
```

Define two query points.

```
QP = [0.25 0.25; 0.5 0.5];
```

Find the IDs of the enclosing triangles for each query point.

```
ti = pointLocation(DT,QP)
```

```
ti =
```

delaunayTriangulation.pointLocation

```
8  
7
```

Examine the connectivity of the enclosing triangles.

```
DT.ConnectivityList(ti,:)
```

```
ans =
```

```
19    15    8  
4     10    6
```

Find Enclosing Tetrahedra and Barycentric Coordinates in 3-D

Create a 3-D Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);  
y = gallery('uniformdata',[20 1],1);  
z = gallery('uniformdata',[20 1],2);  
DT = delaunayTriangulation(x,y,z);
```

Find the tetrahedra that enclose the query points and calculate the barycentric coordinates of the query points.

```

See Also `triangulation | nearestNeighbor`

delaunayTriangulation.voronoiDiagram

Purpose Voronoi diagram

Syntax `[V,R] = voronoiDiagram(DT)`

Description `[V,R] = voronoiDiagram(DT)` returns the Voronoi vertices, `V`, and the Voronoi regions, `R`, of the points, `DT.Points`.

The *Voronoi diagram* of a set of points, such as `DT.Points`, decomposes the space around each point, `DT.Points(j,:)`, into a region of influence, `R{j}`. Locations within the region, `R{j}`, are closer to point `j` than any other point in `DT.Points`. The region of influence is called the *Voronoi region*. The collection of all the Voronoi regions is the Voronoi diagram.

The Voronoi regions associated with points that lie on the convex hull of `DT.Points` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

Input Arguments

DT
A Delaunay triangulation, see `delaunayTriangulation`.

Output Arguments

V
Voronoi vertices, returned as a matrix. Each row of `V` contains the coordinates of a Voronoi vertex.

R
Voronoi regions, returned as a vector cell array the same length as `DT.Points`. The elements of `R` are row numbers of `V`. The coordinates of the Voronoi vertices bounding a region are `V(R{j},:)`. The Voronoi region associated with the point `DT.Points(j)` is `R{j}`.

Examples

Compute the Voronoi Diagram of a 2-D Triangulation

Create a Delaunay triangulation from a set of points.

```
P = [ 0.5    0
      0     0.5
```

delaunayTriangulation.voronoiDiagram

```
        -0.5  -0.5  
        -0.2  -0.1  
        -0.1   0.1  
         0.1  -0.1  
         0.1   0.1 ];  
DT = delaunayTriangulation(P);
```

Calculate the Voronoi vertices and regions.

```
[V,R] = voronoiDiagram(DT);
```

Examine the connectivity of the Voronoi region associated with the third point in the triangulation.

```
R{3}
```

```
ans =
```

```
     1     10     7     4
```

Examine the coordinates of the Voronoi vertices bounding the region.

```
V(R{3},:)
```

```
ans =
```

```
      Inf      Inf  
    0.7000   -1.6500  
   -0.0500   -0.5250  
   -1.7500    0.7500
```

The Inf values indicate that the region contains points on the convex hull.

[triangulation](#) | [convexHull](#) | [voronoi](#) | [voronoin](#)

delete

Purpose Remove files or objects

Syntax

```
delete('fileName1', 'filename2', ...)  
delete(h)  
delete(handle_array)  
delete fileName
```

Description

`delete('fileName1', 'filename2', ...)` deletes the files `fileName1`, `fileName2`, and so on, from the disk. `fileName` is a string and can be an absolute path or a path relative to the current folder. `fileName` also can include wildcards (*).

`delete(h)` deletes the graphics object with handle `h`. `h` can also be a vector or matrix of handles. Delete multiple objects by appending their handles as additional arguments, separated by commas. The function deletes objects without requesting verification, even if when they are windows.

`delete(handle_array)` is a method of the `handle` class. It removes from memory the handle objects referenced by `handle_array`.

When deleted, any references to the objects in `handle_array` become invalid. To remove the handle variables, use the `clear` function.

`delete fileName` is the command syntax. Delete multiple files by appending filenames, separated by spaces. When filenames contain space characters, you must use the functional form.

As `delete` does not ask for confirmation, to avoid accidentally losing files or graphics objects, make sure to specify accurately the items to delete. To move files to a different location when running `delete`, use the **General** preference for **Deleting files**, or the `recycle` function.

The `delete` function deletes files and graphics objects only. To delete folders, use `rmdir`.

Examples Delete all files with a `.mat` extension in the `../mytests/` folder:

```
delete('../mytests/*.mat')
```

Create a figure and an axes, and then delete the axes:

```
hf = figure, ha = axes
```

```
hf =  
    1
```

```
ha =  
    170.0332
```

```
delete(ha)
```

The axes is deleted, but the figure remain. The axes handle `ha` remains in the workspace but no longer points to an object.

See Also

`dir` | `recycle` | `rmdir`

How To

-
- “Specify File Names”
- “Deleted Handle Objects”

delete (COM)

Purpose Remove COM control or server

Syntax h.delete
delete(h)

Description h.delete releases all interfaces derived from the specified COM server or control, and then deletes the server or control itself. This is different from releasing an interface, which releases and invalidates only that interface.

delete(h) is an alternate syntax.

Tips COM functions are available on Microsoft Windows systems only.

See Also release | save (COM) | load (COM) | actxcontrol | actxserver

Purpose Remove file on FTP server

Syntax `delete(ftpobj, filename)`

Description `delete(ftpobj, filename)` removes the specified file from the current folder on the FTP server associated with `ftpobj`.

Input Arguments

ftpobj
FTP object created by `ftp`.

filename
String enclosed in single quotation marks that specifies the name of the file to delete.

Examples Suppose that a hypothetical host, `ftp.testsite.com`, contains `myfile.m`. Connect to the server and delete the file:

```
test=ftp('ftp.testsite.com');  
delete(test, 'myfile.m');
```

See Also `rmdir` | `ftp`

delete (handle)

Purpose Handle object destructor

Syntax `delete(h)`

Description `delete(h)` deletes a handle object, but does not clear the handle variable from the workspace. The handle variable is not valid once the handle object has been deleted.

A subclass of `handle` can implement a method named `delete` to perform cleanup tasks just before MATLAB destroys the handle object. MATLAB calls the `delete` method of any handle object (if it exists) when the object is destroyed. `h` is a scalar handle object.

A `delete` method should not generate errors or create new handles to the object being destroyed. If the `delete` method has a different signature (having output arguments or more than one input argument) it is not called when the handle objects is destroyed. See “Handle Class Destructor” information on defining destructors for `handle` subclasses.

See Also `handle` | `(handle) isvalid`

Purpose Remove serial port object from memory

Syntax `delete(obj)`

Description `delete(obj)` removes `obj` from memory, where `obj` is a serial port object or an array of serial port objects.

Tips When you delete `obj`, it becomes an *invalid* object. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command. If multiple references to `obj` exist in the workspace, then deleting one reference invalidates the remaining references.

If `obj` is connected to the device, it has a `Status` property value of `open`. If you issue `delete` while `obj` is connected, then the connection is automatically broken. You can also disconnect `obj` from the device with the `fclose` function.

Examples This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, disconnects `s` from the device, removes `s` from memory using `delete`, and then removes `s` from the workspace using `clear`.

```
s = serial('COM1');  
fopen(s)  
fprintf(s, '*IDN?')  
idn = fscanf(s);  
fclose(s)  
delete(s)  
clear s
```

See Also `clear` | `fclose` | `isvalid` | `Status`

deleteproperty

Purpose Remove custom property from COM object

Syntax `h.deleteproperty('propertyname')`
`deleteproperty(h,'propertyname')`

Description `h.deleteproperty('propertyname')` deletes the property specified in the string `propertyname` from the custom properties belonging to object or interface `h`.

`deleteproperty(h,'propertyname')` is an alternate syntax.

You can only delete properties created with the `addproperty` function.

COM functions are available on Microsoft Windows systems only.

Examples Remove a custom property from an instance of the MATLAB sample control:

1 Create an instance of the control:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.get
```

MATLAB displays its properties:

```
Label: 'Label'
Radius: 20
```

2 Add a custom property named `Position` and assign a value:

```
h.addproperty('Position');
h.Position = [200 120];
h.get
```

MATLAB displays (in part):

```
Label: 'Label'
Radius: 20
```

```
Position: [200 120]
```

3 Delete the custom property Position:

```
h.deleteproperty('Position');  
h.get
```

MATLAB displays the original list of properties:

```
Label: 'Label'  
Radius: 20
```

See Also

[addproperty](#) | [get \(COM\)](#) | [set \(COM\)](#) | [inspect](#)

delevent

Purpose Remove `tsdata.event` objects from `timeseries` object

Syntax

```
ts = delevent(ts,event)
ts = delevent(ts,events)
ts = delevent(ts,event,n)
```

Description

`ts = delevent(ts,event)` removes the `tsdata.event` object from the `ts.events` property, where `event` is an event name string.

`ts = delevent(ts,events)` removes the `tsdata.event` object from the `ts.events` property, where `events` is a cell array of event name strings.

`ts = delevent(ts,event,n)` removes the `n`th `tsdata.event` object from the `ts.events` property. `event` is the name of the `tsdata.event` object.

Examples The following example shows how to remove an event from a `timeseries` object:

1 Create a time series.

```
ts = timeseries(rand(5,4))
```

2 Create an event object called 'test' such that the event occurs at time 3.

```
e = tsdata.event('test',3)
```

3 Add the event object to the time series `ts`.

```
ts = addevent(ts,e)
```

4 Remove the event object from the time series `ts`.

```
ts = delevent(ts,'test')
```

See Also `addevent` | `timeseries` | `tsdata.event`

Purpose Remove sample from tscollection object

Syntax
`tsc = delsamplefromcollection(tsc, 'Index', N)`
`tsc = delsamplefromcollection(tsc, 'Value', Time)`

Description `tsc = delsamplefromcollection(tsc, 'Index', N)` deletes samples from the `tscollection` object `tsc`. `N` specifies the indices of the `tsc` time vector that correspond to the samples you want to delete.

`tsc = delsamplefromcollection(tsc, 'Value', Time)` deletes samples from the `tscollection` object `tsc`. `Time` specifies the time values that correspond to the samples you want to delete.

See Also `addsampletocollection` | `tscollection`

demo

Purpose Access product examples in Help browser

Syntax
demo
demo type
demo type name

Description demo displays the list of MATLAB examples in the Help browser.

demo type lists the examples for the specified product. Valid values for type are matlab or simulink.

demo type name lists the examples for products other than MATLAB or Simulink. Valid values for type include matlab, simulink, toolbox, or blockset.

Input Arguments

type - Product name or type
matlab (default) | simulink | toolbox | blockset

Product name or type, specified as one of these strings: matlab, simulink, toolbox, or blockset. For products other than MATLAB or Simulink, you must also specify a name input that corresponds to the product name.

name - Product name other than MATLAB or Simulink
string

Product name other than MATLAB or Simulink, specified as a string. If name requires multiple words, enclose it in single quotes.

On non-English systems, name sometimes uses the localized language.

Examples

MATLAB Examples

```
demo matlab
```

Statistics Toolbox™ Examples

```
demo toolbox statistics
```

Communications System Toolbox™ Examples

```
demo toolbox 'communications system'
```

Simulink Control Design™ Examples

```
demo simulink 'simulink control design'
```

Tips

- To access third-party and custom examples without using the demo command, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

depdir

Purpose

List dependent folders for function or P-file

Note `depdir` will be removed in a future release. Use `matlab.codetools.requiredFilesAndProducts` instead.

Syntax

```
list = depdir('file_name')  
[list, prob_files, prob_sym, prob_strings] = depdir('file_name')  
[...] = depdir('file_name1', 'file_name2',...)
```

Description

The `depdir` function lists the folders of all the functions that a specified function or P-file needs to operate. This function is useful for finding all the folders that need to be included with a run-time application and for determining the run-time path.

`list = depdir('file_name')` creates a cell array of strings containing the folders of all the function and P-files that `file_name.m` or `file_name.p` uses. This includes the second-level files that are called directly by `file_name`, as well as the third-level files that are called by the second-level files, and so on.

`[list, prob_files, prob_sym, prob_strings] = depdir('file_name')` creates three additional cell arrays containing information about any problems with the `depdir` search. `prob_files` contains filenames that `depdir` was unable to parse. `prob_sym` contains symbols that `depdir` was unable to find. `prob_strings` contains callback strings that `depdir` was unable to parse.

`[...] = depdir('file_name1', 'file_name2',...)` performs the same operation for multiple files. The dependent folders of all files are listed together in the output cell arrays.

Examples

```
list = depdir('mesh')
```

See Also

`matlab.codetools.requiredFilesAndProducts`

- Purpose** List dependencies of function or P-file
- Compatibility** depfun will be removed in a future release. Use `matlab.codetools.requiredFilesAndProducts` instead.
- Syntax**
- ```
list = depfun(fun)
[list,builtins] = depfun(fun)
[list,builtins,classes] = depfun(fun)
[list,builtins,classes,prob_files] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings]
= depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,
called_from] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,called_from,
opaque_classes] = depfun(fun)

___ = depfun(fun1,...,funN)

___ = depfun(___,option1,...,optionM)
```
- Description** `list = depfun(fun)` returns the paths of MATLAB program files that `fun` requires to run, where `fun` is a function, a P-file, or a figure file for a user interface. The output `list` includes second-level functions that `fun` calls directly, functions that the second-level functions call, and so on. The `depfun` function also displays a report in the Command Window.

---

**Note**

- `depfun` does not always list all dependent files. For example, `depfun` does not list files hidden in callbacks or files whose names are constructed dynamically for evaluation.
  - The output list often includes extra files that are not called when the function is actually evaluated.
  - If `depfun` returns a parse error for any of the required functions, then the rest of the output of `depfun` might be incomplete. Correct the problematic files and invoke `depfun` again.
- 

`[list,builtins] = depfun(fun)` returns the built-in functions that `fun` requires.

`[list,builtins,classes] = depfun(fun)` returns the MATLAB classes that `fun` requires.

`[list,builtins,classes,prob_files] = depfun(fun)` returns the files that `depfun` cannot parse, find, or access. If there are problematic files (that is, if `prob_files` is not empty), then the rest of the output of `depfun` might be incomplete. Correct the problematic files, and then invoke `depfun` again.

`[list,builtins,classes,prob_files,~,eval_strings] = depfun(fun)` returns a list of files that contain calls to `eval` or related functions (`evalin`, `feval`, or `evalc`). These calls potentially use functions that are not in `list`.

The fifth output argument for `depfun` is not implemented, and returns an empty structure array. To request arguments later in the list, use the tilde symbol (`~`) as a placeholder. The tilde suppresses the creation of an extra, empty variable.

`[list,builtins,classes,prob_files,~,eval_strings,called_from] = depfun(fun)` returns a cell array of indices that maps each function in `list` to the set of functions that call it. That is, `list{called_from{k}}` returns the paths to the functions that call the function in `list{k}`.

`[list,builtins,classes,prob_files,~,eval_strings,called_from,opaque_classes] = depfun(fun)` returns the opaque classes that `fun` requires, such as Java or COM classes.

`___ = depfun(fun1,...,funN)` returns the functions required for multiple functions `fun1,...,funN`. You can request any of the outputs from the previous syntaxes.

`___ = depfun(___,option1,...,optionM)` modifies the output as described by the specified options. For example, specify `'-toponly'` to list only the functions that `fun` calls directly. You can precede the options with one or more function names.

## Input Arguments

### **fun - Function name**

string | cell array of strings

Function name, specified as a string or a cell array of strings.

`fun` must be on the MATLAB path, as determined by the `which` function. If the path contains any relative folders, then files in those folders also will have a relative path in the output.

**Example:** `'plot.m'`

**Example:** `'plot.m','mesh.m'`

**Example:** `{'plot.m','mesh.m'}`

### **Data Types**

char | cell

### **option - Reporting option**

'-toponly' | '-verbose' | '-quiet' | '-print' | ...

Reporting option, specified as one of the following strings.

| Option             | Description                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| '-toponly'         | Identify only the files used directly by the specified function(s), fun.                                                                                                                 |
| '-verbose'         | Display additional internal messages.                                                                                                                                                    |
| '-quiet'           | Display only error and warning messages, and not a summary report.                                                                                                                       |
| '-print', filename | Print a full report to the specified file.                                                                                                                                               |
| '-all'             | Display all outputs in the report, but return only the specified output arguments.                                                                                                       |
| '-expand'          | Include both indices and full paths in an exported report for the call or called_from list. Requires the '-print' option. This information does not appear in the Command Window report. |
| '-calltree'        | Replaces the called_from list with a list of functions that each file calls, as derived from the called_from list.                                                                       |

**Example:** '-print', 'myreport.txt'

## Data Types

char

## Output Arguments

### list - Paths to required files

cell array of strings

Paths to required files, returned as a cell array of strings.

### builtins - Required MATLAB built-in functions

cell array of strings

Required MATLAB built-in functions, returned as a cell array of strings.

**classes - Required MATLAB classes**

cell array of strings

Required MATLAB classes, returned as a cell array of strings.

**prob\_files - Files that depfun cannot parse or access**

structure

Files that depfun cannot parse or access, returned as a structure with these fields:

- `name` — Path to the file
- `listindex` — Index of the file in `list`
- `errmsg` — Error message that describes the problem
- `errid` — Error identifier, if present

**eval\_strings - Files that call evaluation functions**

cell array of strings

Files that call evaluation functions, returned as a cell array of strings.

**called\_from - Indices to files that call each function in list**

cell array

Indices to files that call each function in `list`, returned as a cell array. Each element of the cell array is a numeric array of indices that correspond to elements in `list`. The `list` and `called_from` outputs have the same length.

**opaque\_classes - Paths to opaque classes**

cell array of strings

Paths to opaque classes, such as Java or COM classes, returned as a cell array of strings.

**Examples****Identify Required Functions**

Identify the MATLAB program files that `strtok.m` requires to run.

```
fun = 'strtok.m';
list = depfun(fun);
```

MATLAB displays a summary report in the Command Window and stores the list of files in variable `list`.

## Identify Top-Level Dependencies Only

List only the program files that `strtok.m` calls directly.

```
fun = 'strtok.m';
list = depfun(fun, '-toponly')
```

```
=====
depfun report summary:(top only)

-> trace list: 2 files (total)
 1 files (total arguments)
 0 files (arguments off MATLABPATH)
 0 files (argument duplicates on MATLABPATH)

Notes: 1. Use argument '-quiet' to not print this summary.
 2. Use arguments '-print','file' to produce a full
 report in file.
 3. Use argument '-all' to display all possible
 left hand side arguments in the report(s).
=====
```

```
list =

 'matlabroot\toolbox\matlab\strfun\strtok.m'
 'matlabroot\toolbox\matlab\strfun\@cell\strtok.m'
```

## Determine Which File Invokes Each Function

One of the functions that `strtok.m` depends upon is `num2cell`. Determine which file in the dependency list calls `num2cell`.

Identify the functions that `strtok.m` requires (`list`) and the files that invoke each of those functions (`called_from`).

```
fun = 'strtok.m';
[list,builtins,classes,prob_files,~,eval_strings,...
 called_from] = depfun(fun);
```

Find the index for `num2cell` within the dependency list.

```
num2cell_path = which('num2cell');
num2cell_index = find(ismember(list,num2cell_path))
```

```
num2cell_index =
 5
```

Identify the file that calls `num2cell`.

```
calls_num2cell = list{called_from{num2cell_index}}
```

```
calls_num2cell =
 matlabroot\toolbox\matlab\elmat\repmat.m
```

## Concepts

- “Identify Program Dependencies”

# det

---

**Purpose** Matrix determinant

**Syntax** `d = det(X)`

**Description** `d = det(X)` returns the determinant of the square matrix `X`.

**Tips** Testing singularity using `abs(det(X)) <= tolerance` is not recommended as it is difficult to choose the correct tolerance. The function `cond(X)` can check for singular and nearly singular matrices.

**Algorithms** The determinant is computed from the triangular factors obtained by Gaussian elimination

```
[L,U] = lu(A)
s = det(L) % This is always +1 or -1
det(A) = s*prod(diag(U))
```

**Examples** The statement `A = [1 2 3; 4 5 6; 7 8 9]` produces

```
A =
 1 2 3
 4 5 6
 7 8 9
```

This happens to be a singular matrix, so `det(A)` produces a very small number. Changing `A(3,3)` with `A(3,3) = 0` turns `A` into a nonsingular matrix. Now `d = det(A)` produces `d = 27`.

**See Also** `cond` | `condest` | `inv` | `lu` | `rref` | `mldivide`

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Purpose</b>         | Display array details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>          | <code>details(A)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b>     | <p><code>details(A)</code> displays detailed information about the array, <code>A</code>.</p> <p>When <code>A</code> is a MATLAB object array, <code>details</code> displays more information than the default display. This information includes:</p> <ul style="list-style-type: none"> <li>• Fully qualified class name, including package names</li> <li>• Link to class documentation</li> <li>• Link to <code>handle</code> class documentation for classes that subclass <code>handle</code></li> <li>• List of all properties that have public get access</li> <li>• List of property values if the array is scalar</li> <li>• Link to list of public methods</li> <li>• Link to list of events</li> <li>• Link to list of all nonhidden superclasses</li> </ul> |
| <b>Input Arguments</b> | <p><b>A - Input array</b><br/> <i>scalar or nonscalar array of any type</i></p> <p>Input array, specified as a scalar or nonscalar array of any type. The <code>details</code> function displays detailed information about this array.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Examples</b>        | <p><b>Display Object Details</b></p> <p>Display object details for a class that overloads its own object display. The <code>details</code> function never calls overloaded display methods. Therefore, you can use this function to obtain information about the object array in all cases.</p> <p>Suppose <code>PolyNom</code> is a class that provides a specialized default display for polynomials. Use <code>details</code> to display information about the object.</p> <p>Create an object using the polynomial coefficients:</p>                                                                                                                                                                                                                                 |

# details

---

```
pn = PolyNom([1,2,3,0,4])
```

The overloaded `disp` method displays the code for evaluating the polynomial:

```
pn =
x^4 + 2*x^3 + 3*x^2 + 4
```

Calling the `details` function provides information about the object:

```
details(pn)
```

`PolyNom` with properties:

```
coef: [1 2 3 0 4]
```

`Methods`

## See Also

`classdef` | `disp` | `display`

**Purpose** Remove linear trends

**Syntax**

```
y = detrend(x)
y = detrend(x, 'constant')
y = detrend(x, 'linear', bp)
```

**Description** `detrend` removes the mean value or linear trend from a vector or matrix, usually for FFT processing.

`y = detrend(x)` removes the best straight-line fit from vector `x` and returns it in `y`. If `x` is a matrix, `detrend` removes the trend from each column.

`y = detrend(x, 'constant')` removes the mean value from vector `x` or, if `x` is a matrix, from each column of the matrix.

`y = detrend(x, 'linear', bp)` removes a continuous, piecewise linear trend from vector `x` or, if `x` is a matrix, from each column of the matrix. Vector `bp` contains the indices of the breakpoints between adjacent linear segments. The breakpoint between two segments is defined as the data point that the two segments share.

`detrend(x, 'linear')`, with no breakpoint vector specified, is the same as `detrend(x)`.

## Examples

```
sig = [0 1 -2 1 0 1 -2 1 0]; % signal with no linear trend
trend = [0 1 2 3 4 3 2 1 0]; % two-segment linear trend
```

# detrend

---

```
x = sig+trend; % signal with added trend
y = detrend(x, 'linear',5) % breakpoint at 5th element

y =

-0.0000
 1.0000
-2.0000
 1.0000
 0.0000
 1.0000
-2.0000
 1.0000
-0.0000
```

Note that the breakpoint is specified to be the fifth element, which is the data point shared by the two segments.

## Algorithms

detrend computes the least-squares fit of a straight line (or composite line for piecewise linear trends) to the data and subtracts the resulting function from the data. To obtain the equation of the straight-line fit, use `polyfit`.

## See Also

`polyfit`

**Purpose** Evaluate solution of differential equation problem

**Syntax**

```
sxint = deval(sol,xint)
sxint = deval(xint,sol)
sxint = deval(sol,xint,idx)
sxint = deval(xint,sol,idx)
[sxint, spxint] = deval(...)
```

**Description** `sxint = deval(sol,xint)` and `sxint = deval(xint,sol)` evaluate the solution of a differential equation problem. `sol` is a structure returned by one of these solvers:

- An initial value problem solver (`ode45`, `ode23`, `ode113`, `ode15s`, `ode23s`, `ode23t`, `ode23tb`, `ode15i`)
- A delay differential equations solver (`dde23`, `ddesd`, or `ddensd`),
- A boundary value problem solver (`bvp4c` or `bvp5c`).

`xint` is a point or a vector of points at which you want the solution. The elements of `xint` must be in the interval `[sol.x(1),sol.x(end)]`. For each `i`, `sxint(:,i)` is the solution at `xint(i)`.

`sxint = deval(sol,xint,idx)` and `sxint = deval(xint,sol,idx)` evaluate as above but return only the solution components with indices listed in the vector `idx`.

`[sxint, spxint] = deval(...)` also returns `spxint`, the value of the first derivative of the polynomial interpolating the solution.

---

**Note** For multipoint boundary value problems, the solution obtained by `bvp4c` or `bvp5c` might be discontinuous at the interfaces. For an interface point `xc`, `deval` returns the average of the limits from the left and right of `xc`. To get the limit values, set the `xint` argument of `deval` to be slightly smaller or slightly larger than `xc`.

---

## Examples

### Evaluate van der Pol Equation

This example solves the system  $y' = \text{vdp1}(t,y)$  using `ode45` and plots the first component of the solution.

Solve the system using `ode45`.

```
sol = ode45(@vdp1,[0 20],[2 0]);
```

Evaluate the first component of the solution at 100 points in the interval `[0,20]`.

```
x = linspace(0,20,100);
y = deval(sol,x,1);
```

Plot the solution.

```
plot(x,y)
```

# diag

---

**Purpose** Get diagonal elements or create diagonal matrix

**Syntax**

```
D = diag(v)
D = diag(v,k)

x = diag(A)
x = diag(A,k)
```

**Description** `D = diag(v)` returns a square diagonal matrix with the elements of vector `v` on the main (`k=0`) diagonal.

`D = diag(v,k)` places the elements of vector `v` on the `k`th diagonal. `k=0` represents the main diagonal, `k>0` is above the main diagonal, and `k<0` is below the main diagonal.

`x = diag(A)` returns a column vector of the main (`k=0`) diagonal elements of `A`.

`x = diag(A,k)` returns a column vector of the elements on the `k`th diagonal of `A`.

## Input Arguments

### **v - Diagonal elements**

vector

Diagonal elements, specified as a vector. If `v` is a vector with `N` elements, then `diag(v,k)` is a square matrix of order `N+abs(k)`.

`diag([])` returns an empty matrix, `[]`.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### **A - Input matrix**

matrix

Input matrix, specified as a matrix. `diag` returns an error if `ndims(A) > 2`.

`diag([])` returns an empty matrix, `[]`.

### Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

**Complex Number Support:** Yes

### k - Diagonal number

integer

Diagonal number, specified as an integer.  $k=0$  represents the main diagonal,  $k>0$  is above the main diagonal, and  $k<0$  is below the main diagonal.

For an  $m$ -by- $n$  matrix,  $k$  is in the range  $(-m+1) \leq k \leq (n-1)$ .

## Examples

### Create Diagonal Matrices

Define a 1-by-5 vector.

```
v = [2 1 -1 -2 -5];
```

Use `diag` to create a matrix with the elements of `v` on the main diagonal.

# diag

---

```
D = diag(v)
```

```
D =
```

```
 2 0 0 0 0
 0 1 0 0 0
 0 0 -1 0 0
 0 0 0 -2 0
 0 0 0 0 -5
```

The result is a 5-by-5 diagonal matrix.

Create a matrix with the elements of `v` on the first super diagonal (`k=1`).

```
D1 = diag(v,1)
```

```
D1 =
```

```
 0 2 0 0 0 0
 0 0 1 0 0 0
 0 0 0 -1 0 0
 0 0 0 0 -2 0
 0 0 0 0 0 -5
 0 0 0 0 0 0
```

The result is a 6-by-6 matrix. When you specify a vector of length `n` as an input, `diag` returns a square matrix of size `n+abs(k)`.

## Get Diagonal Elements

Create a random 6-by-6 matrix.

```
rng(0);
A = randi(10,6)
```

```
A =
```

```
 9 3 10 8 7 8
 10 6 5 10 8 1
```

```
 2 10 9 7 8 3
 10 10 2 1 4 1
 7 2 5 9 7 1
 1 10 10 10 2 9
```

Get the elements on the main diagonal of A.

```
x = diag(A)
```

```
x =
```

```
 9
 6
 9
 1
 7
 9
```

The result is a column vector of the elements on the main diagonal of A.

Get the elements on the first sub diagonal ( $k=-1$ ) of A.

```
x1 = diag(A, -1)
```

```
x1 =
```

```
 10
 10
 2
 9
 2
```

The result has one less element than the main diagonal.

Nest calls to `diag` to generate a new diagonal matrix from the diagonal elements.

```
A1 = diag(diag(A))
```

# diag

---

A1 =

```
 9 0 0 0 0 0
 0 6 0 0 0 0
 0 0 9 0 0 0
 0 0 0 1 0 0
 0 0 0 0 7 0
 0 0 0 0 0 9
```

The result is a square diagonal matrix with the same main diagonal elements as A.

## Tips

- When you specify a vector input, `diag` returns a square diagonal matrix. When you specify a matrix input, `diag` returns a column vector of diagonal elements.
- The trace of a matrix is equal to `sum(diag(A))`.

## Purpose

Summary of classes in MATLAB Diagnostics Interface

## Description

Use diagnostics to communicate relevant information in the event of a failure. To add a diagnostic message to a test case, use the `diagnostic` argument in any of the `matlab.unittest.qualifications` methods. The framework also displays diagnostic messages related to the nature of the qualification failure. The `matlab.unittest.diagnostics` package consists of the following classes:

`matlab.unittest.diagnostics.ConstraintDiagnostic` Diagnostic specific to `matlab.unittest.constraints`

`matlab.unittest.diagnostics.Diagnostic` Fundamental interface class for `matlab.unittest.diagnostics`

`matlab.unittest.diagnostics.DisplayDiagnostic` Diagnostic using a value's displayed output

`matlab.unittest.diagnostics.FunctionHandleDiagnostic` Diagnostic using a function's displayed output

`matlab.unittest.diagnostics.StringDiagnostic` Diagnostic using string

# matlab.unittest.diagnostics.ConstraintDiagnostic

---

**Superclasses** Diagnostic

**Purpose** Diagnostics specific to matlab.unittest constraints

**Description** The ConstraintDiagnostic class provides various textual fields that are common to most constraints. These fields may be turned on or off depending on their applicability.

The ConstraintDiagnostic class is a helper class for displaying diagnostics when using constraints. The ConstraintDiagnostic class provides custom constraint authors a way to add a common look and feel to diagnostics produced by the getDiagnosticFor method of constraints.

Constraint diagnostics are displayed in the following order: Description, Conditions, Actual Value, and Expected Value.

## Properties

### ActVal

The actual value passed to the constraint for testing.

### ActValHeader

Header information for the actual value property, ActVal, specified as a string. The default header is 'Actual Value:'.

### Conditions

Formatted list of conditions, specified as a single string. Each condition starts on a new line and begins with an arrow (-->) delimiter. Conditions are added to the list using the addCondition and addConditionsFrom methods.

### ConditionsCount

Number of conditions in the condition list. This is a read-only property generated from the conditions list. The conditions list is defined in the Conditions property.

### Description

General diagnostic information, specified as a string.

## **DisplayActVal**

Indicator whether to display the actual value property, `ActVal`, specified as a boolean. By default, the actual value is not displayed and the value of this property is `false`.

## **DisplayConditions**

Indicator of whether to display the `Conditions` property, specified as a boolean. By default, the conditions are not displayed and the value of this property is `false`. Even if `DisplayConditions` is set to `true`, if there are no conditions on the conditions list, neither the conditions header or the conditions list are displayed.

## **DisplayDescription**

Indicator of whether to display the `Description` property, specified as a boolean. By default, the description is not displayed and the value of this property is `false`.

## **DisplayExpVal**

Indicator whether to display the expected value property, `ExpVal`, specified as a boolean. By default, the expected value is not displayed and the value of this property is `false`.

## **ExpVal**

If applicable, the expected value. This property can be turned off if the associated constraint does not contain an expected value.

## **ExpValHeader**

Header information for the expected value property, `ExpVal`, specified as a string. The default header is 'Expected Value:'.

## **Inherited Properties**

### **DiagnosticResult**

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of

# matlab.unittest.diagnostics.ConstraintDiagnostic

---

diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Concepts

# matlab.unittest.diagnostics.ConstraintDiagnostic.addCondition

---

**Purpose** Add condition to condition list

**Syntax** `addCondition(diag, cond)`

**Description** `addCondition(diag, cond)` adds the condition, `cond`, to the condition list. Add conditions to the condition list one at a time. When the condition list is displayed, each condition is preceded by an arrow ( - ->) delimiter and indented.

**Input Arguments**

**cond**  
Condition, specified as a string containing information specific to the cause of the constraint failure or another Diagnostic instance, which acts as a “subdiagnostic”.

**diag**  
`matlab.unittest.diagnostics.Diagnostic` instance.

**See Also** `addConditionsFrom`

# matlab.unittest.diagnostics.ConstraintDiagnostic.addCond

**Purpose** Add condition from another ConstraintDiagnostic to condition list

**Syntax** addConditionsFrom(constDiag, otherConstDiag)

**Description** addConditionsFrom(constDiag, otherConstDiag) adds the conditions from the ConstraintDiagnostic instance, constDiag, to the condition list in the Diagnostic instance, diag. This is useful when a constraints composes another constraint, and needs to use the conditions produced in the diagnostics of the composed constraint.

## Input Arguments

### constDiag

Diagnostic to add conditions to, specified as a matlab.unittest.diagnostics.ConstraintDiagnostic instance

### otherConstDiag

Diagnostic to add conditions from, specified as a matlab.unittest.diagnostics.ConstraintDiagnostic instance

## Examples

### Add Conditions from a Constraint

```
% This demonstrates a constraint that composes another constraint
% and uses the addConditionsFrom method to utilize the conditions
% from the composed ConstraintDiagnostic.
classdef IsDouble < matlab.unittest.constraints.Constraint

 properties(Constant, GetAccess=private)
 DoubConst=matlab.unittest.constraints.IsInstanceOf(?double)
 end

 methods
 function tf = satisfiedBy(constraint, actual)
 tf = constraint.DoubConst.satisfiedBy(actual);
 end
 function diag = getDiagnosticFor(constraint, actual)
```

# matlab.unittest.diagnostics.ConstraintDiagnostic.addConditions

---

```
 diag = ConstraintDiagnostic;

 % Now add conditions from the IsInstanceOf
 % Diagnostic
 otherDiag = constraint.DoubConst.getDiagnosticFor(actual);
 diag.addConditionsFrom(otherDiag);

 % ...
 end
end
end
```

**See Also** [addCondition](#)

# matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString

---

**Purpose** Convert object to string for display

**Syntax** `str = matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString(value)`

**Description** `str = matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString(value)` converts the object, `obj` to a string, `str` for display in a diagnostic result. This conversion determines if hotlinks should be included in the string and truncates large numeric or cell arrays.

**Input Arguments**

**value**  
Object of arbitrary class

# matlab.unittest.diagnostics.ConstraintDiagnostic.getPreDescrip

---

**Purpose** Returns text to be displayed prior to description

**Syntax** `str = getPreDescriptionString(constDiag)`

**Description** `str = getPreDescriptionString(constDiag)` returns text to be displayed prior to the description. This method can be overridden to inject strings prior to displaying the `Description` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Description` property. Its placement relative to other fields is not guaranteed.

**Input Arguments**

**constDiag**  
matlab.unittest.diagnostics.ConstraintDiagnostic instance.

**See Also** `ConstraintDiagnostic` | `getPostActValString` | `getPostDescriptionString` | `getPostConditionString` | `getPostExpValString`

# matlab.unittest.diagnostics.ConstraintDiagnostic.getPostD

---

**Purpose** Returns text to be displayed following description

**Syntax** `str = getPostDescriptionString(constDiag)`

**Description** `str = getPostDescriptionString(constDiag)` returns text to be displayed following the description. This method can be overridden to inject strings subsequent to displaying the `Description` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Description` property. Its placement relative to other fields is not guaranteed.

**Input Arguments**

**constDiag**  
matlab.unittest.diagnostics.ConstraintDiagnostic instance.

**See Also** `ConstraintDiagnostic` | `getPreDescriptionString` | `getPostActValString` | `getPostConditionString` | `getPostExpValString`

**Purpose** Returns text to be displayed following conditions list

**Syntax** `str = getPostConditionsString(constDiag)`

**Description** `str = getPostConditionsString(constDiag)` returns text to be displayed following the conditions list. This method can be overridden to inject strings subsequent to displaying the `Conditions` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Conditions` property. Its placement relative to other fields is not guaranteed.

**Input Arguments**

**constDiag**  
matlab.unittest.diagnostics.ConstraintDiagnostic instance.

**See Also** `ConstraintDiagnostic` | `getPreDescriptionString` | `getPostDescriptionString` | `getPostActValString` | `getPostExpValString`

**Purpose** Returns text to be displayed following actual value

**Syntax** `str = getPostActualValString(constDiag)`

**Description** `str = getPostActualValString(constDiag)` returns text to be displayed following the actual value. This method can be overridden to inject strings subsequent to displaying the `ActVal` property of the `ConstraintDiagnostic`. The location of this text is tied to the `ActVal` property. Its placement relative to other fields is not guaranteed.

**Input Arguments**

**constDiag**  
matlab.unittest.diagnostics.ConstraintDiagnostic instance.

**See Also** `ConstraintDiagnostic` | `getPreDescriptionString` | `getPostDescriptionString` | `getPostConditionString` | `getPostExpValString`

**Purpose** Returns text to be displayed following expected value

**Syntax** `str = getPostExpValString(constDiag)`

**Description** `str = getPostExpValString(constDiag)` returns text to be displayed following the expected value. This method can be overridden to inject strings subsequent to displaying the `ExpVal` property of the `ConstraintDiagnostic`. The location of this text is tied to the `ExpVal` property. Its placement relative to other fields is not guaranteed.

**Input Arguments**

**constDiag**  
matlab.unittest.diagnostics.ConstraintDiagnostic instance.

**See Also** `ConstraintDiagnostic` | `getPreDescriptionString` | `getPostDescriptionString` | `getPostConditionString` | `getPostActValString`

## Purpose

Fundamental interface class for `matlab.unittest` diagnostics

## Description

The `Diagnostic` interface class is the means by which the `matlab.unittest` framework and its clients package diagnostic information. All diagnostics are derived from `Diagnostic`, whether they are user-supplied test diagnostics for an individual comparison or diagnostics associated with the `Constraint` used in the comparison.

Classes which derive from `Diagnostic` encode the diagnostic actions to be performed. They produce a diagnostic result that is displayed appropriately by the test running framework. In exchange for meeting this requirement, any `Diagnostic` implementation can be used directly with `matlab.unittest` qualifications. These qualifications execute the diagnostic action and store the result to be utilized by the test running framework.

As a convenience, the framework creates appropriate diagnostic instances for strings and function handles when they are user supplied test diagnostics. To retain good performance, these values are only converted into `Diagnostic` instances when a qualification failure occurs or when the test running framework is explicitly observing passing qualifications. The default test runner does not explicitly observe passing qualifications.

## Properties

### `DiagnosticResult`

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <code>diagnose</code> | Execute diagnostic action                     |
| <code>join</code>     | Join multiple diagnostics into a single array |

# matlab.unittest.diagnostics.Diagnostic

---

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Use Diagnostic Result

```
import matlab.unittest.constraints.IsEqualTo;

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Create StringDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), 'User supplied Diagnostic');

% Create FunctionHandleDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), @() system('ps'));

% Usage of user defined Diagnostic upon failure (see definition below)
testCase.verifyThat(1, IsEqualTo(2), ProcessStatusDiagnostic...
 ('Could not close my third party application!'));

%%
% Diagnostic definition
%%
classdef ProcessStatusDiagnostic < matlab.unittest.diagnostics.Diagnostic
 % ProcessStatusDiagnostic - an example diagnostic
 %
 % Simple example to demonstrate how to create a custom
 % diagnostic.

 properties

 % HeaderText - user-supplied header to display
 HeaderText = '(No header supplied)';
 end

 methods
 function diag = ProcessStatusDiagnostic(header)
```

```
% Constructor - construct a ProcessStatusDiagnostic
%
% The ProcessStatusDiagnostic constructor takes an
% optional header to be displayed along with process
% information.
if (nargin > 0)
 diag.HeaderText = header;
end
end

function diagnose(diag)

 [status processInfo] = system('ps');
 if (status ~= 0)
 processInfo = sprintf(...
 ['!!! Could not obtain status diagnostic informati
 ' [exit status code: %d]\n%s'], status, processInfo);
 end
 diag.DiagnosticResult = sprintf('%s\n%s', diag.HeaderText,
 processInfo);
 end
end

end %classdef
```

## Concepts

- “Types of Qualifications”

# matlab.unittest.diagnostics.Diagnostic.diagnose

---

**Purpose** Execute diagnostic action

**Syntax** `diagnose(diag)`

**Description** `diagnose(diag)` executes diagnostic action for the `matlab.unittest.diagnostics.Diagnostic` instance, `diag`. The `diagnose` method is the means by which individual `Diagnostic` implementations can perform their respective diagnostic evaluations. Each concrete implementation is responsible for populating the `DiagnosticResult` property of the `Diagnostic` object. Typically, text printed to the Command Window during diagnostic evaluation is not considered part of the diagnostic result and is ignored by the testing framework.

**See Also** `Diagnostic`

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Join multiple diagnostics into a single array                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Syntax</b>           | <code>diagArray = join(diag1,...,diagN)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>      | <code>diagArray = join(diag1,...,diagN)</code> joins multiple diagnostics, specified by <code>diag1</code> through <code>diagN</code> , into a single array, <code>diagArray</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Input Arguments</b>  | <p><b>diag</b></p> <p>Diagnostic content, specified as an instance of a <code>Diagnostic</code> object, a string, a function handle, or an arbitrary type.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Output Arguments</b> | <p><b>diagArray</b></p> <p>Array of joined diagnostic content.</p> <ul style="list-style-type: none"><li>• If <code>diagN</code> is an object that derives from <code>Diagnostic</code>, it is included in the array unmodified.</li><li>• If <code>diagN</code> is a char, it is formed into a <code>StringDiagnostic</code> and included in the array.</li><li>• If <code>diagN</code> is a <code>function_handle</code>, it is formed into a <code>FunctionHandleDiagnostic</code> and included in the array.</li><li>• If <code>diagN</code> is any other type, it is formed into a <code>DisplayDiagnostic</code> and included in the array.</li></ul> |
| <b>Alternatives</b>     | <p>You can use array concatenation <code>join</code> diagnostics into an array if at least one of the values is a diagnostic. The <code>join</code> method prevents the need to have any <code>Diagnostics</code> in the array. Considering the following example.</p> <pre>arbitraryValue = 5; testCase.verifyThat(false, IsTrue, ...     ['should have been true', ...     @() system('ps'), ...     arbitraryValue, ...     MyCustomDiagnostic]);</pre>                                                                                                                                                                                                  |

# matlab.unittest.diagnostics.Diagnostic.join

---

Since MyCustomDiagnostic is a Diagnostic, the other values are correctly converted to diagnostics as well.

## Examples

### Join Diagnostic Content

```
% The following example creates a diagnostic array of length 4,
% demonstrating standard Diagnostic conversions. Note:
% MyCustomDiagnostic is for example purposes and is not executable
% code.
```

```
import matlab.unittest.diagnostics.Diagnostic;
import matlab.unittest.constraints.IsTrue;
```

```
arbitraryValue = 5;
testCase.verifyThat(false, IsTrue, ...
 Diagnostic.join(...
 'should have been true', ...
 @() system('ps'), ...
 arbitraryValue, ...
 MyCustomDiagnostic))
```

**See Also** [matlab.mixin.Heterogeneous](#)

**Superclasses** Diagnostic

**Purpose** Diagnostic using a value's displayed output

**Description** The DisplayDiagnostic class provides a diagnostic result that uses a value's displayed output. This output is the same text displayed using the `display` function. When the diagnostic information is accessible through a variable in the current workspace, the DisplayDiagnostic class is a means to provide quick diagnostic information.

**Construction** `DisplayDiagnostic(diagValue)` creates a new DisplayDiagnostic instance.

## Input Arguments

### diagValue

The value that the Diagnostic uses to generate diagnostic information.

The resulting diagnostic information is equivalent to displaying this value at the MATLAB command prompt. The result is packaged for consumption by the testing framework, which may or may not display the information at the command prompt.

**Properties** **Value**

The value that the Diagnostic uses to generate diagnostic information, specified in the `diagValue` input argument. This property is read-only.

## Inherited Properties

### DiagnosticResult

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

# matlab.unittest.diagnostics.DisplayDiagnostic

---

## Methods

## Inherited Methods

|          |                                               |
|----------|-----------------------------------------------|
| diagnose | Execute diagnostic action                     |
| join     | Join multiple diagnostics into a single array |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create DisplayDiagnostic Object

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.diagnostics.DisplayDiagnostic;
```

```
testCase = TestCase.forInteractiveUse;
```

Use a `DisplayDiagnostic` to display diagnostic information upon test failure.

```
testCase.verifyThat(1, IsEqualTo(2), DisplayDiagnostic(inputParser));
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
inputParser with properties:
```

```
 FunctionName: ''
 CaseSensitive: 0
 KeepUnmatched: 0
 PartialMatching: 1
 StructExpand: 1
 Parameters: {1x0 cell}
```

```
Results: [1x1 struct]
Unmatched: [1x1 struct]
UsingDefaults: {1x0 cell}
```

```

Framework Diagnostic:

IsEqualTo failed.
--> NumericComparator failed.
 --> The values are not equal using "isequaln".

Actual Value:
 1
Expected Value:
 2
```

In the test diagnostic section of the output, the output from `inputParser` object is the same as MATLAB displays at the command prompt.

## Concepts

# matlab.unittest.diagnostics.FunctionHandleDiagnostic

---

**Superclasses** Diagnostic

**Purpose** Diagnostic using a function's displayed output

**Description** The FunctionHandleDiagnostic class provides a diagnostic result using a function's displayed output. This output is the same as the text displayed at the command prompt when MATLAB executes the function handle. When the diagnostic information is accessible through information displayed as output of the function handle, the FunctionHandleDiagnostic is a means to provide quick diagnostic information.

When using matlab.unittest qualifications, a function handle can be supplied directly as a test diagnostic. In this case, the testing framework automatically creates a FunctionHandleDiagnostic object.

**Construction** FunctionHandleDiagnostic(fcnHandle) creates a new FunctionHandleDiagnostic instance.

## Input Arguments

### fcnHandle

The function handle that the Diagnostic uses to generate diagnostic information.

The resulting diagnostic information is equivalent to output displayed at the MATLAB command prompt. The result is packaged for consumption by the testing framework, which may or may not display the information at the command prompt.

**Properties** Fcn

The function handle that the Diagnostic uses to generate diagnostic information, specified in the fcnHandle input argument. This property is read-only.

## Inherited Properties

### DiagnosticResult

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

### Inherited Methods

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <code>diagnose</code> | Execute diagnostic action                     |
| <code>join</code>     | Join multiple diagnostics into a single array |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Create FunctionHandleDiagnostic Object

Create a diagnostic result that displays the output of the `dir` function when a test fails.

Create a folder in your current working folder.

```
mkdir('subfolderInCurrentFolder');
```

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.diagnostics.FunctionHandleDiagnostic;

testCase = TestCase.forInteractiveUse;
```

Use a `FunctionHandleDiagnostic` to display diagnostic information upon test failure.

# matlab.unittest.diagnostics.FunctionHandleDiagnostic

---

```
testCase.verifyThat(1, IsEqualTo(2), FunctionHandleDiagnostic(@dir));
```

```
Interactive verification failed.
```

```

Test Diagnostic:
```

```

```

```
. .. subfolderInCurrentFolder
```

```

Framework Diagnostic:
```

```

```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
 --> The values are not equal using "isequaln".
```

```
Actual Value:
```

```
 1
```

```
Expected Value:
```

```
 2
```

Upon test failure, the diagnostic displays the contents of the current working folder. In this example output, the folder only contains the subfolder `subfolderInCurrentFolder`.

Alternatively, the test framework can create a `FunctionHandleDiagnostic` object for you from a function handle input to the `verifyThat` qualification.

```
testCase.verifyThat(1, IsEqualTo(2), @dir);
```

```
Interactive verification failed.
```

```

Test Diagnostic:
```

# matlab.unittest.diagnostics.FunctionHandleDiagnostic

---

```

.
.. subfolderInCurrent
```

```

Framework Diagnostic:

IsEqualTo failed.
--> NumericComparator failed.
 --> The values are not equal using "isequaln".

Actual Value:
 1
Expected Value:
 2
```

The testing framework only creates the `FunctionHandleDiagnostic` object as needed, typically only in the event of a test failure.

`StringDiagnostic` | `matlab.unittest.diagnostics` |  
`matlab.unittest.plugins.DiagnosticsValidationPlugin`

## Concepts

# matlab.unittest.diagnostics.StringDiagnostic

---

**Superclasses** Diagnostic

**Purpose** Diagnostic using string

**Description** The StringDiagnostic class provides a diagnostic result that uses a string. When the diagnostic information is known at the time of construction, the StringDiagnostic is a means to provide quick diagnostic information.

When using matlab.unittest qualifications, a string can be supplied directly as a test diagnostic. In this case, the testing framework automatically creates a StringDiagnostic object.

**Construction** StringDiagnostic(diagString) creates a new StringDiagnostic instance.

## Input Arguments

### diagString

The string that the Diagnostic uses to generate diagnostic information.

**Properties** **Inherited Properties**

### DiagnosticResult

The DiagnosticResult property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the diagnose method.

**Methods** **Inherited Methods**

diagnose

Execute diagnostic action

join

Join multiple diagnostics into a single array

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create StringDiagnostic Object

Create a test case for interactive testing.

```
import matlab.unittest.TestCase;
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.diagnostics.StringDiagnostic;
```

```
testCase = TestCase.forInteractiveUse;
```

Use a `StringDiagnostic` to display diagnostic information upon test failure.

```
testCase.verifyThat(1, IsEqualTo(2), ...
 StringDiagnostic('actual was supposed to be equal to expected'))
```

```
Interactive verification failed.
```

```

Test Diagnostic:
```

```

actual was supposed to be equal to expected
```

```

Framework Diagnostic:
```

```

IsEqualTo failed.
--> NumericComparator failed.
 --> The values are not equal using "isequaln".
```

```
Actual Value:
```

```
 1
```

```
Expected Value:
```

```
 2
```

# matlab.unittest.diagnostics.StringDiagnostic

---

Alternatively, the test framework can create a `StringDiagnostic` object for you from a string input to the `verifyThat` qualification.

```
testCase.verifyThat(1, IsEqualTo(2), ...
 'actual was supposed to be equal to expected');
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
actual was supposed to be equal to expected
```

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
--> The values are not equal using "isequaln".
```

```
Actual Value:
```

```
 1
```

```
Expected Value:
```

```
 2
```

The testing framework only creates the `StringDiagnostic` object as needed, typically only in the event of a test failure.

`FunctionHandleDiagnostic` | `matlab.unittest.diagnostics`

## Concepts

**Purpose** Create and display empty dialog box

**Syntax** `h = dialog('PropertyName',PropertyValue,...)`

**Description** `h = dialog('PropertyName',PropertyValue,...)` returns a handle to a dialog box. The dialog box is a figure graphics object with properties recommended for dialog boxes. You can specify any valid figure property value except `DockControls`, which is always `off`.

The following table contains the properties that `dialog` sets and their default values.

| Property            | Value                                        |
|---------------------|----------------------------------------------|
| 'ButtonDownFcn'     | 'if isempty(allchild(gcf)), close(gcf), end' |
| 'Colormap'          | []                                           |
| 'Color'             | DefaultUicontrolBackgroundColor              |
| 'DockControls'      | 'off'                                        |
| 'HandleVisibility'  | 'callback'                                   |
| 'IntegerHandle'     | 'off'                                        |
| 'InvertHardcopy'    | 'off'                                        |
| 'MenuBar'           | 'none'                                       |
| 'NumberTitle'       | 'off'                                        |
| 'PaperPositionMode' | 'auto'                                       |
| 'Resize'            | 'off'                                        |
| 'Visible'           | 'on'                                         |
| 'WindowStyle'       | 'modal'                                      |

---

**Note** By default, the dialog box is modal. A modal dialog box prevents users from interacting with other windows before responding to the modal dialog box. For more information, see `WindowStyle` in the MATLAB Figure Properties.

---

The default `ButtonDownFcn` value causes the dialog box to terminate itself when a user clicks it, if the dialog box contains no child objects. Replace the default `ButtonDownFcn` value with another value or an empty value if you do not want this behavior. You can do this only from a script or function if the dialog box is modal (the default `WindowStyle`).

Any property you can specify for the figure function is valid for the `ButtonDownFcn` function.

## Examples

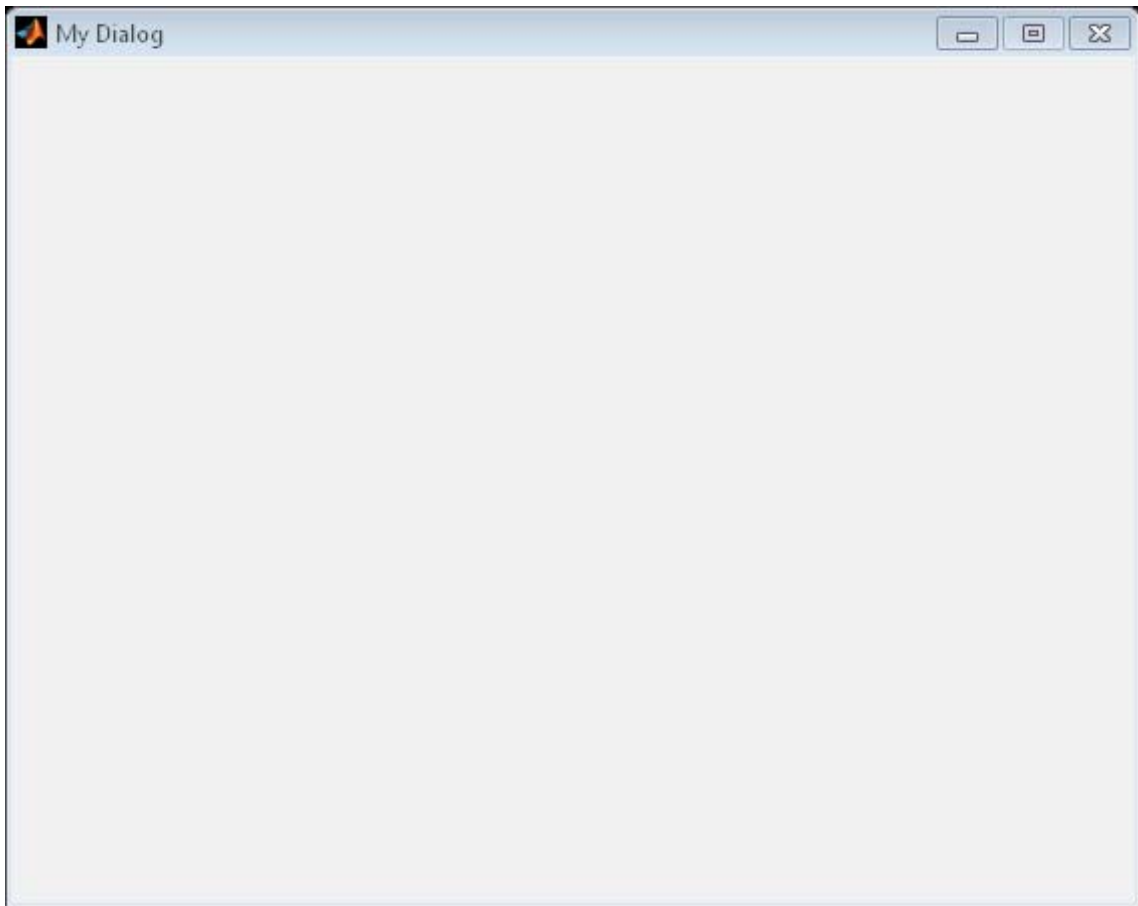

### Default modal dialog box

```
out = dialog;
```

### Nonmodal dialog box

Create a nonmodal dialog box with a name on its title bar.

```
out = dialog('WindowStyle', 'normal', 'Name', 'My Dialog');
```

# diary

---

**Purpose** Save Command Window text to file

**Syntax**

```
diary
diary('filename')
diary off
diary on
diary filename
```

**Description** The `diary` function creates a log of keyboard input and the resulting text output, with some exceptions (see “Tips” on page 1-1756 for details). The output of `diary` is an ASCII file, suitable for searching in, printing, inclusion in most reports and other documents. If you do not specify `filename`, the MATLAB software creates a file named `diary` in the current folder.

`diary` toggles diary mode on and off. To see the status of `diary`, type `get(0, 'Diary')`. MATLAB returns either `on` or `off` indicating the diary status.

`diary('filename')` writes a copy of all subsequent keyboard input and the resulting output (except it does not include graphics) to the named file, where `filename` is the full pathname or `filename` is in the current MATLAB folder. If the file already exists, output is appended to the end of the file. You cannot use a `filename` called `off` or `on`. To see the name of the diary file, use `get(0, 'DiaryFile')`.

`diary off` suspends the diary.

`diary on` resumes diary mode using the current filename, or the default filename `diary` if none has yet been specified.

`diary filename` is the unquoted form of the syntax.

**Tips** Because the output of `diary` is plain text, the file does not exactly mirror input and output from the Command Window:

- Output does not include graphics (figure windows).
- Syntax highlighting and font preferences are not preserved.

- Hidden components of Command Window output such as hyperlink information generated with `matlab:` are shown in plain text. For example, if you enter the following statement

```
str = sprintf('%s%s', ...
 '', ...
 'Generate magic square');
disp(str)
```

MATLAB displays

[Generate magic square](#)

However, the diary file, when viewed in a text editor, shows

```
str = sprintf('%s%s', ...
 '', ...
 'Generate magic square');
disp(str)
Generate magic square
```

If you view the output of `diary` in the Command Window, the Command Window interprets the `<a href ...>` statement and displays it as a hyperlink.

- Viewing the output of `diary` in a console window might produce different results compared to viewing `diary` output in the desktop Command Window. One example is using the `\r` option for the `fprintf` function; using the `\n` option might alleviate that problem.

## How To

- “Command History”

# diff

---

## Purpose

Differences and Approximate Derivatives

## Syntax

```
Y = diff(X)
Y = diff(X,n)
Y = diff(X,n,dim)
```

## Description

$Y = \text{diff}(X)$  calculates differences between adjacent elements of  $X$  along the first array dimension whose size does not equal 1:

- If  $X$  is a vector of length  $m$ , then  $Y = \text{diff}(X)$  returns a vector of length  $m-1$ . The elements of  $Y$  are the differences between adjacent elements of  $X$ .

$$Y = [X(2)-X(1) \quad X(3)-X(2) \quad \dots \quad X(m)-X(m-1)]$$

- If  $X$  is a nonempty, nonvector  $p$ -by- $m$  matrix, then  $Y = \text{diff}(X)$  returns a matrix of size  $(p-1)$ -by- $m$ , whose elements are the differences between the rows of  $X$ .

$$Y = [X(2,:) - X(1,:); \quad X(3,:) - X(2,:); \quad \dots \quad X(p,:) - X(p-1,:)]$$

- If  $X$  is a 0-by-0 empty matrix, then  $Y = \text{diff}(X)$  returns a 0-by-0 empty matrix.

$Y = \text{diff}(X,n)$  calculates the  $n$ th difference by applying the  $\text{diff}(X)$  operator recursively  $n$  times. In practice, this means  $\text{diff}(X,2)$  is the same as  $\text{diff}(\text{diff}(X))$ .

$Y = \text{diff}(X,n,\text{dim})$  is the  $n$ th difference calculated along the dimension specified by  $\text{dim}$ . The  $\text{dim}$  input is a positive integer scalar.

## Input Arguments

### **X** - Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**Complex Number Support:** Yes

**n - Difference order**

positive integer scalar | []

Difference order, specified as a positive integer scalar or []. The default value of n is 1.

It is possible to specify n sufficiently large so that dim reduces to a single ( $\text{size}(X, \text{dim}) = 1$ ) dimension. When this happens, diff continues calculating along the next array dimension whose size does not equal 1. This process continues until a 0-by-0 empty matrix is returned.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**dim - Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional p-by-m input array, A:

- `diff(A,1,1)` works on successive elements in the columns of A and returns a (p-1)-by-m difference matrix.
- `diff(A,1,2)` works on successive elements in the rows of A and returns a p-by-(m-1) difference matrix.

# diff

## Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

## Output Arguments

### Y - Difference array

scalar | vector | matrix | multidimensional array

Difference array, returned as a scalar, vector, matrix, or multidimensional array. If X is a nonempty array, then the dimension of X acted on by diff is reduced in size by n in the output.

## Examples

### Differences Between Vector Elements

Create a vector, then compute the differences between the elements.

```
X = [1 1 2 3 5 8 13 21];
Y = diff(X)
```

```
Y =
```

```
0 1 1 2 3 5 8
```

Note that Y has one fewer element than X.

### Differences Between Matrix Rows

Create a 3-by-3 matrix, then compute the first difference between the rows.

```
X = [1 1 1; 5 5 5; 25 25 25];
Y = diff(X)
```

Y =

```

 4 4 4
 20 20 20

```

The output Y is a 2-by-3 difference matrix.

### Multiple Differences

Create a vector and compute the second-order difference between the elements.

```

X = [0 5 15 30 50 75 105];
Y = diff(X,2)

```

Y =

```

 5 5 5 5 5

```

### Differences Between Matrix Columns

Create a 3-by-3 matrix, then compute the first-order difference between the columns.

```

X = [1 3 5;7 11 13;17 19 23];
Y = diff(X,1,2)

```

Y =

```

 2 2
 4 2
 2 4

```

The output Y is a 3-by-2 difference matrix.

### Approximate Derivatives with diff

Use the diff function to approximate partial derivatives with the syntax  $Y = \text{diff}(f)/h$ , where  $f$  is a vector of function values evaluated over some domain,  $X$ , and  $h$  is an appropriate step size.

# diff

---

For example, the first derivative of  $\sin(x)$  with respect to  $x$  is  $\cos(x)$ , and the second derivative with respect to  $x$  is  $-\sin(x)$ . You can use `diff` to approximate these derivatives.

```
h = 0.001; %step size
X = -pi:h:pi; %domain
f = sin(X); %range
Y = diff(f)/h; %first derivative
Z = diff(Y)/h; %second derivative
plot(X(:,1:length(Y)),Y,'r',X,f,'b', X(:,1:length(Z)),Z,'k')
```

In this plot the blue line corresponds to the original function,  $\sin$ . The red line corresponds to the calculated first derivative,  $\cos$ , and the black line corresponds to the calculated second derivative,  $-\sin$ .

### See Also

[gradient](#) | [prod](#) | [cumsum](#) | [sum](#)

# diffuse

---

**Purpose** Calculate diffuse reflectance

**Syntax** `R = diffuse(Nx,Ny,Nz,S)`

**Description** `R = diffuse(Nx,Ny,Nz,S)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` specifies the direction to the light source. You can specify these directions as three vectors `[x,y,z]` or two vectors `[Theta Phi]` (in spherical coordinates).

Lambert's Law:  $R = \cos(\text{PSI})$  where `PSI` is the angle between the surface normal and light source.

**See Also** `specular` | `surfnorm` | `surf1`

**How To**

- “Lighting Overview”

**Purpose**

List folder contents

**Syntax**

```
dir
dir name
listing = dir(name)
```

**Description**

`dir` lists the files and folders in the MATLAB current folder. Results appear in the order returned by the operating system.

`dir name` lists the files and folders that match the string `name`. When `name` is a folder, `dir` lists the contents of the folder. Specify `name` using absolute or relative path names. You can use wildcards (\*).

`listing = dir(name)` returns attributes about `name`.

**Tips**

- To obtain a list of available drives on Microsoft Windows platforms:

Use the DOS `net use` command in the Command Window:

```
dos('net use')
```

Or

```
[s,r] = dos('net use')
```

MATLAB returns the results to the character array `r`.

- Short DOS file name support

The MATLAB `dir` function is consistent with the Microsoft Windows operating system `dir` command in that both support short file names generated by DOS.

- Structure Results for Nonexistent Files

When you run `dir` with an output argument and the results include a nonexistent file or a file that `dir` cannot query for some other reason, then `dir` returns the following default values:

```
date: ''
bytes: []
```

# dir

---

```
isdir: 0
datenum: []
```

The most common occurrence is on UNIX<sup>1</sup> platforms when `dir` queries a file that is a symbolic link, which points to a nonexistent target. A nonexistent target is a target that was moved, removed, or renamed. For example, if `my_file` in `my_dir` is a symbolic link to another file that was deleted, then running

```
r = dir('my_dir')
```

includes this result for `my_file`:

```
r(n) =
 name: 'my_file'
 date: ''
 bytes: []
 isdir: 0
 datenum: []
```

where  $n$  is the index for `my_file`, found by searching `r` by the `name` field.

## Input Arguments

### **name**

A string value specifying a file or folder name.

## Output Arguments

### **listing**

| Field Name | Description                 | Class      |
|------------|-----------------------------|------------|
| name       | File or folder name         | char array |
| date       | Modification date timestamp | char array |

1. UNIX is a registered trademark of The Open Group in the United States and other countries.

| Field Name | Description                                                             | Class   |
|------------|-------------------------------------------------------------------------|---------|
| bytes      | Size of the file in bytes                                               | double  |
| isdir      | 1 if name is a folder; 0 if not                                         | logical |
| datenum    | Modification date as serial date number. The value is locale-dependent. | double  |

## Examples

### View the Contents of a Folder

View the contents of the matlab/audioplayer folder:

```
dir(fullfile(matlabroot, 'toolbox/matlab/audioplayer'))
```

### Find Information in the Return Structure

Return the folder listing, restricted to files with a .m extension, to the variable av\_files:

```
av_files = dir(fullfile(matlabroot, ...
 'toolbox/matlab/audioplayer/*.m'))
```

MATLAB returns the information in a structure array:

```
av_files =
25x1 struct array with fields:
 name
 date
 bytes
 isdir
 datenum
```

Index into the structure to access a particular item:

```
av_files(3).name
ans =
 audioplayerreg.m
```

## - Use the Wildcard Character to Find Multiple Files

View the MAT-files in the current folder that include the term `my_data` by using the wildcard character:

```
dir *my_data*.mat
```

MATLAB returns all file names that match this specification. For instance, it returns the following if they are in the current folder:

```
old_my_data.mat my_data_final.mat my_data_test.mat
```

## - Exclude Certain Files from the Output

Return the list of files in the current folder, excluding those files that `dir` cannot query:

```
y = dir;
y = y(find(~cellfun(@isempty,{y(:).date})));
```

## - Find the Date a File Was Modified

To get the serial date number for the date and time a file was last modified, use the `datenum` field of the structure returned by the `dir` command:

```
DirInfo = dir('startup.m');
filedate = DirInfo.datenum
```

Using the `datenum` function to convert the string returned in the `date` field of the structure is not recommended as this can behave differently in different locales.

```
filedate = datenum(DirInfo.date)
```

## Alternatives

Use the Current Folder browser to view the list of files in a folder.

## See Also

`cd` | `fileattrib` | `isdir` | `ls` | `mkdir` | `rmdir` | `what`

## How To

- “Specify File Names”

**Purpose** View contents of folder on FTP server

**Syntax**

```
dir(ftpobj)
dir(ftpobj, folder)
details = dir(ftpobj, folder)
```

**Description**

`dir(ftpobj)` lists the files in current folder on the FTP server associated with `ftpobj`.

`dir(ftpobj, folder)` lists the files in the specified folder.

`details = dir(ftpobj, folder)` returns the results in a structure array that contains the name, modification date, and size of each file.

**Input Arguments**

**ftpobj**  
FTP object created by `ftp`.

**folder**  
String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

**Output Arguments**

**details**  
`m`-by-1 structure array, where `m` is the number of files in the folder. Each element of the structure array contains the following fields:

| Field Name | Description                              | Data Type |
|------------|------------------------------------------|-----------|
| name       | File name                                | char      |
| date       | Modification date<br>timestamp           | char      |
| bytes      | Number of bytes<br>allocated to the file | double    |

# FTP.dir

---

| Field Name | Description                                 | Data Type |
|------------|---------------------------------------------|-----------|
| isdir      | If a folder, isdir = 1, otherwise isdir = 0 | logical   |
| datenum    | Modification date as serial date number     | char      |

## Examples

Connect to the MathWorks FTP server and view the contents:

```
mw=ftp('ftp.mathworks.com');
dir(mw)
```

This code returns:

```
README incoming matlab outgoing pub pubs
```

---

Continuing the previous example, save the folder contents to the structure `m`, close the connection, and view details about the `pub` subfolder:

```
m=dir(mw);
close(mw);
```

```
m(5)
```

This code returns:

```
ans =
 name: 'pub'
 date: '13-Aug-2008 00:00:00'
 bytes: 512
 isdir: 1
 datenum: 733633
```

## See Also

`cd` | `ftp` | `mkdir` | `rmdir`

**Purpose** Display text or array

**Syntax** disp(X)

**Description** disp(X) displays the contents of X without printing the variable name. disp does not display empty variables.

**Input Arguments** **X - Variable to display**  
variable name  
Variable to display, specified by the variable name.

### Examples **Display Matrix with Column Labels**

Display a matrix and label the columns as Corn, Oats, and Hay.

```
X = gallery('uniformdata',[5 3],0);
disp(' Corn Oats Hay')
disp(X)
```

| Corn   | Oats   | Hay    |
|--------|--------|--------|
| 0.9501 | 0.7621 | 0.6154 |
| 0.2311 | 0.4565 | 0.7919 |
| 0.6068 | 0.0185 | 0.9218 |
| 0.4860 | 0.8214 | 0.7382 |
| 0.8913 | 0.4447 | 0.1763 |

### Display Hyperlink in Command Window

Include the full hypertext string on a single line as input to disp.

```
X = 'MathWorks Web Site';
disp(X)
```

```
MathWorks Web Site
```

The `disp` function generates a hyperlink in the Command Window. Click the link to display the MathWorks home page in a MATLAB Web browser.

## Display Multiple Items on Same Line

Concatenate strings together using the `[]` operator. Convert any numeric values to characters using the `num2str` function.

```
name = 'Alice'; age = 12;
X = [name, ' will be ', num2str(age), ' this year.'];
```

Display the string.

```
disp(X)
```

```
Alice will be 12 this year.
```

You also can use `sprintf` to create a string. Terminate the `sprintf` command with a semicolon to prevent "X = " from being displayed. Then, use `disp` to display the string.

```
name = 'Alice'; age = 12;
X = sprintf('%s will be %d this year.', name, age);
disp(X)
```

```
Alice will be 12 this year.
```

Alternatively, use `fprintf` to create and display the string. Unlike the `sprintf` function, `fprintf` does not display the "X = " text. However, you need to end the string with the newline (`\n`) metacharacter to terminate its display properly.

```
name = 'Alice'; age = 12;
X = fprintf('%s will be %d this year.\n', name, age);
```

```
Alice will be 12 this year.
```

**Tips**

- The `disp` function accepts only one input. To display more than one array or string, you can use concatenation or the `sprintf` or `fprintf` functions as shown in the Example, “Display Multiple Items on Same Line” on page 1-1772.

**See Also**

`format` | `int2str` | `num2str` | `rats` | `sprintf` | `fprintf` | `colon` (`:`)

# disp (MException)

---

**Purpose** Display MException object

**Syntax** disp(exception)  
disp(exception.property)

**Description** disp(exception) displays all properties (fields) of MException object exception.

disp(exception.property) displays the specified property of MException object exception.

**Examples** Using the surf command without input arguments throws an exception. Use disp to display the identifier, message, stack, and cause properties of the MException object:

```
try
 surf
catch exception
 disp(exception)
end
```

MException object with properties:

```
 identifier: 'MATLAB:narginchk:notEnoughInputs'
 message: 'Not enough input arguments.'
 cause: {}
 stack: [1x1 struct]
```

Display only the stack property:

```
disp(exception.stack)
 file: 'C:\Program Files\MATLAB\toolbox\matlab\graph3d\surf.m'
graph3d\surf.m'
 name: 'surf'
 line: 54
```

### See Also

isequal(MException) | MException | assert | error | try, catch

# disp (serial)

---

**Purpose** Serial port object summary information

**Syntax** obj  
disp(obj)

**Description** obj or disp(obj) displays summary information for obj, a serial port object or an array of serial port objects.

**Tips** In addition to the syntax shown above, you can display summary information for obj by excluding the semicolon when:

- Creating a serial port object
- Configuring property values using the dot notation

Use the display summary to quickly view the communication settings, communication state information, and information associated with read and write operations.

**Examples** The following commands display summary information for the serial port object s. on a Windows platform

```
s = serial('COM1')
s.BaudRate = 300
s
```

**Purpose** Display text and numeric expressions

**Syntax** `display(X)`

**Description** `display(X)` prints the value of `X`. MATLAB implicitly calls `display` after any variable or expression that is not terminated by a semicolon. To customize the display of objects, overload the `disp` function instead of the `display` function. `display` calls `disp`.

**Examples** **Display a Matrix**

```
X = magic(3);
display(X)
```

```
X =
```

```
 8 1 6
 3 5 7
 4 9 2
```

**Input Arguments** **X - Input value**  
`variable` | `expression`

Input value, specified as a variable or expression.

**See Also** `disp` | `ans` | `sprintf`

| <b>Purpose</b>       | Convert image, increasing apparent color resolution by dithering                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Syntax</b>        | <pre>X = dither(RGB, map) X = dither(RGB, map, Qm, Qe) BW = dither(I)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>   | <p><code>X = dither(RGB, map)</code> creates an indexed image approximation of the RGB image in the array <code>RGB</code> by dithering the colors in the colormap <code>map</code>. The colormap cannot have more than 65,536 colors.</p> <p><code>X = dither(RGB, map, Qm, Qe)</code> creates an indexed image from <code>RGB</code>, where <code>Qm</code> specifies the number of quantization bits to use along each color axis for the inverse color map, and <code>Qe</code> specifies the number of quantization bits to use for the color space error calculations. If <code>Qe &lt; Qm</code>, dithering cannot be performed, and an undithered indexed image is returned in <code>X</code>. If you omit these parameters, <code>dither</code> uses the default values <code>Qm = 5</code>, <code>Qe = 8</code>.</p> <p><code>BW = dither(I)</code> converts the grayscale image in the matrix <code>I</code> to the binary (black and white) image <code>BW</code> by dithering.</p> |
| <b>Class Support</b> | <code>RGB</code> can be <code>uint8</code> , <code>uint16</code> , <code>single</code> , or <code>double</code> . <code>I</code> can be <code>uint8</code> , <code>uint16</code> , <code>int16</code> , <code>single</code> , or <code>double</code> . All other input arguments must be <code>double</code> . <code>BW</code> is <code>logical</code> . <code>X</code> is <code>uint8</code> , if it is an indexed image with 256 or fewer colors; otherwise, it is <code>uint16</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Algorithms</b>    | <code>dither</code> increases the apparent color resolution of an image by applying Floyd-Steinberg's error diffusion dither algorithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Purpose** Compute divergence of vector field

**Syntax**

```
div = divergence(X,Y,Z,U,V,W)
div = divergence(U,V,W)
div = divergence(X,Y,U,V)
div = divergence(U,V)
```

**Description** `div = divergence(X,Y,Z,U,V,W)` computes the divergence of a 3-D vector field `U, V, W`.

The arrays `X, Y, and Z`, which define the coordinates for `U, V, and W`, must be monotonic, but do not need to be uniformly spaced. `X, Y, and Z` must have the same number of elements, as if produced by `meshgrid`.

`div = divergence(U,V,W)` assumes `X, Y, and Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`div = divergence(X,Y,U,V)` computes the divergence of a 2-D vector field `U, V`.

The arrays `X and Y`, which define the coordinates for `U and V`, must be monotonic, but do not need to be uniformly spaced. `X and Y` must have the same number of elements, as if produced by `meshgrid`.

`div = divergence(U,V)` assumes `X and Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

**Examples** This example displays the divergence of vector volume data as slice planes, using color to indicate divergence.

```
load wind
div = divergence(x,y,z,u,v,w);
```

# divergence

---

```
h = slice(x,y,z,div,[90 134],59,0);
shading interp
daspect([1 1 1])
axis tight
camlight
set([h(1),h(2)], 'ambientstrength', .6)
```

## How To

- “Displaying Divergence with Stream Tubes”

**Purpose**

Read ASCII-delimited file of numeric data into matrix

**Syntax**

```
M = dlmread(filename)
M = dlmread(filename, delimiter)
M = dlmread(filename, delimiter, R, C)
M = dlmread(filename, delimiter, range)
```

**Description**

`M = dlmread(filename)` reads the ASCII-delimited numeric data file `filename`, and returns the data in output matrix `M`. The `filename` input is a string enclosed in single quotes. `dlmread` infers the delimiter from the formatting of the file.

`M = dlmread(filename, delimiter)` reads data from the file, using the specified `delimiter`. Use `'\t'` to specify a tab delimiter.

`M = dlmread(filename, delimiter, R, C)` reads data whose upper left corner is at row `R` and column `C` in the file. Values `R` and `C` are zero-based, so that `R=0, C=0` specifies the first value in the file.

`M = dlmread(filename, delimiter, range)` reads the range specified by `range = [R1 C1 R2 C2]` where `(R1,C1)` is the upper left corner of the data to read and `(R2,C2)` is the lower right corner. You can also specify the range using spreadsheet notation, such as `range = 'A1..B7'`.

**Tips**

- All data in the input file must be numeric. `dlmread` does not read files that contain nonnumeric data, even if the specified rows and columns contain only numeric data.
- When `dlmread` infers the delimiter from the formatting of the file, it treats repeated white spaces as a single delimiter. By contrast, if you specify a delimiter, `dlmread` treats any repeated delimiter character as a separate delimiter.
- If you want to specify an `R, C, or range` input, but not a `delimiter`, set the `delimiter` argument to the empty string, (two consecutive single quotes with no spaces in between, `' '`). For example,

```
M = dlmread('myfile.dat', ' ', 5, 2)
```

# dlmread

---

In this case, `dlmread` treats repeated white spaces as a single delimiter.

- `dlmread` fills empty delimited fields with zero. If each line ends with a nonspace delimiter, such as a semicolon, the output matrix contains an additional last column of zeros.
- `dlmread` imports any complex number as a whole into a complex numeric field. Valid forms for a complex number are

`--<real>--<imag>i|j`                      Example: `5.7-3.1i`

`--<imag>i|j`                                Example: `-7j`

Embedded white-space in a complex number is invalid and is regarded as a field delimiter.

## Examples

### Example 1

Export a 5-by-8 test matrix `M` to a file, and read it with `dlmread`, first with no arguments other than the filename:

```
M = gallery('integerdata', 100, [5 8], 0);
dlmwrite('myfile.txt', M, 'delimiter', '\t')
```

```
dlmread('myfile.txt')
ans =
 96 77 62 41 6 21 2 42
 24 46 80 94 36 20 75 85
 61 2 93 92 82 61 45 53
 49 83 74 42 1 28 94 21
 90 45 18 90 14 20 47 68
```

Now read a portion of the matrix by specifying the row and column of the upper left corner:

```
dlmread('myfile.txt', '\t', 2, 3)
ans =
 92 82 61 45 53
```

```

42 1 28 94 21
90 14 20 47 68

```

This time, read a different part of the matrix using a range specifier:

```

dlmread('myfile.txt', '\t', 'C1..G4')
ans =
 62 41 6 21 2
 80 94 36 20 75
 93 92 82 61 45
 74 42 1 28 94

```

## Example 2

Export matrix M to a file, and then append an additional matrix to the file that is offset one row below the first:

```

M = magic(3);
dlmwrite('myfile.txt', [M*5 M/5], ' ')

dlmwrite('myfile.txt', [M/3], '-append', ...
 'roffset', 1, 'delimiter', ' ')

```

```
type myfile.txt
```

```

40 5 30 1.6 0.2 1.2
15 25 35 0.6 1 1.4
20 45 10 0.8 1.8 0.4

```

```

2.6667 0.33333 2
1 1.6667 2.3333
1.3333 3 0.66667

```

When dlmread imports these two matrices from the file, it pads the smaller matrix with zeros:

```

dlmread('myfile.txt')
 40.0000 5.0000 30.0000 1.6000 0.2000 1.2000

```

# d1mread

## Purpose

Write matrix to ASCII-delimited file

## Syntax

```
dlmwrite(filename,M)
dlmwrite(filename,M,'-append')

dlmwrite(___,Name,Value)

dlmwrite(filename,M,delimiter)
dlmwrite(filename,M,delimiter,row,col)
```

## Description

`dlmwrite(filename,M)` writes numeric data in array `M` to an ASCII format file, `filename`, using the default delimiter (`,`) to separate array elements. If the file, `filename`, already exists, `dlmwrite` overwrites the file.

`dlmwrite(filename,M,'-append')` appends the data to the end of the existing file, `filename`.

`dlmwrite(___,Name,Value)` additionally specifies delimiter, newline character, offset, and precision options using one or more name-value pair arguments.

`dlmwrite(filename,M,delimiter)` writes array `M` to the file, `filename`, using the specified delimiter, `delimiter`, to separate array elements.

`dlmwrite(filename,M,delimiter,row,col)` writes the array starting at the specified row and column `row` and `col`, in the destination file. Empty elements separated by `delimiter` fill the leading rows and columns.

## Input Arguments

### **filename** - Name of file to write

string

Name of file to write, specified as a string.

**Example:** 'myFile.txt'

## Data Types

char

## **M - Numeric data to write**

matrix | cell array of numeric values

Numeric data to write, specified as a matrix or a cell array of numeric values with one value per cell.

**Example:** [1,2,3;4,5,6]

**Example:** {1,2,3;4,5,6}

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | cell

**Complex Number Support:** Yes

## **delimiter - Delimiter to separate array elements**

',' (default) | string

Delimiter to separate array elements, specified as a string containing a single character or control character. Use '\t' to produce tab-delimited files.

**Example:** ';'

**Example:** '\t'

## Data Types

char

## **row - Row offset**

0 (default) | scalar

Row offset, specified as a scalar. The row offset indicates the number of rows to skip before writing the numeric data. `row` is zero-based, so that `row = 0` instructs MATLAB to begin writing in the first row of the destination file. Skipped rows are populated with the specified delimiter.

**col - Column offset**

0 (default) | scalar

Column offset, specified as a scalar. The column offset indicates the number of columns to skip before writing the numeric data. `col` is zero-based, so that `col = 0` instructs MATLAB to begin writing in the first column of the destination file. Skipped columns are separated with the specified delimiter.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:**

```
dlmwrite('myFile.txt',M,'precision',4,'delimiter',' ') writes
the numeric values in array M with four significant digits and
delimited using the whitespace character.
```

**'delimiter' - Delimiter to separate array elements**

' , ' (default) | string

Delimiter to separate array elements, specified as the comma-separated pair consisting of `'delimiter'` and string containing a single character or control character. Use `'\t'` to produce tab-delimited files.

**Example:** `'delimiter',';'`

**Example:** `'delimiter','\t'`

**Data Types**

char

**'roffset' - Row offset**

0 (default) | scalar

Row offset, specified as the comma-separated pair consisting of `'roffset'` and a scalar. The row offset indicates the number of rows to

skip before writing the numeric data. These rows are populated with the specified delimiter. When appending to an existing file, the new data is offset from the end of the existing data.

The row offset is zero-based, so that `'roffset',0` instructs MATLAB to begin writing in the first row of the destination file, which is the default. However, when appending to a file, `'roffset',0` instructs MATLAB to begin writing in the first row immediately following existing data.

**Example:** `'roffset',2`

### **'offset' - Column offset**

0 (default) | scalar

Column offset from the left side of the destination file, specified as the comma-separated pair consisting of `'offset'` and a scalar. The column offset indicates the number of columns to skip before writing the numeric data. These columns are separated with the specified delimiter.

The column offset is zero-based, so that `'offset',0` instructs MATLAB to begin writing in the first column of the destination file, which is the default.

**Example:** `'offset',1`

### **'precision' - Numeric precision**

5 (default) | scalar | C-style format string

Numeric precision to use in writing data to the file, specified as the comma-separated pair consisting of `'precision'` and a scalar or a C-style format string that begins with %, such as `'%10.5f'`. If the value of precision is a scalar, then it indicates the number of significant digits.

**Example:** `'precision',3`

**Example:** `'precision','%10.5f'`

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | char

**'newline' - Line terminator**`'pc' | 'unix'`

Line terminator, specified as the comma-separated pair consisting of 'newline' and either 'pc' to use a carriage return/line feed (CR/LF), or 'unix' to use a line feed (LF).

**Example:** 'newline', 'pc'

**Examples****Write Comma-Separated Data**

Create an array of sample data, M.

```
M = magic(3);
```

Write matrix M to a file, 'myFile.txt', using the default delimiter (,).

```
dlmwrite('myFile.txt',M)
```

View the data in the file.

```
type('myFile.txt')
```

```
8,1,6
```

```
3,5,7
```

```
4,9,2
```

**Write Tab-Delimited Data and Specify Precision**

Create an array of sample data, M.

```
M = magic(3)*pi
```

```
M =
```

```
25.1327 3.1416 18.8496
```

```
9.4248 15.7080 21.9911
```

```
12.5664 28.2743 6.2832
```

# dlmwrite

---

Write matrix `M` to a file, `'myFile.txt'`, delimited by the tab character and using a precision of 3 significant digits.

```
dlmwrite('myFile.txt',M,'delimiter','\t','precision',3)
```

View the data in the file.

```
type('myFile.txt')
```

```
25.1 3.14 18.8
9.42 15.7 22
12.6 28.3 6.28
```

## Write and Append Data to File

Create two arrays of sample numeric data.

```
M = magic(5);
N = magic(3);
```

Export matrix `M` to a file and use whitespace as the delimiter.

```
dlmwrite('myFile.txt',M,'delimiter',' ');
```

Append matrix `N` to the file, offset from the existing data by one row. Then, view the file.

```
dlmwrite('myFile.txt',N,'-append',...
'delimiter',' ','roffset',1)
type('myFile.txt')
```

```
17 24 1 8 15
23 5 7 14 16
4 6 13 20 22
10 12 19 21 3
11 18 25 2 9
```

```
8 1 6
3 5 7
```

```
4 9 2
```

Read the data in 'myFile.txt' using dlmread.

```
dlmread('myFile.txt')
```

```
ans =
```

```
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
 8 1 6 0 0
 3 5 7 0 0
 4 9 2 0 0
```

When dlmread reads the two matrices from the file, it pads the smaller matrix with zeros.

### Write Data and Specify Precision As String

Create an array of sample numeric data.

```
M = magic(3);
```

Export matrix M to a file using a precision of 6 decimal places.

```
dlmwrite('myFile.txt',M,'precision','%.6f');
```

View the data in the file.

```
type('myFile.txt')
```

```
8.000000,1.000000,6.000000
3.000000,5.000000,7.000000
4.000000,9.000000,2.000000
```

# dlmwrite

---

## Tips

- `dlmwrite` writes a file that spreadsheet programs can read. Alternatively, if your system has Excel for Windows installed, you can create a spreadsheet using `xlswrite`.

`dlmread` | `xlswrite` | `writetable`

**Purpose** Dulmage-Mendelsohn decomposition

**Syntax**  $p = \text{dmperm}(A)$   
 $[p,q,r,s,cc,rr] = \text{dmperm}(A)$

**Description**  $p = \text{dmperm}(A)$  finds a vector  $p$  such that  $p(j) = i$  if column  $j$  is matched to row  $i$ , or zero if column  $j$  is unmatched. If  $A$  is a square matrix with full structural rank,  $p$  is a maximum matching row permutation and  $A(p, :)$  has a zero-free diagonal. The structural rank of  $A$  is  $\text{sprank}(A) = \text{sum}(p > 0)$ .

$[p,q,r,s,cc,rr] = \text{dmperm}(A)$  where  $A$  need not be square or full structural rank, finds the Dulmage-Mendelsohn decomposition of  $A$ .  $p$  and  $q$  are row and column permutation vectors, respectively, such that  $A(p,q)$  has a block upper triangular form.  $r$  and  $s$  are index vectors indicating the block boundaries for the fine decomposition.  $cc$  and  $rr$  are vectors of length five indicating the block boundaries of the coarse decomposition.

$C = A(p,q)$  is split into a 4-by-4 set of coarse blocks:

```
A11 A12 A13 A14
0 0 A23 A24
0 0 0 A34
0 0 0 A44
```

where  $A12$ ,  $A23$ , and  $A34$  are square with zero-free diagonals. The columns of  $A11$  are the unmatched columns, and the rows of  $A44$  are the unmatched rows. Any of these blocks can be empty. In the coarse decomposition, the  $(i,j)$ th block is  $C(rr(i):rr(i+1)-1,cc(j):cc(j+1)-1)$ . For a linear system,

- $[A11 \ A12]$  is the underdetermined part of the system—it is always rectangular and with more columns and rows, or 0-by-0,
- $A23$  is the well-determined part of the system—it is always square, and

- [A34 ; A44] is the overdetermined part of the system—it is always rectangular with more rows than columns, or 0-by-0.

The structural rank of A is  $\text{sprank}(A) = \text{rr}(4) - 1$ , which is an upper bound on the numerical rank of A.  $\text{sprank}(A) = \text{rank}(\text{full}(\text{sprand}(A)))$  with probability 1 in exact arithmetic.

The A23 submatrix is further subdivided into block upper triangular form via the fine decomposition (the strongly connected components of A23). If A is square and structurally nonsingular, A23 is the entire matrix.

$C(r(i):r(i+1)-1, s(j):s(j+1)-1)$  is the  $(i, j)$ th block of the fine decomposition. The  $(1, 1)$  block is the rectangular block [A11 A12], unless this block is 0-by-0. The  $(b, b)$  block is the rectangular block [A34 ; A44], unless this block is 0-by-0, where  $b = \text{length}(r) - 1$ . All other blocks of the form  $C(r(i):r(i+1)-1, s(i):s(i+1)-1)$  are diagonal blocks of A23, and are square with a zero-free diagonal.

## Tips

If A is a reducible matrix, the linear system  $Ax=b$  can be solved by permuting A to a block upper triangular form, with irreducible diagonal blocks, and then performing block backsubstitution. Only the diagonal blocks of the permuted matrix need to be factored, saving fill and arithmetic in the blocks above the diagonal.

In graph theoretic terms, dmperm finds a maximum-size matching in the bipartite graph of A, and the diagonal blocks of  $A(p, q)$  correspond to the strong Hall components of that graph. The output of dmperm can also be used to find the connected or strongly connected components of an undirected or directed graph. For more information see Pothen and Fan [1].

| <b>Syntax</b>          | <code>doc</code><br><code>doc name</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>     | <p><code>doc</code> opens the Help browser. If the Help browser is already open, but not visible, then <code>doc</code> brings it to the foreground and opens a new tab.</p> <p><code>doc name</code> displays documentation for the functionality specified by <code>name</code>, such as a function, class, or block.</p> <ul style="list-style-type: none"><li>• If there is a MathWorks reference page corresponding to <code>name</code>, then <code>doc</code> displays the page in the Help browser. The <code>doc</code> command does not display third-party or custom HTML documentation.</li><li>• If there is no reference page corresponding to <code>name</code>, then <code>doc</code> searches for help text in a file named <code>name.m</code>. When help text is available, <code>doc</code> displays it in the Help browser.</li><li>• If there is no reference page and no help text associated with <code>name</code>, then <code>doc</code> searches the documentation for <code>name</code> and displays the search results in the Help browser.</li></ul> |
| <b>Input Arguments</b> | <p><b>name - Name of function, class, block, or other functionality</b><br/><code>string</code></p> <p>Name of a function, class, block, or other functionality, specified as a string. Alternatively, an operator symbol.</p> <p>Some classes and other packaged items require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, such as:</p> <pre>doc className.name<br/>doc packageName.name<br/>doc packageName.className.name</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Methods for some classes are not accessible using the `doc` command; instead, use links on the class reference page.

## **Examples**      **Function Reference Pages**

Display the reference page for the `abs` function.

```
doc abs
```

Several products include different versions of `abs`. If your Help preferences support displaying documentation for those products, then the Help browser displays the MATLAB `abs` reference page and a message with links to other versions of `abs`. This message appears at the top of the page.

## **Class and Method Reference Pages**

Display the reference page for the `handle` class.

```
doc handle
```

Display the reference page for the `findobj` method in the `handle` class.

```
doc handle.findobj
```

Display the reference page for the `Map` class in the `containers` package.

```
doc containers.Map
```

## **Custom Class Pages**

Display formatted help text for a custom class.

MATLAB includes a set of example files that show how to create a class, including a class file named `sads.m`. Add the example folder to the path, and request documentation for `sads`.

```
addpath(...
 fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', ...
 'examples'))
doc sads
```

---

Display the help for the `steer` method of the `sads` class.

```
doc sads.steer
```

Because the help text follows MATLAB conventions, MATLAB formats the display in the browser.

### Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

# docsearch

---

**Purpose** Help browser search

**Syntax** docsearch  
docsearch expression

**Description** docsearch opens the Help browser and displays the documentation home page. If the Help browser is already open, but not visible, then docsearch brings it to the foreground.

docsearch expression searches MathWorks documentation for pages with words that match the specified expression and highlights them. To clear highlighting, press the **Esc** key. The docsearch command does not search third-party or custom documentation.

## Input Arguments

**expression - Expression that defines search terms**  
string

Expression that defines search terms, specified as a string. Expressions can include:

- Quotation marks to specify exact phrases, such as "plot tools".
- Boolean operator keywords in uppercase (listed here in order of precedence): NOT, OR, AND.
- Asterisk (\*) wildcard characters, except at the beginning of a word or in an exact phrase. Searches require that at least two characters in the expression are *not* wildcard characters.

## Examples

### Single Words

Find all documentation pages that contain the word *plot*.

```
docsearch plot
```

### Multiple Words

Find documentation pages with the words *plot* and *tools*.

```
docsearch plot tools
```

Expand the search to include variations of the word *plot*, such as *plotting* or *plots*, using a wildcard character.

```
docsearch plot* tools
```

Narrow the search to pages that include an exact phrase by enclosing the phrase in quotation marks.

```
docsearch "plot tools"
```

Find pages with either word, but not necessarily both words, using the OR operator.

```
docsearch plot OR tools
```

### Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

### Concepts

- “Search Syntax and Tips”

# dos

---

## Purpose

Execute DOS command and return output

## Syntax

```
status = dos(command)
[status,cmdout] = dos(command)
[status,cmdout] = dos(command, '-echo')
```

## Description

`status = dos(command)` executes the specified DOS command for Windows platforms, and waits for the command to finish execution before returning the exit status to the `status` variable.

`[status,cmdout] = dos(command)` additionally returns the output of the DOS command to `cmdout`. This syntax is most useful for DOS console commands that do not require user input, such as `dir`.

`[status,cmdout] = dos(command, '-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for DOS console commands that require user input and that run correctly in the MATLAB Command Window, such as `comp`.

## Input Arguments

### **command** - MS-DOS® command

string

MS-DOS command, specified as a string. The command can be a Windows UI program that opens a graphical user interface, or a DOS console command that you typically run in a DOS command window. The command executes in a DOS shell, which might not be the shell from which you launched MATLAB.

**Example:** 'dir'

## Output Arguments

### **status** - Command exit status

0 | nonzero integer

Command exit status, returned as either 0 or a nonzero integer. When the command is successful, `status` is 0. Otherwise, `status` is a nonzero integer.

- If command includes the ampersand character (&), then `status` is the exit status upon command launch.
- If command does not include the ampersand character (&), then `status` is the exit status upon command completion.

### **cmdout - Output of operating system command**

string

Output of the operating system command, returned as a string.

## **Limitations**

- DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `dos` with a DOS command that relies on the current folder fails. MATLAB returns this error:

```
Error using dos
DOS commands may not be executed when the current directory is a UNC
```

To work around this limitation, change the folder to a mapped drive before running `dos` or a function that calls `dos`.

## **Examples**

### **Save DOS Command Exit Status**

Issue a DOS command to create a new folder named `mynew` and save the exit status to a variable.

```
command = 'mkdir mynew';
status = dos(command)
```

```
status =
```

```
0
```

The `status` of zero indicates that the `mynew` folder was created successfully.

## Open and Run a Windows UI Command

Open Notepad and immediately return the exit status to MATLAB by appending an ampersand (&) to the notepad command.

```
status = dos('notepad &')
```

```
status =
```

```
0
```

The status of zero indicates that Notepad successfully started.

## Save Successful DOS Command Status and Output

Execute the DOS command, `dir`, and view the exit status and command output.

```
[status,cmdout] = dos('dir');
```

```
status, cmdout
```

```
status =
```

```
0
```

```
cmdout =
```

```
Volume in drive C is OSDisk
Volume Serial Number is XXX-XXXX
```

```
Directory of C:\my_MATLAB_files
```

```
04/10/2012 12:08 PM <DIR> .
04/10/2012 12:08 PM <DIR> ..
04/21/2011 09:24 AM 171 base.mat
02/08/2010 05:14 PM 73 baseball.dat
04/10/2012 12:08 PM 474 collatz.asv
04/10/2012 11:56 AM 480 collatz.m
```

```
.
. .
. . .
```

When you issue a valid DOS command, `status` indicates success and `cmdout` contains the command output.

### **Save Unsuccessful DOS Command Status and Output**

Attempt to execute a command called `foo`. Then, view the status and results output arguments.

```
[status,results] = dos('foo');
status, results
```

```
status =
```

```
1
```

```
results =
```

```
'foo' is not recognized as an internal or external command,
operable program or batch file.
```

When you issue an invalid DOS command, `status` indicates failure and `results` contains the DOS error message.

### **Display DOS Command Output in MATLAB Command Window**

Display command output and prompts in the Command Window as the command executes, and also assign the command output to the `results` variable.

```
[status,results] = dos('comp', '-echo');
```

```
Name of first file to compare: collatz.m
collatz.m
```

```
Name of second file to compare: collatz.asv
collatz.asv
Option: /A
/A
Option:

Comparing collatz.m and collatz.asv...
Files compare OK

Compare more files (Y/N) ? N
N
>>
```

## Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the command argument (for example, `'notepad &'`). The exit status is immediately returned to the status variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note** If command includes the trailing `&` character, then `cmdout` is empty.

---

**Purpose**

Dot product

**Syntax**

$C = \text{dot}(A,B)$   
 $C = \text{dot}(A,B,\text{dim})$

**Description**

$C = \text{dot}(A,B)$  returns the scalar dot product of A and B.

- If A and B are vectors, then they must have the same length.
- If A and B are matrices or multidimensional arrays, then they must have the same size. In this case, the dot function treats A and B as collections of vectors. The function calculates the dot product of corresponding vectors along the first array dimension whose size does not equal 1.

$C = \text{dot}(A,B,\text{dim})$  evaluates the dot product of A and B along dimension, dim. The dim input is a positive integer scalar.

**Input Arguments****A,B - Input arrays**

numeric arrays

Input arrays, specified as numeric arrays.

**Data Types**

single | double

**Complex Number Support:** Yes

**dim - Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider two 2-D input arrays, A and B:

- $\text{dot}(A,B,1)$  treats the columns of A and B as vectors and returns the dot products of corresponding columns.

- `dot(A,B,2)` treats the rows of A and B as vectors and returns the dot products of corresponding rows.

A

`dot(A,B,1)`

`dot(A,B,2)`

`dot` returns `conj(A) .* B` if `dim` is greater than `ndims(A)`.

## Examples

### Dot Product of Real Vectors

Create two simple, three-element vectors.

```
A = [4 -1 2];
B = [2 -2 -1];
```

Calculate the dot product of A and B.

```
C = dot(A,B)
```

```
C =
```

```
8
```

The result is 8 since

$$C = A(1) * B(1) + A(2) * B(2) + A(3) * B(3)$$
$$C = 8 + 2 - 2.$$

### Dot Product of Complex Vectors

Create two complex vectors.

```
A = [1+i 1-i -1+i -1-i];
B = [3-4i 6-2i 1+2i 4+3i];
```

Calculate the dot product of A and B.

`C = dot(A,B)`

`C =`

```
1.0000 - 5.0000i
```

The result is a complex scalar since A and B are complex. In general, the dot product of two complex vectors is also complex. An exception is when you take the dot product of a complex vector with itself.

Find the inner product of A with itself.

`D = dot(A,A)`

`D =`

```
8
```

The result is a real scalar. The inner product of a vector with itself is related to the Euclidean length of the vector,  $\text{norm}(A)$ .

### **Dot Product of Matrices**

Create two matrices.

`A = [1 2 3;4 5 6;7 8 9];`

`B = [9 8 7;6 5 4;3 2 1];`

Find the dot product of A and B.

`C = dot(A,B)`

`C =`

```
54 57 54
```

The result, C, contains three separate dot products. `dot` treats the columns of A and B as vectors and calculates the dot product of

corresponding columns. So, for example,  $C(1) = 54$  is the dot product of  $A(:,1)$  with  $B(:,1)$ .

Find the dot product of A and B, treating the *rows* as vectors.

```
D = dot(A,B,2)
```

```
D =
```

```
46
73
46
```

In this case,  $D(1) = 46$  is the dot product of  $A(1,:)$  with  $B(1,:)$ .

## Dot Product of Multidimensional Arrays

Create two multidimensional arrays.

```
A = cat(3,[1 1;1 1],[2 3;4 5],[6 7;8 9])
```

```
B = cat(3,[2 2;2 2],[10 11;12 13],[14 15; 16 17])
```

```
A(:,:,1) =
```

```
1 1
1 1
```

```
A(:,:,2) =
```

```
2 3
4 5
```

```
A(:,:,3) =
```

```
6 7
8 9
```

$$B(:, :, 1) =$$

$$\begin{array}{cc} 2 & 2 \\ 2 & 2 \end{array}$$

$$B(:, :, 2) =$$

$$\begin{array}{cc} 10 & 11 \\ 12 & 13 \end{array}$$

$$B(:, :, 3) =$$

$$\begin{array}{cc} 14 & 15 \\ 16 & 17 \end{array}$$

Calculate the dot product of A and B along the third dimension (dim = 3).

$$C = \text{dot}(A, B, 3)$$

$$C =$$

$$\begin{array}{cc} 106 & 140 \\ 178 & 220 \end{array}$$

The result, C, contains four separate dot products. The first dot product,  $C(1, 1) = 106$ , is equal to the dot product of  $A(1, 1, :)$  with  $B(1, 1, :)$ .

## Definitions

### Scalar Dot Product

The scalar dot product of two real vectors of length  $n$  is equal to

$$u \cdot v = \sum_{i=1}^n u_i v_i = u_1 v_1 + u_2 v_2 + \dots + u_n v_n.$$

# dot

---

This relation is commutative for real vectors, such that `dot(u,v)` equals `dot(v,u)`. If the dot product is equal to zero, then  $u$  and  $v$  are perpendicular.

For complex vectors, the dot product involves a complex conjugate. This ensures that the inner product of any vector with itself is real and positive definite.

$$u \cdot v = \sum_{i=1}^n \bar{u}_i v_i.$$

Unlike the relation for real vectors, the complex relation is not commutative, so `dot(u,v)` equals `conj(dot(v,u))`.

## Algorithms

- When inputs  $A$  and  $B$  are real or complex vectors, the dot function treats them as column vectors and `dot(A,B)` is the same as `sum(conj(A).*B)`.
- When the inputs are matrices or multidimensional arrays, the `dim` argument determines which dimension the sum function operates on. In this case, `dot(A,B)` is the same as `sum(conj(A).*B,dim)`.

## See Also

`cross` | `sum` | `conj`

**Purpose** Convert to double precision

**Syntax** `double(x)`

**Description** `double(x)` returns the double-precision value for *X*. If *X* is already a double-precision array, `double` has no effect.

**Tips** The `double` function should be overloaded for any object when it makes sense to convert it to a double-precision value.

# dragrect

---

**Purpose** Drag rectangles with mouse

**Syntax** `[finalrect] = dragrect(initialrect)`  
`[finalrect] = dragrect(initialrect,stepsize)`

**Description** `[finalrect] = dragrect(initialrect)` tracks one or more rectangles anywhere on the screen. The n-by-4 matrix `initialrect` defines the rectangles. Each row of `initialrect` must contain the initial rectangle position as `[left bottom width height]` values. `dragrect` returns the final position of the rectangles in `finalrect`.

`[finalrect] = dragrect(initialrect,stepsize)` moves the rectangles in increments of `stepsize`. The lower left corner of the first rectangle is constrained to a grid of size equal to `stepsize` starting at the lower left corner of the figure, and all other rectangles maintain their original offset from the first rectangle.

`[finalrect] = dragrect(...)` returns the final positions of the rectangles when the mouse button is released. The default step size is 1.

**Tips** `dragrect` returns immediately if a mouse button is not currently pressed. Use `dragrect` in a `ButtonDownFcn`, or from the command line in conjunction with `waitforbuttonpress`, to ensure that the mouse button is down when `dragrect` is called. `dragrect` returns when you release the mouse button.

If the drag ends over a figure window, the positions of the rectangles are returned in that figure's coordinate system. If the drag ends over a part of the screen not contained within a figure window, the rectangles are returned in the coordinate system of the figure over which the drag began.

---

**Note** You cannot use normalized figure units with `dragrect`.

---

## Examples

Drag a rectangle that is 50 pixels wide and 100 pixels in height.

```
waitforbuttonpress
point1 = get(gcf, 'CurrentPoint') % button down detected
rect = [point1(1,1) point1(1,2) 50 100]
[r2] = dragrect(rect)
```

## See Also

[rbbox](#) | [waitforbuttonpress](#)

# drawnow

---

**Purpose** Update figure window and execute pending callbacks

**Syntax** drawnow  
drawnow expose  
drawnow update

**Description** drawnow causes figure windows and their children to update. Any callbacks generated by user actions (for example, mouse or key presses, button clicks, and so on) are executed before drawnow returns.

Use drawnow in animation loops to update the figure during function execution and to update graphical user interfaces.

drawnow expose causes graphics and user-interface objects to refresh with all pending changes. However, it does not allow pending callbacks to execute.

drawnow update causes only user-interface objects to refresh. It does not allow pending callbacks to execute and does not refresh graphics objects.

---

**Note** On Macintosh systems, drawnow update produces the same results as described for drawnow expose

---

## Other Actions That Cause Queue Processing

Other actions and function calls that cause the MATLAB software to flush the queue and update the figure include:

- Returning to the MATLAB prompt
- Executing the following functions:
  - figure
  - getframe
  - input
  - pause

- keyboard
- Functions that wait for user input (i.e., `waitforbuttonpress`, `waitfor`, `ginput`)
- Any code that causes one of the above functions to execute. For example, suppose `h` is the handle of an axes. Calling `axes(h)` causes its parent figure to be made the current figure and brought to the front of all displayed figures, which is the equivalent of executing a `drawnow`.

## Examples

Using `drawnow` in a loop causes the display to update while the loop executes:

```
t = 0:pi/100:2*pi;
y = exp(sin(t));
h = plot(t,y,'YDataSource','y');
for k = 1:0.01:10
 y = exp(sin(t.*k));
 refreshdata(h,'caller')
 drawnow
end
```

## See Also

`snapnow` | `waitfor` | `waitforbuttonpress`

# dsearchn

---

**Purpose** N-D nearest point search

**Syntax**  
`k = dsearchn(X,T,XI)`  
`k = dsearchn(X,T,XI,outval)`  
`k = dsearchn(X,XI)`  
`[k,d] = dsearchn(X,...)`

**Description** `k = dsearchn(X,T,XI)` returns the indices `k` of the closest points in `X` for each point in `XI`. `X` is an `m`-by-`n` matrix representing `m` points in `n`-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in `n`-dimensional space. `T` is a `numt`-by-`n+1` matrix, a triangulation of the data `X` generated by `delaunayn`. The output `k` is a column vector of length `p`.

`k = dsearchn(X,T,XI,outval)` returns the indices `k` of the closest points in `X` for each point in `XI`, unless a point is outside the convex hull. If `XI(J,:)` is outside the convex hull, then `K(J)` is assigned `outval`, a scalar double. `Inf` is often used for `outval`. If `outval` is `[]`, then `k` is the same as in the case `k = dsearchn(X,T,XI)`.

`k = dsearchn(X,XI)` performs the search without using a triangulation. With large `X` and small `XI`, this approach is faster and uses much less memory.

`[k,d] = dsearchn(X,...)` also returns the distances `d` to the closest points. `d` is a column vector of length `p`.

**Algorithms** `dsearchn` is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>. For copyright information, see <http://www.qhull.org/COPYING.txt>.

**References** [1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," *ACM Transactions on Mathematical Software*, Vol. 22, No. 4, Dec. 1996, p. 469–483.

**See Also** `delaunayTriangulation`

**Purpose** Abstract class used to derive handle class with dynamic properties

**Syntax** `classdef myclass < dynamicprops`

**Description** `classdef myclass < dynamicprops` makes *myclass* a subclass of the `dynamicprops` class, which is a subclass of the `handle` class.

Use the `dynamicprops` class to derive classes that can define dynamic properties (instance properties), which are associated with a specific objects, but have no effect on the objects class definition. Dynamic properties are useful for attaching temporary data to one or more objects.

### **dynamicprops Methods**

This class defines one method `addprop` and, as a subclass of the `handle` class, inherits all the `handle` class methods.

- `addprop` — adds the named property to the specified handle objects. See “Dynamic Properties — Adding Properties to an Instance” for more information.

**See Also** `handle`

# echo

---

**Purpose** Display statements during function execution

**Syntax**

```
echo on
echo off
echo
echo fcnname on
echo fcnname off
echo fcnname
echo on all
echo off all
```

**Description** The echo command controls the display (or *echoing*) of statements in a function during their execution. Normally, statements in a function file are not displayed on the screen during execution. Command echoing is useful for debugging or for demonstrations, allowing the commands to be viewed as they execute.

The echo command behaves in a slightly different manner for script files and function files. For script files, the use of echo is simple; echoing can be either on or off, in which case any script used is affected.

|          |                                                       |
|----------|-------------------------------------------------------|
| echo on  | Turns on the echoing of commands in all script files  |
| echo off | Turns off the echoing of commands in all script files |
| echo     | Toggles the echo state                                |

With function files, the use of echo is more complicated. If echo is enabled on a function file, the file is interpreted, rather than compiled. Each input line is then displayed as it is executed. Since this results in inefficient execution, use echo only for debugging.

|                         |                                              |
|-------------------------|----------------------------------------------|
| echo <i>fcnname</i> on  | Turns on echoing of the named function file  |
| echo <i>fcnname</i> off | Turns off echoing of the named function file |

|                                  |                                                   |
|----------------------------------|---------------------------------------------------|
| <code>echo <i>fcnname</i></code> | Toggles the echo state of the named function file |
| <code>echo on all</code>         | Sets echoing on for all function files            |
| <code>echo off all</code>        | Sets echoing off for all function files           |

## Tips

- To avoid confusing syntax, do not use `on` or `off` as a function name.

`function`

# echodemo

---

**Purpose** Run example script step-by-step in Command Window

**Syntax**  
`echodemo filename`  
`echodemo(filename,index)`

**Description** `echodemo filename` runs the script specified by `filename` step-by-step in the Command Window. The file must contain sections defined with two percent signs (%) to enable pausing after each step. At each step, you can click links in the Command Window to proceed or stop. If the Command Window is not large enough to show the links, scroll up to see them.

---

## Caution

If variables in your base workspace have the same name as variables that the example file creates, the example could overwrite your data. Preserve your data by saving it to a MAT-file before running the example.

---

`echodemo(filename,index)` starts with the section number specified by `index`. If the example relies on results of previous steps, using this syntax can produce errors or unexpected results.

## Input Arguments

### **filename - Script file name**

string

Script file name, specified as a string.

When you use the function syntax for `echodemo` and specify its inputs within parentheses, enclose the `filename` input in single quotes.

### **index - Section index**

scalar integer

Section index, specified as a scalar integer.

The link text in the Command Window shows the current section number,  $n$ , and the total number of sections,  $m$ , as  $n/m$ .

## Examples

### Run Example Script in Command Window

Run the Loma Prieta Earthquake example.

```
echodemo quake
```

### Start Script from Specified Section

Start the Loma Prieta Earthquake example from the third section.

```
filename = 'quake';
index = 3;
echodemo(filename,index)
```

This code errors because the example requires variables created in earlier sections.

## Tips

- Only use `echodemo` to display scripts, not functions. `echodemo` can run any script that you can execute, but only scripts with sections pause between steps.

# TriRep.edgeAttachments

---

**Purpose** (Will be removed) Simplices attached to specified edges

---

**Note** `edgeAttachments(TriRep)` will be removed in a future release. Use `edgeAttachments(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax**  
`SI = edgeAttachments(TR, V1, V2)`  
`SI = edgeAttachments(TR, EDGE)`

**Description**  
`SI = edgeAttachments(TR, V1, V2)` returns the simplices `SI` attached to the edges specified by `(V1, V2)`. `(V1, V2)` represents the start and end vertices of the edges to be queried.  
`SI = edgeAttachments(TR, EDGE)` specifies edges in matrix format.

**Input Arguments**

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TR</code>     | Triangulation representation.                                                                                                                      |
| <code>V1, V2</code> | Column vectors of vertex indices into the array of points representing the vertex coordinates.                                                     |
| <code>EDGE</code>   | Matrix specifying edge start and end points. <code>EDGE</code> is of size <code>m-by-2</code> , <code>m</code> being the number of edges to query. |

**Output Arguments**

|                 |                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>SI</code> | Vector cell array of indices into the triangulation matrix. <code>SI</code> is a cell array because the number of simplices associated with each edge can vary. |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Definitions** A simplex is a triangle/tetrahedron or higher dimensional equivalent.

**Examples** **Example 1**

Load a 3-D triangulation to compute the tetrahedra attached to an edge.

```
load tetmesh
trep = TriRep(tet, X);
v1 = [15 21]';
v2 = [936 716]';
t1 = edgeAttachments(trep, v1, v2);
```

You can also specify the input as edges.

```
e = [v1 v2];
t2 = edgeAttachments(trep, e);
isequal(t1,t2);
```

## Example 2

Create a triangulation with `DelaunayTri`.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Query the triangles attached to edge (1,5).

```
t = edgeAttachments(dt, 1,5);
t{:};
```

# TriRep.edges

---

**Purpose** (Will be removed) Triangulation edges

---

**Note** `edges(TriRep)` will be removed in a future release. Use `edges(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `E = edges(TR)`

**Description** `E = edges(TR)` returns the edges in the triangulation in an `n`-by-2 matrix. `n` is the number of edges. The vertices of the edges index into `TR.X`, the array of points representing the vertex coordinates.

**Input Arguments**

|                 |                               |
|-----------------|-------------------------------|
| <code>TR</code> | Triangulation representation. |
|-----------------|-------------------------------|

**Output Arguments**

|                |              |
|----------------|--------------|
| <code>E</code> | Edge matrix. |
|----------------|--------------|

**Examples**      **Example 1**

Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y);
```

Return all edges.

```
e = edges(trep);
```

**Example 2**

Query a 2-D DelaunayTri-generated triangulation.

```
X = rand(10,2);
```

```
dt = DelaunayTri(X);
e = edges(dt);
```

[edgeAttachments](#) | [triangulation](#) | [delaunayTriangulation](#)

# edit

---

**Purpose** Edit or create file

**Syntax**

```
edit
edit file
edit file1 ... fileN
```

**Description** edit opens a new file called `Untitled` in the Editor. MATLAB does not automatically save `Untitled`.

`edit file` opens the specified file in the Editor. If `file` does not already exist, MATLAB asks if you want to create it. `file` can include a partial path, complete path, relative path, or no path. If `file` includes a partial path or no path, `edit` will look for the file on the search path. You must have write permission to the path to create `file`, otherwise, MATLAB ignores the argument.

You must specify the extension to open `.mat` and `.mdl` files. MATLAB cannot directly edit binary files, such as `.p` and `.mex` files.

`edit file1 ... fileN` opens each file, `file1 ... fileN`, in the Editor.

## Examples

### Open a New File

```
edit
```

A new file titled `Untitled` opens in the MATLAB Editor (or default editor). `Untitled` does not appear in your Current Folder.

### Create a New File

```
mkdir tests
edit tests/new_script.m
```

A dialog box appears, asking if you want to create `new_script.m`. If you select **Yes**, MATLAB creates and opens `tests/new_script.m`.

## Open Files

```
edit file1 file2 file3 file4
```

MATLAB sequentially creates and opens the files: `file1`, `file2`, `file3`, and `file4` in sequence.

## Input Arguments

### **file** - Name of file

string

Name of file, specified as a string. If `file` specifies a path that contains a nonexistent folder, MATLAB throws an error. Specify multiple files on the same line by separating filenames with a space.

If `file` is overloaded (that is, appears in multiple folders on the search path), then include a partial path to edit the correct page, such as

```
edit folderName/file
```

If you do not specify the extension, then `edit` opens a file with the specified name and a `.m` extension.

```
edit name
```

If the file is part of a class or package, then either specify the path and extension, or separate the components of the name with periods, such as:

```
edit className.name
edit packageName.name
edit packageName.className.name
edit packageName.name
```

### **Data Types**

char

`open` | `type`

## Concepts

- “Change Default Editor”

**Purpose** Eigenvalues and eigenvectors

**Syntax** `lambda = eig(A)`  
`lambda = eig(A,balanceOption)`

`lambda = eig(A,B)`  
`lambda = eig(A,B,algorithm)`

`[V,D] = eig( __ )`  
`[V,D,W] = eig( __ )`

`[ __ ] = eig( __ ,eigvalOption)`

**Description** `lambda = eig(A)` returns a column vector containing the eigenvalues, with multiplicity, that satisfy the equation  $Av = \lambda v$ , where  $A$  is an  $n$ -by- $n$  matrix,  $v$  is a column vector of length  $n$ , and  $\lambda$  is a scalar. The values of  $\lambda$  that satisfy the equation are the eigenvalues. The corresponding values of  $v$  that satisfy the equation are the right eigenvectors.

`lambda = eig(A,balanceOption)` specifies a balancing option as one of two strings: 'balance', which enables a preliminary balancing step, or 'nobalance' which disables it.

`lambda = eig(A,B)` returns a vector containing the generalized eigenvalues of the pair,  $(A,B)$ , that satisfy the equation  $Av = \lambda Bv$ , where  $A$  and  $B$  are  $n$ -by- $n$  matrices,  $v$  is a column vector of length  $n$ , and  $\lambda$  is a scalar. The values of  $\lambda$  that satisfy the equation are the generalized eigenvalues. The corresponding values of  $v$  are the generalized right eigenvectors.

`lambda = eig(A,B,algorithm)` specifies the generalized eigenvalue algorithm as one of two strings: 'qz', which uses the QZ algorithm, or 'chol', which uses the Cholesky factorization of  $B$ .

`[V,D] = eig( ___ )` returns two optional outputs for any of the previous input syntaxes. D is a diagonal matrix containing the eigenvalues. V is a matrix whose columns are the corresponding right eigenvectors.

`[V,D,W] = eig( ___ )` also returns W, a matrix whose columns are the corresponding left eigenvectors, using any of the previous input syntaxes. The left eigenvectors,  $w$ , satisfy the equation  $w^\dagger A = \lambda w^\dagger$ .

`[ ___ ] = eig( ___, eigvalOption)` returns the eigenvalues in the form specified by `eigvalOption` using any of the previous syntaxes or outputs. Specify `eigvalOption` as 'vector' to return a column vector of eigenvalues, `lambda`, or as 'matrix' to return a diagonal matrix of eigenvalues, D.

## Input Arguments

### A - Input matrix

square matrix

Input matrix, specified as a real or complex square matrix.

#### Data Types

double | single

**Complex Number Support:** Yes

### B - Generalized eigenvalue problem input matrix

square matrix

Generalized eigenvalue problem input matrix, specified as a square matrix of real or complex values. B must be the same size as A.

#### Data Types

double | single

**Complex Number Support:** Yes

### balanceOption - Balance option

'balance' (default) | 'nobalance'

Balance option, specified as one two strings: 'balance', which enables a preliminary balancing step, or 'nobalance' which disables it. In most

cases, the balancing step improves the conditioning of A to produce more accurate results. However, there are cases in which balancing produces incorrect results. Specify 'nobalance' when A contains values whose scale differs dramatically. For example, if A contains nonzero integers, as well as very small (near zero) values, then the balancing step might scale the small values to make them as significant as the integers and produce inaccurate results.

'balance' is the default behavior. The eig function ignores balanceOption when A is symmetric.

## Data Types

char

## algorithm - Generalized eigenvalue algorithm

'chol' | 'qz'

Generalized eigenvalue algorithm, specified as 'chol' or 'qz', which selects the algorithm to use for calculating the generalized eigenvalues of a pair.

| algorithm | Description                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------|
| 'chol'    | Computes the generalized eigenvalues of A and B using the Cholesky factorization of B.                                    |
| 'qz'      | Uses the QZ algorithm, also known as the generalized Schur decomposition. This algorithm ignores the symmetry of A and B. |

In general, the two algorithms return the same result. The QZ algorithm can be more stable for certain problems, such as those involving badly conditioned matrices.

When you omit the algorithm argument, the eig function selects an algorithm based on the properties of A and B. It uses the 'chol'

algorithm for symmetric (Hermitian) A and symmetric (Hermitian) positive definite B. Otherwise, it uses the 'qz' algorithm.

Regardless of the algorithm you specify, the `eig` function always uses the QZ algorithm when A or B are not symmetric.

### **eigvalOption - Eigenvalue option**

'vector' | 'matrix'

Eigenvalue option, specified as 'vector' or 'matrix'. This option allows you to specify whether the eigenvalues are returned in a column vector, `lambda`, or a diagonal matrix, `D`. The default behavior varies according to the number of outputs specified:

- If you specify one output, such as `lambda = eig(A)`, then the eigenvalues are returned as a column vector, `lambda`, by default.
- If you specify two or three outputs, such as `[V,D] = eig(A)`, then the eigenvalues are returned as a diagonal matrix, `D`, by default.

**Example:** `D = eig(A, 'matrix')` returns a diagonal matrix of eigenvalues with the one output syntax.

### **Data Types**

char

## **Output Arguments**

### **lambda - Eigenvalues**

column vector

Eigenvalues, returned as a column vector containing the eigenvalues (or generalized eigenvalues of a pair) with multiplicity.

- When A is real and symmetric or complex Hermitian, the values of `lambda` that satisfy  $Av = \lambda v$  are real.
- When A is real and skew-symmetric or skew-Hermitian, the values of `lambda` that satisfy  $Av = \lambda v$  are purely imaginary or zero.

### **V - Right eigenvectors**

square matrix

Right eigenvectors, returned as a square matrix whose columns are the right eigenvectors of  $A$  or generalized right eigenvectors of the pair,  $(A,B)$ . The form and normalization of  $V$  depends on the combination of input arguments:

- $[V,D] = \text{eig}(A)$  returns matrix  $V$ , whose columns are the right eigenvectors of  $A$  such that  $A*V = V*D$ . The eigenvectors in  $V$  are normalized so that the 2-norm of each is 1.
- $[V,D] = \text{eig}(A, 'nobalance')$  also returns matrix  $V$ . However, the 2-norm of each eigenvector is not necessarily 1.
- $[V,D] = \text{eig}(A,B)$  and  $[V,D] = \text{eig}(A,B, \text{algorithm})$  returns  $V$  as a matrix whose columns are the generalized right eigenvectors that satisfy  $A*V = B*V*D$ . The 2-norm of each eigenvector is not necessarily 1. In this case,  $D$  contains the generalized eigenvalues of the pair,  $(A,B)$ , along the main diagonal.

If  $A$  is symmetric and  $B$  is symmetric positive definite, then the eigenvectors in  $V$  are normalized so that the  $B$ -norm of each is 1.

## **D - Diagonal eigenvalues matrix**

diagonal matrix

Diagonal eigenvalues matrix, returned as a matrix containing the eigenvalues of  $A$  or the generalized eigenvalues of the pair,  $(A,B)$ , with multiplicity.

- When  $A$  is real and symmetric or complex Hermitian, the values of  $D$  that satisfy  $Av = \lambda v$  are real.
- When  $A$  is real and skew-symmetric or skew-Hermitian, the values of  $D$  that satisfy  $Av = \lambda v$  are purely imaginary or zero.

## **W - Left eigenvectors**

square matrix

Left eigenvectors, returned as a square matrix whose columns are the left eigenvectors of  $A$  or generalized left eigenvectors of the pair,  $(A,B)$ . The form and normalization of  $W$  depends on the combination of input arguments:

- $[V,D,W] = \text{eig}(A)$  returns matrix  $W$ , whose columns are the left eigenvectors of  $A$  such that  $W' * A = D * W'$ . The eigenvectors in  $W$  are normalized so that the 2-norm of each is 1. If  $A$  is symmetric, then  $W$  is the same as  $V$ .
- $[V,D,W] = \text{eig}(A, 'nobalance')$  also returns matrix  $W$ . However, the 2-norm of each eigenvector is not necessarily 1.
- $[V,D,W] = \text{eig}(A,B)$  and  $[V,D,W] = \text{eig}(A,B, \text{algorithm})$  returns  $W$  as a matrix whose columns are the generalized left eigenvectors that satisfy  $W' * A = D * W' * B$ . The 2-norm of each eigenvector is not necessarily 1. In this case,  $D$  contains the generalized eigenvalues of the pair,  $(A,B)$ , along the main diagonal.

If  $A$  and  $B$  are symmetric, then  $W$  is the same as  $V$ .

## Examples

### Eigenvalues of Real Symmetric Matrix

Use the gallery function to create symmetric positive definite matrix.

```
A = gallery('lehmer',4)
```

```
A =
```

```

1.0000 0.5000 0.3333 0.2500
0.5000 1.0000 0.6667 0.5000
0.3333 0.6667 1.0000 0.7500
0.2500 0.5000 0.7500 1.0000
```

Calculate the eigenvalues of  $A$ .

```
lambda = eig(A)
```

```
lambda =
```

```

0.2078
0.4078
0.8482
2.5362
```

The result is a column vector.

Alternatively, use `eigvalOption` to return the eigenvalues in a diagonal matrix.

```
D = eig(A, 'matrix')
```

```
D =
```

```
 0.2078 0 0 0
 0 0.4078 0 0
 0 0 0.8482 0
 0 0 0 2.5362
```

## Eigenvalues and Eigenvectors of Nonsymmetric Matrix

Use the `gallery` function to create a circulant matrix.

```
A = gallery('circul',3)
```

```
A =
```

```
 1 2 3
 3 1 2
 2 3 1
```

Calculate the eigenvalues and right eigenvectors of A.

```
[V,D] = eig(A)
```

```
V =
```

```
-0.5774 + 0.0000i 0.2887 - 0.5000i 0.2887 + 0.5000i
-0.5774 + 0.0000i -0.5774 + 0.0000i -0.5774 + 0.0000i
-0.5774 + 0.0000i 0.2887 + 0.5000i 0.2887 - 0.5000i
```

```
D =
```

```

6.0000 + 0.0000i 0.0000 + 0.0000i 0.0000 + 0.0000i
0.0000 + 0.0000i -1.5000 + 0.8660i 0.0000 + 0.0000i
0.0000 + 0.0000i 0.0000 + 0.0000i -1.5000 - 0.8660i

```

Verify that matrix  $V$  diagonalizes  $A$ , since the eigenvalues are distinct and the eigenvectors are independent.

```
V\A*V
```

```
ans =
```

```

6.0000 + 0.0000i 0.0000 - 0.0000i -0.0000 + 0.0000i
-0.0000 - 0.0000i -1.5000 + 0.8660i -0.0000 - 0.0000i
-0.0000 + 0.0000i -0.0000 + 0.0000i -1.5000 - 0.8660i

```

### Eigenvalues and Eigenvectors of a Matrix Whose Elements Differ Dramatically in Scale

```

A = [3.0 -2.0 -0.9 2*eps;
 -2.0 4.0 1.0 -eps;
 -eps/4 eps/2 -1.0 0;
 -0.5 -0.5 0.1 1.0];

```

Calculate the eigenvalues and right eigenvectors using the default (balancing) behavior.

```
[VB,DB] = eig(A)
```

```
VB =
```

```

0.6153 -0.4176 -0.0000 -0.1437
-0.7881 -0.3261 -0.0000 0.1264
-0.0000 -0.0000 -0.0000 -0.9196
0.0189 0.8481 1.0000 0.3432

```

```
DB =
```

```
5.5616 0 0 0
 0 1.4384 0 0
 0 0 1.0000 0
 0 0 0 -1.0000
```

Check to see if the results satisfy  $A*VB = VB*DB$ .

$A*VB - VB*DB$

ans =

```
0.0000 0.0000 -0.0000 0.0000
 0 -0.0000 0.0000 -0.0000
0.0000 -0.0000 0.0000 0.0000
 0 0.0000 0.0000 0.6031
```

This result does not satisfy  $A*VB = VB*DB$ . Ideally, the eigenvalue decomposition satisfies this relationship. Since MATLAB performs the decomposition using floating-point computations, then  $A*V$  can, at best, approach  $V*D$ . In other words,  $A*V - V*D$  is close to, but not exactly, 0.

Now, try calculating the eigenvalues and right eigenvectors without the balancing step.

$[VN, DN] = \text{eig}(A, 'nobalance')$

VN =

```
0.6153 -0.4176 -0.0000 -0.1528
-0.7881 -0.3261 0 0.1345
-0.0000 -0.0000 -0.0000 -0.9781
0.0189 0.8481 -1.0000 0.0443
```

DN =

```
5.5616 0 0 0
```

```

0 1.4384 0 0
0 0 1.0000 0
0 0 0 -1.0000

```

Verify that the results satisfy  $A*VN = VN*DN$ .

$A*VN - VN*DN$

ans =

```

1.0e-14 *
-0.1776 -0.0111 -0.0559 -0.0167
0.3553 0.1055 0.0336 -0.0194
0.0017 0.0002 0.0007 0
0.0264 -0.0222 0.0222 0.0097

```

$A*VN - VN*DN$  is much closer to 0, so the 'nobalance' option produces more accurate results in this case.

### Left Eigenvectors

Create a 3-by-3 matrix.

```
A = [1 7 3; 2 9 12; 5 22 7];
```

Calculate the right eigenvectors, V, the eigenvalues, D, and the left eigenvectors, W.

```
[V,D,W] = eig(A)
```

V =

```

-0.2610 -0.9734 0.1891
-0.5870 0.2281 -0.5816
-0.7663 -0.0198 0.7912

```

D =

```
25.5548 0 0
 0 -0.5789 0
 0 0 -7.9759
```

W =

```
-0.1791 -0.9587 -0.1881
-0.8127 0.0649 -0.7477
-0.5545 0.2768 0.6368
```

Matrix W contains the left eigenvectors.

Verify the results satisfy  $W' * A = D * W'$ .

$W' * A - D * W'$

ans =

```
1.0e-13 *
-0.0444 -0.1066 -0.0888
-0.0011 0.0442 0.0333
 0 0.0266 0.0178
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since MATLAB performs the decomposition using floating-point computations, then  $W' * A$  can, at best, approach  $D * W'$ . In other words,  $W' * A - D * W'$  is close to, but not exactly, 0.

## **Eigenvalues and Eigenvectors of Nondiagonalizable (Defective) Matrix**

Create a 3-by-3 matrix.

```
A = [3 1 0; 0 3 1; 0 0 3];
```

Calculate the eigenvalues and right eigenvectors of A.

```
[V,D] = eig(A)
```

```
V =
```

```
 1.0000 -1.0000 1.0000
 0 0.0000 -0.0000
 0 0 0.0000
```

```
D =
```

```
 3 0 0
 0 3 0
 0 0 3
```

A has repeated eigenvalues and the eigenvectors are not independent. This means that A is not diagonalizable and is, therefore, defective.

Verify that V and D satisfy the equation,  $A*V = V*D$ , even though A is defective.

```
A*V - V*D
```

```
ans =
```

```
 1.0e-15 *
 0 0.8882 -0.8882
 0 0 0.0000
 0 0 0
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since MATLAB performs the decomposition using floating-point computations, then  $A*V$  can, at best, approach  $V*D$ . In other words,  $A*V - V*D$  is close to, but not exactly, 0.

## Generalized Eigenvalues and Eigenvectors

Create two matrices, A and B, then solve the generalized eigenvalue problem for the eigenvalues and right eigenvectors of the pair (A,B).

```
A = [1/sqrt(2) 0; 0 1];
B = [0 1; -1/sqrt(2) 0];
[V,D]=eig(A,B)
```

```
V =
```

```
1.0000 + 0.0000i 1.0000 + 0.0000i
0.0000 - 0.7071i 0.0000 + 0.7071i
```

```
D =
```

```
0.0000 + 1.0000i 0.0000 + 0.0000i
0.0000 + 0.0000i 0.0000 - 1.0000i
```

Verify that the results satisfy  $A*V = B*V*D$ .

```
A*V - B*V*D
```

```
ans =
```

```
0 0
0 0
```

The residual error  $A*V - B*V*D$  is exactly zero.

## Generalized Eigenvalues Using QZ Algorithm for Badly Conditioned Matrices

Create a badly conditioned symmetric matrix containing values close to machine precision.

```
format long e
A = diag([10^-16, 10^-15])
```

```
A =
```

```
1.0000000000000000e-16 0
0 1.0000000000000000e-15
```

Calculate the generalized eigenvalues and a set of right eigenvectors using the default algorithm. In this case, the default algorithm is 'chol'.

```
[V1,D1] = eig(A,A)
```

```
V1 =
```

```
1.0000000000000000e+08 0
 0 3.162277660168380e+07
```

```
D1 =
```

```
9.999999999999999e-01 0
 0 1.0000000000000000e+00
```

Now, calculate the generalized eigenvalues and a set of right eigenvectors using the 'qz' algorithm.

```
[V2,D2] = eig(A,A,'qz')
```

```
V2 =
```

```
1 0
0 1
```

```
D2 =
```

```
1 0
0 1
```

Check to see how well the 'chol' result satisfies  $A*V1 = A*V1*D1$ .

```
format
```

```
A*V1 - A*V1*D1
```

```
ans =

1.0e-23 *

0.1654 0
0 -0.6617
```

Now, check to see how well the 'qz' result satisfies  $A*V2 = A*V2*D2$ .

```
A*V2 - A*V2*D2
```

```
ans =

0 0
0 0
```

When both matrices are Hermitian, `eig` uses the 'chol' algorithm by default. In this case, the QZ algorithm returns more accurate results.

## **Generalized Eigenvalues and Eigenvectors of a Pair in Which One Matrix is Singular**

Create a 2-by-2 identity matrix, A, and a singular matrix, B.

```
A = eye(2);
B = [3 6; 4 8];
```

Try to calculate the generalized eigenvalues of the matrix,  $B^{-1}A$ .

```
[V,D] = eig(B\A)
```

```
Warning: Matrix is singular to working precision.
Error using eig
Input to EIG must not contain NaN or Inf.
```

Now calculate the generalized eigenvalues and right eigenvectors by passing both matrices to the `eig` function.

```
[V,D] = eig(A,B)
```

```
V =
 -0.7500 -1.0000
 -1.0000 0.5000
```

```
D =
 0.0909 0
 0 Inf
```

It's better to pass both matrices separately, and let `eig` choose the best algorithm to solve the problem. In this case, `eig(A,B)` returned a set of eigenvectors and at least one real eigenvalue, even though `B` is not invertible.

Verify  $Av = \lambda Bv$  for the first eigenvalue and the first eigenvector.

```
eigval = D(1,1);
eigvec = V(:,1);
A*eigvec - eigval*B*eigvec
```

```
ans =
 1.0e-15 *
 0.1110
 0.2220
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since the decomposition is performed using floating-point computations, then `A*eigvec` can, at best, approach `eigval*B*eigvec`, as it does in this case.

## Tips

- The `eig` function returns the eigenvalues of a real, symmetric, sparse matrix for the syntax, `lambda = eig(A)`. Use the `eigs` function for all other sparse eigenvalue and eigenvector problems.

# eig

---

## **See Also**

balance | condeig | eigs | hess | qz | schur

**Purpose**

Largest eigenvalues and eigenvectors of matrix

**Syntax**

```
d = eigs(A)
[V,D] = eigs(A)
[V,D,flag] = eigs(A)
eigs(A,B)
eigs(A,k)
eigs(A,B,k)
eigs(A,k,sigma)
eigs(A,B,k,sigma)
eigs(A,K,sigma,opts)
eigs(A,B,k,sigma,opts)
eigs(Afun,n,...)
```

**Description**

`d = eigs(A)` returns a vector of *A*'s six largest magnitude eigenvalues. *A* must be a square matrix. *A* should be large and sparse, though `eigs` will work on full matrices as well. See “Tips” below.

`[V,D] = eigs(A)` returns a diagonal matrix *D* of *A*'s six largest magnitude eigenvalues and a matrix *V* whose columns are the corresponding eigenvectors.

`[V,D,flag] = eigs(A)` also returns a convergence flag. If `flag` is 0 then all the eigenvalues converged; otherwise not all converged.

`eigs(A,B)` solves the generalized eigenvalue problem  $A*V == B*V*D$ . *B* must be the same size as *A*. `eigs(A,[],...)` indicates the standard eigenvalue problem  $A*V == V*D$ .

`eigs(A,k)` and `eigs(A,B,k)` return the *k* largest magnitude eigenvalues.

`eigs(A,k,sigma)` and `eigs(A,B,k,sigma)` return *k* eigenvalues based on *sigma*, which can take any of the following values:

scalar (real or complex, including 0)      The eigenvalues closest to *sigma*. If A is a function, Afun must return  $Y = (A - \textit{sigma} * B) \backslash x$  (i.e.,  $Y = A \backslash x$  when *sigma* = 0).

'lm'      Largest magnitude (default).

'sm'      Smallest magnitude. Same as *sigma* = 0. If A is a function, Afun must return  $Y = A \backslash x$ .

For real symmetric A and symmetric positive-definite B, the following are also options:

'la'      Largest algebraic

'sa'      Smallest algebraic

'be'      Both ends (one more from high end if k is odd)

For nonsymmetric and complex problems, the following are also options:

'lr'      Largest real part

'sr'      Smallest real part

'li'      Largest imaginary part

'si'      Smallest imaginary part

---

**Note** The syntax `eigs(A,k,...)` is not valid when A is scalar. To pass a value for k, you must specify B as the second argument and k as the third (`eigs(A,B,k,...)`). If necessary, you can set B equal to [], the default.

---

`eigs(A,K,sigma,opts)` and `eigs(A,B,k,sigma,opts)` specify an options structure. Default values are shown in brackets ({}).

| Parameter   | Description                                                                                                                                                                                                                                                                     | Values                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| opts.issym  | 1 if A or $A\text{-}\sigma*B$ represented by Afun is symmetric, 0 otherwise.                                                                                                                                                                                                    | {0   1}                                        |
| opts.isreal | 1 if A or $A\text{-}\sigma*B$ represented by Afun is real, 0 otherwise.                                                                                                                                                                                                         | {0   {1}}                                      |
| opts.tol    | Convergence: Ritz estimate residual $\leq \text{tol}*\text{norm}(A)$ .                                                                                                                                                                                                          | [scalar   {eps}]                               |
| opts.maxit  | Maximum number of iterations.                                                                                                                                                                                                                                                   | [integer   {300}]                              |
| opts.p      | Number of Lanczos basis vectors.<br>$p \geq 2k$ ( $p \geq 2k+1$ real nonsymmetric) advised. $p$ must satisfy $k < p \leq n$ for real symmetric, $k+1 < p \leq n$ otherwise.<br>Note: If you do not specify a $p$ value, the default algorithm uses at least 20 Lanczos vectors. | [integer   {2*k}]                              |
| opts.v0     | Starting vector.                                                                                                                                                                                                                                                                | [n-by-1 vector   {randomly generated by rand}] |
| opts.disp   | Diagnostic information display level.                                                                                                                                                                                                                                           | {0   1   2}                                    |
| opts.cholB  | 1 if B is really its Cholesky factor $\text{chol}(B)$ , 0 otherwise.                                                                                                                                                                                                            | {0   1}                                        |
| opts.permB  | Permutation vector permB if sparse B is really $\text{chol}(B(\text{permB}, \text{permB}))$ .                                                                                                                                                                                   | [permB   {1:n}]                                |

`eigs(Afun,n,...)` accepts a function handle, `Afun`, instead of the matrix `A`.

`y = Afun(x)` should return:

|                            |                                                                                                                                              |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>A*x</code>           | if <i>sigma</i> is not specified, or is a string other than 'sm'                                                                             |
| <code>A\x</code>           | if <i>sigma</i> is 0 or 'sm'                                                                                                                 |
| <code>(A-sigma*I)\x</code> | if <i>sigma</i> is a nonzero scalar (standard eigenvalue problem). <code>I</code> is an identity matrix of the same size as <code>A</code> . |
| <code>(A-sigma*B)\x</code> | if <i>sigma</i> is a nonzero scalar (generalized eigenvalue problem)                                                                         |

“Parameterizing Functions” explains how to provide additional parameters to the function `Afun`, if necessary.

The matrix `A`, `A-sigma*I` or `A-sigma*B` represented by `Afun` is assumed to be real and nonsymmetric unless specified otherwise by `opts.isreal` and `opts.issym`. In all the `eigs` syntaxes, `eigs(A,...)` can be replaced by `eigs(Afun,n,...)`.

## Tips

`d = eigs(A,k)` is not a substitute for

```
d = eig(full(A))
d = sort(d)
d = d(end-k+1:end)
```

but is most appropriate for large sparse matrices. If the problem fits into memory, it may be quicker to use `eig(full(A))`.

Unless you provide a start vector with `opts.v0`, the default start vector is generated by `rand`, possibly leading to different iterations each run, and perhaps even different convergence behavior. In order to control this, specify your start vector via `opts.v0`.

## Examples

### Smallest Eigenvalues of Sparse Matrix

```
A = delsq(numgrid('C',15));
d1 = eigs(A,5,'sm')
```

returns

```
d1 =
 0.5520
 0.4787
 0.3469
 0.2676
 0.1334
```

### Smallest Eigenvalues of Function-Generated Sparse Matrix

This example replaces the matrix *A* in example 1 with a handle to a function *dnRk*. The example is contained in file *run\_eigs* that

- Calls *eigs* with the function handle *@dnRk* as its first argument.
- Contains *dnRk* as a nested function, so that all variables in *run\_eigs* are available to *dnRk*.

The following shows the code for *run\_eigs*:

```
function d2 = run_eigs
n = 139;
opts.issym = 1;
R = 'C';
k = 15;
d2 = eigs(@dnRk,n,5,'sm',opts);

 function y = dnRk(x)
 y = (delsq(numgrid(R,k))) \ x;
 end
end
```

## Largest Eigenvalue Pairs of Sparse Matrix

west0479 is a real-valued 479-by-479 sparse matrix with both real and complex pairs of conjugate eigenvalues. `eig` computes all 479 eigenvalues. `eigs` easily picks out the largest magnitude eigenvalues.

This plot shows the 8 largest magnitude eigenvalues of west0479 as computed by `eig` and `eigs`.

```
load west0479
d = eig(full(west0479));
d1m = eigs(west0479,8);
[dum,ind] = sort(abs(d));
plot(d1m,'k+'); hold on
plot(d(ind(end-7:end)),'ks'); hold off
legend('eigs(west0479,8)', 'eig(full(west0479))')
```

### Repeated Eigenvalues of Symmetric Positive Definite Sparse Matrix

`A = delsq(numgrid('C',30))` is a symmetric positive definite matrix of size 632 with eigenvalues reasonably well-distributed in the interval  $(0, 8)$ , but with 18 eigenvalues repeated at 4.

Use the `eig` function to compute all 632 eigenvalues, and the `eigs` function to compute the six largest and smallest magnitude eigenvalues.

```
A = delsq(numgrid('C',30));
d = sort(eig(full(A)));
d1m = eigs(A);
dsm = eigs(A,6,'sa');
```

Plot the results from `eig` and `eigs` for the six largest and smallest magnitude eigenvalues.

```
subplot(2,1,1)
plot(d1m,'k+'), hold on
plot(d(end:-1:end-5),'ks'), hold off
legend('eigs(A)', 'eig(full(A))',3)
set(gca,'XLim',[0.5 6.5])

subplot(2,1,2)
plot(dsm,'k+'), hold on
plot(d(1:6),'ks'), hold off
legend('eigs(A,6,\'sa\')', 'eig(full(A))',2)
set(gca,'XLim',[0.5 6.5])
```

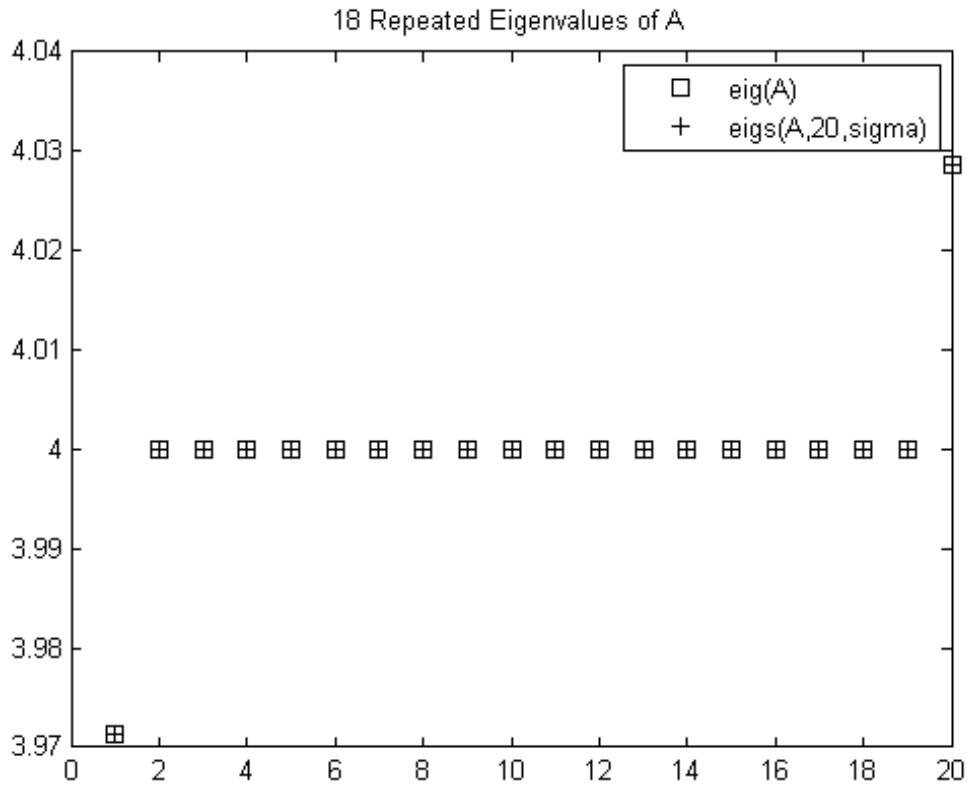

The repeated eigenvalue at 4 must be handled more carefully. The call `eigs(A,20,4.0)` to compute 20 eigenvalues near 4.0 tries to find eigenvalues of  $A - 4.0 \cdot I$ . This involves divisions of the form  $1/(\lambda - 4.0)$ , where  $\lambda$  is an estimate of an eigenvalue of  $A$ . As  $\lambda$  gets closer to 4.0, `eigs` fails. We must use `sigma` near but not equal to 4 to find those eigenvalues.

```
sigma = 4 - 1e-6;
D = sort(eigs(A,20,sigma));
```

# eigs

The plot below shows the 20 eigenvalues closest to 4 that were computed by eig, along with the 20 eigenvalues closest to  $4 - 1e-6$  that were computed by eigs.

```
figure(2);
plot(d(307:326),'ks'), hold on
plot(D,'k+'), hold off
legend('eig(A)', 'eigs(A,20,sigma)')
title('18 Repeated Eigenvalues of A')
```

# ellipj

---

**Purpose** Jacobi elliptic functions

**Syntax** [SN,CN,DN] = ellipj(U,M)  
[SN,CN,DN] = ellipj(U,M,tol)

**Definitions** The Jacobi elliptic functions are defined in terms of the integral:

$$u = \int_0^\phi \frac{d\theta}{\sqrt{1 - m \sin^2 \theta}}.$$

Then

$$sn(u) = \sin \phi, \quad cn(u) = \cos \phi, \quad dn(u) = \sqrt{1 - m \sin^2 \phi}.$$

Some definitions of the elliptic functions use the modulus  $k$  instead of the parameter  $m$ . They are related by

$$k^2 = m = \sin^2 \alpha,$$

where  $\alpha$  is the modular angle.

The Jacobi elliptic functions obey many mathematical identities; for a good sample, see [1].

**Description** [SN,CN,DN] = ellipj(U,M) returns the Jacobi elliptic functions SN, CN, and DN, evaluated for corresponding elements of argument U and parameter M. Inputs U and M must be the same size (or either can be scalar).

[SN,CN,DN] = ellipj(U,M,tol) computes the Jacobi elliptic functions to accuracy tol. The default is eps; increase this for a less accurate but more quickly computed answer.

**Algorithms** ellipj computes the Jacobi elliptic functions using the method of the arithmetic-geometric mean of [1]. It starts with the triplet of numbers:

$$a_0 = 1, b_0 = \sqrt{1-m}, c_0 = \sqrt{m}$$

ellipj computes successive iterates with

$$a_i = \frac{1}{2}(a_{i-1} + b_{i-1})$$

$$b_i = (a_{i-1} b_{i-1})^{\frac{1}{2}}$$

$$c_i = \frac{1}{2}(a_{i-1} - b_{i-1})$$

Next, it calculates the amplitudes in radians using:

$$\sin(2\phi_{n-1} - \phi_n) = \frac{c_n}{a_n} \sin(\phi_n)$$

being careful to unwrap the phases correctly. The Jacobian elliptic functions are then simply:

$$sn(u) = \sin \phi_0$$

$$cn(u) = \cos \phi_0$$

$$dn(u) = \sqrt{1 - m \cdot sn(u)^2}$$

## Limitations

The ellipj function is limited to the input domain  $0 \leq m \leq 1$ . Map other values of  $m$  into this range using the transformations described in [1], equations 16.10 and 16.11.  $u$  is limited to real values.

ellipke

# ellipke

---

**Purpose** Complete elliptic integrals of first and second kind

**Syntax**  
`K = ellipke(M)`  
`[K,E] = ellipke(M)`  
`[K,E] = ellipke(M,tol)`

**Description** `K = ellipke(M)` returns the complete elliptic integral of the first kind for the each element in `M`.

`[K,E] = ellipke(M)` returns the complete elliptic integral of the first and second kinds.

`[K,E] = ellipke(M,tol)` computes the complete elliptic integral to accuracy `tol`. The default is `eps(class(M))`; increase the tolerance for a less accurate but more quickly computed answer.

**Limitations** `ellipke` is limited to the input domain  $0 \leq m \leq 1$ .

**Definitions** The *complete* elliptic integral of the first kind is

$$[K(m)] = \int_0^1 [(1-t^2)(1-mt^2)]^{-\frac{1}{2}} dt.$$

where  $m$  is the first argument of `ellipke`.

The complete elliptic integral of the second kind is

$$E(m) = \int_0^1 (1-t^2)^{-\frac{1}{2}} (1-mt^2)^{\frac{1}{2}} dt.$$

Some definitions of `K` and `E` use the elliptical modulus  $k$  or modular angle  $\alpha$  instead of the parameter  $m$ . They are related by

$$k^2 = m = \sin^2 \alpha.$$

# ellipsoid

---

## Purpose

Generate ellipsoid

## Syntax

```
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)
ellipsoid(axes_handle,...)
ellipsoid(...)
```

## Description

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)` generates a surface mesh described by three  $n+1$ -by- $n+1$  matrices, enabling `surf(x,y,z)` to plot an ellipsoid with center  $(xc,yc,zc)$  and semi-axis lengths  $(xr,yr,zr)$ .

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)` uses  $n = 20$ .

`ellipsoid(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`ellipsoid(...)` with no output arguments plots the ellipsoid as a surface.

## Algorithms

`ellipsoid` generates the data using the following equation:

$$\frac{(x-xc)^2}{xr^2} + \frac{(y-yc)^2}{yr^2} + \frac{(z-zc)^2}{zr^2} = 1$$

Note that `ellipsoid(0,0,0,.5,.5,.5)` is equivalent to a unit sphere.

**Examples****Surface Plot of Ellipsoid**

Generate data for an ellipsoid with a center at (0,0,0) and semi-axis lengths (5.9,3.25,3.25). Use surf to plot the ellipsoid.

```
[x, y, z] = ellipsoid(0,0,0,5.9,3.25,3.25,30);
figure
surf(x, y, z)
axis equal
```

# ellipsoid

## Examples

Use `empty` to create a rectangular empty array of class `int16`:

```
A = int16.empty(5,0);
whos
 Name Size Bytes Class Attributes
 ---- -
 A 5x0 0 int16
```

Using the `empty` method of the `int16` class to produce an empty array in which some dimensions are not zero is simpler than using conversion and reshape operations:

```
A = int16([]);
A = reshape(A,5,0);
whos
 Name Size Bytes Class Attributes
 ---- -
 A 5x0 0 int16
```

Given the following definition for a class,

```
classdef ExEmpty
 properties
 Color = [1,0,0];
 end
 methods
 function obj = ExEmpty(c)
 if nargin > 0
 obj.Color = c;
 end
 end
 end
end
```

```

 end
 end
end

```

Create an empty array of class ExEmpty:

```

A = ExEmpty.empty;
whos
 Name Size Bytes Class Attributes
 ---- -
 A 0x0 104 ExEmpty

```

One dimension of an empty array must be zero:

```

A5 = ExEmpty.empty(0,5);
whos
 Name Size Bytes Class Attributes
 ---- -
 A5 0x5 104 ExEmpty

```

Empty object arrays follow array concatenation behavior:

```

B = [A,A5]
B =

```

0x5 ExEmpty array with properties:

```

 Color

```

You cannot index into an empty array:

```

A5(1)
Index exceeds matrix dimensions.

```

You can use the `isempty`, `size`, and `length` functions to identify empty object arrays:

```

isempty(A5)

```

# empty

---

```
ans =
 1
size(A5)
```

```
ans =
 0 5
length(A5)
```

```
ans =
 0
```

## **Class of Empty Object Array**

The empty method enables you to initialize arrays of a specific class:

```
C = char.empty(0,7)
```

```
C =
```

```
 Empty string: 0-by-7
```

```
class(C)
ans =
```

```
char
```

Initializing an array with empty brackets ([]):

```
a = [];
```

produces an array of class double:

```
class(a)
ans =
```

double

|                         |                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Enable access to .NET commands from network drive                                                                                                                                                                   |
| <b>Syntax</b>           | <code>enableNETfromNetworkDrive</code>                                                                                                                                                                              |
| <b>Description</b>      | <code>enableNETfromNetworkDrive</code> adds an entry for the MATLAB interface to .NET module to the security policy on your machine. You must have administrative privileges to make changes to your configuration. |
| <b>Compatibility</b>    | Use <code>enableNETfromNetworkDrive</code> for MATLAB releases R2012b or earlier, which support installed versions 2.0, 3.0, and 3.5 of the Microsoft .NET Framework.                                               |
| <b>Related Examples</b> | <ul style="list-style-type: none"><li>• “Troubleshooting Security Policy Settings From Network Drives”</li></ul>                                                                                                    |

**Purpose** Enable, disable, or report status of MATLAB Automation server

**Syntax**

```
state = enableservice('AutomationServer',enable)
state = enableservice('AutomationServer')
```

**Description**

`state = enableservice('AutomationServer',enable)` enables or disables the MATLAB Automation server. If `enable` is true (logical 1), `enableservice` converts an existing MATLAB session into an Automation server. If `enable` is false (logical 0), `enableservice` disables the MATLAB Automation server. `state` indicates the previous state of the Automation server. If `state = 1`, MATLAB was an Automation server. If `state = 0`, MATLAB was not an Automation server.

`state = enableservice('AutomationServer')` returns the current state of the Automation server. If `state` is logical 1 (true), MATLAB is an Automation server.

COM functions are available on Microsoft Windows systems only.

**Examples** Enable the Automation server in the current MATLAB session:

```
state = enableservice('AutomationServer',true);
```

---

Show the current state of the MATLAB session. MATLAB displays true:

```
state = enableservice('AutomationServer')
```

---

Enable the Automation server and show the previous state. MATLAB displays true. The previous state can be the same as the current state:

```
state = enableservice('AutomationServer',true)
```

# enableservice

---

## How To

- “MATLAB COM Automation Server Interface”

**Purpose** Terminate block of code, or indicate last array index

**Syntax** end

**Description** end terminates for, while, switch, try, if, and parfor statements. Without an end statement, for, while, switch, try, if, and parfor wait for further input. Each end is paired with the closest previous unpaired for, while, switch, try, if, or parfor and serves to delimit its scope.

end also marks the termination of a function, although in many cases it is optional. If your function contains one or more nested functions, then you must terminate every function in the file, whether nested or not, with end. This includes primary, nested, private, and local functions.

The end function also serves as the last index in an indexing expression. In that context, end = (size(x,k)) when used as part of the kth index. Examples of this use are X(3:end) and X(1,1:2:end-1). When using end to grow an array, as in X(end+1)=5, make sure X exists first.

You can overload the end statement for a user object by defining an end method for the object. The end method should have the calling sequence end(obj,k,n), where obj is the user object, k is the index in the expression where the end syntax is used, and n is the total number of indices in the expression. For example, consider the expression

```
A(end-1,:)
```

The MATLAB software calls the end method defined for A using the syntax

```
end(A,1,2)
```

**Examples** This example shows end used with the for and if statements.

```
for k = 1:n
 if a(k) == 0
 a(k) = a(k) + 2;
 end
end
```

# end

---

In this example, `end` is used in an indexing expression.

```
A = magic(5)
```

```
A =
```

```
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

```
B = A(end,2:end)
```

```
B =
```

```
 18 25 2 9
```

## Examples

The following examples show how to call delegates with various input and output arguments. Each example contains:

- 1** The C# delegate signature. In order to execute the MATLAB code, build the delegate code into an assembly named `SignatureExamples` and load it into MATLAB. For information, see “Build a .NET Application for MATLAB Examples”.
  - 2** An example MATLAB function to use with the delegate, which must exist on your path.
  - 3** The `BeginInvoke` and `EndInvoke` signatures MATLAB creates. To display the signatures, create a delegate instance, `myDel`, and call the `methodsview` function.
  - 4** Simple MATLAB example.
- 

This example shows how to use a delegate that has no return value.

- 1** C# delegate:

```
public delegate void delint(Int32 arg);
```

- 2** MATLAB function to call:

```
%Display input argument
function dispfnc(A)
%A = number
['Input is ' num2str(A)]
end
```

- 3** MATLAB creates the following signatures. For `BeginInvoke`:

```
System.IAsyncResultRetVal
BeginInvoke (
 SignatureExamples.delint this,
 int32 scalar arg,
```

```
System.AsyncCallback callback,
System.Object object)
```

The EndInvoke signature:

```
EndInvoke (
 SignatureExamples.delint this,
 System.IAsyncResult result)
```

#### 4 Call dispfnc:

```
myDel = SignatureExamples.delint(@dispfnc);
asyncRes = myDel.BeginInvoke(6, [], []);
while asyncRes.IsCompleted ~= true
 pause(0.05); % Use pause() to let MATLAB process event
end
myDel.EndInvoke(asyncRes)
```

Input is 6

---

This example shows how to use a delegate with a return value. The delegate does not have out or ref parameters.

#### 1 C# delegate:

```
public delegate Int32 del2int(Int32 arg1, Int32 arg2);
```

#### 2 MATLAB function to call:

```
%Add input arguments
function res = addfnc(A, B)
%A and B are numbers
res = A + B;
end
```

#### 3 MATLAB creates the following signatures. For BeginInvoke:

# EndInvoke

---

```
System.IAsyncResultRetVal
BeginInvoke (
 SignatureExamples.del2int this,
 int32 scalar arg1,
 int32 scalar arg2,
 System.AsyncCallback callback,
 System.Object object)
```

The EndInvoke signature:

```
int32 scalarRetVal
EndInvoke (
 SignatureExamples.del2int this,
 System.IAsyncResult result)
```

#### 4 Call addfnc:

```
myDel = SignatureExamples.del2int(@addfnc);
asyncRes = myDel.BeginInvoke(6,8,[],[]);
while asyncRes.IsCompleted ~= true
 pause(0.05); % Use pause() to let MATLAB process event
end
result = myDel.EndInvoke(asyncRes)

result =
 14
```

---

This example shows how to use a delegate with a ref parameter, refArg, and no return value.

#### 1 C# delegate:

```
public delegate void delrefvoid(ref Double refArg);
```

#### 2 MATLAB maps the ref argument as both RHS and LHS arguments. MATLAB function to call:

```
%Increment input argument
function res = incfnc(A)
%A = number
res = A + 1;
end
```

**3** MATLAB creates the following signatures. For BeginInvoke:

```
[System.IAsyncResult RetVal,
double scalar refArg]
BeginInvoke (
 SignatureExamples.delrefvoid this,
 double scalar refArg,
 System.AsyncCallback callback,
 System.Object object)
```

The EndInvoke signature:

```
double scalar refArg
EndInvoke (
 SignatureExamples.delrefvoid this,
 double scalar refArg,
 System.IAsyncResult result)
```

**4** Call incfnc:

```
x = 6;
myDel = SignatureExamples.delrefvoid(@incfnc);
asyncRes = myDel.BeginInvoke(x,[],[]);
while asyncRes.IsCompleted ~= true
 pause(0.05); % Use pause() to let MATLAB process event
end
myRef = 0;
result = myDel.EndInvoke(myRef,asyncRes);
disp(['Increment of ' num2str(x) ' = ' num2str(result)]);

Increment of 6 = 7
```

# EndInvoke

---

This example shows how to use a delegate with an out parameter, `argOut`, and one return value.

**1** C# delegate:

```
public delegate Single deloutsingle(Single argIn, out Single argOut);
```

**2** MATLAB maps the out argument as a return value for a total of two return values. MATLAB function to call:

```
%Double input argument
function [res1 res2] = times2fnc(A)
res1 = A*2;
res2 = res1;
end
```

**3** MATLAB creates the following signatures. For `BeginInvoke`:

```
[System.IAsyncResult RetVal,
single scalar argOut]
BeginInvoke (
 SignatureExamples.deloutsingle this,
 single scalar argIn,
 System.AsyncCallback callback,
 System.Object object)
```

The `EndInvoke` signature:

```
[single scalar RetVal,
single scalar argOut]
EndInvoke (
 SignatureExamples.deloutsingle this,
 System.IAsyncResult result)
```

**4** Call `times2fnc`:

```
myDel = SignatureExamples.deloutsingle(@times2fnc);
```

```
asyncRes = myDel.BeginInvoke(6,[],[]);
while asyncRes.IsCompleted ~= true
 pause(0.05); % Use pause() to let MATLAB process event
end
[a1 a2] = myDel.EndInvoke(asyncRes);
a1

a1 =
 12
```

## Related Links

- [MSDN Calling Synchronous Methods Asynchronously](#)

# eomday

---

**Purpose** Last day of month

**Syntax** E = eomday(Y, M)

**Description** E = eomday(Y, M) returns the last day of the year and month given by corresponding elements of arrays Y and M.

**Examples** Show the end of month for January through September for the year 1900:

```
eomday(1900, 1:9)
ans =
 31 28 31 30 31 30 31 31 30
```

Find the number of days during that period:

```
sum(eomday(1900, 1:9))
ans =
 273
```

Because 1996 is a leap year, the statement eomday(1996,2) returns 29. To show all the leap years in the twentieth century, try:

```
y = 1900:1999;
E = eomday(y, 2);
y(find(E == 29))

ans =
Columns 1 through 6
 1904 1908 1912 1916 1920 1924

Columns 7 through 12
 1928 1932 1936 1940 1944 1948

Columns 13 through 18
 1952 1956 1960 1964 1968 1972
```

Columns 19 through 24

1976      1980      1984      1988      1992      1996

**See Also**

`datenum` | `datevec` | `weekday`

# enumeration

---

**Purpose** Display class enumeration members and names

**Syntax**

```
enumeration ClassName
enumeration(obj)
m = enumeration(ClassName)
m = enumeration(obj)
[m,s] = enumeration(ClassName)
[m,s] = enumeration(obj)
```

**Description**

`enumeration ClassName` displays the names of the enumeration members for the MATLAB class with the name `ClassName`.

`enumeration(obj)` displays the names of the enumeration members for the class of `obj`.

`m = enumeration(ClassName)` returns the enumeration members for the class in the column vector `m` of objects.

`m = enumeration(obj)` returns the enumeration members for the class of object, `obj`, in the column vector `m` of objects.

`[m,s] = enumeration(ClassName)` returns the names of the enumeration members in the cell array of strings `s`. The names in `s` correspond element-wise to the enumeration members in `m`.

`[m,s] = enumeration(obj)` returns the enumeration members for the class of object, `obj`, in the column vector `m` of objects.

- Tips**
- An enumeration class that derives from a built-in class can specify more than one name for a given enumeration member.
  - When you call the `enumeration` function with no output arguments, MATLAB displays only the first name for each enumeration member (as specified in the class definition). To see all available enumeration members and their names, use the two output arguments (for example, `[m, s] = enumeration(obj);`).

**Input Arguments**

**ClassName**  
The name of the enumeration class, in single quotes.

**obj**

A instance of an enumeration class.

**Output Arguments****m**

Column vector of enumeration members.

**s**

Cell array of strings containing the enumeration names.

**Examples**

All examples use the following enumeration class.

```
classdef Boolean < logical
 enumeration
 No (0)
 Yes (1)
 Off (0)
 On (1)
 end
end
```

---

Display the names of the enumeration members for class Boolean:

```
enumeration Boolean
Enumerations for class Boolean:
```

```
 No
 Yes
```

---

Get the enumeration members for class Boolean in a column vector of objects:

```
members = enumeration('Boolean')
members =
```

# enumeration

---

```
No
Yes
```

---

Get all available enumeration members and their names:

```
[members, names] = enumeration('Boolean')
members =
```

```
No
Yes
No
Yes
```

```
names =
```

```
'No '
'Yes '
'Off '
'On '
```

classdef

## Tutorials

- “Working with Enumerations”

**Purpose** Floating-point relative accuracy

**Syntax**

```
eps
d = eps(X)
eps('double')
eps('single')
```

**Description** eps returns the distance from 1.0 to the next largest double-precision number, that is  $\text{eps} = 2^{(-52)}$ .

$d = \text{eps}(X)$  is the positive distance from  $\text{abs}(X)$  to the next larger in magnitude floating point number of the same precision as  $X$ .  $X$  may be either double precision or single precision. For all  $X$ ,

$$\text{eps}(X) = \text{eps}(-X) = \text{eps}(\text{abs}(X))$$

$\text{eps}('double')$  is the same as  $\text{eps}$  or  $\text{eps}(1.0)$ .

$\text{eps}('single')$  is the same as  $\text{eps}(\text{single}(1.0))$  or  $\text{single}(2^{-23})$ .

Except for numbers whose absolute value is smaller than  $\text{realmin}$ , if  $2^E \leq \text{abs}(X) < 2^{(E+1)}$ , then

$$\begin{aligned} \text{eps}(X) &= 2^{(E-23)} \text{ if } \text{isa}(X, 'single') \\ \text{eps}(X) &= 2^{(E-52)} \text{ if } \text{isa}(X, 'double') \end{aligned}$$

For all  $X$  of class double such that  $\text{abs}(X) \leq \text{realmin}$ ,  $\text{eps}(X) = 2^{(-1074)}$ . Similarly, for all  $X$  of class single such that  $\text{abs}(X) \leq \text{realmin}('single')$ ,  $\text{eps}(X) = 2^{(-149)}$ .

Replace expressions of the form:

```
if Y < eps * ABS(X)
```

with

```
if Y < eps(X)
```

**Examples**

```
double precision
eps(1/2) = 2^(-53)
```

```
eps(1) = 2^(-52)
eps(2) = 2^(-51)
eps(realmax) = 2^971
eps(0) = 2^(-1074)

if(abs(x) <= realmin, eps(x) = 2^(-1074)
eps(realmin/2) = 2^(-1074)
eps(realmin/16) = 2^(-1074)
eps(Inf) = NaN
eps(NaN) = NaN

single precision
eps(single(1/2)) = 2^(-24)
eps(single(1)) = 2^(-23)
eps(single(2)) = 2^(-22)
eps(realmax('single')) = 2^104
eps(single(0)) = 2^(-149)
eps(realmin('single')/2) = 2^(-149)
eps(realmin('single')/16) = 2^(-149)
if(abs(x) <= realmin('single'), eps(x) = 2^(-149)
eps(single(Inf)) = single(NaN)
eps(single(NaN)) = single(NaN)
```

**Purpose** Determine equality

**Syntax** A == B  
eq(A,B)

**Description** A == B returns a logical array with elements set to logical 1 (true) where arrays A and B are equal; otherwise, it returns logical 0 (false). The test compares both real and imaginary parts of numeric arrays. eq returns logical 0 (false) where A or B have NaN or undefined categorical elements.

eq(A,B) is an alternative way to execute A == B, but is rarely used. It enables operator overloading for classes.

**Input Arguments**

**A - Left array**

numeric array | logical array | character array | categorical array

Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**B - Right array**

numeric array | logical array | character array | categorical array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## Examples

### Equality of Two Vectors

Create two vectors containing both real and imaginary numbers.

```
A = [1+i 3 2 4+i];
B = [1 3+i 2 4+i];
```

Compare the two vectors for equality.

```
A == B
```

```
ans =
```

```
0 0 1 1
```

The `eq` function tests both real and imaginary parts for equality, and returns logical 1 (true) only where both parts are equal.

### Find Characters in String

Create a string of characters.

```
M = 'masterpiece';
```

Test the string for the presence of a specific character using ==.

```
M == 'e'
```

```
ans =
```

```
 0 0 0 0 1 0 0 0 1 0 1
```

The value of logical 1 (true) in the vector indicates the presence of the character 'e' in the string.

### Find Values in Categorical Array

Create a categorical array.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =
```

```
 heads heads tails
 tails heads tails
```

The array has two categories: 'heads' and 'tails'.

Find all values in the 'heads' category.

```
A == 'heads'
```

```
ans =
```

```
 1 1 0
 0 1 0
```

A value of logical 1 (true) indicates a value in the category.

Compare the rows of A for equality.

```
A(1,:) == A(2,:)
```

```
ans =
 0 1 1
```

The function returns logical 1 (true) where the rows have equal category values.

## Compare Floating-Point Numbers

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the == operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in `C`.

```
C = 0.5-0.4-0.1
```

```
C =
-2.7756e-17
```

Intuitively, `C` should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare `C` to zero for equality.

```
C == 0
```

```
ans =
 0
```

The result is logical 0 (false).

Compare floating-point numbers using a tolerance, `tol`, instead of ==.

```
tol = eps;
abs(C-0) < tol
```

```
ans =
```

```
1
```

The two numbers, `C` and `0`, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

**Tips**

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequal` to determine if objects with different handles have equal property values.

**See Also**

`ge` | `gt` | `le` | `lt` | `ne`

## eq (MException)

---

**Purpose** Compare scalar MException objects for equality

**Syntax** eObj1 == eObj2

**Description** eObj1 == eObj2 tests scalar MException objects eObj1 and eObj2 for equality, returning logical 1 (true) if the two objects are identical, otherwise returning logical 0 (false).

**See Also** last(MException) | addCause(MException) |  
throwAsCaller(MException) | rethrow(MException) |  
throw(MException) | disp(MException) | getReport(MException)  
| ne(MException) | isequal(MException) | MException | assert  
| error | try, catch

**Purpose** Error function

**Syntax**  $Y = \text{erf}(X)$

**Definitions** The error function  $\text{erf}(X)$  is twice the integral of the Gaussian distribution with 0 mean and variance of 1/2.

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

**Description**  $Y = \text{erf}(X)$  returns the value of the error function for each element of real array  $X$ .

**See Also** `erfc` | `erfcinv` | `erfcx` | `erfinv`

# erfc

---

**Purpose** Complementary error function

**Syntax**  $Y = \text{erfc}(X)$

**Definitions** The complementary error function  $\text{erfc}(X)$  is defined as

$$\begin{aligned}\text{erfc}(x) &= \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt \\ &= 1 - \text{erf}(x)\end{aligned}$$

**Description**  $Y = \text{erfc}(X)$  computes the value of the complementary error function.

**Tips** The relationship between the complementary error function  $\text{erfc}$  and the standard normal probability distribution returned by the Statistics Toolbox function  $\text{normcdf}$  is

$$\text{normcdf}(x) = \left(\frac{1}{2}\right) \times \text{erfc}\left(\frac{-x}{\sqrt{2}}\right)$$

**See Also** [erf](#) | [erfcinv](#) | [erfcx](#) | [erfinv](#)

**Purpose** Inverse complementary error function

**Syntax** `X = erfcinv(Y)`

**Description** `X = erfcinv(Y)` returns the value of the inverse of the complementary error function for each element of `Y`. Elements of `Y` must be in the interval `[0 2]`. The function `erfcinv` satisfies  $y = \text{erfc}(x)$  for  $2 \geq y \geq 0$  and  $-\infty \geq x \geq \infty$ .

**Tips** The relationship between the inverse complementary error function `erfcinv` and the inverse standard normal probability distribution returned by the Statistics Toolbox function `norminv` is:

$$\text{norminv}(p) = (-\sqrt{2}) \times \text{erfcinv}(2p).$$

**See Also** `erf` | `erfc` | `erfcx` | `erfinv`

# erfcx

---

**Purpose** Scaled complementary error function

**Syntax**  $Y = \text{erfcx}(X)$

**Definitions** The scaled complementary error function  $\text{erfcx}(X)$  is defined as

$$\text{erfcx}(x) = e^{x^2} \text{erfc}(x)$$

For large  $X$ ,  $\text{erfcx}(X)$  is approximately  $\left(\frac{1}{\sqrt{\pi}}\right)\frac{1}{x}$

**Description**  $Y = \text{erfcx}(X)$  computes the value of the scaled complementary error function.

**See Also** `erf` | `erfcinv` | `erfc` | `erfinv`

|                    |                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Inverse error function                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>      | <code>X = erfinv(Y)</code>                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <code>X = erfinv(Y)</code> returns the value of the inverse error function for each element of <code>Y</code> . Elements of <code>Y</code> should be in the interval <code>[-1 1]</code> or the function will return NaN. The function <code>erfinv</code> satisfies $y = \text{erf}(x)$ for $-1 \leq y \leq 1$ and $-\infty \leq x \leq \infty$ . |
| <b>Examples</b>    | <code>erfinv(1)</code> is Inf<br><code>erfinv(-1)</code> is -Inf.                                                                                                                                                                                                                                                                                  |
| <b>See Also</b>    | <code>erf</code>   <code>erfcinv</code>   <code>erfcx</code>   <code>erfc</code>                                                                                                                                                                                                                                                                   |

# error

---

**Purpose** Display message and abort function

**Syntax** `error('msgIdent', 'msgString', v1, v2, ..., vN)`  
`error('msgString', v1, v2, ...)`  
`error('msgString')`  
`error(msgStruct)`

**Description** `error('msgIdent', 'msgString', v1, v2, ..., vN)` generates an exception if the currently-running function tests for and confirms a faulty or unexpected condition. Depending on how the program has been designed to respond to the error, MATLAB either enters a catch block to handle the error condition, or exits the program.

The *msgIdent* argument is a unique *message identifier* string that MATLAB attaches to the error message when it throws the error. A message identifier has the format `component:mnemonic`. Its purpose is to better identify the source of the error (see Message Identifiers for more information).

The *msgString* argument is a character string that informs the user about the cause of the error and can also suggest how to correct the faulty condition. The *msgString* string can include escape sequences such as `\t` or `\n`, as well as any of the format specifiers supported by the `sprintf` function (such as `%s` or `%d`). Additional arguments *v1*, *v2*, ..., *vN* provide values that correspond to and replace the conversion specifiers.

For example, if *msgString* is “Error on line `%d`, command `%s`”, then *v1* is the line number at which the error was detected, and *v2* is the command that failed. See “Formatting Strings” for more detailed information on using string formatting commands.

All string input arguments must be enclosed in single quotation marks. If *msgString* is an empty string, the error command has no effect.

`error('msgString', v1, v2, ...)` reports an error without including a message identifier in the error report. Although including a message identifier in an error report is recommended, it is not required.

`error('msgString')` is the same as the above syntax, except that the `msgString` string contains no conversion specifiers, no escape sequences, and no substitution value (`v1, v2, ...`) arguments. All characters in `msgString` are interpreted exactly as they appear in the `msgString` argument. MATLAB displays the `\t` in `'C:\testFolder'` for example, as a backslash character followed by the letter `t`, and not as a horizontal tab.

`error(msgStruct)` accepts a scalar error structure input `msgStruct` with at least one of the fields `message`, `identifier`, and `stack`. When the `msgStruct` input includes a `stack` field, the `stack` field of the error will be set according to the contents of the `stack` input. When specifying a `stack` input, use the absolute file name and the entire sequence of functions that nests the function in the stack frame. This is the same as the string returned by `dbstack('-completenames')`. If `msgStruct` is an empty structure, no action is taken and `error` returns without exiting the function.

## Tips

The `error` function captures what information it can about the error that occurred and stores it in a data structure that is an object of the `MException` class. This *error record* contains the error message string, message identifier, the error stack, and optionally an array of other exception objects that are intended to provide information as to the cause of the exception. See “Capture Information About Exceptions” for more information on how to access and use an exception object.

You can access information in the exception object using the `catch` function as documented in the `try, catch` reference page. If your program terminates because of an exception and returns control to the Command Prompt, you can access the exception object using the `MException.last` command.

The `error` function also determines where the error occurred and provides this information in the `stack` field of the `MException` object. This field contains a structure array that has the same format as the output of the `dbstack` function. This stack points to the line where the `error` function was called.

# error

---

The following table shows the MATLAB functions that can be useful for throwing an exception:

| Function      | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| error         | Throw exception with specified error message.                             |
| assert        | Evaluate given expression and throw exception if false.                   |
| throw         | Throw exception based on specified MException object.                     |
| throwAsCaller | Throw exception that appears to have been thrown by the calling function. |
| rethrow       | Reissue previously caught exception.                                      |

## Examples

### Example 1 – Simple Error Message

Write a short function `errtest1` that throws an error when called with an incorrect number of input arguments. Include a message identifier `'myApp:argChk'` and error message:

```
function errtest1(x, y)
if nargin ~= 2
 error('myApp:argChk', 'Wrong number of input arguments')
end
```

Call the function with an incorrect number of inputs. The call to `nargin`, a function that checks the number of inputs, fails and the program calls `error`:

```
errtest1(pi)
```

```
Error using errtest1 (line 3)
Wrong number of input arguments
```

If you run this function from the Command Window, you can use the `MException.last` method to view the exception object:

```

err = MException.last
err =
 MException

 Properties:
 identifier: 'myApp:argChk'
 message: 'Wrong number of input arguments'
 cause: {}
 stack: [1x1 struct]
 Methods

err.stack
ans =
 file: 'c:\work\errtest1.m'
 name: 'errtest1'
 line: 3

```

## Example 2 – Special Characters

MATLAB converts special characters (like `\n` and `%d`) in the error message string only when you specify more than one input argument with `error`. In the single-argument case shown below, `\n` is taken to mean backslash-n. It is not converted to a newline character:

```
error('In this case, the newline \n is not converted.')
```

In this case, the newline `\n` is not converted.

But, when more than one argument is specified, MATLAB does convert special characters. This holds true regardless of whether the additional argument supplies conversion values or is a message identifier:

```
error('ErrorTests:convertTest', ...
 'In this case, the newline \n is converted.')
```

In this case, the newline  
is converted.

## error

---

last(MException) | getReport(MException) |  
addCause(MException) | throwAsCaller(MException) |  
rethrow(MException) | throw(MException) | MException | warndlg  
| warning | errordlg | dbstop | assert | try

**Purpose** Plot error bars along curve

**Syntax**

```
errorbar(Y,E)
errorbar(X,Y,E)
errorbar(X,Y,L,U)
errorbar(...,LineStyle)
h = errorbar(...)
```

**Description** Error bars show the confidence intervals of data or the deviation along a curve.

`errorbar(Y,E)` plots  $Y$  and draws an error bar at each element of  $Y$ . The error bar is a distance of  $E(i)$  above and below the curve so that each bar is symmetric and  $2 \cdot E(i)$  long.

`errorbar(X,Y,E)` plots  $Y$  versus  $X$  with symmetric error bars  $2 \cdot E(i)$  long.  $X$ ,  $Y$ ,  $E$  must be the same size. When they are vectors, each error bar is a distance of  $E(i)$  above and below the point defined by  $(X(i), Y(i))$ . When they are matrices, each error bar is a distance of  $E(i, j)$  above and below the point defined by  $(X(i, j), Y(i, j))$ .

`errorbar(X,Y,L,U)` plots  $X$  versus  $Y$  with error bars  $L(i)+U(i)$  long specifying the lower and upper error bars.  $X$ ,  $Y$ ,  $L$ , and  $U$  must be the same size. When they are vectors, each error bar is a distance of  $L(i)$  below and  $U(i)$  above the point defined by  $(X(i), Y(i))$ . When they are matrices, each error bar is a distance of  $L(i, j)$  below and  $U(i, j)$  above the point defined by  $(X(i, j), Y(i, j))$ .

`errorbar(...,LineStyle)` uses the color and line style specified by the string '`LineStyle`'. The color is applied to the data line and error bars. The linestyle and marker are applied to the data line only. See `linespec` for examples of styles.

`h = errorbar(...)` returns handles to the `errorbarseries` objects created. `errorbar` creates one object for vector input arguments and

# errorbar

---

one object per column for matrix input arguments. See `errorbarseries` properties for more information.

When the arguments are all matrices, `errorbar` draws one line per matrix column. If `X` and `Y` are vectors, they specify one curve.

## Examples

### Symmetric Error Bars

Draw symmetric error bars that are two standard deviation units in length.

```
x = 0:pi/10:pi;
y = sin(x);
e = std(y)*ones(size(x));
```

```
figure
errorbar(x,y,e)
```

### Change Error Bar Marker and Color

Load the count data set to get the three-column matrix count that contains traffic volume for three street locations over the course of a day. Compute the mean of count for each row.

```
load count.dat;
y = mean(count,2);
```

## errorbar

---

Compute the standard deviation of count for each row and normalize by the number of elements in the sample by setting the second input argument to 1.

```
e = std(count,1,2);
```

Plot the computed average traffic volume,  $y$ , and the computed standard deviations,  $e$ , for the three street locations. Set the `LineStyle` to specify a red color, cross markers, and no line.

```
figure
errorbar(y,e,'rx')
```

**How To**

- `ConfidenceBounds`

# Errorbarseries Properties

---

## Purpose

Description of errorbarseries properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property editor (`propertyeditor`).

Note that you cannot define default property values for errorbarseries objects. See “Plot Objects” for more information on errorbarseries objects.

## Errorbarseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

Annotation

`hg.Annotation` object (read-only)

*Control the display of errorbarseries objects in legends.* Specifies whether this errorbarseries object is represented in a figure legend.

Querying the Annotation property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the errorbarseries object is displayed in a figure legend.

| <b>IconDisplayStyle Value</b> | <b>Purpose</b>                                                                           |
|-------------------------------|------------------------------------------------------------------------------------------|
| on                            | Include the errorbarseries object in a legend as one entry, but not its children objects |
| off                           | Do not include the errorbarseries or its children in a legend (default)                  |
| children                      | Include only the children of the errorbarseries as separate entries in the legend        |

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Control Legend Content” for more information and examples.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to

# Errorbarseries Properties

---

perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## Children

array of graphics object handles

*Children of the errorbarseries object.* An array containing the handles of all line objects parented to the errorbarseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

# Errorbarseries Properties

---

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is [0 0 0] (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

`CreateFcn`  
string | function handle

*Not available on errorbarseries objects.*

`DeleteFcn`  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see `Function Handle Callbacks`.

See the `BeingDeleted` property for related information.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the errorbarseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

### EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

# Errorbarseries Properties

---

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

# Errorbarseries Properties

---

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the curve or error bars that compose the graph. If `HitTest` is off, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

on | {off}

*Select the object by clicking lines or area of extent.* Select plot objects by:

- Clicking curve or error bars (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is off, you must click the curve or error bars to select the object. When `HitTestArea` is on, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the lines).

## Interruptible

off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

# Errorbarseries Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LData

array equal in size to XData and YData

*Errorbar length below data point.* The `errorbar` function uses this data to determine the length of the errorbar below each data point. Specify these values in data units. See also UData.

## LDataSource

string (MATLAB variable)

*Link LData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the LData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change LData.

You can use the `refreshdata` function to force an update of the object’s data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

## LineStyle

{-} | -- | : | -. | none

*Line style of errorbarseries object.*

## Line Style Specifiers Table

| Specifier | Line Style           |
|-----------|----------------------|
| '-'       | Solid line (default) |
| '--'      | Dashed line          |
| ':'       | Dotted line          |
| '-.'      | Dash-dot line        |
| 'none'    | No line              |

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

### LineWidth

size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

### Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

| Specifier | Marker Type |
|-----------|-------------|
| '+'       | Plus sign   |
| 'o'       | Circle      |

# Errorbarseries Properties

---

| Specifier            | Marker Type                   |
|----------------------|-------------------------------|
| '*'                  | Asterisk                      |
| '.'                  | Point                         |
| 'x'                  | Cross                         |
| 'square' or 's'      | Square                        |
| 'diamond' or 'd'     | Diamond                       |
| '^'                  | Upward-pointing triangle      |
| 'v'                  | Downward-pointing triangle    |
| '>'                  | Right-pointing triangle       |
| '<'                  | Left-pointing triangle        |
| 'pentagram' or 'p'   | Five-pointed star (pentagram) |
| 'hexagram' or 'h' '' | Six-pointed star (hexagram)   |
| 'none'               | No marker (default)           |

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the Color property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`  
handle of parent axes, `hgroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgroup`, or `hgtransform` object that contains the object.

`Selected`  
`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

# Errorbarseries Properties

---

SelectionHighlight  
{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing selection handles on the curve and error bars. When SelectionHighlight is off, MATLAB does not draw the handles.

Tag  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

For example, create an errorbarseries object and set the Tag property:

```
t = errorbar(Y,E,'Tag','errorbar1')
```

To access the errorbarseries object, use findobj to find the errorbarseries object's handle.

The following statement changes the MarkerFaceColor property of the object whose Tag is errorbar1.

```
set(findobj('Tag','errorbar1'),'MarkerFaceColor','red')
```

Type  
string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For errorbarseries objects, Type is 'hgggroup'. The following statement finds all the hgggroup objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

## UData

array equal in size to XData and YData

*Errorbar length above data point.* The errorbar function uses this data to determine the length of the errorbar above each data point. Specify these values in data units.

## UDataSource

MATLAB variable, as a string

*Link UData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the UData. The default value is an empty array.

```
set(h, 'UDataSource', 'Udatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's UDataSource does not change the object's UData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the errorbarseries object.* Assign this property the handle of a uicontextmenu object created in the errorbarseries object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the errorbarseries object.

## UserData

array

# Errorbarseries Properties

---

*User-specified data.* Data you want to associate with the errorbarseries object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of errorbarseries object and its children.* By default, errorbarseries object visibility is on. This means all children of the errorbarseries object are visible unless the child object's Visible property is off. Setting an errorbarseries object's Visible property to off also makes its children invisible.

## XData

array

*X-coordinates of the curve.* The `errorbar` function plots a curve using the *x*-axis coordinates in the XData array. XData must be the same size as YData.

If you do not specify XData (which is the input argument *X*), the `errorbar` function uses the indices of YData to create the curve. See the XDataMode property for related information.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the input argument *x*), the `errorbar` function sets this property to manual.

If you set XDataMode to auto after having specified XData, the `errorbar` function resets the *x* tick-mark labels to the indices of the YData.

## XDataSource

string (MATLAB variable)

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change XData.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

scalar | vector | matrix

*Data defining curve.* YData contains the data defining the curve. If YData is a matrix, the `errorbar` function displays a curve with error bars for each column in the matrix.

The input argument Y in the `errorbar` function calling syntax assigns values to YData.

## YDataSource

string (MATLAB variable)

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData.

# Errorbarseries Properties

---

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change YData.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Purpose** Create and open error dialog box

**Syntax**

```
h = errordlg
h = errordlg(errorstring)
h = errordlg(errorstring,dlgname)
h = errordlg(errorstring,dlgname,createmode)
```

**Description** `h = errordlg` creates and displays a dialog box with title Error Dialog that contains the string This is the default error string. The `errordlg` function returns the handle of the dialog box in `h`.

`h = errordlg(errorstring)` displays a dialog box with title Error Dialog that contains the string `errorstring`.

`h = errordlg(errorstring,dlgname)` displays a dialog box with titled `dlgname` that contains the string `errorstring`.

`h = errordlg(errorstring,dlgname,createmode)` specifies whether the error dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `errorstring` and `dlgname`. The `createmode` argument can be a string or a structure.

If `createmode` is a string, it must be one of the values shown in the following table.

| createmode Value    | Description                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| modal               | Replaces the error dialog box having the specified <code>Title</code> , that was last created or clicked on, with a modal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal. |
| non-modal (default) | Creates a new nonmodal error dialog box with the specified parameters. Existing                                                                                                                                                                                                          |

# errordlg

---

| createmode Value | Description                                                                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | error dialog boxes with the same title are not deleted.                                                                                                                                                                                                                       |
| replace          | Replaces the error dialog box having the specified Title, that was last created or clicked on, with a nonmodal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal. |

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

If you open a dialog with `errordlg`, `msgbox`, or `warndlg` using 'CreateMode', 'modal' and a non-modal dialog created with any of these functions is already present and *has the same name as the modal dialog*, the non-modal dialog closes when the modal one opens.

For more information about modal dialog boxes, see `WindowStyle` in the `Figure Properties`.

---

If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings 'tex' or 'none'. The default value for `Interpreter` is 'none'.

## Tips

MATLAB sizes the dialog box to fit the string 'errorstring'. The error dialog box has an **OK** push button and remains on the screen until you press the **OK** button or the **Return** key. After pressing the button, the error dialog box disappears.

The appearance of the dialog box depends on the platform you use.

**Examples**

This code,

```
errordlg('File not found','File Error');
```

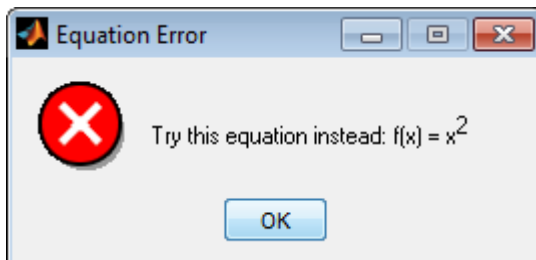

displays this dialog box:

This code,

```
mode = struct('WindowStyle','non-modal',...
 'Interpreter','tex');
h = errordlg('Try this equation instead: f(x) = x^2',...
 'Equation Error', mode);
```

displays this dialog box:

# etime

---

**Purpose** Time elapsed between date vectors

**Syntax** `e = etime(t2,t1)`

**Description** `e = etime(t2,t1)` returns the number of seconds between two date vectors or matrices of date vectors, `t1` and `t2`.

**Input Arguments** **t2,t1 - Date vectors**  
1-by-6 vector | m-by-6 matrix

Date vectors, specified as 1-by-6 vectors or m-by-6 matrices containing `m` full date vectors in the format:[Year Month Day Hour Minute Second].

**Example:** [2012 03 27 11 50 01]

**Data Types**  
double

**Examples** **Compute Elapsed Time**

Compute the time elapsed between a specific time and the current time, to 0.01-second accuracy.

Define the initial date and time and convert to date vector form.

```
format shortg
str = 'March 28, 2012 11:51:00';
t1 = datevec(str,'mmm dd, yyyy HH:MM:SS')
```

```
t1 =
```

```
 2012 3 28 11 51 0
```

Determine the current date and time.

```
t2 = clock
```

```
t2 =
 2014 1 17 16 0
```

The `clock` function returns the current date and time as a date vector. Use `etime` to compute the number of seconds between `t1` and `t2`.

```
e = etime(t2,t1)
```

```
e =
 5.7039e+07
```

## Tips

- To time the duration of an event, use the `timeit` or `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.

## Algorithms

`etime` does not account for the following:

- Leap seconds.
- Daylight savings time adjustments.
- Differences in time zones.

`tic` | `toc` | `cputime` | `clock` | `now` | `timeit`

# etree

---

**Purpose** Elimination tree

**Syntax**  
`p = etree(A)`  
`p = etree(A, 'col')`  
`p = etree(A, 'sym')`  
`[p,q] = etree(...)`

**Description** `p = etree(A)` returns an elimination tree for the square symmetric matrix whose upper triangle is that of `A`. `p(j)` is the parent of column `j` in the tree, or 0 if `j` is a root.

`p = etree(A, 'col')` returns the elimination tree of  $A^*A$ .

`p = etree(A, 'sym')` is the same as `p = etree(A)`.

`[p,q] = etree(...)` also returns a postorder permutation `q` of the tree.

**See Also** `treelayout` | `treeplot` | `etreeplot`

|                    |                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Plot elimination tree                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>      | <code>etreeplot(A)</code><br><code>etreeplot(A,nodeSpec,edgeSpec)</code>                                                                                                                                                                                                                                              |
| <b>Description</b> | <code>etreeplot(A)</code> plots the elimination tree of $A$ (or $A+A'$ , if non-symmetric).<br><code>etreeplot(A,nodeSpec,edgeSpec)</code> allows optional parameters <code>nodeSpec</code> and <code>edgeSpec</code> to set the node or edge color, marker, and linestyle. # eval

---

**Purpose** Execute MATLAB expression in text string

**Syntax**  
`eval(expression)`  
`[output1,...,outputN] = eval(expression)`

**Description** `eval(expression)` evaluates the MATLAB code in the string `expression`. If you use `eval` within an anonymous function, nested function, or function that contains a nested function, the evaluated expression cannot create a variable.

`[output1,...,outputN] = eval(expression)` stores output from `expression` in the specified variables.

- Tips**
- Many common uses of the `eval` function are less efficient and are more difficult to read and debug than other MATLAB functions and language constructs. For more information, see “Alternatives to the `eval` Function”.
  - Whenever possible, do not include output arguments within the input to the `eval` function, such as `eval(['output = ',expression])`. The preferred syntax,

```
output = eval(expression)
```

allows the MATLAB parser to perform stricter checks on your code, preventing untrapped errors and other unexpected behavior.

**Input Arguments** **expression**  
String that contains a valid MATLAB expression.  
To include a numeric value in the expression, convert it to a string with `int2str`, `num2str`, or `sprintf`.

**Output Arguments** **output1,...,outputN**  
Outputs from the evaluated expression.

## Examples

### Variable Name Evaluation

Select a matrix to plot at runtime.

This example requires that you have a matrix in the current workspace. For example:

```
aMatrix = magic(5);
```

Interactively request the name of a matrix to plot, and call `eval` to use its value.

```
expression = input('Enter the name of a matrix: ','s');
if (exist(expression,'var'))
 mesh(eval(expression))
end
```

If you type `aMatrix` at the input prompt, this code creates a mesh plot of `magic(5)`.

**Purpose**

Execute MATLAB expression in specified workspace

**Syntax**

```
evalin(ws, expression)
[a1, a2, a3, ...] = evalin(ws, expression)
```

**Description**

`evalin(ws, expression)` executes *expression*, a string containing any valid MATLAB expression, in the context of the workspace *ws*. *ws* can have a value of 'base' or 'caller' to denote the MATLAB base workspace or the workspace of the caller function. You can construct *expression* by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2,...]
```

`[a1, a2, a3, ...] = evalin(ws, expression)` executes *expression* and returns the results in the specified output variables. Using the `evalin` output argument list is recommended over including the output arguments in the expression string:

```
evalin(ws, '[a1, a2, a3, ...] = function(var)')
```

The above syntax avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior.

**Tips**

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line.

`evalin('caller', expression)` finds only *variables* in the caller's workspace; it does not find *functions* in the caller. For this reason, you cannot use `evalin` to construct a handle to a function that is defined in the caller.

If you use `evalin('caller', expression)` in the MATLAB debugger after having changed your local workspace context with `dbup` or `dbdown`,

# evalin

---

MATLAB evaluates the expression in the context of the function that is one level up in the stack from your current workspace context.

## Examples

This example extracts the value of the variable `var` in the MATLAB base workspace and captures the value in the local variable `v`:

```
v = evalin('base', 'var');
```

## Limitation

`evalin` cannot be used recursively to evaluate an expression. For example, a sequence of the form `evalin('caller', 'evalin(''caller'', ''x'')` doesn't work.

**Purpose**

Base class for all data objects passed to event listeners

**Description**

The event package contains the `event.EventData` class, which defines the data objects passed to event listeners. If you want to provide additional information to event listeners, you can do so by subclassing `event.EventData`. See “Defining Event-Specific Data” for more information.

---

**Note** Subclasses of `event.EventData` must set the class `ConstructOnLoad` attribute.

---

**Properties**

The `event.EventData` class defines two properties and no methods:

- `EventName` — The name of the event described by this data object.
- `Source` — The source object whose class defines the event described by the data object.

**See Also**

`event.PropertyEvent`

**How To**

- “Learning to Use Events and Listeners”
- “Customizing Event Data”

# event.listener

---

**Purpose** Class defining listener objects

**Syntax** `lh = event.listener(Hobj, 'EventName', @CallbackFunction)`

**Description** The `event.listener` class defines listener objects. Listener objects respond to the specified event and identify the callback function to invoke when the event is triggered.

`lh = event.listener(Hobj, 'EventName', @CallbackFunction)` creates an `event.listener` object, `lh`, for the event named in `EventName`, on the specified object, `Hobj`.

If `Hobj` is an array of object handles, the listener responds to the named event on any of the objects referenced in the array.

The listener callback function must accept at least two input arguments. For example,

```
function CallbackFunction(source, eventData)
 ...
end
```

where `source` is the object that is the source of the event and `eventData` is an `event.EventData` object.

The `event.listener` class is a handle class.

## Limiting Listener Lifecycle

Generally, you create a listener object using `addListener`. However, you can call the `event.listener` constructor directly to create a listener. When you use the `event.listener` constructor, the listener's lifecycle is not tied to the object(s) being listened to—once the listener object goes out of scope, the listener no longer exists. See “Ways to Create Listeners” for more information on creating listener objects.

## Removing a Listener

If you call `delete(lh)` on the listener object, the listener ceases to exist, which means the event no longer causes the listener callback function to execute.

## Disabling a Listener

You can enable or disable a listener by setting the value of the listener's `Enabled` property (see Properties table below).

## More Information on Events and Listeners

See “Events” for more information and examples of how to use events and listeners.

## Properties

| Property  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                           |

| EventName | Name of the event                                                                                                                                                                                                                                                                                                                                                                                                 |
| Callback  | Function to execute when the event is triggered and the <code>Enabled</code> property is set to <code>true</code>                                                                                                                                                                                                                                                                                                 |
| Enabled   | The callback executes when the event occurs if and only if <code>Enabled</code> is set to <code>true</code> (the default).                                                                                                                                                                                                                                                                                        |
| Recursive | <p>When <code>false</code> (the default), this listener does not execute recursively. Therefore, if the callback triggers its own event, the listener does not execute again.</p> <p>When <code>true</code>, the listener callback can cause the same event that triggered the callback. This scheme can lead to infinite recursion, which ends when the MATLAB recursion limit eventually triggers an error.</p> |

# event.PropertyEvent

---

**Purpose** Data for property events

**Description** The `event.PropertyEvent` class defines the data objects passed to listeners of the `meta.property` events:

- `PreGet`
- `PostGet`
- `PreSet`
- `PostSet`

`event.PropertyEvent` is a sealed subclass of `event.EventData` (i.e., you cannot subclass `event.PropertyEvent`).

**Properties** `event.PropertyEvent` inherits the first two properties from the `event.EventData`, and defines one new property:

- `EventName` — One of the four event names listed in the Description section
- `Source` — `meta.property` object that triggers the event
- `AffectedObject` — The object whose property is affected.

**See Also** `event.EventData` | `meta.property`

**How To** • “Listen for Changes to Property Values”

**Purpose**

Define listener object for property events

**Syntax**

```
lh = event.proplistener(Hobj, Properties, 'PropEvent',
 @CallbackFunction)
```

**Description**

lh = event.proplistener(Hobj, Properties, 'PropEvent', @CallbackFunction) creates a property listener object for one or more properties on the specified object.

- **Hobj** — handle of object whose property or properties are to be listened to. If Hobj is an array, the listener responds to the named event on all objects in the array.
- **Properties** — an object array or a cell array of meta.property object handles representing the properties to which you want to listen.
- **PropEvent** — must be one of the strings: PreSet, PostSet, PreGet, PostGet
- **@CallbackFunction** — function handle to the callback function that executes when the event occurs.

The event.proplistener class defines property event listener objects. It is a subclass of the event.listener class and adds one property to those defined by event.listener:

- **Object** — Cell array of objects whose property events are being listened to.

You can call the event.proplistener constructor instead of calling addlistener to create a property listener. However, when you do not use addlistener, the listener's lifecycle is not tied to the object(s) being listened to.

See “Listen for Changes to Property Values”.

See “Getting Information About Properties” for more information on using meta.property objects.

event.listener | addlistener

# eventlisteners

---

**Purpose** List event handler functions associated with COM object events

**Syntax**  
`info = h.eventlisteners`  
`info = eventlisteners(h)`

**Description** `info = h.eventlisteners` lists the events and their event handler routines registered with COM object `h`. The function returns a cell array of strings `info`, with each row containing the name of a registered event and the handler routine for that event. If the object has no registered events, `eventlisteners` returns an empty cell array. You can register events either when you create the control, using `actxcontrol`, or at any time afterwards, using `registerevent`.

`info = eventlisteners(h)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Manage events for an instance of the MATLAB control `mwsamp`:

```
f = figure('position', [100 200 200 200]);
%Create an mwsamp control and
%register the Click event
h = actxcontrol('mwsamp.mwsampctrl.2', ...
 [0 0 200 200], f, ...
 {'Click' 'myclick'});
h.eventlisteners
```

```
ans =
 'Click' 'myclick'
```

MATLAB displays the event name and its event handler, `myclick`.

---

Register two more events, `Db1Click` and `MouseDown`:

```
h.registerevent({'Db1Click', 'my2click'; 'MouseDown' 'mymoused'});
h.eventlisteners
```

```
ans =
```

```
'Click' 'myclick'
'Dblclick' 'my2click'
'MouseDown' 'mymoused'
```

MATLAB displays all event names and handlers.

---

Unregister all events for the control:

```
h.unregisterallevents
h.eventlisteners
```

```
ans =
 {}
```

MATLAB displays an empty cell array, indicating the control has no registered events.

events (COM) | registerevent | unregisterevent |
unregisterallevents | isevent | actxcontrol
```

# events

---

**Purpose** Event names

**Syntax** `events('classname')`  
`events(obj)`  
`e = events(...)`

**Description** `events('classname')` displays the names of the public events for the MATLAB class `classname`, including events inherited from superclasses.

`events(obj)` `obj` is a scalar or array of objects of a MATLAB class.

`e = events(...)` returns the event names in a cell array of strings.

An event is public when the value of its `ListenAccess` attribute is `public` and its `Hidden` attribute value is `false` (default values for both attributes). See “Event Attributes” for a complete list of attributes.

`events` is also a MATLAB class-definition keyword. See `classdef` for more information on class definition keywords.

**Examples** Get the names of the public events for the `handle` class:

```
events('handle')
Events for class handle:

 ObjectBeingDestroyed
```

**See Also** `properties` | `methods`

**Tutorials**

- “Events”

**Purpose** List of events COM object can trigger

**Syntax**  
 S = h.events  
 S = events(h)

**Description** S = h.events returns structure array S containing all events, both registered and unregistered, known to the COM object, and the function prototype used when calling the event handler routine. For each array element, the structure field is the event name and the contents of that field is the function prototype for that event's handler.  
 S = events(h) is an alternate syntax.

**Tips** COM functions are available on Microsoft Windows systems only.

**Examples** **List Control Events Example**

Create an mwsamp control and list all events:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.events
```

MATLAB software displays information similar to:

```
Click = void Click()
Db1Click = void Db1Click()
MouseDown = void MouseDown(int16 Button, int16 Shift,
 Variant x, Variant y)
Event_Args = void Event_Args(int16 typeshort, int32 typelong,
 double typedouble, string typestring, bool typebool)
```

Assign the output to a variable and get one field of the returned structure:

```
ev = h.events;
ev.MouseDown
```

## events (COM)

---

MATLAB displays:

```
ans =
 void MouseDown(int16 Button, int16 Shift, Variant x, Variant y)
```

### List Workbook Events Example

Open a Microsoft Excel application and list all events for a Workbook object:

```
myApp = actxserver('Excel.Application');
wbs = myApp.Workbooks;
wb = wbs.Add;
wb.events
```

The MATLAB software displays all events supported by the Workbook object.

```
Open = void Open()
Activate = void Activate()
Deactivate = void Deactivate()
BeforeClose = void BeforeClose(bool Cancel)
:
:
```

### See Also

[isevent](#) | [eventlisteners](#) | [registerevent](#) | [unregisterevent](#)  
| [unregisterallevts](#)

**Purpose** Execute MATLAB command in Automation server

**Syntax** **IDL Method Signature**

```
BSTR Execute([in] BSTR command)
```

**Microsoft Visual Basic® Client**

```
Execute(command As String) As String
```

**MATLAB Client**

```
result = h.Execute('command')
result = Execute(h, 'command')
result = invoke(h, 'Execute', 'command')
```

**Description**

The `Execute` function executes the MATLAB statement specified by the string `command` in the MATLAB Automation server attached to handle `h`.

The server returns output from the command in the string, `result`. The `result` string also contains any warning or error messages that might have been issued by MATLAB software as a result of the command.

Note that if you terminate the MATLAB command string with a semicolon and there are no warnings or error messages, `result` might be returned empty.

**Tips**

If you want to be able to display output from `Execute` in the client window, you must specify an output variable (i.e., `result` in the above syntax statements).

Server function names, like `Execute`, are case sensitive when used with dot notation (the first syntax shown).

If there is an error, the `Execute` function returns the MATLAB error message with the characters `???` prepended to the text.

COM functions are available on Microsoft Windows systems only.

**Examples**

From a Visual Basic .NET client, execute the MATLAB `version` function in the server and return the output to the client.

# Execute

---

```
Dim Matlab As Object
Dim server_version As String
Matlab = CreateObject("matlab.application")
server_version = Matlab.Execute("version")
```

**Purpose** Read EXIF information from JPEG and TIFF image files

## Syntax

---

**Note** `exifread` will be removed in a future release. Use `imfinfo` instead.

---

```
output = exifread(filename)
```

## Description

`output = exifread(filename)` reads the Exchangeable Image File Format (EXIF) data from the file specified by the string `filename`. `filename` must specify a JPEG or TIFF image file. `output` is a structure containing metadata values about the image or images in `imagefile`.

---

**Note** `exifread` returns all EXIF tags and does not process them in any way.

---

EXIF is a standard used by digital camera manufacturers to store information in the image file, such as, the make and model of a camera, the time the picture was taken and digitized, the resolution of the image, exposure time, and focal length. For more information about EXIF and the meaning of metadata attributes, see <http://www.exif.org/>.

# exist

---

**Purpose** Check existence of variable, function, folder, or class

**Syntax**  
`exist name`  
`exist name kind`  
`A = exist('name','kind')`

**Description** `exist name` returns the status of name:

|   |                                                                                                                                                                                                                                                                                              |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | name does not exist.                                                                                                                                                                                                                                                                         |
| 1 | name is a variable in the workspace.                                                                                                                                                                                                                                                         |
| 2 | One of the following is true: <ul style="list-style-type: none"><li>• name exists on your MATLAB search path as a file with extension <code>.m</code>.</li><li>• name is the name of an ordinary file on your MATLAB search path.</li><li>• name is the full pathname to any file.</li></ul> |
| 3 | name exists as a MEX-file on your MATLAB search path.                                                                                                                                                                                                                                        |
| 4 | name exists as a Simulink model or library file on your MATLAB search path.                                                                                                                                                                                                                  |
| 5 | name is a built-in MATLAB function.                                                                                                                                                                                                                                                          |
| 6 | name is a P-file on your MATLAB search path.                                                                                                                                                                                                                                                 |
| 7 | name is a folder.                                                                                                                                                                                                                                                                            |
| 8 | name is a class. ( <code>exist</code> returns 0 for Java classes if you start MATLAB with the <code>-nojvm</code> option.)                                                                                                                                                                   |

If name is a class, then `exist('name')` returns an 8. However, if name is a class file, then `exist('name')` returns a 2.

If a file or folder is not on the search path, then name must specify either a full pathname, a partial pathname relative to `MATLABPATH`, a partial

pathname relative to your current folder, or the file or folder must reside in your current working folder.

If `name` specifies a filename, that filename may include an extension to preclude conflicting with other similar filenames. For example, `exist('file.ext')`.

`exist name kind` returns the status of `name` for the specified `kind`. If `name` of type `kind` does not exist, it returns 0. The `kind` argument may be one of the following:

|                      |                                     |
|----------------------|-------------------------------------|
| <code>builtin</code> | Checks only for built-in functions. |
| <code>class</code>   | Checks only for classes.            |
| <code>dir</code>     | Checks only for folders.            |
| <code>file</code>    | Checks only for files or folders.   |
| <code>var</code>     | Checks only for variables.          |

If you do not specify a `kind` argument, and `name` belongs to more than one of these categories, `exist` returns one value according to the order of evaluation shown in the table below. For example, if `name` matches both a folder and a file that defines a MATLAB function, `exist` returns 7, identifying it as a folder.

| <b>Order of Evaluation</b> | <b>Return Value</b> | <b>Type of Entity</b> |
|----------------------------|---------------------|-----------------------|
| 1                          | 1                   | Variable              |
| 2                          | 5                   | Built-in              |
| 3                          | 7                   | Folder                |
| 4                          | 3                   | MEX-file              |
| 5                          | 4                   | SLX or MDL-file       |
| 6                          | 6                   | P-file                |

| Order of Evaluation | Return Value | Type of Entity  |
|---------------------|--------------|-----------------|
| 7                   | 2            | MATLAB function |
| 8                   | 8            | Class           |

`A = exist('name', 'kind')` is the function form of the syntax.

## Tips

If `name` specifies a filename, MATLAB attempts to locate the file, examines the filename extension, and determines the value to return based on the extension alone. MATLAB does not examine the contents or internal structure of the file.

You can specify a partial path to a folder or file. A partial pathname is a pathname relative to the MATLAB path that contains only the trailing one or more components of the full pathname. For example, both of the following commands return 2, identifying `mkdir.m` as a MATLAB function. The first uses a partial pathname:

```
exist('matlab/general/mkdir.m')
exist([matlabroot '/toolbox/matlab/general/mkdir.m'])
```

To check for the existence of more than one variable, use the `ismember` function. For example,

```
a = 5.83;
c = 'teststring';
ismember({'a', 'b', 'c'}, who)
```

```
ans =
 1 0 1
```

## Examples

This example uses `exist` to check whether a MATLAB function is a built-in function or a file:

```
type = exist('plot')
type =
```

5

This indicates that `plot` is a built-in function.

Run `exist` on a class folder and then on the constructor within that folder:

```
exist('@portfolio')
ans =
 7 % @portfolio is a folder

exist('@portfolio\portfolio')
ans =
 2 % portfolio is a MATLAB function
```

The following example indicates that `testresults` is both a variable in the workspace and a folder on the search path:

```
exist('testresults','var')
ans =
 1
exist('testresults','dir')
ans =
 7
```

|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>      | Terminate MATLAB program (same as quit)                                                                                                                                                                                                                                                                                                                               |
| <b>Alternatives</b> | As an alternative to the <code>exit</code> function, click the Close box in the MATLAB desktop.                                                                                                                                                                                                                                                                       |
| <b>Syntax</b>       | <code>exit</code><br><code>exit(code)</code>                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>  | <p><code>exit</code> terminates the current session of MATLAB after running <code>finish.m</code>, if the file <code>finish.m</code> exists. It performs the same as <code>quit</code> and takes the same termination options, such as <b>force</b>.</p> <p><code>exit(code)</code> returns exit code when calling a MATLAB command from the system command line.</p> |
| <b>See Also</b>     | <code>quit</code>   <code>finish</code>                                                                                                                                                                                                                                                                                                                               |
| <b>How To</b>       | <ul style="list-style-type: none"><li>• “Stop Execution”</li></ul>                                                                                                                                                                                                                                                                                                    |

**Purpose** Exponential

**Syntax**  $Y = \exp(X)$

**Description**  $Y = \exp(X)$  returns the exponential for each element of array  $X$ . The function accepts both real and complex inputs. For real values of  $X$  in the interval  $(-\text{Inf}, \text{Inf})$ ,  $\exp$  returns real values in the interval  $(0, \text{Inf})$ . For complex values of  $X$ ,  $\exp$  returns complex values.

**Input Arguments**

**X - Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**

single | double

**Complex Number Support:** Yes

**Examples**

**Calculate Scalar Exponential Values**

Examine several common values of the exponential function.

Calculate the exponential of 0.

```
exp(0)
```

```
ans =
```

```
1
```

The result is 1, which is the y-intercept of the  $\exp$  function.

Calculate the exponential of 1.

```
exp(1)
```

```
ans =
```

2.7183

The result is equal to Euler's number,  $e$ .

Calculate the exponential of  $i\pi$ .

```
exp(1i*pi)
```

```
ans =
```

```
-1.0000 + 0.0000i
```

The result of -1 is due to Euler's famous formula

$$e^{i\theta} = \cos\theta + i\sin\theta.$$

Calculate the exponential of -Inf.

```
exp(-Inf)
```

```
ans =
```

```
0
```

The result is 0 since `exp` returns small values for negative inputs.

## **Plot Real-Valued Exponential Function**

Define the domain.

```
X = (-1:0.5:5)';
```

Calculate the exponential of the vector, X.

```
Y = exp(X)
```

```
Y =
```

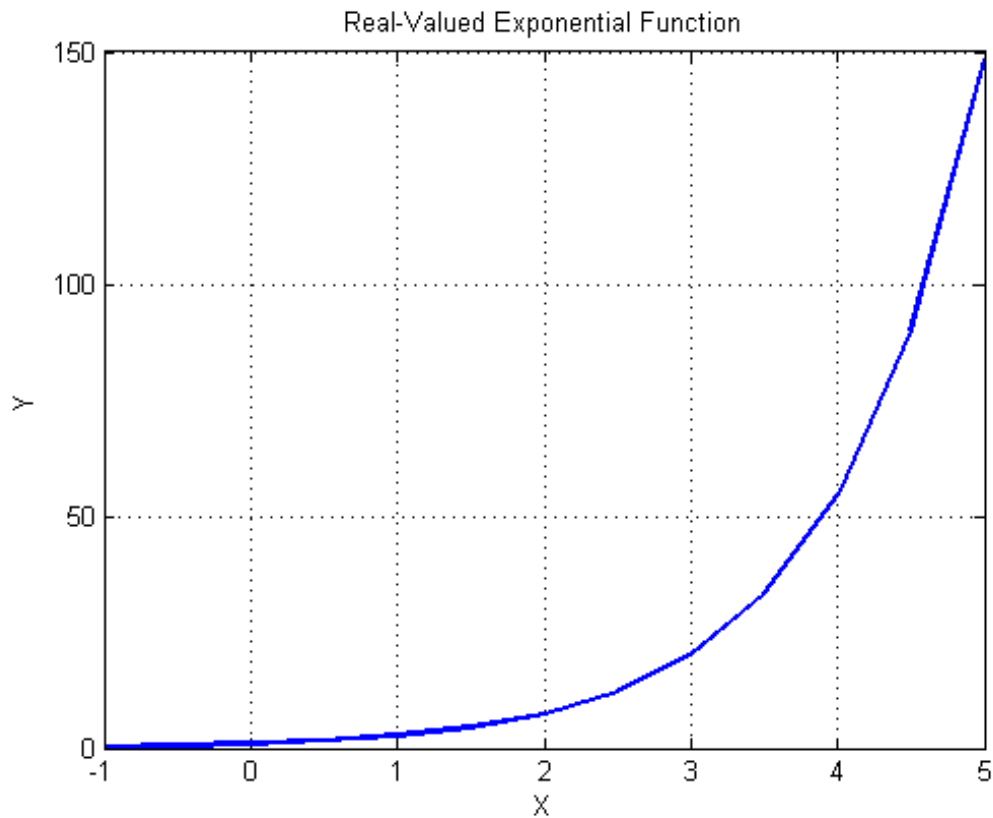

---

```
0.3679
0.6065
1.0000
1.6487
2.7183
4.4817
7.3891
12.1825
20.0855
33.1155
54.5982
90.0171
148.4132
```

The result is a vector of exponential values.

Plot the function values.

```
plot(X,Y,'LineWidth',1.5)
grid on;
title('Real-Valued Exponential Function');
xlabel('X'); ylabel('Y');
```

The real-valued exponential function maps values in the domain of all real numbers to the range of  $(0, \infty)$ .

### **Plot Complex-Valued Exponential Function**

Define a grid of values for the (X,Y) domain.

```
[X,Y] = meshgrid(0:0.5:10,0:0.5:10);
```

Calculate the complex exponential on the grid.

```
Z = exp(X+1i*Y);
```

Make a surface plot of the imaginary portion of the function.

```
surf(X,Y,imag(Z))
grid on; hold on;
xlabel('X'); ylabel('Y'); zlabel('Z');
view(44,42)
```

exp is a continuous function on the complex plane.

Plot the real portion of the function in the same figure.

```
surf(X,Y,real(Z))
view(63,14)
```

In this plot, the real and complex portions of the function are 90 degrees out of phase. Analytically, this is because the real portion depends on  $\cos$ , whereas the complex portion depends on  $\sin$ .

**Algorithms**

For complex inputs  $z = x + 1i*y$ , the `exp` function calculates the complex exponential `exp(x).*(cos(y) + 1i*sin(y))`.

**See Also**

`expm` | `log` | `expm1` | `log10` | `expint` | `power` | `mpower`

# expint

---

**Purpose** Exponential integral

**Syntax**  $Y = \text{expint}(X)$

**Definitions** The exponential integral computed by this function is defined as

$$E_1(x) = \int_x^{\infty} e^{-t} / t dt$$

Another common definition of the exponential integral function is the Cauchy principal value integral

$$\text{Ei}(x) = \int_{-\infty}^x e^t / t dt$$

which, for real positive  $x$ , is related to `expint` as

$$E_1(-x) = -\text{Ei}(x) - i\pi$$

**Description**  $Y = \text{expint}(X)$  evaluates the exponential integral for each element of  $X$ .

**References** [1] Abramowitz, M. and I. A. Stegun. *Handbook of Mathematical Functions*. Chapter 5, New York: Dover Publications, 1965.

**Purpose** Matrix exponential

**Syntax**  $Y = \text{expm}(X)$

**Description**  $Y = \text{expm}(X)$  computes the matrix exponential of  $X$ .

Although it is not computed this way, if  $X$  has a full set of eigenvectors  $V$  with corresponding eigenvalues  $D$ , then

$$[V,D] = \text{EIG}(X) \text{ and } \text{EXPM}(X) = V \cdot \text{diag}(\exp(\text{diag}(D))) / V$$

Use `exp` for the element-by-element exponential.

**Algorithms** `expm` uses the Padé approximation with scaling and squaring. See reference [3], below.

---

**Note** The files, `expdemo1.m`, `expdemo2.m`, and `expdemo3.m` illustrate the use of Padé approximation, Taylor series approximation, and eigenvalues and eigenvectors, respectively, to compute the matrix exponential. References [1] and [2] describe and compare many algorithms for computing a matrix exponential.

---

**Examples** This example computes and compares the matrix exponential of  $A$  and the exponential of  $A$ .

```
A = [1 1 0
 0 0 2
 0 0 -1];
```

```
expm(A)
ans =
 2.7183 1.7183 1.0862
 0 1.0000 1.2642
 0 0 0.3679
```

```
exp(A)
ans =
 2.7183 2.7183 1.0000
 1.0000 1.0000 7.3891
 1.0000 1.0000 0.3679
```

Notice that the diagonal elements of the two results are equal. This would be true for any triangular matrix. But the off-diagonal elements, including those below the diagonal, are different.

# export2wsdlg

---

## Purpose

Export variables to workspace

## Syntax

```
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected,helpfunction)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected,helpfunction,functionlist)
hdialog = export2wsdlg(...)
[hdialog,ok_pressed] = export2wsdlg(...)
```

## Description

`export2wsdlg(checkboxlabels,defaultvariablenames,itemstoexport)` creates a dialog with a series of check boxes and edit fields. `checkboxlabels` is a cell array of labels for the check boxes. `defaultvariablenames` is a cell array of strings that serve as a basis for variable names that appear in the edit fields. `itemstoexport` is a cell array of the values to be stored in the variables. If there is only one item to export, `export2wsdlg` creates a text control instead of a check box.

---

**Note** By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding.

---

`export2wsdlg(checkboxlabels,defaultvariablenames,itemstoexport,title)` creates the dialog with `title` as its title.

`export2wsdlg(checkboxlabels,defaultvariablenames,itemstoexport,title,selected)` creates the dialog allowing the user to control which check boxes are checked. `selected` is a logical array whose length is the same as `checkboxlabels`. True indicates that the check box should initially be checked, false unchecked.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected,helpfunction)` creates the dialog with a help button. `helpfunction` is a callback that displays help.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected,helpfunction,functionlist)` creates a dialog that enables the user to pass in `functionlist`, a cell array of functions and optional arguments that calculate, then return the value to export. `functionlist` should be the same length as `checkboxlabels`.

`hdialog = export2wsdlg(...)` returns the handle of the dialog.

`[hdialog,ok_pressed] = export2wsdlg(...)` sets `ok_pressed` to true if the OK button is pressed, or false otherwise. If two return arguments are requested, `hdialog` is [] and the function does not return until the dialog is closed.

The user can edit the text fields to modify the default variable names. If the same name appears in multiple edit fields, `export2wsdlg` creates a structure using that name. It then uses the `defaultvariablenames` as field names for that structure.

The lengths of `checkboxlabels`, `defaultvariablenames`, `itemstoexport` and `selected` must all be equal.

The strings in `defaultvariablenames` must be unique.

## Examples

This example creates a dialog box that enables the user to save the variables `sumA` and/or `meanA` to the workspace. The dialog box title is `Save Sums to Workspace`.

```
A = randn(10,1);
checkLabels = {'Save sum of A to variable named:' ...
 'Save mean of A to variable named:'};
varNames = {'sumA','meanA'};
items = {sum(A),mean(A)};
export2wsdlg(checkLabels,varNames,items,...
 'Save Sums to Workspace');
```

## Purpose

Identity matrix

## Syntax

```
I = eye
I = eye(n)
I = eye(n,m)
I = eye(sz)

I = eye(classname)
I = eye(n,classname)
I = eye(n,m,classname)
I = eye(sz,classname)

I = eye('like',p)
I = eye(n,'like',p)
I = eye(n,m,'like',p)
I = eye(sz,'like',p)
```

## Description

`I = eye` returns the scalar, 1.

`I = eye(n)` returns an n-by-n identity matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(n,m)` returns an n-by-m matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(sz)` returns an array with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)`. For example, `eye([2,3])` returns a 2-by-3 array with ones on the main diagonal and zeros elsewhere.

`I = eye(classname)` returns a scalar, 1, where the string, `classname`, specifies the data type. For example, `eye('int8')` returns a scalar, 8-bit integer.

`I = eye(n,classname)` returns an n-by-n identity matrix of data type `classname`.

`I = eye(n,m,classname)` returns an n-by-m matrix of data type `classname` with ones on the main diagonal and zeros elsewhere.

`I = eye(sz,classname)` returns a matrix with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)` and `classname` defines `class(I)`.

`I = eye('like',p)` returns a scalar, 1, with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`I = eye(n, 'like', p)` returns an n-by-n identity matrix like `p`.

`I = eye(n,m, 'like', p)` returns an n-by-m matrix like `p`.

`I = eye(sz, 'like', p)` returns a matrix like `p` where the size vector, `sz`, defines `size(I)`.

## Input Arguments

### **n - Size of first dimension of I**

integer value

Size of first dimension of I, specified as an integer value.

- If `n` is the only integer input argument, then I is a square n-by-n identity matrix.
- If `n` is 0, then I is an empty matrix.
- If `n` is negative, then it is treated as 0.

### **Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**m - Size of second dimension of I**

integer value

Size of second dimension of I, specified as an integer value.

- If m is 0, then I is an empty matrix.
- If m is negative, then it is treated as 0.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**sz - Size of I**

row vector of no more than two integer values

Size of I, specified as a row vector of no more than two integer values.

- If an element of sz is 0, then I is an empty matrix.
- If an element of sz is negative, then the element is treated as 0.

**Example:** sz = [2,3] defines I as a 2-by-3 matrix.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**classname - Output class**

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

**Data Types**

char

**p - Prototype**

numeric variable

Prototype, specified as a numeric variable.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**Complex Number Support:** Yes

**Examples****Square Identity Matrix**

Create a 4-by-4 identity matrix.

```
I = eye(4)
```

```
I =
```

```
 1 0 0 0
 0 1 0 0
 0 0 1 0
 0 0 0 1
```

**Rectangular Matrix**

Create a 2-by-3 identity matrix.

```
I = eye(2,3)
```

```
I =
```

```
 1 0 0
 0 1 0
```

**Identity Vector**

Create a 3-by-1 identity vector.

```
sz = [3,1];
```

```
I = eye(sz)
```

```
I =
```

```
 1
 0
```

0

### **Nondefault Numeric Data Type**

Create a 3-by-3 identity matrix whose elements are 32-bit unsigned integers.

```
I = eye(3, 'uint32'),
class(I)
```

I =

```
 1 0 0
 0 1 0
 0 0 1
```

ans =

uint32

### **Complex Identity Matrix**

Create a 2-by-2 identity matrix that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create an identity matrix that is complex like p.

```
I = eye(2, 'like', p)
```

I =

```
 1.0000 + 0.0000i 0.0000 + 0.0000i
 0.0000 + 0.0000i 1.0000 + 0.0000i
```

### Sparse Identity Matrix

Define a 5-by-5 sparse matrix.

```
p = sparse(5,5,pi);
```

Create a 5-by-5 identity matrix that is sparse like P.

```
I = eye(5, 'like', p)
```

```
I =
```

```
 (1,1) 1
 (2,2) 1
 (3,3) 1
 (4,4) 1
 (5,5) 1
```

### Size and Numeric Data Type Defined by Existing Array

Define a 2-by-2 matrix of single precision.

```
p = single([1 3 ; 2 4]);
```

Create an identity matrix that is the same size and data type as P.

```
I = eye(size(p), 'like', p),
class(I)
```

```
I =
```

```
 1 0
 0 1
```

```
ans =
```

```
single
```

**See Also**

speye | ones | zeros

**Concepts**

- “Class Support for Array-Creation Functions”

**Purpose** Easy-to-use contour plotter

**Syntax**

```
ezcontour(fun)
ezcontour(fun,domain)
ezcontour(...,n)
ezcontour(axes_handle,...)
h = ezcontour(...)
```

**Description** `ezcontour(fun)` plots the contour lines of `fun(x,y)` using the `contour` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle for a MATLAB file function or an anonymous function (see [function handle](#) and “Anonymous Functions”) or a string (see [Tips](#)).

`ezcontour(fun,domain)` plots `fun(x,y)` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\min < x < \max$ ,  $\min < y < \max$ ).

`ezcontour(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontour(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezcontour(...)` returns the handle to a contour object in `h`. `ezcontour` automatically adds a title and axis labels.

**Tips** **Passing the Function as a String**

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontour`. For example, the MATLAB syntax for a contour plot of the expression

```
sqrt(x.^2 + y.^2)
```

is written as

```
ezcontour('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezcontour`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontour('u^2 - v^3', [0,1], [3,6])` plots the contour lines for  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontour`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontour(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezcontour` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then use an anonymous function to specify that parameter:

```
ezcontour(@(x,y)myfun(x,y,2))
```

## Examples

### Create Contour Plot of Mathematical Expression

This mathematical expression defines a function of two variables,  $x$  and  $y$ .

$$f(x, y) = 3(1 - x)^2 e^{-x^2 - (y+1)^2} - 10 \left( \frac{x}{5} - x^3 - y^5 \right) e^{-x^2 - y^2} - \frac{1}{3} e^{-(x+1)^2 - y^2}$$

The ezcontour function requires a function handle argument. Write this mathematical expression in MATLAB® syntax as an anonymous function with handle f. You can define an anonymous function in the command window without creating a separate file. For convenience, write the function on three lines.

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
- 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
- 1/3*exp(-(x+1).^2 - y.^2);
```

Pass the function handle, f, to ezcontour. Specify a domain from -3 to 3 in both the x-direction and y-direction and use a 49-by-49 computational grid.

```
ezcontour(f, [-3,3], 49)
```

## ezcontour

In this particular case, the title string is too long to fit at the top of the graph so MATLAB® abbreviates the string.

**Purpose** Easy-to-use filled contour plotter

**Syntax**

```
ezcontourf(fun)
ezcontourf(fun, domain)
ezcontourf(..., n)
ezcontourf(axes_handle, ...)
h = ezcontourf(...)
```

**Description** `ezcontourf(fun)` plots the contour lines of `fun(x,y)` using the `contourf` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see Tips).

`ezcontourf(fun, domain)` plots `fun(x,y)` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]`, where  $\min < x < \max$ ,  $\min < y < \max$ .

`ezcontourf(..., n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontourf(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = ezcontourf(...)` returns the handle to a contour object in `h`.

`ezcontourf` automatically adds a title and axis labels.

**Tips** **Passing the Function as a String**

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontourf`. For example, the MATLAB syntax for a filled contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezcontourf('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezcontourf`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontourf('u^2 - v^3',[0,1],[3,6])` plots the contour lines for  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontourf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontourf(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezcontourf` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezcontourf(@(x,y)myfun(x,y,2))
```

## Examples

### Create Filled Contour Plot of Mathematical Expression

This mathematical expression defines a function of two variables,  $x$  and  $y$ .

$$f(x, y) = 3(1 - x)^2 e^{-x^2 - (y+1)^2} - 10 \left( \frac{x}{5} - x^3 - y^5 \right) e^{-x^2 - y^2} - \frac{1}{3} e^{-(x+1)^2 - y^2}$$

The `ezcontourf` function requires a function handle argument. Write this mathematical expression in MATLAB® syntax as an anonymous function with handle `f`. You can define an anonymous function in the command window without creating a separate file. For convenience, write the function on three lines.

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
 - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
 - 1/3*exp(-(x+1).^2 - y.^2);
```

Pass the function handle, `f`, to `ezcontourf`. Specify a domain from -3 to 3 in both the x-direction and y-direction and use a 49-by-49 computational grid.

```
ezcontourf(f, [-3,3],49)
```

# ezcontourf

In this particular case, the title string is too long to fit at the top of the graph so MATLAB® abbreviates the string.

## How To

- [Anonymous Functions](#)

**Purpose** Easy-to-use 3-D mesh plotter

## Syntax

```
ezmesh(fun)
ezmesh(fun, domain)
ezmesh(funx, funy, funz)
ezmesh(funx, funy, funz, [smin, smax, tmin, tmax])
ezmesh(funx, funy, funz, [min, max])
ezmesh(..., n)
ezmesh(..., 'circ')
ezmesh(axes_handle, ...)
h = ezmesh(...)
```

## Description

`ezmesh(fun)` creates a graph of  $\text{fun}(x, y)$  using the mesh function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezmesh(fun, domain)` plots `fun` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\text{min} < x < \text{max}$ ,  $\text{min} < y < \text{max}$ ).

`ezmesh(funx, funy, funz)` plots the parametric surface  $\text{funx}(s, t)$ ,  $\text{funy}(s, t)$ , and  $\text{funz}(s, t)$  over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezmesh(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezmesh(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezmesh(..., n)` plots `fun` over the default domain using an  $n$ -by- $n$  grid. The default value for  $n$  is 60.

`ezmesh(..., 'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmesh(...)` returns the handle to a surface object in `h`.

## Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmesh`. For example, the MATLAB syntax for a mesh plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmesh('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezmesh`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmesh('u^2 - v^3',[0,1],[3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmesh`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmesh(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezmesh` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmesh(@(x,y)myfun(x,y,2))
```

**Examples**

This example visualizes the function

$$f(x, y) = xe^{-x^2-y^2}$$

with a mesh plot drawn on a 40-by-40 grid. The mesh lines are set to a uniform blue color by setting the colormap to a single color:

```
fh = @(x,y) x.*exp(-x.^2-y.^2);
ezmesh(fh,40)
colormap([0 0 1])
```

# ezmesh

---

[ezmeshc](#) | [function\\_handle](#) | [mesh](#)

## How To

- [Anonymous Functions](#)

**Purpose**

Easy-to-use combination mesh/contour plotter

**Syntax**

```
ezmeshc(fun)
ezmeshc(fun,domain)
ezmeshc(funx,funy,funz)
ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])
ezmeshc(funx,funy,funz,[min,max])
ezmeshc(...,n)
ezmeshc(...,'circ')
ezmesh(axes_handle,...)
h = ezmeshc(...)
```

**Description**

`ezmeshc(fun)` creates a graph of `fun(x,y)` using the `meshc` function. `fun` is plotted over the default domain  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezmeshc(fun,domain)` plots `fun` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\min < x < \max$ ,  $\min < y < \max$ ).

`ezmeshc(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezmeshc(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezmeshc(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmeshc(...,'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmeshc(...)` returns the handle to a surface object in `h`.

## Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmeshc`. For example, the MATLAB syntax for a mesh/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmeshc('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezmeshc`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmeshc('u^2 - v^3',[0,1],[3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmeshc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmeshc(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezmeshc` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmeshc(@(x,y)myfun(x,y,2))
```

**Examples**

Create a mesh/contour graph of the expression

$$f(x,y) = \frac{y}{1+x^2+y^2}$$

over the domain  $-5 < x < 5$ ,  $-2\pi < y < 2\pi$ :

```
ezmeshc('y/(1 + x^2 + y^2)', [-5,5, -2*pi,2*pi])
view(-65.5,26)
```

Use the mouse to rotate the axes to better observe the contour lines  
(this picture uses a view of azimuth = -65.5 and elevation = 26)

## How To

- [Anonymous Functions](#)

**Purpose** Easy-to-use function plotter

**Syntax**

```
ezplot(fun)
ezplot(fun, [xmin,xmax])
ezplot(fun2)
ezplot(fun2, [xymin,xymax])
ezplot(fun2, [xmin,xmax,ymin,ymax])
ezplot(funx,funy)
ezplot(funx,funy, [tmin,tmax])
ezplot(...,figure_handle)
ezplot(axes_handle,...)
h = ezplot(...)
```

**Description** `ezplot(fun)` plots the expression  $\text{fun}(x)$  over the default domain  $-2\pi < x < 2\pi$ , where  $\text{fun}(x)$  is an explicit function of only  $x$ .

`fun` can be a function handle or a string.

`ezplot(fun, [xmin,xmax])` plots  $\text{fun}(x)$  over the domain:  $x_{\min} < x < x_{\max}$ .

For an implicit function,  $\text{fun2}(x,y)$ :

`ezplot(fun2)` plots  $\text{fun2}(x,y) = 0$  over the default domain  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`ezplot(fun2, [xymin,xymax])` plots  $\text{fun2}(x,y) = 0$  over  $x_{\min} < x < x_{\max}$  and  $y_{\min} < y < y_{\max}$ .

`ezplot(fun2, [xmin,xmax,ymin,ymax])` plots  $\text{fun2}(x,y) = 0$  over  $x_{\min} < x < x_{\max}$  and  $y_{\min} < y < y_{\max}$ .

`ezplot(funx,funy)` plots the parametrically defined planar curve  $\text{funx}(t)$  and  $\text{funy}(t)$  over the default domain  $0 < t < 2\pi$ .

`ezplot(funx,funy, [tmin,tmax])` plots  $\text{funx}(t)$  and  $\text{funy}(t)$  over  $t_{\min} < t < t_{\max}$ .

`ezplot(..., figure_handle)` plots the given function over the specified domain in the figure window identified by the handle `figure`.

`ezplot(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot(...)` returns the handle to all the plot objects in `h`.

## Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot`. For example, the MATLAB syntax for a plot of the expression

```
x.^2 - y.^2
```

which represents an implicitly defined function, is written as

```
ezplot('x^2 - y^2')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezplot`.

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot`,

```
fh = @(x,y) sqrt(x.^2 + y.^2 - 1);
ezplot(fh)
axis equal
```

which plots a circle. Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezplot` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
```

```
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezplot(@(x,y)myfun(x,y,2))
```

### Controlling Line Color

ezplot colors lines according to the type of graphics object it chooses to plot the input function.

- For an implicit function, ezplot uses a `LineSeries` object to generate the graph. To change the color, you should set the `Color` property.
- For an explicit function, the graph generated is a `Hgroup` object. So, to change the color, you should set the `LineColor` property.

### Example

#### Plot an Explicit Function

Plot the explicit function  $x^2$  over the domain  $[-2\pi, 2\pi]$ .

```
ezplot('x^2')
```

# ezplot

---

The default domain is  $[-2\pi, 2\pi]$ .

## Plot an Implicit Function

Plot the implicitly defined function  $x^2 - y^4 = 0$  over the domain  $[-2\pi, 2\pi]$ .

```
ezplot('x^2-y^4')
```

The default domain is  $[-2\pi, 2\pi]$ .

**See Also**

[ezplot3](#) | [ezpolar](#) | [function\\_handle](#) | [plot](#)

**How To**

- [Anonymous Functions](#)

# ezplot3

---

**Purpose** Easy-to-use 3-D parametric curve plotter

**Syntax**

```
ezplot3(funx,funy,funz)
ezplot3(funx,funy,funz,[tmin,tmax])
ezplot3(...,'animate')
ezplot3(axes_handle,...)
h = ezplot3(...)
```

**Description** `ezplot3(funx,funy,funz)` plots the spatial curve  $\text{funx}(t)$ ,  $\text{funy}(t)$ , and  $\text{funz}(t)$  over the default domain  $0 < t < 2\pi$ .

`funx`, `funy`, and `funz` can be function handles or strings (see the Tips section).

`ezplot3(funx,funy,funz,[tmin,tmax])` plots the curve  $\text{funx}(t)$ ,  $\text{funy}(t)$ , and  $\text{funz}(t)$  over the domain  $t_{\min} < t < t_{\max}$ .

`ezplot3(...,'animate')` produces an animated trace of the spatial curve.

`ezplot3(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot3(...)` returns the handle to the plotted objects in `h`.

**Tips** **Passing the Function as a String**

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot3`. For example, the MATLAB syntax for a plot of the expression

```
x = s./2, y = 2.*s, z = s.^2;
```

which represents a parametric function, is written as

```
ezplot3('s/2','2*s','s^2')
```

That is,  $s/2$  is interpreted as `s./2` in the string you pass to `ezplot3`.

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot3`.

```
fh1 = @(s) s./2; fh2 = @(s) 2.*s; fh3 = @(s) s.^2;
ezplot3(fh1,fh2,fh3)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezplot3` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfunkt`:

```
function s = myfunkt(t,k)
s = t.^k.*sin(t);
```

then you can use an anonymous function to specify that parameter:

```
ezplot3(@cos,@(t)myfunkt(t,1),@sqrt)
```

## Examples

### Plot a Parametric Curve

Plot this parametric curve over the domain  $[0, 6\pi]$ .

$$x = \sin(t), \quad y = \cos(t), \quad z = t$$

```
ezplot3('sin(t)', 'cos(t)', 't', [0,6*pi])
```

# ezplot3

## See Also

[ezplot](#) | [ezpolar](#) | [function\\_handle](#) | [plot3](#)

## How To

- [Anonymous Functions](#)

**Purpose**

Easy-to-use polar coordinate plotter

**Syntax**

```
ezpolar(fun)
ezpolar(fun,[a,b])
ezpolar(axes_handle,...)
h = ezpolar(...)
```

**Description**

`ezpolar(fun)` plots the polar curve  $\rho = \text{fun}(\theta)$  over the default domain  $0 < \theta < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezpolar(fun,[a,b])` plots `fun` for  $a < \theta < b$ .

`ezpolar(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezpolar(...)` returns the handle to a line object in `h`.

**Tips****Passing the Function as a String**

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezpolar`. For example, the MATLAB syntax for a plot of the expression

```
t.^2.*cos(t)
```

which represents an implicitly defined function, is written as

```
ezpolar('t^2*cos(t)')
```

That is, `t^2` is interpreted as `t.^2` in the string you pass to `ezpolar`.

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezpolar`.

```
fh = @(t) t.^2.*cos(t);
ezpolar(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezpolar` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k1` and `k2` in `myfun`:

```
function s = myfun(t,k1,k2)
s = sin(k1*t).*cos(k2*t);
```

then you can use an anonymous function to specify the parameters:

```
ezpolar(@(t)myfun(t,2,3))
```

## Examples

### Polar Plot of Mathematical Function

Plot the function  $1 + \cos(t)$  over the domain  $[0, 2\pi]$ .

```
figure
ezpolar('1+cos(t)')
```

**See Also**

**How To**

- [Anonymous Functions](#)

## Purpose

Easy-to-use 3-D colored surface plotter

## Syntax

```
ezsurf(fun)
ezsurf(fun, domain)
ezsurf(funx, funy, funz)
ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])
ezsurf(funx, funy, funz, [min, max])
ezsurf(..., n)
ezsurf(..., 'circ')
ezsurf(axes_handle, ...)
h = ezsurf(...)
```

## Description

`ezsurf(fun)` creates a graph of  $\text{fun}(x, y)$  using the `surf` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezsurf(fun, domain)` plots `fun` over the specified domain. `domain` must be a vector. See the “Algorithms” on page 1-2008 section for details on vector inputs vs axes limit outputs.

`ezsurf(funx, funy, funz)` plots the parametric surface  $\text{funx}(s, t)$ ,  $\text{funy}(s, t)$ , and  $\text{funz}(s, t)$  over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezsurf(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezsurf(..., n)` plots `fun` over the default domain using an  $n$ -by- $n$  grid. The default value for  $n$  is 60.

`ezsurf(..., 'circ')` plots `fun` over a disk centered on the domain.

`ezsurf(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurf(...)` returns the handle to a surface object in `h`.

## Tips

ezsurf and ezsurfz do not accept complex inputs.

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to ezsurf. For example, the MATLAB syntax for a surface plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to ezsurf.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints  $u_{\min}$ ,  $u_{\max}$ ,  $v_{\min}$ , and  $v_{\max}$  are sorted alphabetically. Thus, `ezsurf('u^2 - v^3', [0,1], [3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to ezsurf.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since ezsurf does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

## Examples

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

ezsurf does not graph points where the mathematical function is not defined (these data points are set to NaNs, which do not plot). This example illustrates this filtering of singularities/discontinuous points by graphing the function

$$f(x, y) = \text{real}(a \tan(x + iy))$$

over the default domain  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ :

```
ezsurf('real(atan(x+i*y))')
```

Using surf to plot the same data produces a graph without filtering of discontinuities (as well as requiring more steps):

```
[x,y] = meshgrid(linspace(-2*pi,2*pi,60));
z = real(atan(x+1i.*y));
surf(x,y,z)
```

Note also that `ezsurf` creates graphs that have axis labels, a title, and extend to the axis limits.

## Algorithms

`ezsurf` determines the  $x$ - and  $y$ -axis limits in different ways depending on how you input the domain (if at all). In the following table,  $R$  is the vector  $[x_{\min}, x_{\max}, y_{\min}, y_{\max}]$  and  $v$  is the manually entered domain vector.

| Number of domain values specified:                      | Resulting domain vector:                                                 |
|---------------------------------------------------------|--------------------------------------------------------------------------|
| <code>v = [ ];</code>                                   | <code>R = [-2*pi, 2*pi, -2*pi, 2*pi];</code>                             |
| <code>v = [ v(1) ];</code>                              | <code>R = double([-abs(v),abs(v),-abs(v),abs(v)]);</code>                |
| <code>v = [ v(1) v(2) ];</code>                         | <code>R = double([v(1),v(2),v(1),v(2)]);</code>                          |
| <code>v = [ v(1) v(2) v(3) ];</code>                    | <code>R = double([-v(1),v(2),-abs(v(3)),abs(v(3))]);</code>              |
| <code>v = [ v(1) v(2) v(3) v(4) ];</code>               | <code>R = double(v);</code>                                              |
| <code>v = [ v(1)..v(n) ];</code><br><code>n&gt;4</code> | <code>R = double([-abs(v(1)), abs(v(1)), -abs(v(1)), abs(v(1))]);</code> |

If you specify a single number in non-vector format (without square brackets, [ ]), ezsurf interprets it as the n, the number of points desired between the axes max and min values.

By default, ezsurf uses 60 points between the max and min values of an axes. When the min and max values are the default values (R = [-2\*pi, 2\*pi, -2\*pi, 2\*pi]); ezsurf ensures the 60 points fall within the non-complex range of the specified equation. For example,

$\sqrt{1-x^2-y^2}$  is only real when  $x^2-y^2 \leq 1$ . The default graph of this function looks like this:

```
ezsurf('sqrt(1-x^2-y^2)')
```

You can see that there are 60 points between the minimum and maximum values for which  $\sqrt{1-x^2-y^2}$  has real values. However, when you specify the domain values to be the same as the default ( $R = [-2*\pi, 2*\pi, -2*\pi, 2*\pi]$ ), a different result appears:

```
ezsurf('sqrt(1-x^2-y^2)',[-2*pi 2*pi])
```

In this case, the graphic limits are the same, but ezsurf used 60 points between the user-defined limits instead of checking to see if all those points would have real answers.

[ezmesh](#) | [ezsurf](#) | [function\\_handle](#) | [surf](#)

## How To

- [Anonymous Functions](#)

## Purpose

Easy-to-use combination surface/contour plotter

## Syntax

```
ezsurf(fun)
ezsurf(fun, domain)
ezsurf(funx, funy, funz)
ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])
ezsurf(funx, funy, funz, [min, max])
ezsurf(..., n)
ezsurf(..., 'circ')
ezsurf(axes_handle, ...)
h = ezsurf(...)
```

## Description

`ezsurf(fun)` creates a graph of  $fun(x, y)$  using the `surf` function. The function `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezsurf(fun, domain)` plots `fun` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\min < x < \max$ ,  $\min < y < \max$ ).

`ezsurf(funx, funy, funz)` plots the parametric surface  $funx(s, t)$ ,  $funy(s, t)$ , and  $funz(s, t)$  over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezsurf(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezsurf(..., n)` plots  $f$  over the default domain using an  $n$ -by- $n$  grid. The default value for  $n$  is 60.

`ezsurf(..., 'circ')` plots  $f$  over a disk centered on the domain.

`ezsurf(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurf(...)` returns the handles to the graphics objects in `h`.

## Tips

`ezsurf` and `ezsurf` do not accept complex inputs.

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezsurf`. For example, the MATLAB syntax for a surface/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezsurf`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurf('u^2 - v^3', [0,1], [3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezsurf` does not alter the syntax, as in the case with string inputs.

### Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

## Examples

Create a surface/contour plot of the expression

$$f(x,y) = \frac{y}{1+x^2+y^2}$$

over the domain  $-5 < x < 5$ ,  $-2\pi < y < 2\pi$ , with a computational grid of size 35-by-35:

```
ezsurf('y/(1 + x^2 + y^2)', [-5,5, -2*pi,2*pi], 35)
```

Put the plot in `rotate3d` mode to use the mouse to rotate the axes to better observe the contour lines (this picture uses a view of azimuth = -65.5 and elevation = 26).

**How To**

- [Anonymous Functions](#)

# TriRep.faceNormals

---

## Purpose

(Will be removed) Unit normals to specified triangles

---

**Note** `faceNormals(TriRep)` will be removed in a future release. Use `faceNormal(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

## Syntax

`FN = faceNormals(TR, TI)`

## Description

`FN = faceNormals(TR, TI)` returns the unit normal vector to each of the specified triangles `TI`.

---

**Note** This query is only applicable to triangular surface meshes.

---

## Input Arguments

`TR`                      Triangulation representation.  
`TI`                      Column vector of indices that index into the triangulation matrix `TR.Triangulation`.

## Output Arguments

`FN`                      m-by-3 matrix. `m = length(TI)`, the number of triangles to be queried. Each row `FN(i, :)` represents the unit normal vector to triangle `TI(i)`.  
  
If `TI` is not specified the unit normal information for the entire triangulation is returned, where the normal associated with triangle `i` is the `i`'th row of `FN`.

## Examples

Triangulate a sample of random points on the surface of a sphere and use the `TriRep` to compute the normal to each triangle:

```
numpts = 100;
```

```
theta = rand(numpts,1)*2*pi;
phi = rand(numpts,1)*pi;
x = cos(theta).*sin(phi);
y = sin(theta).*sin(phi);
z = cos(phi);
dt = DelaunayTri(x,y,z);
[tri Xb] = freeBoundary(dt);
tr = TriRep(tri, Xb);
P = incenters(tr);
fn = faceNormals(tr);
trisurf(tri,Xb(:,1),Xb(:,2),Xb(:,3), ...
 'FaceColor', 'cyan', 'faceAlpha', 0.8);
axis equal;
hold on;
```

Display the result using a quiver plot:

```
quiver3(P(:,1),P(:,2),P(:,3), ...
 fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');
hold off;
```

# TriRep.faceNormals

# factorial

---

```
1.124000727777608e+21
```

In this case, `f` is accurate up to 15 digits, `1.12400072777760e+21`, because double-precision numbers are only accurate up to 15 digits.

Reset the output format to the default.

```
format
```

## Factorial of Array Elements

```
n = [0 1 2; 3 4 5];
f = factorial(n)
```

```
f =
```

```
 1 1 2
 6 24 120
```

## Factorial of Unsigned Integer Values

```
n = uint64([5 10 15 20]);
f = factorial(n)
```

```
f =
```

```
 120 3628800 1307674368000 2432902008176640000
```

## Limitations

- For double-precision inputs, the result is exact when `n` is less than or equal to 21. Larger values of `n` produce a result that has the correct order of magnitude and is accurate for the first 15 digits. This is because double-precision numbers are only accurate up to 15 digits.
- For single-precision inputs, the result is exact when `n` is less than or equal to 13. Larger values of `n` produce a result that has the correct order of magnitude and is accurate for the first 8 digits. This is because single-precision numbers are only accurate up to 8 digits.

### Saturation

- The table below describes the saturation behavior of each data type when used with the `factorial` function. The values in the last column indicate the saturation point; that is, the first positive integer whose actual factorial is larger than the maximum representable value in the middle column. For `single` and `double`, all values larger than the maximum value are returned as `Inf`. For the integer data types, the saturation value is equal to the maximum value in the middle column.

| Data type           | Maximum Value                  | Factorial Saturation Threshold     |
|---------------------|--------------------------------|------------------------------------|
| <code>double</code> | <code>realmax</code>           | <code>factorial(171)</code>        |
| <code>single</code> | <code>realmax('single')</code> | <code>factorial(single(35))</code> |
| <code>uint64</code> | $2^{64}-1$                     | <code>factorial(uint64(21))</code> |
| <code>int64</code>  | $2^{63}-1$                     | <code>factorial(int64(21))</code>  |
| <code>uint32</code> | $2^{32}-1$                     | <code>factorial(uint32(13))</code> |
| <code>int32</code>  | $2^{31}-1$                     | <code>factorial(int32(13))</code>  |
| <code>uint16</code> | $2^{16}-1$                     | <code>factorial(uint16(9))</code>  |
| <code>int16</code>  | $2^{15}-1$                     | <code>factorial(int16(8))</code>   |
| <code>uint8</code>  | $2^8-1$                        | <code>factorial(uint8(6))</code>   |
| <code>int8</code>   | $2^7-1$                        | <code>factorial(int8(6))</code>    |

### See Also

`prod`

# false

---

**Purpose** Logical 0 (false)

**Syntax**

```
false
F = false(n)
F = false(sz)
F = false(sz1, ..., szN)
F = false(__, 'like', p)
```

**Description** `false` is shorthand for `logical(0)`.

`F = false(n)` is an n-by-n array of logical zeros.

`F = false(sz)` is an array of logical zeros where the size vector, `sz`, defines `size(F)`. For example, `false([2 3])` returns a 2-by-3 array of logical zeros.

`F = false(sz1, ..., szN)` is a `sz1`-by-...-by-`szN` array of logical zeros where `sz1, ..., szN` indicates the size of each dimension. For example, `false(2,3)` returns a 2-by-3 array of logical zeros.

`F = false( __, 'like', p)` returns an array of logical zeros of the same sparsity as the logical variable `p` using any of the previous size syntaxes.

## Input Arguments

### **n - Size of square matrix**

integer

Size of square matrix, specified as an integer. `n` sets the output array size to n-by-n. For example, `false(3)` returns a 3-by-3 array of logical zeros.

- If `n` is 0, then `F` is an empty matrix.
- If `n` is negative, then it is treated as 0.

### **Data Types**

int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**sz - Size vector**

row vector of integers

Size vector, specified as a row vector of integers. For example, `false([2 3])` returns a 2-by-3 array of logical zeros.

- If the size of any dimension is 0, then `F` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, `F`, does not include those dimensions.

**Data Types**

`int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**sz1,...,szN - Size inputs**

comma-separated list of integers

Size inputs, specified by a comma-separated list of integers. For example, `false(2,3)` returns a 2-by-3 array of logical zeros.

- If the size of any dimension is 0, then `F` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, `F`, does not include those dimensions.

**Data Types**

`int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**p - Prototype**

logical variable

Prototype, specified as a logical variable.

**Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

# false

---

## Output Arguments

### F - Output of logical zeros

scalar | vector | matrix | N-D array

Output of logical zeros, returned as a scalar, vector, matrix, or N-D array.

### Data Types

logical

## Examples

### Generate Square Matrix of Logical Zeros

Use `false` to generate a 3-by-3 square matrix of logical zeros.

```
A = false(3)
class(A)
```

```
A =
 0 0 0
 0 0 0
 0 0 0
```

```
ans =
logical
```

The result is of class `logical`.

### Generate Array of Logical Zeros with Arbitrary Dimensions

Use `false` to generate a 3-by-2-by-2 array of logical zeros.

```
false(3,2,2)
```

```
ans(:,:,1) =
 0 0
 0 0
 0 0
```

```
ans(:,:,2) =
 0 0
 0 0
 0 0
```

Alternatively, use a size vector to specify the size of the matrix.

```
false([3 2 2])
```

```
ans(:,:,1) =
 0 0
 0 0
 0 0
```

```
ans(:,:,2) =
 0 0
 0 0
 0 0
```

Note that specifying multiple vector inputs returns an error.

### Execute Logic Statement

`false` along with `true` can be used to execute logic statements.

Test the logical statement  $\sim(A \text{ and } B) \equiv (\sim A) \text{ or } (\sim B)$  for  $A =$  logical false and  $B =$  logical true.

```
~(false & true) == (~false) | (~true)
```

```
ans =
 1
```

The result is logical 1 (true), since the logical statements on both sides of the equation are equivalent. This logical statement is an instance of De Morgan's Law.

### Generate Logical Array of Selected Sparsity

Generate a logical array of the same data type and sparsity as the selected array.

```
A = logical(sparse(5,3));
whos A
F = false(4,'like',A);
```

# false

---

```
whos F
```

|      |      |       |         |            |
|------|------|-------|---------|------------|
| Name | Size | Bytes | Class   | Attributes |
| A    | 5x3  | 41    | logical | sparse     |
| Name | Size | Bytes | Class   | Attributes |
| F    | 4x4  | 49    | logical | sparse     |

The output array  $F$  has the same `sparse` attribute as the specified array  $A$ .

## Tips

- `false(n)` is much faster and more memory efficient than `logical(zeros(n))`.

## See Also

`true` | `logical`

## Concepts

- “Class Support for Array-Creation Functions”

**Purpose** Close one or all open files

**Syntax** `fclose(fileID)`  
`fclose('all')`  
`status = fclose(...)`

**Description** `fclose(fileID)` closes an open file. *fileID* is an integer file identifier obtained from `fopen`.  
`fclose('all')` closes all open files.  
`status = fclose(...)` returns a *status* of 0 when the close operation is successful. Otherwise, it returns -1.

**See Also** `ferror` | `fopen` | `frewind` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf` | `fread` | `fwrite`

# fclose (serial)

---

**Purpose** Disconnect serial port object from device

**Syntax** `fclose(obj)`

**Description** `fclose(obj)` disconnects `obj` from the device, where `obj` is a serial port object or an array of serial port objects.

**Tips** If `obj` was successfully disconnected, then the `Status` property is configured to `closed` and the `RecordStatus` property is configured to `off`. You can reconnect `obj` to the device using the `fopen` function.

An error is returned if you issue `fclose` while data is being written asynchronously. In this case, you should abort the write operation with the `stopasync` function, or wait for the write operation to complete.

**Examples** This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, and then disconnects `s` from the device using `fclose`.

```
s = serial('COM1');
fopen(s)
fprintf(s, '*IDN?')
idn = fscanf(s);
fclose(s)
```

At this point, the device is available to be connected to a serial port object. If you no longer need `s`, you should remove from memory with the `delete` function, and remove it from the workspace with the `clear` command.

**See Also** `clear` | `delete` | `fopen` | `stopasync` | `RecordStatus` | `Status`

**Purpose**

Plot velocity vectors

**Syntax**

```
feather(U,V)
feather(Z)
feather(...,LineStyle)
feather(axes_handle,...)
h = feather(...)
```

**Description**

A feather plot displays vectors emanating from equally spaced points along a horizontal axis. You express the vector components relative to the origin of the respective vector.

`feather(U,V)` displays the vectors specified by `U` and `V`, where `U` contains the  $x$  components as relative coordinates, and `V` contains the  $y$  components as relative coordinates.

`feather(Z)` displays the vectors specified by the complex numbers in `Z`. This is equivalent to `feather(real(Z), imag(Z))`.

`feather(...,LineStyle)` draws a feather plot using the line type, marker symbol, and color specified by `LineStyle`.

`feather(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = feather(...)` returns the handles to line objects in `h`.

**Examples****Create Feather Plot**

Define `theta` as values between  $-2\pi$  and  $2\pi$ . Define `r` as a vector the same size as `theta`.

```
theta = -pi/2:pi/16:pi/2;
r = 2*ones(size(theta));
```

# feather

---

Create a feather plot showing the direction of `theta`. Since `feather` uses Cartesian coordinates, convert `theta` and `r` to Cartesian coordinates using `pol2cart`.

```
[u,v] = pol2cart(theta,r);
feather(u,v);
```

## Purpose

(Will be removed) Sharp edges of surface triangulation

---

**Note** `featureEdges(TriRep)` will be removed in a future release. Use `featureEdges(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

## Syntax

`FE = featureEdges(TR, filterangle)`

## Description

`FE = featureEdges(TR, filterangle)` returns an edge matrix `FE`. This method is typically used to extract the sharp edges in the surface mesh for the purpose of display. Edges that are shared by only one triangle and edges that are shared by more than two triangles are considered to be feature edges by default.

---

**Note** This query is only applicable to triangular surface meshes.

---

## Input Arguments

|                          |                                                                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TR</code>          | Triangulation representation.                                                                                                                                                                                                      |
| <code>filterangle</code> | The threshold angle in radians. Must be in the range $(0, \pi)$ . <code>featureEdges</code> will return adjacent triangles that have a dihedral angle that deviates from $\pi$ by an angle greater than <code>filterangle</code> . |

## Output Arguments

|                 |                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>FE</code> | Edges of the triangulation. <code>FE</code> is of size <code>m-by-2</code> where <code>m</code> is the number of computed feature edges in the mesh. The vertices of the edges index into the array of points representing the vertex coordinates, <code>TR.X</code> . |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# TriRep.featureEdges

---

## Examples

Create a surface triangulation:

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
dt = DelaunayTri(x,y);
tri = dt(:,:);
```

Elevate the 2-D mesh to create a surface:

```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(tri,x,y,z, 'FaceColor', 'cyan');
axis equal;
% TRISURF display of surface mesh
% showing mesh edges
```

Compute the feature edges using a filter angle of  $\pi/6$ :

```
tr = TriRep(tri, x,y,z);
fe = featureEdges(tr,pi/6)';
subplot(1,2,2);
trisurf(tr, 'FaceColor', 'cyan', 'EdgeColor','none', ...
 'FaceAlpha', 0.8); axis equal;
```

Add the feature edges to the plot:

```
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
% TRISURF display of surface mesh
% suppressing mesh edges
% and showing feature edges
```

## See Also

`edges` | `delaunayTriangulation` | `triangulation`

# feof

---

**Purpose** Test for end-of-file

**Syntax** `status = feof(fileID)`

**Description** `status = feof(fileID)` returns 1 if a previous operation set the end-of-file indicator for the specified file. Otherwise, `feof` returns 0. `fileID` is an integer file identifier obtained from `fopen`.

Opening an empty file does *not* set the end-of-file indicator. Read operations, and the `fseek` and `frewind` functions, move the file position indicator.

**Examples** Read `bench.dat`, which contains MATLAB benchmark data, one character at a time:

```
fid = fopen('bench.dat');

k = 0;
while ~feof(fid)
 curr = fscanf(fid,'%c',1);
 if ~isempty(curr)
 k = k+1;
 benchstr(k) = curr;
 end
end

fclose(fid);
```

**See Also** `fclose` | `ferror` | `fopen` | `frewind` | `fseek` | `ftell`

**How To** • “Testing for End of File (EOF)”

**Purpose**

Information about file I/O errors

**Syntax**

```
message = ferror(fileID)
[message, errnum] = ferror(fileID)
[...] = ferror(fileID, 'clear')
```

**Description**

*message* = ferror(*fileID*) returns the error message for the most recent file I/O operation on the specified file. If the operation was successful, *message* is an empty string. *fileID* is an integer file identifier obtained from fopen, or an identifier reserved for standard input (0), standard output (1), or standard error (2).

[*message*, *errnum*] = ferror(*fileID*) returns the error number. If the most recent file I/O operation was successful, *errnum* is 0. Negative error numbers correspond to MATLAB error messages. Positive error numbers correspond to C library error messages for your system.

[...] = ferror(*fileID*, 'clear') clears the error indicator for the specified file.

**See Also**

fclose | fopen | fseek | ftell | feof | fscanf | fprintf | fread | fwrite

# feval

---

**Purpose** Evaluate function

**Syntax** `[y1, y2, ...] = feval(fhandle, x1, ..., xn)`  
`[y1, y2, ...] = feval(fname, x1, ..., xn)`

**Description** `[y1, y2, ...] = feval(fhandle, x1, ..., xn)` evaluates the function handle, `fhandle`, using arguments `x1` through `xn`. If the function handle is bound to more than one built-in or `.m` function, (that is, it represents a set of overloaded functions), then the data type of the arguments `x1` through `xn` determines which function is dispatched to.

---

**Note** It is not necessary to use `feval` to call a function by means of a function handle. This is explained in “Calling a Function Using Its Handle” in the MATLAB Programming Fundamentals documentation.

---

`[y1, y2, ...] = feval(fname, x1, ..., xn)`. If `fname` is a quoted string containing the name of a function (usually defined within a file having a `.m` file extension), then `feval(fname, x1, ..., xn)` evaluates that function at the given arguments. The `fname` parameter must be a simple function name; it cannot contain path information.

**Tips** The following two statements are equivalent.

```
[V,D] = eig(A)
[V,D] = feval(@eig, A)
```

Nested functions are not accessible to `feval`. To call a nested function, you must either call it directly by name, or construct a function handle for it using the `@` operator.

**Examples** The following example passes a function handle, `fhandle`, in a call to `fminbnd`. The `fhandle` argument is a handle to the `humps` function.

```
fhandle = @humps;
x = fminbnd(fhandle, 0.3, 1);
```

The `fminbnd` function uses `feval` to evaluate the function handle that was passed in.

```
function [xf, fval, exitflag, output] = ...
 fminbnd(funfcn, ax, bx, options, varargin)
 .
 .
 .
fx = feval(funfcn, x, varargin{:});
```

**See Also**

[assignin](#) | [function\\_handle](#) | [functions](#) | [builtin](#) | [eval](#) | [evalin](#)

# Feval (COM)

---

**Purpose** Evaluate MATLAB function in Automation server

**Syntax** **IDL Method Signature**

```
HRESULT Feval([in] BSTR functionname, [in] long numout,
[out] VARIANT* result, [in, optional] VARIANT arg1, arg2, ...)
```

**Microsoft Visual Basic Client**

```
Feval(String functionname, long numout,
arg1, arg2, ...) As Object
```

**MATLAB Client**

```
result = h.Feval('functionname', numout, arg1, arg2, ...)
result = Feval(h, 'functionname', numout, arg1, arg2, ...)
```

**Description**

`result = h.Feval('functionname', numout, arg1, arg2, ...)` executes the MATLAB function specified by the string `functionname` in the Automation server attached to handle `h`. The function name is case-sensitive.

`result = Feval(h, 'functionname', numout, arg1, arg2, ...)` is an alternate syntax.

Indicate the number of outputs to be returned by the function in a 1-by-1 double array, `numout`. The server returns output from the function in the cell array, `result`.

You can specify as many as 32 input arguments to be passed to the function. These arguments follow `numout` in the `Feval` argument list. The following table shows ways to pass an argument.

| Passing Mechanism           | Description                                                                                                                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pass the value itself       | To pass any numeric or string value, specify the value in the Feval argument list:<br><br><code>a = h.Feval('sin', 1, -pi:0.01:pi);</code>                                                                                                                       |
| Pass a client variable      | To pass an argument assigned to a variable in the client, specify the variable name alone:<br><br><code>x = -pi:0.01:pi;<br/>a = h.Feval('sin', 1, x);</code>                                                                                                    |
| Reference a server variable | To reference a variable defined in the server, specify the variable name followed by an equals (=) sign:<br><br><code>h.PutWorkspaceData('x', 'base', -pi:0.01:pi);<br/>a = h.Feval('sin', 1, 'x=');</code><br><br>MATLAB does not reassign the server variable. |

## Tips

To display the output from Feval in the client window, assign a return value.

COM functions are available on Microsoft Windows systems only.

## Examples

### Passing Arguments

This example shows how to pass arguments using Feval to execute MATLAB commands on a MATLAB Automation server from a Visual Basic .NET client.

- Pass two strings to the MATLAB function strcat on the server:

```
Dim Matlab As Object
Dim out As Object
out = Nothing
Matlab = CreateObject("matlab.application")
Matlab.Feval("strcat", 1, out, "hello", " world")
```

# Feval (COM)

---

- Define `clistr` locally and pass this variable:

```
Dim clistr As String
clistr = " world"
Matlab.Feval("strcat", 1, out, "hello", clistr)
```

- Pass the name of a variable defined on the server:

```
Matlab.PutCharArray("srvstr", "base", " world")
Matlab.Feval("strcat", 1, out, "hello", "srvstr=")
```

## Defining Feval Return Values

`Feval` returns data from the evaluated function in a cell array. The cell array has one row for every return value. You control the number of return values using the `numout` argument.

```
Dim Matlab As Object
Dim out As Object
Matlab = CreateObject("matlab.application")
Matlab.Feval("fileparts", 3, out, "d:\work\ConsoleApp.cpp")
```

**Purpose** Fast Fourier transform

**Syntax**

```
Y = fft(x)
Y = fft(X,n)
Y = fft(X,[],dim)
Y = fft(X,n,dim)
```

**Definitions** The functions  $Y = \text{fft}(x)$  and  $y = \text{ifft}(X)$  implement the transform and inverse transform pair given for vectors of length  $N$  by:

$$X(k) = \sum_{j=1}^N x(j)\omega_N^{(j-1)(k-1)}$$

$$x(j) = (1/N) \sum_{k=1}^N X(k)\omega_N^{-(j-1)(k-1)}$$

where

$$\omega_N = e^{(-2\pi i)/N}$$

is an  $N$ th root of unity.

**Description**  $Y = \text{fft}(x)$  returns the discrete Fourier transform (DFT) of vector  $x$ , computed with a fast Fourier transform (FFT) algorithm.

If the input  $X$  is a matrix,  $Y = \text{fft}(X)$  returns the Fourier transform of each column of the matrix.

If the input  $X$  is a multidimensional array,  $\text{fft}$  operates on the first nonsingleton dimension.

$Y = \text{fft}(X, n)$  returns the  $n$ -point DFT.  $\text{fft}(X)$  is equivalent to  $\text{fft}(X, n)$  where  $n$  is the size of  $X$  in the first nonsingleton dimension. If the length of  $X$  is less than  $n$ ,  $X$  is padded with trailing zeros to length  $n$ . If the length of  $X$  is greater than  $n$ , the sequence  $X$  is truncated. When  $X$  is a matrix, the length of the columns are adjusted in the same manner.

$Y = \text{fft}(X,[],\text{dim})$  and  $Y = \text{fft}(X,n,\text{dim})$  applies the FFT operation across the dimension  $\text{dim}$ .

## Examples

A common use of Fourier transforms is to find the frequency components of a signal buried in a noisy time domain signal. Consider data sampled at 1000 Hz. Form a signal containing a 50 Hz sinusoid of amplitude 0.7 and 120 Hz sinusoid of amplitude 1 and corrupt it with some zero-mean random noise:

```
Fs = 1000; % Sampling frequency
T = 1/Fs; % Sample time
L = 1000; % Length of signal
t = (0:L-1)*T; % Time vector
% Sum of a 50 Hz sinusoid and a 120 Hz sinusoid
x = 0.7*sin(2*pi*50*t) + sin(2*pi*120*t);
y = x + 2*randn(size(t)); % Sinusoids plus noise
plot(Fs*t(1:50),y(1:50))
title('Signal Corrupted with Zero-Mean Random Noise')
xlabel('time (milliseconds)')
```

It is difficult to identify the frequency components by looking at the original signal. Converting to the frequency domain, the discrete Fourier transform of the noisy signal  $y$  is found by taking the fast Fourier transform (FFT):

```
NFFT = 2^nextpow2(L); % Next power of 2 from length of y
Y = fft(y,NFFT)/L;
f = Fs/2*linspace(0,1,NFFT/2+1);

% Plot single-sided amplitude spectrum.
plot(f,2*abs(Y(1:NFFT/2+1)))
title('Single-Sided Amplitude Spectrum of y(t)')
xlabel('Frequency (Hz)')
ylabel('|Y(f)|')
```

The main reason the amplitudes are not exactly at 0.7 and 1 is because of the noise. Several executions of this code (including recomputation of  $y$ ) will produce different approximations to 0.7 and 1. The other reason is that you have a finite length signal. Increasing  $L$  from 1000 to

10000 in the example above will produce much better approximations on average.

## Algorithms

The FFT functions (`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, `ifftn`) are based on a library called FFTW [3],[4]. To compute an  $N$ -point DFT when  $N$  is composite (that is, when  $N = N_1 N_2$ ), the FFTW library decomposes the problem using the Cooley-Tukey algorithm [1], which first computes  $N_1$  transforms of size  $N_2$ , and then computes  $N_2$  transforms of size  $N_1$ . The decomposition is applied recursively to both the  $N_1$ - and  $N_2$ -point DFTs until the problem can be solved using one of several machine-generated fixed-size "codelets." The codelets in turn use several algorithms in combination, including a variation of Cooley-Tukey [5], a prime factor algorithm [6], and a split-radix algorithm [2]. The particular factorization of  $N$  is chosen heuristically.

When  $N$  is a prime number, the FFTW library first decomposes an  $N$ -point problem into three  $(N - 1)$ -point problems using Rader's algorithm [7]. It then uses the Cooley-Tukey decomposition described above to compute the  $(N - 1)$ -point DFTs.

For most  $N$ , real-input DFTs require roughly half the computation time of complex-input DFTs. However, when  $N$  has large prime factors, there is little or no speed difference.

The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `fft` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

---

## Data Type Support

`fft` supports inputs of data types `double` and `single`. If you call `fft` with the syntax `y = fft(X, ...)`, the output `y` has the same data type as the input `X`.

# fft2

---

**Purpose** 2-D fast Fourier transform

**Syntax**  
`Y = fft2(X)`  
`Y = fft2(X,m,n)`

**Description** `Y = fft2(X)` returns the two-dimensional discrete Fourier transform (DFT) of `X`. The DFT is computed with a fast Fourier transform (FFT) algorithm. The result, `Y`, is the same size as `X`.

If the dimensionality of `X` is greater than 2, the `fft2` function returns the 2-D DFT for each higher dimensional slice of `X`. For example, if `size(X) = [100 100 3]`, then `fft2` computes the DFT of `X(:, :, 1)`, `X(:, :, 2)` and `X(:, :, 3)`.

`Y = fft2(X,m,n)` truncates `X`, or pads `X` with zeros to create an `m`-by-`n` array before doing the transform. The result is `m`-by-`n`.

**Algorithms** `fft2(X)` can be simply computed as

```
fft(fft(X).').'
```

This computes the one-dimensional DFT of each column `X`, then of each row of the result. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `fft2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

**Data Type Support** `fft2` supports inputs of data types `double` and `single`. If you call `fft2` with the syntax `y = fft2(X, ...)`, the output `y` has the same data type as the input `X`.

**See Also**`fft | fftn | fftw | fftshift | ifft2`

**Purpose** N-D fast Fourier transform

**Syntax** `Y = fftn(X)`  
`Y = fftn(X,siz)`

**Description** `Y = fftn(X)` returns the discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`Y = fftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the transform. The size of the result `Y` is `siz`.

**Algorithms** `fftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
 Y = fft(Y,[],p);
end
```

This computes in-place the one-dimensional fast Fourier transform along each dimension of `X`. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `fftn` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

---

**Data Type Support** `fftn` supports inputs of data types `double` and `single`. If you call `fftn` with the syntax `y = fftn(X, ...)`, the output `y` has the same data type as the input `X`.

**See Also**

`fft` | `fft2` | `fftw` | `ifftn`

# fftshift

---

**Purpose** Shift zero-frequency component to center of spectrum

**Syntax**  $Y = \text{fftshift}(X)$   
 $Y = \text{fftshift}(X, \text{dim})$

**Description**  $Y = \text{fftshift}(X)$  rearranges the outputs of `fft`, `fft2`, and `fftn` by moving the zero-frequency component to the center of the array. It is useful for visualizing a Fourier transform with the zero-frequency component in the middle of the spectrum.

For vectors, `fftshift(X)` swaps the left and right halves of  $X$ . For matrices, `fftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth.

For higher-dimensional arrays, `fftshift(X)` swaps “half-spaces” of  $X$  along each dimension.

$Y = \text{fftshift}(X, \text{dim})$  applies the `fftshift` operation along the dimension `dim`.

For dim = 1:

For dim = 2:

---

**Note** `ifftshift` will undo the results of `fftshift`. If the matrix  $X$  contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original  $X$ . Simply performing `fftshift(X)` twice will not produce  $X$ .

---

## Examples

For any matrix  $X$

```
Y = fft2(X)
```

has  $Y(1,1) = \text{sum}(\text{sum}(X))$ ; the zero-frequency component of the signal is in the upper-left corner of the two-dimensional FFT. For

```
Z = fftshift(Y)
```

this zero-frequency component is near the center of the matrix.

The difference between `fftshift` and `ifftshift` is important for input sequences of odd-length.

```
N = 5;
X = 0:N-1;
Y = fftshift(fftshift(X));
Z = ifftshift(fftshift(X));
```

Notice that  $Z$  is a correct replica of  $X$ , but  $Y$  is not.

# fftshift

**Purpose**

Interface to FFTW library run-time algorithm tuning control

**Syntax**

```
fftw('planner', method)
method = fftw('planner')
str = fftw('dwisdom')
str = fftw('swisdom')
fftw('dwisdom', str)
fftw('swisdom', str)
```

**Description**

fftw enables you to optimize the speed of the MATLAB FFT functions `fft`, `ifft`, `fft2`, `ifft2`, `fftn`, and `ifftn`. You can use `fftw` to set options for a tuning algorithm that experimentally determines the fastest algorithm for computing an FFT of a particular size and dimension at run time. MATLAB software records the optimal algorithm in an internal data base and uses it to compute FFTs of the same size throughout the current session. The tuning algorithm is part of the FFTW library that MATLAB software uses to compute FFTs.

`fftw('planner', method)` sets the method by which the tuning algorithm searches for a good FFT algorithm when the dimension of the FFT is not a power of 2. You can specify `method` to be one of the following. The default method is `estimate`:

- 'estimate'
- 'measure'
- 'patient'
- 'exhaustive'
- 'hybrid'

When you call `fftw('planner', method)`, the next time you call one of the FFT functions, such as `fft`, the tuning algorithm uses the specified method to optimize the FFT computation. Because the tuning involves trying different algorithms, the first time you call an FFT function, it might run more slowly than if you did not call `fftw`. However, subsequent calls to any of the FFT functions, for a problem of the same size, often run more quickly than they would without using `fftw`.

---

**Note** The FFT functions only use the optimal FFT algorithm during the current MATLAB session. “Reusing Optimal FFT Algorithms” on page 1-2058 explains how to reuse the optimal algorithm in a future MATLAB session.

---

If you set the method to 'estimate', the FFTW library does not use run-time tuning to select the algorithms. The resulting algorithms might not be optimal.

If you set the method to 'measure', the FFTW library experiments with many different algorithms to compute an FFT of a given size and chooses the fastest. Setting the method to 'patient' or 'exhaustive' has a similar result, but the library experiments with even more algorithms so that the tuning takes longer the first time you call an FFT function. However, subsequent calls to FFT functions are faster than with 'measure'.

If you set 'planner' to 'hybrid', MATLAB software

- Sets method to 'measure' method for FFT dimensions 8192 or smaller.
- Sets method to 'estimate' for FFT dimensions greater than 8192.

`method = fftw('planner')` returns the current planner method.

`str = fftw('dwisdom')` returns the information in the FFTW library's internal double-precision database as a string. The string can be saved and then later reused in a subsequent MATLAB session using the next syntax.

`str = fftw('swisdom')` returns the information in the FFTW library's internal single-precision database as a string.

`fftw('dwisdom', str)` loads fftw wisdom represented by the string `str` into the FFTW library's internal double-precision wisdom database. `fftw('dwisdom', '')` or `fftw('dwisdom', [])` clears the internal wisdom database.

`fftw('swisdom', str)` loads fftw wisdom represented by the string `str` into the FFTW library's internal single-precision wisdom database. `fftw('swisdom', '')` or `fftw('swisdom', [])` clears the internal wisdom database.

---

**Note on large powers of 2** For FFT dimensions that are powers of 2, between  $2^{14}$  and  $2^{22}$ , MATLAB software uses special preloaded information in its internal database to optimize the FFT computation. No tuning is performed when the dimension of the FFT is a power of 2, unless you clear the database using the command `fftw('wisdom', [])`.

---

For more information about the FFTW library, see <http://www.fftw.org>.

## Examples

### Comparison of Speed for Different Planner Methods

The following example illustrates the run times for different settings of `planner`. The example first creates some data and applies `fft` to it using the default method, `estimate`.

```
t=0:.001:5;
x = sin(2*pi*50*t)+sin(2*pi*120*t);
y = x + 2*randn(size(t));
```

```
tic; Y = fft(y,1458); toc
Elapsed time is 0.000521 seconds.
```

If you execute the commands

```
tic; Y = fft(y,1458); toc
Elapsed time is 0.000151 seconds.
```

a second time, MATLAB software reports the elapsed time as essentially 0. To measure the elapsed time more accurately, you can execute the command `Y = fft(y,1458)` 1000 times in a loop.

```
tic; for k=1:1000
Y = fft(y,1458);
end; toc
Elapsed time is 0.056532 seconds.
```

This tells you that it takes on order of 1/10000 of a second to execute `fft(y, 1458)` a single time.

For comparison, set `planner` to `patient`. Since this planner explores possible algorithms more thoroughly than `hybrid`, the first time you run `fft`, it takes longer to compute the results.

```
fftw('planner','patient')
tic;Y = fft(y,1458);toc
Elapsed time is 0.100637 seconds.
```

However, the next time you call `fft`, it runs at approximately the same speed as before you ran the method `patient`.

```
tic;for k=1:1000
Y=fft(y,1458);
end;toc
Elapsed time is 0.057209 seconds.
```

### **Reusing Optimal FFT Algorithms**

In order to use the optimized FFT algorithm in a future MATLAB session, first save the “wisdom” using the command

```
str = fftw('wisdom')
```

You can save `str` for a future session using the command

```
save str
```

The next time you open a MATLAB session, load `str` using the command

```
load str
```

and then reload the “wisdom” into the FFTW database using the command

```
fftw('wisdom', str)
```

# fgetl

---

**Purpose** Read line from file, removing newline characters

**Syntax** `tline = fgetl(fileID)`

**Description** `tline = fgetl(fileID)` returns the next line of the specified file, removing the newline characters. `fileID` is an integer file identifier obtained from `fopen`. `tline` is a text string unless the line contains only the end-of-file marker. In this case, `tline` is the numeric value `-1`.

`fgetl` reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use `fopen`.

**Examples** Read and display the file `fgetl.m` one line at a time:

```
fid = fopen('fgetl.m');

tline = fgetl(fid);
while ischar(tline)
 disp(tline)
 tline = fgetl(fid);
end

fclose(fid);
```

Compare these results to the `fgets` example, which replaces the calls to `fgetl` with `fgets`.

**See Also** `fclose` | `feof` | `ferror` | `fgets` | `fopen` | `fprintf` | `fread` | `fscanf` | `fwrite`

**How To**

- “Testing for EOF with `fgetl` and `fgets`”

**Purpose** Read line of text from device and discard terminator

**Syntax**

```
tline = fgetl(obj)
[tline,count] = fgetl(obj)
[tline,count,msg] = fgetl(obj)
```

**Description** `tline = fgetl(obj)` reads one line of text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data does not include the terminator with the text line. To include the terminator, use `fgets`.

`[tline,count] = fgetl(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgetl(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

**Tips** Before you can read text from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgetl` is issued.

### Rules for Completing a Read Operation with fgetl

A read operation with `fgetl` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.
- The time specified by the `Timeout` property passes.
- The input buffer is filled.

**Examples** On a Windows platform, create the serial port object `s`, connect `s` to a Tektronix® TDS 210 oscilloscope, and write the `RS232?` command with

# fgetl (serial)

---

the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s, 'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable
```

```
ans =
 17
```

Use `fgetl` to read the data returned from the previous write operation, and discard the terminator.

```
settings = fgetl(s)
```

```
settings =
9600;0;0;NONE;LF
```

```
length(settings)
```

```
ans =
 16
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Read line from file, keeping newline characters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Syntax</b>      | <pre><i>tline</i> = fgets(<i>fileID</i>)<br/><i>tline</i> = fgets(<i>fileID</i>, <i>nchar</i>)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p><i>tline</i> = fgets(<i>fileID</i>) reads the next line of the specified file, including the newline characters. <i>fileID</i> is an integer file identifier obtained from fopen. <i>tline</i> is a text string unless the line contains only the end-of-file marker. In this case, <i>tline</i> is the numeric value -1. fgets reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use fopen.</p> <p><i>tline</i> = fgets(<i>fileID</i>, <i>nchar</i>) returns at most <i>nchar</i> characters of the next line. <i>tline</i> does not include any characters after the newline characters or the end-of-file marker.</p> |
| <b>Examples</b>    | <p>Read and display the file fgets.m. Because fgets keeps newline characters and disp adds a newline character, this code displays the file with double-spacing:</p> <pre>fid = fopen('fgets.m');<br/><br/>tline = fgets(fid);<br/>while ischar(tline)<br/>    disp(tline)<br/>    tline = fgets(fid);<br/>end<br/><br/>fclose(fid);</pre> <p>Compare these results to the fgetl example, which replaces the calls to fgets with fgetl.</p>                                                                                                                                                                                                                                    |

# fgets (serial)

---

**Purpose** Read line of text from device and include terminator

**Syntax**

```
tline = fgets(obj)
[tline,count] = fgets(obj)
[tline,count,msg] = fgets(obj)
```

**Description** `tline = fgets(obj)` reads one line of text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data includes the terminator with the text line. To exclude the terminator, use `fgetl`.

`[tline,count] = fgets(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgets(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

**Tips** Before you can read text from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgets` is issued.

## Rules for Completing a Read Operation with fgets

A read operation with `fgets` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.
- The time specified by the `Timeout` property passes.
- The input buffer is filled.

**Examples** Create the serial port object `s`, connect `s` to a Tektronix TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function.

RS232? instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s, 'RS232?')
```

Because the default value for the ReadAsyncMode property is continuous, data is automatically returned to the input buffer.

```
s.BytesAvailable
```

```
ans =
 17
```

Use fgets to read the data returned from the previous write operation, and include the terminator.

```
settings = fgets(s)
```

```
settings =
9600;0;0;NONE;LF
```

```
length(settings)
```

```
ans =
 17
```

Disconnect s from the scope, and remove s from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

# fieldnames

---

**Purpose** Field names of structure, or public fields of object

**Syntax**

```
names = fieldnames(s)
names = fieldnames(obj)
names = fieldnames(obj, '-full')
```

**Description**

`names = fieldnames(s)` returns a cell array of strings containing the names of the fields in structure `s`.

`names = fieldnames(obj)` returns a cell array of strings containing the names of the public properties of `obj`. MATLAB objects can overload `fieldnames` and define their own behavior.

`names = fieldnames(obj, '-full')` returns a cell array of strings containing the name, type, attributes, and inheritance of the properties of `obj`. Only supported for COM or Java objects.

## Examples

### Structure Fields

Create a structure array and view its fields.

```
s(1,1).name = 'alice';
s(1,1).ID = 0;
s(2,1).name = 'gertrude';
s(2,1).ID = 1;
```

```
names = fieldnames(s)
```

```
names =
 'name'
 'ID'
```

### Java Object Properties

Create a Java® object and view its public properties.

```
obj = java.lang.Integer(0);
names = fieldnames(obj)
```

```
names =

 'MIN_VALUE'
 'MAX_VALUE'
 'TYPE'
 'SIZE'
```

## How To

- “Generate Field Names from Variables”

# figure

---

**Purpose** Create figure graphics object

**Syntax**

```
figure
figure
figure('PropertyName',propertyvalue,...)
figure(h)
h = figure(...)
```

**Properties** For a list of properties, see [Figure Properties](#).

**Description** `figure` creates figure graphics objects. Figure objects are the individual windows on the screen in which the MATLAB software displays graphical output.

`figure` creates a new figure object using default property values. This automatically becomes the current figure and raises it above all other figures on the screen until a new figure is created or called.

`figure` creates a new figure object using default property values. This automatically becomes the current figure and raises it above all other figures on the screen until a new figure is created or called.

Number property has been assigned the smallest positive integer not already assigned to another Figure. This number also appears in the new Figure's title bar.

`figure('PropertyName',propertyvalue,...)` creates a new figure object using the values of the properties specified. For a description of the properties, see [Figure Properties](#). MATLAB uses default values for any properties that you do not explicitly define as arguments.

`figure(h)` does one of the following (assuming `IntegerHandle` is its default value, `on`):

- If `h` is the handle to an existing figure, `figure(h)` makes the figure identified by `h` the current figure, makes it visible, and attempts to raise it above all other figures on the screen. The current figure is the target for graphics output.

- If `h` is not the handle to an existing figure, but is an integer, `figure(h)` creates a figure and assigns it the handle `h`.
- If `h` is not the handle to a figure, and is not an integer, MATLAB returns an error.

`h = figure(...)` returns the handle to the figure object.

## Tips

To create a figure object, MATLAB creates a new window whose characteristics are controlled by default figure properties (both factory installed and user defined) and properties specified as arguments. See [Figure Properties](#) for a description of these properties.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

Use `set` to modify the properties of an existing figure or `get` to query the current values of figure properties.

The `gcf` command returns the handle to the current figure and is useful as an argument to the `set` and `get` commands.

Figures can be docked in the desktop. The `DockControls` property determines whether you can dock the figure.

### Making a Figure Current

The current figure is the target for graphics output. There are two ways to make a figure `h` the current figure.

- Make the figure `h` current, visible, and displayed on top of other figures:

```
figure(h);
```

- Make the figure `h` current, but do not change its visibility or stacking with respect to other figures:

```
set(0, 'CurrentFigure', h);
```

## Examples

### Specifying Figure Size and Screen Location

To create a figure window that is one quarter the size of your screen and is positioned in the upper left corner, use the root object's `ScreenSize` property to determine the size. `ScreenSize` is a four-element vector: [left, bottom, width, height]:

```
scrsz = get(0, 'ScreenSize');
figure('Position', [1 scrsz(4)/2 scrsz(3)/2 scrsz(4)/2])
```

To position the full figure window including the menu bar, title bar, tool bars, and outer edges, use the `OuterPosition` property in the same manner.

### Specifying the Figure Window Title

You can add your own title to a figure by setting the `Name` property and you can turn off the figure number with the `NumberTitle` property:

```
figure('Name', 'Simulation Plot Window', 'NumberTitle', 'off')
```

See [Figure Properties](#) for a description of all properties.

## Setting Default Properties

You can set default figure properties only on the root object level.

```
set(0, 'DefaultFigureProperty', PropertyValue...)
```

where *Property* is the name of the figure property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access figure properties.

See “Setting Default Property Values” for more information.

## Purpose

Define figure properties

## Creating Figure Objects

Use `figure` to create figure objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “Customize Objects in Graph” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of Handle Graphics properties.

To change the default values of properties, see “Setting Default Property Values” in the Handle Graphics Objects documentation.

## Figure Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Alphamap

m-by-1 matrix of alpha values

*Figure alphamap.* An array of non-NaN alpha values. MATLAB accesses alpha values by their row number. For example, an index of 1 specifies the first alpha value, an index of 2 specifies the second alpha value, and so on. Alphamaps can be any length. The default alphamap contains 64 values that progress linearly from 0 to 1.

Alphamaps affect the rendering of surface, image, and patch objects, but do not affect other graphics objects.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted`

# Figure Properties

---

property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

See the `close` and `delete` function reference pages for related information.

## `BusyAction`

`cancel` | `{queue}`

*Callback function interruption.* The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callback functions. If there is a callback function executing, callback functions invoked subsequently always attempt to interrupt it. If the `Interruptible` property of the object whose callback is executing is `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback function.
- `queue` — Queue the event that attempted to execute a second callback function until the current callback finishes.

## `ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is in the figure window, but not over a child object (i.e., `uicontrol`, `uipanel`, `axes`, or `axes child`).

Define the `ButtonDownFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with the mouse button press and an empty event structure).

See the figure's `SelectionType` property to determine whether modifier keys were also pressed.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## Using the `ButtonDownFcn`

This example creates a figure and defines a function handle callback for the `ButtonDownFcn` property. When the user **Ctrl**-clicks the figure, the callback creates a new figure having the same callback.

[Click to view in editor](#) — This link opens the MATLAB Editor with the following example.

[Click to run example](#) — **Ctrl**-click the figure to create a new figure.

```
fh_cb = @newfig; % Create function handle for newfig function
figure('ButtonDownFcn',fh_cb);

function newfig(src,evnt)
 if strcmp(get(src,'SelectionType'),'alt')
 figure('ButtonDownFcn',fh_cb)
 else
 disp('Use control-click to create a new figure')
 end
end
```

Children  
vector of handles

# Figure Properties

---

*Children of the figure.* A vector containing the handles of all axes, user-interface objects displayed within the figure. You can change the order of the handles and thereby change the stacking of the objects on the display.

When an object's `HandleVisibility` property is `off`, it is not listed in its parent's `Children` property. See `HandleVisibility` for more information.

## Clipping

{on} | off

*Clipping mode.* This property has no effect on figures.

## CloseRequestFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Function executed on figure close.* Executes whenever you issue the `close` command (either a `close(figure_handle)` or a `close all`), when you close a figure window from the computer's window manager menu, or when you quit MATLAB.

The `CloseRequestFcn` provides a mechanism to intervene in the closing of a figure. It allows you to, for example, display a dialog box to ask a user to confirm or cancel the close operation or to prevent users from closing a figure that contains a GUI.

The basic mechanism is:

- 1 A user issues the `close` command from the command line, by closing the window from the computer's window manager menu, or by quitting MATLAB.
- 2 The close operation executes the function defined by the figure `CloseRequestFcn`. The default function is `closereq`.

`closereq` unconditionally deletes the current figure, destroying the window. `closereq` takes advantage of the fact that the

`close` command makes each figure specified as arguments the current figure before calling its respective close request function.

Note that `closereq` honors the `ShowHiddenHandles` setting during figure deletion and will not delete hidden figures.

## Redefining the `CloseRequestFcn`

Define the `CloseRequestFcn` as a function handle. For example:

```
set(gcf, 'CloseRequestFcn', @my_closefcn)
```

Where `@my_closefcn` is a function handle referencing function `my_closefcn`.

Unless the close request function calls `delete` or `close`, MATLAB never closes the figure. (Note that you can always call `delete(figure_handle)` from the command line if you have created a window with a nondestructive close request function.)

A useful application of the close request function is to display a question dialog box asking the user to confirm the close operation. The following function illustrates how to do this.

[Click to view in editor](#) — This link opens the MATLAB editor with the following example.

[Click to run example](#) — **Ctrl-** click the figure to create a new figure.

```
function my_closereq(src, evnt)
% User-defined close request function
% to display a question dialog box
 selection = questdlg('Close This Figure?', ...
 'Close Request Function', ...
 'Yes', 'No', 'Yes');
 switch selection,
```

# Figure Properties

---

```
 case 'Yes',
 delete(gcf)
 case 'No'
 return
 end
end
```

Now create a figure using the `CloseRequestFcn`:

```
figure('CloseRequestFcn',@my_closereq)
```

To make this function your default close request function, set a default value on the root level.

```
set(0,'DefaultFigureCloseRequestFcn',@my_closereq)
```

MATLAB then uses this setting for the `CloseRequestFcn` of all subsequently created figures.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## Color

### ColorSpec

*Background color.* Controls the figure window background color. You can specify a color using a three-element vector of RGB values or one of the MATLAB predefined names. See `ColorSpec` for more information.

## Colormap

m-by-3 matrix of RGB values

*Figure colormap.* An array of red, green, and blue (RGB) intensity values that define *m* individual colors. MATLAB accesses colors by their row number. For example, an index of 1 specifies the first RGB triplet, an index of 2 specifies the second RGB triplet, and so on.

## Number of Colors Allowed

Colormaps can be any length, but must be three columns wide. The default figure colormap contains 64 predefined colors.

## Objects That Use Colormaps

Colormaps affect the rendering of surface, image, and patch objects, but generally do not affect other graphics objects. See `colormap` and `ColorSpec` for more information.

### CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during figure creation.* Executes when MATLAB creates a figure object. You must define this property as a default value on the root level. For example, the statement:

```
set(0,'DefaultFigureCreateFcn',@fig_create)
```

defines a default value on the root level that causes all figures created to execute the setup function `fig_create`, which is defined below:

```
function fig_create(src,evnt)
set(src,'Color',[.2 .1 .5],...
 'IntegerHandle','off',...
 'MenuBar','none',...
 'ToolBar','none')
end
```

MATLAB executes the create function after setting all properties for the figure. Setting this property on an existing figure object has no effect.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

# Figure Properties

---

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo` or the handle of the object generating the callback (the source of the event). For example, this,

```
f = figure('CreateFcn',@(o,e) keyboard)
K>> gcbo
```

and this each return 1:

```
f = figure('CreateFcn',@(o,e) keyboard)
K>> o
```

## CurrentAxes

handle of current axes

*Target axes in this figure.* MATLAB sets this property to the handle of the figure's current axes (the handle returned by the `gca` command when this figure is the current figure). In all figures for which axes children exist, there is always a current axes. The current axes does not have to be the topmost axes, and setting an axes to be the `CurrentAxes` does not restack it above all other axes.

You can make an axes current using the `axes` and `set` commands. For example, `axes(axes_handle)` and `set(gcf, 'CurrentAxes', axes_handle)` both make the axes identified by the handle *axes\_handle* the current axes. In addition, `axes(axes_handle)` restacks the axes above all other axes in the figure.

If a figure contains no axes, `get(gcf, 'CurrentAxes')` returns the empty matrix. Note that the `gca` function actually creates an axes if one does not exist.

## CurrentCharacter

single character

*Last key pressed.* MATLAB sets this property to the last key pressed in the figure window. Use `CurrentCharacter` to obtain user input.

`CurrentObject`  
object handle

*Handle of current object.* MATLAB sets this property to the handle of the last object clicked on by the mouse. This object is the foremost object in the view. You can use this property to determine which object a user has selected. The function `gco` provides a convenient way to retrieve the `CurrentObject` of the `CurrentFigure`.

Note that the `HitTest` property controls whether an object can become the `CurrentObject`.

## Hidden Handle Objects

Clicking an object whose `HandleVisibility` property is `off` (such as axis labels and title) causes the `CurrentObject` property to be set to empty `[]`. To avoid returning an empty value when users click hidden objects, set the hidden object's `HitTest` property to `off`.

## Mouse Over

Note that cursor motion over objects does not update the `CurrentObject`; you must click objects to update this property. See the `CurrentPoint` property for related information.

`CurrentPoint`  
two-element vector: [*x*-coordinate, *y*-coordinate]

*Location of last button click in this figure.* MATLAB sets this property to the location of the pointer at the time of the most recent mouse button press. MATLAB updates this property

# Figure Properties

---

whenever you press the mouse button while the pointer is in the figure window.

Note that if you select a point in the figure and then use the values returned by the `CurrentPoint` property to plot that point, there can be differences in the position due to round-off errors.

## CurrentPoint and Cursor Motion

In addition to the behavior described above, MATLAB updates `CurrentPoint` before executing callback routines defined for the figure `WindowButtonMotionFcn` and `WindowButtonUpFcn` properties. This enables you to query `CurrentPoint` from these callback routines. It behaves like this:

- If there is no callback routine defined for the `WindowButtonMotionFcn` or the `WindowButtonUpFcn`, then MATLAB updates the `CurrentPoint` only when the mouse button is pressed down within the figure window.
- If there is a callback routine defined for the `WindowButtonMotionFcn`, then MATLAB updates the `CurrentPoint` just before executing the callback. Note that the `WindowButtonMotionFcn` executes only within the figure window unless the mouse button is pressed down within the window and then held down while the pointer is moved around the screen. In this case, the routine executes (and the `CurrentPoint` is updated) anywhere on the screen until the mouse button is released.
- If there is a callback routine defined for the `WindowButtonUpFcn`, MATLAB updates the `CurrentPoint` just before executing the callback. Note that the `WindowButtonUpFcn` executes only while the pointer is within the figure window unless the mouse button is pressed down initially within the window. In this case, releasing the button anywhere on the screen triggers callback execution, which is preceded by an update of the `CurrentPoint`.

The figure `CurrentPoint` is updated only when certain events occur, as previously described. In some situations (such as when the `WindowButtonMotionFcn` takes a long time to execute and the pointer is moved very rapidly), the `CurrentPoint` might not reflect the actual location of the pointer, but rather the location at the time when the `WindowButtonMotionFcn` began execution.

The `CurrentPoint` is measured from the lower-left corner of the figure window, in units determined by the `Units` property.

The root `PointerLocation` property contains the location of the pointer updated synchronously with pointer movement. However, the location is measured with respect to the screen, not a figure window.

See `uicontrol` for information on how this property is set when you click a `uicontrol` object.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete figure callback function.* Executes when the figure object is deleted (for example, when you issue a `delete` or a `close` command). MATLAB executes the function before destroying the object's properties so these values are available to the callback routine.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

The handle of the object whose `DeleteFcn` is being executed is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See also the figure `CloseRequestFcn` property

# Figure Properties

---

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

DockControls  
{on} | off

*Displays controls used to dock figure.* Determines whether the figure enables the **Desktop** menu item and the dock figure button in the title bar that allow you to dock the figure into the MATLAB desktop.

- on — Figure docking controls are visible.
- off — The **Desktop** menu item that enables you to dock the figure is disabled and the figure dock button is not displayed.

See the `WindowState` property for more information on docking figure.

DoubleBuffer  
{on} | off

---

**Note** This property is now obsolete and has no effect. It was provided for older computer systems to produce flash-free animations.

---

*Flash-free rendering for simple animations.* Double buffering is the process of drawing to an off-screen pixel buffer and then printing the buffer contents to the screen once the drawing is complete. Double buffering generally produces flash-free rendering for simple animations (such as those involving lines, as opposed to objects containing large numbers of polygons). Use double buffering with the animated objects’ `EraseMode` property set to `normal`. Use the `set` command to disable double buffering.

```
set(figure_handle, 'DoubleBuffer', 'off')
```

Double buffering works only when the figure `Renderer` property is `painters`.

**FileName**  
String

*GUI FIG-file name.* GUIDE stores the name of the FIG-file used to save the GUI layout in this property. In non-GUIDE GUIs, by default `FileName` is empty. You can set the `FileName` property in non-GUIDE GUIs as well, and get it to verify what GUI is running or whether it has been previously saved.

**FixedColors**  
m-by-3 matrix of RGB values (read-only)

*Noncolormap colors.* Fixed colors define all colors appearing in a figure window that are not from the figure colormap. These colors include axis lines and labels, the colors of `line`, `text`, `uicontrol`, and `uimenu`, and `text` objects, and any colors explicitly defined, for example, with a statement like:

```
set(gcf, 'Color', [0.3,0.7,0.9])
```

Fixed color definitions reside in the system color table and do not appear in the figure colormap. For this reason, fixed colors can limit the number of simultaneously displayed colors if the number of fixed colors plus the number of entries in the figure colormap exceed your system's maximum number of colors.

(See the root `ScreenDepth` property for information on determining the total number of colors supported on your system. See the `MinColorMap` property for information on how MATLAB shares colors between applications.)

---

**Note** The `FixedColors` property is being deprecated and will be removed in a future release

---

# Figure Properties

---

`HandleVisibility`  
`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

Handles are always visible when `HandleVisibility` is `on`.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Visibility and Handles Returned by Other Functions

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Making All Handles Visible

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

## Validity of Hidden Handles

Handles that are hidden are still valid. If you know an object's handle, you can pass it to any function that operates on handles, and set and get its properties.

`HitTest`  
{on} | off

*Selectable by mouse click.* Determines if the figure can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the figure. If `HitTest` is `off`, clicking the figure sets the `CurrentObject` to the empty matrix.

`IntegerHandle`  
{on} | off

*Figure handle mode.* Figure object handles are integers by default. When creating a new figure, MATLAB uses the lowest integer that is not used by an existing figure. If you delete a figure, its integer handle can be reused.

If you set this property to `off`, MATLAB assigns nonreusable real-number handles (for example, `67.0001221`) instead of integers. This feature is designed for dialog boxes where removing the handle from integer values reduces the likelihood of inadvertently drawing into the dialog box.

`Interruptible`  
{on} | off

# Figure Properties

---

*Callback routine interruption mode.* Controls whether a figure callback function can be interrupted by subsequently invoked callbacks.

## How Callbacks Are Interrupted

MATLAB checks for queued events that can interrupt a callback function only when it encounters a call to `drawnow`, `figure`, `getframe`, or `pause` in the executing callback function. When executing one of these functions, MATLAB processes all pending events, including executing all waiting callback functions. The interrupted callback then resumes execution.

## What Property Callbacks Are Interruptible

The `Interruptible` property only affects callback functions defined for the `ButtonDownFcn`, `KeyPressFcn`, `KeyReleaseFcn`, `WindowButtonDownFcn`, `WindowButtonMotionFcn`, `WindowButtonUpFcn`, `WindowKeyPressFcn`, `WindowKeyReleaseFcn`, and `WindowScrollWheelFcn`.

See the `BusyAction` property for related information.

`InvertHardcopy`  
{on} | off

*Change hardcopy to black objects on white background.* Affects only exported and printed output. Printing a figure having a background color (`Color` property) that is not white results in poor contrast between graphics objects and the figure background and also consumes a lot of printer toner.

When `InvertHardCopy` is on, MATLAB eliminates this effect by changing the color of the figure and axes to white and the axis lines, tick marks, axis labels, etc., to black. Lines, text, and the edges of patches and surfaces might be changed, depending on the print command options specified.

If you set `InvertHardCopy` to `off`, the exported and printed output matches the colors displayed on the screen.

See `print` for more information on printing MATLAB figures.

## `KeyPressFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Key press callback function.* Callback function invoked by a key press that occurs while the figure window has focus. Define the `KeyPressFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key press and an event structure).

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

When no callback is specified for this property (which is the default state), MATLAB passes any key presses to the Command Window. However, when you define a callback for this property, the figure retains focus with each key press and executes the specified callback with each key press.

## **KeyPressFcn Event Structure**

When you specify the callback as a function handle, MATLAB passes to it a structure to containing the following fields.

# Figure Properties

---

| Field     | Contents                                                                                                                                                                                                                      |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Character | The character displayed as a result of the pressing the key(s), which can be empty or unprintable                                                                                                                             |
| Key       | The key being pressed, identified by the lowercase label on key or a descriptive string                                                                                                                                       |
| Modifier  | A cell array containing the names of one or more modifier keys being pressed (i.e., <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, it contains 'command' when pressing the <b>command</b> modifier key |

## ExploreKeyPressFcn Behavior

To view the values of the event data fields for any key or key combination, run the following code:

```
figure('NumberTitle','off','Menubar','none',...
 'Name',...
 'Press keys to put event data in Command Window',...
 'Position',[560 728 560 200],...
 'KeyPressFcn',@(obj,evt)disp(evt));
```

Each time you press a key, the `KeyPressFcn` uses `disp` to display the event data in the Command Window.

You can also view and run an example GUI, `ex_KeyPressFcn.m`, which displays keystroke event data in the figure window, and provides an option to write the event data structure to your workspace.

- [Click here to view the example in the MATLAB editor](#)
- [Click here to add the example to the MATLAB path](#)
- [Click to run the example](#) — Press and release various key combinations while the figure has focus. The callback displays

event data in text fields in the figure window. The **Char Code** data is the Character field displayed as a number, not a separate event data field.

Event data passed to a `KeyPressFcn` and `KeyReleaseFcn` callbacks have the following characteristics:

- The `Key` field is always in lower case (contains the non-shifted symbol).
- Modifier keys (**Alt**, **Ctrl**, **Shift**,) return data when pressed alone as well as when pressed in combination with other keys.
- `Modifier` fields contain a cell array with zero or more strings.
- Modifier keys can affect the `Character` field, but do not change the `Key` field.
- Certain keys, plus keys modified with **Ctrl**, put unprintable characters in the `Character` field.
- **Ctrl**, **Alt**, **Shift**, function and several other keys generate no `Character` field data.

## Using the `KeyPressFcn`

This example creates a figure and defines a function handle callback for the `KeyPressFcn` property. When you press the **p** key, the callback exports the figure as a PNG image file. When you press **Ctrl+p**, the callback exports the figure as a PDF file.

```
function figure_keypress
 figure('KeyPressFcn',@printfig);
 surf(peaks)

 function printfig(src,event)
 % Callback to parse keypress event data to print a figure
 if event.Character == 'p'
 % On some systems you must send the file to a printer manually
 if length(event.Modifier) == 1 && ...
```

# Figure Properties

---

```
 strcmp(event.Modifier{:},'control')
 % Create PDF file of figure when Ctrl key is down
 print ('-dpdf',['-f' num2str(src)])
 elseif isempty(event.Modifier)
 % Print PNG image of figure when Ctrl is not pressed
 print ('-dpng','-r200',['-f' num2str(src)])
 end
end
end
end
```

## KeyReleaseFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Key release callback function.* Callback function invoked by a key release that occurs while the figure window has focus. Define the `KeyReleaseFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## KeyReleaseFcn Event Structure

When the callback is a function handle, MATLAB passes a structure as the second argument to the callback function that contains the following fields.

| Field     | Contents                                                                                                                                                                                                                        |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Character | The character displayed as a result of the releasing the key(s), which can be empty or unprintable                                                                                                                              |
| Key       | The key being released, identified by the lowercase label on key or a descriptive string                                                                                                                                        |
| Modifier  | A cell array containing the names of one or more modifier keys being released (i.e., <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, it contains 'command' when releasing the <b>command</b> modifier key |

## Properties Affected by the KeyReleaseFcn

When a callback is defined for the KeyReleaseFcn property, MATLAB updates the CurrentCharacter figure property just before executing the callback.

## Multiple-Key Press Events and a Single-Key Release Event

Consider a figure having callbacks defined for both the KeyPressFcn and KeyReleaseFcn. In the case where you press multiple keys at close to the same time, MATLAB generates repeated KeyPressFcn events only for the last key pressed.

For example, suppose you press and hold down the **a** key, then press and hold down the **s** key. MATLAB generates repeated KeyPressFcn events for the **a** key until you press the **s** key, at which point MATLAB generates repeated KeyPressFcn events for the **s** key. If you then release the **s** key, MATLAB generates a KeyReleaseFcn event for the **s** key, but no new KeyPressFcn events for the **a** key. When you then release the **a** key, the KeyReleaseFcn again executes. The KeyReleaseFcn executes its callback every time you release a key while the figure is in focus, regardless of what any KeyPressFcn does.

# Figure Properties

---

Event structures passed to a `KeyPressFcn` and `KeyReleaseFcn` callbacks have the following characteristics:

- The `Key` field is always in lower case (contains the non-shifted symbol).
- Modifier keys (**Alt**, **Ctrl**, **Shift**,) return data when pressed alone as well as when pressed in combination with other keys.
- `Modifier` fields contain a cell array with zero or more strings.
- Modifier keys can affect the `Character` field, but do not change the `Key` field.
- Certain keys, plus keys modified with **Ctrl**, put unprintable characters in the `Character` field.
- **Ctrl**, **Alt**, **Shift**, function and several other keys generate no `Character` field data.

## Modifier Keys

When you press and release a key and a modifier key, the modifier key is returned in the event structure `Modifier` field. If you press and release a modifier key only, its name is not returned in the event structure of the `KeyReleaseFcn`, but is returned in the event structure of the `KeyPressFcn`.

## Explore `KeyReleaseFcn` Behavior

The following code example creates a figure and defines a function handle callback for the `KeyReleaseFcn` property which reports the event data that the callback receives.

- [Click here to view the example in the MATLAB editor](#)
- [Click here to add the example to the MATLAB path](#)
- [Click to run the example](#) — Press and release various key combinations while the figure has focus. The callback displays event data in the Command Window.

```
function key_releaseFcn
figure('KeyReleaseFcn',@cb)
function cb(src,evt)
if ~isempty(evt.Modifier)
for ii = 1:length(evt.Modifier)
out = sprintf('Character: %c\nModifier: %s\nKey: %s\n',...
evt.Character,evt.Modifier{ii},evt.Key);
disp(out)
end
else
out = sprintf('Character: %c\nModifier: %s\nKey: %s\n',...
evt.Character,'No modifier key',evt.Key);
disp(out)
end
end
end
```

## MenuBar

none | {figure}

*Enable-disable figure menu bar.* Enables you to display or hide the menu bar that MATLAB places at the top of a figure window. The default (figure) is to display the menu bar.

This property affects only built-in menus. This property does not affect menus defined with the `uimenu` command.

Changing the `WindowStyle` of a window to 'modal' hides both its toolbar and menu bar, if they exist. Changing `WindowStyle` from 'modal' to 'normal' or 'docked' displays any toolbar or menu bar a figure has.

## MinColormap

scalar (default = 64)

*Minimum number of color table entries used.* Specifies the minimum number of system color table entries used by MATLAB to store the colormap defined for the figure (see the `Colormap`

# Figure Properties

---

property). In certain situations, you might need to increase this value to ensure proper use of colors.

For example, suppose you run color-intensive applications in addition to MATLAB and have defined a large figure colormap (for example, 150 to 200 colors). MATLAB might select colors that are close but not exact from the existing colors in the system color table because there are not enough slots available to define all the colors you specified.

To ensure that MATLAB uses exactly the colors you define in the figure colormap, set `MinColormap` equal to the length of the colormap.

```
set(gcf, 'MinColormap', length(get(gcf, 'ColorMap')))
```

Note that the larger the value of `MinColormap`, the greater the likelihood that other windows (including other MATLAB figure windows) will be displayed in false colors.

---

**Note** The `MinColormap` property is being deprecated and will be removed in a future release

---

Name

string

*Figure window title.* Specifies the title displayed in the figure window. By default, Name is empty and the figure title is displayed as Figure 1, Figure 2, and so on. When you set this parameter to a string, the figure title becomes Figure 1: *<string>*. See the `NumberTitle` property.

NextPlot

new | {add} | replace | replacechildren

*How to add next plot.* Determines which figure MATLAB uses to display graphics output. If the value of the current figure is:

- **new** — Create a new figure to display graphics (unless an existing parent is specified in the graphing function as a property/value pair).
- **add** — Use the current figure to display graphics (the default).
- **replace** — Reset all figure properties except **Position** to their defaults and delete all figure children before displaying graphics (equivalent to `clf reset`).
- **replacechildren** — Remove all child objects, but do not reset figure properties (equivalent to `clf`).

The `newplot` function provides an easy way to handle the `NextPlot` property. For more information, see the axes `NextPlot` property and “Controlling Graphics Output”.

**NumberTitle**

`{on} | off` (GUIDE default `off`)

*Figure window title number string.* Determines whether the string `Figure No. N` (where `N` is the figure number) is prefixed to the figure window title. See the `Name` property.

**OuterPosition**

four-element vector

*Figure position including title bar, menu bar, tool bars, and outer edges.* Specifies the size and location on the screen of the full figure window including the title bar, menu bar, tool bars, and outer edges. Specify the position rectangle with a four-element vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` and `bottom` define the distance from the lower-left corner of the screen to the lower-left corner of the full figure

# Figure Properties

---

window. `width` and `height` define the dimensions of the window. See the `Units` property for information on the units used in this specification. The `left` and `bottom` elements can be negative on systems that have more than one monitor.

## Position of Docked Figures

If the figure is docked in the MATLAB desktop, then the `OuterPosition` property is specified with respect to the figure group container instead of the screen.

## Moving and Resizing Figures

Use the `get` function to obtain this property and determine the position of the figure. Use the `set` function to resize and move the figure to a new location. You cannot set the figure `OuterPosition` when it is docked.

---

**Note** On Microsoft Windows systems, figure windows cannot be less than 104 pixels wide, regardless of the value of the `OuterPosition` property.

---

`PaperOrientation`  
{portrait} | landscape

*Horizontal or vertical paper orientation.* Determines how to orient printed figures on the page.

- `portrait` — Orients the longest page dimension vertically.
- `landscape` — Orients the longest page dimension horizontally.

See the `orient` command for more information.

`PaperPosition`  
four-element rect vector

*Location on printed page.* A rectangle that determines the location of the figure on the printed page. Specify this rectangle with a vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` specifies the distance from the left side of the paper to the left side of the rectangle and `bottom` specifies the distance from the bottom of the page to the bottom of the rectangle. Together these distances define the lower-left corner of the rectangle. `width` and `height` define the dimensions of the rectangle. The `PaperUnits` property specifies the units used to define this rectangle.

`PaperPositionMode`  
auto | {manual}

*WYSIWYG printing of figure.*

- `manual` — MATLAB honors the value specified by the `PaperPosition` property.
- `auto` — MATLAB prints the figure the same size as it appears on the computer screen, centered on the page.

`PaperSize`  
[width height]

*Paper size.* Size of the current `PaperType`, measured in `PaperUnits`. See `PaperType` to select standard paper sizes.

`PaperType`  
Select a value from the following table.

*Selection of standard paper size.* Sets the `PaperSize` to one of the following standard sizes.

# Figure Properties

---

**Paper Sizes Table**

| <b>Property Value</b> | <b>Size (Width x Height)</b> |
|-----------------------|------------------------------|
| usletter (default)    | 8.5-by-11 inches             |
| uslegal               | 8.5-by-14 inches             |
| tabloid               | 11-by-17 inches              |
| A0                    | 841-by-1189 mm               |
| A1                    | 594-by-841 mm                |
| A2                    | 420-by-594 mm                |
| A3                    | 297-by-420 mm                |
| A4                    | 210-by-297 mm                |
| A5                    | 148-by-210 mm                |
| B0                    | 1029-by-1456 mm              |
| B1                    | 728-by-1028 mm               |
| B2                    | 514-by-728 mm                |
| B3                    | 364-by-514 mm                |
| B4                    | 257-by-364 mm                |
| B5                    | 182-by-257 mm                |
| arch-A                | 9-by-12 inches               |
| arch-B                | 12-by-18 inches              |
| arch-C                | 18-by-24 inches              |
| arch-D                | 24-by-36 inches              |
| arch-E                | 36-by-48 inches              |
| A                     | 8.5-by-11 inches             |
| B                     | 11-by-17 inches              |
| C                     | 17-by-22 inches              |

| Property Value | Size (Width x Height) |
|----------------|-----------------------|
| D              | 22-by-34 inches       |
| E              | 34-by-43 inches       |

Note that you might need to change the `PaperPosition` property in order to position the printed figure on the new paper size. One solution is to use normalized `PaperUnits`, which enables MATLAB to automatically size the figure to occupy the same relative amount of the printed page, regardless of the paper size.

## PaperUnits

normalized | {inches} | centimeters | points

*Hardcopy measurement units.* Specifies the units used to define the `PaperPosition` and `PaperSize` properties. MATLAB measures all units from the lower-left corner of the page. normalized units map the lower-left corner of the page to (0, 0) and the upper-right corner to (1.0, 1.0). inches, centimeters, and points are absolute units (one point equals 1/72 of an inch).

If you change the value of `PaperUnits`, it is good practice to return the property to its default value after completing your computation so as not to affect other functions that assume `PaperUnits` is set to the default value.

## Parent

handle

*Handle of figure's parent.* The parent of a figure object is the root object `object`. The handle to the root is always 0.

## Pointer

crosshair | {arrow} | watch | topl |  
topr | botl | botr | circle | cross |  
fleur | left | right | top | bottom |  
fullcrosshair | ibeam | custom | hand

# Figure Properties

---

Pointer symbol, specified as a string listed in the following table. By convention, each symbol commonly indicates a particular usage. However, MATLAB does not enforce rules for the use of any symbols. The appearance of the symbol that displays for a given string is operating-system dependent.

| <b>Commonly Indicates</b>                                 | <b>Symbol String</b> |
|-----------------------------------------------------------|----------------------|
| Editing location in text                                  | 'ibeam'              |
| Point on a graphics object                                | 'crosshair'          |
| Point anywhere in the figure                              | 'arrow'              |
| Busy system                                               | 'watch'              |
| Resizing an object from a top-left or bottom-right corner | 'topl' or 'botr'     |
| Resizing an object from a top-right or bottom-left corner | 'topr' or 'botl'     |
| A hot spot                                                | 'circle'             |
| A point                                                   | 'cross'              |
| Moving an object                                          | 'fleur'              |
| Resizing an object from the left or right                 | 'left' or 'right'    |
| Resizing an object from the top or bottom                 | 'top' or 'bottom'    |
| Aligning a point with other objects on the display        | 'fullcross'          |
| Clickable icon                                            | 'hand'               |

Setting `Pointer` to `custom` allows you to define your own pointer symbol. See the `PointerShapeCData` property for more information.

**PointerShapeCData**  
16-by-16 matrix

*User-defined pointer.* Defines the pointer used when you set the **Pointer** property to **custom**. It is a 16-by-16 element matrix defining the 16-by-16 pixel pointer using the following values:

- 1 — Color pixel black.
- 2 — Color pixel white.
- NaN — Make pixel transparent (underlying screen shows through).

Element (1,1) of the **PointerShapeCData** matrix corresponds to the upper-left corner of the pointer. Setting the **Pointer** property to one of the predefined pointer symbols does not change the value of the **PointerShapeCData**. Computer systems supporting 32-by-32 pixel pointers fill only one quarter of the available pixmap.

**PointerShapeHotSpot**  
two-element vector

*Pointer active area.* Specifies the row and column indices in the **PointerShapeCData** matrix defining the pixel indicating the pointer location. The location is contained in the **CurrentPoint** property and the root object's **PointerLocation** property. The default value is element (1,1), which is the upper-left corner.

**Position**  
four-element vector

*Figure position.* Specifies the size and location on the screen of the figure window, not including title bar, menu bar, tool bars, and outer edges. Specify the position rectangle with a four-element vector of the form:

```
rect = [left, bottom, width, height]
```

# Figure Properties

---

where `left` and `bottom` define the distance from the lower-left corner of the screen to the lower-left corner of the figure window. `width` and `height` define the dimensions of the window. See the `Units` property for information on the units used in this specification. The `left` and `bottom` elements can be negative on systems that have more than one monitor.

## Position of Docked Figures

If the figure is docked in the MATLAB desktop or in a figure window container, then the `Position` property is specified with respect to the figure group container instead of the screen.

## Moving and Resizing Figures

You can use the `get` function to obtain this property and determine the position of the figure and you can use the `set` function to resize and move the figure to a new location. You cannot set the figure `Position` when it is docked.

---

**Note** On Windows systems, figure windows cannot be less than 104 pixels wide, regardless of the value of the `Position` property.

Also, the figure window includes the area to which MATLAB can draw; it does not include the title bar, menu bar, tool bars, and outer edges. To place the full window, use the `OuterPosition` property.

---

Renderer

`painters` | `zbuffer` | `OpenGL`

*Rendering method used for screen and printing.* Selects the method used to render MATLAB graphics. `painters` is the default. The choices are:

- **painters** — The original rendering method used by MATLAB is faster when the figure contains only simple or small graphics objects.

If you set `Renderer` to `painters` on a Windows system, set `Colormap` no longer than 256 rows.

- **zbuffer** — MATLAB draws graphics objects faster and more accurately because it colors objects on a per-pixel basis and MATLAB renders only those pixels that are visible in the scene (thus eliminating front-to-back sorting errors). Note that this method can consume a lot of system memory if MATLAB is displaying a complex scene.
- **OpenGL** — OpenGL is a renderer that is available on many computer systems. This renderer is generally faster than `painters` or `zbuffer` and in some cases enables MATLAB to access graphics hardware that is available on some systems.

## Hardware vs. Software OpenGL Implementations

There are two kinds of OpenGL implementations — hardware and software.

The hardware implementation uses special graphics hardware to increase performance and is therefore significantly faster than the software version. Many computers have this special hardware available as an option or might come with this hardware right out of the box.

Software implementations of OpenGL are much like the `ZBuffer` renderer that is available on MATLAB Version 5.0 and later; however, OpenGL generally provides superior performance to `ZBuffer`.

## OpenGL Availability

# Figure Properties

---

OpenGL is available on all computers that run MATLAB. MATLAB automatically finds hardware-accelerated versions of OpenGL if such versions are available. If the hardware-accelerated version is not available, then MATLAB uses the software version (except on Macintosh systems, which do not support software OpenGL).

The following software versions are available:

- On UNIX systems, MATLAB uses the software version of OpenGL that is included in the MATLAB distribution.
- On Windows, OpenGL is available as part of the operating system. If you experience problems with OpenGL, contact your graphics driver vendor to obtain the latest qualified version of OpenGL.
- On Macintosh systems, software OpenGL is not available.

MATLAB issues a warning if it cannot find a usable OpenGL library.

## **Selecting Hardware-Accelerated or Software OpenGL**

MATLAB enables you to switch between hardware-accelerated and software OpenGL. However, Windows and UNIX systems behave differently:

- On Windows systems, you can toggle between software and hardware versions any time during the MATLAB session.
- On UNIX systems, you must set the OpenGL version before MATLAB initializes OpenGL. Therefore, you cannot issue the `opengl info` command or create graphs before you call `opengl software`. To reenabte hardware accelerated OpenGL, you must restart MATLAB.
- On Macintosh systems, software OpenGL is not available.

If you do not want to use hardware OpenGL, but do want to use object transparency, you can issue the following command.

```
opengl software
```

This command forces MATLAB to use software OpenGL. Software OpenGL is useful if your hardware-accelerated version of OpenGL does not function correctly and you want to use image, patch, or surface transparency, which requires the OpenGL renderer. To reenable hardware OpenGL, use the command:

```
opengl hardware
```

on Windows systems or restart MATLAB on UNIX systems.

By default, MATLAB uses hardware-accelerated OpenGL.

See the `opengl` reference page for additional information

### **Determining the OpenGL Library Version**

To determine the version and vendor of the OpenGL library that MATLAB is using on your system, type the following command at the MATLAB prompt:

```
opengl info
```

The returned information contains a line that indicates if MATLAB is using software (`Software = true`) or hardware-accelerated (`Software = false`) OpenGL.

This command also returns a string of extensions to the OpenGL specification that are available with the particular library MATLAB is using. Include this information if you report a bug.

Note that issuing the `opengl info` command causes MATLAB to initialize OpenGL.

## OpenGL vs. Other MATLAB Renderers

There are some differences between drawings created with OpenGL and those created with other renderers. The OpenGL specific differences include:

- OpenGL does not do colormap interpolation. If you create a surface or patch using indexed color and interpolated face or edge coloring, OpenGL interpolates the colors through the RGB color cube instead of through the colormap.
- OpenGL does not support the `phong` value for the `FaceLighting` and `EdgeLighting` properties of surfaces and patches.
- OpenGL does not support logarithmic-scale axes.
- OpenGL and Zbuffer renderers display objects sorted in front to back order, as seen on the monitor, and lines always draw in front of faces when at the same location on the plane of the monitor. Painters sorts by child order (order specified).
